## WHAT'S NEXT IN HIGH FIDELITY?

How to get realistic sound reproduction in the home.
One way: a garden hose, ps.3

WHERE WE STAND WITH TUNNEL DIODES

First of a four-part series summarizing five year's
with a new component. p 36

These two quartz oscillators, with 1 part in 1010 short-term stability (averaged over 1 second) are ideal as frequency sources in primary frequency/ time standard systems. Recent advances in manufacturing and aging techniques for these oscillators and their quartz crystal resonators now allow quick delivery at much lower prices.

The 104 AR , available for only $\$ 2300$, is identical to the 103AR, $\$ 1900$, except that it provides a 5 mc output of extreme spectral purity in addition to the 1 mc output. Spectra as little as 2 cps wide may be obtained in the X-band region with the 104AR by multiplication of the 5 mc output. This spectral purity is essential for doppler measurements, microwave spectroscopy and similar applications involving reference multiplication.

Driven by the quartz oscillator, the 115 BR Frequency Divider and Clock provides precise time of

## Specifications; 103AR, 104AR

Output Frequencies: 5 mc (104AR), $1 \mathrm{mc}, 100 \mathrm{kc}, 1 \mathrm{v}$ rms into 50 ohms; 100 kc for driving 115BR Frequency Divider and Clock Aging Rate: < $\pm 5$ parts in $10^{10}$ per 24 hours*
Stability: As a function of input voltage: $< \pm 1$ part in $10^{10}$ for changes of $\pm 4 \mathrm{~V}$ from $26 \vee \mathrm{dc}_{\text {; }}$ as a function of load: $< \pm 1$ part in $10^{10}$ for any load impedance change from 50 ohins; as a function of ambient temperature: < $\pm 3$ parts in $10^{10}$ for changes of $\pm 25^{\circ} \mathrm{C}$ from $25^{\circ} \mathrm{C}$; rms deviation, due to noise and frequency fluctuations, of 1 and 5 mc (104AR only) output; (constant input voltage, load and temperature):

| Averaging <br> Time | 5 MC Output <br> (104AR only) | 1 MC Output <br> (103AR, 104AR) |
| :---: | :---: | :---: |
| 1 ms | 5 parts in $10^{9} \mathrm{rms}$ | 1 part in $10^{7} \mathrm{rms}$ |
| 10 ms | 5 parts in $10^{10} \mathrm{rms}$ | 1 part in $10^{9} \mathrm{rms}$ |
| 0.1 sec | 1 part in $10^{10} \mathrm{rms}$ | 1 part in $10^{9} \mathrm{rms}$ |
| 1 sec | 5 parts in $10^{11} \mathrm{rms}$ | 1 part in $10^{10} \mathrm{rms}$ |
| 10 sec | 5 parts in $10^{11} \mathrm{rms}$ | 5 parts in $10^{11} \mathrm{rms}$ |

RMS phase deviation of 5 mc output (104AR only): Averaging Time

day information and permits comparison with standard broadcast signals for absolute accuracy. Continuous operation of the oscillators and related equipment in such a system can be assured by HewlettPackard Standby Power Supplies, which keep systems operating even when line power fails.

Both the 103 AR and the 104 AR provide 1 mc and 100 kc sinusoidal output signals, plus separate 100 kc outputs for driving the 115BR Frequency Divider and Clock. Completely solid state, all components are conservatively rated for assured high performance. A double oven with proportional control maintains precise temperature stability in both oscillators.

Here are the ultimate in low-cost, efficient and stable frequency-generating oscillators for primary and secondary standards applications. Ask your hp representative for a demonstration.

Harmonic Distortion: Down more than 40 db from rated output Non-Harmonically Related Output: Down more than 80 db from rated 1 mc output; down more than 66 db from rated 5 mc output
Temperature Range: 0 to $50^{\circ} \mathrm{C}$
Dimensions: $19^{\prime \prime}$ wide $\times 51 / 4^{\prime \prime}$ high $\times 111 / 2^{\prime \prime}$ deep behind front panel
Power Requirements: 22 to 30 volts dc, approximately 5 watts operating, 10 watts maximum during warmup; dual power connectors at rear; operates from 724BR or 725AR Standby Power Supply
Complementary Equipment: Model 725AR Standby Power Supply with battery, 2 ampere-hour standby capacity, $\$ 645$; Model 115BR Frequency Divider and Clock, $\$ 2750$
Price: Model 103AR, $\$ 1900$; Model 104AR, $\$ 2300$
*Achieved within 21 days of continuous operation
Data subject to change without notice. Prices f.o.b. factory.

## What Price RFI Control?

## RADIO-FREQUENCY interference (rfi) casts a surprisingly large shadow.

Some people say it costs the electronics industry as much as five percent of the industry's annual sales. The amount of time spent in engineering around rfi is incalculable.

Is five percent far-fetched? Probably not, when you consider rfi-control engineering, and consulting firms' fees, filters, shielding, instrumentation, rfi testing and other direct costs. Then add such indirect costs as engineering work normally charged to actual design, but involving rfi-control considerations like selecting a transmitter tube with low rfi output.

Anyone who delves into rfi and its control realizes that this field covers a broad area of electronics-a much broader area than the "rf" in "rfi" indicates. Rfi-control is the effort to prevent electronic systems, equipments and circuits from interfering with each other's operation and to minimize the effects of man-made and natural rfi. In other words, the aim is to make electronic equipments compatible in their electromagnetic environment.

The electromagnetic environments of a system and its parts may vary in size, but they have this in common: each environment constitutes a world that affects and/or is affected by the system, equipment and component. The electromagnetic world of a noisy computer diode, for example, might be limited to the few computer modules that its rfi directly affects. But the computer may live in a much larger world populated by other systems, each of which may in some way be affected by that obstreperous diode.

Since the rfi field involves all electrical and electronic equipment and components that produce interference and every electronic equipment susceptible to interference, just about every area of electronics from A displays to Z marker beacons is affected directly or indirectly by rfi considerations. And that means just about every electronics engineer, too:

- Government planners working on frequency allocations and assignments are involved in intersystems considerations
- Weapons-systems planners must make sure that existing and future systems will mesh with each other and not create an electromagnetic bedlam
- Systems designers must-or should-con-

sider rfi and its control just as they consider costs, system performance and reliability when working out the design of a system
- Equipment engineers and circuit and component designers must develop electronic hardware that neither creates interference nor is susceptible to interference
- Test engineers must prove that a new system or equipment will meet rfi specifications
- Finally, after operational tests, field engineers may have to fix or modify the system so that it does not bother other systems and is unaffected by the rfi that other systems produce.

Company management, too, needs to consider and provide for rfi-control in equipment under development. Expenses such as the cost of setting up an ri-control department or obtaining the services of an rfi consulting firm are frequently less than the costs incurred by winding up with a system or equipment incompatible with its environment.

These, then, are some of the considerations that make rfi a timeless and timely topic-timeless because engineers have been wrestling with it since it was called static, timely because of the present acceleration of efforts, especially by the military, to control rfi.

These are the reasons why we have set aside 24 pages in next week's issue for a special report on the battle against rfi and the latest techniques for its measurement, analysis and suppression.

> New Bridge Design For Safe, Accurate, Easy Measurement of 'Lytic Capacitors

The Sprague Model 1W2A Capacitance Bridge introduces new, improved technical refinements as well as restyling for added attractiveness and ease of operation. Built by capacitor engineers for capacitor users, it incorporates the best features of bridges used for many years in Sprague laboratories and production facilities.

## Precision Measurements over Entire Range from 0 to $120,000 \mu \mathrm{~F}$

The internal generator of the 1W2A Bridge is a line-driven frequency converter, and detection is obtained from an internal tuned transistor amplifiernull detector, whose sensitivity increases as the balance point is approached. It has provision for 2 -terminal, 3 -terminal, and 4 -terminal capacitance measurements, which are essential for accurate measure,ment $\ldots \pm 1 \%$ of reading $+10 \mu \mu \mathrm{~F}$ ... of medium, low, and high capacitance values, respectively.

## No Damage to Capacitors

The model IW2A Capacitance Bridge will not cause degradation or failure in electrolytic or low-voltage ceramic capacitors during test, as is the case in many conventional bridges and test circuits. The 120 cycle A-C voltage, applied to capacitors under test from a built-in source, never exceeds 0.5 volt! It is usually unnecessary to apply d-c polarizing voltage to electrolytic capacitors because of this safe, low voltage.

## Complete Specifications Available

 For complete technical data on this precision instrument, write for Engineering Bulletin 90,010A to Technical Literature Service, Sprague Electric Company, 35 Marshall Street, North Adams, Massachusetts.COMMENT

## Thermal Resistance

I am sorry that I must write this letter to take very strong exception to the article, Practical Way to Measure Transistor Thermal Resistance (p66, Feb. 15).

The very first sentence is not even true, although this is the least serious of the errors. A check on about ten arbitrary MIL specs showed most but not all referred to thermal resistance; none referred to thermal time constant.
The most serious error, and this invalidates the entire article, is the assumption that the leakage current is a linear function of the junction temperature (Fig. 2B). This is most definitely not so. The bulk leakage current obeys an approximately exponential law, doubling for every increase in temperature of roughly 10 deg C. Surface leakage effects, particularly in nonplanar silicon transistors, tend to be independent of temperature. I have found the reverse leakage in certain silicon rectifiers to be virtually constant from 25 to 100 deg C!
I would like to draw to your readers' attention MIL-STD-750, which in Section 3100 describes tests methods for transistor thermal parameters (also applicable to diodes). It is especially interesting to note that they recommend against using the leakage current method for silicon devices.

Sidney V. Soanes
Research Department
Ferranti-Packard Electric Ltd.
Toronto, Ontario, Canada

## Author Bauman replies directly:

Initially, you state that an arbitrary survey of MIL-SPECS on your part showed no reference to the thermal time constant test. From this, you concluded that my first statement was false.

As of April, 1963, I do not know how many MIL-SPECS have been written governing transistors; however, I do know there are at least 600 devices on the market. Do you think a sampling of ten devices is sufficient to call my statement false?

A random check, made at my request, by an associate, revealed seven out of ten specs required a thermal time constant test!
Secondly, you state that leakage current is definitely not a linear function of temperature. You are correct. For a germanium transistor, $I_{\text {cto }}$ doubles for each increase of 10 deg C . For silicon transistors, a 10 deg C temperature change will increase the $I_{\text {coo }}$ by a factor of three. I therefore assume the curve to be linear only in the flat region, below 45 deg C . Test results bear out this assumption as being valid. The leakage versus junction temperature curve in my article was an approximation of a true exponential curve. As for your observation concerning a constant $I_{\text {cob }}$ reading from 25 to 100 deg C, in nonplanar silicon units, this is quite unusual. I would appreciate knowing what transistor types exhibit this characteristic.
Finally, you point to MIL-STD 750 , Section 3100 , a discussion of transistor thermal testing. You emphatically state that this MILSTD "recommends against using the leakage current as the temperature sensing parameter for silicon devices." For the record, the MILSTD, in fact, states, "When making thermal-resistance measurements of silicon transistors, the methods with $V_{\text {.b }}$ and $V_{c b}$ are preferred." This phrase concurs with a statement in my article that reads, "Although the most reliable temper-ature-sensitive parameter in junction transistors is the forward drop $\left(V_{t}\right)$ of the collection junction, the $I_{\text {ro }}$. parameter is used in this test since it is a required parameter in qualification testing of transistors."
Getting back to MIL-STD 750, let me point out that Method 3126 outlines a procedure that features $I_{\text {coo }}$ as the temperature-sensing parameter. If the controlling government agency is against a procedure, would they, on the following page, recommend it? For information purposes at the November Ad Hoc Meeting for Semiconductor Devices, DESC, the Air Force, BuShips and the Signal Corps agreed to use $I_{\text {co. }}$ as well as $V_{1}$ as temperature-sensing parameters.

## harold bauman

## in mational defense-the words "roliability" and "necessity" are synonymous

With the Strategic Air Command at instant readiness, any break in communications could seriously impair its total defense capability - and possibly also our national survival. To achieve the unusually high reliability demanded in this critical military application, Electronic Communications, Inc., uses Allen-Bradley Type G controls in the airborne transmitters they build for the SAC.

In the Type G control, the solid resistance element, collector track, terminals, and insulating material are hot molded into a single, solid structure that-for all practical consideration-is indestructible. In addition, molded contact brushes are used - no sliding metal contacts. This design assures a low initial noise factor, which
actually improves with use. There's virtually infinite resolution-so control is always smooth and completely devoid of sudden changes in resistance during adjustment.

A-B Type $G$ potentiometers are rated 0.5 watt at $70^{\circ} \mathrm{C}$, and will operate reliably in ambient temperatures from $-55^{\circ} \mathrm{C}$ to $+120^{\circ} \mathrm{C}$. Also, the operational life exceeds 50,000 cycles with less than $10 \%$ resistance change. They can be furnished in maximum resistance values from 100 ohms to 5 megohms. For full details on these quality controls, please write for Technical Bulletin B5201. Allen-Bradley Co., 110 W. Greenfield Ave., Milwaukee 4, Wisconsin. In Canada: Allen-Bradley Canada Ltd., Galt, Ontario.

## For capacitors, specify the extra performance of "Mylar"

Studies of manufacturers' average prices show that capacitors of "Mylar"* are comparable in cost with paper units, over a range of capacitances and voltages. At comparable cost, the higher reliability you get makes capacitors of "Mylar" a better value by far.

Only "Mylar" gives you the extra performance of higher dielectric strength, wider temperature range and higher moisture resistance-at about the same price! Also, capacitors of "Mylar" are smaller than paper units with the same capacitance. In circuits for home-entertainment radio and TV they're perfectly compatible with AC voltages imposed on a DC circuit as long as total voltage doesn't exceed the rated voltage of the capacitor,
and the $A C$ component does not exceed the $A C$ corona level. Remember, within the range from .001 to 1 mfd under 600 volts DC, you can get the added reliability of "Mylar" - at costs similar to paper.

For the full story, write for our detailed booklet comparing performance and prices of various insulation systems. Du Pont Co., Film Department, N-10452, Wilmington 98, Delaware.

# Should a Man or Machine Fly the SST? 

QUICK SURVEY of experts by Electronic's indicates that some of the most difficult and controversial technical decisions involved in the U.S. development of a supersonic air transport (SST) will likely revolve around this question: To what extent should the aircraft be automated? There seems to be little doubt however that the plane-which was given the go-ahead signal last week by President Kennedy-will rely more on electronics than any civilian plane yet.

Here are the main electronic systems now contemplated for the craft:

- Fully-automated flight control system, necessary for stability at the mach-3 speeds being considered for the SST. A mechanical backup would probably be provided
- System for managing fuel, communications, air traffic control instructions and other functions the pilot might be too busy to handle
- All weather landing system. By 1970 a fully-automatic system may

## Bids Asked on Huge Computer Order

BEDFORD, MASS.-The largest single purchase in the history of computers is now in the proposal stage. Invitations have been sent to 24 manufacturers for standardized, compatible EDP systems to perform inventory control at 152 Air Force bases throughout the world.
Contractor proposals-due July 20 -will be evaluated by the Electronic Data Processing Equipment Office at Hanscom Field ( p 24, Feb. 8). The award will be made by the General Services Administration. The manufacturer selected will be prime contractor for procurement, installation and maintenance of the entire integrated network.

The program will increase by 50 percent the computer inventory of the Air Force-already the industry's largest cus-tomer-and it will increase the government's computer inventory 20 percent. The first system is to be installed for February, 1964, with 10 installations a month beginning three months later
be feasible, although pilots have traditionally insisted on landing planes themselves

- Self-contained navigation system. The problem here is to reconcile spced with reliability. Some automation is probable however.

The FAA says improvements al-

## Computer Collects Data on Factory Floor

FEATURES OF IBM's new 1030 production data collection and processing system include plastic device used by individual employecs to log work data (left) and factory stations that foremen can use to obtain printed inventory machine-tool availability or other data (right)
ready planned for the air traffic control system should be able to take care of the SST but that a method will have to be developed to eliminate or cut down delays. "It would be terribly uneconomical to have these planes flying around at low levels," a spokesman said.

President Kennedy's decision on the SST followed by one day an announcement by Pan American that it had ordered six $1,500-$ mile-anhour jetliners being developed jointly by British and French manufacturers. In Paris, Sud Aviation told Electronics that this plane will largely use electronic systems now flying in subsonic jets. Speculation has it that the six planes built for Pan American will be outfitted with U. S. electronic gear.

## Nine Frequency Bands Proposed for ComSat

washington - Preliminary decision on the type of communication satellite system to be used by the Communications Satellite Corporation is due at the Extraordinary Administrative Radio Conference of ITU in Geneva in October, accord-
ing to informed sources here. A medium-altitude system with satellites in circular, polar orbits from 6,000 to 12,000 miles continues to be favored as the method for going operational earliest (p 8, May 24).

Meanwhile, FCC will suggest to ITU nine frequency bands for "com-munication-satellite service" including: 3.7 to 4.2 Gc , downward direction only; 5.925 to 6.425 Gc , upward only; 6.425 to 7.150 Gc , either direction; 7.250 to 7.3 Gc , downward only (for exclusive use of ComSat service and space stations) ; 7.3 to 7.65 Gc , downward only; 7.650 to 7.750 Gc , downward (for meteorological as well as communication satellites, in addtion to existing services) ; 7.9 to 7.975 Gc , upward; 7.975 to 8.025 Gc , upward (for exclusive ComSat use); and 8.025 to 8.4 Gc , upward.

## C-W Operation Achieved For Indium Arsenide Laser

CAmbridge, mass. - Magnetically tunable c-w indium-arsenide diode lasers have been developed by MIT Lincoln Laboratory. I. Melngailis and R. H. Rediker operated forwardbiased indium-arsenide diodes as $\mathrm{c}-\mathrm{w}$ lasers, and essentially all the radiation output was stimulated emission. Previously, emission of coherent infrared radiation has been observed from indium-arsenide diodes in pulsed operation, but not $\mathrm{c}-\mathrm{w}$.

In gallium-arsenide diodes, c-w operation has been previously observed, but only 10 percent of the total radiation output was stimulated emission. Emission wavelength of the new diode lasers has been changed by shifting the radiation from one cavity mode to another by means of a magnetic field. By varying the field between 4.1 kilogauss and 9.1 kilogauss, the laser's ir emission can be tuned to either 31,168 or $31,125 \mathrm{~A}$.

## Computer Provides <br> Nationwide Ad Data

NEW YORK-Standard Rate and Data Service, Inc. demonstrated this week its Honeywell 400 computer system, programmed to handle such advertising areas as scheduling and estimating, inser-
tions, billing and media mix.
A Honeywell data communications system links the computer with the Telex network, permitting agencies anywhere in the country to ask it questions directly. If a special button is pressed, a stored identification code at the querying agency tells who is on the line.

## MM Radio Telescope <br> Has Gain of 67.8 db

MILLIMETER-WAVELENGTH $r$ adio telescope capable of operating at up to 300 Gc has been built by Philco for the University of Texas. Normal operating range is 10 to 150 Gc . Gain of the instrument has been measured at 67.8 db , making it one of the most powerful in the world. The 16 -foot-diameter parabolic dish will be used for basic research and explorations for NASA, which sponsored its construction. One of its assignments will be the accurate mapping of the surface of the moon, including spacecraft landing sites.

## Thin-Film Costs

## Down in England

LONDON-The economics of thinfilm and integrated circuits are becoming comparable with conventional component assembly techniques. Thin-film costs in the UK will be comparable with conventional techniques by January, 1964 and should be lower from then on. Costs of solid-state integrated circuits are not expected to become comparable in the UK until 1965.

These estimates were presented to 300 delegates at a two-day conference on solid circuits and microminiaturization at the West Ham College of Technology. In a comparative example presented by A. T. Lawton, of E.M.I. Electronics, design studies were performed on both thin-film and solid-circuit versions of a radar data processing unit. Using thin-film techniques operating at the same power level, the expected reliability increased by eight times. Using solid circuits operating at lower power levels, reliability increased even more, by factors of between 19 to 47 times according to the manufacturer chosen.

## In Brief . . .

INSTRUMENTS designed at Dartmouth College will record natural radio signals from outer space when NASA sends up its Polar Orbiting Geophysical Observatory satellite next year.

RAYTHEON received $\$ 900,000$ initial funding for ATBM program to extend capability of Hawk missile to engage tactical ballistic missiles as well as low-altitude aircraft (p 8, May 31).

FRANCE PLANS to place a research satellite into orbit by late next year using Diamant three-stage launch vehicle it developed itself.

JAMES E. WEBB, NASA administrator, said last week he is against an MA-10 shot (p 7, May 24). He would prefer to concentrate on Gemini. A final decision is expected soon.

SPERRY will develop an automatic flight control system for the Douglas DC-9 jetliner. Initial contract is for $\$ 4,262,000$.
associated electrical Industries Ltd. of England has sold the majority of its industrial vacuum tube interests to ITT.
admiral's new hi-fi line includes four completely transistorized models. Peak output is 250 w .

SUD AVIATION has ordered 20 allweather landing systems from Lear Siegler. By next January Sud hopes to retrofit all Caravelle airliners with the devices.

- agreement to buy the assets of the Motorola aviation products business, Culver City, Calif. has been signed by Bendix; Hickok Electrical Instrument has purchased all outstanding stock of Stark Electronic Instruments Ltd., Ajax, Ont.; Electronic Devices Inc. purchased Columbus Semiconductor Division from Columbus Electronics Corp.
aUTOMatic message-processing system called Amps will be installed by Burroughs at Ford Ritchie, Md., under a $\$ 2,500,000$ Army contract.

## NIXIE ${ }^{*}$ TUBES . . . . the only

 segmented display that gives you:- All DC operation . . . . +170 volts
- Uniform continuous line characters of equal helght for easy readability
- Memory with simple solld state or gas tube drive circuits
- Readability in high ambient light . . . 200 foot lamberts brightness
- Maintenance-free operation ... 200,000 hours rated life WITH NO LOSS OF BRIGHTNESS

actual size

And Burroughs Alpha Numeric NIXIE Tubes also feature - low power ( 100 mw per segment) - wide viewing angle ( $150^{\circ}$ ) - complete alphabet, numerals $0-9$ and special symbols in a single tube - low cost ( $\$ 19.00$ in single quantities)
Available now, the first in the series . . . Type B-5971 standard size with $.780^{\prime \prime}$ characters. Tubes may be ordered singly or in groups as complete readout assemblies. The rectangular shape allows mounting on $800^{\prime \prime}$ centers.

## WASHINGTON OUTLOOK

ADVISOR-
SUPPLIER BARRIERS

FIRM UP

WHO BUYS
WHAT IN
NAVY NOW?

FCC BOOSTS

PENTAGON'S new conflict-of-interest regulations spell out more precisely than ever restrictions on a contractor with systems engineering, technical direction or other advisory functions. He can't supply any of the system's major components unless he also has hardware development or production responsibilities.

Similarly, if he is hired to prepare specs, he can't get in on competitive bidding "for a reasonable time." If he helps detail performance characteristics for a new weapon to be bought competitively, he can only be a supplier if he is a recognized sole source. If, as a study contractor or military advisor, he has access to other firms' proprietary data, he is barred from exploiting the trade secrets in subsequent production work.

This sort of ban has been widely imposed in the past. But lack of firm guidelines has resulted in many cases of what one official calls "pseudo-competition."

NAVY PROCUREMENT organization is being centralized. Chief of Naval Material will get expanded power and authorities of the separate Bureaus will be trimmed. Bureaus will continue to award contracts, but the Chief of Naval Material will now supervise shipbuilding, aircraft and electronics production, and development. He will coordinate production schedules of the four bureaus, hold the purse strings and decide who handles specific projects.

One big area to be clarified: responsibilities for electronics procurement and design, now divided between the Bureaus of Ships and Weapons. BuShips now controls shipboard electronics (except "weapon-related" electronics) and most shore electronics. BuWeps buys airborne electronics, most equipment for air stations and weapon-related shipboard electronics. This fuzzy division, and the resulting deficiencies in mating electronic gear to new vessels, largely caused the reorganization.

FOUR UNRELATED FCC actions last week add up to a powerful boost for uhf tv. FCC abolished option time, which gave tv networks first call on certain hours of station affiliates' time. Networks were asked to make programs available to uhf outlets in intermixed markets. FCC refused to add vhf stations in seven major markets, leaving them open for third network service at uhf. It denied exemption from the all-channel set law. Motorola and others wanted to make vhf-only sets for use in sehools, hospitals, hotels, and so on. FCC turned this down, but extended date of the all-channel requirements for school sets by two years, to April 30, 1966.

FIRST ROUND of discussions for a global satellite communications system have been successful, report Leo D. Welch, Communications Satellite Corp. Chairman, and Joseph V. Charyk, president, after talks with officials in Canada, England, Germany, France and Italy. Talks with other countries will come soon. European countries want to supply men and hardware and own part of the system.

Meanwhile, the corporation has named Sidney Metzger, formerly with RCA, manager for components development and systems research; S. N. Reiger, formerly with the Rand Corp., manager for systems analysis; and Edwin J. Istvan, formerly with the Air Force Office of Space Systems, technical assistant to the president.

(Photo 2 $\frac{1}{6}$ times actual size)

## Got a match?

Any ordinary book match will do.
Placed over our AMPin-cert* 50-position Subminiature Pin and Socket Connector, the match completely covers the contact area which is a full $50 \%$ of the total! Compare this with other connectors of only $20 \%$ area-use efficiency and obviously this gives you the density you need. But we didn't stop there.

This is the only connector of its type which gives you crimped, snap-in type contacts. Here is an important plus feature when you're working in close quarters. It does away with cold solder joints, burned insulation, fine wire breakage and permanently fixed connections. Add to all this our controlled crimping process which delivers terminated contacts all perfectly identical in appearance and performance and you've got something that's difficult to match-density, versatility and reliability, at the lowest applied cost in the industry. -Truomark of Amp incorporateo

That's it, except for-
9 wire range-stranded or solid-26-36 AWG

* working voltage of 300 volts AC RMS or better
- .060 center to center spacing in single line ( 050 in clusters)
- polarized for error free assembly
* self extinguishing housing

If you're looking for a sub-miniature connector that really packs in working features, send for complete information on our AMPin-cert Subminiature Pin and Socket Connector today!

# Computer Runs Missile Tracker 

## Atlantic range's newest

 giant interferometer is a lot easier to workBy JOHN W. WASIK<br>McGraw-Hill World News

CAPE CANAVERAL-The second of two Mistram (Missile Trajectory Measurement Systems) developed by General Electric for the Atlantic Missile Range is scheduled to become operational and begin supporting missile flight tests this July.

Located on the down-range island of Eleuthera, the huge interferometer will perform much the same as does the first system at Valkaria, Florida, will have the same operational requirements and approximately the same accuracies (Electronics, p 38, July 29, 1960 and p 109, Nov. 17, 1961).

But much of the equipment in the second system is new or revised. It will be much easier to operate
than at Valkaria thanks to a digital computer in the precision measuring subsystem. The computer replaces a number of other items and can perform several tasks.

Another big difference is in the layout of the site. Because of geographical limitations the station is laid out in a $V$ shape rather than the $L$ shape of the first site. Also, Eleuthera has only two remote stations while Valkaria has four.

The Eleuthera Mistram is called System II by GE and the Air Force. Valkaria, some 30 miles south of Cape Canaveral, is System I.

NEW SHAPE-Basically, Mistram is a missile tracking radar that employs interferometer techniques along very long baselines for extremely high accuracies. It transmits signals to a missile-borne transponder, receives the return signals and calculates the missile's position and velocity.

At Valkaria, two baselines stretch out at right angles from the central station. On each baseline is a 10,000 -foot station and a 100,000 -foot station.

## Global Mistram Next?

CAPE CANAVERAL-A General Electric study of mobile tracking stations could result in a global or even space version of Mistram.

Designated Cobra (Compatible On-Board Ranging), the system could be placed on land, at sea or in space vehicles. Unlike the Mistram sites, Cobra would need a navigation system to get accurate location data.

Mistram's range-measuring philosophy is employed in Cobra, making it compatible. Being compatible, Cobra elements in a missile would function as a Mistram transponder near a Mistram station, but would change their mode of operation once out of range and become a prime station, interrogating Cobra transponders spotted around the globe or in space. The
missile-borne system could then receive the responses and extract the ranges.

A modest data link, says GE, would provide a means of identifying the transponders and sending their position and velocity to the prime station aboard the missile.

All the ground-based equipment and about 80 percent of the airborne equipment could be constructed with existing Mistram modules and circuit elements. The "flying" part of Cobra would contain an X-band c-w transmitter, four receivers, data extraction equipment and telemetry gear.

General Electric says Cobra's measurement errors will not exceed 4 feet in range and 0.12 -fps range rate (smoothed over one second), at ranges to $1,000 \mathrm{n}$. miles.

In Eleuthera's V-shaped layout, the central station is at the vertex of the two baselines. One remote station is 88,000 feet from the central station. The other is $155,-$ 000 feet away, located across a bay.
The 10,000 -foot stations at Valkaria are connected by buried cable and waveguide and the 100 ,000 -foot stations by microwave. System II depends entirely on microwave.

PHASE STABILIZATION - At both sites, phase-stabilization methods developed by GE are used on the microwave links to overcome phase-shift due to changes in the electrical length of the baselines resulting from physical or circuit changes.

The signal received from a Mistram transponder at the central station goes to a mixer and also on a round-trip to a remote station. The round-trip phase shift is compared with the one-way shift of the signal received at the remote site from the transponder and sent directly to the central station over the baseline path. A mixing process then eliminates the baseline phase shift from the signals.

Another problem at the Eleuthera site resulted from one baseline link being over water. Atmospheric fading caused temporary loss of signals transmitted across this baseline.

The solution is to use two microwave antennas at the remote site. If the signal begins to fade, it is automatically switched to the second antenna, offset by a distance sufficient to slightly change the path of the signal across the water. This, in effect, cancels the fading area.

DIGITAL PROCESSOR-The digital data processor of System II makes operation much simpler with far less gear. In addition, a complete set of test and checkout programs is avilable on command from the operator's console. Special programs also permit post-flight analysis, trajectory synthesis and other similar tasks.

CONTROL CONSOLE at Eleuthera central station directs Mistram site and hand-over to Valkaria. Plotters show missile trajectory and position

In System I, an analog computer subsystem drives the remote antennas. Analog pointing data received from the acquisition and tracking subsystem is converted into digital form for transmission to the remote sites, where the signals are corrected for parallax, reconverted to analog form and used to point the antennas.
System II's digital computer accepts the pointing data, corrects for parallax for each remote site, and points the remote antennas, all in one simple operation.

LESS EQUIPMENT-A great deal of equipment was eliminated from

DIGITAL DATA processor simplifies operation of the new system. This is the processor's control center (top left)

DATA FROM missile tests and system calibration tests within the system are recorded on these digital/analog recorders (top right)

WAVEGUIDE running from central station to microwave tower at Eleuthera carries simulated signals transmitted to the system during functional analysis (lower left)

RADOMES atop central station house the dishes for the precision measuring and the acquisition and tracking subsystems. Microwave antenna at left is link with a remote site (lower right)

East Bethpage Road - Plainview, New York

System II by the digital computer. System I employs the servo-loop technique, using phase delay and other equipment to keep the transponder signals' two frequenciesreference and calibrate-in phase. The digital data processor at Eleuthera does all this.

Other changes include a simpler antenna design, more GE equipment in the communication link subsystem and a slight revision in the data transmission subsystem. Data goes to Cape Canaveral over a submarine cable.

RANGE TESTS-Tests using aircraft are being run with the Eleuthera system and the data compared with ballistic camera data for evaluation. So far, the system is working within specs.

One attempt was made to track a Titan II passively, but an isolated malfunction precluded completion of the test. Engineers didn't anticipate getting very good data from the test, incidentally.

Since the beacon antenna in the missile was pointed toward Valkaria, the Eleuthera Mistram could get only side-lobe tracking.

Main-lobe tracking will be possible from both stations when the system is operational. A common transponder in the missile will be used with, first, the Valkaria site tracking actively and Eleuthera passively, and then at the most opportune time in the flight, switch to Eleuthera active and Valkaria passive.

The ultimate calibration and checkout of both Mistram systems will come only when a Mistram transponder is placed in a circu-lar-orbit satellite with known orbital parameters.

## Microwaves Will Link Western Power Project

CONSTRUCTION will begin soon on a \$2.3-million multichannel microwave system to link the Bureau of Reclamation's power generation and transmission facilities in the Colorado River Storage Project. Utah, Wyoming, Colorado, Arizona and New Mexico will be served by the federally operated system. General Dynamics' Stromberg-Carlson division will build the network.

## Military Communication Get Simpler, Smaller,

## AFCEA exhibits put

 emphasis on gear suited to tactical conditionsBy BARRY A. BRISKMAN<br>Assistant Editor

MOBILITY is emphasized in designs like the AN/TRC-66 C-band troposcatter system shown by General Instrument

WASHINGTON - Our national ability to meet rapidly expanding military communications demands was demonstrated last week at the 17th annual Armed Forces Communications and Electronics Convention and Exhibition.

Throughout the more than 175 exhibits, there was an obvious accent on improvements in communications speed, capacity, flexibility and reliability, and on reduction in equipment size and weight through solid-state techniques.

RADIO-The stability of military radio equipment is being raised by advanced frequency-synthesis techniques. Solid-state synthesizers result in receiver stabilities
as high as 1 part in $10^{\circ}$ a day for practical 2 to $32-\mathrm{Mc}$ superhets.
The Manson Laboratories ASR-2, for example, will receive a wide variety of signal modes, has sensitivity better than $6.2 \mu \mathrm{v}$ for $10-\mathrm{db}$ $S+N / N$, image rejection greater than 95 db at 16 Mc and four independent agc's.

A number of companies emphasized modernization of operational military equipment by offering modification kits that allow in-thefield updating to state-of-the-art performance.
While multi-mode transmitters are still available, emphasis is strongly centered on single-sideband for voice communications. Compact linear amplifiers permit very high talk-power even for mobile use. New vacuum tube techniques and cooling systems allow equipment in one mobile van to do a job requiring three vans a few years ago. This greatly enhances tactical flexibility.

BROADBAND TANKS - To reduce operator error, transmitters eliminate complicated tuning by using broadband tank circuits. These have almost constant power output over a given frequency range between 1 and 30 Mc . Frequency is changed by selector switches. Some high-ranking military communications personnel feel that all h-f transmitters may be so equipped in the near future. Equip-

COMMERCIALLY styled equipment such as this SSB transceiver by RF Communications Associates drew high interest. Conventional squarish look may be on the way out in military gear

## Systems Faster

ment of this type has already been delivered to the service; the AN/ GRC-106 recently standardized on by the Army has a completely broadband final amplifier.

HIGH-SPEED DATA-Electronic teletypewriters with new characteristics were shown at AFCEA. Kleinschmidt's all-transistor printer, for one, prints 60 to 400

EMPHASIS on portability was demonstrated in Sylvania's new millimeter-wave communications set. Radiations from internal horn antenna produce a beam
wpm and could print $10,000 \mathrm{wpm}$, a line at a time. It can handle standard direct-wire communications and input and output for computers requiring high-speed printing.

Data equipment shown fills military needs for handling high-volume communications in limited bandwidths over wire, cable, carrier and microwave facilities. One duobinary system (Electronics, p 61, March 22) shown by Lenkurt, features switch-selected discrete rates of $2,400,1,200$ or 600 bits per second, with continuous rates at any speed up to $1,200 \mathrm{bps}$.

GE's AN/FCC-18 multiplexer set is typical of latest high-capacity,

Commercially Available FOR THE FIRST TIME X-BAND TRIODE Oscillator

Trak Type 9170-Diameter $5 / 6 \mathrm{in}$., length $21 / 4$ in. including projections. Weight 2 ounces.

## COMPARE ITS PERFORMANCE

cillator. with ony other type of local X-Band oscillator

- It is tuneable over 500 Mc in the range from 8.0 to 9.6 Gc . (Compare this with solid state crystal oscillator-multiplier chains which are fixed frequency.)
* Power output is greater than 3 milliwatts, CW.
- Low voltoge requirements- 150 volts B+ and 6.3 volt heater supply. (Compare this with a Klystron.)
- Cleaner spectrum-residual AM and FM noise is far below reflex Klystrons.
- Frequenicy stable- $5 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ from $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
* Smaller and Iighter-than any other XBand local oscillator that we know of on the market today.
- Replacement cost is low. You almost get a second oscillator free because the tube is replaceable.
- It's much more rugged-meets the toughest enviranmental tests for shock and vibrafion.
- Delivery now-small quantifies are immediately available. On lorge orders. Trak Mitrowave has production farilties to meet your requirements.

## TRAK STOCK OSCILLATORS COVER 400 Mc to 10 Gc .

> Trak offers a complete line of microwave oscillators, 400 Me . to 10 Ge ., harmonic generators and amplifiers.

> You can get immediate dalivery of stock liems and quick delivery of modified devices or prototypes.

> Send for full information, or, if you are in a hurry, PHONE COLLECT-TAMPA 877.6735.
miniaturized, communications systems for fixed or portable use. An all-transistor duplex carrier unit for microwave relay, troposcatter or cable use, it operates on singlesideband suppressed carrier, offers up to 600 full duplex voice channels. Lenkurt Electric's AN/ FCC-17 provides voice, teletypewriter data or graphic services over circuits of at least six tandem voice-frequency links covering a total of 6,000 miles or more.

FACSIMILE - Among improved facsimile systems is the UXH-2, developed by Litton's RADCOMWestrex division and Navy. It prints on pressure-sensitive paper that has unlimited shelf life and can be copied. Carbon paper and plain white sheets can be used. Speed is 60,90 or 120 scans a minute, resolution is 96 lires an inch. The company's mobile AN/GXC-4, manufactured for Army, will transmit photos or other copy half way around the world in $4 \frac{1}{2}$ minutes.

RADAR - General Dynamics showed its new high-resolution radar (Electronics, p 36, May 31). It can identify a moving vehicle in a forest or it can discriminate between objects only a few inches apart.
The Bendix RDR-1E version of the RDR-1 airborne weather radar has a power of 50 Kw and extends range to 210 nautical miles. It uses 60 transistors, four vacuum tubes and three Nuvistors, while the RDR-1 has 38 tubes.

IONOSPHERIC SOUNDINGMilitary interest was high on systems that predict best selection of frequency for communications over a given path. Called synchronizedoblique ionosphere sounders, one system by Granger Associates devices provides direct, real-time display of maximum and lowest optimum frequencies and multipath distortion and input of propagation parameters to on-line computers programmed to give intermediateterm path predictions.

## Transmitters Fly to Troops

ARMY'S Strategic Communications Command is now testing in the desert near Yuma, Ariz., an air-transportable broadcasting system designed for psychological warfare and for communicating with people in occupied areas.

Army says the need for such a system was demonstrated in Korea, Lebanon, Viet Nam and during the Cuban crisis. The system's main studios can be located in a rear area, while the transmitters go along with tactical forces.

The mobile transmitters, airlifted to the test site, broadcast programs originating at Fort Lewis, Wash., 1,000 miles away. Broadcasts are monitored in the

Canal Zone, for an overall test transmission distance of $\mathbf{5 , 0 0 0}$ miles. Both the field transmitting stations, and the base studios, can be transported by helicopter.

Gates Radio built the system for Army in less than a year, under a \$1.6-million contract awarded last summer (Electronics, p 8, Aug. 24,1962 ).

Called the AN/TRQ-20, the system consists of two $50-\mathrm{Kw}$ mediumwave a-m stations, a $50-\mathrm{Kw}$ shortwave station, two receiving or monitoring stations, single-sideband 2 to $30-\mathrm{Mc}$ studio-transmitter communications equipment with a range of 1,200 miles, and supporting equipment, in 23 vans.

SHELTERS in desert. These are two of six studio and transmitter shelters

## A MIGHTY BIG STEP

A MIGHTY IMPORTANT STEP FOR YOU! YOU CAN NOW BUY PRINTED CIRCUITS WITH YOUR CONDUCTOR AND HOLE PATTERN... WITHOUT ARTWORK ... WITHOUT QUOTATIONS ... WITHOUT TOOL CHARGES, AND IN MOST CASES, AT HALF THE USUAL COST AND IN HALF THE USUAL DELIVERY TIME! Our new Standard Circuit Division reduces printed circuit manufacturing overhead to the barest minimuin by automation and standardization. Mass production techniques drastically reduce costs, delivery time, and improve qualityyet still give you flexibility in board design. Sound exciting? For complete information write today for our 16 page Photocircuits brochure detailing this major printed circuit breakthrough.

# Objectivity 

If you're tired of hearing about the "perfect" printed circuit connector, you're just the man we want to talk to.

We're here to offer you freedom of choice, because that's where objectivity begins. The boy blowing his last penny on candy wants to be able to choose between the 30 -second delicacies and the stuff that lasts all afternoon. It's licorice versus jawbreakers, root-beer-barrels versus bubble-gum. They're all good, but none are perfect.

That's why we make such a variety of printed circuit connectors. Each type and style has its own special bailiwick. They're all "perfect" when they're applied properly.

## OUR NEW BELLOWS-TYPE

Take the new Amphenol 225-series. This bellows-type connector has the smoothest, gentlest, most efficient mating action you'll find anyplace. Even after thousands of insertions, the delicate conductive surfaces of the printed board are unscathed by the 225 .

The 225 -series has remarkably low contact resistance, too. For the solder terminated style, it's under 25 millivolts at 5 amperes.

The bellows-type contact on the 225 -series is split down the middle. You get two contact points for every interconnection. This helps keep the contact resistance low, of course, but it also conforms readily to irregular mating surfaces.

The 225 is convex. It meets and mates the printed circuit board with a wiping action that assures contact.

## AND, FURTHERMORE

The 225 -series contact is self anchored in the connector body. Con-
tact faces will not distort at the slightest pull on the terminals.

The 225 -series has twice the flexing range that you'll find on other bellowstype contacts. This means you can rock the board twice as far with no danger of contact distortion.

The 225 -series does not waste valuable contact space with a polarizing key. The key is sandwiched in between contacts.

The 225 -series can be terminated with solder lugs, taper pins, removable crimps, or Wire-Wrap* terminals.

Contact styles? Contact positions? Mounting provisions? Well, let's just say that there are over 100,000 combinations available in the Amphenol 225 -series bellows-type connector.

## WhO NEEDS ITP

And now for the facts of life. Some people simply don't need the 225 series. Some printed circuit boards are inserted once and never disturbed again. Some printed circuits are never subjected to pull on the terminations. Some printed circuits are not really so delicate that they must be protected from contact wear. Some printed circuit boards never get rocked. And in some applications, the space taken up by a conventional polarizing key is of no consequence. And so forth.

And that is why Amphenol makes Prin-Cir ${ }^{\text {® }}$ connectors, Micro-Edge ${ }^{(1)}$ connectors, Micro-Min ${ }^{( }$connectors, and specials that haven't been named yet. They are all printed circuit connectors. They are all "right" where the need dictates their use.

The hero of this story is the Amphenol Sales Engineer. He's the only man who has access to a complete

[^0]line. Thus he's the only man who can look you in the eye and tell you exactly which printed circuit connector you need. Objectivity.

You won't hear Amphenol Sales Engineers telling you about perfect connectors. They don't have to. They know better.

## DETAILS, DETAILS

If you're really interested in seeing what a complete line of printed circuit connectors looks like, we invite you to write for our new 20-page catalog PC-1. Just contact your local Amphenol Sales Engineer, or write to Dick Hall, Vice President, Marketing, Amphenol Connector Division, 1830 South 54th Avenue, Chicago 50, Illinois.

Problem: To make contacts that give an extremely low millivolt drop, yet do not mar printed circuit conductors, even after thousands of insertions.
Solution: Bifurcated, convex faces for sure contact. Double spring action with wide flexing range. Then double-plate and polish so smooth they caress the mating surface.

## Sonotone batteries spark portable power to action!

Mite or might-if it's portable, the chances are it relies on Sonotone rechargeable sintered-plate, nickel-cadmium cells and batteries. That goes for everything from space satellites and missiles to cordless razors and toothbrushes, and even to small, delicate medical instruments. The reason is this: Sonotone pioneered in the development of high-power/low-weight rechargeable batteries. With more years of experience in this field than any other American company, Sonotone has built up an unmatched record of reliability... and an unmatched reputation for cooperation with design engineers. What new product are
you working on? Let Sonotone help you solve your power prob-「em Write today for technical data, stating your application requirements ... and we'll be happy to lend you a hand.

Sonotone Batteries MM-13 have been used in U.S. ICBM Titan I and Sonotone Batteries MM- 14 have been used in the emergency grolnd support. Many electric toothbrushes use Sonotone Sealed Battery S-113. These are just three of more than 300 Sonotone rechargeable sintered-plate, Sonotone Batteripe batteries available to you. portable power for progress

## Micropower Talks Hit the

## Traveling speakers will

 tell Europe about new military and space designsFIRST INTERNATIONAL conference on micropower electronics was slated to open in Paris yesterday. Sponsored by NATO's Advisory Group of Aeronautical Research and Development, the meeting will deal with new electronic devices and circuits that operate at very low power levels and permit high packaging densities.

Conference chairman Edward Keonjian, of American Bosch Arma, said AGARD recommended
the meeting because NATO as a whole is vitally interested in continued reduction in the size and weight of military electronics.
To enable maximum participation, the conference will be held in several European countries. It will end in Rome.

Robert C. Baron, of Computer Control Co., will speak on designing minimum power digital circuits for space applications. He will describe the scientific data conditioning system (SDCS) his company built for Mariner II.
Easiest way to reduce power requirements, says Baron, is to reduce voltages lower and lower, then devise circuit tricks to mini-

# Monica Watches Her Weight 

## Integrated circuits and etched-plane memory keep new military computer slim

LOS ANGELES - Autonetics plans to have its new integratedcircuit Monica computer ready to fly late this year and follow up with a more powerful central computer next spring. The company expects reliability to be better than 2 years mean time between failures.
The computers are designed for airborne inertial guidance, flight control and automatic checkout, and for submarine navigation. There are two military models, C and J. Monica C is more powerful and features parallel operation.
Among packaging techniques
used to keep down size (Monica C measures $53 \times 9 \times 13$ inches) are:

- Multilayer circuit boards interconnect integrated circuits and modules. Photochemical methods build up and interconnect the layers with no holes drilled through the board
- Memory-core planes are made by fixing cores in holes etched in a copper-clad epoxy-glass board. Cores are through-plated and the board is then etched to get the conductor pattern.
- Power supply circuit boards are laminated to metal to conduct heat to the computer's sidewalls.
The computers have a randomaccess core memory of 8,192 words expandable to 32,768 words. A rapid-access memory of 256 words cycles in 1 microsecond.

ONE OF MONICA'S 4,096-bit memory planes is eyed by James Slauson, project engineer (left). Multilayer boards (right) interconnect integrated circuits and modules

## NATO Road

mize circuit inefficiency and further cut power requirements. One of the primary areas for circuit optimization, says Baron, is charge and discharge of stray capacitances.

SDCS weighed less than six pounds, occupied 144 cubic inches, required less than one watt. Equivalent circuitry of conventional design would have used about 50 watts, says Baron.

AMPLIFIER DESIGN-An opti-mum-design technique for applying micropower transistors in linear broadband amplifiers will be reported in a paper by J. D. Meindl, R. A. Gilson, O. Pitzalis and W. Kiss, of U. S. Army Electronics $R$ \& $D$ Laboratory. The technique, which unifies $d-c$ and large-signal a-c design, also serves as the basis for a worst-case design procedure for linear amplifiers considering transistor and resistor tolerance margins.

Micropower amplifiers have been designed using a simple thermis-tor-compensation technique whose gain and terminal impedances are virtually insensitive to large temperature changes between -50 C and 100 C. A common-emitter broadband amplifier operating from a 3-v supply with load and source impedance of 50 K can provide $180-\mathrm{mv}$ peak a-c voltage over this range. Power drain is 23 microwatts, power gain is 25 db. If peak-load voltage capability is reduced to 150 mv , the amplifier can accept 10 percent worst case resistor tolerance.

Bandwidths vary from 7 Kc to 25 Kc but increases of 2 to 5 times are possible with a cascode circuit. (For a power drain of approximately 30 microwatts, $140-\mathrm{Kc}$ bandwidths have been obtained at room temperature.)

Other speakers include J. W. Moll, of Stanford University; A. W. Lo, of Princeton University and IBM; W. W. Gaertner, of CBS Labs; G. E. Moore, of Fairchild Semiconductor; M. A. Boulter, of Semiconductor Ltd., and A. T. Watts, of Mullard Radio Valve Co., both of England.

EVANOHM, the time-tested standard of the precision wire-wound resistor industry, features the lowest thermal EMF versus copper of all resistance alloys . . . with stability within a few parts per million per year. EVANOHM is recommended for all precision requirements where highest reliability is essential, and is well suited for analog computers and guidance equipment for space applications. EVANOHM, in .0004 and heavier gauges, can be supplied from stock, either bare or enameled, for immediate delivery. The Wilbur B. Driver Company's engineering "know how" is available to help solve your problems. Call or write WBD for recommendations on your requirements, or request EVANOHM brochure!

## Newark 4, New Jersey - Tel. HUmbold 2-5550 (Area Code 201)

MFG. PLANTS-1875 McCarter Highway, Newark 4, New Jersey; 50 Ronson Drive, Rexdale (Toronto), Ontario, Canada BRANCH OFFICES-Chicago*, Philadelphia, Los Angeles*, Minneapolis, Cleveland*, Hartford (*Indicates Warehouse)

Melters and Manufacturers of Custom Electrical, Electronic; Mechanical and Chemical Alloys for all industries

No other single line of matching panel meters can equal the flexibility and performance of Weston Series 1900. That's because these instruments are designed to give you almost unlimited freedom of choice in all important electrical and physical characteristics. Now, there's no need to compromise on any feature!

These instruments are supplied with Weston pivot and jewel movements or new Weston Taut Band Suspension for highest accuracy and sensitivity. You select the mechanism you want-self-shielded Cormag*, external magnet or iron vane. And all instruments of the same size are physically interchangeable ... regardless of the mechanism or movement.

This unique line is supplied in five sizes from $21 / 2^{\prime \prime}$ to $7 \frac{1}{2} 2^{\prime \prime}$, in a wide variety of $\alpha-\mathrm{c}$ and d-c functions, with full-scale accuracies of $\pm 2 \%, \pm 1 \%$, or higher on special order. All meters have $100^{\circ}$ arcs for easy reading.

Styling is important, too. You can choose conventional Bakelite fronts or modern, clear plastic with provision for inserts for color coding. And only Weston Series 1900 Panel Meters offer a choice of three mounting methods - surface, flush or recess. Write for detailed technical bulletin.

## Factory Truck Trend: More Remote Control

Chicago-An accelerating trend toward solid-state electronic control of warehouse and factory vehicles was evident last week at the Materials Handling Show.
Jarvis Webb Company's new or-der-picker lets a warehouseman on an elevated platform pick orders from 20 -foot-high shelves while the tractor follows a magnetic or optical guide path on the floor. Various switches and sensors provide for such functions as coupling, horn-blowing and opening doors.

For magnetic operation, wires carrying radio energy are buried in the floor. A blocking system allows several vehicles on the same circuit without collisions. For optical guidance, painted guidelines or colored tapes are placed on the floor. Radio controls can be adapted to either system.

Barrett Electronics showed an attachment for electric trucks that permits magnetic or optical guidance and dispatching. The company's radio-command system for overhead cranes uses a repetitive coding technique and redundant decoding receivers to prevent accidents being caused by stray rfi signals or loss of command signals.
Telemotive division of Dynascan Corp. reports it has sold 22 of its radio control systems for hot-metal, acid-pickling and high-carbon-dust area remote control applications.

ORDER-PICKER takes high road while truck follows guide path on warehouse floor

## WESTON

 1900 SERIES

## You choose size, function, accuracy, mounting and style!

Illustrated above are only 15 Weston Series 1900 Panel Meters. The possible combinations of features these instruments offer is almost unlimited. In fact, for any given function and range, you can select from more
than 100 possible configurations of size, accuracy, style and type of mounting. Specify the features you want, and you'll see why this line of matching instruments is the broadest and most flexible ever offered!

Size: Weston Series 1900 Panel Meters are available in

Function: d-c; a-c; VU; Thermo; Rectifier; and Log-scale. Range, full scale: Ten standard d-c $\mu$ a ranges 20 to 500 ); d-c ma in 9 ranges ( 1 to 500); d-c amps in 7 ranges ( 100 to 500 ); d-c volts in 11 ranges ( 2 to 500 ). Three standard a-c $\mu$ a ranges ( 100 to 500 ; a-c ma in 9 ranges (1 to 500); a-c amps in 6 ranges (l to 30); a-c volts in 16 ranges ( 3 to 500); Thermo amps in 5 ranges ( 1.5 to 15). Other ranges on request.

Accuracy: $\pm 2 \% ; \pm 1 \%$; higher on request.
Pointers: Lance pointer, $100^{\circ}$ arc scale; knife-edge pointer and mirror scale for highest accuracy. Movement: Iron vane; external magnet; or Cormag ${ }^{(3)}$

THREE MOUNTING METHODS

to protect against external magnetic fields. With proved Weston pivot and jewel movement, or new Weston Taut Band Suspension with Co-planarms Suspension which provides complete control of ribbon length and movement. Style: Conventional Bakelite fronts for all except $71 / 2^{\prime \prime}$ size; all sizes available with modern clear plastic cases with provision for inserts for color coding or styling. Mounting method: Only Weston Series 1900 can be mounted in three ways - surface, flush or recess. Illumination: Available for recess mounting.

No matter what features you've indicated above, lay. out problems are simplified because all instruments of the same size are directly interchangeable.
Full information is contained in our technical bulletin.

NAVY'S SHRIKE missile is designed to home in on radiation of enemy radar and destroy it

Mass production to begin on air-launched radar-busting missile

## Shrike Will Be "BIG BUY"

WHILE THE \$1.5-million award just given to Texas Instruments Incorporated for the Shrike missile is relatively small as weapons contracts go, it signals the start of a major new missile-buying program by Navy and Air Force.

Shrike is slated to become one of the most important air-launched tactical missiles. The solid-fueled missile is designed to home in passively on enemy radar emissions and destroy the radar system while the plane that launched it remains a safe distance from enemy antiaircraft missile batteries.

Shrike was one of the new weapons seen last Friday by President Kennedy on his tour of West Coast military bases. He saw it during a "turkey shoot" at the Naval Ordnance Test Station (NOTS), China Lake, Calif., where Shrike was developed.

PROCUREMENT-Navy and Air Force are mum on the number of missiles bought. However, defense officials say the 1963 procurement represents only pilot production, that there is going to be a "pretty big buy" of Shrike. The big purchase orders will come during fiscal 1964.

In 1964, Shrike will be introduced in Navy's fleet and in the Air Force. Navy will use it on fighter and attack aircraft. Air Force has halted work on a comparable antiradar missile and is to adopt the Navy weapon.

Production models of Shrike will
be bought competitively, as is done with Sidewinder, Sparrow and other high-volume air-launched missiles. Procurement will be by fixed-price contracts with cost-plus incentive fee contracts. Initially, procurement will be on a solesource basis, with assembly done at NOTS. NOTS is system manager and technical director of the project. Navy owns design rights on the missile.

Texas Instruments is building the guidance equipment and airframes and, has so far, received over $\$ 5$ million in development contracts. TI is building a 435,000 -sqft building for mass production.

MISSION-Earlier in its develop-
ment, Shrike was known as ARM (Anti-Radiation Missile). Some of the experience Navy gained with its Corvus anti-radar missile proj-ect-cancelled some time ago-has been applied to Shrike.

While details of the missile's performance are secret, indications are that it is designed to operate against control radar like those employed by Nike batteries. It's mission may be to come in under the radar beam to avoid detection until it has zeroed in on the target. This could prevent radar operators from turning off the beam-the homing signal-until it is too late.

The Shrike is aptly named. A shrike is a bird that pecks at the eyes of its enemy.

## Cape Gets New Radar

## Design permits future adaptation for tracking as far as the moon

PATRICK AFB, FLA.-First of seven new-generation radar was officially turned over to the Atlantic Missile Range here last week by designer/builder RCA's Missile and Surface Radar division. Two more are scheduled to go to the National Aeronautics and Space Administration.

Designated AN/FPQ-6, the radar uses a 29-ft Cassegrainian antenna with 5-horn monopulse feed and a high power ( 3 Mw ) transmitter. Its prime function is to make precise position and velocity measurements of missile and space vehicles (Electronics, p 26, Dec. 15, 1961).

Design of the system permits later adaptation to a number of design advances and applications. The basic echo-tracking range of 500 nautical miles for a one-squaremeter target can be extended to 900 miles by using the full pulse-

# eight meadaches you can't get 

SIMPSON ELECTRIC COMPANY 5203 West Kinzie Street, Chlcago 44, III.
Phone: (312) EStebrook 9-1121 In Canada: Bach-Simpson Ltd., London, Ontarlo

If you are an equipment builder, you yourself may not come down with the headaches shown above. But your customers can. The shortcuts in meter quality which cause such malfunctions don't always show up during incoming inspection . . . but just wait 'til the equipment is in use.
That's what makes "price meters" so treacherous. You try to cut costs on one end, but lose your shirt on service calls and returned merchandise at the other.

The remedy is Simpson meters. Through experienced engineering, and a policy of no shortcuts in design, Simpson eliminates these meter troubles . . . and the price for this quality insurance is surprisingly close to so-called "price meters."
You can get stock Simpson meters immediately from your distributor in 1300 sizes and types ... or custom meters from the factory in almost infinite variety. Write for General Catalog No. 18.

# RFI: In Microcircuits 

## It all depends on

## how the circuit and

source are coupled

PHILADELPHIA - One of the first clear pictures of the radiofrequency interference (rfi) susceptibilities of microelectronic circuits, as compared to conventional circuits, was presented last week at the 5th National Conference on RFI.

Heretofore, little has been said about rif problems in microelectronics. Generally, engineers think that microelectronics will simplify rfi control, because: smaller circuit areas mean less pickup and radiation of rfi fewer interfaces between circuits provide fewer entry and escape points for ri; smaller circuit sizes and weights allow proportionately more room for shields and filters. These factors should more than offset microelectronics' denser circuit and component spacings and lower operating levels, which tend to increase susceptibil-
ity to rfi.
The new analysis, by $R$. B. Schulz, of Boeing, gets right down to cases in analyzing the susceptibilities of three types of microelectronic circuits: discrete microminiature components such as micromodules, thin-film circuits, and semiconductor integrated circuits.

Here are Schulz's conclusions:

- For common-mode conduc-tively-coupled rfi, where the interfering current flows through element that is common to the rfi source and the victimized circuit, the shorter common-mode paths of all microelectronic-circuit types make them less susceptible to this type of rfi than conventional circuits. However, the higher resistivities of thin-film and integrated circuits tend to enhance rfi that is coupled to them over common-mode paths.
- In most cases microelectronic circuits are less susceptible to rfi coupled by magnetic fields, but more susceptible to ri coupled by electric fields than conventional electronics. Microcircuit designers'
get tracking is possible at 32,000 n.mi. RCA is developing an expanded digital ranging unit that will extend the zoning capabilities and thus the unambiguous range to lunar range of 256,000 miles. Conceivably, the improved system could track an Apollo flight to the moon.

Second FPQ-6 will go to the island of Antigua on June 21. Other islands will get the air-transportable version of the system (designated AN/TPQ-18). Others go to Grand Turk on July 1; Ascension and Grand Bahama in September; Praetoria, South Africa, in March, 1964; Merritt Island (near Canaveral) in May, 1964.

One of NASA's two FPQ-6 systems will go to Wallops Island, Va. in December, the other to Australia in January, 1964.

## It's Different

should try to use low-impedance circuits. Rfi sources should be placed on different substrates than circuits susceptible to rfi.

- It is not difficult to shield microelectronic circuits, but the lack of large inductances makes it difficult to adequately filter them.

Computer Rolls Steel

SLAB AND PLATE mill at Houstov, Texas, says Armco Steel, is first to be controlled by digital computer. Computer used is Westinghouse E'lectric's Prodac 4449. Photo shows operator's pulpit

## Fast, foolproof production testing and sorting of 2 and 3 terminal devices

1

Automatic sorting to 16 categories

No operator decision

Texas Instruments Model 654 Transistor and Diode Tester with 16 -Bin Automatic Sorter provides production-speed testing and accurate automatic grouping of two- and three-terminal devices.

Operation requires only three simple manual steps, completely eliminating operator decision. Sorting logic determined by printed plug-in circuit boards in the tester automatically routes the component to the proper bin. At the conclusion of the test, the operator merely drops the device into the entry chute. Sorting logic is held during the testing of the next device.

The Model 654 combines speed and accuracy with flexibility of circuit board programming. The Automatic Sorter and other accessory equipment insure continued maximum effectiveness of the basic instrument.

## IF

you need close-tolerance overload protection

AND fast interruption of low-value overloads

## BUT

## you have an inrush surge to contend with

then the Heinemann Type C overload relay is what you've been looking for. The Type C can provide instantaneous response to overloads as low as $300 \%$-and still give you a time-delayed response to overcurrents of lesser magnitude, permitting equipment to get on the line without surge-caused interruptions.

These, we submit, are tight tripping specs. And two aspects of Type C design make them even tighter. First, you can get the exact ampere rating you need-any integral or fractional rating from 0.02 amps to 70 amps. Second, the rated must-hold and instantaneous-trip points are not affected by the rise and fall of ambient temperature.

If you want longer delays and higher instantaneous-trip points, we've got a selection of three standard response curves that give you a lot of latitude. Or, for specials, you can specify just about anything you want-within reason and within the limits set out on the small chart below.

The Type C comes in automatic or manual reset forms, with or without trip indication. All of these options are described fully in Bulletin 5103, a copy of which is yours for the asking.

## tektronix type P6016 AC CURRENT PROBE

You can select from two current－detecting systems for use with your Tektronix Oscilloscope．
One system comprises the P6016 AC Current Probe and Type 131 Amplifier ．．． with current range extending from less than one milliampere to 10 amperes ．．．and pass－ band，with a $30-\mathrm{Mc}$ oscilloscope，covering 50 cps to 17 Mc ．

A less versatile system comprises the P6016 AC Current Probe with a Passive Termination ．．．for observation and measurement of current waveforms at frequencies to 20 Mc ， with a $30-\mathrm{Mc}$ oscilloscope．

Easy to use，the current probe has a long narrow shape and con－ venient thumb control．Just place probe slot over the conductor and close slide with your thumb－no direct electrical connection is required．Wiping action keeps the core surfaces clean．Loading introduced is so light that it can almost always be disregarded．

## P6016 and CURRENT PROBE AMPLIFIER

Sensitivity with $50 \mathrm{mv} / \mathrm{div}$ Oscilloscope In － put： 1 ma／div basic sensitivity． 10 －position switch provides calibrated steps from 1 mal div to 1 amp／div，1－2－5 sequence，accuracy within $3 \%$ ．Continuous uncalibrated adjust－ ment is possible by using variable control on the oscilloscope．Noise：Equivalent to a $100 \mu \mathrm{mpp} \mathrm{pk} \cdot \mathrm{to}-\mathrm{pk}$ input signal．Risetime （with Fast－Rise Plug－In Unit in a Type 540－ Series Oscilloscope）： 20 nsec （approxi－ mately 17－Mc passband at $3-\mathrm{db}$ down）． Delay Time： 40 nsec or less measured at the $50 \%$ pulse－amplitude points．Low－frequency Response： 50 cps at $3 \cdot \mathrm{db}$ down．AC Current Saturation Rating： 15 amps pk－to－pk，de－ creasing to 8 amps at $400 \mathrm{cps}, 400 \mathrm{ma}$ at 50 cps．Power Requirement： $105-125$ volts ac， approximately $1 / 2$ watt at 117 volts（part num－ ber 015－030）；210－250 volts ac，approximately 1 watt at 234 volts（part number 015－045）．

## P6016 and PASSIVE TERMINATION

Sensitivity：Either $2 \mathrm{ma} / \mathrm{mv}$ or $10 \mathrm{ma} / \mathrm{mv}$ of oscilloscope sensitivity，accuracy within $3 \%$ ． Risetime（with Fast－Rise Plug－In Unit in a Type 540－Series Oscilloscope）： 18 nsec （approximately $20-\mathrm{Mc}$ passband at 3 －db down）．Delay Time： 20 nsec or less measured at the $50 \%$ pulse－amplitude points．Low Fre－ quency Response：At $2 \mathrm{ma} / \mathrm{mv}$－about 850 cps at 3 －db down（ $5 \%$ tilt of $10-\mu \mathrm{sec}$ square pulse）．At $10 \mathrm{ma} / \mathrm{mv}-\mathrm{about} 230 \mathrm{cps}$ at 3－db down（ $5 \%$ tilt of $35 \cdot \mu \mathrm{sec}$ square pulse）． Maximum Current Rating： 15 amps pk－to－pk．

## COMMON TO BOTH SYSTEMS

Direct Current Saturation Threshold： $1 / 2$ amp．Maximum Breakdown Voltage Rating： 600 v，with thumb slide closed．Insertion Impedance：After a step function has been applied to the conductor under test，the im－ pedance inserted in series is：（1） $0.06 \Omega$ after 50 nsec ，（2） $0.04 \$ 2$ after 100 nsec ，（3） $0.015 \Omega$ after $1 \mu \mathrm{sec}$ ，and（4） $0.006 \Omega$ after $10 \mu \mathrm{sec}$ ．Capacitance between conductor and probe case is typically 1 pf，depending upon wire size．

## Series 6200 Includes Dual Range Supplies

Now available! A series of 7 models of mechanically compatible power supplies - 3 of which feature Constant Voltage/Constant Current circuitry. All are designed as a "family" in dimensions and styling, and can easily be used in conjunction with other units of the series, either in bench or rack combinations.
Any number of units of mixed model numbers can be "stacked" in Auto-Series up to 300 volts off ground to obtain output voltages higher than that of one unit, or to achieve a chain of regulated voltages.
Other features include Auto-Parallel operation, short circuit proof operation, remote programming, remote sensing, floating output, front and rear output terminals, silicon transistor differential amplifier front end, and low series transistor dissipation. Open end construction makes all components and adjustments easily accessible. Design embodies epoxy glass laminate printed circuit board. Provision is made for standard rack mounting in a $31 / 2^{\prime \prime \prime}$ height.

Prices start at only $\$ 99.00$

PETER C. GOLDMARK, president of CBS Labs, talks to Senior Associate Editor Wolff

# HOW HI 

IS FI?

By MICHAEL F. WOLFF, Senfor Assoclate Editor

## Interviewing

PETER C. GOLDMARK President. CBS Labs, Stamford, Conn.

## Next step in audio

 reproduction: greater realism. Here are some things you can do nowone method employs just
## a garden hose

FIFTEEN YEARS AGO this month Peter C. Goldmark and his associates at CBS Laboratories developed long-playing records. We felt this anniversary made a good time to step back from the more exotic areas of electronics and take a look at the state-of-the-art in one of our oldest fields-audio. Result was the following exclusive interview.
Q. In your opinion, Dr. Goldmark, where do we stand today in the art of recording and reproducing sound?
A. The technology has come a long way. Notable improvements have been made in all phases of sound recording so that it's possible now to have virtually noiseless records with extremely little distortion, good fidelity and more playing time. In reproduction the vast strides made in pickups, tone arms, amplifiers, loudspeaker packaging and so forth have all contributed to better sound, less distortion and long record life.

The question is, however, have we attained the real objective, namely to provide realism in the home so far as music reproduction goes?

The word high fidelity is a misnomer, I believe. First of all, either you have fidelity or you don't. If you have fidelity, then "high" doesn't add any more to it, and if we use the word "fidelity," the question arises: fidelity to what? What is it we are trying to copy properly? The paramount question is: given a 2,000 -cubic-foot living room, what can you hope to reproduce that will give the maximum realism? Realism is a word I would like to stress and is the goal I believe much more effort should be directed to-an area, perhaps, which has been neglected. We have the technology for obtaining realism-we have abundant technology-but now we have to use common sense and apply . this technology to give us this reality.

## Q. Do you mean to say that our records are not realistic?

A. I always mean realism in reproduction. When I said we have sufficient technology I mean this also applies to the record. I believe what we have up to the point of the loudspeaker-even what acoustically comes out of the loudspeaker-has all the ingredients to give us realism, and we have other aids, other devices, which are all usable. It is how we apply these and how we educate people that we have to

"The technology has come a long way"

"The word high fidelity is a misnomer"

"Realism is a word I would like to stress"

"I believe we have to get back to the composer"

"Another means . . . is through the use of a hose"
think about now.
First, I believe we have to get back to the composer. Somewhere in the 18th century he wrote a symphony having in mind an orchestra of between 50 and 80 musicians. The composition was meant to be listened to in a concert hall-not in the home. If we wish to hear this symphony in the home and with realism (which I'm sure we all want) what choices do we have? We have amplifiers, loudspeakers and, of course, pickups and records, which are good enough and powerful enough to reproduce in nur living room sound volume adequate to place us in the orchestra pit and perhaps give us the illusion that we are sitting where perhaps the conductor normally stands. This, however, I am sure is not what we want because very few of us ever sat in that place. What we really want is the effect of sitting in the concert hall, say, half way down or in the first or second balcony. These are difficult effects to reproduce in the home . . . very difficult.

## Q. How then would you reproduce them?

A. Sound, as it now appears on the record, contains to a large extent the direct sound from the orchestra and to a lesser extent the spatial, indirect or ambient sound in the concert hall. We now have to try to reproduce this ambient sound. Let's consider a specific situation in which one was located about 150 feet from the orchestra. The original sound from the orchestra will take approximately one-sixth of a second to arrive. Let's assume that another 100 feet back of us the concert hall ends and sound which went past us is reflected from the wall and arrives another one-fifth of a second later. Now there are a great many sounds which fare similarly but not to the same extent. In other words, many sounds between the first one-sixth of a second and the next one-fifth of a second would arrive together at our ears. Also there are sounds which will reach us past the second one-fifth of a second period which travel around the hall and are reflected and bounced back to us so that the sum of all these sounds spreads over a period of a few seconds before they completely die out.

The overall effect is measured as the well known reverberation time. It is possible to capture a portion of this reverberation effect-together with the clarity of the original sound from the orchestra. In the home try to listen from another room or from the far end of the living room. Then do two things: first, cut the sound level and emphasize treble and bass (and not just the very low bass) to get a natural effect.

Now, the second item is not quite as easy to accomplish and requires some real enthusiasm to carry out. It is something we have experimented with in the Laboratories and resulted finally in placing auxiliary speakers in the rear of a listening room. These speakers need not be stereophonic, though there is no harm if they are. It is now necessary to take the sounds from the right and left track of the original record and mix them to create a sound signal, which would then be equivalent to a monaural content. Next, it is desirable to delay the sound by an amount of time that would simulate the distance between the listener and the rear wall of the auditorium. This may correspond to a total delay of approximately one-fifth of a second, keeping in mind that it is not a single slap of sound that returns to us in one-fifth of a second. This period is filled with sound impulses coming from walls nearer to us, for instance the sides. A single delayed sound impulse of one-fifth of a second would be objectionable.

It is thus desirable that this delayed sound be made to contain a large amount of reverberated sound as well as the original sound. One practical way of providing the reverberation would be to use one of the spring-type reverberation devices on the market.

Delaying this reverberated sound is a bit more difficult. We would like to delay it about one-fifth of a second and one way to accomplish this would be through an endless tape and a tape machine traveling at low speed to keep the tape wear at a minimum. Also it would augment the realism by providing speakers half way down the room carrying the sum signal reverberated and delayed by approximately one-tenth
of a second. A tape loop traveling at 33 inches per second several feet long and guided over rollers would do a credible job. This would provide a spacing of the pickup head with respect to the recording head of approximately 0.4 inch for the one-tenth of a second delay and 0.8 inch for the one-fifth of a second delay. If this is difficult, the tape speed should be increased to $7 \frac{1}{2} \mathrm{ips}$, or some higher speed compatible with a minimum spacing between the record and reproduce head.

Another means of producing the desired delay is through the use of a hose-a garden hose, perhaps. If one can place this in one's basement sufficiently insulated from surrounding noises-a hundred feet of hose with a proper microphone and loudspeaker correctly coupled in and out of the hose-it can also create the desired delay. When using such a hose one would have the advantage of providing inbetween points of shorter delays such as one-tenth of a second through the use of an additional microphone tapping in half way along the hose. This hose now assumes the role of an acoustic delay line and permits having inbetween points to locate several speakers between the main speakers and the far end of the listening space, thereby simulating additional reflective surfaces such as in a concert hall.

Essentially what we are trying to do is to reproduce in time, but not in space, the spatial sound as generated in a concert hall and compress this by means of the artificial delays and reverberations into a given space of relatively small volume such as in one's own home. I do not want to create the impression that this approach, which would probably create maximum satisfaction, is easy to accomplish. The means are available-the techniques and the instrumentation are known-the experimentation, however, is not well known. It opens up a new field of challenge.
Q. Is there equipment adequate to help the listener do these things?
A. I think that one has to be a bit of an experimenter. I hope that it is possible, perhaps, to stimulate the industry to produce some of the auxiliary equipment such as delays and not have to use, maybe, a garden hose. I think the tape could be perfectly well used for this.

It may be of interest that we ourselves have provided for an effect such as this in one of our developments, the Minnesota Mining tape cartridge system which is now marketed by Revere. Originally it was intended that this would carry a third track. The dimensions of the cartridge system are such that the tape has two tracks, widely spaced, located at the outside of the tape, so that there's room for a third track. We actually built machines and gave demonstrations where we put into the center of the tape a third track which carried delayed reverberation of the left and right sum signal. The plan was that an optional instrument would carry a third amplifier to extract this delayed reverberation and channel it to an auxiliary speaker in the rear of the room. This, you see, would have made the problem much easier: you would have delayed sound, it would have been reverberated and there would be amplifiers and speakers provided for.
Q. These ideas for realistic sound reproduction are primarily for more engineering-minded listeners. Is anything in sight for the others?
A. Well, we have had an idea for a device that would give all the necessary delays and reverberations in one unit. This would be a magnetic tape or drum system. Sound is taken off from a number of heads and a continuous reverberation signal is generated by means of feedback. This reverberated signal would then be fed through various delays to a number of external speakers. The maximum delayed signal goes to a speaker in the rear of the room, the less delayed to a speaker half way down, and the undelayed but reverberated signal is added to the original signal at the front of the room. Since the nature and amount of reverberations and the amount of delay can be adjusted relatively easily, one can conceive of his own audi-torium-a sort of "space box". In fact, we have built a reverberation generator and used it to simulate the effects of large halls and to liven sound in dead studios. We call it the "Reverbertron."

"One has to be a bit of an experimenter"

"Need to eliminate the needle has largely disappeared"

"I don't believe transducers are the bottleneck"

"One can conceive of ... a sort of space box"

#### Abstract

First of a four-part survey discusses oscillator principles, stability criteria, electronic tuning circuits, temperature-frequency monitoring, wide-frequency operation, and ability to control remote receivers. Succeeding parts will cover amplifiers, mixers and converters, and switching circuits

By ERICH GOTTLIEB and JOHN GIORGIS, Consultante GE Semiconductor Producta Division, Syracuse, New York

FIVE YEARS have passed since the invention of the tunnel diode. Semiconductor manufacturers and users have investigated a great many of the potential applications for this device and the widespread interest is reflected in the great number of papers published in the literature since 1958.

The scope of this article is to check the "boxscore" of achievements to date. Emphasis is put not on the purely analytical achievements nor on crystal-ball forecasts but rather on the practical present and future uses of the tunnel diode.

In the early tunnel diode days its simple characteristics and twoterminal aspects prompted some exciting forecasts. Here was a device, which, with the simplest of circuits, could oscillate, amplify, convert, switch and even do several of these things simultaneously. It could do all these things at high speeds or frequencies with minute power consumption under extremes of temperature and nuclear radiation. Its small size would permit large packing densities while its light weight and simple circuitry would reduce equipment weight.

Generally speaking, all these claims were legitimate. However, in industry a device must enjoy quantity acceptance or it tends to become a high-priced specialty item. Mass acceptance reduces manufacturing costs which when passed on to the user promotes yet greater market acceptance. To obtain this industrial chain reaction, the device must offer competitive advantages not only in unit cost but also in

- Ease of design
- Total system cost
- Competitive circuit or system performance
- Reproducibility in manufactured equipment

The tunnel diode must compete in these areas with other devices, not only such solid-state ones as the transistor or parametric diode, but also with tubes, masers, and even electromechanical arrangements of relays, wiping contacts, pressure transducers, microphones, and so on. These consideration have influenced both the semiconductor applications engineer and the semiconductor circuit designer in their task of finding hardware uses for the device.

In the second half of 1959, tunnel diodes left the research stage and became available to the circuit designer. It became apparent quickly that the device although seemingly physically simple, is electrically complex. In those days the

EQUIVALENT circuit of tunnel diode and its external circuit ( $A$ ), graphical conditions for operating-stability ( $B$ ), istics (C), evolution of tunnel diode package for minimum self-inductance, (photo, right)-Fig. 1

## Them as Sinusoidal Generators

electronic circuit designer needed considerable help to understand the device and its operation. This need was quickly filled by a number of articles (see references) some of which have become classics.

## UNDERSTANDING THE DEVICE

-The first essential requirement in applying the tunnel diode is to understand the equivalent circuit, Fig. 1 A , and its stability conditions. A fundamental article' analyzed this problem and illustrated it by a simple graph relating the parameters of the equivalent circuit of the diode, Fig. 1B, to stability.
The tunnel-diode V-I characteristic, Fig. 1C shows where to place the operating point for any given application. Thus, for an amplifier, oscillator, or self-oscillating converter, the tunnel diode must operate in the negative conductance part of the curve. In staying stably biased in these nonswitching applications the bias must come from a voltage source. For switching applications on the other hand a cur-rent-source drive will keep the operating point below the peak current point until a trigger pulse is applied. If this trigger pulse, when added to the operating bias current, is large enough to exceed the peak current, the operating point is tripped to a higher voltage state bevond the valley, thereby exhibiting a low voltage off state and a higher voltage on state.

voltage-current and I-V character-

REMOTE-control transmitter features circuit simplicity, component economy, and long life from low-voltage batteries

The stability graph, Figure 1B, shows that an exact ratio of $R_{r}, L_{r}$, $g_{\text {t }}$ and $C_{\text {s }}$ must be maintained for the amplifier circuit's operation to stay within the boundaries of $R_{T}=L_{T}\left|g_{n}\right| / C_{n}$ and $R_{T}=1 /\left|g_{H}\right|$. Of these parameters, $R_{T}$ is the total circuit series resistance, $L_{r}$ the total circuit series inductance, $C_{d}$ the diode's capacitance and $\left|g_{d}\right|$ is the absolute value of (negative) conductance.

The closer $R_{r}$ gets to $1 /\left|g_{0}\right|$ the greater the gain becomes, until, at $R_{T}=1 /\left|g_{\|}\right|$infinite gain is reached. At this point the circuit is prone to switch its operating point to the oN state and hence this point is unstable. On the other hand, if $R_{r}$ is made equal to $L_{r}\left|g_{d}\right| / C$, the circuit will start breaking into sinusoidal oscillations. Lowering $R_{T}$ further will increase the strength of these os-
cillations until the limit cycle reaches a contour $V_{p}$ to $V_{t \mu}$ down to $V_{r}$ and back up to $V_{r}$ (see Fig. 4D, p 40) constituting a relaxa-tion-mode oscillation. This well defined stable ratio of circuit and device constants is not always easy to maintain since the negative conductance of the tunnel diode varies nonlinearly with bias voltage and temperature. Although the tunneldiode capacitance varies slightly with voltage also, this is not generally a problem. The magnitude of the inductance of the diode package, however, is an important stability impediment and tunnel-diode packages of 6 to 12 nanohenry inductance have gradually given way to low inductance housings of 0.1 to 0.5 nh as seen in Fig. 1D.

Some of the early technical papers ${ }^{\text {5. } 0.7}$ described converter appli-
cations; others ${ }^{\text {s. }}$, 12, 11 discussed noise topics, while still more papers ${ }^{12,}$ 18. 14.15 is considered oscillator operation. Further papers on logic applications of tunnel diodes ${ }^{10,17,20}$
helped set the foundation of technical knowledge.

TUNNEL-DIODE OSCILLATORS
-Tunnel-diode oscillators are at-

GRAPHICAL determination of time-average conductance $g_{d}(t)$ and of its average value $|g|.(A)$. Lumped-constant circuits: series configuration, (B), parallel circuit (C), series-parallel version (D)-Fig. 2

NYQUIST plot of tunnel-diode impedance-versus-frequency characteristic (A), theoretical oscillator circuit (B), practical circuit (C); series suppression of lower-frequency oscillations ( $D$ ), parallel suppression of unwanted lower-frequency oscillations (E)-Fig. \&
tractive because of their high frequency capability, low power consumption, good frequency stability, and circuit simplicity. These advantages enable a designer to produce stable miniature oscillators with a wide variety of uses as will be described in due course. The disadvantage of the tunnel diode is primarily its low power output owing to the small fixed voltageswing between peak and valley.

The tunnel diode's negative conductance characteristic lends itself ideally to use in oscillator circuits. All the circuit designer has to do is to bias the device from a voltage source (making $R_{T}<\left|R_{d}\right|$ ) and adds sufficient inductance to the circuit such that

$$
\begin{equation*}
L_{T(\omega)}=R_{T(\omega)} C /\left|g_{d}\right| \tag{1}
\end{equation*}
$$

When $L_{r} \approx R_{r} C /\left|g_{d}\right|$, the oscillation amplitude is small but reasonably sinusoidal. Increasing $L_{T}$ increases the oscillator's amplitude and this expanding limit cycle eventually swings beyond the peak and valley points yielding a great deal of harmonic content.

Oscillator design starts with the choice of diode capable of delivering the required power output at the desired frequency. The maximum quasi-sinusoidal output obtainable from a tunnel diode is then given by

$$
\begin{equation*}
P_{0 \max }=f\left(V_{v}-V_{p}\right)\left(I_{p}-I_{r}\right) \tag{2}
\end{equation*}
$$

At this point the oscillator amplitude swings from peak to valley. The bulk of today's tunnel diode usage is in germanium units having typical peak voltages ( $V_{p}$ ) of 65 mv , valley voltages ( $V_{v}$ ) of 350 mv and peak-to-valley ratios $\left(I_{p} / I_{r}\right)$ of eight. Hence a rule of thumb would make

$$
\begin{align*}
P_{0}=\mathrm{man} & \approx \frac{1}{1}(0.35-0.065)\left(0.875 I_{p}\right) \\
& \approx \frac{I_{p}}{40} \tag{3}
\end{align*}
$$

or

$$
\begin{equation*}
I_{p(\text { m in })} \approx 40 P_{o} \text { (required) } \tag{4}
\end{equation*}
$$

The required power determines the peak current of the diode since the voltage parameters of the tunnel diode are fixed by the semiconductor material. The conductance of the diode is also heavily dependent on the peak current since
$g_{d}=d_{i} / d_{c}$ (for large swings $G_{d}=\Delta_{t} / \Delta_{i}$ ) (i)
Therefore the maximum voltage swing $\Delta V_{\text {max }}=V_{0}-V_{p}$. These
voltages are fixed by the semiconductor material, hence only a change in the maximum $\Delta I$ will give an equivalent change in (large signal) conductance.

In an oscillator circuit, two conductances are important

- The initial starting smallsignal conductance ( $g_{\text {t1 }}$ )
- The steady-state large-signal conductance ( $g_{o}$ )

If the stability criteria is met, namely that there be a resonant circuit such that $I_{\mathrm{m}}|Y|=0$ and that there be effective negative resistance left in the circuit, such that $R_{0}|Y|<\left|g_{0,}\right|$, the circuit will start to oscillate. Thus the starting of the oscillator depends on smallsignal parameters. As the oscillations expand, they are limited by the losses in the circuit, expressed by

$$
\begin{equation*}
\eta_{0}=R_{T} \bar{C}_{d} / L_{T} \tag{6}
\end{equation*}
$$

For a given $L / C$ ratio, $R_{T}$ determines the minimum value of $g_{0}$. If $R_{T}$ is small, $g$. becomes small, which means a large oscillator swing, Fig. 2 A .

A designer can choose from several circuits, each with its own specific advantages. Choices are

- the series oscillator
- the parallel oscillator
- the series-parallel oscillator

For lumped-constant circuits, Figs. 2B, 2C and 2D, the series arrangement yields the highest operating frequency, since if $C_{1}$ is the diode capacitance $\left(C_{s}\right)$ and $C$ is eliminated, then both the parallel and the series-parallel circuits revert to the series connection. The maximum frequency of oscillation in this mode is

$$
\begin{equation*}
f_{0}^{\max x}=\frac{1}{2 \pi} \sqrt{\frac{1}{L C}-\left(\frac{R_{T}}{L_{T}}\right)^{2}} \tag{7}
\end{equation*}
$$

At lower frequencies, the series circuit would have to add $C_{1}$ across $C$, to use reasonable $L / C$ ratios. It is generally more convenient and stable to use the series-parallel connection. In this mode, the oscillation frequency ${ }^{(13)}$ is

$$
\begin{equation*}
f_{0}=\frac{1}{2 \pi} \sqrt{\frac{1}{L_{T}\left(C+C_{1}\right)}-\frac{\bar{g}_{d^{2}}}{C_{1}\left(C+C_{1}\right)}} \tag{8}
\end{equation*}
$$

In the parallel oscillator circuit, $R_{r}$ is bypassed (considering the d-c coil resistance negligible) which increases the limit cycle and the oscillator amplitude to yield a larger but nonsinusoidal output. To obtain a sinusoidal output from this

## UNDER ONE ROOF

THERE was a time when it was possible for one man to comprehend all contemporary scientific knowledge. That time is long past. Nowadays, it puts a researcher on his mettle to keep abreast of developments in his own field-and usually his own field is a subdivision of a much broader discipline.

Tunnel diodes are a subdivision of the solid-state electronics art, which in turn is a subdivision of the total electronics effort. Yet in the five years since Esaki's celebrated paper on tunneling effects, the volume of technical tunnel diode literature, ranging from basic physics to circuit applications, has expanded enormously. Following tunnel diode developments has become a major effort.

In this and subsequent sections of a four-part survey on tunnel diode applications, authors Gottlieb and Giorgis have collated a wide range of application data and presented their material in easily assimilated form
connection, $\boldsymbol{R}_{T}$ must be considered to be only the series resistance of the diode (plus the d-c coil resistance) and the $L / C$ ratio adjusted such that the limit cycle is kept small, which occurs when

$$
\begin{equation*}
R_{s} \approx \bar{g}_{d} L_{T} \bar{C} \tag{9}
\end{equation*}
$$

This means that the $L / C$ ratio must be drastically reduced.

## MICROWAVE OSCILLATORS -

 At microwave frequencies, two basic modes of operations are possible- Operation below the self-resonant frequency of the diode ( $f_{\text {so }}$ ).
- Operation above the self-resonant frequency of the diode.

The Nyquist plot of impedance versus frequency (Fig. 3A) shows that the diode has two characteristic frequencies. When the real part of the tunnel diode impedance goes to zero, the resistive cut-off frequency ( $f_{r o}$ ) is reached since beyond that frequency there is no remaining negative resistance. Hence no active gain or oscillation can be obtained from this device as it exhibits only positive resistance and either inductive or capacitive reactance. The second frequency occurs where the imaginary part of the impedance goes to zero, hence, where the diode inductance and capacitance resonate. Below this frequency the device looks capacitive, above, it looks inductive. Figure 3A shows the two diode characteristics. Diode $D_{1}$ reaches $f_{m b}$ before reaching $f_{r n}$, while diode $D_{2}$ reaches $f_{\text {ro }}$ first. This means that
when $D_{1}$ reaches $f_{r}$. it still has a certain amount of negative resistance left and hence theoretically it could oscillate beyond $f_{s .}$. Diode $D_{:}$, however, has passed $f_{r o}$ first, hence has no negative resistance left and therefore cannot oscillate above $f_{r}$ (where $f_{80}$ is located). Assuming two diodes exactly identical in $C_{d}$ $\left|g_{d}\right|, I_{p}, R_{s}$ and all other parameters, the difference between these two diodes can be found in the series inductance of the housing $\left(L_{s}\right)$ as shown by Eq. 10 and 11

$$
\begin{align*}
& f_{r o}=\frac{\left|-g_{d}\right|}{2 \pi C_{d}} \sqrt{\frac{1}{1-g_{d} \mid \cdot \bar{R}_{s}}-1}  \tag{10}\\
& f_{s o}=\frac{1}{2 \pi} \sqrt{\frac{1}{L_{s} C_{d}}-\frac{\left|g_{d}\right|^{2}}{C_{d}^{2}}} \tag{11}
\end{align*}
$$

These equations show that both capacitance $\left(C_{d}\right)$ and conductance $\left(-g_{\mathrm{d}}\right)$ are directly proportional to the peak current $\left(I_{p}\right)$, hence to junction area. The resistive cutoff frequency is thus not affected by junction size or peak current (to a first approximation). The self-resonant frequency does, however, depend heavily on junction area, and therefore on peak current. If $I_{p}$ is large, $g_{\Delta}{ }^{\prime \prime} / C_{i}{ }^{2}$ becomes appreciable compared to $1 / L_{0} C_{d}$. When $1 / L, C_{d}=\mid g_{*_{1} \mid}{ }^{12} / C_{*}^{2}$ the device ceases to function as a sinusoidal oscillator. Therefore a high current (high power) device generally has a low self-resonant frequency and high cut-off frequency. To obtain relatively high power (greater than 1 mw ) at high frequencies with one diode, the series inductance ( $L$.) must be re-
duced. This can be done by using a circuit that presents a capacitive reactance at the resonant frequency, thereby tuning out some of the internal device inductance. Figure 3B illustrates a lumped-constant circuit ${ }^{14}$ of this kind.

In Fig. 3C, $C_{r}$ is the capacitance necessary to tune out the undesirable tunnel diode inductance and $R_{\text {c }}$ is the bias resistance whose $\mathrm{d}-\mathrm{c}$ value is smaller than $\left|-R_{\text {d }}\right|_{--} \mid$. Since $\left|-R_{d}\right|_{\text {a.e }}$ decreases as the cut-
off frequency is approached, its op-erating-frequency value will be smaller than $R_{\text {c }}$. The bias-circuit indactance, $L_{p}$, has now been put outside the main oscillator loop. Another paper ${ }^{18}$ describes a similar approach using transmission-line techniques shown in Fig. 3D and 3E. The "negative inductance" is obtained by using a short-circuited transmission line having length $\lambda / 4<\mathrm{L}<$ $\lambda / 2$ at the desired oscillation frequency. However, at a lower fre-

(D)

EQUIVALENT and practical cirsuits of multi-diode oscillator (A) with test results; crystal oscillator for $40 \mathrm{Mc}(\mathrm{B})$, alternative oscillator locks onto 5 th overtone of crystal at $160 \mathrm{Mc}(\mathrm{C})$, characteristic surve traces operation of tunnel diode as it executes cycle of operation (D)-Fig. 4

SELF-MODULATED low pouer transmitter (A) operates at 73.5 Me; wide range oscillator (B) covers range 3 to 260 Mc using different plug-in tuning coils. Temperaturesensing oscillator changes frequency with changing temperature ( $C$ ), voltage-variable capacitor enables oscillator to be tumed electrically over the 12-22 Mc range (D); highfrequency electrically tuned oscillator operates in the 200 to $400-M c$ range (E)-Fig. 5
control is less straightforward. If a cristal is simply shunted across a tank circuit, it will lock in only weakly.

A more sophisticated crystal-controlled circuit discussed in the literature ${ }^{\text {mit }}$ claims frequency variations of $7.5 / 10^{n}$ per degree centigrade in a $40-\mathrm{Mc}$ oscillator. (Fig. 4B). This circuit works on the basis of matching the crystal impedance ( $10-30 \mathrm{ohm}$ range) to the tunnel diode (1N2939 and 1N3712 have approximately 120 ohm negative $R_{\text {I }}$ ) by the use of a pi network.

A nother extremely stable crystalcontrolled oscillator ${ }^{3 s}$ as oscillates only at the series-resonant mode of the quartz crystal, Fig. 4C, and is said to exhibit excellent lock-in characteristics up to the 9 th overtone (roughly 100 Mc ) and some lock-in action up to the 15 th overtone (about 160 Mc ) ${ }^{\text {na }}$.

The value of $R$ is made slightly smaller than $-R_{t}$ at the operating point. This gives bias stability and prevents the circuit from oscillating at an undesired frequency. The L-C circuit is tuned to the seriesresonant frequency of the crystal where the crystal appears as a low resistance. The resulting high impedance of the tank circuit is now in series with the parallel combination of the two equal-valued resistors ( $R$ ). It is necessary that the series resonant crystal resistance
( $R_{r_{R}}$ ) is small compared to $R$.
This high value of resonant impedance is now sufficient to permit the circuit to oscillate stably. The impedance seen by the crystal is $Z_{\text {in }}=R\left(1+R / R_{\text {er }}\right)$

TUNNEL DIODE CHRONOM-ETER-One of the applications of this quartz crystal controlled oscillator circuit is in a ultra-table chronometer having a maximum error of only a few seconds per year ${ }^{(2) 1}$.

In this circuit, tunnel diodes are also used as stable frequency dividers for division by 10,10 and 20 respectively. The divider circuits are of the synchronized relaxation oscillator type. A tunnel-diode clock is shown, lower right.

## REMOTE CONTROL TRANSMIT-

TER-A 73.5 Mc crrstal controlled oscillator was designed for use as self-modulated low-power transmitter.

This unit has sufficient energy to remote-control toys, trains, garage doors; it can also be voice modulated. Figure 5A shows the oscillator circuit ${ }^{\text {sn. } 21}$. The design of this circuit starts with the choise of diode to get adequate range. A 1N3716 diode having a peak current of about 4.7 ma was selected to give a power output of approximately 120 microwatts.

For the IN3716, tunnel diode $\left|g_{\text {rı }}\right|$ at 130 mv is approximately 33 ohms.

In this circuit, Fig 5A, when $X_{r}$ $=X_{\mathrm{t}}$, at $73.5 \mathrm{Mc}, L$ was calculated to be only about 22 nanohenries and $C$ about 218 pf.

To use a more practical $L / C$ ratio, $L$ was increased to 130 nanohenries and $C$ reduced to 35 pf . The effect was to reduce $g_{n}$, hence oscillations were larger (more output power) but distorted. The output taken across the tank circuit helps clean the waveform, however. The diode is operated at 130 mv and about 2.5 ma and the total battery drain is approximately 18 ma at 1.34 v. Line-of-sight transmission of 200 yards was achieved. The oscillator

TUNNEL diode clock features accuracy considerably better than maritime chronometers

is self-modulated by an audio tank circuit ( $L_{1}$ and $C_{1}$ ). The resulting audio tone activates a relay in the receiver. In place of $L_{1}$ and $C_{1}$ a microphone and a one-stage transistor amplifier to voice-modulate the transmitter could be used. External pulse modulation can be fed to the oscillator in a similar manner.

Frequency modulation is nhtained by the conductance and capacitance variation of the diode when the $d-c$ bias is voice modulated.

## WIDE-RANGE OSCILLATOR -

One example of such a circuit is the Heathkit Tunnel Dipper, a tunneldiode dip meter tunable from 3 to 260 Mc. The simplified oscillator portion of this circuit is shown in Fig. 5B.

This oscillator circuit is essentially of the parallel type, since $C_{s}$ bypasses $R_{7}$. The reason for this is to enhance the oscillator amplitude at the high frequency end. The diode is a low current, low capacitance axial unit. The circuit is tunable over the $3-260$ Mc band in 6 ranges of $3-7,5-13,12-32,30-90$, $80-160$, and $150-260 \mathrm{Mc}$, using plugin circuits. Capacitor $C_{2 A}$ tunes with each coil to cover the required band. Capacitor $C_{z B}$ is in parallel with $C_{m}$ on the four lower frequency ranges only. This gives a smaller $L / C$ ratio necessary at these lower frequencies
to obtain clean sinewave operation of the oscillator. ( $R_{T}$ being bypassed, is small, making $R_{\mathrm{r}} /\left|g_{\mathrm{H}}\right|$ small. To maintain reasonable sinewave oscillations $R_{r} /_{\mathrm{kd}}=L_{r} / C_{r}$, hence $L / C$ must be reduced.

A recent article ${ }^{81}$ discusses a tunnel diode r-f generator covering the 170 Kc to 46 Mc range in 5 bands of about $3 / 1$ spreads.

## TEMPERATURE SENSITIVITY-

A tunnel-diode oscillator can be made deliberately temperature-sensitive by the use of a capacitor or inductor with known and repeatable temperature characteristic.

The circuit shown in Fig 5C is a conventional series-parallel tunnel diode oscillator in which the sensor is a Mylar capacitor with known and reproducible temper-ature-versus-capacitance characteristics. To take care of frequency shifts due to bias-changes, a diode bias regulator circuit is used.

ELECTRONIC TUNING - The simplest electronically tuned tunneldiode oscillator uses the fact that $\left|g_{*}\right|$ can be varied with bias voltage. In the simple series oscillator for instance, the oscillator frequency is

$$
\begin{equation*}
f_{0}=\frac{1}{2 \pi} \sqrt{\frac{1-R_{T} g_{1}}{L C}} \tag{13}
\end{equation*}
$$

This expression shows that a variation of bias, which changes $10 \mathrm{~A}^{\prime}$, can affect $f_{0}$. One paper ${ }^{* 5}$ on a
microwave oscillator discusses $\varepsilon$. circuit with a 12 percent tuning range.

## EXTENDED-RANGE TUNING -

To extend electronic tuning ranges further, Varicaps can be used in conjunction with the tunnel-diode oscillator. Frequency ranges of almost 2:1 have been reported ${ }^{n, x}$.

One" low-frequency circuit, uses a 1 N2939 germanium tunnel diode and a PC-117-47 Varicap with a maximum supply voltage of 60 volts. With a tunnel-diode bias of 150 mv , it achieves a tuning range of from $12-22 \mathrm{Mc}$ by varying the Varicap bias from 0.4 to 60 v , Fig. 5D.

The high-frequency circuit operating in the $200-400 \mathrm{Mc}$ range, Fig. 5E uses a higher-power tunnel diode capable of 0.6 -milliwatt output.
Finally, a uhf varactor-tuned tunnel-diode oscillator has been described ${ }^{\text {* }}$ having a power output of 0.45 to 0.65 mw delivered into a $50-\mathrm{ohm}$ load. A voltage-variable capacitor, used above its self resonant frequency, is the tunable element. Using a 22 -ma, low-inductance ( 0.3 nh ) tunnel diode having a 20 -percent capacitance variation for the voltage swings encountered, and a PC-117-Hi-Q Varicap having a capacitance change of 8 to 1 for a $\Delta \mathrm{V}$ of 100 v below 400 Mc , a $600-$ 900 Mc tuning range was achieved.

OUTPUT voltage versus input voltage for an ideal logic element (A); basic circuit for near-ideal output-input relationship and interaction of FET and current-limiter characteristics (B); and screen-electrode principle with two fieldeffect transistors (C)-Fig. 1

## Put More Snap in Logic Circuits

## With Field-Effect Transistors

## Circuits using field-effect transistors with a current-limiter load achieve a snapaction

 rapid transition between switching states with a very small range of input voltageBy G. CSANKY and R. M. WARNER JR., Semiconductor Prod. Div., Motorola, Phoenix, Arizona

FULL EXCURSION of output voltage in an ideal logic element occurs within a very small range of input voltage. Moreover, the output excursion should occur near the middle of the input range as shown in Fig. 1A. An analogous relationship between input and output currents would serve as well. This type of logic element is efficient because switching occurs within minimum input drive. Furthermore, large margins are allowed for the initial and final values of the input drive and a switching speed-up effect is realized to the minimum rownon of the logic element.

The ideal characteristic can be closely approximated in several respects by using a field-effect transistor ${ }^{1}$ in combination with a cur-rent-limiter ${ }^{2}$ load as shown in Fig. 1B. Here the characteristic of the current limiter is plotted as a load
line and is nearly parallel to the field-effect transistor characteristic over a wide voltage range. As a negative voltage is applied at the input, the transistor characteristic is driven down, and the intersection of the two curves moves very rapidly from point 1 to point 2. As a result, a behavior similar to that
shown in Fig. 1 is realized.
The transition can be adjusted to the center portion of the input range by proper selection of relative pinch-off currents. The speed of transition from point 1 to point 2 is dependent upon the transconductance of the field-effect transistor as well as the slope of the

## SNAPPY LOGIC

Field-effect transistors are naturals for logic elements because switching occurs within minimum input drive when the FET's are combined with a current-limiter load. Moreover, both NAND and NOR functions can be performed with this circuit by varying FET and current-limiter diode pinch-off currents.

In this article, the authors describe the operation and applications of their circuit and point out the advantages that should allow it to find wide use

PHASE-INVERTING logic element with source follower (A); nonphaseincerting element with source jollower (B); element with high fan-in/ fan-out capability (C); and snap-action circuit for NAND and NOR functions (D)—Fig. 2
characteristic curves. Switching becomes more abrupt if the two interacting characteristics are flattened.

An appreciable increase in output impedance of a field-effect device can be achieved with the screen electrode principle. ${ }^{3}$ This principle may be applied to either or both of the devices shown in Fig. 1B. In the screen electrode principle two field-effect transistors are connected as shown in Fig. 1C. The basic requirement is that FET 1 has greater pinch-off current and voltage than FET 2. In this case, FET 1 will act like a voltage sponge; therefore, the drain of FET 2 will remain at a nearly constant voltage. This drain is the screen electrode which is analogous to the screen grid of a vacuum tube. This effect increases the output impedance of the field-effect transistor by two orders of magnitude; it has been shown experimentally that this reduces the switching time of the logic circuit comparably since the transconductance of the screenelectrode transistor is similar to that of FET 2 alone.

A steplike switching characteris-
tic can also be obtained with a negative resistance device under conditions where its characteristic makes multiple intersections with the load line during some portion of the switching cycle; however, in a case like this, hysteresis will occur. If the configuration shown in Fig. 1B is used, there is no hysteresis because the two characteristics intersect at only a single point during the entire cycle.

The circuit shown in Fig. 1B is a low-frequency configuration because the drain-gate capacitance imposes a frequency limitation that is similar to the Miller effect. During the transition from point 1 to point 2, the overall gain of the circuit approaches the $\mu$ of the fieldeffect transistor, and the input capacitance rises to a point where it has an important frequency limiting effect.

This circuit also poses a voltage translation problem. That is, negative voltages are required at the input, while positive voltages are delivered at the output. Therefore, a complementary element must follow this circuit, or a fairly large off-
set voltage must be provided.
MODIFICATION-Both problems can be solved with a slight modification of the basic element and two different solutions exist ${ }^{6,5}$. Both optimize the frequency response and eliminate the voltage translation problem by basically adding a source-follower stage to the circuitry. The two positions for the source follower lead to differing properties for the two circuits; however, both circuits make direct coupling possible (without voltage translation) and enhance frequency response. Moreover, they can be used to perform logic.

In case one, the source-follower stage is added to the input as shown in Fig. 2A. The source-follower voltage gain is close to unity so the effect of drain-gate capacitance is minimized. The output impedance of the source-follower stage is low, mitigating the high input capacitance of the field-effect transistor current-limiter combination.

The voltage translation problem is eliminated because the source of the field-effect transistor is kept above ground by $R_{s}$; therefore, the source-follower stage and voltagedivider $R_{1} R_{3}$ can carry the gate of the field-effect transistor negative with respect to its source. Voltage divider $R_{1} R_{\mathrm{z}}$ is introduced only to compensate for voltage drop occurring in the field-effect transistor.

This circuit inverts the phase; if increasing voltage is applied at the input, decreasing voltage is delivered at the output. However, it is possible to modify the circuit so that it will be noninverting. A circuit that possesses all the advantages previously discussed and does not invert phase appears in Fig. 2B. Basically, it is a special type of difference amplifier with the snapaction feature added.

Logic functions can be performed with either phase-inverting or nonphase inverting circuits by the parallel connection of input source follower stages. However, in this way, NOR or OR circuits can be produced having a fan-in of only 3 to 5 , because the range of currents permissible in the voltage divider is limited for satisfactory operation. The fan-out factor is also about 3 to 5 because of the high output impedance of the logic element that
is sensitive to capacitive loads.
In case two, a greater flexibility of circuit design is achieved with the added feature of high fan-in and fan-out. Here, the source-follower state is added to the output of the snap-action switch, as shown in Fig. 2C. This provides a low output impedance with the required voltage translation. Zener diode $D_{z}$, acts as a level-translator voltage buffer; thus, approximately the full voltage swing is realized at the output of the source follower.

The input of the logic element is the gate of the field-effect transistor in the FET-CL combination. A great variation of input capacitance during the switching cycle is realized through the Miller effect; however, its effect is mitigated by driving with the source follower of a similar preceding stage.

Both NAND and NOR logic functions can be performed with this circuit by varying the pinch-off currents of the field-effect transistors and current-limiter diode. A circuit which will perform the two functions is shown in Fig. 2D. It is a single circuit and only the choice of current determines the type of function performed. If the currents of field-effect transistors 1 to $n$ are selected so that when all are on, their current sum exceeds the current of the current-limiter diode CL, but will be less if any one is off, then the function performed will be NAND as this circuit inverts phase. However, if the drain current of any field-effect transistor 1 to $n$, if on, exceeds the current of the current limiter diode CL, the function will be NOR. This relationship is shown in Fig. 3A \& 3B.

A limitation of the circuit shown in Fig. 2A is its relatively low fan-in and fan-out capability. The fan-in of the circuit shown in Fig. 2 C and 2 D is extremely high. An ultimate limitation is the value of the cut-off currents of the fieldeffect transistors. Another limitation for the NAND circuit is technological; how close can the drain currents of the FET's be held? The value of drain current is geometry dependent and therefore the problem reduces to one of geometry control. It appears possible to obtain a fan-in of 50 .

The fan-out of the logic element is high too. When the logic element
is driven by a $10-\mathrm{Kc}$ sinusoidal input having a peak value of 10 volts and operating into one and ten paralleled inputs, respectively, the waveform for ten inputs, though slightly distorted, is still quite satisfactory. A greater distortion of the output waveform results if the logic element is driven by fast pulses having a greater repetition rate.
An interesting feature of these elements is that if driven with a sinusoidal input, the switching time is a constant percentage of the complete cycle $1 / f$ of the sine wave up to the maximum operational frequency. Also, the dimensionless factor of $f \tau_{\text {a....ion }}$ is constant within this frequency range.

It is possible to achieve snap action in a circuit analogous to that of Fig. 1B by substituting conventional transistors for the field-effect devices. The fact that an FET is voltage operated and can be self biased produces significant simplifications. Moreover, in all circuits, any kind of FET can be employed; that is, the principles are general and not applicable merely to an FET of certain special properties.

CONCLUSIONS - These elements cannot compete in speed at present with circuits employing conventional transistors, since the frequency range within which proper operation can be obtained is a few hundred kilocycles. However, in applications where speed is not a basic requirement, such as for periheral equipment in computers, their advantages can be fully exploited.

In addition to snap-action and direct d-c coupling, these circuits have the potential advantage of very low power dissipation. This relates again to the fact that an FET is voltage operated, and that very low operating currents can be chosen.

Field-effect transistors can be easily integrated in a monolithic configuration, because the current axis of a field-effect transistor integrated circuit lies in the plane of the wafer, rather than normal to it. Since certain electrical parameters are geometry dependent, simple concentric patterns can be used to integrate the circuit.

Finally, an advantage of the circuits is temperature compensation, because both the current limiter and field effect transistor have the same relative temperature coefficient. This means that the shft in operating point caused by temperature variation is small. In addition, the negative temperature coefficient of the devices will prohibit the thermal runaway of the circuits, making it a useful tool for higher temperature operation.

## Taking Human Error

THE ELECTRONIC TIMER described here provides both flexibility and accuracy. Time intervals can be varied from 0.1 sec to over 24 hrs with an accuracy dependent on the frequency standard used.

Figure 1 gives a breakdown of a programmed experiment where a number of runs make up an experiment. Each run has a set-up time and an active time interval. Set-up time is used to select the instruments and rotate the positioning equipment for the next run. At the same time, data from the previous run is read out. Active time intervals, $\Delta T_{1}$, $\Delta T_{2}-\Delta T_{n}$, are independent preset intervals during which data is accumulated.

SYSTEM COMPONENTS-The active time interval is controlled by the present timer. The timer includes a multiple preset six decade counter with binary coded decimal (bcd) outputs. Preset switches connected to the decade output lines control the counting interval.

The programmer is a seven-level paper-tape reader. Six levels are decoded to give sixty-four command characters, which controls position, mode, and readout commands.

The program tape format includes a position, mode select, and readout command. The experiment is controlled by the tape program and the preset timer. Active time of a run depends on the timer capacity, while the only limit to the number of runs in an experiment is the quantity of programmed tape available. When a number of runs are identical, or cyclic, the program tape can be a closed loop. An experimental run includes the steps laid out in Fig. 2.

While readout onto punched paper tape is in progress, the program reader gives the next positioning command. This allows the two dead time processes of data readout and positioning to occur simultaneously.

OPERATION-The timer scaling unit (Fig. 2B) consists of six decimal counting units (dcu) and

[^1]
# Control unit decides when to take measurements and what to measure, and also reads out data at intervals onto magnetic or punched-paper tape 

## Out of NUCLEAR EXPERIMENTS

a seventh unit is a scale of six. The time base input can be either the 60 cycle line frequency or an external reference oscillator. When line frequency is the time base, the scale of six counting unit converts the 60 cps to 10 cps . Output pulses, occurring at 0.1 second rate, are counted in the six decade scaling unit. The full count capacity gives a time interval of $99,999.9$ seconds. Each decade has four bed output lines (1, 2, 4, 8 weights). The coded output lines of a decade connect to a thumbwheel switch. This is a 10 position printed circuit switch whose contacts are arranged to accept the four line bed input. An output is produced when the count registered in the decade agrees with the number showing on the switch. For example, referring to Fig. 3, when a 7 is preset on the switch, the 1, 2, and 4 weight lines of the decade connect to the corresponding input lines on the switch. The 8 weight line is opened by the switch. When the decade registers 7 , all three inputs to the switch are posi-

EXPERIMENTAL timetable is followed by automatic timing equipment-Fig. 1
tive and transistor $Q_{1}$ is cut off. A preset of 7 on the thumbwheel switch connected to the least sig. nificant decade gives an output when 7 pulses are registered ( 0.7 seconds). Assume a second switch is connected to the next decade (seconds register). When a 4 is preset on the switch, an output is gen-

SEQUENCE of operations follows the numerical order shown in (A); logic diagram of timer unit (B)-Fig. 2

THUMBWHEEL logic requires all lines to be positive to produce an output-Fig. 3
erated when 4 counts are registered ( 4.0 seconds). The logical product of these two signals produces an output when 4.7 seconds have elapsed.

Up to this point, two decades of the timer have been connected to two thumbwheel switches. Preset intervals over the full time range are set up in the following way. A series of selector plugs have been prewired. Each plug connects two of the six decades to the two thumbwheel switches.

Four independent preset intervals ( $A B C D$ ) are available to control the active time of each of the twelve modes. Each mode switch selects one of the four preset intervals as shown in Fig. 4A.

The timer provides the start command to all data collection equipment. At the end of the active time interval, the timer gives the stop command to all circuits. To provide accurately controlled $\Delta T$ 's the synchronizing circuits shown in Fig. 4B are used. These circuits ensure the active time interval is synchronized with the time base oscillator.

A Schmitt trigger shapes the sine wave output of the reference oscillator to a fast rising square wave. The square wave is differentiated and gated with the shaped mode setup complete signal such that the first negative pulse after the rise of the mode setup complete signal (pulse 1 in Fig. 4B) sets the referENCE flip-flop.

Pulse 2 sets the Delete 1 flip-flop and starts the
active time interval. A delayed output of the delete 1 circuit is gated with the time base pulse train. This permits pulse 4 and each successive positive pulse to be counted.

The timer advances until the count registered is the same as the thumb-wheel switch preset. At this time, both the reference and delete 1 flip-flops are reset and the active time interval ends. Pulse 2 started the active time interval while pulse 4 was the first registered in the timer. This ensures that the active time and preset time intervals are of the same length. Since an advance timer pulse determines the end of a period, pulse 2 must be inhibited.

ALTERNATE DESIGN-The program preset timer is one variation of the idea of programming a series of time intervals by means of a program tape and reader. In another approach, the program reader can control the timing interval without the use of selector plugs and preset switches. Programmed commands directly select the timing interval. These commands consist of a group of characters. When the timer count agrees with the timer command, the active time interval stops.

A decision as to which of the two approaches to use depends on the particular application. In this experiment the programmer controls devices other than the timer, and was limited by sixty-four output commands. The four preset time intervals are sufficient for all anticipated $\Delta T$ 's. If more than 6 or 8 separate preset time intervals are required, controlling the timer directly from the program tape might prove more efficient. In this case it would have been necessary to record the time interval information of each data run in the experiment.

CONCLUSION-The programmable preset timer can be adapted to any sequentially dependent series of functions that contain a time variable. For the nuclear experiment at Argonne the timer provided the flexibility needed for useful automation. Once the program is written, the time setup and the modes of operation preset, the system will operate automatically.

This work was performed under the auspices of the U. S. Atomic Energy Commission.

SIGNAL FLOW and switch-setup for a single presct time (A) synchronizing circuit shows how avay of mode switches selects a preset time interval (B)-Fig. 4

## 2 nanoseconds/cm: impossible to photograph until now

Polaroid has a new film that is so fast, it will reproduce scope traces that are almost invisible to the naked eye. The one above, a scintillation pulse, has never been photographed until now. Pulse duration was ten nanoseconds. Scope sweep speed was 2 nanoseconds/cm. The new $10,000-$ speed Polaroid PolaScope Land film produced a finished usable print ten seconds after exposure.

The maximum writing speed of the 10,000 -speed film is about twice that of the Polaroid Land

3000 -speed film, which is currently the standard for high speed photography. The new film not only gets "impossible" pictures, it also produces far better shots of slower pulses and steady state waveforms. Because of its high speed, less light is required; camera aperture and scope intensity can be reduced considerably, producing sharper pictures.

And besides oscillography, the PolaScope film opens up new possibilities in applications where light is at a premium, such as pho-
tomicrography and metallogra. phy. It is not suited, however, for pictorial work due to its high contrast and relatively coarse grain.

PolaScope film (designated Type 410) is packed twelve rolls to a carton. The price is about the same as the 3000 -speed film.

The film can be obtained through industrial photographic dealers. For the name of the dealer nearest you, write to Technical Sales Department, Polaroid Corporation, Cambridge 39, Massachusetts.

# Rapid Method Measures Diode Characteristics

## Thin-Film Growth In Electric Field

APPLIED ELECTRIC d-c field causes dendritic growth in silver telluride thin film. Recrystallization process is illustrated at left. Effect of a-c field on silver telluride growth is shown at right. From paper presented by C. Paparoditis of C.N.R.S. Laboratories, Bellevue, France, at single-crystal thin-film conference at Philco Research Center, Blue Bell, Pa.

## Diode parameters can

be read off directly
on scope screen

MOST USEFUL semiconductor diodes follow the law $I=I_{0}\left(\epsilon^{\text {ap }}-1\right)$, where $I$ and $V$ are the diode current and voltage, and $I_{0}$ and a are constants which characterize the diode. The parameter $a$ is important since it is a measure of the diode nonlinearity.

For $a V \gg 1, \log I=a V$, and thus a can be determined by plotting the characteristic on semilog paper and measuring the slope. This however is time consuming, and a faster method will be described.

The circuit of Fig. 1 will produce a display of $\log I$ against $V$ on a scope face. The logarithmic voltage compressor unit, manufactured by Kane Engineering Laboratories, is capable of producing an output voltage proportional to the logarithm of the input voltage when the input voltage is greater than 0.3 volt. The current measuring resistor $R$, must be small compared to the input impedance of the logarithmic voltage compressor, and at the same time high enough to develop the minimum input voltage at low diode current. A value of 50 K works well.

There is still the problem of measuring the slope. Consider that the I-V curve for a resistor is $I=$ $G V$ where $G$ is the inverse of the resistance. Taking the $\log$ of both sides, $\log I=\log G+\log V$. Thus $d \log I / d V=1 / V$, or the slope of $\log I$ against $V$ is $1 / V$. This means that if a resistor $R$, is substituted for the diode, the slope is given by $1 / V$, independent of the value of the resistor. Figure 2 is a double-exposure photograph of curves for a 1 N 263 diode and for a

FLEXLEAD MB is Markel's answer to your bonding problems for applications requiring encapsulation of wires insulated with Teflon. Factory-applied to any of the FLEXLEAD Teflon Wires, extruded or tape-wrapped, the MB process renders the surface bondable with the commonly used elastomeric and epoxy-base potting and encapsulating compounds. Without affecting the color or electrical properties of the insulation, the MB treatment provides a bond with up to 150 psi pull-out strength, and a surface receptive to marking and printing.

## TWISTED PAIRS

The new FLEXLEAD Fused Twisted Pair construction of Teflon insulated wire provides all the characteristics of a balanced twisted pair, with the added advantage that it will not unravel during installation or after repeated flexing.

150 -ohm resistor. There must be some voltage, $V_{\text {o }}$, at which the diode slope is equal to the resistor slope. This voltage is read off the horizontal scale and $a=1 / V_{n}$. If $R_{r}$ is too large, the minimum input voltage
will not be developed across $R_{\text {. }}$. If $R_{\text {e }}$ is very small, the scale of the trace on the scope face will be inconvenient. A $2,000 \mathrm{ohm}$ potentiometer was used for $R_{r}$, varying $R_{r}$ to permit accurate slope comparison.

## Laser Link in Gemini?

Next stage of manned<br>space program may give lasers a tryout

HOUSTON-The future of the laser in manned space programs is getting a big boost here at the Instrumentation and Electronics System Division (IESD) of NASA's Manned Spacecraft Center. Several R\&D study programs-designed to screen out the "plausible from the far-fetched" applications-are now in progress.

The first actual applications of MSC's laser work could come on one of the early two-man Gemini space flights, which will probably start in 1965.

Present plans call for an experiment in which an astronaut would point a small hand-carried, voice-modulated, gallium-arsenide laser transmitter from the Gemini spacecraft toward a flare-marked ground receiver. Upon command, a 30 -second message would be beamed. This experiment has not been approved yet, but it is recommended by W. L. Thompson, who heads laser R\&D at MSC.

MSC engineers say, citing a more sophisticated possible application, that a Mars-bound astronaut could be supplied with instantaneous information on altitude and rate of descent from laser beacons dropped earlier by unmanned probes. Three beacons, forming a triangle, could reflect the laser beam from a descending spacecraft without signal interruption by rocket blast, pin-pointing the landing spot.

COMMUNICATIONS - IESD has had Hughes Aircraft studying the feasibility of an ultimate deep space communication system for several months. Electronics was
told that extending the study has been recommended.

Hughes is studying three areas: beaming the laser between spacecraft and the earth; between a spacecraft and an earth-oribiting satellite, then relaying to earth by microwave; and beaming the laser between a spacecraft and a lunarbased laser station, then relaying the signal to earth by microwave.

The study compares the laser and microwave. First reports reveal "the laser is winning out in performance and poundage."

RADAR AND RANGING-IESD has also been study development of optical radar, with Lincoln Laboratory. This may lead to the use of optical radar on later versions of the Apollo lunar excursion module (LEM). Presumably, says MSC, "it could replace a number of microwave systems now proposed for the Apollo mission amounting to a weight saving of about 100 pounds."

The division is studying laser beam attenuation through rocket exhaust. This may lead to a ranging device, or altimeter, aboard a later generation LEM. It could beam the laser directly downward through the exhaust's ion sheath to "feel" out the lunar surface for a safe descent.

MSC engineers also foresee a laser in an earth-orbiting satellite used as a navigation "fix" by a spacecraft returning from a deepspace mission.

# NEW GEN-PRO 700 SERIES INDUSTRIAL TERMINAL BOARDS 

ALL SIZES AVAILABLE NOW FOR TIMED DELIVERY AS NEEDED

Superior features - Competitively priced - Conveniently packaged

When you need terminal boards for any application, rely on Gen-Pro's great new 700 Series for the quality and interchangeability you want-on Gen-Pro's unique timed delivery for prompt as-needed shipments. Greater length-up to 46 terminals-permits a larger number of connections than ever before possible. Thicker, stronger barriers with rounded corners reduce breakage-creepage path is longer-saddle plates available for more secure mounting. All sizes and variations in number of stationspackaged in lots of 5,10 and 20. The boards of your choice are delivered from stock in the quantities you require-when you need them. All types of hardware and special molding compounds are available in addition to standard-purpose phenolic. Write today to Dept. SMMD for illustrated literature.

Your assurance of quality.
700 Series terminal boards are subject to the same rigorous quality control procedures as Gen.Pro's famous 400 Series - the finest commercial terminal boards available anywhere today.

## NEW from DEI PUSH-RUTTON PCM SYNCHRONIZER

- Exceptional Stability and Calibration Accuracy
- Correlating Bit Detection
- All Digital Loop Filter
- Wide Dynamic Input Range

100

1000
NOW-for the first time, push-button bit rate selection is possible!
From Defense Electronics, Inc. comes the latest in a line of PCM Digital Products.
The solid state BRS-1 Bit Synchronizer/ Conditioner has been designed for PCM telemetry applications and fea. tures accurate setting (within 0.1 per cent) for a known bit rate prior to actual, signal reception.
This exceptionally stable and highly accurate synchronizer accepts a serial PCM signal at rates up to 1 mc , automatically conditions the incoming data and generates a stable clock signal.
Automatic circuitry adjusts to input signals over a 40 db dynamic range. The unit incorporates a unique digital loop filter that maintains bandwidth proportional to bit rate at all frequencies. Output of the synchronizer is a reshaped, noise-free, serial PCM signal and a set of clock signals phase coherent with the output data.
The BRS-1-which can be remotely-controlled-performs the functions of data regeneration, format conversion and serves as the "front-end" for any digital telemetry system.

gasoline, diesel oil, methane and propane, operates at moderate temperatures ( 150 deg C ), much lower than previous hydrocarbon cells.

Developed with support from ARPA, the new cell converts the complex-molecule hydrocarbon fuels directly to pure water and carbon dioxide, with 100 percent oxidation and no byproducts. Practical efficiency is 50 to 70 percent, compared to 20 to 25 percent for combustion engines. Power densities to 25 watts a square foot have been achieved.

## Hybrid Computer Tells Pilot Where He Is Going

hybrid airborne computer weighing 30 pounds has been developed by General Precision to supply pilots with position, ground track and wind information. Called the Minac-5, the system uses solidstate components and has a selfcontained power supply. The pilot may change destinations, set required inputs and correct position information without loss of computations. The computer can store an alternate destination which may be selected at any time during flight.

## 100-Kilogauss Coil

SUPERCONDUCTING MAGNET has achieved 101,000-gauss magnetic field at General Electric's Research Lab (see ELECTRONICS p 7, June 7). Coil has 600 turns of special niobium-tin conductor $1 / 40$ inch diameter, passed 266 amperes at 1.8 deg Kelvin to achieve a field that, without superconductivity, would vequire about two million watts

for mounting on precision multiturn potentiometers, controls of precision Estimate $1 / 1000^{\text {th }}$ instruments, machine tools, etc.

# French Reveal New Field-Effect Structure 

#### Abstract

Overseas version uses majority carriers in a bulk conducting layer

By A. V. J. MARTIN, Paris, France

AN EXPERIMENTAL semiconductor device, developed at Compagnie Generale De Telegraphie Sans Fil in France, works on basic principles proposed for field-effect devices.

Structure of the French version, called the Statistor, is shown in Fig. 1. The photo shows a model that has been constructed based on this basic configuration.

The insulated control electrode can be driven either positive or negative with no detrimental effect on input impedance, which exceeds one million megohms. The associated input capacitance is 0.4 pf .

The lower bar of silicon in the diagram has noninjecting ohmic contacts at each end. One contact is the source, the other is the drain. The thin insulating layer of silicon oxide, placed over the semiconductor, is partially metalized, and provides the control electrode or gate.

A suitable control voltage applied to the gate creates a depletion region inside the semiconductor and modifies semiconductor resistance between source and drain. Varying the control voltage results in conductance modulation of the semiconductor. The conducting region of the semiconductor, called the channel, can be either $p$ or $n$ type.

Input impedance to the gate reaches $10^{12}$ to $10^{14}$ ohms in laboratory samples. The basic device uses no junction, so that noise and production problems associated with junctions are eliminated.

In actual practice, these advantages are only partially realized, mainly because of the necessity of obtaining a thin enough layer of semiconductor for field effect to
become significant. This imposes production techniques based on injection transistor experience, so that a junction is incorporated in practical design. However, this junction is a convenient production process, and is in no way a requirement of the device.

Performance of the unit depends upon the particular technique used in constructing hand-made specimens. Several methods have been investigated, and these have resulted in sizable dispersion of characteristics. Representative parameter values of constructed units are as follows: pinch-off voltage, gate shorted to source: 6 to 20 volts;

BASIC structure of field-effect device developed at CSF is shown in diagram. Photo shows actual construction of working model-Fig. 1
pinch-off current: 200 to 800 microamps; gate transconductance (positive gate): 80 to 200 microamps/ volt; gate transconductance (negative gate) : 80 to $180 \mu \mathrm{a}$ volt.

A production process results in a second gate, called the large gate, on the face opposite the control gate. This large gate can be used to bias the device and set the quiescent point in a better region of operation. Such a structure is properly called a tetrode. Diffusion, photolithography, mesa, epitaxy and planar techniques can be used to construct the basic structure.

A structure based on planar technology uses, as starting material, a $p$-type silicon monocrystal of 4 ohm resistivity. Oxide production and phosphorous diffusion are conducted through masks, those used for injection transistors.

In the present state of development, this device is relatively large ( $500 \times 200$ microns). The various points of the conducting channel are connected to the large gate (silicon body) not only through capacity, but also through the whole thickness of the high-resistivity silicon bulk. Consequently it would be advantageous to use a deep counter-diffusion and only a thin layer of high-resistivity silicon. Channel length may be reduced to ease voltage breakdown problems.

When used with a floating gate (no external resistor), the device can serve as a solid-state electrometer. A simple modification of structure leads to a symmetrical device that corresponds to double electrometer tubes. The device can be used in this way in all cases where a high input resistance is required.

BIOLOGICAL SIGNALS-Typical applications of the solid-state electrometer are in the measurement of very small potentials, as encountered in pH work or in biological signals, and also in the measurement of very small charges. Elec-

## with a DI-ACRO ROL-FORM DIE

Workmarking from forming sheet materials in press brakes and punch presses is greatly reduced and in many metals completely eliminated when formed with the Di-Acro Rol-Form Die. Hardened and precision ground rolls pivot smoothly in the die block to fold material without strain. You save costs by discarding elaborate and time consuming preparation and work methods, reducing polishing time, eliminating scrap parts. You also cut costs in press brakes and punch presses by reducing the number of dies needed and the set-up time.

One Di-Acro Rol-Form Die with a $60^{\circ}$ upper die forms any angle to $60^{\circ}$ and any thickness of metal to $1 / 8^{\prime \prime}$ just by adjusting the ram or bed of the brake. Where ultrahigh finish material is to be formed, nylon inserts can be used in the die block to further reduce the possibility of work marks.

The Rol-Form Die is offered in five styles and in lengths from 6 inches to 12 feet for use in all sizes and models of press brakes and punch presses.
For ordinary press brake forming ask about Di-Acro Standard Press Brake Dies.

trical charges due to ionization can probably be measured, with eventual direct integration by the long input time constant.

High-sensitvity high-impedance voltmeters can be designed around these field-effect devices.

A Statistor has been connected in a simple arrangement shown in Fig. 2. The photo shows a working model of this circuit. The entire circuit, including the battery, is concealed inside the sphere. The gate is connected to the sphere, supported by an insulating bushing. A current of about 40 microamps flows in the circuit and is indicated by the meter. When the hand, or any conductor however poor, is brought within distance of the sphere, an electrostatic charge builds up on the gate, and blocks the Statistor. The current drops to zero. The transistor is added in series to limit current.

Figure 3 is a trace showing two voltage-current curves corresponding to the two states of the fieldeffect device in the demonstration.

The Statistor is only one of a family of devices, called dielectrons, whose operation is based on field effect through a dielectric layer.

The research laboratories of CSF have been investigating field effect for several years. Their first commercial product was the Alcatron, a high power (several watts), highfrequency (above 100 Mc ) device.

PROXIMITY detector circuit is constructed in sphere shown in photo. French cigarette case in photo indicates size of actual unitFig. 2

VOLTAGE-CURRENT curves correspond to the two states of the Statistor in the proximity indicator circuit-Fig. 3

Investigation of space-charge control in a semiconductor through a dielectric layer has been carried on at CSF by R. Tribes, assisted by J. Barthez at the solid-state laboratory headed by J. Grosvalet.

## Low-Oxygen Silicon Crystals Hit Market

NEW PROCESS for manufacturing high-grade silicon semiconductor crystals has been developed by Texas Instruments. Crystals reportedly have low oxygen content and low etch-pit density.

Marketed under the name Lopex, the crystals have been sampled in industry since last November. Evaluation quantities have sold at prices ranging up to $\$ 10$ per gram, but the material now will be sold for $\$ 2.90$ per gram. Ralph Stroup, manager of TI's Materials \& Sensors Department, reports this price is competitive with premium-grade conventional float-zone crystals, but higher than typical crucible-pull crystal prices of $\$ 1.10$.

TI's Dallas Materials Plant, which claims the industry's largest output of semiconductor silicon, will have converted at least onethird of its capacity to the new process by the end of $1963, \mathrm{E}$. O. Vetter, Vice-President, reports.

The new process, according to Stroup, combines some of the technique of the float zone and crucible pull manufacturing processes. Beside being low in both oxygen content and etch-pit density, the Lopex crystals are high in minority carrier lifetime, Stroup said. Available in resistives up to 300 ohm-

Despite the tremendous speed and ravenous appetite of today's most advanced computers, scientists at Lockheed Missiles \& Space Company's Computer Research Laboratories feel that there is room for a great deal of improvement. They have dedicated themselves to the discovery and development of ways to increase the speed and reliability of computers while simplifying their operation.
Though today's computer circuits are capable of operating at speeds measured in tens of nanoseconds, the useful computation rate is far slower. One of the roadblocks hindering speed is the need for the computer to wait for the carryovers from one column of figures to catch up with the main calculation. A possible an-

swer to this problem is modular arithmetic, which avoids carryover. Based on the ancient Chinese Remainder Theorem, this concept is being re-examined at Lockheed for potential computer applications.

Lockheed's Computer Research Laboratories are studying a very broad group of related computer research areas, and the company can boast that an unusual number of its specialists are at the very forefront of their specific fields.

Among the major areas of research being undertaken at this time are basic physical phenomena, such as phonons; quantum mechanics; switching theory; residue arithmetic (number system research); threshold logic and pattern recognition and logic design techniques.

LOOK AT LOCKHEED... AS A CAREER
Consider Lockheed's leadership in space technology. Evaluate its accomplishments -such as the Polaris missile, the Agena vehicle's superb record of space missions. Examine its outstanding advantages -location, advancement policies, creative climate, opportunity for recognition.

Then write for a brochure that gives you a more complete Look at Lockheed. Address: Research \& Development Staff, Dept. M-48A, P.O. Box 504, Sunnyvale, California. Lockheed is an equal opportunity employer.
SCIENTISTS \& ENGINEERS: In addition to positions relating to computer research, such as logical design specialists and mathematicians, otherimportant openings exist for specialists in: Trajectory analysis - Inertial guidance . Electromagnetics • Orbit thermodynamics • Gas dynamics • Chemical \& nuclear propulsion - Systems engineering - Electronic engineering • Communications \& optics research

## LOOK AT LOCKHEED IN DIGITAL TECHNIQUES:

Basic research toward simpler, faster, more reliable computers

## VOLTRON ANNOUNGES A FUNDAMENTAL ADVANCE IN THE CALIBRATION ART

## The VOLTRON.GALMAN

AVERAGE VALUE TRANSFER STANDARD

WITH $\left\{\begin{array}{l} \pm 0.01 \% \pm 1 \mathrm{MV} \text { absolute ACCURACY } \\ \pm 0.001 \% \text { REPEATABILITY } \\ 10 \mathrm{MV} \text { RESOLUTION }\end{array}\right.$

Based on the unique Voltron-Galman Operational Rectifier configuration (patent applied for), this instrument permits rapid, positive calibration of digital voltmeters, transducers, analog data channels, and related averagesensing equipments, at secondary-standard levels of accuracy, with COMPLETE CONFIDENCE. Rectifier non-linearities, harmonic effects, and frequency distortion are all rendered negligible by this exclusive new circuit. This device responds to true-full-wave-rectified-average values - it does not employ peak-sensing or RMS-sensing.
The Voltron-Galman circuit is as fundamental and as readily standardized for average values as the well-known Hermach thermal standard configuration is for RMS values. Performance levels are comparable.
Model 12.583, shown above, generates 0.300 volts, in 10 MV steps, at low impedance, at discrete frequencies between 50 and 3000 cps ; distortion $<0.1 \%$. An unsaturated standard cell is the primary reference.
The Model 12.583 is COMPLETELY self.CONTAINED, including not only an ultra-stable oscillator, precision toroidal dividers, and operational rectifier, but also a standard cell, normalizing and standardizing networks, and a null-indicating galvanometer. No auxiliary equipment is required.

RODUCTS, INC.
1020 So. Arroyo Parkway, Pasadena, California

We have prepared a complete technical exposition of the theory of operation of this new circuit, including performance specifications. May we send you a copy?
centimeters, minority carrier lifetimes of crystals are more than 1 msec for resistivities over 50 ohm-cm.

Dislocation densities are reported to be so low that they generally are reported as nondetectable with presently used measuring techniques.

## Seek Efficient Approach To Reliability Analysis

TIME AND MONEY spent on rigorous testing procedures for component parts for advanced systems are fast becoming prohibitive. At the same time the consequences of system failure are becoming more intolerable. What is needed, according to Morton E. Goldberg, is a new approach to the reliability problem. An approach that does not treat the development of every new system as a separate reliability problem.

Goldberg is manager of reliability and components at Armour. He heads a program for determining reliability through analysis of failure mechanisms.

A number of investigators, including several at Armour Research Foundation, have struck out a new path through a broad program initiated by the Rome Air Development Center. General name given to the program is Physics of Failure. As its name implies, it is concerned with establishing, through considerations of the laws of physics, the mechanisms which lead to failure.

The ultimate hope of such an approach, according to Goldberg, is that mathematical models for computer programming be developed for related types of components.

## New Glass for CRT's

## Glows in Electron Beam

owens-ILLinois Glass Company reports it has developed a luminescent silica glass that may eventually permit fabrication of tv picture tubes without separate application of phosphors.

Normally colorless, the glass becomes colored, but still transparent when exposed to electron beams. The company says they may be used in the near future for radarscopes, displays and computer readouts.

TRUE CONCENTRIC STRANDED WIRE CONSTRUCTION
in your TEFLON`insulated wire components
Teflon wire suppliers can deliver premium products with the ultimate in conductor reliability built into them at no added cost by supplying true concentric conductor. Experience shows that true concentric strand costs less to insulate than second class substitutes.
And true concentric strand is the yardstick against which the performance of all other constructions is measured. No responsible authority has ever questioned the stature of true concentric as the ultimate in quality and reliability.
To engineer products that will endure, specify the construction that has withstood the test of time . . . specify True Concentric Strand.

# Infrared Inspection Promises to Assure Production Reliability 

## $R \& D$ work explores new in-line checking techniques

EXPLORATORY work at Raytheon continues to uncover significant applications of infrared techniques in production reliability control as well as in maintainability of electronic equipment. Early phases of work, basic techniques and equipment needed were discussed in the July 6, 1962 issue of Electronics (p. 72). Although work accomplished since then has been rather limited and in some areas has only scratched the surface, the findings are definitely promising. Important initial developments have been made by Raytheon engineers at the Communications and Data Processing Operation in Norwood, Mass. under the direction of Riccardo Vanzetti. But it has become apparent that the scope of work in the following areas transcends possibility of a single company bringing them to completion :

- Recombination reflection-energy liberated by current carriers in semiconductors
- IR detecting and measuring equipment
- IR microscopes
- Advanced equipment needed to perform "close-distance" work
- IR transmitting fibers to help detection of infrared emissions from components that are hidden, inconveniently located, or inside potted units
- New lines of semiconductors with encapsulation transparent to recombination radiation
- Welded or soldered connection tester.

Though there is still a long way to go in perfecting infrared inspec-

MICROWAVE plumbing is production-tested with Barnes Engineering radiometer. Infrared instrument pinpoints areas of r-f loss which manifest themselves as heat sources. This is one of numerous infrared manufacturing applications being investigated by Raytheon
tion, work already accomplished in the following areas provides a solid basis for further efforts:

- Checking components during manufacture
- Checking components at the receiving-inspection level
- Checking circuits and assemblies at in-process inspection level
- Locating failure causes during production test and troubleshooting
- Post-production maintainability of equipment.

## MANUFACTURE CHECKING-

Thermal resistance, heat flow lines, inhomogeneties, etc. might go undetected by most conventional test equipment. However, when examined with infrared equipment, such factors produce tell-tale anmolies in infrared emission patterns.

For example, in graphs showing recorded pattern of a wire-wound resistor variation in $d-c$ resistance caused by a nick in wire is indicated by an abrupt pattern peaking caused by a localized increase in temperature. Poor welds between the wire and the terminal metal cap and winding irregularities would also show up as a local increase in
temperature and infrared radiation.

RECEIVING INSPECTIONTwenty power transistors (type JAN 2N174) will serve as a good example of the value of ir receiving inspection. These twenty transistors were meeting all the specifications of electrical inspection. Consequently, all were rated as good. But, when energized, ir inspection showed that each of them had different initial infrared characteristics as indicated in the curves recorded.

Some of them had a fast initial rise in infrared emission but soon settled to a rather low final level. While others showing a slow initial rise, eventually attained a higher final level. But with one transistor, the curve is drastically higher than other curves. Obviously, something was probably wrong with a transistor showing such a high operating temperature.

This was borne out when all twenty transistors were left running in a life test at 0.6 of their rated power dissipation. After 1,000 hours, this transistor was the first failure.

A second failure did not occur

## How General Dynamics/Electric Boat precision-cleans missile launching-tube components for Polaris subs!

PROBLEM: Pneumatic launching-tube systems for the Polaris, involving miles of pipes, tees, valves, unions, etc., must be kept scrupulously clean at all times, according to Electric Boat. In an environment of high air pressure, the most minute organic contaminants could support a dangerous explosion. The previous cleaner was rated only 83 to $88 \%$ effective in removing a known hydrocarbon contaminant; also it had to be heated to $160^{\circ} \mathrm{F}$. before use. SOLUTION: All launching system components are now cleaned in an ultrasonic bath of Freon fluorocarbon solvent, both initially and during subsequent maintenance. Freon scores $100 \%$ every time on the hydrocarbon contaminant test, and works perfectly at ambient temperature.

Electric Boat continues, "Besides cleaning effectiveness, Freon has high purity, extremely low toxicity, nonflammability and ease of handling. Then, it's noncorrosive to metals and generally inert to plastics and elastomersso Freon is ideal for cleaning when many different materials of construction are involved. Also, Du Pont supplied us with plenty of research data, which saved us time because we didn't have to run extensive analyses ourselves."

We'd be happy to show you how Freon can improve your own cleaning operation. First send the coupon or Reader Service Card for our new booklet on cleaning!

until after 2,000 hours. This time it appeared at first look rather surprising since its infrared characteristic curve lies at the bottom of the individual curves. However, subsequent transistor examination indicated that it possessed very high thermal resistance. This would cause a large temperature gradient between the junction and the outside envelope of the transistor. Thus, while the envelope looks rather cool under infrared examination, the junction inside runs at much higher temperature because it doesn't have adequate heat-dissipation capabilities.

Hence, there is promise of being able to detect at least two types of transistor failure mechanisms. However, further work has to be done to determine degree of success in weeding out early failures in transistors and diodes and how well ir can help one to predict life expectancy. The other eighteen transistors are still running in the life test. So far no further failures have developed-after a full year of continuous operation.

To further evaluate scope and capabilities of inspection system, Raytheon has recently started testing much larger groups of transistors and diodes, hoping to discover the correlation laws between ir readings and life expectancy.

IN-PROCESS INSPECTION-Infrared techniques should allow one to identify in-process defects that are otherwise not only difficult to detect but are also most often the causes for early system failures. Welded and soldered joints suffer their fair share of such defects.

Visual examination of these joints cannot disclose any faults hidden below the visible surface. Thus, poor spot welds and cold soldered joints often go undetected. However, infrared examination of heat developed when adequate electrical current flows through joints will tell whether area of fusion is large enough.

Another in-process inspection area is the identification of semiconductors that have been damaged by heat of soldering. Presently, while there is information of a statistical nature for forecasting failures, nothing exists to locate damaged components prior to actual operational failure.

The implementation of infrared location techniques in this area calls for comparison of infrared radiation levels from semiconductors in their energized circuits, before and after soldering. This can be done in at least two ways:

- One way is to use semi-liquid solder paste that can be washed away for making temporary connections
- The other (when working on printed circuit boards) is to use a counter-bottom plate with small cavities filled with mercury to provide temporary connections between wires and lands.

Using these approaches, infrared recordings before soldering can be compared with those after soldering to point out components whose parameters have deteriorated.

ASSEMBLY CHECKS-When individual circuits are assembled into systems, the nature of resulting circuitry can bring out component defects not noticed during unit electrical tests. Frequently, no easy electrical measures will reveal conditions that are conspicuously indicated in infrared recordings:

One very interesting example involved detection of an overstressed transistor that would have caused an early failure. Transistor operated in a building block having three identical inverter circuits. After having passed all electrical specifications tests, the energized panel was scanned by an ir detector. Examination of resulting ir profile showed that transistor in center circuit had a much higher infrared emission than expected indicating an undesirably high power dissipation level.

TROUBLE SHOOTING-In production check-out of assemblies and subassemblies, an infrared profile obtained by scanning the energized units can be used to locate failure sources and their nature. Detection is based on the fact that every operating condition of an electronic assembly has a typical profile that could be called its "fingerprint" since it is unique in shape and configuration.

A graph illustrates such a normal pattern by means of solid blocks indicating "proper" infrared emission. Improper circuit functioning is shown by jagged lines related to

## THIS IS THE DVM THAT REVOLUTIONIZED DIGITAL INSTRUMENTATION

Introduced in 1961, the all solid-state, automatic ranging Series 5001 has in the past two years become accepted as the standard for laboratory and digital systems instrumentation. $\square$ Keystone of the EAI line of all solid-state digital voltmeter instruments, the Series 5001 is priced at only $\$ 3,950$ and features:
> $\pm .01 \%+1$ digit absolute accuracy
> 100 microvalt resolution
> 4 ranges to 1199.9 volts dc.
> 200 readings/second
> guaranteed 6 months stability
> all solid-state reliabiliy
> completely automatic and programmable
> complete system flexibility

Companion instruments to the 5001 also feature 6 months stability, all solid-state reliability and complete system flexibility. They include:

accompanying abnormal infrared emission. It often happens that infrared emission of almost every component has changes because the failure source is located at the front end of system thus altering performance of subsequent components in signal-flow path.

The fact that every type of failure has its own typical "fingerprint" should be extremely useful in an automated test and trouble shooting operation: The standard profile that units are supposed to meet is put into a memory along with all the infrared profiles of every possible failure. Coincidence comparison is made of "live" profile with standard and failure profiles to determine acceptance or failure classification indicating required corrective work.

## 25-Ton Press Features Large Mold Area

dESIGNED especially for encapsulation molding of resistors, capacitors, diodes, and similar electronic and electrical components, using epoxy or silicone resins requiring low to moderate pressures, a new 25 -ton semi-automatic compression/transfer molding press has a relatively large platen area for a press of this tonnage. It was developed by F. J. Stokes Corporation, Philadelphia.

Mold area is 18 by 19 inches to allow a considerable number of pieces to be molded in a single shot. Multiple-cavity molds for as many as 120 capacitors can be accommodated.

A fixed lower platen makes it suited for automatic loading of work-holding fixtures. Height of platen above floor-level is 38 inches so that platform for the operator is not needed.

Standard configuration of the press (Model 735) utilizes top clamp and bottom transfer and ejec-tion-an arrangement which reduces cycle-time. However, the press can be built to provide bottom clamping and top transfer if desired to accommodate existing tooling.

Separate hydraulic circuits for the clamping and transfer rams are provided, both fitted with pressure adjustments for rapid setup. Speed
of travel of the transfer ram can be regulated by a pressure-compensated flow control valve, providing fast movement, initially, then slowing to complete the transfer of material. Low-pressure clamping protects the mold from damage as well as providing protection for the items being encapsulated.

The mechanical ejection system is operated by the opening and closing motions of the clamping system. Hydraulic ejection is available as an optional feature.

The electrical control panel is mounted on one of the front tierods. The base of the press is designed with the hydraulic equipment to its left, so that an electronic preheater can be positioned close alongside the press. An oil filter and double heat-exchanger are included as standard equipment. Provision for electrically heating the mold, with pyrometer temperature controls, and a safety gate are optional features.

## Verifies Linearity of Dial Indicators

MICROMETER instrument weighs 6 pounds and measures 5 衣 by $6 \frac{1}{2}$ inches

EASY-TO-USE instrument for verifying linearity of dial indicators on dimension gaging fixtures is available from Sheffield Corp. Instrument consists of an ultra-precise micrometer that is guaranteed to be accurate to within 10 millionths of an inch per inch. Operating over a measuring range of one inch, the instruments 4 -inch barrel provides the 10 -millionth/inch vernier-scale reading. As shown in photo, micrometer's rotating anvil is worked-in against cartridge of gaging fixture. Linear verification is made by comparison of reading obtained from gage and that on micrometer barrel. Rotating thimble on micrometer zeroes instrument in with indicatting system of inspected gage.

# How to cutyour handling time . 

The Leesona No. 115 Bachi Bobbin Winder reduces coil handling time to a minimum for a singlehead machine. All the operator has to do is load the bobbin on the arbor, close the tailstock, let the wire slip into the wire guide, and close the safety guard.

## The No. 115 automatically:

- Starts
- Runs smoothly and quietly to 12,500 rpm
- Stops at $\pm 2$ turns
- Re-indexes the wire guide
- Resets counter

Also available is the No. 115-B winder with bonding attachment to produce perfectly self-supporting coreless coils.

For full details write Leesona Corporation, Warwick, R. I. Or call Leesona at 5700 W. Diversey Avenue, Chicago 39, TUxedo 9-5735; 1500 Walnut St., Philadelphia 2, KIngsley 6-1720, or A. R. Campman \& Co., 1762 Vernon Ave., Los Angeles, AXminister 3-6265.

## Generator Simulates Megapulse Source

#### Abstract

Four-pulse trains can be manipulated for parallel, serial, or staircase output

PULSE-TRAIN generator provides a versatile combination of four independent pulse sources, with outputs capable of being fed along separate lines, fed out serially, or superimposed, on common line. Spaced with 5 nanoseconds p-p separation the output-train simulates a $200-$ Mc pulse source of 25 volt amplitude. Individual pulses can be switched in or out, inverted, or combined to produce a single

2.5 ns rise-time pulse delivering 2 amps into a 50 ohm load. The pulses can also be combined to produce a staircase waveform (top oscillogram) or simulate a 300 megapulse source with reduced

## Linear Encoder Follows Absolute Motion

NEW one-brush linear-motion encoder translates absolute positional data with resolution of 1 ,000 counts in 11 inches and a onecount accuracy. Life of the unit is in excess of 4 million brush passes, starting force on the single brush is about 1 gram, and the unit accommodates a total count of 999 using only six wires rather than the customary 12. Owing to the unit's use of storage flip-flops the commutator is not obliged to feedout continuous data but need only feed the flip-flops with change-ofposition information.

Logic is binary coded decimal and the encoders come in 11 inch

lengths; they are intended for use in a wide range of industrial applications involving linear motion, including plotting tables, machine tools, strip-chart recorders, and so forth. The manufacturer is Perkin Elmer Corporation, Norwalk, Connecticut. (302)

## L-Band Transformer Aids Radar Tracking

miniature transponder was developed for the Air Force as a radar tracking aid for supersonic tow targets. Feature of the transmitter output is the use of a swept frequency pulse to insure that the signal is within the narrow bandpass of the search radar receiver when the radar is subject to frequency drift. Unit is also available in a variety of receiver sensitivities, transmitter power outputs and coding modes for use as a "poor man's iff beacon" for drone targets and other small aircraft. Weight is 3.75
pulse height as shown in the bottom oscillogram. The generator manufacturer is Nanosecond Systems, Inc., 176 Linwood Avenue, Fairfield, Connecticut.

Mixer-Amplifiers
Aid System Designer
NEW waveguide mixer-amplifier, type 135, solves the problem of matching the mixer and amplifier stages for the system design engineer. He is no longer reliant upon several sources of supply to ensure proper system operation. From r-f input to i-f output, the type 135 provides results that are predictable, specified, and guaranteed. Type 135 units use standard type 134 hybrid preamplifiers, and combination amplifiers, which have been designed and tested to meet the most demanding requirements. Units were tested to comply with the environmental requirements of MIL-E-5400E, Class 1 temperature and Ourve IV vabration. The mixers are integrated with solid-state low-noise preamplifiers providing 30 or $60-\mathrm{Mc}$ output. Airborne Instruments Laboratory, Deer Park, L. I., N. Y. (306)

Magnetic Reed Relays Feature Long Life
DESIGNED for direct p-c boaru mounting, these magnetic reed relays feature contact ratings of 4 w , $0.125 \mathrm{amp}, 250 \mathrm{v}$, from 1-12 contacts, in standard 6,12 , or 24 v coils. In addition to standard form $\mathbf{A}$ (spst) normally open contacts, combinations of form $A$ and form $B$ normally closed contacts are also available as are contact ratings up

## "'NAVCOR, OR EQUAL"'

Why not specify the most carefully crafted digital systems modules made? All the printed circuitry of Navcor 400 Series modules is gold-plated. Every joint is precision soldered by hand. Each module is designed to 'worst case' tolerances, quality controlled in manufacture to meet highest MIL Standards. And each Series 400 is a system function module with unmatched packing density. ## Attention Module Makers! INCREASE WELD CONSISTENCY, RELIABILITY

THIS NEW WELDMATIC 1065 DUAL PULSE POWER SUPPLY

Want more Facts? Write Weldmatic Division/ Unitek, 950 Royal Oaks Drive, Monrovia, California. Request Bulletin P8-26.

## Has Two Optimum Pulse Shapes

Long - for high conductivity metals like Tinned Copper

Normal-for high resistivity metal like Kovar, Dumet

## FOR SUPERIOR QUALITY CONTROL -

Precise pulse of heat energy is accurately matched to metal's weld characteristics. Hence, a wider latitude of weld reliability on every joint you weld.
Each pulse has an ultra high stability. It is exactly repeatable, weld after weld.
Energy pulse generated by two separate circuits. Optimum shape of each pulse based on 18 months of intensive field research.

Dual range (20/100WS) power supply is further matched to follow up characteristics of Weldmatic 1032 head promoting even greater weld accuracy.

## WELDMATIC DIVISION / UNTTEK

cps is provided for $\mathrm{a}-\mathrm{m}$ and $\mathrm{f}-\mathrm{m}$, or an external source may be used. External video modulation from 3 cps to 6.5 Mc is also possible. Type SDAF has a vswr of less than 1.1 at 50 ohms output impedance, and less than 1.15 at 75 ohms. Rohde \& Schwarz, 111 Lexington Ave., Passaic, N. J. (309)

Tantalum Capacitors Feature Small Size
TYPE DPSD epoxy dipped, solid electrolyte, tantalum capacitors offer a substantial reduction in size over conventional type CS-12's and CS-13's of Mil 26655/2A, and are lower in cost. Their design suits them for printed circuit applications. They are also avaliable with axial leads for conventional applications (all leads are weldable). Capacitance is $0.0047 \mu \mathrm{f}$ to $330 \mu \mathrm{f}$. GLP Electronics, Inc., 350 Riverside Ave., Bristol, Conn. (310)

Tunable Magnetron Weighs Only 22 Ounces
MODEL BLM-104 is a 5 Kw tunable magnetron weighing only 22 oz . It is designed for Ku band beacon applications in airborne and missile environments, and for altimeters, and may be used in portable ground equipment where minimum weight and maximum efficiency are important. Tunable frequency is 15.8 to 16.2 Gc , peak power output (min), 5 Kw ; peak anode voltage (max), 6.8 Kv; peak anode current (nom.), 3.75 amp . Varian Associates, Salem Road, Beverly, Mass. (311)

## ON THE SHELFARNOLD CORES IN WAREHOUSE STOCK FOR IMMEDIATE DELIVERY

Let us handle your inventory problems and save you time and money on your magnetic core requirements.
Extensive stocks of four types of Arnold cores in the most popular sizes have been set up in our Marengo, Illinois and Fullerton, Calif. plants. Subject of course to temporary exhaustion of stock by prior sales, these cores will be shipped the same day on orders received at the warehouse by 12:00 noon. When cores are out of stock at the nearest plant, we may be able to ship within 24 hours from. the other.

Arnold core products covered by this warehouse stock program
include: 1) Silectron C, E and O cores in 2, 4 and 12 -mil tape. 2) Type 6T aluminum-cased cores of Deltamax, Square Permalloy and Supermalloy, in 1, 2 and 4 -mil tape. 3) Mo-Permalloy powder cores, both temperature-stabilized and unstabilized types, ranging. down to $0.260^{\prime \prime}$ diameter. 4) Iron powder toroids, threaded cores and insert cores.

All four products are available in a wide range of selection, for your convenience and economy in ordering either prototype design lots or regular production quantities. - Stock lists and technical material are available-write for data.

## Hughes Fills Three Management Posts

HUGHES AIRCRAFT Company's ground systems group, Fullerton, Calif., announces three appointments to management posts.

Francis J. Alterman has been named manager of the computer division. He was formerly president of Advanced Scientific Instruments, Inc.

The computer division is engaged in the development of high speed, general purpose, real-time computer systems for military and commercial application.
Adam E. Abel has been appointed manager of the communications division. Before joining Hughes, he was general manager of the radio division of Bendix Corp.

The communications division is engaged in the development and manufacture of advanced communications systems and components, including air-to-ground and point-to-point radio, signal processors for high-speed data transmission, ground terminals for space communications, and laser communications.

## Lear Siegler Reports Building Plans

PLANS FOR CONSTRUCTION of a $\$ 1.3$-million, 100,000-square-foot building on the 65-acre Lear Siegler Aerospace Complex, in Grand Rapids, Mich., have been announced by Joseph M. Walsh, president of the Instrument division. The new administration building is in addition to the 270,000-square-foot manufacturing facility completed in 1959 and the 80,000-square-foot Aerospace Development Center dedicated in December. 1962. Construction will begin this summer with completion scheduled for June, 1964

Lloyd C. Myers moves from manager of materiel department to manager of the engineering fabrication and procurement department.
This department maintains the fabrication, assembly and planning capabilities in support of the engineering divisions and incorporates the additional support functions of purchasing, quality assurance, finance, material control, receiving and stores under a single line responsibility.

## Mallory Capacitor Appoints Etter

Wayne etter has been named president and general manager of Mallory Capacitor Co., a division of P. R. Mallory \& Co., Inc., Indianapolis, Ind.

Prior to this appointment, Etter was president of the Mallory Timers Co., another major Mallory division.

Mallory Capacitor Company manufactures a complete line of aluminum and tantalum as well as a-c dielectric capacitors. Plants are located in Huntsville, Ala., and Crawfordsville, Greencastle, and Indianapolis, Ind. Etter will direct all operations from company headquarters in Indianapolis.

## General Technology Elects Heilman

LEONARD J. HEILMAN has been elected president of General Technology Corp., Torrance, Calif. He

## Are you a COMPLETELY INFORMED electronics engineer?

Today you may be working in microwaves. But on what project will you be working tomorrow? You could have read electronics this past year and kept abreast of, say, microwave technology. There were 96 individual microwave articles between July, 1961 and June, 1962!

But suppose tomorrow you work in some area of standard electronic components, in semiconductors, in systems? Would you be up-to-date in these technologies? Did you read the more than 3,000 editorial pages that electronics' 28 -man editorial staff prepared last year?
electronics is edited to keep you current wherever you work in the industry, whatever your job function(s). If you do not have your own copy of electronics, subscribe today via the Reader Service Card in this issue. Only $71 / 2$ cents a copy at the 3 year rate.

INSTRUMENTATION COMPANY
583 Monterey Pass Rd., Monterey Park, Calif.-Phone: CUmberland 3.7773
participated in the formation of GTC and for the past year was vice president and general manager.

General Technology Corp. is engaged in the development of advanced space simulation test facilities, electronic frequency control instrumentation and plasma propulsion research.

IMC Magnetics Promotes Morreale
ANTHONY MORREALE has been promoted to a vice presidency of IMC Magnetics Corporation's Western division, at Maywood, Calif. He was formerly manager of the division's rotating components section.

The Western division manufactures solenoids, synchros, servos and pulse-driven step-servo motors and systems for a variety of electronics and aerospace applications.

Corporate headquarters of IMC Magnetics is in Westbury, N. Y.

Harr Moves Up at Teleregister
LUTHER A. HARR, JR., has been named executive vice president, The Teleregister Corp., Stamford, Conn. He has been assistant to the chairman since January.

Harr had previously been director of Univac operations for Europe, Africa and the Middle

## EMPLOYMENT OPPORTUNITIES

The advertisements in this section includa all employment opportunities-executive, monagement, technical, selling, office, skilled, manual, etc.
Look in the forward section of the magazine for additional Employment Opportunitios advertisins.

- RATES -

DISPLAYED: The advertising rate is $\$ 40.17$ per inch for all advertising appearing on other than a contract basis. Contract rates quoted on request.
An advertising inch is measured $\mathbf{z}^{\prime \prime}$ vertically on a column-3 col-umns- 30 inches to a page.
Subject to Agency Commission.
UNDISPLAYED: $\$ 2.70$ per line, minimum 3 lines. To figure advance payment count 5 average words as a line.

Box numbers-count as 1 line.
Discount of $10 \%$ if full payment is made in advance for 4 consecutive insertions.

Not subject to Agency Commission.

## INSTRUMENT TECHNICIANS THE OAK RIDGE NATIONAL LABORATORY Operated by

UNION CARBIDE NUCLEAR COMPANY

## at <br> Oak Ridge, Tennessee

HAS OPENINGS FOR
highly skilled instrument fechnicians to work with enginears in the inatillation and maintenance on for nuclenr reactors and asectiated experiments. Nuclear reactor control system experience desir. able but not essential.
Minimum high school aducation. with additional training in oither the physical sciences, instru. mentalion. or elactronics. and at least 3 years alox Instrumenfation and control systems. Entrance rate $\$ 3.19$ per hour: $\$ 3.25$ per hour after six months. Reasonable interview and relocation ex penses paid by the Company.

Excellent Working Conditions Employes Benafit Plan

## Kollsman Motor Names Cohen

STANLEY COHEN, former chief engineer of Kollsman Motor Corp., Dublin, Pa., has moved up to vice president of engineering.

Kollsman Motor manufactures synchronous and servo motors, amplifiers, servo systems and components.

## PEOPLE IN BRIEF

Joe Adkins moves up to mgr. of quality control of Stewart-Warner Electronics. William E. Brown, formerly with Fansteel Metallurgical Corp., named chief engineer of the Hi-Voltage div. of Wabash Magnetics, Inc. Richard W. Cobean leaves GE to join G-V Controls Inc. as mgr. of product engineering. IBM promotes Donald W. Seager to mgl . of corporate mfg. planning. Roy J. Keller advances to the post of mgr . of operations planning at Stromberg div., General Time Corp. Arthur F. Chace, Jr., elevated to president of Vitramon, Inc. David R. Steenhausen, previously with ShephardWinters Co., appointed applications mgr. for the Berkeley div. of Beckman Instruments, Inc. He succeeds Edward F. Mullen who has been named product line mgr . for special projects. Alan J. Brown promoted to senior communication engineer, Lynch Communication Systems Inc. Kenneth R. Jackson moves up to asst. $\mathrm{g}-\mathrm{m}$ of the Computer div. of Packard Bell Electronics. Elbert Leon Aiton, exUnited ElectroDynamics, Inc., joins Electro-Optical Systems, Inc., as mgr. of reliability. LearSiegler, Inc. ups George L. Loomis to director of operations, Power Equipment div. Edwin J. Deadrick, with Audio Devices, Inc., since 1950, elected v-p in charge of mfg . Nazzareno P. Cedrone, previously with Bendix Systems div., named chief engineer, defense products, at Singer Metrics div. of The Singer Mfg. Co. Robert A. Nelson leaves Litton Industries to become v-p and g-m of its Triad Transformer Corp. division.

MEMORY-as constant as the North Star, as lively as the last incremental count. General Time's INCREMAG provides this needed characteristic in electronic digital systems. Peak of the current state of the art, this completely solid state magnetic counter has proven its reliability in scores of military and industrial applications. It performs many functions.

- Counting
- Frequency Dividing
- Programming
- Timing
- Memory Storage
- Pulse Delay

Integrating
INCREMAG will count either periodic or random pulses without loss of prior count. Even if power fails, INCREMAG remembers.
Like all Gencral Time electronic systems and components, INCREMAG offers these advantages.

## - Simplicity of design-dependability <br> - Low power consumption <br> - Minimum size and weight <br> - Rugged construction

INCREMAG is available on an off-the-shelf basis, or can be readily modified to meet special needs.

# electronics WEEKLY QUALIFICATION FORM FOR POSITIONS AVAILABLE 

## ATTENTION: Engineers, scIENTISTS, PHYSICISTS

This Qualification Form is designed to help you advance in the electronics industry. It is unique and compact. Designed with the assistance of professional personnel management, it isolates specific experience in electronics and deals only in essential background information.<br>The advertisers listed here are seeking professional experience. Fill in the Qualification Form below.

## STRICTLY CONFIDENTIAL

Your Qualification form will be handled as "Strictly Conidential" by ELECTRONICS. Our processing system is such that your form will be forwarded within 24 hours to the proper executives in the campanies you select. You will be contacted af your home by the interested companies.

## WHAT TO DO

1. Review the pasitions in the advertisements.
2. Select those for which you qualify.
3. Notice the key numbers.
4. Circle the corresponding key number below the Qualification Form.
5. Fill out the form completely. Please print clearly.
6. Mail to; Classified Advertising Div., ELECTRONICS, Box 12, Now York 36, N. Y. (No charge, of course).

 ENGINEER
have you considered the UNIQUE OPPORTUNITIES

## ...At General Dynamics / Electronics in Rochester, N.Y.?

Work is in progress here on electronic equipment intended for the most advanced tactical aircraft under design. This includes the most sophisticated equipment that can be designed in the aireas of airborne radar, airborne communications, navigation and fire control.

The singular advantage to the Design Engineer at General Dynamics/Electronics is the opportunity to learn at the inception stage the complete equipment - its operation, capability, circuitry - and to grow with a long range program.

## Positions Are Open for Graduate EE's with Design Experience in the Following Areas:

Space communications<br>Telemetry receivers \& transmitters<br>Tracking equipment<br>Mobile communication sets<br>Reconnaissance/countermeasures<br>Doppier systems<br>Data communications

Computer logic circuits
Navigation aids
USW/ASW equipment
IFF equipment
Aerospace ground equipment
RF circuitry
Advanced pulse circuitry
UNIQUE LIVING ADVANTAGES, TOO. When you come to General Dynamics/Electronics you join two professional communities - the Company and the city of Rochester, which has the largest percentage of professional people for a city of its size $(500,000)$ in the nation. And, in many ways Rochester is an ideal spot for an engineer or scientist to live and raise a family - noted for its cultural advantages, excellent educational opportunities, friendly neighborhoods, modern hospitals, unrivaled city parks, exciting nearby historical and vacation spots.
If you would like to get in on this unique opportunity, send a resume now to Mr. R. W. Holmes, Registered Engineer, Dept. 22

## For higher TWT efficiency...a hollow beam

STS-188, a 2 kW, S band TWT proves Sperry's capability in depressed collectors. Six other models ranging through $S, C$, and $X$ bands, are also operational at $10 \mathrm{~W}, 20 \mathrm{~W}$ and 2 kW power levels.

This photograph of a hollow, high-perveance electron beam helps us measure our progress toward a goal of higher efficiency for traveling wave tubes. That's because its halo shows us how we're doing on beam control, and lets us know how our higher perveance electron gun designs are working out.

We do a lot of other things to increase TWT efficiency. Seven different types of depressed-collector TWT's are already in the field . . . operating at power levels as high as 2 kW . And we're making constant progress on the design and manufacture of shorter, more effective attenuators.

In short, Sperry is doing quite a job on the technical considerations that improve efficiency of traveling wave tubes. $25 \%$ efficiency is already a reality on many of our models, and better things are coming.

A FREE TECHNICAL PAPER gives the details, both theoretical and practical. If you are searching for higher efficiency in broadband microwave systems, get your copy today. Write Sperry, Gainesville, Florida, or contact your Cain \& Co. representative. In Europe, contact Sperry Europe Continental, Paris.

## KLYSTRON TUBE AIDS STUDY OF NUCLEAR STRUCTURES

The RCA-A1230, developed under the sponsorship of Stanford University, is the result of years of RCA experience in power tube design and development. It's the super-power klystron that will produce the tremendous pulse power required in electron linear accelerators like the one at Stanford University.

RCA-A1230 is designed to provide 24 Megawatts peak power output with better than 21 kilowatts of average power at $2,856 \mathrm{Mc}$. This fixed-frequency superpower klystron features permanent magnet focusing, 50
db gain, and long-life matrix cathode. The RCA-A1230 is offered with a choice of either single or double RF output ports, solenoid or permanent magnet focusing.

In other areas, RCA klystrons will soon be available for tropospheric scatter communications, telephone relay, and long-range radar.

Consult your RCA Industrial Tube Representative about klystrons in configurations to meet your special requirements. Or write: Manager, Super-Power Tube Marketing, RCA Electron Tube Division, Lancaster, Pa.

[^0]:    *T.M. Gardner-Denver Co.

[^1]:    - Presently attending Northwestern Unlversity.

[^2]:    Voltage gain; 1.0 through 30.0 in 4 steps, continuously Input filter; low-pass, 12 db/octave. Customer can variable between steps.
    Wide Bandwidth: $\pm 3 \mathrm{db}$ at 0.6 cps and $200,000 \mathrm{cps}$ (without filter). specify cutoff frequency.

    Noise: $\mathbf{3 0}$ microvolts rms or less, with shorted input.
    Output Capability: 20 volts peak to peak into 0.05 mfd

    Instrument is compatible with many other Dynamics amplifiers and signal conditioners for use in standard 6-channel, rack mounting module. Write for literature on Model 6083, or on the entire line.
