

Never had your favourite programmes spoilt by a background of hissing, crackling and spluttering noises? No? Lucky you! But for thousands living in towns and cities near industrial electrical apparatus, near trolleybus routes or in the vicinity of high-frequency equipment such interference is only too common.

B.I.Callender's Anti-Interference Aeria! when properly erected, will give you better listening and reveal many stations you never heard before.

The acrial is a 60 ft . polyethylene insulated dipole type with suspension insulator and matching transformer. The 8oft. down lead is a fully screened coaxial cable with polyethylene plugs moulded to each end; it is matched to the receiver by a transformer with easily fixed suction mounting.

It acts as a " $T$ " type acrial on long and medium waves and as a true dipole on short waves.

Write to-day for descriptive folder No. 22IS on "Anti-Interference Aerial."

BRITISH INSULATED CALLENDER'S CABLES LIMITED NORFOLK HOUSE, NORFOLK STREET, LONDON, W.C. 2

In response to popular request, we are now pleased to announce the availability of the following accessories, which provide an inexpensive means of bringing the "Avo" Valve Tester completely up to date. Possession of these accessories will, furthermore, render it a simple matter to maintain the "Avo" Valve Tester in a condition capable of testing any new types of valves that may be produced in the future.

## ACCESSORIES for the 'AVO' VALVE TESTER

## FILAMENT VOLTAGE EXTENSION UNIT

For providing filament voltages of 1.4 to 117 volts for testing valves recently introduced into general use and which are not covered by the original " Avo " Valve Tester.

This unit is plugged in between the Meter panel and the S.S. panel, where it may be left permanently in position regardless of whether the original or the additional heater voltages are being used.

VALVE BASE ADAPTORS
These Adaptors have been specially designed for plugging into the international octal socket of any "Avo" Valve Tester Panel which is fitted with a rotary selector switch. The following types, covering recently introduced valve bases not provided for on the existing Valve Panel, are now available :-

Other types will be made available as required, and Adaptars can alsa be supplied far any special valve base.

Price: 12/6 each, nett.

## -conacial construction'

## ensures longer life

The greatly advanced design and production methods employed in the manufacture of the "Series 700" Reproducer ensures long trouble-free life under all climatic conditions. Special purpose machines, tools and jigs ensure mechanically accurate co-axial alignment of all component parts. The magnet assembly is shock proof with virtually no external field. The voice coil and centring member assembly is of moulded Bakelised linen with integral beryllium copper leads. All types are completely dust proof. Each speaker and transformer passes Air Ministry K. 110 tropical tests and is made to exacting limits with $100 \%$ inspection at all stages.

Reproducers © Amplifiers Ltd., Wolverhampton.

## DEVELOPED FOR VIBRATION ANALYSIS \& KINDRED INVESTIGATIONS

Built on the L.A.L. UNIRACK System an extension of our well tried UNIT Construction, all apparatus is instantaneously interchangeable.

The centre Unit comprises three six inch tubes with independent power supplies, working at 2.5 or 5 Kv . together with their associated shift voltages. Beneath the tubes is situated a Four Beam Electronic Switch which may be connected to any or all tubes, displaying up to 12 simultaneous phenomena. The Four Beam Switch is operated by the Time Base and the maximum useful switching frequency is about 10 Kc .

The Side Extensions to the desk contain the amplifiers, time-bases, etc., for the work in hand, with storage space for 6 spare or special UNITS. Four $X$ and Four $Y$ channels are actually available for use, and comprehensive interconnection can be neatly made through an "exchange board" situated in an accessible position above the tubes.

The L.A.L. UNIVERSAL OSCILLOSCOPE represents perhaps the most versatile industrial oscilloscope so far developed for vibration analysis and kindred investigations.

## The

RA9TMST Dubilier Volume Control

Fully Tropical to withstand extreme conditions of temperature and humidity.

- Miniature size.
- Minimum weight.
- Extremely robust.
- Also available in Non-Tropical form.

Attention Please! The Taylor Cathode Ray Oscillograph is Now Available for IDIMEDIATE DELIVERY

A general purpose instrument incorporating a high sensitivity electrostatically deflected 3 各in. tube. A linear time base covering $10-10,000$ c.p.s. with coarse and fine frequency control is provided. Horizontal deflection can also be obtained at 50 c.p.s. or from an external source. Push-pull amplification for the vertical plates up to $100 \mathrm{k} / \mathrm{c}$ is provided.
Internal. 50 c.p.s. or external synchronisation can be applied to the test signal. Provision is made for connecting directly to deflector plates.

## DISTORTIONS AND FAULTS CAUSED BY APPARATUS

Now let us deal with the distortions and faults which are introduced by the apparatus in the complete chain from the pick-up nicrophone through the amplifiers, modulators, and power stages of the transmitter - the receiving R.1F. amplifier, de-modulator, power output stage, and loudspeaker. In each and all of these stages distortions of all forms can, must, and do occur, and the engineer's job consists of reducing them to the greatest extent which

## the economics of the installation will allow. <br> Perfect Reproduction?

What types of distortion are there? In general they can be divided into three main forms. Firstly, unevenness of frequency response, i.e., the over accentuation of some audiofrequencies with respect to others. This distortion is always accompanied by relative phase shifts between components of different frequency which alter the wave form, often to unrecognisability. Since the ear is very largely unconscious of phase differences, this latter point is of lesser importance. Frequency distortion, as described above, is caused by combination of re-actances and resistances which produce frequency selective networks.

The second form of distortion is usually called harmonic distortion, and it is caused by "non-linear" elements in the circuit. When a sinusoidal input is applied to a nonlinear device, the resulting output is a distorted sinewave, which can be represented by a wave similar to the original input, plus a series of harmonics. The number and strength of these harmonics depend on the type of non-linearity shown by the clement. In practice there are two nonlinear circuit elements in common use - thermionic valves (including metal rectifiers) and transformer iron. In addition to producing harmonics, non-lincarity also causes intermodulation. If two pure sinusoidal inputs are passed through a nonlinear device, there will be found in the output components of the sum and difference of the two input frequencies. This is an extremely inportant form of distortion, since the components produced bear no musical relationship to the input. They are thus exceedingly distressing to the ear.

Frequency distortion and harmonic distortion are also likely to occur in mechanically moving systems - such as loudspeakers. This is particularly true in the bass register, where the movement of the core is relatively large; and may exceed the range where the curve connecting displacement with force is linear; in other words, we are dealing with a non-
WELWYN GARDENCITY. HERTS linear mechanical system.

The third form of distortion is the introduction of unwanted " noise" of any form. Obvious cases are atmospherics or man-made static ; thermal or valve noise, gramophone record noise, and mains hum. These unwanted noises can either be superimposed on the wanted sounds, or may be in the form of a modulation of them. A very common difficulty is modulation hum, which is often produced by a badly designed frequency changing circuit in a supersonicheterodyne receiver.

Apart from these three main types of distortion there is one other which must be mentioned. It occurs in loudspeakers and is only serious at very high volume level; in fact, it is virtually negligible in domestic receivers and is only included here for the sake of completeness.

Imagine a loudspeaker diaphragm to which is being fed a large input at, say, 100 cycles and 5,000 cycles. The diaphragm will be moving backwards and forwards by quite an appreciable distance as it follows the 100 cycle input, and since it is at the same time the source of the 5,000 cycle radiation, this source is also moving backwards and forwards.

If a stationary observer, standing in front of the loudspeaker, listens carefully, he will find that the frequency of the 5,000 cycle note is varying up and down slightly at a rate of 100 cycles per second. This is a case of the well known Döppler effect, many examples of which are matters of every day experience. For example, if one is passed by a railway engine while it is whistling, the pitch of the whistle changes quite wildly as the engine passes. By measurement of the frequencies of light waves emitted from the stars, physicists are able to measure the relative velocities of the stars and the earth.

All these forms of distortion are inherent in the apparatus involved in sound transmission and reception. In practice they can never be completely eliminated, although by careful design -and the spending of a great deal of money-they can in the main be reduced to very low limits. In our next notes we will examine some of the more important ways of rendering them as innocuous as possible.

The illustration above shows an ACOUSTICAL product of ten years ago-an amplifier designed for high quality reproduction of records and radio programmes. Using push-pull triodes throughout- RC coupled through-out-independent treble, middle and bass controls etc., it was considered about the best that could then be obtained. Indeed the circuit is often specified today for high quality reproduction.
A comparison of the performance with that of the QAi2/P reveals the extent of recent developments.

|  | Pre-War | QA12/P | Improvement achieved |
| :---: | :---: | :---: | :---: |
| Outpur deviation within 20-20,000 c.p.s. range | 3 db | 0.3 db | 7 times better (\% power change). |
| $\begin{aligned} & \text { Crequency } \quad \text { range } \\ & \text { within } \pm \mathrm{db} \end{aligned}$ | $\begin{gathered} 30-15,000 \\ \text { c.p.s. } \end{gathered}$ | $\begin{gathered} 15-30,000 \\ \text { e.p.s. } \end{gathered}$ | Increase of two octaves. |
| Total distortion at 10 watts (Both models rated $10-12$ watts). | 2\% | $0.1 \%$ | 20 times less distortion. |
| Sensitivity (r.m.s. for full outpur) | 0.2 V | 0.0015 v | 120 times more gain |
| Background noise (equivalent r.m.s. at input) ... | $\begin{gathered} 120 \\ \text { microvolts } \end{gathered}$ | $\stackrel{1}{\text { microvolt }}$ | with no background increase. |
| Background for equal (low) gain ... | $-65 \mathrm{db}$ | $-80 \mathrm{db}$ | 15 db lower background. |

## We'd like you to know-

# Straight Speaking 

No part of a radio receiver is so complex in its behaviour as the loudspeaker, and improvement in its performance is always a source of interest.

Of the factors influencing the efficiency of the loudspeaker a high flux density in the gap is the most important.

The efficiency is the ratio of the sound energy radiated to the electrical energy supplied. To radiate sound the cone must of course be put in motion. Because the cone, the voice coil, and the air adjacent to the cone and moving with it, together have quite a substantial mass, a substantial force is required to put them in motion and keep them in motion. This force is proportional to the current flowing in the voice coil, so that a considerable part of the current which flows is used only to maintain the motion of the cone itself. This current develops heat in the ordinary ohmic resistance of the voice coil and so wastes a large part of the electrical energy supplied by the output stage.

At the bass resonance, the mass
of the voice coil, cone, and adjacent air is "tuned" by the spring consisting of the spider and corrugated cone edge, and very little force is required to maintain motion. Indeed the problem is to obtain sufficient damping to stop the motion at the conclusion of the appropriate notes in the music, as otherwise we are afflicted with bass boom and muddled reproduction. So at resonance very little voice coil current is required to maintain motion and the efficiency is much higher.

At frequencies below resonance the motion of the cone has to be quite large, and the force required to bend the spring consisting of the spider and cone edge in the course of moving the cone becomes large, so that the voice coil current rises rapidly and the efficiency becomes very low. For this reason the bass resonance frequency is made as low as possible-practically there is no output below the bass resonance.

Turning to frequencies above the bass resonance, where the efficiency is more or less steady, the problem is to increase the efficiency.

Since the losses occur in the resistance of the voice coil, a decrease of this resistance is indicated, for example by increasing the thickness of the wire, which of course means a bigger gap and bigger magnet to maintain the flux. This course may be uneconomic, but in any case the mass of the voice coil is an important part of the combined mass of the cone etc., so that an increased size of voice coil winding tends to defeat itself and only a small improvement can be expected.

Again, the use of a material for the winding of the voice coil having a smaller mass/resistance ratio will help, and in fact aluminium is sometimes used in place of copper, but here also the possible improvement is limited.

The mass of the cone is of course kept as small as possible, but there is a limit set by the necessity of rigidity.

Finally, since the force exerted on the cone etc. is proportional to the flux as well as to the voice coil current, an increase in the flux will decrease the current required and so decrease losses and increase efficiency. Also a better control can be exercised over the bass resonance. In fact this is the most effective way of improving the speaker performance.
Thechoice of loudspeakercharacteristics for Ferranti receivers is always given a great deal of care, and the availability of new magnet steels and field designs has enabled the flux density to be economically increased to 10,000 lines $/ \mathrm{sq}$. cm . as compared with about 7,000 lines/ sq. cm. in pre-war receivers.
 chassis; square casting for the magnet seating, secured with large hexagon head bolts; centre pole and bottom plate all in one forging ; ring-clamped cone ; diecast centring ring ; practical construction matched by excellent response and high sensitivity - all made for
 Speaker will convince your most critical friends that your latest amplifier " has something." Truvox leaflet SH/l52 gives all the technical detail - a postcard brings it to you.

## Sensitivity <br> The bat is

 said to derive its amazing sensitivity in flight from the echo of a high pitched sound which it emits. The Weston Model E772 Analyser, however, relies upon the more tangible asset of a sensitivity rating of 20,000 ohms per volt on all D.C. ranges and 1,000 ohms pervolt on all A.C. ranges. This instrument is designed to assist you in the tracing of difficult electrical faults and its quality is in accord with the highest Weston standards.
## E 772 <br> WESTON Unalyser

## NEW <br> vibration ELIMINATORS

ISOLATION :Rom VIBRATION

"Equiflex" Mountings are invaluable for the mounting and suspension of machines, equipment, instruments, electrical apparatus, motors, etc., and whenever elimination of vibration and shock is required.

SPECIAL FEATURES
Flexible in all directions at an equal deflection. Can be loaded on any side, thus eliminating vibration in Vertical, Horizontal and Longitudinal planes employing best quality natural rubber spring elements and complete with snubbing device. Special Fittings made to suit customers' requirements.
Also available as previously advertised, the ALL-METAL construction comprising an ingenious Damped Spring System.

Write for illustrated brachure, and
send us details of your requirements.

## NEW SOUND EQUIPMENT. NEW IDEAS.

## A range of entirely new amplifiers

THE G/Q PLUS. THREE CHANNEL GRAMOPHONE
AMPLIFIER. 15 GNS
Factory built chassis, complete ready for use. Good quality reproduction from radio or records with wide range tone control system. First stage, triode amplifier as cathode coupled divider, separate amplifiers for bass and treble, together with middle frequencies, resultant output electronic mixed by second valve, a double triode. Another double triode as self balance phase changer driving two 6L6 in P.P. Output 6 watts. Distortion less than I per cent. Excellent reproducer for modern pick-ups. Write for technical data and basic circuit ( $2 \frac{1}{2} d$. stamp).
THE HOME GRAMO AMPLIFIER PP/II. 10 GNS.
A new chassis which has all the advantages of push pull output. Double triode phase changer and two KT6I's giving 10 watts. Two inputs and tone control. A very reasonable outfit for general purposes.
PUBLICADDRESS AMPLIFIERS. Portable steel cases.
GP/IS watt. P.P.Output. With high gain microphonestage. 16 Gns. Bass Lift and Treble cut. A very popular equipment.
GP/25 wate. P.P. general purpose high gain amplifier. 19 Gns. Perfect for stage work, schools, social elubs, etc.
TRANSFORMERS. As used in our own productions.
Mains types $350 / 0 / 350$ v. 100 ma .5 v. 2 a., 6.3 v. 4 a. $30 / \mathrm{m}$.
As above but 150 ma., 35/-.
$500 / 0 / 500$ v. from 60/-
We have transformers for all applications, from our range you can select output and mains for all amplifiers and sets. Output transformers. for $3 / 8 / 15$ ohms. 25 watts. Plate loads of 8,000 and 10,000 . Price $25 /$

If you have not had any leaflets from us recently write-
GENERAL LAMINATION PRODUCTS LTD.
"Winder House," 294, Brosiwiy, Bexlepheath, KENT. Bexleyheath 3021.

THE $Z 77$ is the first of a new range of OSRAM miniatures. It is a high-gain pentode, mounted on the B7G base and is suitable for use in television, wide-band radio, amplifier and electronic instrument circuits.

## INTERESTING FEATURES

Small size and rugged construction make it an eminently suitable valve for use in mobile and portable equipment.
Suitable for operation up to 100 megacycles per second. Owing to smaliness of size and low thermal capacity the valve rapidly reaches a stable operating condition.

List Price 17/6. Purchase Tax $3 / 10$ extra.

THE GENERAL ELECTRIC CO.. LTD.. MAGNET HOUSE, KINGSWAY, W.C.2.

All parts plated and keyed to body. Available in bracket or clip-fixing types,

## R.F. E.H.T.

Manufacturers and home constructors will be pleased to learn that the HAZLEHURST R.F. E.H.T. Supply Units are now available. They have many outstanding advantages over the usual E.H.T. supplies:
i. Operation is independent of adjustments to time base circuits and regulation is excellent.
ii. The high voltage is non-lethal, dropping almost to earth potential on touch.
iii. Radiation is made negligible by efficient screening.
iv. A $5 K V-8 K V$ unit requires a D.C. supply of $320 \mathrm{v}, 30 \mathrm{~mA}$ and an A.C. of $6.3 \mathrm{~V}, 0.45$.
Units are available to supply any voltage between 5 KV and 25 KV with stabilized outputs to special order.

Price of complete supply (5KV-8KV) 5 Gns.
Price of coil unit (as illustrated) El.6.8
Trade and Export enquiries welcomed.

## FOLDED DIPOLES

The development of the folded dipole made from twin lead low loss transmission line has become very popular in the U.S. It is inherently a broad band antenna, and performs wel over an entire amateur band, not a single frequency.

We have been fortunate in obtaining a quantity of this 300 ohen twin lead, and can offer it at a price which will make our "W" friend envious, so get some while it lasts.

```
HEAVY DUTY 2\frac{1}{2}
TWIN LEAD PERFOOT
```

Might we also point out that in addition to the Government surplus gear offered in our list, we have the largest stock at the lowest prices of standard Receivers etc., namely National H.R.O. and NCl 20, R.C.A. AR 88, Hallicrafter S.27, Eddystone 358, National NTE Exciter, TCS Transmitters and Receivers.
REMEMBER G5NI has served you for years, knows what he is buying and has the largest stock of "worth while" short wave equipment.
SEND S.A.E. FOR RAYMART STANDARD LIST "W" AND NO. 7 SPECIAL OFFERS LIST.
RADIOMART
48, HOLLOWAY HEAD, BIRMINGHAM, I.
Telephone: Midland 3254

The Pullin $S$ Meter has been designed for use on amateur band communication receivers. The meter is mounted in a bench stand with terminals on top. Two scales are printed on the dial, thus serving as a dual purpose meter. An instructional leaflet is supplied with each meter. This gives the user full instructions for wiring up and explains in detail the value of the resistors and potentiometer to be used in the circuit. Price, $£ 3$.6.0.

We can give early deliveries - write for full details MEASURING INSTRUMENTS (PULLIN) LTD.

## CELESTION <br> SPEAKERS

The new and special magnets used in the construction of the Celestion 5 in . and $6 \frac{1}{2} \mathrm{in}$. speakers detailed below, provide a degree of efficiency hitherto unobtainable with permanent magnets. They represent the very latest method of speaker design and construction.
Chassis Model P6Q is also available as a Cabinet Speaker (size 9in. $\times 8 \mathrm{in}$. $\times 4 \frac{1}{2} \mathrm{in}$.). The attractive cabinet is fitted with volume control. Cabinet finish in Green, Cream or Brown. Ask for Cabinet Model CTII5. Price 62/17/- (without transformer), suitable for outputs l-5 ohms; or, price 63/3/- (with universal transformer). Suitable for all receivers.

## S H E F I MOVING COIL <br> Licensed under Voist's Patent No. 538058.

It uses miniature needles suitable for modern fulı range recordings A terrous coil former concentrates the flux on the coil and also adds armature effect, thus increasing output voltage sufficiently to operate direct into a normal radio set.
Free needle movement and low do inward pressure ensure long record life.
The lundamental simplicity of this robust design keeps down manu facturing costs. Price including transformer $£ 2$ plus P.T. De Lixe model, with spring counter balance $£ 2.11 .0$ plus P.T.

## CARRIED AWAY

## with enthusiasm.

Our new " Measurtest" series is so exciting to radio engineers that they - and consequently the instruments !-are carried away with enthusiasm. The PORTABLE RECEIVER TESTER, for instance, is a complete range of test equipment in itself, yet is no bigger than a small attache case and no heavier than a portable radio. In one assembly, it combines a crystal-standardised signal generator, a tone source and an a.f. power meter; further, it can be either mains or battery operated. For servicing or testing radio receivers, therefore, and checking radio amplifiers, the RECEIVER TESTER is the long-awaited universal instrument. Your enquiries are invited.

We believe that the only way to build a receiver is to begin at the beginning with a sound circuit design-a design that's been tested and re-tested-a design that will stand up to the most critical examination. From this design a prototype is constructed in which every component receives the same rigorous testing. We leave the experts to pass judgment on the resulting Sobell receivers. We are confident that for ease of control and absolute fidelity of reproduction this model will be found to have no equal-that, in fact, you will pronounce it to be 'technically outstanding'.
 loudspeaker. Covers long, medium and two short wave ranges.

## Valves and their applications

## EHT SUPPLIES <br> FOR TELEVISION RECEIVERS

The conventional EHT Supply for a Cathode Ray Tube consists of a high voltage transformer, a high voltage rectifier such as the HVR2, and a smooth. ing capacitor of appropriate voltage rating with a value of about $0.1 \mu \mathrm{~F}$. Experience has shown this arrangement to be rather unreliable unless a very well-made, and therefore expensive transformer is used. This is because the peak current requirement of the C.R. tube may be no more than 0.1 mA so that the fineness of wire used in the transformer secondary is determined only by the difficulty of winding it. ( 45 S .W.G. wire will carry 6.2 mA at $1,000 \mathrm{~A}$ per sq . in.) In consequence cheap transformers may be wound with such fine wire that the expansion and contraction of the winding during use will eventually produce a breakage.

## EHT from Line Time-base

One way of avoiding this difficulty in the case of Television Receivers is to rectify the high peak voltage produced across the primary of the line scanning transformer during the flyback period. This is an economical method as the cost of the high voltage winding is saved and a smoothing capacitor of only $0.001 \mu \mathrm{~F}$ is adequate because of the high pulse frequency ( $10,125 \mathrm{c} / \mathrm{s}$ ). Unfortunately it is difficult to get more than about $5 \frac{1}{2} \mathrm{kV}$. in this way unless one uses voltage doubling circuits, which, in turn, involve two rectifiers and three high voltage condensers, when the saving is not so great. One disadvantage of obtaining the E.H.T. voltage in this way is that the voltage depends on the setting of the line width control.

## C.W. R.F. Oscillator

Another method is to use a radio-frequency oscillator feeding a tuned high frequency transformer as originally described by O.H. Schade. (Proc. I.R.E. Vol. 31, No. 4.) In this case the "goodness" of a design depends mainly on the $Q$ of the secondary winding, and Litz wire has often to be used in order to obtain a sufficiently high $Q$ in a reasonably small winding space. The oscillator valve can be a small triode, or a small output pentode such as the EL33, and the anode need not be insulated to a high voltage as the voltage step-up is obtained in the transformer. A limit to the efficiency which can be obtained with this circuit is set by the voltage regulation of the device, but for a given regulation this circuit is generally more efficient than the ringing choke circuit described below.

## Ring Choke Circuit

In the ringing choke circuit a pentode such as the EL38 is used because the anode must be capable of withstanding high peak voltages. An inductor is inserted in the anode circuit of the valve, and its grid is supplied with a suitable voltage waveform. Current is allowed to build up in the inductor, and is then rapidly cut off. The inductive "kick"
produced across the anode load is rectified to produce the high voltage D.C. output. In this circuit the $Q$ of the anode inductance is not so important as in the case of the oscillator circuit because only the first peak of voltage is rectified. In consequence a very cheap construction can be used, and this consideration may more than offset the disadvantage of its lower efficiency.

## Advantages of the EY51

The Mullard EY51 high voltage rectifier has been specifically developed for these applications. The filament consumption is only 80 mA at 6.3 volts-i.e., 0.5 watt, less than a fifth of that taken by the HVR2. It is therefore quite practicable to operate the heater from a winding on the line scanning transformer, oscillator coil or ringing choke. Adequate insulation for such a winding is easily provided and expensive high voltage filament transformers are avoided. The damping is small even in the case of the R.F. oscillator in which power losses are so important. The valve itself is so small that it can easily be supported in the wiring. This greatly simplifies the problem of insulation.

| TURE | HIGH | VOLTAG | R | CTIFIER | EY5I |

| $\mathrm{V}_{\mathrm{h}}$... | ... | ... | $\ldots$ | ... |  |
| ${ }^{\mathrm{l}_{\mathrm{h}}} \ldots \ldots$ | ... | $\ldots$ | ... | .... | 80 mA $0.8 \mu \mu \mathrm{~F}$ |

OPERATION WITH SINSUISOIDAL INPUT UP TO 500kc/s.
Max. peak inverse voltage ... 15 kV
Max. rectified current $\ldots . \quad \ldots \quad 0.5 \mathrm{~mA}$
operation with pulse input
Max. peak input voltage ... ... lOkV
Max. rectified current ... ... 0.ImA
In later articles the detailed design of these circuits will be considered. Each has its oun sphere of usefulness and, if properly made, all are as reliable as the conventional circuit using a good transformer, more reliable than one using a cheap transformer, and, especially to the amateur who can make his own coils, they are considerably cheaper.

# Wireless World 

# H. H.C. Television: Healistic Tochnical Standards 

EVEN before the war ended most of us showed a deep concern for the restoration of the British television service, and heated discussions arose as to the technical standards to be adopted. Everyone agreed that the service should be re-started at the earliest possible moment ; that, if any change was to be made, it should be made then; but at that point unanimity ended. One group maintained that as speed was essential the pre-war 405 -line system should be restored without change as soon as hostilities ended. Their opponents contended that the wartime suspension of the service gave an opportunity to make a change to a high-definition system that would endure for a long time. A third school of thought urged that definition should be increased, slightly to a value giving a potentially "perfect" picture, claiming that this could be done without involving any fundamental change in the wellproven receiver manufacturing technique of which we had had several years' experience.

This attractive middle-course scheme, advanced with vigour and eloquence by its proponents, gained many adherents, but it was finally decided to restore the service with the pre-war standards basically unchanged. Though at the time many of us regarded this decision with mixed feelings, there can now be no doubt that it was a wise one. Equally wise, we are convinced, was the issue of the recent unequivocal statement that the B.B.C. standards would remain unchanged for a number of years. This decision, made by the PostmasterGeneral on the advice of the Television Advisory Committee and with full support of the industry, has cleared the air and removed all uncertainty.

As we see it, there was a real danger that definition, as expressed by number of lines, would become a fetish, and television would develop into a "technician's racket." That expression, perhaps, ill becomes a technical journal, but clearly a stage has been reached where considerations of practicability, economics and even expediency
must outweigh questions of purely technical development.

In this matter there seems to be a very close parallel with newspaper illustrations, the standard of which has undergone little fundamental change for a generation. It would no doubt be technically possible for us to be given reproduced photographs of a vastly higher "definition," but to do so would be entirely unpractical and hopelessly uneconomic, So we find that the newspaper publishers of the whole world have tacitly agreed on a more or less uniform standard, which certainly seems to give an acceptable picture.

Does 405 -line television also give an acceptable picture? We think it does, and at any rate until other links in the chain between object and viewer have been strengthened, it is extremely doubtful if it is worth while increasing the number of lines, with all the disadvantages inherent in such an increase. Some of the technical arguments in support of this statement are given elsewhere in this issue. In any case, the decision to retain 405 lines does not mean that all progress is at an end for perhaps as long as ten years. On the contrary, the B.B.C. system is susceptible to great technical improvement without any change whatever being made to its basic transmission standards. As somebody said the other day, "No one has yet seen a real 405 -line picture."

Naturally enough, the decision to retain 405 lines indefinitely has provoked some criticism, though that we have heard so far is not convincing. One rather emotional complaint--deploring the fact that we are committed to the lowest definition standard in the world-seems to call for some comment. In this matter we can stand on our own feet; it is not necessary for us to peer anxiously around to see what others are doing. We have had the longest experience of a practical working television service, and we may yet convince other countries that our system is the right one on which to base an international standard.

Fig. I. Constructional details of the Vidor
ally the construction of the "Kalium" cell. The outer P.V.C. sheath is used as

IT is good to be able to record yet another step forward in dry cell construction, this time from our own country. The Vidor "Kalium" cell has certain points of resemblance to the Ruben-Mallory mercury cell described in a previous article*: the negative electrode is zinc in both cases, the electrolyte caustic potash ( KOH ) and the depolarizer mercuric oxide ( HgO ) ; but the two cells are entirely different in design and appearance. They differ also to some extent in their performance, though both maintain a substantially constant E.M.F. for long periods under relatively heavy loads. The RubenMallory cell is squat in shape and reverses the familiar Leclanché construction by having the can as the positive electrode, whilst the small round cap at the centre of the top forms the negative connection. The new Vidor cell looks almost exactly like its Leclanché dry cell counterpart. It is made in seven sizes of precisely the same dimensions as the dry Leclanché $\mathrm{U}_{1}$ to $\mathrm{U}_{7}$ series; its negative electrode is a zinc can; the positive electrode is a central carbon rod.

The only differences in appearance are that the can is enclosed (save at the bottom) in a polyvinyl chloride sheath and that the top of the cell carries not a black bitumen seal and a brass cap forming the positive contact, but a tin-plated cover with a raised central boss. The " Kalium " cell is thus completely interchangeable with existing Leclanché cells

Fig. I shows diagrammatica precaution against any possible damage to equipment; should a can become punctured and allow electrolyte to escape. Actually puncturing of the can is of the rarest occurrence, even when cells stand in a fully discharged state; the sheath, however, makes assurance doubly sure. It also serves another purpose. The top of it is turned
over inside the can ; thus when the walls of the can are bent over to fix the tin cap in position, the P.V.C. forms an insulating washer and a leak-proof gasket. The positive electrode is normally a carbon rod, but may be of ferrous metal.

Surrounding the rod is a bob-bin-shaped mass of mercuric oxide and powered carbon, which forms the depolarizer. The electrolyte element consists of paper coated with zinc particles and soaked in caustic potash solution. A plastic seal at the top and a polythene washer at the bottom make all secure. Near the top of each can is a small vent hole which, with the P.V.C. sheath, forms a release valve should internal pressure occur. This deals adequately
"Kalium " cell.
with any gassing that may take place when the cell is in series with others and current is driven through it continuously.

The makers state that the cells store particularly well; their shelf-life is, in fact, considerably better than that of dry Leclanche cells, for after 9-12 months' storage in normal conditions and six months of "tropical" storage, deterioration is slight. The working life, to a cut-off E.M.F. of $\mathrm{I} . \mathrm{oV}$, of cells so treated, is very little shorter than that of new cells; there is, however, a fallingoff of 10 to 15 per cent in the watt-hour output, but research work is going forward with a view to making considerable improvement here.
The chemical reactions of the cell are complex and interesting.

Like those of other mercurydepolarizer cells, their exact nature has not yet been established with certainty; they are, however, probably as follows:-
(1) $\mathrm{Zn}+2 \mathrm{H}_{2} \mathrm{O}=\mathrm{Zn}(\mathrm{OH})_{2}+2 \mathrm{H}$.

The hydrogen is removed by
(2) $2 \mathrm{H}+\mathrm{HgO}=\mathrm{Hg}+\mathrm{H}_{2} \mathrm{O}$.

The zinc hydroxide is removed by
(3) $\mathrm{Zn}(\mathrm{OH})_{2}+4 \mathrm{KOH}=\mathrm{K}_{2} \mathrm{ZnO}_{2}+$ $2 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{KOH}$.
The last is a comparatively slow reaction, but if the area of zinc is made sufficiently large there is no such build-up of zinc hydroxide as to impair the efficiency of the cell. The slowness of this reaction, though, may possibly be responsible for the slight fall in E.M.F. (vide Figs. 2 and 3), followed by a rise, which takes place at first

# IN DRY BATTERIES <br> The Vidor "Kalium" Cell 

By R. W. HALLOWS, M.A. (Cantab.), M.I.E.E.

when the cell is discharged at a high rate. From reactions (1) and (2) one ampere-hour is given by:

| Zinc | $\ldots$ | $\ldots$ | 1.22 |
| :--- | :--- | :--- | :--- |
| Mercuric oxide | $\cdots$ | 402 |  |
| Water | $\ldots$ | .. | 0.65 |

If I read the designer's mind aright, he set himself the task of producing a dry cell as like the Leclanché as possible an:d containing all its good points, but none of its bad ones. Zinc-the
"fuel" of the Leclanche cellis, as metals go nowadays, reasonably plentiful and cheap; the construction of cells with the container forming the negative electrode and a carbon rod, surrounderl by the depolarizing compound, acting as a conductor between the circuit and the positively charged electrolyte is both sound, from the manufacturing point of view, and convenient when cells have to be marle into batteries.

These are excellent points. Can they be retained in a cell of vastly improved performance? The answer is that they can, providerl that it is possible to fund an efficient substitute for the combination of sal-ammoniac electrolyte and manganese dioxide depolarizer to which nearly all the major shortcomings of the Leclanché cell are due. With

Fig. 3. Discharge continuously through 25s (hearing aid conditions) of $\mathrm{U}_{1}, \mathrm{U}_{2}, \mathrm{U}_{4}$ and $\mathrm{U}_{6}$ sizes.
them polarization is rapid and heavy, whilst clepolarization is slow and never quite complete. The electro-chemical reactions of both primary and secondary cells
were neutralized. The internal resistance of the cell would then remain constant, and the discharge curve of a cell would be a horizontal straight line, terminating in an almost vertical fall to zero when the electrolyte was exhausted.

The "Kalium" cell is not perfect, but the curves shown in Figs. 2, 3 and 4, show that the inventor has advanced a considerable way along the road towards his ideal. It will be seen that the E.M.F.s are substantially con

Fig. 4. Comparative performances of "Kalium " and Leclanché cells of the same size under Medical Research Council hearing aid test conditions (18.5 $\Omega$ per cell). Note that the "Kalium" cell was discharged continuously and the Leclanché intermittently at 8 hours per day.

are by no means beyond doubt; a simple working picture, however, of polarization and depolarization in a Leclanché cell inay be obtained in the following way. In the ionized electrolyte, when the cell is under discharge, hydrogen molecules travel in vast numbers towards the carbon rod, round which they form a resistive envelope. There is no way of preventing the arrival of the hydrogen molecules, for they are the positive ions which convery positive charge to the carbon rod. What is needed is a means of making them " move on," once they have dome their job and have been neutralized by collecting electrons delivered from the negative elec trodes via the circuit and the carbon rod.

In a cell with a perfect depolarizing system, the hydrogen would be removed just as fast as its molecules arrived and
stant uncler loads very heavy in relation to the sizes of the cells.

A particularly interesting point is that the hours of life of a "Kalium" cell are the same for a given load, whether it is discharged continuonsly or intermittently. There is no marked recuperation when a partly discharged cell is rested. Is this a strong point or a weak one? In years gone by some makers of dry-cell Leclanché batteries proudly proclaimed the marvellous recuperating powers of their wares. Your II.'T.B. might drop to volts cluring an evening's lis tening; but whilst you slept it put nine of them back again. Was!': that fine? Iuman beings do not have to recuperate unless they have been under the weather. And the same is true of primary batteries; only those suffering from a hangover resulting from a surfeit of undigested hydrogen need to make recoveries of that kind. In the "Kalium" cell depolarization very nearly keeps pace with electrolytic action, and the discharge curve has not the vicious sawtooth jags of the Lelanché.

My own tests are not yet complete, but so far as they have gone

## Fresh Progress in Dry Batteries-

 they bear out the maker's claims. Some may criticize the E.M.F.s as being on the low side, ranging as they do from about 1.4 V on open circuit to between approximately 1.10 V and 1.25 V (according to the load) on closed circuit. But it is surely more useful to have a cell which starts with a comparatively low E.M.F. and maintains it than one with a higher initial E.M.F. which shows a continual falling away under load. Certainly a source of constant E.M.F. for both H.T. and L.T. circuitsshould vastly simplify the problems of those who design hearing aids, portable wireless sets and personal receivers, of those who make the valves for them-and of those who use them.

The fly in the ointment as regards the "Kalium" cell is that it is considerably more expensive to make than the Leclanché. Mercury is, unfortunately, neither plentiful nor cheap, and the "Kalium" cell needs over 4 grams of its oxide for each am-pere-hour that it gives. If we cannot have more and cheaper
mercury (and there seems little immediate likelihood of that), a new task for the research chemist working on dry cells must be to discover something less costly and less scarce which can take its place as a depolarizer. Both the Ruben-Mallory and the Vidor systems have shown that better dry cells can be made-at a price. What we need is the better cell at little or no extra cost. In view of the present state of activity in dry battery research, I have no doubt that it will come our way in the not-too-distant future.

# ELECTRONIC MEGOHMMETERS 

Measurement of Very High Resistance<br>By H. G. M. SPRATT

TTHE D.C. measurement of resistance, using portable non-electronic meters or galvanometers, becomes increasingly difficult as the order of the resistance value increases. This difficulty can be traced to either the low impedance or the low sensitivity of the indicating instrument, depending upon the method of measurement used, for it must be remembered that highly sensitive mirror galvanometers cannot be employed outside the laboratory. If, for example, a Wheatstone bridge is used, the supply voltage must be raised considerably when the unknown resistance is several megohms, if a noticeable deflection is to be obtained as balance is approached. Other methods employing a voltmeter and microammeter will probably be quite impracticable.

[Courtesy fournal I.E.E.
Fig. 1. This curve shows the relation between anode current and resistance for a grid-current type of megohmmeter.

The characteristics of the normal triode valve, however, are such as to enable some of the conventional methods to be utilized for resistance measurement up to $10^{12} \Omega$ and higher, as well as

The circuit ${ }^{1}$ depends upon the grid-voltage-grid-current characteristic of the normal triode. This characteristic, for small grid currents, approximates to the exponential form $\mathrm{I}_{g}=\mathrm{A} e^{\mathrm{BV}}$ where $V$ is the negative grid voltage, $\mathrm{I}_{g}$ is the grid current and $A$ and $B$ are constants for a fixed anode voltage. If a resistance $R$ is connected between grid and

introducing at least one new method. Furthermore, no difficulty is experienced in constructing instruments based on these principles in a compact and portable form.

Grid - Current Method. - The new circuit referred to above appears to have received earlier consideration than adaptations of methods already known but it is not self-calibrating to the same extent and does not lend itself to extremely accurate measurements. As the following paragraphs show, however, it is a low-voltage instrument of great simplicity.
cathode, we get

$$

& \mathrm{V} / \mathrm{R}=-\mathrm{I}_{y} \\
& \mathrm{~S}()-\mathrm{V} / \mathrm{R} e^{\mathrm{BV}}=
\end{aligned}
$$

or $\log \mathrm{R}=\log \mathrm{V}+13 \mathrm{~V}+$ a con stant.

As the anode current depends upon the grid voltage, there is seen to be a definite relationship between it and the grid resistance, this relationship being indicated by the curve in Fig. I, where $\mathrm{I}_{a}$, the anode current, is plotted against $\log R$. This curve approximates to a straight line over a considerable range and circuits operating on this principle will permit resistance measurements
up to $10^{8} \Omega$ with an accuracy of a few per cent, or to considerably higher values if a positive voltage is included in series with the resistance.

Practical Applications. - Fig. $z$ (a) shows the basic form ${ }^{2}$ and Fig. 2(b) a practical form of this circuit. The latter gives satisfactory operation with a $45-60-$ volt battery and, if the indicator is a $50-100-\mu \mathrm{A}$ meter, will cover a range exceeding $10^{5}$ to $10^{10} \Omega$. A guard terminal helps to eliminate surface leakage by returning such paths to cathode, while a capacitor of the order of $100-500$

Fig. 3. The basic circuit of a substitution method of measuring resistance.
pF between grid and cathode reduces fluctuations due to noise voltages. The resistor $\mathrm{R}_{1}$, between grid and H.T. negative, is some hundreds of megohms and ensures that the grid is never left entirely 'open.' Initial adjustment consists in setting the variable resistor in the cathode lead to give maximum deflection of the meter with the input terminals short-circuited.

It can be seen that a full calibration of this instrument can only be carried out by the application of a range of standard resistors. This prejudices its use as an instrument of high accuracy as the grid-voltage-grid-current characteristic may alter with time owing to grid emission caused by contamination. On the other hand it enables a varicty of nondestructive insulation tests to be carried out to the order of accuracy usually required.

Substitution Method.- The outstanding asset of the normal triode for present purposes is its high grid-cathode D.C. resistance when the grid is maintained negative with respect to the
cathode. This feature is immediately applicable to a substitution method of resistance measurement. It has been widely adopted and is described below.

Considering Fig. 3, let us assume that the valve is provided with H.T. and grid-bias supplies $V_{12}$ and $V_{23}$ respectively. The magnitude of $V_{23}$ is somewhat higher arithmetically than the value $V_{42}$ required for the normal operating point. Then if we connect across the terminals AB a potentiometer as shown, with the slider connected to the grid, we shall have to adjust it so that the drop across $R_{1}$ is equal to $V_{23}-V_{42}$ in order to obtain the normal anode current. Then, since $\mathrm{R}=\mathrm{R}_{1}+\mathrm{R}_{2}$;

$$
\begin{aligned}
& \frac{\mathrm{R}_{1}}{\mathrm{R}}=\frac{V_{23}-V_{42}}{V_{42}+V_{23}} \\
& \frac{\mathrm{R}_{2}}{\mathrm{R}}=\frac{V_{12}+V_{42}}{V_{42}+V_{23}} \\
& \frac{\mathrm{R}_{2}}{\mathrm{R}_{1}}=\frac{V_{42}+V_{42}}{V_{23}-V_{42}}
\end{aligned}
$$

Suppose we make $V_{12}=100$ volts, $V_{23}=3$ volts, $V_{42}=1 \frac{1}{2}$ volts and R a $\mathrm{I}-\mathrm{M} \Omega$ potentiometer. Then :

$$
\mathrm{R}_{1} \text { will be } 14,600 \Omega
$$

$\mathrm{R}_{2}$ will be $0.985 \mathrm{M} \Omega$
and $\frac{\mathrm{R}_{2}}{\mathrm{R}_{1}}=67$.
Now the grid-cathode resistance is high, and is likely to be of the order of $10^{9}-10^{10} \Omega$, so that the value given above for the ratio $R_{2} / R_{1}$ will still hold good even if $R_{1}$ and $R_{2}$ are increased a thousand-fold, so that $R_{2}$ is of the order of $10^{9} \Omega$.

Very High Resistances.-In applying this circuit to the measurement of very high resistances, the unknown is connected in place of $\mathrm{R}_{2}$ and $\mathrm{R}_{1}$ is made a calibrated variable resistor (preferably a decade resistance box). Calibration is effected by introducing a known standard resistor, not inconveniently high, in place of $R_{2}$. The ratio $R_{2} / R_{3}$, corresponding to a chosen value of anode current, can then be determined at comparatively low values of $R_{2}$ and $R_{1}$. In carrying out a measurement, the unknown is connected in place of $R_{2} ; \mathrm{R}_{1}$ is then adjusted to give the same anode current, the value of the unknown being determined by multiplying

A commercial meter, the Dawe Instruments Type 402 B Insulation
Tester, which operates on the grid-current principle.
$R_{1}$ by $R_{2} / R_{1}$. In practice there will probably be a demand for not only a specific meter deflection but also a specific and convenient value of $\mathrm{R}_{2} / \mathrm{R}_{3}$. This can quite easily be effected by providing a backing-off or balancing circuit, such as is shown in Fig. 4, where the meter is connected between the anode and a tap on the H.T. supply and a variable resistor included in the anode lead. Alternatively, by a small circuit change, the bias voltage can be made slightly adjustable to fulfil the same purpose. All

Fig. 4. The addition of a backing-off circuit to Fig. 3 is shown here.
instruments are then calibrated with $R_{2}$ as the standard resistor and $R_{1}$ as the calibrated variable, the anode or bias adjustment being set to give the required meter deflection at the correct

## Electronic Megohmmeters-

$\mathrm{R}_{2} / \mathrm{R}_{1}$ ratio. For certain applications where precision measurements are not required and a simplified form of $\mathrm{R}_{1}$ is justifiable, the meter scale can be provided with subsidiary markings indicating $\pm 5 \%, \pm 10 \%$, etc., off the calibration values.

The limit of measurement with the values given above would be about $10^{9} \Omega 2$ for an accuracy of $\mathrm{I}-5 \%$, this figure of accuracy depending mainly upon the quality of the resistance elements in $\mathrm{R}_{1}$. Above this point, however, the grid-cathode resistance of the valve may start to become a significant factor. Nevertheless, the range can be extended upwards if such accuracy is not required, as is frequently the case. Moreover, by increasing $V_{12}$ and/or decreasing $V_{23}-V_{42}$, we can easily raise the limit by another order.

There is a number of modifications and refinements to the basic circuit which may be introduced with advantage, and it is proposed to discuss them briefly: For example, the high-potential point of the unknown resistor is sometimes made negative by using a separate battery between $B$ of Fig. 3 and $\mathrm{K}_{2}$ instead of connecting $\mathrm{R}_{2}$ to A . This arrangement has the advantage of preventing a high positive potential from being applied to the grid if a short-circuit across the test terminals occurs. If the positive potential is retained, a resistor of a few megohms inserted in the grid lead (see Fig. 4) will provide the same safeguard. liurthermore, this resistor, in conjunction with a small capacitor connected between grid and cathode, will reduce the effect of extraneous noise voltages.

Preventing Leakage. - lt is normal practice to change over from standard to unknown resistor by means of a switch. With this arrangement it is necessary to guard the highpotential point of the standard resistor so as to prevent leakage to it from H.T. when it is out of circuit (see Fig. 4). For this purpose it is generally convenient to return both guard and cathode to earth potential. Guarding may also be desirable at the terminals or electrodes across which the unknown resistor is placed, for
this point is one of the weakest as regards leakage.

Where precise measurements of the higher orders of resistance are required and the necessary care has been taken to reduce stray leakage to the absolute minimum, the use of an electrometer valve is essential. Otherwise it is not justifiable, but a type of valve with low internal leakage between grid and cathode should be chosen and individual valves will probably have to be selected. Furthermore it may be desirable to keep the resistance in the grid-cathode circuit constant by using the connections shown in Fig. 4 in preference to those of Fig .3 .

Feedback can sometimes be introluced with advantage into this circuit as it assists in reducing (a) changes in circuit constants accompanying valve replacement and ageing and (b) unsteadiness due to voltage variations if the instrument is mains-driven. As regards (a), we have so far envisaged operation at a fixed meter reading, supplemented possibly with the $5 \%$ and $10 \%$ markings mentioned above, with continuous variation of $\mathrm{R}_{1}$. Such an arrangement is not always convenient or cconomical if $R_{1}$ is of the order of $10^{9} \Omega$ because of the demand for a large number of
lead (shown dotted in Fig. 4). In referring to mains variations it should be recognized that operation of the valve from raw A.C. is quite feasible although, if the potential applied to the resistance under test is to be negative, a smoothed I.C. supply is advised for this purpose.

It is perhaps needless to add that, where the resistor elements in $R_{1}$ are too high to be wirewound, it is essential for precision working, to use the best type of high-stability carbon resistors with low temperature coefficients.

Ultra-high Megohmmeter. - A modification of the basic circuit discussed above which is claimed to be capable of measuring up to $10^{17} \Omega$ is of interest ${ }^{3}$ and is shown in lig. 5. Here an electrometer valve is used in a slide-back circuit. A reading of the output is taken with $S_{1}$ open and $\mathrm{E}_{2}=0$. $S_{1}$ is then closed and $E_{2}$ adjusted to give the same output reading. Then

$$
\mathrm{R}_{x}=\mathrm{R}_{s}\left(\frac{\mathrm{~F}_{-_{1}}}{\mathrm{~F}_{r_{2}}}-\mathrm{I}\right)
$$

The accuracy of results depend upon the accuracy with which $\mathrm{E}_{1}$ and $\mathrm{E}_{2}$ can be determined by conventional-type voltmeters and upon that of $\mathrm{R}_{\mathrm{s}}$ which will have

close-tolerance and stable resistors of high value. If the fixed meter reading can be replaced by a long calibrated scale of wide range (e.g.. ro to i) and sufficient stability maintained, it will obviously be possible to make up $\mathrm{R}_{1}$ of a comparatively small number of resistors differing in value by a factor of ro. In such a case the extra stability derived from negative feedback is particularly advantageous. This feedback is usually introluced in the form of a resistor in the cathode
to be of the order of $10^{15} \Omega$ for measuring resistances of $10^{17} \Omega$.

Bridge Circuits. - At the beginning of this article mention was made of the Wheatstone bridge and the impossibility of maintaining sensitivity with normal portable galvanometers when the unknown resistance exceeded a few megohms. This lack of sensitivity is due to the low input resistance of the indicating instrument in comparison with the output resistance of the bridge. The difficulty can be
overcome by substituting a sensitive value voltmeter in place of the usual galvanometer. The usual precautions must be taken to ensure a high input resistance. such as selection of valves and

correct biasing. Furthermore a regulated power supply is advisable otherwise the zero point of the indicator will drift too much to make an accurate balance possible. The outline of this circuit is shown in Fig. 6. Such an instrument does not show the same degree of superiority over other methods of measurement at
${ }^{1}{ }^{10} \Omega$ and upwards as does the normal Wheatstone bridge at lower orders of resistance, Apart from the likelihood of drift mentioned above it is difficult to reduce leakage to a negligible quantity. There is yet one further difficulty, 'The standard

Fig. 6. Bridge circuit using a valve voltmeter as an indicator.
bridge equation, $\mathrm{X}=\mathrm{AB} / \mathrm{C}$ holds good and even when $C$ has been reduced to its lowest practical value $A$ and/or $H$ will have to include calibrated resistors of the order of $10^{6}-10^{8} \Omega$. Such components are extremely difficult to obtain to the order of accuracy and stability normally expected in a Wheatstone bridge.

The instruments which have been described provide an easy means of extending the study of high resistance and insulation phenomena. The insulation resistance of electro-dynamic machinery and of power cables, for example, frequently increases at a steady rate from the moment of application for a period of hours and time plots of such characteristics can be taken without difficulty with the aid of these meters. lurthermore, of recent years insulation resistance has proved to be a satisfactory measure of other physical qualities, such as moisture content and instruments of this type lend themselves immediately to these fields of application.

## IMPROVED HEARING AID

Automatic Volume Compression and long Battery Life

ADEVELOPMENT of special interest to students of hearing aid design is the introduction by Multitone Electric, 223, St. Johns Street, Clerkenwell, London, E.C.I, of a new instrument, the " Mlonostat," in which fully automatic volume control has been introduced to overcome the irritation and distress of widely fluctuating souncl intensity levels and loud percussive noises, such as the slamming of doors.

The threevalve amplifier consists of the usual power output stage preceded by two stages of voltage amplification, and control of volume. looth automatic and general level, is effecterl in the first stage. A small metal-oxide contact rectifier connected across the output from the final stage developes a negative voltage, which is applio! through resistance-capacity filter circuits in the grid of the first stage. Thr time constants of the filter circuits have been adjusted to give almost instantaneous response in reducing gain and a recovering time which is long enough to avoid undure levelling and yet does not produce noticeable "holes" in the reproduction following sudden noises.

On test the A.V.C. system proved to be enmpletely effective; in fact.

> "Monostat" hearing aid with crystal earpiece.

persons with normal hearing might use the aid with advantage under noisy conditions, say, in a workshop. We found it much less distracting to carry on conversation in this way against an artificially produced background than be direct
listening, and the quality of the voice, using a crystal-type earpiece appeared to be quite as natural.
A selector switch enables the A.V.C. to he switched on or off and a third position gives a characteristic with falling H.F. response and no A.V.C. for special types of deafness

Battery replacement is simple, both II.T. and I.T. being of the plug-in type. The hinged back of the instrument is spring loaded and flies open when a catch is depressed, revealing an engraverl diagram showing how the fresh batteries should be inserted.

The $22 \frac{1}{2}$-volt H.T. battery (costing 3s) gives a life of 350 hours on intermittent discharge, For the L.T. supply the new Vidor "Kalium" cell (see p. 352 this issut) will he. employerl. The l'f size costing is has a life of 30 hours. Alternativels, half al No. 8 T.eclanché battery costing 2 al can be used, but the duration will then be only about $4 \frac{1}{2}$ hours.
The instrument, which measures only $+\frac{1}{2}$ in $\times 2 \frac{1}{2}$ in $\times 1$ in and weighs $630 \%$ will be available in black with chromium and silver plated fittings or ivory with gilt finish. It is in no, sense a cheap model and the price will be in the region of 37 guineas.

# AMPLIFYING CRYSTAL 

## The Transistor : a 3-Electrode Germanium Contact Device

WORKING in Bell Telephone Laboratories, J. Bardeen and W. H. Brattain have developed a threeelectrode germanium crystal contact device, known as the Transistor, details of which have been published in the Physical Review. Vol. 74, July 15 th, 1948 , pp. 230233. Their experiments show that

Fig. I. Basic circuit of the Transistor.
by placing point contacts of tungsten or phosphor bronze in close proximity ( 0.05 to 0.25 mm ) on the specially prepared surface of a germanium block; interdependenice of currents in the vicinity of the contacts can be utilized to obtain power amplification of the order of 20 db .

A positive bias of about I volt is applied to the "emitter" contact, which also carries the input signal, and negative bias on the "collector" contact is adjusted until the collector current is of the same order as the emitter. A large proportion of the emitter current passes to the collector, and amplification results from the fact that the collector contact, and the load to which it is matched, has an impedance about 100 times that of the input (emitter) circuit. Thus the input/output impedance relationships as well as the polarity of the "II.T." supply voltage are the reverse of those found in conventional thermionic triodes.

Typical D.C. characteristics are
shown in Fig, 2. The emitter current is given approximately by the expression:

$$
I_{e}=f\left(V_{n}+R_{v} I_{r}\right)
$$

Where $R_{F}$ is a constant which is independent of the bias. There is positive feedback, represented by the term $R_{b} I_{c}$, which under some conditions may cause instability. The device can, in fact, be used as an oscillator.

## Theory

A reasonable explanation of the mechanism of conduction in the region of the contacts is possible in terms of statistical mechanics, but it is difficult to convey a plausible physical picture of the transport of current. According to prevailing theories, there are two types of semi-conductor, the n-type involving the migration of electrons and the p-type in which permissible but unoccupied electronic energy, levels or "holes" are propagated through the crystal lattice structure, and are equivalent to a flow of positive electricity in the opposite direction to the electron flow. The nature of the conduction is influenced by impurities in the material.

In the Transistor the main body of the ger-

Fig. 2. Typical D.C. characteristics. The currents are the independent variables and the corresponding voltages, the dependent variables.

Indicating the size of a typical Transistor semi-conductor triode.
manium is of the n-type with a thin surface layer of p-type germanium. It is thought that the current between the emitter contact and the main body of the germanium is conveyed by "holes," and that a large proportion of these "carriers" are attracted to the collector.

The mobility of the carriers is

dependent on temperature and the field strength. In practice, the finite mobility is equivalent to transit time in a valve, and limits the response of the Transistor, at the contact spacings quoted, to frequencies below $10 \mathrm{Mc} / \mathrm{s}$.

If satisfactory circuit tech-
niques can be developed to meet the conditions of low input and high output impedance and positive feedback, and if signal/noise ratio is not unduly low, there would seem to be many applications in which Transistors could usefully take the place of valves. Bell Telephone Laboratories have
already constructed an experimental radio receiver with a power output of 25 mW , using Transitors throughout and have also demonstrated a repeater amplifier and an A.F. oscillator.

The D.C. power consumption is o.r watt, and the overall effciency is 25 per cent.

# RADIO INTERFERENCE MEASUREMENT 

# Difficulties in Devising a Standard 

#### Abstract

This summary of the present position in regard to Interference measurement was written by a member of the Technical Executive Committee of the Radio Industry Council, and is endorsed by that Committee. It is reproduced by permission from the "Technical Bulletin" of the Radio Component Manufacturers' Federation.

THE impression is very common around the radio industry that "they" ought to do something about radio interference measuring sets and that for want of a measuring set the whole interference position is getting out of hand. The note sets out the real position and outlines the possibilities of progress.

The fundamental catch is that the measuring set has to accept an input of any of an immense variety of types and assess not its magnitude but its annoyance. Working on a basis of a few types of interference an ad hoc international committee (C.I.S.I'.K.) started work in Berlin in 1934 and proposed a design of valve voltmeter whose readings were somewhat like the annoyance factor of the interference. Since then there has been some doubt expressed in many places whether the proposed valve voltmeter is a close enough copy of the human brain while at the same time the gamut of interfering sources has been extended by the widespread introduction of thermostats and similar devices which create bursts of interference at fairly long intervals. At the moment therefore the interference measuring set must line up with the ear tolerably well all the way from the pure tone of the heterodyne interference through "white" noise and the smoothly repetitive noises to the ragged and discontinuous types. An attempt has been made by tinkering with the time constants of charge and discharge proposed by C.I.S.P.R. but these changes while cloing good in
some directions are thought to have done more harm in others, and an E.R.A. committee is now attempting to examine a wide enough range of interfering sources to provide an answer which will last for some time.

This difficulty has been the biggest of all the difficulties. Anyone can make a field strength measuring set and those of us who have to measure the C.W. or white types of interference in the absence of a measuring set do so by improvising with a calibeated receiver by a standard signal generator. The Americans have produced such field strength measuring sets and have attempted to use them for noise measurement by building time constants into the AGC system of the same order as those recommended by C.I.S.P.R. Such devices are fundamentally wrong since in the absence of an input the receiver turns itself up to full gain and may not turn itself down until after a short burst of input is passed. This weakness is now realized and the convenience of this type of measuring set must, it is agreed, be sacrificed.
There is a British Standard describing a measuring set covering medium and long broadcast bands and incorporating the measuring technique of the C.I.S.P.K. This measuring set has been extended to cover short-wave broadcast bands by its original designers, the Post Office, still using the same technique and in fact taking this technique into frequencies for which there is as
yet no international agreement for its use. This measuring set used old-fashioned circuit arrangements and components and is clumsy and costly by modern standards. The Post Office has recently modernized this equipment and is having it manufactured.
-1his equipment is admittedly a stop-gap and has many faults: one which has been mentioned is that it has (in common with most broadcast receivers) a gap in its coverage near $460 \mathrm{kc} / \mathrm{s}$ to dodge its intermediate frequency. Apparently by so doing it also dodges a number of industrial oscillators. However, it would have been better to have raised this point with the B.S.I. committee when discussing this receiver rather than now when it is too late to do anything about it in this design. The work which the I3.S.I. committee did is being incorporated by Marconi Instruments in a design sponsored by R.A.E., but this will be a very large and ambitious research tool and will not be of immediate use to the engineering or electrical industries. There is no project in operation which will produce a really good measuring set of wide applicability, nor will there be as long as the radio industry omits to do anything about getting one made. For years I have suggested that the radio industry had within its members the means for doing all the stages of this work but the industry has always taken the attitude that this mysterious "they" ought to do it. The present position is unsatisfactory though in practically no other country is it really much better. In some countries (e.g., Switzerland) there is legislation based upon obsolete technique and measuring sets. In other countries (e.g., North America) there is widespread activity based upon unsound measuring sets. The fact that other countries are doing things badly is no excuse for us to do them as badly and the radio industry itself must find a way of doing better.

# REDUCING HEATER HUM 

# Neutralizing by Injection of Anti-phase Voltages 

By K. G. BRITTON, D.Phil. (with P. E. BAYLIS)

THE sources of hum in high gain amplifiers have been discussed from time to time in this journal,' and practical steps have been suggested for mitigating the nuisance. There are, however, two points which require consideration. First, in experimental work, it is not always expedient that time be spent on an elaborate layout which may have to be rejected, ind, secondly, when even quite elementary precautions are taken it is the heater hum which becomes the predominant factor and each valve makes its own indivilual contribution.

Various methods have teen suggested for overcoming this nuisance, such as varying the heater-cathode potential and by balancing the earth connection of the heater system by means of the so-called humdinger. Far too often these methods prove only partially effective, and for really high-gain amplifiers one is driven back to D.C. heating for the early stages. It was clesired to avoid this alternative and to make. a hum control system which could be applied rapidly and effectively to each valve in turn, and it is believed that the system to be described is effective enough to make the valve noises themselves the more important factor in the circuit.

At best, the overall application of a humdinger can only give an approximate solution, for each individual valve requires its own particular setting of the control The only solution along these lines is, therefore, to supply each early value with its own heater winding and centre-point contiol. an expensive and elaborate solution. It was found by experiment that the heater hum introduced by each individual valve was substantially in phase with

[^2]the heater voltage at the terminals of the valve. The solution which suggested itself, therefore, was to inject into the valve the appropriate proportion of the heater voltage in anti-phase to the hum. This proved to be singularly effective, and was achieved in a number of ways of which a typical one is shown in the figure.

> Method of balancing out hum voltage.

The heater winding itself must be centre earthed, and the hest method of achieving this will be discussed later. Each valve to be treated then has connected across its heater pins a low-resistance potentiometer of 50 or 100 ohms. A hum voltage is picked up from the slider of the potentiometer. In pentode valves the best point of injection proves to be the suppressor grid, which is connected to this potentiometer slider. In valves of the tetrode type a similar effect may be obtained by taking the screen decoupling condenser to this point rather than to earth. With triodes a considerable measure of control may be obtained by taking the lower end of the cathode resistor to this point, but in this case the resistance of the potentiometer in relation to the value of the bias
resistor must be considered. In any case, the control is not so good, and it is nearly always advantageous to use tetrodes or pentodes rather than triodes even when small gains are required. ${ }^{2}$

The only point needing further consideration is the centre earthing of the heater winding. It must be remembered that there are now certain points, which are normally earthed, which are separated from earth by the two halves (approximately) of the potentiometer in parallel with each other plus whatever centre earthing arrangement there may be on the heater winding. Often it is perfectly satisfactory to use the normal centre tap of the winding if one is provided, but there is the possibility of a rather long loop which can introduce trouble. Another solution which we have tried and which seems to be free from unpleasant defects is to discard the centre tap and connect a 50 -ohm resistor from each side of the heater system to earth at a point near the place where num control is taking place. A similar solution which gives a further measure of control is to use a norma: humdinger. Valves which are to be controlled by hum injection are removed and the centre tap is adjusted to give the best results for the remaining stages. When this adjustment has been made it must not be touched again. The earlier stages are then introduced one by one and their hum removed by means of their individual controls.

In conclusion, it may be said that work is proceeding on this and kindred problems, but that in a high-gain amplifier made for test purposes, using a single heater winding throughout, the hum could be reduced so as to be quite inaudible below the level of the valve noises.

# NEGATIVE FREQUENCY How to Distinguish -f from $+f$ 

STUDY of modulation, frequency changing and related arts during the last two months brought us inescapably into the realm of negative frequency. We found, for example, that the Synchrodyne works by means of a frequency changer which shifts the carrier-wave frequency of the selected transmission to zero, so that the lower sideband is bound to be negative. Then again, if a signal is modulated by another of higher frequency, the "difference" frequency is negative.

What, if anything, does a negative frequency mean? Can it be distinguished from a positive frequency, and if so how? It would certainly sound odd if the Elec tricity Board were to offer their supply at $-50 \mathrm{c} / \mathrm{s}$ (though it sometimes seems to be moving in that direction!) just as it would for the voltage to be specified as $230 \sqrt{-1}$. Both statements, on the face of them, are nonsense; but we saw (in " $j$," Feb., 1948, issue) that $\sqrt{-1}$ can be given a reasonable interpretation in terms of phase. So can $-50 \mathrm{c} / \mathrm{s}$. Even the highbrow books dodge the issue or gloss over it most shamefully, but let us away with such evasiveness and face it boldly.

Consider a single alternating current, frequency $f \mathrm{c} / \mathrm{s}$. As we ought to know by now, it can be represented by a single vector rotating at $f$ revs per sec, as in Fig. I. The length of the vector is fixed, to represent the peak value of current, I; but when it is viewed from a position such as A, it looks as if it were alternately growing from a point to full length, back to zero length, then negatively, and so on, as in the succession of suap-shots shown at P. If hundreds of snapshots were taken during one revolution and placed side by side they would fill up the wave-shaped outline shown dotted. This continually changing apparent length represents the instantaneous value of current, $i$. (Of course, unless $f$ were well below $10 \mathrm{c} / \mathrm{s}$ a real human

# By <br> "CATHODE RAY" 

observer would see nothing but a blur; but that does not alter the fact that a vector revolving at any speed presents an end-on view that goes through the sequence shown.) The thing to

Fig. I. At P is shown a succession of "snapshots" of the vector as seen from A , during one revolution. Seen from B, its appearance varies as shown at $Q$. Neither viewpoint reveals the direction of rotation. For that one has to have both views at once. Views P and $Q^{\prime}$ together would indicate reverse rotation, or negative frequency.
note is that it is impossible to say, from this one viewpoint, whether the vector is rotating anti-clockwise (which is conventionally described as positive rotation), or clockwise (which means negative). Positive and negative frequency both appear
the same, which is what we have been assuming for the last month or two and getting away with it.

The reason for this ambiguity is that the vector looks the same pointing towards one as it does when pointing away in the opposite direction. If one were to move to position 3 -or any other in the plane of rotation-it would be no better. The sequence of appearances would be as shown at $Q$, which is the same as $P$ with a phase difference of godeg (corresponding to the angle through which the viewer has moved from A to B) ; and without reference to A the direction of this phase difference is unknown, so one still cannot tell which way round the vector is going,

But if it were possible to have an eye in both places at once (or do the same thing in a more practical way with the help of mirrors) one would see both $P$ and $Q$ simultaneously, and correlation of these two views would prove that the vector was rotating positively. If, however, the two views were $P$ and $Q^{\prime}$, together they would indicate negative rotation.

Considering the thing vectorially, then, leads to the conclusion that the sign of the frequency ( + or - ) has no meaning when the alternating signal or supply is single phase, but can be given a conventional meaning with a 2 (or more)-phase supply. Note the word "conventional," which means that this is one of those things that people have to agree on: not an absolute unalterable fact of the universe. People agreed to mark the carbon electrode of a Léclanché cell " + ," and continue to do so, even though what is now known about the direction of electric currents would make a " -" a more sensible convention. Still, as long as everybody agrees, even a cock-eyed convention works. In a similar way, + and - signs are useful for distinguishing alternating currents that look alike by a single-phase test but neverthe-

## Negative Frequency-

less turn out to be different when examined in two different phases at once.

You will probably lodge an objection at this stage; namely that vectors are imaginary things, which may help to make A.C. theory clearer in the mind but are not A.C. itself. Coming down from airy fancies to physical realities, how does one tell a - from $\mathrm{a}+f$ on the bench?

If you have a single-beam oscilloscope and connect one pair of its deflection plates to a source of very low frequency voltage, the deflection of the spot from its normal position will vary in exactly the same way as the apparent length of the imaginary vector. If the other pair of plates is fed from a linear time-base generator, the spot will trace out a wave like the dotted line at P in Fig. r. And if the time base is locked to the frequency under observation, it will retrace the same wave over and over again, so there is no need for the frequency to be low enough for the spot to be followed by eye. 'This is a single-phase or single-position observation, which is incapable of showing whether the frecpuency is + or - .
If you have a double-beam scope you can examine a 2 -phase supply if you have a 2 -phase supply. Some people-though very few nowadays, because it is non-standard-do have a 2 -phase electric power supply laid on, and if they connect the two phases to the two beam deflectors, as in Fig. 2 , the beams will trace out a pair of waves either like $P$ and $Q$ or $P$ and $Q^{\prime}$ in Fig. i. (Unlike the output from a push-pull amplifier. which has a phase difference of iSo deg, the difference between the two "live" wires in a 2-phase power supply is normatly oo deg.) Taking one of them (say Phase 1) as the reference or standard, the other can be cither leading or lagging. 'The fregucncy of Phase 2 is the same in both cases-equal to that of Phase 1 --and the voltage is normally the same. The distinction between the two possible sorts of Phase 2 can be made by calling one of them a positive frequency and the other a negative. Hcavy electrical engineers may not have a doublebeam 'scope handy, but they are
quite likely to have a 2 -phase induction motor. Such a motor distinguishes between positive and negative frequencies (as just defined) in a very practical and significant fashion, by rotating anticlockwise (positively) with one and clockwise (negatively) with the other. But, of course, it all clepends on how Phase 1 has been connected to the motor (or 'scope). The Phase 2 that was cleclared "negative" with one Phase $I$ connection will be "positive" if Phase I is reversed. There is nothing new about that with + and - ; the sign can only l:o decided by reference to something else, such as earth in the case of potentials. A positive potential with one reference may

Fig. 2. A practical method of distinguishing negative from positive frequency.
be a negative with another. In the same way, the sign of a frequency has no meaning in a single-phase circuit. That is how we have been able to ignore it in recent issues, and many radio people ignore it all the time.

After all that discussion, then, the mysterious negative frequency seems to be just an arbitrary way of labelling leading and lagging phase differences for the sake of distinguishing them, So why bring frequency into it at all, and make a mystery about something that is quite simple and vell known? And is there any guidance at all about which label to put on, like there is with potential (with reference to earth), or is any guess as good as another?

The whole matter begins to make much better sense when one looks closely into frequency changers and such-like, and especially the Synchrodyne and the modulation filter system I described. In case you have forgotten about them, or didn't read it, consider an ordinary superbet.

As is well known, it is liable to "second-channel interference." That is because there are always two signal frequencies that can combine with the oscillator frequency to give the intermediate frequency, so the I.F. amplifier is quite unable to distinguish between them, and amplifies both equally, though one may be the wanted programme and the other an interfering station on a different frequency. It is necessary to rely entirely on the " pre-selector" tuning circuits to discriminate between the two, and if those circuits are not sufficiently selective it is just too bad.

In the days when receivers had an I.F. of about $110 \mathrm{kc} / \mathrm{s}$, secondchannel interference was quite a problem, because the wanted and unwanted stations were separated by only $220 \mathrm{kc} / \mathrm{s}$, and two or even three tuned circuits are not enough to make a strong signal, $220 \mathrm{kc} / \mathrm{s}$ off tune, negligible compared with a weak signal on tume. The present-day $465-\mathrm{kc} / \mathrm{s}$ I.F. separates the two channels by $930 \mathrm{kc} / \mathrm{s}$, and gives the tuner a better chance.

Suppose, for example, that the wanted station is on $I, 000 \mathrm{kc} / \mathrm{s}$. If the I.F. is $465 \mathrm{kc} / \mathrm{s}$, the oscil. lator must be set to oscillate at $535 \mathrm{kc} / \mathrm{s}$ or $1,465 \mathrm{kc} / \mathrm{s}-$ usually the latter. A station working on $1,930 \mathrm{kc} / \mathrm{s}$ can also combine with 1465 to give $465 \mathrm{kc} / \mathrm{s}$, so that is the " second channel "-twice I.F. from the first or intended channel. Although these two channels are indistinguishable from the I.F. amplifier's point of view, they are different frequencies originally, so can be distinguished by pre-fre-quency-changer tuning.

A Synchrodyne, as I said last month, is a superhet in which the I.F. is zero. One of its advantages is that a low-pass filter accepting all frequencies below some specified frequency-say, $5 \mathrm{kc} / \mathrm{s}$ -is generally easier to design to an exacting specification than a band-pass filter covering the same total band of frequencies placed high up in the R.F. spec. trum. For example, if it is necessary to accept a $5-\mathrm{kc} / \mathrm{s}$-wide band, cutting off all others sharply, it is easier if that band is $0-5 \mathrm{kc} / \mathrm{s}$ than if it is, say, 5,000 $5,005 \mathrm{kc} / \mathrm{s}$. For some purposes in telecommunications (such as single-sideband amplification) the
$5,000-5,005$ sort of proposition is so unattractive that it is worth the trouble of frequency-changing it down to o-5, by using a 5,000 $\mathrm{kc} / \mathrm{s}$ oscillator, so as to be able to use a $5-\mathrm{kc} / \mathrm{s}$ low-pass filter The snag is that signals in the band 4,995-5,000 kc/s also som bine with $5,000 \mathrm{kc} / \mathrm{s}$ to give sig. nals in the $0-5-\mathrm{kc} / \mathrm{s}$ band; and to the low-pass filter they are all the same as if they had originated in the desired $5,000-5,005$ band And the design of a pre-selector to weed out the $4,995-5,000$ signals is just the nasty sort of job that the scheme is intended to avoid.

Since the $5,000-\mathrm{kc} / \mathrm{s}$ oscillator can be said to reduce the frequencies of all the original signals by $5,000 \mathrm{kc} / \mathrm{s}$, the wanted band can be said to be moved to o to $+5 \mathrm{kc} / \mathrm{s}$ and the unwanted tbut unavoidably accepted) band ., -5 to $0 \mathrm{kc} / \mathrm{s}$. In this way the two lots of signals can be given + and - frequency labels ac. cording to a definite and reasonable system. $5,005 \mathrm{kc} / \mathrm{s}$ when modulated by 5,000 gives 5,005 $+5,000=10,005$ and 5,005$5,000=5$, whereas 4,995 modlulated by 5,000 gives 9,995 and -5 .

A low-pass filter, being a singlephase device, cannot tell $-5 \mathrm{kc} / \mathrm{s}$ from $+5 \mathrm{kc} / \mathrm{s}$. It can, in fact. be regarded as a bandpass filterthe one in the example admits the band -5 to $+5 \mathrm{kc} / \mathrm{s}$; a total width of $10 \mathrm{kc} / \mathrm{s}$.

That idea, possibly still rather novel to mosit readers (though I certainly don't claim originality) ties up with a diagram 1 showed in "Channels of Communication" (June, 1947), regarding which I said that the audio-frequency band can be considered to be a side-band of a zero-frequency carrier wave, and that whatever carrier wave was ased for a channel of communication the bandwith occupied was the same. This might have seemed to contradict the cammon impression that whereas a telephone channel to convey speech frequencies ap to, say, $5 \mathrm{kc} / \mathrm{s}$. has to have a band width of just under $5 \mathrm{kc} / 6$, directly they are used to modulate a transmitter for a radio link the bandwith has to be doubled to accommodate two sidebands each nearly $5 \mathrm{kc} / \mathrm{s}$ wide. That apparent discrepancy can be cleared
one way by pointing out that (with suitable precautions) he full range of the information ran bs conveyed by one sideband only. We now see-I hope-that it can be cleared in another way by saying that an A.F. low-piss filter to separate o to $5 \mathrm{kc} / \mathrm{s}$ from other frequencies also accepts o to $-5 \mathrm{kc} / \mathrm{s}$; a total band of
(a)

Fig. 3. A high frequency (rooo$\mathrm{kc} / \mathrm{s}$ ) carrier wave modulated at $3 \mathrm{kc} / \mathrm{s}$, represented in three ways$a, b$, and $c$. A zero-frequency "carrier wave" modulated at the same frequency is shown in the same ways at $d, e$ and $f . g$ is an alternative to $d$, representing a different "phase" of the "carrier wave."
$10 \mathrm{kc} / \mathrm{s}$, just as in the R.F. con. dition. o to $-5 \mathrm{kc} / \mathrm{s}$ can, in fact be regarded as the other sideband of the zero-frequency carrier wave.
I am going to return to the system in which the negative frequencies represent second-chamel interference; but in the meantime this Z.F. carrier-wave idea is worth thinking about a little
more. Suppose we start off with the old familiar case of a R.F. carrier wave modulated by a single A.F.-say, i, ouo kc/s and $3 \mathrm{kc} / \mathrm{s}$ respectively-and express this in various words and diagrams. The way that everybody finds easiest to "see"" is to describe the froduct of the process as a $1,000-\mathrm{kc} / \mathrm{s}$ wave-train varying in amplitude at a rate of $3 \mathrm{kc} / \mathrm{s}$. The diagrammatic representation of this description must be an amplitude/time graph, and assuming the modulation to be 100 per cent, it will look something like Fig. $3 a$ if prolonged for the space of two-thirds of a millisecond (i.e., two cycles of the modulation frequency). the R.F. cycles are too numerous to show separately, but we know there are more than 600 of them in the short length of graph shown.

The alternative description that everybody finds so much more difficult to visualize, and some never quite believe, though in is a much easier form to handle mathematically, is that the thing consists of a $\mathrm{r}, 000-\mathrm{kc} / \mathrm{s}$ carrier wave plus waves of half the amplitude at 997 and $1,003 \mathrm{kc} / \mathrm{s}$. Using the same form of diagram, an incredibly patient person could draw a few hundred cycles of these three, correctly to scale, add them all together to make a single graph, and arrive at-Fig. $3 a$. While a complete cure for the sceptic, this is one he is not likely to be persuaded to take. A much more practical diagrammatic expression of the statement is the spectrum form-an amplitude/ freyuency diagram-as in Fig. $3 b$. which explains itself. $\Lambda$ third form of diagram-yes, it is the vector or amplitude/phase diagram, Fig, $3 c$, which you will be getting tired of. All these diagrams are just different views of the same thing. The spectrum is a Fig. I view of the vector diagram with all the vectors simultaneously pointed up and spaced along their axis to mark their respective frequencies. The two little vectors in Fig. $3 c$ rotate respectively $3 \mathrm{kc} / \mathrm{s}$ faster and slower than the big vector, which is doing $\mathrm{I}, 000 \mathrm{kc} / \mathrm{s}$; and as a succession of diagrams during one modulation cycle demonstrates. this condition ensures that the resultant-the single vector equi-

## Negative Frequency-

valent to the two small ones-is always in the same line as the carrier vector, so the combination with it is equivalent to a carrier vector which varies its length between double-normal and zero, at carrier frequency. Such a pulsating vector, viewed as from A in Fig. 1 , appears to vary in amplitude in exactly the way traced out in the amplitude/time graph, Fig. $3 a$.

Now suppose, to the great relief of anyone who is trying to visualize Fig. $3 c$ rotating at its various working speeds, that the carrier frequency is drastically reduced. To give the greatest possible relief, let us suppose that the carrier frequency is reduced to zero, so that its vector is brought to a standstill. Then the two side vectors rotate at equal speeds but in opposite directions. One is doing $+3 \mathrm{kc} / \mathrm{s}$ and the other - $3 \mathrm{kc} / \mathrm{s}$. The slowingdown of all the radio frequencies by an equal amount can be done physically by a frequency changer; and the Synchrodyne is a practical case in which the carrier wave is reduced to zero, but of course the usual apparatus does not distinguish between $+3 \mathrm{kc} / \mathrm{s}$ and $-3 \mathrm{kc} / \mathrm{s}$-all we know is that we get $3 \mathrm{kc} / \mathrm{s}$.

The vector diagram, however, does suggest that these two frequencies do exist, and that a twophase system ought to be able to distinguish them. Before examining this point, take another look at the slowed-down Fig. 3c. The resultant of the oppositely rotating side vectors is always either straight up or down, directly adding to or subtracting from the stationary carrier vector. I needn't go through it all in detail again; you will easily see that the resultant of the whole lot can be represented (if the carrier vector has come to rest in a vertically upward position) in amplitude/time form as in Fig. 3d, which is drawn to the same scale as Fig. 3a. The blur of R.F. cycles has been replaced by D.C. ; and we have the sort of thing that one might get in the anode circuit of a fully loaded (and surprisingly perfect!) audio amplifier. If the carrier vector had stuck in the downward position, that would represent the same thing with leads reversed. And if it had finished horizontally,
so as to be invisible from viewpoint A in Fig. I, the two sideband vectors would be left on their own to give Fig. $3 g^{g}$ - a pure A.C. of frequency $3 \mathrm{kc} / \mathrm{s}$. In fact, the amplitude of A.C. of any single frequency varies in a manner which is represented by the resulant of two half-size vectors rotating in opposite directions. So it looks as if any A.C. may, for all we know, consist of equal parts + and - frequency.

Turning from this shattering thought to the apparatus in which, for practical convenience of filter construction, a $5,000-$ $5,005-\mathrm{kc} / \mathrm{s}$ band had been transported by a $5,000-\mathrm{kc} / \mathrm{s}$ modulator to $0-5 \mathrm{kc} / \mathrm{s}$, only to run into interference from signals in the band $4,995-5,000 \mathrm{kc} / \mathrm{s}$, is there any way out of the difficulty? You have, I hope, been well prepared to look for the solution in a 2 -phase system. Such a system is described by N. F. Barber in Wireless Engineer, May, 1947; and as it is a rather specialized type, not likely to be adopted by many in what I might make bold to refer to as my constituency, I will not attempt to reduce it in detail to " Cathode Ray" terms. In brief, applying it to our example, the original signal is put in to a 2 -phase modulator, giving two outputs, in both of which the wanted signals are in the band -2.5 to $+2.5 \mathrm{kc} / \mathrm{s}$; that is to say, the modulating frequency is $5,002.5 \mathrm{kc} / \mathrm{s}$ instead of 5,000 . Each of these outputs is put through a separate low-pass filter with a cut-off at $2.5 \mathrm{kc} / \mathrm{s}$. All the interference is thereby disposed of. The trouble now, in a
single-phase system, would be that signals which were originally 5,000 and $5,005 \mathrm{kc} / \mathrm{s}$ would both appear indistinguishably as 2.5 $\mathrm{kc} / \mathrm{s}$. But by using another $2^{-}$ phase modulator to shift the frequencies into an all-positive band the two are given their proper $5 \mathrm{kc} / \mathrm{s}$ separation. The second frequency-changer could also have a $5,002-5$ oscillator, to restore the signals to their original places in the spectrum, rid of all unwanted frequencies. Or they could be transferred elsewhere, as required.

We have managed to get through all this without any sin-and-cos! But in case any readers deplore that, here, as a tailpiece, is what it has to say about negative frequency. The situation we saw at the start-the minus going unnoticed because to a single observer there is no difference between $-f$ and $+f$-arises in mathematics because $\sin$ and $\cos$ are ambiguous. Cos starts from a positive peak, and decreases in exactly the same manner whether one goes forwards or backwards. Put concisely, $\cos \theta=\cos (-\theta)$.
Also $\sin \left(\frac{\pi}{2}+\theta\right)=\sin \left(\frac{\pi}{2}-\theta\right)$. When the books deal with modulation (etc.) by multiplying two cos and/or sin terms together, they conveniently forget this ambiguity, to save themselves the embarrassment of producing a negative frequency and having to explain it. They give the results $f_{1}+f_{2}$ and $f_{1}-f_{2}$ (if $f_{1}$ is higher than $f_{2}$ ), but drop out $f_{1}-f_{1}$. It exists, all the same, and, as we have seen, can even be separated from its mirror image, $f_{1}-f_{2}$ !

## LIGHTWEIGHT PICKUP

TIIE Decca ""ffrr", pickup, used in "Decola" electric gramophones, is now available separately either as a replacement head ( $t+1458 \mathrm{~d}$ ) or with 8 -in tone

$\operatorname{arm}\left(t^{6}\right.$ I 4 s 4d); both prices including purchase tax. Replacement sapphire stylus elements will be avail. able.

# SEAFARER'S RECEIVER 

## Eddystone Model 670 Broadcast Superhet

ALTHOUGH described as a marine receiver the new Eddystone Model 670 is essentially a broadcast set ansl not, as might be supposed, one of the communications type.

The set is primarily intended for personal use on board ship ant in view of this has been designed for operation on either A.C. or D.C. supplies of from 100 to 110 volts or 200 to 250 volts.

Particular attention has been given to the performance of the set
band and the four amateur bands of $1.7,7,1+$ and $28 \mathrm{Mc} / \mathrm{s}$.

Seven miniature valves on $\mathrm{B8A}$ bases are used in a superheterolyne circuit having one R.F. stage, combined frequency changer, one I.F. amplifier, A.G.C., detector and A.F. amplifier and finally a push-pull ontput stage delivering about 2 watts to a din loudspeaker mounted on the left-hand side of the chassis.
A.C.-I).C. technique with seriesconnected valve heaters and a tapped voltage dropping resistor is

The layout of the Eddystone 670 chassis is particularly neat and gives access to all parts. The coil box is below the deck.
on the short waves, as for long periods the high frequencies will often be the sole medium for broadcast reception. The use of a novel expanded tuning scale ensures precise re-setting of the set to any previously logged station. It is a mechanical system embodied in the reduction drive and provides the equivalent of goins of scale for each range.

There are four wavebands in this set, covering, respectively, 1,220 to $522 \mathrm{kc} / \mathrm{s}(246-575 \mathrm{~m}), 2.75$ to 1.2 $\mathrm{Mc} / \mathrm{s}(110-250 \mathrm{~m}), 13$ to $5.8 \mathrm{Mc} / \mathrm{s}$ $(23.1-5 \mathrm{I} .7 \mathrm{~m})$ and 30 to $12.8 \mathrm{Mc} / \mathrm{s}$ ( $10-23.5 \mathrm{~m}$ ). In addition to the short and medium broadcast bands the set covers the so-called trawler
employed with a selenium-type rectifier providing H.T.

Special care has been taken to prevent interference to, or from, other radio sets in the vicinity, a very inlportant matter on board a ship where so much depends on radio for navigation and other essential services. Modern shins use a vast amount of electrical machinery and as interference from them may be carried along the ship mains, a mains filter for use external to the set is available if required.

The coil unit is a 3 -compartment die-cast metal box in which all trimmers and padders are included and the whole set is enclosed in a compact and stout metal cabinet

This view of the Eddystone 670 shows the large calibrated dial and the disposition of the controls. The bandspread dial is in the top right-hand corner of the main dial.
measuring only $16 \frac{3}{4}$ in by gin by tol $\frac{1}{2}$ in overall and finished in brown criackle enamel.

A point of interest regarding the supply circuit is that the mains leads and their plugs and sockets are completely insulated. Particular attention has, in fact, been given to insulation throughout, in addition to which all components are the tropical grade, so necessaty in a set of this kind which is almost sure to be used in every conceivable variety of climate ans! wenther.

The controls comprise a spinwhere tuning system, large illuminated dial with calibrated scales and the subsidiary band-spread scales previously mentioned, waveband switch, volume control and a combined tone compensator and onoff switch.

On the back are sockets for the mains input, voltage adjusting panel and sockets for a single wire or dipole aerial. There is also a pair of sockets and a plug which enables the internal loudspeaker to be disconnected and an external one, or headphone, plugged in instead.

We were able to give the set a brief test and knowing the condlitions under which it would normally be used it was made in fairly close proximity to a considerable amount of electrical machinery and with a mediocre aerial. Performance was very satisfactory; the A.G.C. system works particularly well and the mains filter was found to be definitely worth having in this location. Adjacent chammel selectivity is very good and the wavelength and frequency calibrations are extremely accurate.

The makers are Stratton \& Company, Ltd.. Eddystone Works, Alvechurch Road, West Heath, Birmingham, 3I, and the price of the re. ceiver is 637 los., the filter unit costing $f 2$ ios.

# AIR COMMUNICATIONS 

is divided into four lands. each f-Mc/s wide, and by motor-operated switching any one of the bands can be selected from the remote control unit. The five chosen crystals can be arranged either to bee all in one + -Mc /s band or distributed ower the whole range. The same crystal serves for both the transmitter and receiver.
(Left) Marconi portable radio telephone for use on airfelds.
(Right) Murphy MR6o 5-channel V.H.F. transmitterreceiver and control unit.

TNIIE fine display of V.H.F radio telephone equipment for ground and air use was a notable feature of the wireless section at the 1 llying Display and Exhibition held this year at Farnborough by the society of british Aircralt constructors.

Standard Telephones were show ing two V.H.F. aircraft sets, the STR12 and STRG, the former being a 12 - and the latter a 4 -chamed set giving crestal control of transmitter and receiver. As with all aircraft sets of this kincl, remote control is employed and the crystals (of which there are 2.4 miniatures in the STRiz) are fitted in an accessible position on the control unit. 'The main reason for this is to enable the crystals to be changed in the air if other spot frequencies are required.

A similar arrangement is adopted by Murphy in their MRoo aircraft set. Five spot frequencies are provided with the crystals and crystal oscillator included in the remote

> Chassis assembly of the G.E.C. BRT 600 V.H.F. set. The power unit is in the base.
control unit. The set covers the aircraft band of 116 to $132 \mathrm{Mc} / \mathrm{s}$, but in order to avoid retuning for each change of crystal this range

Since size and weight is at a preminm in all aircraft efpuipment, these sets are condensed into the smallest possible whame They are outstanding examples ot what can be achiewed with miniature valves and components.

The new G.E.C. set type 13RTroo, which measures $3 \begin{gathered}\text { ? } \\ \times 7 \% \\ 7 \%\end{gathered}$ $\times 0 \underline{2} 1 \mathrm{in}$, contains a transmitter, a receiver and a rotary transformer. some of its 11 miniature valves
dre used in a dual capacity, the crystal oscillator and frequency multipliers being one example. These serve either as a crystal drive

components has heen adopted Still another lightweight radio, telephone set for aircraft was seen on the Plessey stand. Described as the Model TR5I it provides five channels using the same crystal for transmit and receive and covers it 6, to $132 \mathrm{Mc} / \mathrm{s}$. The alesign permits crystals to be changerl in the air if other channels than those chosen are required. The overall size is $12 \frac{2}{2} \times 6 \times 5$ in and the weight is $9 \frac{1}{2}$ th only. The R.F. output is $I$ watt and the power consumption 50 watts.

In addition to providing air-toground II.C.W. and R.T. communication the new Cossor V.H.F. set can be used also for reception of beam approach marker signals. In the latter case a small B.A. amplifier is used and the output is fed into the main part of the V.I.1: receiver. For commnnication purposes the range of the set is Ioo to $124 \mathrm{Mc} / \mathrm{s}$ and four pre-set channels are available.

For transmission a crystal oscillator is followed by a doubler and push-pull trebler which drives a push-pull P.A. to 6 or 7 watts R.F.
output. The receiver has an R.F. stage, a mixer with local oscillations derived from a crystal oscillatortrebler and a sext. rupler, three I.F. amplifiers, detector, A.G.C. and two A.F. stages. With motor generator and B.A. receiver the whole occupies only $13 \times 17 \times 8$ in
) ther radio equip ment in the V.II.F category shown included the latest standard Telephones instrument landing and runway approach re

Chassis view of the new Redifon R50 communications receiver.

ceivers, the STRIt and STRis. Ground equipment was represented by two distinct classes. There were the higher-powered transmitters built in rack torm for flying control on and ower the airport and in the approach areas, and some very compact portable amel mobile sets for use by ground personnel at remote parts of the airfield.

One example of the litst menfioned is the Marconi 「(i) $\mathrm{f}_{7} 2$ trams-

contained and very compact, weighing but $15 \frac{1}{2} \mathrm{lb}$ and measuring $2 \times 15 \frac{1}{2} \times 7 \frac{1}{2} \mathrm{in}$, and it can be either battery or mains operated. It is thus suitable for use in vehicles on the airfield. There was also a "Walkie-Talkie" set described as the type 1119.

Self-contained units assembled in a standard 19 -in rack and made up for single- or multi-channel operation were a feature of the I've Telecommunication exhibit. The transmitter panel gives 12 -watts output and includes modulator and power supply. The same form of construction is used for the receiver units each of which consists of a 17 -valve superhet, loudspeaker and power pack. It is A.C.-operated.

An interesting feature of the Ekco airport V.H.F. station is

## (Left) Standard

Telephones STR 16/17 medium and high frequency aircraft installation.

mitter of 50 watts output and covering a wide V.M.I: band including the aircraft one of ith to $132 \mathrm{Mc} / \mathrm{s}$. Single-or multi-chanmel operation can he provided, also amplitude or frequency modulation.

As a stand-by for this set, or where lower power will suffice, Marconi's have a ro-watt set, A.M. or $\mathrm{F} . \mathrm{M}$. as required, which is known as the type TAVfio. It is self.
the inclusion of 1 . F . facilities using a moslified form of the communications receiver and a pair of rotatable dipoles controlled from the operating position in the tower.
The latest H.F.-M.I: communications equipment made by standard Telephones provides for operation oyer a wide
range of frequencies. The STRi6 H.F. installation, for example, includes a jo-watt transmitter giving a range of about 500 miles on telegraphy at 5 ,oooft and 150 miles on telephony. The receiver covers 2.4 to $13 \mathrm{Mc} / \mathrm{s}$ in two bands. There is a companion rowatt M.1. communications set covering 150 to $505 \mathrm{kc} / \mathrm{s}$ giving a range of about 150 miles and including 1).F. facilities. It is rescribed as the STRI7

One of the latest pieces of equipment introduced by Marconi's is a 12-value communications rectiver, the ADg. It has six ranges, two (o)ering $150 \mathrm{kc} / \mathrm{s}$ to $510 \mathrm{kc} / \mathrm{s}$ and tour cowering 2 to $18.5 \mathrm{Mc} / \mathrm{s}$. The B.F.O. is crystal controlled. The normal I.F bandwilth is $5 \mathrm{kc} / \mathrm{s}$, but for C.W. operation a crystal filter can be brought into use giving r kc/s bandwidth. The calibration of this receiver is such that pretuning to any desired frequency can be effected with an accuracy of $\pm 2 \mathrm{kc} / \mathrm{s}$. Its power supply is provided by a built-in rotary converter consuming I amp at 28 volts.

Designed for use in large aircraft is a new Marconi high-power transmitter type Alotoz, covering the high and medium freguencies with

## Air Communications-

independent, but complimentary, units. Each section provides for io crystal-controlled spot frequencies with either local or remote control and the power output is between 100 and 150 watts over 2 to $18.5 \mathrm{kc} / \mathrm{s}$. The equipment is fully tropicalized and wide use is made of miniature parts in order to conserve space and weight.

Several different models of transmitters and receivers for ground stations and for conmunication with aircraft were shown by Rediffusion. There was a joo-watt transmitter, the type $G_{54}$, designed for C.W., telephony and navigational services on 250 to $520 \mathrm{kc} / \mathrm{s}$. Eight crystal-controlled spot frequencies or a continuously tunable electron-coupled master oscillator can be provided, the latter having a stability of o.r per cent.

The transmitter consists of four separate units mountel it a steel cabinet. They comprise power supply, modulator, R.F. and acrial coupling units, and the form of

## Radio sonde meteorological balloon transmitter shown by Salford.

construction facilitates servicing when the need arises. The whole equipment is fully tropicalized.
A new communications receiver was also seen on this stand. Known as the model $\mathrm{R}_{50}$ it is a 12 -valve superhet covering, in eight bands, the exceptional frequency range of $13.5 \mathrm{kc} / \mathrm{s}$ to $32 \mathrm{Mc} / \mathrm{s}$. Two R.F. and three I.F. amplifiers are employed and there is also a doublediode noise limiter. The A.C. power unit has a voltage stabilizer. A D.C. version is available.

A unique feature of the set is that the I.F. is switched from $465 \mathrm{kc} / \mathrm{s}$ to $I I O \mathrm{kc} / \mathrm{s}$ when receiving on 13.5 to $26 \mathrm{kc} / \mathrm{s}$ and on 240 to $606 \mathrm{kc} / \mathrm{s}$. Also, there is the choice of five bandwidths, ranging from $250 \mathrm{c} / \mathrm{s}$ to $17 \mathrm{kc} / \mathrm{s}$.

Since meteorological reports play such a vital part in flying, special interest attaches to the various devices used in compiling them. For investigating the conditions prevailing in the upper atmosphere radioequipped balloons

Decca Navigator Mark VI aircraft receiver with power unit.

shown by Salford Electrical Instruments.

Last year saw the introduction of

Plessey 5-channel V.H.F. radio telephone for light aircraft.
have long been used, and the latest form these transmitters take were
two automatic radio direction finders for use in aircraft, and both G.E.C. and Marconi were showing the latest version of these sets. Decca were showing a new aircraft receiver for the Decca system of long-range radio navigation. Some of the latest improvements incorporated include continuous and automatic lane identification, independent cross check of position and provision for use on up to five Decca Navigator clains. Receiver and power unit fit into the standard aircraft racking and operate from the low-voltage D.C. supply. Remote indicators, described as Decometers, are provided for the pilot and the navigator.
-

## GRAPHICAL CIRCUIT SYMBOLS

Revised British Standard Issued

AREVISION of " Graphical Symbols for 'Telecommunications" has just been issued (BS530:1948; British Standards Institution, 28, Victoria Street, London, S.W.I; price 10s 6d.) This revision (the second) appears after a gap of eleven years, and, as might be expected, the number of symbols has grown considerably to keep pace with advances in the art. The publication of this new edition is a matter of some importance, especially in the world of wireless, as, out of 100 pages, a bare halfdozen only are exclusive to such non-radio subjects as wire telephony.
In addition to symbols purely for circuit diagrams, there are also representations of units comprising groups of components (e.g., amplifier, modulator) for use in " block schematics" or skeleton diagrams. There is also a set of symbols (e.g., direction finder, vision pick-up) for use on plans.
Where the Britisl standard symbol differs from the international standard issued by the
I.E.C. the difference is indicated and the I.E.C. symbols which so differ are given.

It is stressed in the foreword that circuit symbols should not be pictures, but should be simple in form, so they can be easily drawn. The primary purpose of graphical symbols is to indicate the electrical functions of the circuit. They are not intended to give guidance in the constructional details of apparatus; mechanical construction of apparatus to be represented is thus of secondary importance.

## FOR CONSTRUCTORS

ALIMITED number of receiver chassis, suitable for incorporation in radio-gramophones, will shortly be for disposal from Multitorie Electric, 223, St. Johns Street, Clerkenwell, London, E.C.I. The circuit is similar to that used in Multitone Radio Set for the Deaf (Wireless World, October, 1946) and includes a push-pull output stage. It covers short, medium and long waves, but the auxiliary microphone amplifier circuits are umitted. The price, including tax, will be 212 I4s fil.

 <br> <br> Plan + Kits of Parts Taxable - B.B.C. Finance}

## 405 Lines to Stay

Simultaneous statements issued last month by the Post ()ffice, the Television Advisory Committee and the Radio Industry Council make it clear that the present technical standards of the B.B.C. television service are to remain unchanged for a number of years, unofficially interpreted as five years if the next step is to be a comparatively minor one, and up to ten years if it is to be something sweeping, like colour.

The Post ()ffice statement is welcomed by the industry for several reasons, the main one being that the present system allows the development of television services at minimum cost. The official industry statement urges the adoption of the 405 -line system as a European standard.

## Exporting Television

BRITISH television is being featured at the British Exhibition which opened in Copenhagen on September 18th.

Arrangements have been made by the R.I.C. for cameras and transmitting gear, similar to that used by the B.B.C., to be installed by Pye for the demonstration of $405^{-}$ line television throughout the period of the exhibition. The equipment is housed in two vehicles, one containing the picture control room and the other the 25 -watt transmitter. E.M.I. 605 -line film-scanning equipment is being used for film transmissions.

Television receivers are being demonstrated in the Nimb Restaurant, where the transmitted picture is received by a master receiver from which the output is fed to the sets being demonstrated by Bush, Cossor, Ekco, Ferranti, G.E.C., H.M.V., Marconiphone, Mullard, Murphy, Pye and Ultra.

In addlition to the television exhibit, which is a concerted effort under the ægis of the R.I.C., the British radio industry is well represented by over thirty firms who have stands of their own.

## Amateur Exhibition

THE second annual amateur radio exhibition organized by the R.S.G.B. will be opened at $2.30 \mathrm{p} . \mathrm{m}$. on November 17th, by Jr. R. I. Smith-Rose, Director of Radio Research, D.S.I.R. It will
be held at the Royal Hotel, Woburn Place, London, W.C.r, and will remain open until November 20th (hours II a.m. to 9 p.m.).

Admission will be by catalogue, price is if purchased at the door, or is 3 d by prost from the society, New Ruskin House, Little Russell street, London, W.C.i.

## European Wavelengths

$I^{T}$T is anticipated that by the time this issue appears a new European frequency allocation plan wil! have been agreed upon by the delegates of the thirty-two nations participating in the European Broadcasting Conference which has been meeting in Copenhagen since June 25 th.

The responsibility for drawing up the final frequency plan for European broadcasting stations (below $1605 \mathrm{kc} / \mathrm{s}$ ) has been entrusted to the Frequency Allocation Committeeone of six set up by the Conference. This has been presided over by H. Faulkner, Deputy Engineer-inChief, G.P.O., one of the delegates of the U.K. It will be recalled that alternative provisional allocation plans were drawn up by a committee of representatives of eight European countries for consideration by the present Conference (see Wireless W'orld, June, p. 223).

It is learned from the International Broadcasting Organization, which is participating as an observer, that the question of allocating frequencies to the various occupied zones of Germany provoked considerable discussion in the general asseinbly.

## P.T. on Kits

TIIE Commissioners of Customs and Excise have decided that for the present the following kits of parts including any loudspeaker or cabinet supplied therewith, are liable for Purchase Tax at the rate of $33^{\frac{1}{3}}$ per cent of the wholesale value:-
(i) R.F. tuned coil assemblies covering the medium- and/or long-wave broadcast wavebands, or television waveband.
(ii) Kits of parts, whether or not complete or assembled, which include a coil assembly as at (i) above.
(iii) Kits of parts, whether or not coniplete or assembled, which are sold for the assembly of domestic, portable or car receivers, e.g., an unassembled receiver sold in two or more separate kits for use in assembling a particular receiver.

## B.B.C. Report

THE Governors of the B.B.C. have issued the Report for the year ended March 3ist last, which is the first full year of operation under the new Charter issued on January 1st, I9.47.
I.ittle that is not already known of the activities on the engineering side is inclucled in the report. The financial statement shows that the income for the Home and Television Services totalled $£ 9,986,420$, of which $£ 8,027,363$ came from licence fees and $L_{1,047,253}$ from publica-

## BRAZILIAN STATION.

The recently opened broadcasting station near Recife, Brazil, which was equipped by Marconi with a 20-kW M.W. transmitter and two 15kW S.W. transmitters. A square section mast radiator is used for medium waves and the.S.W. arrays are supported on six short masts

## World of Wireless-

tions. A balance of over a million pounds was brought forward into this year. The Corporation received a Government grant-in-aid for the Overseas Services of $\notin 4,025,000$.

It is announced in the report that negotiations are being made for securing a site in London for a new televisicn headquarters.

The Report has been published by H.M.S.O. as Cmd. 7506.

## PERSONALITIES

L. W. Hayes, chief of the 13.B.C. Overseas Engineering and Information Department, who has been one of Great Britain's representatives at most of the international radio conferences during the past few years, has been elected vice-director (in charge of broadcasting matters) of the International Radio Consultative Committee. The C.C.I.R. is one of the permanent organs of the International Telecommunication C'nion, the duties of which are to study technical radio questions regarding the operation of stations. The new director is Dr. Jalth van der Hol, of Germany

Major H. E. Watterson, who was with Marconi's before the war, has returned from Shanghai where he has been for the last two years with U.N.R.R.A. as consultant and adviser on telecommunications. He was commissioned in the Royal Signals at the outbreak of the war and was posted to the Radio Security Section of M.I. 8 (War Office). From 194 ? until V.J. Day he was with the Embassy in Chungking.
A. F. Bulgin, M.B.E., chairman and managing director of the compans bearing his name, has been promoted to the rank of Wing Commander in the R.A.F.V.R. Training Branch.

## IN FRIEF

An increase of 3,400 over the previous month was shown in the number of television licences in force at the end of July, when the total was 58,250 . The month's figure for broadcast receiving licences, including those for television, was approximately $11,292,750$.
Amateurs' Examination.-Of the 700 entrants for the City and Guilals Radio Amateurs' Examination held in May. 528 were successful. Ten of the thirteen overseas candidates passed. The examiner's report states that the standard of the candidates' work was much higher than in previous examinations. Copies of the question papers for the past three vears are available, price 4d each, from the Iepartment of Technology, 31, Brechin Place, London, S.W.7. The next examination will be held on May 1 ith, 1949, from 7 to io p.m
U.S.W. Amateur Band.-It is learned that the nequtiations for the release of the $420-460 \mathrm{Jc} / \mathrm{s}$ hand for l3ritish amateurs, to which reference was made last month, have been concluded and that the band will be ayailable from October ist. Power will be limited to io watts.

Gee. -The Scottish Gee Chain, which has for some time been under construction, is now operating experimentally on $73.8 \mathrm{Mc} / \mathrm{s}$. It will eventually work on $69 \mathrm{Mc} / \mathrm{s}$. The master station is at Lowther Hill, Dumfries; with slates at Craigowl Hill, Angus; Ru Stafnish, Argyill and Great Dun Fell, Cumberland.
S.I.M.A. - The Electronics Section ot the Scientific Instrument Manufacturers' Association has arranged for a series of technical papers to be read at meetings to be held at the Caxton Hall, Westminster, S.W.i, on November 18th and 19th. The morning and afternoon sessions on the first day will be devoted to electronics in scientific research and those on the second day to electronics in industry. Full particulars and tickets are obtainable from S.I.M.A., 26, Russell Square, London, W.C.I.
F.M. Patents.-Dr. Edwin Armstrong, the inventor of the F.MI. method of transmission, has filed a suit against the Radio Corporation of America and the National Broadcasting Company for alleged infringement of five of his basic F.M. patents.

Readership in Electronics.-Mullard's offer to finance a Readership in Electronics at the City and Guilds College of Imperial College has been accepted by the University of London. The Readership will be mainly concerned with post-graduate teaching of research.
E.M.I. Scholarships.-A scholarship carrying a three-year course in telecommunications engineering at E.M.I. Institutes is being sponsored by E.M.I. It will be awarded by open competition through recognized educational authorities. There is also a postal course scholarship.

Mullards.-A complete list of all reference cards for Mullard valye testers issued up to July, 1948, together with details of the valve types each card will test, has been prepared by the manufacturers. Owners of Mullard Master 'Test Boards wanting a free copy should write, mentioning the serial number of the instrument, to Mullard Flectronic Products, L.tr., Valve Sales Department, Century House, Shaftesbury Avenue, London, W.C.2.

Wire Broadcasting, - The development of wire broadcasting in this country is traced by IR. H. Coase in the August issue of Economica. The first relay exchange was opened in January, 1925; by December, 1929 there were 34 exchanges with some 8,500 subscribers. At the end of September last year there were 293 exchanges and 755,925 subscribers.
"Wireless Engineer."-With the October issue of our sister journal, Wircless Engincer, it celebrates its twenty-fifth anniversary. Originally Experimental Wireless, it later became Fxperimental Wireless and Wircless Enginerer. and eventually, in Septemher, 193I, adopted its present title. The changes in the title illustrate the gradual change of the coverage of the contents from the original experimental outlook to the present engineering standard. With this change the Abstracts and References section of the journal, which includes abstracts from and references to articles on radio and allied subjects in the world's technical
press, has grown from its original $1 \frac{1}{2}$ pages to the present average of 21 pages a month.

Servo-Mechanism.-A course of seventeen lectures on servo-mechanism is to be given at the Manchester College of Technology on Friday evenings from 7.0 to 9.0 , commencing on November i2th. The fee for the course, which is one of many sponsored by the Nanchester and District Advisory Council tor Further Education, is two guineas. The pamphlet covering the series of post-advanced lectures in electrical and mechanical engineering is obtainable from the Education Offices, Deansgate, Manchester, 3 .

Scientific Films.-This year's International Festival of Scientific Films will be held at the Royal Empire Society IIall, Northumberland Avenue, London, W.C.2, from October 8th-roth. Tickets for the two daily sessions (2.30-5.30 and 7.30-10.30) and details of the programme may be obtained from the Scientific Film Association, 34, Soho Square, London, W.I,

Marconi Veterans.-A reunion and luncheon is being held on October 9th at Caxton Hall, Westminster, London, S.W.I, for veterans of the Marconi International Marine Communication Co.

Broadcasting Stations.-The fourth erlition of our booklet "Guide to Broadcasting stations," will be published during October. It has bwen entirely revised and the information given has been checked against the records of the B.B.C. Tatsfield Receiving Station. The 64-page booklet, which is obtainable from booksellers and newsagents, price is, or by post from our Publishers, price is 2d, contains details of frequency, wavelength and power of European M.W. and L. W. broadcasting stations and S.W. stations of the world.
British Kinematograph Society. - The headquarters of the society are now at 53, New Oxford Street, London, W.C.I (Tel.: Temple Bar 2092).

Wanted.-Copies of the July and dugust issues of Wiveless World are wanted by our Publishers to complete their files. Full price will be paid.

## FPOM ARPOAD

Personal Television.-It is announced by the Pilot Radio Corp. of America that it is producing a small television set with a three-inch C.R.T. To be known as the "Candid T-V," it is tunable over the complete thirteen television bands (from 44 to $216 \mathrm{Mc} / \mathrm{s}$ ), includes a built-in aerial, weighs only 15 lb and costs $\$ 99.50$. The aluminium cabinet measures $14 \mathrm{in} \times \mathrm{I} 3 \mathrm{i} \mathrm{in} \times \mathrm{gin}$.
High.Power F.M.-A $250-\mathrm{kW}$ F.M. transmitter has been brought into regular service on $100.5 \mathrm{Mc} / \mathrm{s}$ in California. The station, which is licensed to Eitel-McCullough, Inc., the valve manufacturers, is situated on Mr. Diablo 3849 feet above sea level.
International Television.-In addition to the main lectures mentioned last month, three of the twenty-one short papers read at the International Tele-
vision Convention, held in Zurich from September 6th to Ioth, were by Jritish engineers. They were: "Television Distribution over Short Wire Lines," by P. Arlorian (Rediffusion); Comparison of British and American Television Standards," by L. H. Bedford (Marconi's); and an introduction to the discussion on large screen television by $A$. (i. D. West (Cinema Television).
Amateurs head the list of non-loroatcast stations in the U.S. compiled recently by the F.C.C. with a total of 68,449. Aeronautical services are next with over 20,000, followed by maritime services with over 14.500, It the bottom of the list comes "citizen's radio" with . 30 stations.
U.N. Broadcasts are now radiaterl from Geneva twice each weekday on 18.450 and $6.672 \mathrm{Mc} / \mathrm{s}$; The programmes, of ten-minutes' duration, are broadcast in English and then Frencln at 1 ono and 2 iow G.MI.T.
U.S.S.R. Television.- After an interval of eight years the Leningrad television station has resumed transmissions.

German Radio Exhibition.-It is anncrunced by the International Broadcasting Inion that a radio exhibition is to be held in Dusseldorf, in the British \%one of Germany this autumn. This is the first since the war.
Sound Insulation.-A second supplement has been issued by the U.S. National Bureau of Standards to the report on Sound Insulation of Wall and Floor Construction. This fifteen-page supplement contains the results of tests conducted since $194^{\circ}$ when the first supplement was issued. The original report (B.M.S.17) was prepared in 1939.

## INDUSTRIAL NEWS

Plessey-Ediswan Agreement.Arrangements have been made whereby the sole distribution of the complete range of radio components and accessories manufactured by the Plessey Co., of llford, Essex, will be undertaken

Pye Canada, Ltd., is the name of a new company formed by P'ye, of Cambriclge, to establish at production plant at Ajax, Ontario. The company plans to produce domestic radio and television receivers and other electronic equiprnent.

Holiday and Hemmerdinger are holding an exhibition of electronic equipment, components and accessories at the Granel llotel, Manchester, from October 12th-14th. Admission to the exhibition, which will be opern claily from 10 a.m. to 9 a.m., will be by ticket olstainable from the organizers in $74-78$, Mardman Streert, Deansgate. Manchester, 3.

Tannoy.-The sales, instatlation and maintenance of Tamoy equipment is being taken wer by Sound Rentals, Ltd., of Canterburv Grove, West Norwood, London, S.E.27, who for a long time have specialized in the hire and rental of Tannoy gear, It will be recalled that (iuy K. loountain, l.tel., the mamufacturers of Tannoy products, recently went into compulsory liguidation. The Board of Sound Rentals has been reorganized and Guy K . lountain is now managing director.
B.V.A.-The Board of the 13ritish Radio Valve Manufacturers' Association has re-elected G. A. Marriott (©.E.C.) as chairman and $\mathrm{l}^{\mathrm{F}}$. Jones (Marconiphone) as vice-chairmant.

Beethoven Electric, of Cliase Road, Jondon, N.V.W.io, is to open in the near future a new factory in High l'ycombe which will eventually be the 1 Head Office.

## EXPORT

Target Exceeded.--In antalysis of the export figures for the first half of the year, to which reference was made last month, shows that the radio industry exceeded its Government-set target of firexo,000 it month. The total value for the six months was $26,207,1,30$. Although fewer receivers and radiegrams were exported during the first six months of this year than during the same period last year-the value was

## INDIAN RECEIVER

 H.E. the High Commissioner for India during his visit to the E.M.I. factory, Hayes, was shown a new receiver chassis by H. W. Bowen, managing director. It appears to have onlaid wiring. A similar chassis has been designed for the Indian market.

Wy the Edison Swan Electric Co. One of the first items to be introduced is the new llessey alutomatic record changer which will handle up to eight roin and 12 in mixed dises.

E1,979,000 compared with $2,2,2+9,000-$ the demand for communications equipment ( $1,7,705,000$ ), components ( $£ 1,586,0060$ ) and valses ( $£ 1,025,000$ ) was moprectedenterl.

Australian Television. - The Australian Government has asked for tenders for the supply of two $5-\mathrm{kW}$ television transmitters for erection in Sydney and Melbourne and, alternatively, for 50 -watt stations for erection in each of the six State capital cities. Tenders close on November 25th.
Multicore.-1 25 per cent increase in tonnage of Multicore solder exported luring the first eight months of this sear, compared with 1947, is recorded by Multicore Solders, Ltel. lexport licences are no longer required for cored solders, and, as a result, supplies have been sent to forty-three countries this year.
Export Licences.-The Headguarters of the Board of Trade Export licensing Branch has moved from Stafford House to Kegis Honse, King William Street, London, E.C. 4 (Tel.: Avenue 3II).

## MEETINGS

## Institute of Electrical Engineers

Inaugural address of the president, T. (i. N. LIaldane, M.A., October 7 th. Kadio Section.-Inaugural address of the chairman, F. Smith, O.13.E., on Uctober 13th.
Discussion on " What should be the Design Considerations of Services' Kadio Equipment?" on ()etober rgth. Openers, S. J. Moss and G. C. F. Whittaker.
The above meetings will be held at $5 \cdot 30$ at the I.E.E., Savoy l'lace, London, W.C.2.
Cambridge Rudio Group.-Inangural address of the chairman, 1). H. Hughes, at 6o, on ( )ctoler 12 th, at the (ambridgeshire Technical college, Cambriclge:
North-Eastern Readio and Measurements Group.-Inaugural addresses of the chairmen, F. Smith, O.B.E. (Rarlio Section) and S. Whitehead, Ph.I)., II.A. (Measurements Section) at 6.15 on Uctober isth at King's College, New-castle-on-Tyne.
North-liestern Radio Group.-" The Velodyne", by J'rof. F. C. Williams, O.B.E., D.Sc., J.Phil., and A. M. I'ttley, 1'h. W., at 0.30 on ()ctober zoth at the Eingineers' Club, Albert Spmare, Wanchester
Southern• Centre. -" Three-1)imensiomal Cathode-Ray-Tube Displays," by E. Parker, MI.A., and l'. K. W'allis, B.Sc. (Ens.), at 6.30 on vetoler 13 th, at the K.A.E. College, Farmborough. South Midland Rudio Group.-"The Design of High-Fidelity Bisc-Recording Equipment," by H. Wavies, M.Eng, on Septentber 27 th at 6.0 at the James Watt Memorial Institute, (ireat Charless Street, Sirmingham.

## British Institute of Radio Engineers

Lomdon Section. - Ammal general meeting and address of the president, B.. H. Berlford, O.B.E., MI. A., at 6.0 on (actober 21st, at the Eondon School of Hygiene and Treprical Medicine, Kepmel Street, Iondon, W.C.I.

Scottish Section.-"Secondary Electron Emission," by L. D. Oliphant, B.Sc., at 6.30 on ()ctober 13th, at the Heriot-Watt College, Edinburgh.

## British Sound Recording Association

'The Limitations of the Londspeaker," lecture demonstration by $1^{\prime}$. J. Walker at 7.0 on October 22nd at the Royal Society of Arts, John dam street, London, W.C.s.

# Unbiased 

## By FREE GRID

## "Apologia pro Vita Sua

INN spite of "Diallist's" melliloquent remarks last month about my alleged vain imaginings concerning the meaning of the prefix " ter," I refuse absolutely to do a Galileo as I have still the odd idea, which I share with Cicero and Horace who used the word freely, that it is the best Latin for thrice. Apparently the three hundred-odd bishops who attended the recent Lambeth Conference are labouring under the same delusion, judging i,y their reference to the commemoration next January of the tercentenary of the beheading of that stalwart champion of the Church, Charles I.

But I have certainly never fallen into the error of imagining that its Greek equivalent was "tri" nor yet the adjective "treis." I have always thought it to be "tris." Only a few months ago, when I chanced to be in Cambridge, I heard some uncouth fellows in King's. College chapel " raise the trisagion,", as No. 423 in "Hymns A. \& M." quaintly puts what is more commonly known as singing the tersanctus. But, of course, you can expect anything in a town where a chemist calls himself a chynist. as does one of the pharmaceutical

fraternity whose shop is on the opposite side of the street to King's College.

Where it is a matter of euphony "tris" does sometimes lose its final letter as does the Latin "tria." I have never denied the bilingual nature of "tri," nor was I unaware that it was as much at home on the

Appian Way as in the shadow of the Parthenon. 1 am afraid that like Mr. Winston Churchill I am a bit of a terminological iconoclast. He tells us in an autobiographical sketch how he came up against pedagogic authority quite carly in his scholastic career by drawing attention to the illogicality of there being a vocative case to mensa even though it is the same as the nominative.

I can sympathize with him as I feel much the same about the illogicality of the indiscriminate and apparent do-as-you-please mixing of adverbial and adjectival prefixes (or should I say prefices?). But I have no more hope than Mr. Churchill of getting things straightened out. Why, even the Editor refuses to adopt a logical word like metrocyme, cymatometer or cymometer in place of the seemingly hybrid wavemeter. Like most totalitariocrats he does not lack a specious reason which in this case is that meter, like the word mete, is possitsly clerived from the Anglo-Saxon " metan." Maybe he is right, but where did the AngloSaxons get their word and at what date?

As for Mr. Jefferson, of Stock. holm, who also chides me with equal mellifluence which I heartily reciprocate, surely he is a little illogical. He tells us that in his opinion there is no real reason for sticking to Greek in seeking a prefix for cycles-per-second, when nearly everyone which he mentions and favours is Greek, the remainder hailing from the other side of the Aegean.

## The Marcopoff

$\mathrm{I}^{\mathrm{T}}$T is astonishing how few inventors have given their names or had them given to the things which they invented. I can think of one-the late Mrs. Bloomer of cycling fame, and for aught I know to the contrary her invention has long since been superseded by modern developments more in keeping with the Government's wishes for limiting the consumption of textiles on the home market.

When we come to the world of electricity and magnetism there are, of course, many famous names which are used, either in full or in abbreviated form, to denote units of measurement, for circuit properties and the like. Faraday and a whole
host of others occur to my mind. Even in the world of radio we find that Hartley, Franklin, Colpitts, Schmitt and Puckle among others have received recognition of their work by this means; but unless 1 am very greatly mistaken the most famous name of all in radio has not been used in this manner. I refer, of course, to Marconi, and to forestall anybody who may seek to belittle Marconi's work by pointing out that, academically speaking, he was not numbered among those who sat in the seats of the mighty, I would point out that neither was

"One of the few, the immortal names"
Nelson who was only a humble vice-admiral at the time of his death.

To some of you it may seem a little difficult to choose a unit of measurement to which Marconi's name could be attached, but surely there is one circuit property which cries aloud for it. I refer, of course, to aerial radiation resistance, at present expressed in ohms which have to rub shoulders with the more vulgar sort of ohms used by ordinary electrical engineers. To couple Marconi's name with any property of an aerial would be particularly apposite for reasons which those of you who read $W$.W. diligently will realize. It is not too much to say that it was his idea of an elevated aerial which really changed wireless from a laboratory curiosity to a practical commercial proposition. I have no desire, however, to make Mr. Bevin's task more difficult than it is and so am willing to compromise by calling the new unit a "Marcopoff" as a sop to Popov.
Even in the field of broadcasting programmes there is scope for paying honour to famous radio names and at the same time improving the standard of certain performers by using a carefully chosen yardstick to measure the degree of success or otherwise achieved in their efforts to entertain us, more particularly in the field of spontaneous humour. As a listener from the days of Writtle I would suggest the " Eck" as a suitable unit; some of the moderns might then be surprised to find themselves well down among the micro-ecks.

Providing technical information, service and advice in relation to our products and the suppression of electrical interference

${ }^{* 1}$ The sketch shows the simple method of fixing the "BellingLee' 'distribution lead suppressor L630 which sells at $1 / 6$ each.

## CAR INTERFERENCE WITH TELEVISION

Every reader of this page who drives a motor vehicle should see that a suppressor is fitted to his distributor. In nearly every case our ${ }^{11}$ [. 630 can be fitted without cutting any wires and its use does not in any way affect the performance of the engine.

An unsuppressed car or farm tractor can cause untold harm to air navigation in and around airfields. Within a range of $75-90$ miles of London, particularly between 25 and 90 miles, the greatest hindrance to the full development of television is interference from passing motor vehicles. If you read the "Wireless World," even if you do not yet possess a television receiver, have a thought for others. I.et it be your good deed for the day. It will cost you $1 / 6$ from your radio dealer or garage. You might even help by starting a small campaign amongst your motoring friends.

## WHAT KIND OF TELEVISION FEEDER?

Still one of the most common queries that come our way is "What do we recommend in the way of feeder for television aerials?" This question comes to us from public and dealers alike. Television receiver designers still fall into three schools of .thought. (I) *2Coaxial feeder which needs complicated
matching and balarcing at the dipole end for best results and minimum interference. (2) *3 En screened twin which is the cheapest, but needs a carefully batanced input circuit in the receiver for optimum results and does not provide a screened input to stabilise a super sensitive receiver, and (3) *'Screened twin which gives the advantage of both, but is a triffe dearer than coaxial.

If the receiver manufacturer makes a strong recommendation for his set, it should be adhered to, but otherwise in most localities, the cheapest, i.e., the twin unscreened feeder of 75 to 85 ohms impedance, will give no apparent loss even when connected to a coaxial input. We have been saying this since the inception of television, and we believe that more new designs with be provided to make use of the more effective balanced feeder. Television costs enough alrealy, why make it cost more? Our own installation department carry ont the wishes of any particular manufacturer, but if left to their own devices would almost invariably use balanced feeder to obtain opt imum results.

We would like to remind readers that the reflector of a " BellingLee" television aerial, installed now, can be used immerliately for greatly improved broadcast reception by attaching an insulated lead to the screw on the cross arm. If *5." Eliminoise " equipment is added, this provides an anti-interference aerial system. Both methods can also be applied to the metal mast of the inverted " $V$ " aerial and are covered by U.K. Patents 519883, 520628 .

## LIGHTNING

By the time this is published the thunder and lightning season will be over, but we feel it worth while to let readers know of a really extraordinary case which was brought to our notice by a Wickford (Essex) dealer who wrote, " One of my television customers in this district has had a rather alarming experience during a recent heavy thunderstorm. A flash of lightning went to ground in the garden within six yards of the chimney supporting one of your television aerials. It completely burnt all the leaves oft a small tree, knocked out the housewife who was at the sink indoors,
hut did not affect the aerial or the set which was in operation at the time. This confirms that the addition of a television aerial incurs no extra risk. I should imagine the Cathode ray tube took a nasty flash but it appears to be none the worse for it."

Belling-Lee ":*6 Skyrod antiinterference aerials and *7 Viewrod Television aerials have always carried a one hundred pounds insurance against lightning damage. This becomes operative only in the absence of any collateral insurance, such as the usual Householders Comprehensive schemes. We do not know of any insurance companies who call for increased premium for the erection of an aerial, or which place any restriction in this matter, and if there is a risk, they lose. Insurance companies are grand business people and they know their job, so why worry?

## For better listening use Belling-Lee Aerials

*2 75 ohm Coaxial feeder L600 for T.V. aerials, per yard, $\mathbf{1 / 6}$.
*3 80 ohm unscreened balanced twin feeder, L336, per yard, $7 \frac{1}{2} d$.
*4 70 ohm screened balanced twin feeder, L1221, per yard, 1/9.
${ }^{*} 5$ The equipment required is : L308 pair of " ELIMINOISE" transformers and receiver connecting lead, £4 10s. L622 adaptor kit, 1/6.

Required length of feeder $\mathbf{L 1 2 2 1}$ and earth lead. (L622 is not required with the inverted "V." aerial).
*6 "SKYROD " vertical chimney fixing 18 ft . spike with "ELIMINOISE" transformers, screened feeder and earth wire, etc., L638/K, £10.
*7 "VIEWROD ", television aerial for London frequencies $\mathbf{L} 502 / \mathrm{L}$, for Birmingham frequencies L634, each £6 6s.
Both types include dipole reflector and chimney lashings (less mast) Required length of feeder, extra.

The words "Skyrod" " Eliminoise" and " Viewrod" are Regd. trade marks.

# STABILIZED POWER SUPPLIES 

## 1.-Practical Design Procedure for Series-Valve Types

ALTHOUGII voltage stabilized power units have been fairly widely emploved for some years, it seens that there are still many who do not fully realize how useful they are, or who have insufficient information about their work-
ing and design. As regards the first point, anyone who has once become accustomed to using a stabilized power unit will probably confirm that it is practically indispensable. As to the second, this article may be a partial answer.

At one time the need for sources of steady D.C. was met by secondary batteries, in spite of their high cost and maintenance troubles, because the alternativethe rectified A.C. power unithad a comparatively high internal impedance and consequently bad "regulation." That is to say, the output voltage varied considerably with the current drawn. An additional cause of substantial voltage variations came when power stations, in order to avoid the more drastic operation of load-shedding, began to practise frequency and voltage reduction. In the meantime, requirements for low ripple and noise content have become increasingly stringent. The development of stabilization technique, however, has now reached a state at which it is possible to dispense with batteries for even the most exacting requirements ${ }^{1}$.

Of the several distinct methods that have been adopted, the most popular and generally uscful, and the only one to be considered here, is that shown in principle in Fig. $\mathrm{I}^{2}$.

The whole load current passes through VI, which is made to

[^5]absorb any voltage variations, whether slow or rapid, so that the output is constant and steady. Vi may also, if required, be made to serve the additional purpose of reducing the voltage of the source to any desired level within certain limits of arljustment.

The remainder of the circuit is designed to control the voltage drop in Vi in order to fulfil the purposes just mentioned. This it does by comparing a known fraction $\left(\frac{R_{2}}{R_{1}+R_{2}}\right)$ of the output voltage $\left(\mathrm{V}_{0}\right)$ with a fixed reference voltage, usually (but not always) provided by the drop across a neon tube, N. The difference in voltage is amplified by V2 and applied as grid bias to Vi in the correct polarity to oppose any change in $V_{0}$.

The device is closely analogous to the governor of an engine, and is an example of D.C. negative feedback-a sort of amplified cathode follower. Obviously one of the prime objects in design is to make the voltage amplification so large that the change in $V_{0}$ necessary to neutralize (via V2) any fluctuations in source voltage is negligibly small. At zero frequency the feedback is reduced by the potential divider $\mathrm{R}_{1} \mathrm{R}_{2}$, but this reduction can be avoided at hum frequencies by shortcircuiting $\mathrm{R}_{1}$, with a capacitor.

If the gain, reckoned from the junction of $R_{1}$ and $R_{2}$, is made so large that any variations in voltage across $R_{2}$ necded for feedback are less than, say, I per cent., and the reference standard is also very constant and accurately known, the current through $R_{2}$ is correspondingly constant and $\mathrm{V}_{0}$ is directly proportional (within the working limits of the valves) to $R_{1}+R_{2}$. $R_{1}$ can therefore be calibrated in volts to an accuracy equal to or better than that of a B.S. ist

Grade voltmeter. A notable example is the Tinsley Precision D.C. Stabilizer, in which the reference voltage is a standard cell and the amplifier a reflecting galvanometer and photo-cell. Any voltage from 20 to 600 can be selected, to an accuracy of 1 in 10,000,

However great the gain, some change in output voltage is necessary to effect the stabilization; but such change can be reduced to zero, or even reversed, by compensation for changes in input voltage and output current. By the use of such devices it is possible to make the power unit approximate very closely, over a wide range of working conditions, to a generat( $r$ of constant zerofrequency voltage with zero internal impedance.

Fig. I. Basic circuit of series-valve stabilizer, in which the output voltage $V_{0}$ is adjusted by varying $R_{1}$. N is the voltage reference standard, and $V_{2}$ the negative feedback amplifier.

The practical design of stabilized power supplies on these lines was discussed in an excellent article by F. L. Hogg ${ }^{3}$. The present writer acknowledges that what follows is largely an extension of Mr. Hogg's work.

[^6]
## Stabilized Power Supplies-

Considering now the design of stabilized power units in detail, there is first the question of requirements. The design problem is very much eased if only a fixed output voltage is needed, or one variable within narrow limits; and similarly if the current load is more or less constant, as it often is in built-in power sources. One has then only to provide against minor variations in load, and variations in A.C. supply. The latter can, if necessary, be brought within narrower limits by one of the special transformers sold for the purpose. The residual fluctuations can then be dealt with by valves and other components working on fixed adjustments very close to optimum conditions, and a very high degree of stabilization obtained without much trouble.

It will therefore be more instructive to $\overline{\text { tackle }}$ the relatively difficult case of a unit for general laboratory use, in which the output voltage is required to be variable within wide limits, and the load may be anything from zero to a stated maximum. The procedure for most other specifications should then be more or less obvious.

The design will of course be influenced by whether the most important thing is to stabilize against input voltage fluctuations, or load current fluctuations, or to reduce hum and noise to a very low level, or a combination of these. They correspond respectively, in the theoretical equivalent generator, to constancy of generator voltage, smallness of generator impedance, and absence of any generator frequency appreciably above zero. The length of time over which a specified performance in these respects must be maintained is also a factor to be considered. If an accurate output voltage calibration is wanted, that is yet another.

Let us assume as an objective the best all-round performance obtainable with a reasonably simple system capable of coping with wide voltage and current ranges. Its achievement can best be illustrated by an example. Suppose the maximum output is to be 100 mA at 400 V , with the mains voltage liable to vary
+4 per cent and -8 per cent from normal. The easiest and most instructive procedure is to make a voltage/load-current diagram (Fig. 2). Neglecting current through $V_{I}$ other than the load current $I_{0}$, point $A$ represents maximum output, and the horizontal line through it is the working line at 400 V for all load currents down to zero, assumıing perfect stabilization.

Now consider the drop in the series valve Vi. It can be allowed to reach its minimum under the condition of maximum output and mains 8 per cent low, and that minimum should of course be as

in any particular case, but in general economy calls for a low $r_{a}$.

As a start, take a triodeconnected Mullard EL37, which is typical of a number of similar valves. Fig. 3 shows the $\mathrm{I}_{k} / \mathrm{V}_{a}$ characteristics. From these, at $\mathrm{I}_{k}=100$ and $\mathrm{V}_{\mathrm{g}_{1}}=-\mathrm{I} \frac{1}{2}, \mathrm{~V}_{a}$ is seen to be 140 V . This must be added to $V_{0 \text { max }}$ in Fig 2 to give point $B$, the unstabilized voltage of the source, $V_{i}$. From the data relating to a suitable power supply, the regulation curve BC call then be drawn in. Normally it droops slightly between B and $C$, but a straight line is generally near enough. This line is the lowest allowable, so it relates to 92 per cent of normal mains voltage. Assuming $V$; at zero current to be proportional to mains input, points I) and E can be marked in at ioo per cent and $\mathrm{IO}_{4}$ per cent. Lines through them, parallel to CB , represent approximately the regulation curves for normal and maximum mains.

Fig. 2. Voltage/ current design diagram for a seriesvalve stabilizer.
imposed by the start of grid current ; to be on the safe side, the minimum bias may be assumed to be $-1 \frac{1}{2} \mathrm{~V}$. The shape of a tetrode (or pentode) characteristic gives it a low $V_{a}$ for a given high $I_{n}$, but there is a constant screen voltage to provide. For simplicity let us assume a triode, in which the clue to a low voltage drop is low $r_{a}$. At the same time we want $\mu$ to be as high as possible in order to maximize the stabilization. There is thus no doubt that ligh $g_{m}$ is needed. The best allocation of $v_{a}$ and $\mu$ for a given $g_{m}$ will be seen more clearly later
complete curve showing the minimum drop in I'i at any load current. It is got by (so to speak) hanging the $V_{y_{1}}=-1 \frac{1}{2} V$ curve of Fig. 3 from the line CB. One could, in fact, transfer the whole family of curves from Fig. 3 to Fig. 2 ; but it would be rather confusing to do so for each different mains voltage.

The most important limit is the maximum anode (actually $a+g_{2}$ ) dissipation, in this case $28 \mathrm{WV}^{2}$. It should be hung from the maximum mains line, EF, as shown. (The vertical distance hetween it and EF at any point is

Fig. 3. Characteristic curves for triode-connected EL37 valve for VI duty.
reckoned, of course, by dividing 28 by the current in amperes at that point). The maximum rated $V_{a}$, triode connected, is 400 V , and should be drawn at that distance below IE 1 . The maximum current rating, 200 mA , is not in the picture at all.

We can now see that kecping strictly within these limits we could get any current up to II5 mA at 370 V ; that at any current up to 100 mA the $\mathrm{V}_{0}$ could be varied from 350 to 400 ; that at a fixed output of 70 mA , stabilization against mains voltages from -8 per cent to +4 per cent is possible over a range of $\mathrm{V}_{0}$ from 260 to 450 ; while if $I_{0 \text { max }}$ were restricted to 40 mA , and the $\mathrm{V}_{a}+{ }_{g^{2}}$ limit were ignored, $\mathrm{V}_{0}$ could be varied from o to 500 V .

Study of this diagram should make it a simple matter to decide on a suitable power source and $\mathrm{V}_{1}$ to meet stated requirements. To obtain more than a very small range of $V_{0}$ at a 100 mA rating, it is clear that a higher anode dissipation and/or lower $r_{a}$ is needed. One solution is to use two or more valves in parallel. This is quite feasible, but it is necessary to make sure the valves are well matched, and wise to design a little more conservatively to allow for inequality. To avoid failure of all valves if one of them gres,
individual fuses, or better still a differential relay, may be worth while.

Using a pair of EL37's in parallel, making $2 I_{k \text { mix }}=1$ Io mA to allow for the drain in $R_{1} R_{2}$, etc., ( I , being the cathode current per valve), and reducing the $p_{a}+y_{2}^{2}$ rating per valve to 26 W , $p_{a}+{ }_{y^{2}}$ rating get Fig. 4. The dissipation boundary has almost disappeared; but if one still strictly observes the $V_{a}+g_{2 \text { max }}$ rating at +4 per cent mains and $2 I_{k \text { min }}$ (say romA) the range of $V_{0}$ adjustment cannot be extended below $290 V_{\text {min. }}$ To obtain a wider range, one can assume the valves will not

Fig. 4. Design diagram for a 200-400 $V$ unit using two EL37's in parallel for VI.
mind the possibility of occasional breaches of this limit at low cur-
rents, or else use valves with a higher rating, such as Osram PX25 triode $(500 \mathrm{~V})$ or Mazda 12 EI tetrode ( 700 V ) ; or cover the full range of $V_{0}$ in steps, reducing the source voltage and $R_{1}$ simultaneously with a switch.

Hefore going into this more closely, we should consider $\mathrm{V}_{2}$ and its appurtenances. It is clear from Fig. 1 that $V_{0}$ has to be not less than the reference voltage $\left(V_{\mathrm{s}}\right)$. plus the anode voltage for $V^{\prime} 2\left(V_{2 \pi} *\right)$, plus the bias for $\mathrm{V}_{1}$ ( $V_{1 g 1}$ ). There is therefore a practical minimum $V_{0}$ with this circuit. $V_{N}$ is determined by the characteristics of available tubes, and in any case there are disadvantages in its being a very small fraction of $V_{0 \text { max }}$ - the overall feedback is reduced in the ratio $\frac{R_{n}}{R_{1}+R_{2}}$, and the "error" ( $V_{N}-V_{R 2}$ ) is relatively serious. The table on the following page gives data for some suitable tubes.
$\mathrm{V}_{2 \pi}$ cannot be reduced too far or the gain will fall off, gradually with a triode and suddenly with a pentode. As for $\mathrm{V}_{1 g 1}$, when $\mathrm{V}_{0}$ and $I_{0}$ are least it must be at its greatest. Supposing the lowest $\mathrm{V}_{0}$ to be provided is 200 V , and

[^7]

## Stabilized Power Supplies-

$2 \mathrm{I}_{k \mathrm{ml}}$ is 5 mA , this condition is represented by point $G$ in Fig. 4, which is practically 500 V below $V_{i}$ with mains 4 per cent high. From Fig. 3 the bias required is -65 V . That leaves 135 V for $N$ and V2, which is sufficient for a tube running up to about 100 V , in series with a pentode. With a $\mathrm{G}_{50 / 1 \mathrm{G}}$ tube $\mathrm{V}_{0}$.uisa can be reduced to about 125 V .

The advantage of a high $\mu$ in $I_{1}$ when a wide range of $V_{0}$ is wanted is now clear.

Voltage gain (call it $m$ ) is the chief criterion for V2, and the most generally useful characteristic is a graph of $g_{m}$ against $\mathrm{I}_{n}$, as in Fig. 5. Multiplying both scales by $\mathrm{K}_{3}$ converts it into a graph of approximate stage gain against output voltage $\dagger$. Now the required range of output voltage is known ; it is from $1 \frac{1}{2}$ to 65 V in our example. Whatever value of $\mathrm{R}_{3}$ is chosen, Fig. 5 shows that if it is fed from the cathode of $\mathrm{VI}_{\mathrm{I}}$ as in Fig. I the gain will vary
enormously. U'sing an $\mathrm{EF}_{42}$ with o. $3 \mathrm{M} \Omega$, it ranges from about 6 at $V_{1 g 1}=-I_{2}$ to 230 at $V_{1 g 1}=-$ 65.

It is clear that $m$ can be made
stabilizing tube, Nz, as in Fig. 6. Its running voltage must be substantially less than the minimum drop across $\mathrm{V}_{\mathrm{I}}\left(\mathrm{V}_{1 a}\right)$ in order that the ratio of maximum to

much more nearly constant and at the same time its average level increased by feeding $\mathrm{R}_{3}$ from a more positive point. It could be fed from the anode of Vi; but unfortunately the potential of that point shifts in such a way that the output required from V 2 when $V_{i}$ varies is multiplied by $\mu_{1}+1$. Looked at another way, it is equivalent to multiply-

Fig. 5. Slope/anode-current or gain/output curves for three types of valve for $V_{2}$ duty. $V_{\mathbb{N}_{2}}$ is the zero $V_{1 g 1}$ point using a $G .120 / 1 B$ for $\mathrm{N}_{2}$.
$\dagger$ In Fig. 5 the gains shown were actually measured data, using 0.3 3 $M \Omega$ anole coupling, $\mathrm{K}_{3}$ and the $\mathrm{g}_{\mathrm{m}}$ scale was derived from it on th:

ing $R_{i}$ by $\mu_{1}+1$ (see Appendix in subsequent instalment, Eqn. I 1 b$)$.

The solution is to use another
minimum drop across $R_{5}$ does not exceed the working current ratio for the tube, and at the same time to ensure that the current is always less than that taken by $R_{1}$ and any other permanent drains.

In our example, the limits of $V_{1 a}$ are 105 V (A to B in Fig. 4) and 495 V ( G to H ). Using a $\mathrm{G} .120 / \mathrm{IB}$ for $\mathrm{N}_{2}$, the range across $1 R_{5}$ is thus 50 V to 440 V , and the corresponding current in $\mathbf{R}_{3}$ (if $0.3 \mathrm{M} \Omega)$ is 0.19 mA and 0.40 mA . Limiting the current through $\mathrm{N}_{2}$ to 4 mA say, the total maximum through $\mathrm{R}_{5}$ at 440 V is 4.4 mA , so $\mathrm{R}_{5}$ should be 1oo $\mathrm{k} \Omega, 2 \mathrm{~W}$. The minimum current through $\mathrm{N}_{2}$ is then $\frac{50}{100}-0.19=0.3 \mathrm{ImA}$. This is below the working range for $\mathrm{N}_{2}$, but since appreciable fluctuation of voltage across it can be tolerated that does not matter. If anything, $\mathrm{R}_{5}$ might be increased, because the current through N2 tends to impair stabilization at low $I_{0}$, for it is not controlled by the feedback. It is a function of $V_{1 a}$ and could be allowed for by a modification of Fig. 4, but normally it should not be large enough to be worth this extra complication.

The voltage across $\mathrm{R}_{2}$ is equal to that across $\mathrm{N}_{1}$ less $\mathrm{V}_{2 g 1}$. $\mathrm{VN}_{1}$ is (we hope) constant, and $V_{2 g}$, ought not to vary much if the unit is doing its job. Its mean value may be difficult to find, since valve makers rarely show the working region-below 0.5 mA -very clearly; so unless one plots this part oneself it may be a case of making as good an estimate as possible. With $V_{2 g \underline{2}}$ about $80-100 \mathrm{~V}, \mathrm{~V}_{2 g 1}$ averages -1.5 V for the $\mathrm{EF}_{42}$ and -- 3 V
for the EF36 or EF 37 . Using ant 85 AI and $\mathrm{EF}_{42}$ therefore makes $\mathrm{VR}_{2} 84 \mathrm{~V}$. The value of $\mathrm{R}_{2}$ can then be chosen to pass a suitable current, say 5 mA . The exact value is more conveniently related to $R_{1}$, however, because part of it $\left(R_{1 b}\right)$ is the voltage control and may have to be a value that is available. Stability of $R_{1} R_{2}$ is most essential, and good wirewound components must he used throughout. The range of voltage control in our example is 200 V , so if a $50 \mathrm{k} \Omega$ rheostat is used the current is 4 mA . $\mathrm{R}_{2}$ must then be
$\frac{8_{4}}{4}=21 \mathrm{k} \Omega$, and $\mathrm{R}_{1 a}$ (which must
drop $200-8_{4}=I I 6 \mathrm{~V}$ ) is $29 \mathrm{k} \Omega$. Maximum total roo $\mathrm{k} \Omega$; at 4 mA , 400 V , which is the designed maximum, so correct.

With $2 \mathrm{I}_{1 k}$ as low as $+\mathrm{mA}, \mathrm{R}_{5}$ ought definitely to be raised, say to $I_{50} \mathrm{k} \Omega$, to ensure that $I_{N 2}$ is always less.

The extreme range of $\mathrm{V}_{2 g 1}$ can be deduced from Fig. 5. The mean gain in our example, using $\mathrm{EFF}_{4} 2$, is about 280 ; so a range of 63.5 V output necessitates about 0.23 V at the grid, which is $\pm 0.13^{6}$ per cent of the $x_{t} V^{\prime}$ across $R_{2}$ and therefore the same percentage of $V_{0}$. This can be analyzed with the aicl of Figs. 4 and 3 into the variations due to mains fluctuations and to load current. For example, at 300 V output with normal mains, change of load from zero to 100 mA (neglecting $\mathrm{I}_{\mathrm{R} 1}-\mathrm{I}_{\mathrm{N} 2}$ ) necessitates a change in $V_{1 g 1}$ from $-4^{8} \mathrm{~V}$ to - Ig V, represented by $P$ to $Q$ in Fig. 5. Dividing the voltage change, 29, by the mean gain, 290, gives o.i $V$ as the chan re in 84 V . and so 0.36 V in 300 , corresponding to a mean internal resistance of $0.36 / 0 . \mathrm{I}=3.6 \Omega$. The value varies considerably over the range of $I_{0}$, owing to variation in $I_{1 a}$. being higher when $I_{0}$ is small and vice versa.

Similarly the $V_{0}$ variation corresponding to $\therefore 4$ per cent mains variation from normal at 300 V 100 mA output can be shown to be $\therefore$ o.or 43 per cent, or a stabilization ratio of $280:$ I

Formulæ for these parameters will be derived in the Appendix.

In the above calculations it is assumed that $\mathrm{I}_{2 \pi}$ is not appreciably affected by variations in the potential of any electrode other
than $g_{1}$. The gain $m$ is reckoned on this basis. IReasonable constancy of anode feed voltage has been ensured by $\mathbf{N} 2$. But what about the cathode and $g_{2}$ ? It seems to be generally assumed by writers on the subject that Ni keeps the cathode steady against any variations in the voltage of the source feeding it. That is by no means true. The A.C. resistance of $\mathrm{Ni}^{2}$ at its optimum current is usually of the order of $300 \Omega$, and it is possible for the voltage drop to vary sufficiently to upset completely the performance calculated as abore. Even though the feed resistance 12 , may be, say,

Fig. 6. Modified feeds for $V_{2}$ to ensure higher and more uniform gain.

500 times as great, so that source variations are reduced in the ratio $501: \mathrm{I}$, it must be remembered that they are then multiplied by the total feedback gain, $\mu_{1} m$, which may be of the order of 2500 .

So to preserve the stabilization it is desirable (and to use Ni as a voltage standard it is essential) to feed Ni from a stabilized source. If $V_{n}$ is fixed, it is the obvious source. Keeping the current constant in this way, the best use can be made of a good tube. The makers of the 85 AI claim that its short-term stability is within $\perp$ o.i per cent, and longterm stability $\pm 0.2$ per cent, so that it can be used as an accurate voltage standard. For this purpose it is desirable to use a circuit in which $V_{N}$ is applied
to the grid of a valve, to avoid current changes in $\mathrm{Ni}_{\mathrm{I}}$ via the valve; but for power supply purposes such changes are generally negligible.

If $I_{N_{I}}$ is kept constant in this way, $g_{2}$ can be tapped off the feed resistance, $\mathrm{R}_{4}$, at about $100 \mathrm{~V} . \mathrm{IR}_{4}$ itself is chosen to pass about +mi , compared with which $I_{2,1}$ and $I_{2 g 2}$ are small.
The same arrangement will do if $\mathrm{V}_{0}$ is variable over a moderate range, but it may then be desirable to substitute a regulator tube for $R_{4 b}$, the part of $R_{4}$ between $g_{2}$ and $h$.

For a wide range of $V_{0}$ control it would be necessary to gang $\mathrm{R}_{4,1}$ with $\mathrm{I}_{1 b}$. which would be rather a nuisance. It is therefore usual in a unit such as we are considering to feed Ni from the anode side of Vi. Here the range of voltage variation is relatively small, but, unlike the variations of $\mathrm{V}_{0}$, which occur only while it is being adjusted, they are "stabilization" variations, in opposition to those provided by V2, It will be shown in the Appendix (Eqn. roa) that the effect is as if the source resistance, $\mathrm{R}_{i}$, were increased by a factor equal to the total gain round the loop $\mathrm{R}_{4} \mathrm{~N}_{1} \mathrm{~V}_{2} \mathrm{~V} \mathrm{r}$, that is to say $\mu_{1} m v_{\mathrm{N}_{1} /} / \mathrm{R}_{4}$, which may mean a several-fold increase in apparent $\mathrm{R}_{i}$, and a corresponding loss in stabilization.

A very convenient way out of this trouble is to adjust the resistance across which $V_{g g 2}$ is obtained ( $\mathrm{R}_{1 b}$ ) so that its variations neutralize those in $V_{N 1}$. Neglecting the $I_{2_{2} 2}$ variations, the correct value of $\mathcal{R}_{1 b}$ is thus $\mu_{2 g \frac{2}{2}} r_{\mathrm{N} 1}$, where $\mu_{292}$ is the amplification factor between $g_{1}$ and $g_{2}$ in $V 2$. In the $\mathrm{EF}_{4} 2$ it is $85 ;$ but since $\mathrm{I}_{292}$ variations add to those in Ni the result is as if it were somewhat lower, in a measured example about 65 . The value of $R_{4 b}$ to fulfil this requirement is not necessarily suitable as regards the standing $V_{2 g 2}$ : but in our case it is, for with $r_{N}$, at $300 \Omega$, effective $\mu_{2 g 2}$ say 65 , and $I \mathrm{R}_{4 b}$ at 4 mA , we have $7_{8}^{8 \mathrm{~V}}$, which is quite a satisfactory screen voltage.

Having neutralized the apparent extra $R_{i}$ in this way, one may well ask why the real $\mathrm{R}_{i}$ slould not be neutralized too. As the Appendix will show (Eqn. (a), this operation is equivatent to neutralizing an

## Stabilized Power Supplies-

added resistance in Ni equal to $\mathrm{R}_{4} / \mu_{1} m$. In our example, the mean $V_{i}$ is about $600 \mathrm{~V}^{\prime}$ (Fig. 4) ; less $V_{N 1}$ this is $5^{I} 5 \mathrm{~V}$, so, to pass $4 \mathrm{~mA}, \mathrm{R}_{4}$ should be about i $30 \mathrm{k} \Omega$. Taking $\mu_{1} m$ as 2000 , the extra $R_{4 b}$ required is $4.2 \mathrm{k} \Omega$.

When $\mathrm{R}_{4 b}$ is correctly adjusted, then, the unit behaves as if $\mathrm{R}_{i}$ were zero; and, what is more, stabilization as regards variations in mains voltage is theoretically perfect. It is accomplished solely via the sereen grid of V2, output feedback via the control grid being unnecessary, and variations in $\mathrm{V}_{0}$ nil. In practice it does not work out quite like that, because certain of the factors, notably $m$, are not constant. The slightest
departure from exact adjustment of $\mathrm{R}_{4 b}$ would, if there were no output feedback, make the stabilization fall right off. The designer should therefore aim at the greatest possible basic stabilization by output feedback, which does not depend on critical adjustments ; and then any unavoidable variations in the further improvement conferred by input feedback will be of minor importance.

For this reason it is not altogether recommended that input feedback be used to neutralize the large apparent increase in source resistance that would be produced if $\mathrm{R}_{3}$ were fed from the input side of $V^{\prime}$, although it could do so, and would save $\mathrm{N}_{2}$
and $\mathrm{R}_{5}$ and the uncontrolled current around Vi.

By increasing $\mathrm{R}_{4 b}$ beyond that necessary to neutralize $\mathrm{R}_{i}$, it can be made to neutralize $r_{1 a}$ also, with the result that $R_{0}$ (the resistance of the unit as a whole) is zero, and the output voltage is -subject to variations in $n l$ and $r_{1 n}$-entirely unaffected by changes in load current. At this setting of $\mathrm{R}_{4 b}$ the unit is somewhat overcompensated for mains fluctuations. In practice one would adjust $R_{4 b}$ to give a compromise depending on the relative importance of mains voltage and load current changes. It is practicable in this way to improve on the basic stabilization in both respects.
(To be continued)

# SH0RT-WAVE CONDITIONS 

August in Retrospect : Forecast for October

By T. W. BENNINGTON and L. J. PRECHNER (Engineering Division, B.B.C.)

DURING August, while the average daytime maximum usable frequencies for these latitudes were much higher than in July, the night-time MUFs were considerably lower than during that month. This was in accordance with the normal seasonal trend, and it may be expected that the NUFs will now continue to vary in that manner towards the winter. One should note, however, that the conditions were very disturbed in the first two weeks of August.
Although communication on frequencies higher than $35 \mathrm{Mc} / \mathrm{s}$ was rather infrequent, yet, owing to the rapid increase in the average maximum usable frequencies, many contacts have been made. Frequencies below $14 \mathrm{Mc} / \mathrm{s}$ for distances exceeding 3,000 miles were not often usable at night.
The rate of incidence of Sporadic $E$ was still very high, in accordance with the seasonal trend.
Sunspot activity in August was somewhat greater than in July, and may have had some connection with the exceptionally disturbed conditions in early August. Ionospheric storms were observed on 1 ist-3rd, $4^{\text {th- }} 5$ th, 7 th-1 $3^{\text {th }}$, 2oth21 st and 29 th-3ist.
Not very many "Dellinger" fadeouts have been recorded in August, but those on 6th and 9 th were fairly severe.
Forecast.-- Although the daytime Ml'es should continue to increase
in October and reach very high values, these should be below the $19+7$ values, having regard to the fact that sunspot activity has decreased since last year. Long-distance communication on very high frequencies should therefore be frequently possible in all directions from this country. The $28-\mathrm{Mc} / \mathrm{s}$ amateur hand, for example, should be regularly usable at the suitable time of the day, and frequencies considerably higher than this should also become workable over certain circuits. Night-time working frequencies will probably decrease somewhat as compared with September. Frequencies as low as $9 \mathrm{Mc} / \mathrm{s}$ will become the optimum for many night-time circuits, though frequencies lower than this will not be often necessary.

As the $E$ and $F$, layers will not control transmission for any distance in these latitudes, and as Sporadic E is not likely to be much in evidence, medium distance communication on high frequencies will seldom be possible.

Below are given, in terms of the broadcast bands, the working trequencies which should be regularly usable during October for four longdistance circuits running in different directions from this country. All times in this article are GMT. In addition, a figure in brackets is given for the use of those whose primary interest is the exploitation of certain frequency bands, and this
indicates the highest frequency likely to be usable for about 25 per cent of the time:-

October is often a fairly storn:y month, and some periods of poor communication are therefore to be expected, At the time of writing it would appear that such disturbances are more likely to occur within the periods ist-5th, $14^{\text {th }}$-16th, 2oth-22nd and 28th-3ist than on the other days of the month,

# FOUR-WAY ELECTRONIC MIXER 

This unit with 4 built-in, balanced and screened microphone transformers, normally of $15-30$ ohms impedance. Has 5 valves and selenium rectifier supplied by its own built-in screened power pack: consumption 20 watts.
Suitable for recording and dubbing, or large P.A. Installations since it will drive up to $6-50$ watt amplifiers, whose base dimensions it matches normally for output line of 20,000 or less load since ample feedback is used.

Price in case with valves, etc., $£ 2400$

## 30-WATT RECORD REPRODUCER

This amplifier has been produced for extremely high quality gramophone or microphone quality in large halls or in the open. An output power of 30 watts is obtainable at under $1 \%$ distortion after the output transformer which is arranged for $4,7 \frac{1}{2}$ or is ohm output. The most noticeable point is the absence of background noise or hum. Very generous feedback is employed to help cancel out any distortion developed by the speaker and the large damping factor ensures good transient response. The usual response of 30 to 25,000 cycles plus or minus $\frac{1}{2} \mathrm{db}$ is given, and recording compensation of 5 db per ortave lift below 300 cycles is obtainable on the gramophone input by means of a switch. A carefully balanced treble control is arranged to correct top lift on some recordings as well as to reduce scratch on old records without noticeable effect on frequencies below 3,500 to 4,000 cycles. The input is intended for the high fidelity type of pick-up and is fully loaded by an input of .2 volts on 100,000 ohms or $\frac{1}{4}$ megohm as required. The microphone stage if
 fitted requires an input of .3 millivolts on 15 ohm through the wide response mu-metal shielded microphone transformer. An octal socket is fitted at the rear of the chassis to provide power for feeder units, etc., 6.3 volts at 2 amps and 350 volts at 30 milliamps is available.

As illustrated. Price $30 \frac{1}{2}$ gns.
10 WATT RECORD REPRODUCER WITH MICROPHONE STAGE, IN CASE PRICE $25 \frac{1}{2}$ Gns. SUPER FIFTY-WATT AMPLIFIER PRICE $36 \frac{1}{2}$ Gns.
CP20A FOR A.C. MAINS and 12 VOLT BATTERY PRICE 228

## PमाIIPS

## THE " VOXMOBILE" AMPLIFIER

Type 2856R
Mobile - Indoor - Outdoor
Operates from A.C. Mains or 12 -volt battery Output:-12-watts. Self-contained
The Voxmobile is a really versatile amplifier. While it produces excellent quality, it is light, quickly connected, and operated equally as well either from A.C. mains 250 volts or a 12 -volt car battery.
One of the outstanding features of this amplifier is the high sensitivity; only 3.5 mV being required into I megohm to produce the full output, thus allowing wide pick-up and the use of high quality microphones.

List Price: $£ 38$. 0.0

Excellent reproduction and wide angle distribution. Weatherproof - light - robust.
For use Outdoors, Indoors, or on a Vehicle.
No back radiation and therefore minimum feed-back. The ideal "general-purpose" quality P.A. Speaker. Complete with line transformer tapped at either I, 3 or 6 watts.

List Price: $£ 8.0 .0$
Complete Voxmobile "All-Purpose" Equipment
The ideal general-purpose equipment for Dealers and for Religious, Political, Social and Sporting Organisations. Comprises:-Amplifier, high fidelity moving-coil microphone, substantial stage-type microphone stand and two type $9816 T$ speakers.
List Price: 870 . 0. O. Available to all bona fide Traders

## ELECTRONIC CIRCUITRY

THE time delay flip-lop is a circuit possessing one stable and one unstable state. Normally in the stable state, on the receipt of a short pulse it can be forced into the unstable

## Time Delay Flip-flop Circuits

 state where it remains for a period, $t_{0}$, determined by its own time constant. The leading edge of the resultant rectangular waveform is obviously coincident with the triggering impulse, and a second pulse can be obtained from the trailing edge (by a differentiator circuit for example) after a time $t_{0}$, as shown in Fig. I. Alternatively the rectangular
# Selections from a Designer's Notebook 

J. McG. SOWERBY<br>(Cinema Television Ltd.)

On the receipt of a positive pulse $\mathrm{V}_{1}$ conducts and its anode moves negatively and cuts off $V_{2}$ via $R_{2} C_{2}$. Provided the triggering pulse is very short, $V_{1}$ is then left conducting with a current determined by $\mathrm{R}_{\mathrm{c}}$ operating as a normal cathode bias resistor. The resultant voltage drop across $R_{L}$ is applied to $R_{2} C_{2}$ and keeps $V_{2}$ cut off until most

Fig. I. Waveforms in the flipflop circuit.
waveform itself can be used as a pulse of known duration, or for any other purpose. The time $t_{0}$ may be given any value between about 2 microseconds and 30 seconds without using extreme values of resistance or capacitance, so that this type of circuit can be put to a wide variety of uses.

Several time delay flip-flop circuits are described by $O$. S . Puckle in his book " Time Bases," and many readers will be familiar with the circuit of Fig. 2. Quite often the input time constant $\mathrm{R}_{1} \mathrm{C}_{1}$ is made short (a differentiator) to obtain the triggering pulses of Fig. I from a rectangular waveform. Initially in the stable state $V_{2}$ is conducting, since it is at zero bias, and $R_{c}$ is large enough to permit $V_{I}$ to be cut off.
of the charge on $C_{2}$ has leaked away through $R_{2}$ and $R_{L}$ in series. At some point on this discharge cycle $\mathrm{V}_{2}$ begins to conduct again
and to reduce the current in $\mathrm{V}_{1}$. This action is cumulative and the circuit returns to its stable state again ; in doing so $\mathrm{C}_{2}$ is re-charged partially through $R_{2}$, but prin-

Fig. 2. Simple time delay flipflop. Typical values :- $\mathbf{R}_{1}=$ 100k $\Omega, \quad R_{2}=I M \Omega, \quad R_{L}=100 \mathrm{k} \Omega$, $\mathbf{R}_{\boldsymbol{c}}=1000 \Omega, \mathbf{Z}_{o}=$ required load, $\mathrm{C}_{1}=$ roop $\mathrm{F}, \mathrm{C}_{2}$ according to required $t_{0}, E=200$ volts, $V_{1} V_{2}=$ $\mathrm{ECC}_{32}$ or 6 N 7 .
cipally through $R_{L}$ and the gridcathode path of $\mathrm{V}_{2}$ in series. The circuit therefore requires a little time to recover before it is ready to accept another triggering pulse.

The period $t_{0}$ during which the unstable state persists is generally of the order of $5 \mathrm{R}_{2} \mathrm{C}_{2}$ depending

Typical values:- $R_{1}=100 \mathrm{k} \Omega, \mathrm{R}_{2}=100 \mathrm{k} \Omega-3 \mathrm{M} \Omega$, $R_{6}=6.8 \mathrm{k} \Omega, \mathrm{R}_{\mathrm{L}}=8.2 \mathrm{k} \Omega, \mathrm{R}_{\mathrm{e}}=4 \mathrm{k} \Omega, \mathrm{C}_{1}=100 \mathrm{pF}, \mathrm{C}_{2}$ according to required $t_{0}, \mathrm{E}_{1}=40 \mathrm{~V}$, $\mathrm{E}_{2}=55 \mathrm{~V}, \mathrm{E}=250 \mathrm{~V}$ volts, $\mathrm{V}_{1} \mathrm{~V}_{2}=\mathrm{ECC}_{32}$ or $6 \mathrm{~N} 7, \mathrm{~V}_{4}=\mathrm{V}_{3}=\mathrm{EF} 50, \mathrm{~V}_{5}=\mathrm{EA} 50$. ${ }^{0}$ N.B. For $t_{0}<10 \mu \mathrm{sec}$ miniature valves would be desirable.

## Electronic Circuitry-

on the particular circuit details.
For short times an improved circuit has recently been published ${ }^{1}$ and is shown in Fig. 3. As before, $V_{1}$ and $V_{2}$ together with $\mathrm{R}_{2} \mathrm{C}_{2}$ form the time delay flip-flop. The anode of $V_{1}$ is here coupled to the grid of $\mathrm{V}_{2}$ by the cathode follower $V_{4}$, and the diode $V_{5}$ holds the grid of $\mathrm{V}_{2}$ at the potential $\mathrm{F}_{2}$ which is determined by $R_{5}$ and $\mathrm{K}_{\mathrm{g}}$. The triggering pulse is fed into the anode of $\mathrm{V}_{1}$ (rather than the grid as in Fig. 2) by $\mathrm{V}_{3}$ which is normally cut off.

Initially in the stable state $\mathrm{V}_{\mathrm{g}}$ is conducting because $E_{2}$ is always greater than $E_{1}$, and $V_{1}$ is cut off. When a short positive pulse is applied to the grid of $V_{3}$ through $R_{1} C_{1}$, the grid of $V_{4}$ (and hence of $V_{2}$ ) is driven negative, so that $V_{2}$ is cut off and $V_{1}$ is left conducting with a current of approximately $E_{1} / R_{c}$. The resultant voltage drop across $R_{L}$ is applied to $R_{2} C_{2}$, and $C_{2}$ begins to leak away through $R_{2}$. Since the voltage across $R_{2}$ approximates to the full H.T. potential, this leakage is rapid, and the grid of $\mathrm{V}_{2}$ moves positively. Eventually $\mathrm{V}_{2}$ begins to conduct and to reduce the current in $V_{1}$. This action is cumulative so that $\mathrm{V}_{1}$ is abruptly cut off again, and the consequent voltage change across $\mathrm{R}_{\mathrm{L}}$ attempts -via $\mathrm{V}_{4}$-to drive the grid of $\mathrm{V}_{2}$ positive. However $V_{5}$ now conducts and $C_{2}$ is restored to its initial state of charge relatively rapidly as $R_{6}$ is low compared with $\mathrm{R}_{2}$. Hence the recovery time of the circuit after returning to the stable state is very short, so that it is quickly able to accept another triggering pulse.

The period for which the unstable state persists is given approximately by

$$
t_{0}=2.3 \mathrm{R}_{2} \mathrm{C}_{2}\left[\operatorname { l o g } \left(\mathrm{r}+\frac{\mathrm{R}_{\mathrm{L}}}{\mathrm{R}_{\mathrm{c}}}-\right.\right.
$$

where $\boldsymbol{x}=\mathrm{R}_{4} /\left(\mathrm{R}_{3}+\mathrm{R}_{4}\right)$ and $\beta=$ $R_{6} /\left(R_{5}+R_{6}\right)$.

It is useful to realise that $t_{0}$ can be varied over quite a wide range by the adjustment of $E_{1}$ (i.e. $\alpha$ in the equation). The main advantages of this circuit are (i) delay times down to 2 microseconds are obtainable, (ii) the circuit has a short recovery time

[^8]so that it can spend most of its time in the unstable state if desired, and (iii) the time delay is controllable and constant within a few per cent.

O$N E$ of the uses of the time delay flip-flop is to energise (or more usually de-energise) a relay for a predetermined period, $t_{0}$. It is not always remembered that a relay represents an inductive

> Relay Operation by Valves load, so that if switched by a valve as shown in Fig. 4 quite large peak potentials of several hundred volts or more can easily exist across the relay coil at the instant of switching off (or on). These peaks tend to stray into undesired places in the usual annoying way and cause trouble, so it is often desirable to reduce them.

This reduction can be effected

Fig. 4. Valve-controlled relay with surge suppressor shown dotted.
by a shunt resistor across the relay coil, but this is wasteful of anode
$\beta)-\log (1-x)]$
current. A better solution is to shunt the relay coil (of resistance $R$ and inductance $L$ ) with a resistance $n \mathrm{R}$ and a capacitance C in series as shown dotted in the figure. The peak voltage at the anode is then $\mathrm{E}_{p}=\mathrm{I}_{a} n \mathrm{R}$, where $I_{a}$ is the anode current of the valve. By suitable choice of $n$ it is obviously possible to give $E_{p}$ any value we like. However, $C$ must be chosen correctly or damped oscillations-also undesirable-

## OUR COVER

C.R D.F - The illustration on this month's cover shows the cathode-ray direction-finder used at the Central Forecasting Office (Meteorological Office), Dunstable, for the location of thunderstorms. The equipment, which was made by the Plessey Co., operates on a frequency of about $10 \mathrm{kc} / \mathrm{s}$.
will appear. The correct value is

$$
C=\frac{4 \mathrm{~L}}{(n+1)^{2} R^{2}}
$$

As long as $n$ is greater than one, the current through the relay coil will rise to $I_{a}$ in a finite time- $t^{\prime}$ and we may regard this time as the lag between switching the grid of the valve and the coil current reaching its operating valuebecause $I_{a}$ is not generally much in excess of the minimum operating relay current for reasons of economy. The time taken for the relay current to rise to its operating value (actually $\mathrm{I}_{a}$ ) is, then

$$
t^{\prime}=\frac{2 \mathrm{~L}}{(n-1) \mathrm{I}}
$$

and this lag is the penalty to be paid for the reduction in the peak voltage across the coil.

A relay of the usual P.O. type measured by the writer recently has a resistance of $\mathrm{I}, 000 \mathrm{ohms}$ and an inductance of 3.5 henrys. The energising current ( $\mathrm{I}_{a}$ ) was made 15 mA , and $n$ was made 2.7 giving a peak voltage of 40 volts at the instant of switching on or off. Using the above equations, the shunt impedance was made $2.7 \mathrm{k} \Omega$ in series with a condenser of $2 \mu \mathrm{~F}$ and this yielded a satisfactory result since $t^{\prime}$ worked out to be 4 milliseconds which, of course, was much less than the inherent mechanical lag of the contact assembly, etc.

# TELEVISION STANDARDS The Case for 405 Lines 

IN the early part of 1937 the present British television standards were adopted after some months of experimental transmissions, carried out alternately with the present and with another system. Since then there has been a daily public service of television which was interrupted only during the war years.

It is the oldest regular service in the world and more experience has been gained with it than with any other. It also has the fewest scanning lines of any existing television system. Since it is generally believed that the picture definition obtainable is a direct function of the number of lines there has been a good deal of pressure put on the television authorities for an increase.

This pressure was most marked immediately after the war because the resumption of the service after a six-year break was unquestionably the ideal time for introducing any change of standards. Most existing receivers required overhauling after their spell of idleness and changes to suit them to new standards could have been made at the same time.

However, it was clecided to adhere to the 405 -lines standard, but ever since there have been rumours that this was to be only an interim measure and that a drastic alteration was to be expected in a few years' time. Such rumours did considerable harm to the television industry, for although they were assessed at their true worth-nothing-by the industry itself, they tended to discourage the nontechnical public from buying television apparatus.

The recent statement that the present standard is to be maintained indefinitely and certainly for many years is thus particularly welcome. It may come as a surprise, however, to those who believe that the 405 -line standard is an obsolete one and point to the American use of 525 lines and to their experiments with colour.

The number of scanning lines has become something of a fetish and is often taken as a clirect measure of the picture quality. In fact,
however, it is mothing of the sort. It indicates increly one limit to definition. In fact, under some quite common practical conditions an increase in the number of lines may well reduce the picture quality. This matter is so important and has been so little discussed in the past, that it is advisable to go into it in some detail.

The number of lines used primarily governs the definition only in the direction at right angles to the scan ; that is, vertically with all current systems. The lines divide the picture into narrow strips and it is obvious that the more strips there are the better until the limit set by the size of the scanning spot is reached. If there are too many lines for the size of the spot they will overlap and no advantage is then gained from increasing their number.
The spot size obtainable in practice depends on the design of the cathode-ray tube, the design of the deflecting system and upon the voltage at which the tube is operated. In general, the attainment of a minimum spot size demands highvoltage operation and the use of a deflection sustem of rather low efficiency. Both factors increase the power needed for scanning and consequently make the cost of a receiver greater.

## Horizontal Definition

In the direction of scan-hori-zontally-the number of lines has no direct influence on the definition, which is actually governed only by the overall bandwidth and the size of the scanning spot. The bandwidth limits the maximum rate at which the light intensity of the spot can change. When the spot in the transmitting camera passes across a hard edge-say the edge of a vertical column in the scene being tele-vised-it is required for perfect definition that the light intensity of the spot on the receiving tube shall change instantaneously from one light value to another.

Due to the finite bandwidth of the circuits between the camera and receiving tubes, this cannot occur and a finite time is taken to

PORTABLE MODEL-B65 A completely self-contained low power P.A. system. Battery Operated.
This exceptionally compact equipment incorporates the amplifier complete with loudspeaker, rotary transformer, 6 volt unspillable accumulator, and microphone with cable, all self-contained in an easily portable case. Independent switches allow valve filaments to be kept warm in the non-operating condition at about 1/3rd normal battery consumption. Power output is approximately $s$ watts, and for outdoor use the addition of a separate projection type speaker substantialiy increases the range. A most useful outfit for motor coaches, buses, police, auctioneers, and numerous other applications where no electric supply mains are available. Send for details.

AMPITTERS MICROPHONES - LOUDSPEAKERS

## Television Standards-

accomplish the change. The usual 9 -inch receiving tube gives a picture 19 cm wide, and with the British system the spot travels across it with a velocity of $2.28 \mathrm{~mm} / \mu \mathrm{sec}$. If the system has an overall bandwidth such that a change of light intersity cannot be completed in less than $0.2 \mu \mathrm{sec}$ the spot must travel $2.28 \times 0.2=0.456 \mathrm{~mm}$ while the light is changing. The result is a blurred, instead of a hard, edge.

With a given number of lines, any increase of bandwidth reduces this transition time and so increases the horizontal definition. With the standard 405 lines and a bandwidth of $2.5-3 \mathrm{Mc} / \mathrm{s}$, the vertical and horizontal definitions are roughly equal. Increasing the bandwidth to some $4-5 \mathrm{Mc} / \mathrm{s}$ results in very noticeably higher definition without clianging the number of lines. The horizontal definition is then better than the vertical, but the result is an improved picture.

Now if the $2.5-\mathrm{Mc} / \mathrm{s}$ bandwidth is retained and the number of lines is increased the vertical definition is improved but the horizontal definition is decreased. With more lines the scanning velocity is increased and as the rate of change of light intensity is unaltered the distance travelled by the spot during the change is increased. To maintain the horizontal definition unaltered it is necessary to increase the bandwidth in proportion to the number of lines. To improve both horizontal and vertical definition at the same, rate, the bandwidth must be pripertional to the square of the number of lines.

The size of the scanning spot exercises an effect very similar to that of a finite bandwidth and must be reduced as the bandwidth is increased if it is not to become a limiting factor.

It is clear from this that if the overall bandwidth is limited for any reason there is an optimum number of scanning lines which will result in the best picture. This optimum is roughly the number which results in equal vertical and horizontal definition, but it is not critical. The choice of the number of lines for a television system is, therefore, dictated by the bandwidth which it is practicable to adopt.

It must also be pointed out that the power needed in the receiver for carrying out the horizontal scan is proportional to the number of lines.

As scanning generators for 405 lines consume some 20-50 watts, according to their design, any large increase in the number of lines is likely very appreciably to increase the cost of a receiver. Bearing this in mind it may be preferable to use a number of lines slightly less than the optimum. In other words, it may be desirable to obtain a given picture standard by increasing the horizontal definition at the expense of the vertical since by so doing a cheaper scanning circuit can be used in the receiver.

## Bandwidth

We have now to consider what factors limit the usable bandwidth in practice. The limitations are more economic than technical, but there are practical limits to what can be achieved in the way of reducing the size of the scanning spot in the receiver tube. However, even these are mainly economic.

As the bandwidth is increased the receiver stage gain falls off and more stages of amplification become necessary. The attainment of a smaller spot, while retaining normal brightness, demands a higher operating voltage for the tube and this, in turn, necessitates an increase of scanning power, over and above that needed directly to produce a higher-velocity scan. It is obvious that receiver costs must increase with the number of lines.

It is difficult to find any definite relation between the number of lines and the cost of a receiver but the increase of the one with the other is likely to be considerable. Matters are not helped by the natural tendency for the reduced production rates of higher-priced equipment to be reflected in still higher production costs.

Apart from the receiver there are two factors which materially limit the practical bandwidth. The first is the usual one set by the need for avoiding mutual interference between transmitters operating in a limited frequency spectrum. With the present 405 -line standards there is room for only about five clear channels in the European television band of some $40-70 \mathrm{Mc} / \mathrm{s}$. In a general European service, sharing of channels must be adopted, which means that the transmitters must be widely separated geographically.

However, the fact that the normal range of such stations is
about $50-70$ miles does not mean that interference will not be found between stations much more widely separated. The British station has been received on occasion in South Africa and in the U.S.A., in the latter case with sufficient intensity for a picture to be resolved.

The use of any appreciably greater number of lines would so increase the bandwidth as to make the problem of frequency allocation in the $40-70 \mathrm{Mc} / \mathrm{s}$ band an insoluble one. The use of higher frequencies brings its own problems in its train. The range of the transmitter is reduced and this makes it exceedingly hard to cover rural areas economically. In urban districts, buildings produce reflections which cause serious interference. This is very evident in the American highfrequency transmissions and aerial siting for their avoidance seems to be the major problem of receiver installation.

Because of this trouble from reflections, the use of higher power is not the answer to obtaining increased coverage. The need is for more stations. This in its turn increases the cost of feeding the stations with programme material. To provide each station with its own studio and independent programmes is prohibitively costly. It is necessary to have a very few central studios and programmes and to relay the signals to the transmitters by cable or radio links.

One of the most important programme items in television consists ${ }^{\circ}$. sporting events, and these usually take place remote from a transmitter. Mobile equipment is used and is linked to the main transmitter by cable or radio.

## Relay Links

In any general television scheme, therefore, great use of cables or radio links must be made for conveying the signals to the transmitters. It is the bandwidth economically obtainable in such links which forms the major practical limitation to the number of lines which can be usefully employed.

If we compare two systems, such as the British 405 -line and the American 525 -line, we may expect that the American will give higher definition when the programme originates in a studio near the transmitter, but that it will give poorer definition than the British when the
progranme originates from a remote point and must be conveyed by a link of only $2-2.5-\mathrm{Mc} / \mathrm{s}$ bandwidth. If such remote programme sources are to lee used to any extent, therefore, it is clear that the advantage lies with the British system of fewer lines. This is especially the case when the lower cost of receivers, the greater service area of each transinitter, and the simple installation problems are taken into account.

This question of the bandwidth practicable for television relaying is the crux of the matter. In the case of permanent links for uniting a studio in the heart of a town with a transmitter a few miles away there is no serious difficulty in providing almost any bandwidth. For permanent links of a hundred miles or more a bandwidth of $2-2.5 \mathrm{Mc} / \mathrm{s}$ is probably the most that can be economically achieved with a cable. Radio links with a chain of relay stations offer better hope of greater bandwidth, but are as yet largely untried. One is being erected between London and Birmingham and more will be known of its capabilities when it is in operation. The practicability of such a link, of course, depends much upon the nature of the intervening country.

For the relaying of sporting events, which occupy a large proportion of programme time, it is feasible to install special cable only at a few places from which relays are frequent. In most cases portable equipment must be used with cables of rather narrow bandwidth. The radio link is not always practicable inside a town on account of the difficulty of placing the transmitting aerial suitably. The B.B.C. uses a 'fire-escape' to carry the aerial, but very often it employs the ordinary telephone system! It has been found practicable to equalize such lines up to some $1.5-2 \mathrm{Mc} / \mathrm{s}$ provided only a very few miles is involved.

In view of all this it may fairly be stated that the present 405 -line system is the best suited to the realities of television. If more lines were used better pictures could be obtained from studio transmissions, for there is then little bandwidth difficulty. However, outside broadcasts would usually be poorer than with 405 lines. Outside broadcasts are of great importance in popularizing television, and it is clearly wrong to increase the number of lines if by so doing poorer pictures are obtained on such broad-
casts, especially if the change is reflected in increased receiver prices.

## Optimum Lines

Now what does all this mean in practice? Two tacts are clear. If the bandwidth is limited there is an optimum number of scanning lines for the best definition. Receiver prices increase with an increase in the number of lines. Clearly under icleal conditions there is a practical limit to the bandwidth set ly receiver costs. What this limit is has not yet been determined, but it is possible that quite a considerable increase would be practicable.

Other bandwidth limitations depend very largely on the distribution of the population in a country. If the bulk of the population is concentrated into a few large towns separated by great distances of sparsely inhabited country, any attempt at complete coverage is impracticable in the present state of the art. Each town must have its own independent television system with a central transmitter and its own studios. Outside broadcasts would never originate at, perhaps, more than five miles from the transmitter. There is then little or no difficulty in providing large bandwidth. Systems of some $60 \%$ lines become practicable and desirable.

On the other hand in more densely inhabited countries like Britain and much of the Continent, large towns are separated by 50 miles or less and the rural areas are relatively densely populated. Coverage over a much larger total area is: needed and it is impracticable on economic grounds to provide each of the transmitters required with its own independent local programme.

Cable and radio links of 50-100 miles are needed to feed the outlying transmitters, and in the not distant future, longer links will be necessary. The cost of such links increases enormously when the bandwidth exceeds about $2.5 \mathrm{Mc} / \mathrm{s}$, and so there is a definite limit to the number of scanning lines which is desirable.

All transmitters on such a linked system must operate on the same basic standards, and so we find that for the general requirements of a television service in Britain and the Continent a number of lines around the present 405 is about the optimum.

## GALPIN'S

## ELECTRICAL STORES,

408. HIGH STREET, LEWISHAM, LONDON, S.E.I3
Telephone : Lee Green 0309. Near Lewisham Hospital.
TERMS: CASH WITH ORDER. NO C.O.D. ROTARY CONVERTERS, EX-ADMIRALTY, 110 volts D.C. to 230 volts A.C. 50 cyc. 1 phase rated at 200 watts but capable of 550 watts continuous rating, weighs approx. 100 lbs.. centinuous rating, each, carriage $10 /$-. EX-GOVERNMENT (G.E.C.) ELECTRIC FANS, 12 volts, A.C./D.C. laminated field, complete with 5 in. impellor. New, boxed, 20/-each, post 1/-. Transformer to suit, 230 volts input, $12 / 16$ volts at 4 amps. output, $32 / 6$ each. MAINS VARIABLE RESISTANCES, ex-Govt. (new) 4,000 ohms, 25 amps., $35 /-$ each. Worm wheel control, slider type, 60 ohms, to carry $1 \frac{1}{2}$ amps., $17 / 6$ each ; 5.7 ohms, 8 amps ., $25 /$ each. Dimmer resistances stud switch arm type, 2,700 ohms to carry. 27 amps., $25 /-$ each.
MAINS VARIABLE RESISTANCES (slider type), new, ex-Govt., 14 ohms, carry 1 to 4 amps., graduated, useful as dimmers, etc., $17 / 6$ each; another, 0.4 ohms, carry 25 amps.. $17 / 6$ each, post $1 / 6$. Ex-Gove. Moving-coil Cell Testers, post vols (new), 20/- each.
EX-R.A.F. MICROPHONE TESTERS (new). These consist of a Ferranti 0 to $450 \mathrm{~m} / \mathrm{amp}$. $2 \frac{1}{2}$ in. scale meter shunted to $1 \mathrm{~m} / \mathrm{a}$. incorporated Westinghouse Rectifier, the whole encased in polished teak case, calibrated at present 0 to 10 volts, $32 / 6$ each. 27/6 each.
EX-NAVAL (SELF-ENERGISED) TELEPHONE HANDSETS, $10 / 6$ each, or complete Telephones, Magneto Ringing with Neon Light, Telephones, Magneto Ringing with Neon
$35 /-$ each, post $2 / 6$. Another with BUZZER 35/- each, post 2/6. Ano
calling, $15 /-$ each, post $2 /-$ -
EX-R.A.F. CRYSTAL CALIBRATORS UNITS. Type 18, R.A.F. serial No. 10a/15237. These units contain $100 \mathrm{kc} / \mathrm{s}$. xstal 2-EF 50 valves and numerous other items all new and unused, 35/-each.
ELECTRIC LIGHT CHECK METERS (Watt Hour). A.C., 50 cys., $200 / 250$ voles, 5 amp . load, $18 / 6$, post $2 \% ; 10$ amp., $21 / \mathrm{m}$, post $2 / \mathrm{m} ; 20 \mathrm{amps}$. 25/: post $2 /$; also a few only Pre-Payment 1/- slot type, $20 \mathrm{amp} .$, load, less coin box, complere with synchronous Motor, 35/- each, carriage $3 / 6$. EX-R.A.F. INDICATOR UNITS, rype 48a, new, boxed, consisting of 2 $3 \frac{1}{2}$ in. tubes, type 138a, also time base, $50 /$ - each.
MOTOR ALTERNATORS, EX-R.A.F., as new, 230 volts 50 cys. I phase input, 250 volts. 625 cyc. I phase at .24 amps. output, $75 /$ each. Ditro, I, 725 cys. output, 85/- each. C/P.
EX-NAVAL (CROMPTON PARKINSON) PRONG-TESTERS, 0 to 100 and 0 to 400 amps.. new, in leather carying case, $90 /$ - each. A.C.
$V /$ Merers, 0 to 3006 in . scale, calibrated 50 cys . V/Merers, 0 to 300 6in. scale, calibrated 50 cys.. $37 / 6$ each.
EX-R.A.F. CRYSTAL MONITORS, type 2, complete in wooden carrying case, the frequency depending on crystal used, 5/-each. 5hort Wave Aerial Coupling Units (Wavemeters), 5/- each. FRACTIONAL H.P. MOTORS, 110 volt: with LAMINATED Fields (Ex-Naval Fan Motors) These need slight attention, to brushes or leads, 10/- each. Westinghouse (Blasting) Galvanometers, Moving Coil, very low deflection, 15/• each.

## Television Standards-

Because of the need for common standards in any area over which a common programme is to be distributed it is rather important that neighbouring countries should consider their services jointly. Near their frontiers the stations of their neighbours may be receivable and provide alternative programmes. Then with common standards international relays become practicable. Britain must be considered as a part of the Continent for this purpose, since the English Channel is no barrier to a radio link and the interchange of British and French progranmes is within the realns of the practicable, provided only that
the standards are common and that they do not call for an excessive bandwidth.

Because it is considered that under British conditions an increase in the number of lines is undesirable it should not be concluded that there is no scope for improvement and that British television is a static thing. This is far from being the case. It has already been pointed out that a greater bandwidth with the present standard will give higher definition, and if the difficulties of frequency allocation can be overcome such a change can be effected at any time without in any way affecting existing receivers. It would give better pictures from
studio transmissions without affect. ing outside broadcasts.

Of even greater importance, however, is the attainment of a greater depth of focus in the transmitting camera. This entails the use of a lens of smaller aperture and so requires a more sensitive camera tube. The more sensitive tube also has obvious advantages for outside broadcasts under poor conditions of lighting. Such a tube is already in existence in the C.P.S. Emitron. It has not yet been put into service on a large scale, but it was used for relays during the Olympic Games, and the increased depth of focus and detail were remarkable and set a new standard of picture quality.

## MANUFACTURERS PRODUCTS

## Television Aerials

A$\mathbf{N}$ inductively-loaded dipole in which the dimensions have been reduced to approximately $\frac{1}{4}$ wavelength has been developed by Antiference Ltd., 67, Bryanston Street, London, W.i. It is used in conjunction with a low-impedance stub section which is designed to compensate for variations in the aerial reactance. The impedance is said to be substantially resistive over the television band and is adjusted to $70 \Omega$.

It is intended for indoor use and under average conditions satisfactory reception is claimed up to a range of ro miles.
The overall length of the aerial is 5 ft 6 in and the price is $£^{2}$ Ios.

## Export Battery Receiver

A NEW all-wave bandspread superheterodyne (Model 92) operating from a 6 -volt battery has

19, 25, and 31 metres. A heavyduty roin loudspeaker is used and the set is designed to operate under alverse climatic conditions.

## Cabinet Loudspeaker

TO meet the demand for a loudspeaker which will fit in the angle between two walls, Richard Allen Radio, Caledonia Road, Battery, Yorks, have introduced a "Bafllette Console" model incorporating their Type 81o loudspeaker. The cabinet is of polished walnut on a black plinth and measures $26 \mathrm{in} \times 17 \mathrm{in} \times 6 \mathrm{in}$. The price is $£ 6 \mathrm{Ijs}$, or $£ 7356 \mathrm{~d}$ with output transformer.

## Record Groove Indicator

For identifying and selecting gramophone record, Wilkins and Wright, Holyhead Koad, Birming. ham, 21, have evolved a groove indicator which does
 not impose any extra load on the pickup and which gives a high magnification without backlash.
Designed for use with their "Coil"

## Wilkins and Wright optical record groove indicator

 Type 0.been introduced for the export market by Invicta Radio, Parkhurst IRoad, London, N.7. The consumption is $3 \frac{1}{2} \mathrm{~A}$ at 6 V and the four-valve circuit covers wavelengths of II-25, 25-60, 60-200 and 200-550 metres. There is bandspread tuning on 16 ,
pickup, the Type O indicator consists of a curved graduated scale which is screwed to the motor board and viewed through a mirror attached to the tone arm pivot, and a telescope fitted with cross wires. The scale is divided into too divi-
sions and approximately three revolutions of the record are equivalent to a division. Precise placing of the needle to the nearest groove is easy, provided that the record is concentric ; with eccentric records a little nore skill is required. The indicator is also useful in gauging the height of the needle above the record, since the magnification of vertical movement is comparable with that of the horizontal.
The price of the complete outfit is $\mathcal{L}_{4} 6 \mathrm{~s} 8 \mathrm{~d}$, including purchase tax,

## Wide Scale Meters

ANEW range of wide-scale, mov-ing-coil meters (Series 415) has been introduced by Taylor Electri-

Series 415 sector type meter by Taylor Electrical Instruments.
cal Instruments, 419-424, Montrose Avenue, Slough. D.C. instruments with ranges of $0-10 \mu \mathrm{~A}$ and $0-5 \mathrm{mV}$ upwards are available, and also rectifier types with ranges of $0-25 \mu \mathrm{~A}$ and $o-1 \mathrm{~V}$ upwards. The range will shortly be extended to include mov-ing-iron and thermocouple types.

## " QUIET HIGH-GAIN AMPLIFIER '": A CORRECTION

In this article, the value of $\mathrm{R}_{31}$ was incorrectly given (p. 209, June, I948, issue) as $22!$. It should have been $220 \Omega$.

## LETTERS TO THE EDITOR

## Series Capacitor Circuits - Television Receiver Selectivity + Discriminator Alignment

## Series Capacitor Heater Circuits

$I^{T}$$T$ is rather surprising to read in this otherwise excellent article in your Sept. issue, that " dial lights gradually attain their full brilliance, taking several seconds in the process." Mr. Stanley evidently has not tried this, or he would have noticed the brilliant flashes often obtained at the instant of switching on, and the high probability of lamp burn-out.

Actually the instantaneous current in the circuit at $t$ seconds after the E.M.F. wave has passed through zero, is
$i=1_{m}[\sin (2 \pi f t+\phi)-$
$\left.\epsilon\left(t_{1}-t\right) / R C \sin (2 \pi f t,+\phi)\right]$
where $\mathrm{I}_{m}=\mathrm{E}_{m} / \sqrt{ }\left(\mathrm{R}^{2}-\mathrm{I} / 4 \pi^{2} f^{2} \mathrm{C}^{2}\right)$
$t_{1}=$ value of $t$ when switch is closed
$\phi=$ phase angle $=\tan ^{-1}$

$$
1 / 2 \pi / \mathrm{CR}
$$

The first term within the bracket corresponds to steady-state conditions and the second to the transient. The latter is zero when $2 \pi f t_{1}=-\phi$; i.e., if the switch is closed at the instant during the E.M.F. wave when the steady-state current would have been zero.

This transient current does not harm ordinary indirectly heated valves because of their thermal inertia, but the thermal time conconstant of the typical dial light is short compared with the first few cycles during which the transient current is appreciable.*

Two ways of overcoming the difficulty are (I) to have another switch short-circuiting the dial light and open this not less than, say, $\frac{1}{2}$ second after the main switch is closed, and (2) to arrange the main switch to short-circuit the heater chain plus dial light when it is desired to switch off. The latter method reduces switching to a single operation but leaves the series capacitor permanently across the mains when the set is out of use; however, negligible power is drawn, the set will remain cool, and no consequent rotation of the watt-hour meter should occur.
G. S. LIGHT.

Feltham, Middx.

[^9]$T \mathrm{~T}$HIRTY years of experience with radio components prompts me to raise friendly issue with $A$. W. Stanley in reference to his article.

Like many others, he would ap-
pear to confuse the A.C. working voltage of a capacitor with its D.C. rating by thinking of the former in terms of the latter.

I would suggest an empirical formula for his consideration: "In any capacitor rated for I).C. operation the safe maximum A.C. voltage that can be applied is one-half the D.C. rating or 250 V A.C., whichever is less.

When one considers the severe mechanical stresses that a capacitor has to meet under A.C. conditions it can be readily appreciated that for use on A.C. capacitors (strictly speaking) should be designed for that purpose. The better manufacturers do, in fact, supply components to meet this need.

The question of standard capacity tolerance of $\pm 20$ per cent appears to have been overlooked, and although the regulation of the arrangement shown by Mr. Stanley is excellent, it is doubtful whether it would permit the adoption of capacitors whose capacity just falls within the limits prescribed.

Bearing the foregoing in mind, I would suggest that the arrangement is not entirely foolproof.
J. PARKINSON

Uxbridge, Middx.
The author replies :-
I have used a series capacitor circuit in a number of A.C. mains receivers and these have been in continuous use for more than two years without a single dial light failure which could be attributed to the initial transient current when switching on. In all cases the heater circuits were rated at 0.2 A and the dial lights were $6.3-\mathrm{V}, 0.3-\mathrm{A}$ types. It is a fact that the bulbs appear to warm up more slowly in such circuits than when a constant voltage is applied, but I admit, on reflection, that my "several seconds duration" is a slight exaggeration.

It is possible that the explanation of our differing experiences may lie in the different ratios of bulb to circuit current rating. It is well known that $6.3-\mathrm{V}$ bulbs last longer than $4^{-V}$ types on a $4^{-V}$ R.M.S. A.C. circuit, and it seems reasonable to suppose that 0.3 -A bulbs would last longer than 0.2-A ones on a 0.2-A R.M.S. circuit. My bulbs had a current rating 1.5 times the R.M.S. heater current; Mr. ILight used 0.35-A bulbs on a 0.3-A R.M.S. circuit for which the ratio is less than 1.2.

From the expression given by Mr.

## INSIDE THE HOUSE!

Fixing an aerial inside a house is a very much smaller problem than mounting it on the roof.
The Antiference " COMPACT " Television Aerial is designed to give a satisfactory signal mounted indoors-in the loft or in any room. Under average conditions it will provide good reception within a 10 mile radius of Alexandra Palace.
Overall length $5^{\prime \prime} 6^{\prime \prime}$ (packed in carton $3^{\prime \prime} 4^{\prime \prime}$ long). Supplied complete with universal mounting and backplate in neutral brown finish.

Registered design and patents applied for.
ANTIEERENCE
67 BRYANSTON ST., LONDON, W. 1

## Letters to the Editor-

Light it is interesting to calculate the rate of decay of the transient current. In my receivers the heater circuit has a cold resistance of 60 ohms and the series capacitor is $3 \mu \mathrm{~F}$. This gives a time constant of less than $1 / 5,000$ th second and the transient current has fallen to I/I,oooth second. The question to be settled is whether such a brief pulse of greater than normal current can damage a bulb filament. Mr. Light has found that it can; I have had no trouble from this cause. Probably it depends on the thermal inertia of the bulbs used and, as suggested above, on the ratio of bulb to circuit current rating. It would be very interesting to hear about the experiences of other users of the series-capacitor heater circuit.
Turning to J. Parkinson's letter: I did have two breakdowns of capacitors during my experiments on the series-capacitor circuit, even though my components were rated at 400 volts peak. I put this down to bad luck, but it appears that there is more in the subject than meets the eye. Afterwards I used components rated at 1,000 volts and had no more trouble: this bears out Mr. Parkinson's observations. The capacitance tolerance was $\pm 5$ per cent, and I agree that the normal tolerance of $\pm 20$ per cent is much too wide for this circuit.
A. W. STANLEY.

Selectivity in Television

## Receivers

THE excellent article on selectivity in television receivers in your June issue would, I think, have been somewhat more complete if brief reference had been made to the use of a cathode parallel-resonant circuit for sound rejection, particularly as considerable space is devoted to the series-resonant rejector.

With the series circuit, a few calculations with normal component values show, as you yourself certainly imply, that adequate rejection at $9.5 \mathrm{Mc} / \mathrm{s}$ and inappreciable loss at $10 \mathrm{Mc} / \mathrm{s}$ are well nigh impossible.

If, for example, we assume for C, a value of 3 pF , about the lowest physically possible, then $\mathrm{L}_{1}$ will be $93 \mu \mathrm{H}$. Assuming further, perhaps rather optimistically, a Q-factor of 300, we shall obtain:
at $9.5 \mathrm{Mc} / \mathrm{s}$ an attenuation of about 25 db and
at $10 \mathrm{Mc} / \mathrm{s}$ an attenuation of about 8 db .
The first figure is reasonable, the second undesirably high. At ı $\mathrm{Mc} / \mathrm{s}$ neither $\frac{\omega^{2} L_{1} \mathrm{C}_{1}-1}{\mathrm{C}_{1} \mathrm{R}_{1}}$, (not $\left.\frac{\left(1-\omega^{2} \mathrm{~L} . \mathrm{C}_{\cdot}\right)}{\mathrm{C}_{1} \mathrm{R}_{\mathrm{i}}}\right)$, nor $-\frac{2 \delta f . Q . \mathrm{R}_{1}}{\mathrm{f}_{\gamma_{2}} \mathrm{R}}$ are much
greater than I . They are about o.6, in fact. Furthermore, there does not seem much that can be clone about it.

If we decide to try the paralleltuned circuit in the cathode, we have the same demand for a high Q-factor but this time with the least possible value of $L_{1}$ instead of the highest. Let us take looopF as a value for $\mathrm{C}_{1}$, which gives an $\mathrm{L}_{1}$ of $0.28 \mu \mathrm{H}$, and assume $Q=120$, probably no more difficult to achieve than the previous conditions. Then, if we tap down about 15 per cent on the coil, we shall get attenuations of about 23 db at $9.5 \mathrm{Mc} / \mathrm{s}$ and +db at г $\mathrm{Mc} / \mathrm{s}$.

These results are slightly better than those obtained with the series circuit and do not occasion more difficulty in design.
H. G. M. SPRATT.

Enfield, Middx.

## Discriminator Alignment

AG. CROCKER, in the excellent account of the practical work he has carried out, says (page 316, your Sept. issue): -
"Linearity. - The characteristic (Fig. 2) is linear up to $\pm 125 \mathrm{kc} / \mathrm{s}$, if linear means the distortion effect is less than 2 per cent."

Now this raises again the old question of how much distortion is "distortionless." Two per cent distortion doesn't sound very much, but inspection of Mr. Crocker's curve shows that the slope over the range quoted varies by as much as 20 per cent. This means that if in the modulation there were a strong component (corresponding to nearly maximum deviation) and also weaker components (at other audio frequencies) the strong component would modulate the weak ones by about $\pm 10$ per cent. Can the quality enthusiast accept this amount of distortion in the reception of the very high fidelity signals which F.M. promises us?
E. F. GOOD.

Malvern, Worcs.

## Direct-Coupled Amplifiers

I WAS rather surprised to see the circuit of N. Bonavia Hunt's amplifier in the July issue of the Wireless World, as I would have thought that, to-day, a circuit of this very crude type would have been beyond the serious considera. tion of most readers.

I am not, however, surprised to hear that it sounds very good, since it will presumably give a maximum output of the order of 20 watts, and yet inder average domestic conditions, will have to supply perhaps two or three watts. But surely what an absurdly extravagant way of obtaining such results?

1 would like to know what exactly were the conditions under which comparisons were made with other amplifiers. This amplifier incorporates a tone-control circuit (in which, incidentally, one of the potentiometers varies the anode current of the last three valves as well as controlling the tonel), and, therefore, of course, for a fair comparison, any amplifier with linear frequency characteristic (e.g., D. T. N. Williamson's or my own designs, described in the Wireless World May, 1947 and Jan., 1948, respectively), should have been preceded by a tone-control circuit of the same characteristics. Was this done? If not, the comparison is worthless.
I hope N. Bonavia Hunt will forgive my very outspoken criticisms, but I do sincerely believe it desirable to do what one can to stop people building amplifiers of this kind.

PETER J. BAXANDALL.

## Malvern, Worcs.

## " Principles of Radar"

IN the September issue of Wireless World there appears a review of the book "Principles of Radar," by Taylor and Westcott. The reviewer makes the statement that " metrewave types [of radar] had little or no future even in 1945." I presume by this description he means CH and CHL equipments. Admittedly. the function of CHL has been adequately fulfilled by the multifarious centremetre equipments, but as far as CH is concerned the reviewer can merely be stating his own opinion, which is by no means shared by all, including the Air Ministry, judging from their general policy at the time.
M.G.S. goes on to say that the book does not mention rocketdetecting radar. There may be security reasons for this, as when I was last actively concerned with radar, which is not so very long ago, methods of rocket-detection were still secret. Even if they are not so today, which I doubt, they may have been at the time the book was written.

In view of security requirements I can say little of the actual methods of rocket-detection, but I would inform M.G.S., if indeed he is unaware of the fact, that no small part was played in rocket-detection in 1945 by those equipments "which had little or no future."

Hertford. K. W. PEARSON.

## Aircraft and Television

PPROPOS to the remarks by " Diallist" in the September issue, I should like to submit what appears to me to be the obvious explanation of the "beating"
effect of aircraft on television images. As an ex-radar boffin, I have heard many theories regarding the beating of echoes from objects, but never the present one.

Taking the television effect first: the reflected wave from an aircraft or other object is not locked in phase with the transmitter, with reference to any reception point on the ground. Obviously, as the distance between aircraft and ground varies, direct and reflected signals will be in phase for an instant (adding) then out (subtracting) and so on, at a rate of variation determined by the speed and line of flight.
Regarding the radar beat and the rotating propetler thesis, I can vouch for the fact that jet aircraft, buzzbombs, and barrage balloons all beat regularly and vigorously if any movement is present. This would indicate an effect analogous to the television llutter, caused by phase differences in direct and ground- or sea-reflected paths. In(leed, this path-difference (and
hence phase-difference) between the two was the essential basis of the height-finding facility of ground C.H. radar stations. The fact that an echo would beat fiercely on a high arerial and remain steady on a lower one appears to confirm the reason for the phenomenon.

It has been suggested to me that aircraft might be built of resistive material such as would present a matched load to a T.V. signal, and so prevent reflection ! (" Free Cirid," please note.)
IDOUGLAS M. (IIBSON.

## Ashford, Kent.

REFERRING to "Diallist's" comments in last month's Wireless World, the flopping up and down effect is the only kind of interference from aircraft I experience here.

As this happens frequently with jets it cannot be due to reflections from the revolving propeller.
E. E. S. EARNSIAAW WALL. London, N.W.2.

## NEWS FROM

Birmingham.-Special events have been arranged by the Slade Radio Society in celebration of its twentyfirst anniversary. The week's programme includes a lecture on Oct. ist by Dr. H. A. H. Boot on the cavity magnetron which will be open to nonmembers. Members are to visit the B.13.C.'s Droitwich transmitter on the following day. On the 6th a demonstration of tivo-way working on 80 metres will be given. The society's twenty-first birthday dinner will be held on October 8th. The meetings will be held in the Parochial Hall, Slade Road, Erdington, Birmingham, 23. Sec.: C. N. Smart, 110, Woolmore Road, Birmingham, 23, Warwick.

Birmingham.-Meetings of the South Birmingham Group of the R.S.G.B. are held on the first and third Sundays of each month at $10.30 \mathrm{a} . \mathrm{m}$. at Stirchley Institute. Regular morse classes are being held and those interested in joining are requested to communicate with T. F. Higgins, G8JI, 391, Rednal Road, Northfield, Birmingham, 31, Warwick.
lllustrated leaflet describing power transformers and chokes from Stewart Transformers, 1021, linchley Road, London, N.W.in.

Catalogue of low-current tubular rectifiers (selenium) from Standard Telephones \& Cables, Oakleigh Koad, New Southgate, London, N.II.

Price lists of Government surplus and other components from M. Watts, 38 , Chapel Avenue, Addleston, Surrey.
" M.O.S. Newsletter" No. 3, being a catalogue of Government disposal and , other items in the form of a journal, from Mail Order Supply Co., 3, Robert Street, London, N.W.r.

## THE CLUBS

Middlesbrough.-The Tees-side Anateur Radio Society has secured premises for its headquarters at 400 , Linthorpe Road, Middlesbrough, where future meetings and morse classes will be held. Sec.: H. Walker, G3CBW, 9 , Chester Street, Middlesbrough, Yorks.

Pontypool-Weekly meetings of the recently formed Pontypool and District Radio Club are held in the Abersychan Technical Institute. Sec.: W. F. Chew, Bryn Cottage, Pontropiod, Mon.
Solihull.-Meetings of the Solihull Amateur Radio Society are held on alternate Werdnesdays at the club's II.Q., The Old Manor House, Solihull. Sec.: H. C. Holloway, 20, Danford Lane, Solihull, Warwick.

Tunbridge Wells.-The West Kient Radio. Society, which embraces the Tunbridge Wellis, Sevenoaks, Tonbridge and Southborough areas, meets on the first and third Wednesdays of each month at 7.30 at "Culverden House," Culverden Park Road, Tunbridge Wells. Sec.: R. [luck, 9, Prospect Road, Southborough, Kent.

THE "FLUXITE QUINS" AT WORK
"I told you that set was too small
To cope with the Royal Albert Hall Now look! It's gone mad
You'll need FLUXITE. m'lad
far it's needing a slight overhaul."

See that FLUXITE is always by you - in the house - garage workshop - wherever speedy soldering is needed. Used for over 40 years in Government works and by leading engineers and manufacturers. Of all Iron-mongers-in tins, 10 d., $1 / 6 \& 3 /$.

TO CYCLISTS! Your wheels will NOT keep round and true unless the spokes are tied with fine wire at the crossings $A N D$ SOLDERED. This makes a much stronger wheel. It's simple-with FLUXITE-but IMPORTANT.

## Liverpool's Radar

The Port of Liverpool radar supervision system is remarkable not only for being the first of its kind in the world, but also for having one of the most ingenious display arrangements yet devised. The technical details were dealt with in last month's $W . W$. There's one application, though, that strikes me as exceptionally valuable. The 12 mile channel up the Mersey is nar. row and winding and it is marked by about 60 buoys. It is obviously most important that these should be exactly in their proper positions and that movements of any kind should be spotted at once and communicated to shipping. In the past this meant hard and constant work on the part of a large staff; in foggy weather, when it is of the greatest importance, such verification must have been very difficult if not actually impossible. The checks are now made rapidly and almost automatically by the radar operator, no matter what the weather. In front of each of the screens showing a portion of the channel is a transparency on which the proper position of every buoy is marked by ; green dot. The operator can see at a glance whether the spot of light on the tube corresponding to a buoy coincides with the appropriate green dot. If one of the buoys has shifted he can read off its exact position from a grid on the transparency and can thus notify shipping without delay. The British Sperry Gyroscope Company, who, with Cossors, were responsible for the design and the installation, have made the system a flexible one so that only slight modifications will be needed to make it suitable for any harbour. One doesn't need to be a prophet to foretell that this system, or others like it, will soon be applied to many others of the world's great ports, some of which are now very difficult for shipping in certain kinds of weather.

## Just the Place

The elaborate radar gear in. stalled recently at the tip of Southend's incredibly long pier has pro-
vided some of the lay papers with a magnificent opportunity of getting hold of the wrong end of the stick. To some of them it was just another amenity for trippers. They even went so far as to describe it as "penny-in-the-slot radar" which had taken its place amongst the various fun-and-games machines on the pier. The truth is rather different. The radar installation has a serious object; it is intended primarily for research and development work. It was placed where it is simply because the Southend pier juts right out into the Thames Estuary and the radar scanner is almost as well placed for following the movements of shipping as if it were carried by a vessel in midchannel. It would be difficult to think of a better site than the far end of that immense pier with streans of ships always passing up and down. For the time being, at any rate, a side-show for the public has been provided in the form of a repeater P.P.I. tube in a room open to all comers. That's apparently how the penny-in-the-slot notion originated. I hope the hut housing the gear has been made fairly draught-proof, for the far end of Southend pier can be pretty arctic. I remember being frozen stiff when I had to visit an A.A. gun site there during the awful winter of '40-'4I,

## Navigation

Bradfield of T.R.E. has developed a short range navigational device of considerable interest. By placing his ultrasonic generator at the focal point of a paraboloid he has been able to focus the energy into a beam, and, using radar technique, he transmits pulses, which are echoed back to a receiver, the travel time being measured by a C.R.T. The fire fighting services are watching his development closely, for they see in it a likely means of enabling firemen to find their way about smoke-filled buildings. Other investigators are working on a multiplicity of possible applications of ultrasonics, Conn, of Sheffield University, takes the line that neither
the crystal nor the magnetostriction generator can provide the energy needed commercially at useful frequencies. He is working on a new method of generation by a combination of electric and magnetic fields. Jacob, at Imperial College, is studying the disintegration of bacteria (particularly those of milk) by ultrasonic methods. He has destroyed such bacteria, but is still endeavouring to establish the connection between frequency and lethal effect. At Cambridge, Pinkerton is obtaining valuable data about the construction of liquids by observing the effects of the passage of ultrasonic vibrations through them. He has already established that cavi-tation-the formation of liquid vacuums-may be caused. This may be a very valuable line of investigation, for it has long been known that cavitation in water may cause the eventual break-up of ships' propellers. That, in outline, is some of the story of ultrasonics to-day. No one can say yet what its ultimate possibilities may be; but there can be little doubt that it is a development of first-rate industrial importance.

## Television Policy

The official statement on television policy in this country struck me as being eminently sound. Some people, I know, had been shy about investing in television receivers because of tales they'd been told by the irresponsible and not very knowledgeable about amazing improvements - big-screen, colour, stereoscopic images and the likewhich would shortly render all present sets obsolete. It was no use telling them that such rumours were utter nonsense; they just smiled politely and didn't believe you. The official announcement that 405 -line transmissions are to be continued for many years should put an end to silly talk of that sort. One hopes it will; but human nature being what it is, the people bursting with completely incorrect "inside information" will no doubt get busy again sooner or later. Lots of folk either don't or won't realize that if, say, colour television were perfected to-morrow, transmissions couldn't be made from B.B.C, stations for some years; it takes a long time to build and install new apparatus nowadays, as the history of the Sutton Coldfield station
shows. In any event the receivers for colour transmission would probably be much more expensive than those now in use. It would be a case of twopence coloured, penny plain, so to speak. I fancy that the penny plain 405 -line receiver will be good enough for most people for a long time to come.

## Proving the Pudding

I'm Not sure of the frequency range claimed for the best of the U.S.A. television receivers; nor do 1 know to which their normal tolevision receivers respond adequately But I'm open to wager the shreds of my last prewar shirt that it must take them all their time to get more out of 525 lines than we do out of 405. I admit that I wouldn't hazard even the rags of that prized and irreplaceable garment if I weren't more or less betting on a certainty. American friends who watched events in the Olympic Games on television screens here have been lost in admiration of the steadiness and clarity of the pictures and of their depth of focus. Two other items of interest also came my way from these good friends. The first is that from the home entertainment point of view our television programmes are in the main better than theirs. Like broadcasting, television must consist over there mainly of sponsored items; I gather that Big Business is proving a little coy about taking television to its heart as an advertising medium, and that the quality of the programmes suffers accordingly. There is a surfeit of boxing and of baseball matches and so on and a sad deficiency of matter of general entertainment value. The second item is more or less a consequence of the first. Though the number of televisors in use in the States runs a good way into six figures, comparatively few of them are in private homes. The larger proportion is to be found in bars, restaurants, " hot dog stands" and so on. Some thinking Americans, I'm told, are convinced that the sponsoring system is not at all likely to provide the right sort of entertainment and are trying to find some way of making the programmes more or less independent of advertising by getting the viewer to pay for his fun by means of a receiving licence of some kind or through a subscription service.

SEMI-ROTARY TYPES:

## Guaranteed

## Switch On

Reliability with Bulgin Rotary switches for all needs up to 750 peak Watts, at up to 250 V . Guaranteed life tests of 25,000 operations at full load--SEVENTY TIMES EVERY DAY FOR A
YEAR! A type for every purpose, and new types as new purposes appear. Over 400 types of switches available.

## A Selection of the More Interesting Radio Developments

## Wide-band Aerials

T() be suitable either for frequencymodulated signals, or for television, an aerial should be sulsstantially aperiodic over a band of frequencies covering a ratio of at least two to one. A common expedient is to

use radiators of relatively large diameter, but this is not always convenient.

The desired impedance characteristic is also possessed by certain directional types, such as the Beverage and rhombic aerials, though at the expense of some power that is lost in the surge impedance by which they are terminated. The thin wire aerial shown is of this type, though it is modified to have ant omni-directional radiation pattern, similar to that of a dipole. The two co-planar "loops" or radiators A, B are fed at one side by a two-wire line $l$, and are connected at the other side by a transmission line $T$ to a matched dissipating resistance $K$, which is preferably located some distance away and at ground level. The aerial is stated to be the equivalent of a "rhombus of zero apex angle."
Standurd Telephones and Cables, I.td., and W. L. McI'herson. Application dute, May 25th, 1945 No. 594ino

## Scanning Beams

AIR()TMTING beam acrial, particularly suitable for radar, includes a parabolic reflector which is sprayed with primary wave energy from the slotted and tilted end of a waveguide. The waveguide terminates at a point which is located below both the horizontal scanning-plane and the principal axis of the paraboloid, so that it is also offset from the focus.

The arrangement reduces undesired secondary reflection effects and consequent clistortion of the radiated and received fields. In particular, it avoids the production of large side lobes of energy and prevents the so-called
"polarization splitting" common to horizontal scanning systems, where the linearized waves tend to break up into quadrature and so produce a circularly or elliptically polarized leam.

W'estern Electric Co., Inc. Contenfion date (U.S.A.), Nov. 6th, 1943. No. 595724.

## Aerial Systems

THE diagram shows how two separate aerials are grouped together for the simultaneous transmissions of two broadcast programmes on different wavelengths without mutual interference. One aerial is an insulated mast $A$, which is connected in any suitable way to a first transmitter (not slown). The second aerial consists of four radiators $\mathrm{Br}, \mathrm{B}_{2}, \mathrm{~B}_{3}, \mathrm{~B}_{4}$, supported by triatics which are arranged symmetrically around the centre mast, as illustrated by the two different aspects shown in the drawing.

The radiators of the second aerial are transformer-coupled to a second transmitter through a line comprising phaseshifting networks P1, P2, which respectively introduce a lead and lag of 45 deg. The diametrically opposite limbs BI and 132 are accordingly fed in phase opposition, whilst the currents in adjacent limbs (such as $\mathrm{Bi}_{1}$ and $\mathrm{H}_{3}$ when viewed in plan) are in phase quadrature. The currents induced by the

central mast $A$ in each pair $\mathrm{Br}, \mathrm{Hz}$ and $\mathrm{B}_{3}, \mathrm{H}_{4}$ of the outer aerials will be in phase, and will therefore cancel at the terminals of the second transmitter. The symmetry of the arrangement preserves the normal radiation pattern of both the aerials.

The Brilish Broadcasting Corp. and II. L. Kirke. Application date. Feb. 13th, 1945. No. 5906 29.

## Reducing Interference

THE signal is first divided into two equal but oppositely phased counterparts by passing it through a phase splitter. An electronic switch then feeds an element, taken alternately and
progressively from each of the two counterparts, to the modulator, so that the signal when radiated is "chopped " and alternately reversed in phase.
At the receiving end, the frequency imposed by the high-speed switch is first filtered from the carrier, and is applied through a separate channel to drive a similar electronic switch at the same frequency. This is used to reverse the phase of alternate sections of the rectified signal, and so restore it to its original form.
Any jamming or similar interference picked up by the receiver will also be "chopped" and reversed in phase. But, unlike the signal, the choppers elements are combined in phase opposition, and so cancel out. Suitable filter circuits are provided to protect the sound reproducer from the switching frequency.

Standard Telephones and Cables, Itd. (assignees of N. H. Young, Jr.). Convention dute (U.S.A.), April 16th. 1932. No. 594235.

## Programme Selection

A RECEIVER can be set to reproduce only specially selected items from the daily programme of a given broatdcasting station, provided each of the transmissions from that station is preceded by a pulsed identification signal and is followed by a pulsed "signing-off" signal.

These control signals, preferably supersonic, are filtered out in the receiver and applied to operate the selecting relay through a triggering circuit, which includes a cold - cathode discharge tube. The relav is of the stepped switch or telephone tvpe, and is set each morning by inserting plugs into num.bered apertures corresponding to the selected items. When the same contacts are bridged from the rear, by a wiper operated by the preliminary identification signal, the heaters of the A.F amplifiers are switched on, so that
the inconsing item is
heard. The relay is reset to zero by the "signing-off" signal, and the receiver remains mute until the transmission of the next pre-selected item.
Electrical Components, Ltd., and W'. Sommer. Application date, June 15th, 1945. No. 595805.

## SUMER IS YGOWEN OUT

but not before many of our more distant friends at home and abroad have come to see us while on holiday in London, or trying their strength at the Olympic Games.

Hartley-Turner enthusiasts are drawn from all walks of life, but have the bond of a common interest in good music. Our equipment gives them the results they need for the enjoyment of this most pleasant recreation, and judging from the volume of business we have done in the height of summer-even greater than that in the depths of winter-they seem to think so too.

We have no epoch-making plans for the forth. coming " season " beyond a steady determination to make better goods for better service. If you have not been in touch with us send for our data sheet catalogue to-day, and above all read " New Notes in Radio," a complete non-partisan guide to high-fidelity reproduction. We have secured a supply on cheaper paper and pass on the saving to you. Whilst this small reprint lasts we shall be glad to send you a copy for $2 / 6$ instead of the usual price of $3 / 6$, but supplies are limited and you should write soon.
H. A. HARTLEY CO. LTD.

152, HAMMERSMITH RD., LONDON, W. 6 RIVerside 7387.

## PEERLESS

TYPE 1047 RADIO CHASSIS
This chassis is now available as an $A C / D C$ model, and can also be supplied as a complete Radio Gramophone with twin speakers, Radio Gramophone with twin speakers, acoustic labyrinth, etc. in wanut
one of Britain's leading designers.

Among its principal features are:-

- Io stage superhet circuit.
- Io valves (including magic eye).
- RF amplifier.
- 2 IF stages.
- 4 wave bands
- Io Watts push-pull output.
- Tropicalised components.

Communications enthusiasts should write for details of our 1546 Chassis.

## COMMUNICATIONS RECEIVERS

A 10 valve receiver for use on $100-124 \mathrm{mcs}$, and adaptable for 144 mcs. Excellent A.G.C., and frequency stability. A local osc. gives audible beat when receiving unmodulated carrier wave. Receiver consists of a signal frequency R,F.amp Rellowed by a frequency changer with osc. valve, followed by a frequency changer with osc. valve,
3 I.F. amp stages, double diode det. and A.G.C., 3 I.F. amp stages, double diode det. and A.G.C.s
rect. and 2 stages a.1. amp. BFO included to switch into detector circuit. Functions from A.C. mains (200-250 v.) in conjunction with a separate power pack. Valve: I each $\mathrm{P}_{4} 1$, 7475, EB34, EF32, 6J5G, 2 of SP4I and 3 of EF39. Output impedance 600 ohms, but satisfactory $200+2,000$ ohms. Supplied with circuits and calibration chart. The power pack operates from 200-250 v. A.C. with a switch controlling input voltages. Output 220 v., $70 \mathrm{~m} / \mathrm{a}$ D.C. and 6.3 v. $4-5$ amps A.C. Meters $70 \mathrm{~m} / \mathrm{a}$ D.C. and 6.3 v. $4-5$ amps A.C. Meters measure output voltage and current. Receiver
dimensions 1 gin. $x$ 10tin. $x$. $10 \frac{1}{2}$ in. and the power pack igin. x yin. $x$ iolin. We can offer alternatives as detailed :
Brand new Receiver (Ri132A) with brand new Power Pack (Type 3) in cases. The pair for f7/19/6, (cafr. and pkg. ©1). Receiver only 67/19/6, (carr. and pkg. 1.1 . Receiver only 6.4/19/6, (carr. and pkg. 10/-). Power Pack only,
$6,3 / 10 /=$, (carr. and pkg. 10/-). Slightly soiled Receivers in cases $£ 3 / 9 / 6$, (carr. and pkg. 10/-).

## Mr. A. C. BARKER'S MODEL 148 SPEAKER

is finding much favour amongst sound recording engineers as a monitor, since its command of the sharpest transients and most complex passages reveals details not otherwise apparent. The secrets of this clear cut highly damped response lie in the coil and cone. both of which employ Mr. Barker's exclusive patents.
Model 148 is a laboratory, hand made 12 inch Speaker for those who seek true NATURAL sound. Mr. Barker also invites enquiries from professional users, builders, designers and retailers of the highest quality sound equipment who may be interested in limited numbers of his Model 148.

Armstrong

## BETTER LISTENING

Armstrong have always made "better listening "a first consideration, and for over 12 years have fitted high quality pushpull output to practically all models.
Armstrong chassis described below come in this category.

## Model EXP125. 14-VALVE ALLWAVE RADIOGRAM CHASSIS

giving continuous waveband coverage from 11.9 m . upwards. Waveband expansion. R.F, Pre-amplifier. Two l,F. stages with variable selectivity. Electronic bass and
treble lift controls, 15 watt push-pull treble lift controls, is watt push-pull
output. For $200-250 \mathrm{v}, \mathrm{A} . \mathrm{C}$. mains.

Model RF103. 10-VALVE ALL-WAVE RADIOGRAM CHASSIS
IO-valve circuir. R.F. Pre-amplifier. Waveband expansion (Short waveband covers over 20in.). Large glass scale. 3 stages A.V.C. Treble lift cont,ol (operates on both radio and gramophone). Plus 6 db . Bass lift on Gramophone (to restore bass cut on some records). 10 watt push-pull output For 200-250 y. A.C. mains. Price 19 gns. Plus Tax.

## Model EXP83. 8-VALVE ALLWAVE RADIOGRAM CHASSIS

incorporating waveband expansion. Large glass scale. Treble boost control, Gram. switching, High quality push-pull output gives 10 watts audio. For $200-250$ v. A.C. mains. Price EI5. 8, 8. Plus Tax.

## Model UNI-83. <br> 8-VALVE ALLWAVE RADIOGRAM CHASSIS

incorporating waveband expansion, e.g. the $16-50 \mathrm{~m}$. band covers just over 20 inches on the large glass scale, treble boost control, gram, switching, all control. work on both radio and grim., high quality push-pull output giving 6 watts audio. For $200-250 \mathrm{v}$. D.C. or A.C. mains. Price £15. 8. 8. Plus Tax.

## HOME MARKET

Alimited quota of the above is available to our friends at home, and we shall be glad to send details and to give demonstrations at our showrooms.

## Radio Mains Supply Equipment

By E. M. Squire

A useful guide to the principles of design and operation of the mains supply equipment. Practical radio engineers, mechanics and operators, as well as radio students, will find this up-to-date book invaluable in dealing with faults in the supply equipment. Illustrated. 12/6 net.

## TELEVISION \& OTHER

## HIGH VOLTAGE APPLICATIONS

This well-known range of high voltage condensers is now processed with a new impregnant-"Visconol," a highly viscous mineral oil, the development of which has been dictated by the increasingly stringent operational conditions to which modern equipment is subjected. Among the advantages provided by this new process are:-adequate voltage rating, low power factor, stability of dielectric, and power to withstand sharp-front short-time fleeting surges. The mechanical construction and uniquc sealing technique renders them normally impervious to breakdown or flashover. T.C.C. "VISCONOL" Cathodray Condensers should be first choice where exacting conditions are likely. List No. 132, showing a full and comprehensive range is available on receipt of $2 \frac{1}{d}$. stamp.

CAPACITIES FROM 0.0005-I MFD.

VOLTAGE RATINGS FROM 750-25,000 D.C.

LGS CONDENSERS . . . A PRE-REQUISITE TO "BETTER LISTENING."
