THIRTY FIVE CENTS
UBLERDAY, DORAN & CO., INC. • GARDEN CITY, NEW YORK
WHETHER in cartons or carloads, you will find TRIAD quality absolutely uniform! UNIFORM because the complete materials for TRIAD Tubes (except glass and base) are made right in the TRIAD plant; UNIFORM because the manufacturing process, from first to last, is personally supervised by world-famous radio engineers; UNIFORM because TRIAD Tubes are subjected to nine exhaustive tests for vital characteristics before ever reaching the packing department—and even there they are sorted for uniformity and again inspected before shipment! Even the testing machines themselves are made by the TRIAD Company, and are built to the U.S. Bureau of Standard Specifications. TRIAD Tubes are "honor-built"—throughout! That is why TRIAD alone can insure every tube for six months' perfect service—and it is exactly the reason why you can win (as thousands of other dealers are now doing) far greater tube sales and profits with TRIAD than you have ever enjoyed before!

Call your jobber or write us direct for complete TRIAD dealer information.

TRIAD INSURED RADIO TUBES

Above is shown TRIAD T-24—Screen Grid Tube for AC use.

Tune in on the "Triadors"—every Friday evening 8 to 8:30 Eastern Daylight Time—on WJZ and associated NBC Stations.
The only complete portable radio testing laboratory

THE SUPREME DIAGNOMETER is recognized by every radio engineer and technician as the most complete, thorough and efficient testing apparatus ever devised. Complete in every detail, yet surprisingly simple. All service can be performed so easily and quickly that the cost of servicing is negligible compared with antiquated methods, and returns to distributors or factory for repair or adjustment are completely eliminated. "Scientific Analysis" is substituted for "Guesswork" and "Experimentation," insuring the perfect results that create enthusiastic customer satisfaction and good will.

Tube Testing Plus

The only dependable test on all tubes, including screen grid. Tests each plate separately of '80 type rectifiers. . . . An exclusive feature of prime importance. Tubes tested under actual working conditions, revealing every possible deficiency, many of which cannot be determined by any other service instrument or tube checker.

Screen Grid Analysis, etc.

Accurate screen grid analysis without producing oscillation in the set.
Synchronizing by thermo-couple meter or A. C. meter. Easy and accurate; the same method almost universally employed in factory practice.
Neutralizing external connections to all apparatus.
All continuity tests without the use of batteries.

THE DIAGNOMETER'S COMPLETENESS, RANGE AND FLEXIBILITY WILL PROVE ASTOUNDING. Write for the chart, "A Test That Challenges Attention."

Order Now

Present production permits immediate deliveries but the momentum of sales is such that buyers are cautioned to place their orders now. Reservations will be made against all orders placed for future delivery on specified dates. Make use of this plan to avoid disappointments.

"Set Testers" prove only 29% to 40% efficient in comparison with the SUPREME DIAGNOMETER

Supreme Service League

TO RADIO OWNERS:

Look for this emblem in your radio shop, on the lapel button or card of your service man. It is your guarantee of dependable radio service.

Most good distributors carry the SUPREME DIAGNOMETER in stock. If yours cannot supply you, send direct on form to the right.

THE NEW MODEL 547 Radio Set Tester

- saves time
- simplifies testing
- increases sales

SERVICE men remember the time when radio set testing required hours of time and satchels full of equipment. The Model 537 reduced radio set testing to its utmost simplicity and made servicing a profitable business instead of a necessary evil.

NOW — Model 547 — for A. C. and D. C. Receivers meets the service testing requirements of radio's latest developments, even taking into account the number of new tubes, sets, and circuits. Handsome in appearance, it is light, but rugged, convenient and complete.

Provided with three instruments, carrying case, removable cover, panels and fittings of sturdy bakelite.

A. C. Voltmeter — 750/150/150/84 volts. Only one selector switch is necessary.

D. C. Voltmeter — high range increased to 750 volts. Other ranges — 250/100/50/10/5 volts.

D. C. Milliammeter — double range 100/20 M. A. provides for lower readings with better scale characteristics.

Tests — On A. C. sets the heater voltage and plate current can be read through the test while the D. C. voltmeter may be indicating plate bias or cathode voltage.

Self-contained, double-sensitivity continuity test provided. This can also be used for measuring resistance as well as testing for open circuits. Grid test can be made on A. C. or D. C. screen grid tubes also the '27 tubes when used as a detector — without the use of adapters. Two sockets on the panel — UY tube adapters eliminated.

WRIGHT DE COSTER, Inc.
ST. PAUL, MINNESOTA
The most perfect detector made —
that's why SPEED 227's cost more for us to make, but not for you to buy.
Burn-out proof! Fast heating — 5 seconds flat (not by words — by test!)

New? Not to us. In production in 1928 when demand was only experimental. While others have been announcing, we have been improving. That's what foresight and tube-making experience were able to do.

The SPEED Tube line is, of course, complete*. But these are the "Big Three" now — the ones you're interested in particularly, because they're the ones your customers want. Carry the quality 227's, 224's, 245's, — SPEED — and your tube business is assured.

The SPEED proposition demands the consideration of every wide-awake jobber and dealer as a matter of good business. Work fast — write at once — franchises are going fast.

SUPREME!
in everything that counts in an Electric Pick-up

SALES-PRODUCING features — engineering leadership, correctness of design, precision manufacture, and a resulting magnificence of tone — you get them all in the newest, finest Webster Electric Pick-up!

What a profitable success it has been for dealers everywhere. The few weeks since its introduction have proved this irrefutable fact:

The public wants Webster's product!

They recognize the Webster Electric Pick-up as a perfect medium for the true reproduction of music in any form.

These Features Make the Webster Supreme

1. The famous Webster Low-切入ity stylus bearing, utilizing an all-metal pivoting action, eliminates necessity for bulky construction. Positively no rubber on bearings. Perfect balance is insured.

2. The Webster Pick-up head is small and compact, perfectly balanced, light in weight. Weight of head on record only 4½ ozs. No counterbalancing or springs necessary.

3. Highest grade Cobalt magnet of greatest possible density is used.

4. Shock-absorbing arm bearing with pivot at base — an exclusive Webster development.

5. Unique method of turning head with arm to conveniently insert playing needle.

6. Volume control incorporated in base — compact and easiest to install — an original Webster feature.

7. Base is weighted. Can be screwed to motor board or merely set in place.

8. Cord completely concealed — all bearings free from play and chatter.

9. Construction lends itself easily to use of varied lengths of arm for either standard or talking picture records.

Accurate, life-like interpretation of instrument or voice, in soft whispers or crashing crescendos, determines Webster selection in every comparison.

Webster tone is the logical result of the Webster features listed below. Collectively, they represent the highest pick-up development in the sound-reproduction field.

The new Webster Pick-up is available in two models, each for either battery-operated or A.C. sets. Both models are packed in attractive self-selling cartons — if your jobber has not stocked the Webster, order direct.

The New Webster Model 2A includes Pick-up head, supporting arm, built-in volume control and adapters.

The Webster Electric Theater Pick-up

This special model is offered for use with 10" records operating at 33 1/3 R. P. M. An adjustable counterbalance makes it possible to correctly control the weight on the record. Provisions are made for mounting of base with rubber bands to obtain vibration-free mounting. Standard length from needle point to center of base is 12", but shorter length may be specified. Finished in instrument black.

Model 2D—Standard Impedance Head List $21.00

Model 2D-1—Low Impedance Head (200 ohms) List 10.00

Model 2D-1 can also be furnished with an impedance matching transformer at $7.50 extra.

Only the BEST is Good Enough for The FREED RADIO

A Resistance Unit that embodies an entirely new development in construction—the only doubly-insulated, moisture-proof, wire-wound, non-inductive accurate resistor. Its screw terminals permit its instant use in any type of circuit and in any convenient manner as well as in standard grid-lead mountings or fuse-clip mountings or by soldering.

The SUPER AKRA-OHM besides containing all these unusual features has a very low temperature coefficient, a minimum distributed capacity made to dissipate one watt but will stand an overload without injury. Type 6-111 has a tolerance of accuracy of approximately 1% plus or minus. Closer tolerances made on special order.

Complete stock of all values enables us to make immediate shipments. Full information and prices will be furnished promptly on request.

There are many makes of resistance units—but only one DURHAM—the Resistors and Powerohms which are used by leading quality receivers. Freed Radio could cut the cost of their resistances by a small fraction, but their engineers, their dealers, their jobbers and their ultimate consumers get added value in finer reception because FREED RADIO RECEIVERS use Durhams. The presence of Durhams in a receiver is a guide to the quality of all other parts.

We shall be glad to send engineering data sheets and samples for testing upon request. Please state ratings in which you are interested.

With EVEREADY RAYTHEON 4-PILLAR Tubes, you can get the MOST from your present radio receiver

PEOPLE in all parts of the country are telling of the greater power, increased distance, improved tone, and quick action of these remarkable new tubes. The reason is that Eveready Raytheons are built stronger — immune to the bumps and jolts of shipment and handling. They come to you in as perfect condition as when they leave our laboratory test room.

The Eveready Raytheon 4-Pillar construction is exclusive and patented. Examine the illustration at the bottom of this page. See how the elements of this tube are anchored at eight points.

This is of particular importance in tubes of the 280 rectifier and 224 screen-grid type which have heavier elements, and in tubes used for push-pull audio amplification, where uniform characteristics are most essential. Eveready Raytheon 4-Pillar Tubes come in all types. At your dealer's. He also has the famous B-H tube for “B” eliminator units.

NATIONAL CARBON CO., INC. General Offices: New York, N. Y. Unit of Union Carbide Corporation

Eveready Raytheon Screen-Grid Tube, ER 224. Without Eveready Raytheon’s 4-Pillar construction, this type of tube is delicate, liable to severe damage in shipment.

SHOWING the exclusive, patented Eveready Raytheon 4-Pillar construction. Note the sturdy four-cornered glass stem, the four heavy wire supports, and the bracing by a stiff mica sheet at the top.

PUBLISHED FOR THE RADIO INDUSTRY

VOL. XV. NO. 5

... among other things

THE many readers of this magazine who are
interested in the selling of radio and all that
pertains to it have welcomed the division of our
articles into the two distinct sections of the
magazine. The Merchandising section of Radio
Broadcast contains interesting and useful informa-
tion about selling problems as they are and as we
would like them to be. It happened that in our
August issue, wholesalers and retailers from many
different parts of the country found a number of our
articles notable enough to request reprints. These
were gladly furnished and it is our hope that they
were of help in the merchandising of radio—a con-
tinual problem of this industry in which Radio
Broadcast is primarily interested.

THOSE primarily interested in radio selling will
find the issue now before them of more than usual
service. A successful house-to-house selling plan is described in the story beginning on page 253;
comments on deferred payments selling are helpfully
made by G. S. Corpe (page 256) who has been on the
firing line for years; Howard Dickinson, a merchand-
ising authority of national reputation, discusses
trade gossip and its evils (page 256); the annual
behavior of tube sales are detailed on page 260—
and interesting information it is too; and B. H.
Darrow, who has been associated with schools for
many years, outlines the size of the radio school
market (page 263).

THE October Radio Broadcast will present
many short articles on the most useful sales
ideas, tested in the furnace of practical experience,
a discussion of the best means of advertising a local
radio shop, a consideration of the merchandising
plans for the current year to meet new problems,
and many other articles written from a practical
background.

THE technical section will contain a description,
published for the first time anywhere, of the
new Stromberg-Carlson automatic volume control
set, an engineering discussion of the British pentode
tube (about which we are going to hear much more
in this country as the months roll by), and an
unusual article on detection problems by a tube
engineer of national repute. These articles are all
in addition to the regular features which regularly
appear and which have become so popular.

—Willis Kingsley Wing.
will you trust your ears?

By the only standard which gauges sales success—the ears of the purchaser—the T·C·A Dynamic is a better speaker.

T·C·A’s claim for superiority does not hang on the slender thread of a detail here or a detail there. It does not hang on an obscure characteristic of only academic interest.

It hangs on a definite and perfectly apparent tone value that impresses itself not only upon the critical ear of the engineer, but upon the unpracticed ear of the ultimate layman who buys the set.

After all, the most important function of a speaker is to faithfully reproduce the broadcast program.

It is this characteristic that sells the set and pays the dividends.

As audio amplification specialists, the T·C·A organization is at your service. The T·C·A Dynamic is, however, only the final step in the audio series.

The precision, uniformity and tone quality of the audio transformers and chokes are by no means a secondary consideration. Nor can a noisy, humming power-pack be corrected by any companion parts. Like the links in a chain, each successive unit from the power-pack to the speaker must carry the responsibility for perfect reproduction. T·C·A parts are meeting this responsibility squarely in many of the finest and most popular sets on today’s radio market.
BECAUSE of the PAM installation no one need stand or be turned away for lack of seats at the Second Church of Christ, Scientist, Boston, as long as there is a seat available in the Sunday School Room or other parts of the church.

Every word of the speaker is picked up by microphone and PAM amplified for the loud speakers, which deliver it crystal clear to the overflow assemblages.

Every church or parish house is a logical prospect for PAM equipment for this or entertainment purposes, and every radio dealer should see to its installation.

A new 16-page bulletin giving mechanical and electrical characteristics, representative installations and many new PAM amplifiers will be sent upon receipt of 10c in stamps to cover postage. When writing ask for bulletin No. R.B.-10.
How Two Young Men Built Up a Paying Business in New York City

TER EIGHTEEN months of experience, a small but active organization in New York City has proved to its own satisfaction that the principle of house-to-house canvassing, so successful in selling washing machines, vacuum cleaners, and other electrical appliances, can be applied to radio receiving sets with profit. Furthermore, the two men behind Reynolds Radio, Inc., of 130 West 42nd Street, New York City, have found that when properly modified and amplified to fit the particular needs of the trade, the house-to-house method of radio sales has produced greater profits than can be expected from the less intricate and supposedly more stable appliance lines.

The two men, K. L. Saunders and Herman Resnick, started on January 1, 1928, with what Mr. Saunders describes as “two salesmen, ourselves, and an idea.” The two salesmen were good, Saunders and Resnick had worked successfully together in managing a direct-to-consumer washing-machine business, and the idea seemed to have a few more advantages than disadvantages.

Disadvantages of Plan

The disadvantages which militate against a house-to-house selling business in New York City are more numerous in the radio trade than in any other, especially so since Saunders and Resnick decided to confine their efforts to Manhattan and the Bronx. There are almost as many radio stores in those boroughs as there are drug-stores. The New York newspapers carry more radio advertising of retail shops than do the papers in any other city, and a large proportion of those shops are cut-price stores. Furthermore, house-to-house selling is of necessity a time-payment business, and with one-third of New York’s population “transient,” and one-quarter of the “permanent” residents addicted to moving to new addresses on every October 1st, the possibilities for lost sets and untraceable debtors are large.

The Advantages

To offset those drawbacks, Saunders and Resnick figured that the all-electric set has a greater appeal to apartment dwellers than it has to house-owners, a greater appeal to the always-busy New Yorker than to the suburbanite who has long evenings in which to tinker over his own concoction or keep his old set in good condition. They balanced the possibilities of absconding debtors against the natural honesty of human nature and the highly developed credit statistics available to all New York merchants through the credit associations. And they knew that a radio set is a luxury, and that people will buy luxuries for the home far more readily than they will buy such efficient labor-saving appliances as washing machines.

At the end of the first year, they had a force of fifteen salesmen, had done a gross business of $157,000, and cleared a net profit of $15,000, or 15 per cent. And they had found some very interesting facts.

"From the beginning, we handled only one line of sets. We have found that our policy has more than justified itself. Our salesman know the set thoroughly, and have confidence in it. The customer feels that if we didn’t think it was the best set, we wouldn’t be banking on it to the exclusion of others."
And by handling only one line, our service problem is simplified, and we are sure that our servicemen can give expert work and satisfaction. Once the set is installed and has been serviced, subsequent complaints can often be handled over the telephone. At the present time, we are giving service satisfaction by telephone in about 20 per cent. of our complaints, since we can diagnose the trouble from the customer’s description."

"We never let a repairman work on the interior of a set in the customer’s home, where the customer can see him fiddling around with a soldering iron or puzzling over a diagnosis. We pull the set right out, replacing it with a good set. In many cases, we leave the loaned set there permanently, and, after the other set has been reconditioned to our satisfaction, we treat it as a new set. Our follow-up service system assures us that there will be no dissatisfaction from the purchaser of the set, since if we can’t recondition it properly we discard it," Mr. Saunders explained.

The operations of the interference-elimination department can be shown by one incident, where the cost to the customer ran to the unusual total of $127.50. The usual cost varies from $7.50 to $20. The customer was a wealthy man, living in a large cooperative apartment. He had never been able to get a radio set that suited him, because no dealer could eliminate the house interference. The Reynolds man went to work, and before he was through he had to take care of interference from six elevators, five service pumps, and eight electric ice-boxes. The customer was more than pleased, paid the cost of materials gladly, and, as a result of that work, the salesman was able to place two other sets in the same apartment.

In several apartments, where house interference had made radio reception virtually impossible, the salesman have arranged with four, six, or eight prospective customers to share the cost of eliminating the interference, and in every such case each prospective customer signed a sales contract gladly as soon as the interference was removed.

**Quoting Prices**

The Reynolds salesman always quote the final price to the prospective customer. They are not permitted to use the "less tubes" or "less speaker" quotations. The price given the customer at first approach is the price he will pay for the set complete, installed, and in actual operation, unless there is an interference-elimination charge.

Frank confession of previous troubles in "bad" areas is also a first tenet of the Reynolds sales policy. No set is sold without actual trial in the location where it will be used, and in some cases sets are removed against the prospective customer’s wishes.

"We’ve found that if the set doesn’t function to suit our servicemen’s standards, there is no sense in leaving it there, even though the customer says he doesn’t mind the interference or the other deficiencies. Sooner or later, the customer will mind them, and then we will be in for more service trouble than the sale is worth. Sometimes, of course, if the customer insists that he wants the set and is willing to forego the guarantee which we won’t give him, the set is sold. There was one
case like that, a man who lived in the same building with a beauty parlor. We couldn't eliminate the interference, we tried three different types of filters without getting results that suited us, and finally we told him we couldn't give him the kind of radio service we insist on giving, so we took the set out. A few weeks later, he came in, said he missed the radio, and bought the set because, even with the poor reception he got, he liked it," Saunders said.

Service within twenty-four hours of every complaint has been a fixed rule of the company ever since it started. That service is possible because of the accessibility of all of the company's customers, the boroughs of Manhattan and the Bronx being easily divided into service districts.

Repossessions, or charge-backs, sets which have had to be removed because the customers failed to pay up their installments, amounted to 2 per cent. of the gross business in 1928, and will be smaller in the future because of added safeguards now taken by the company. One thing that the Reynolds company learned during its first year was never to install sets on trial just before an important prize-fight, election, or other major broadcast attraction. The rule now is that no sets are sent out on trial on the two days preceding such events.

"Ninety-five per cent. of the repossessions were due to outside misfortunes which made it impossible for the customers to continue payments, and are the natural hazards of installment selling. Many of those repossessions, however, were transferred directly to friends of the original customer with the service guarantee still in force," said Mr. Resnick. "Less than one-half of one per cent. of our sets were stolen by customers moving away before their payments were completed."

In the accompanying table are figures of sales and general expenses for the year 1928. These will make interesting comparison with those of retail store dealers in the same area. The figures are not completely reproduced here, only the more important and unusual items having been selected. Office salaries were about $5,000.00 larger than necessary during the first year of operation (1928), owing to what Mr. Saunders calls "our experiments and inexperience." They will be considerably lower than the 1928 figure this year, despite the expansion of the business.

### HOW RETURNS AND ALLOWANCES VARY WITH VOLUME OF BUSINESS

**The preliminary report on the National Retail Credit Survey, recently released by the Domestic Commerce Division of the Department of Commerce, includes statistics on the percentage of bad debts on open and installment credit sales for department stores, automobile dealers, and independent retail grocery stores reporting by April 13, 1929.**

The open credit loss, in the case of both department and grocery stores, was found to vary inversely with the size of establishments, i.e., the larger the store the smaller the proportion of open-credit loss. No such relationship was found between the size of department stores and their installment-credit losses.

The average loss for the 440 department stores reporting, representing the ratio of total bad debts to total open and installment credit sales, was 0.4 per cent. on open-credit accounts and 1.1 per cent. on installment accounts. Chain department stores had an average loss on open-credit sales of 0.8 per cent. and on installment sales of 1.3 per cent. compared with 0.4 per cent. and 1.0 per cent. for other department stores.

The 339 automobile dealers, on the other hand, lost less on their installment accounts than on open-credit sales, bad debts representing 0.4 per cent. of installment credit and 0.9 per cent. of open-credit sales.

The percentage of bad debts on open-credit accounts for the 843 grocery stores doing cash and credit business was 0.6 per cent., the range being from 4.9 per cent. loss for stores with total sales under $9000 to 0.4 per cent. for stores with total sales of $250,000 and over.

### VALUE OF CREDIT INFORMATION

The data collected in the study of credit conditions among Louisville retail grocery stores showed that, as a rule, the credit stores which used a credit bureau had a lower percentage of bad debts than those which did not. The difference is brought out by the following table:

<table>
<thead>
<tr>
<th>Volume Group of Stores</th>
<th>No. of Stores</th>
<th>Average Bad Debt Losses</th>
</tr>
</thead>
<tbody>
<tr>
<td>With Credit Bureau</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Without Credit Bureau</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Under $5000</td>
<td>10</td>
<td>9.4%</td>
</tr>
<tr>
<td>$5000 to $9999</td>
<td>9</td>
<td>5.5%</td>
</tr>
<tr>
<td>$10,000 to $24,999</td>
<td>9</td>
<td>3.9%</td>
</tr>
<tr>
<td>$25,000 to $49,999</td>
<td>52</td>
<td>1.7%</td>
</tr>
<tr>
<td>$50,000 to $99,999</td>
<td>25</td>
<td>1.1%</td>
</tr>
<tr>
<td>Over $100,000</td>
<td>10</td>
<td>0.3%</td>
</tr>
</tbody>
</table>

Retail radio dealers who are not using credit information available to them through their local Merchant's Association credit bureau should investigate the cost and compare it with the cost of doing without it. It is especially interesting in examining these Louisville figures to note that the most severe losses were not in the largest volume stores but those doing less than $10,000 annually.
THE DEALER

and the
FINANCE COMPANY

By G. S. CORPE

YOU know, although all of us prefer other parts of our business, the financial side of it just must have at least a small portion of our attention and effort. Whether we like it or not, we have to mix in a little collecting of slow accounts with shooting bugs out of somebody’s hum radio; and we are forced to deal on our banker once in a while, along with our calling on prospects for a new model radio receiver.

Regardless of how much money a radio dealer may have, it seems to be the consensus that it is best to let a finance company handle and collect time-sale paper. And now-a-days, when 85 per cent. or more of our sets are sold on the monthly payment plan, what dealer has not a connection with some sort of a finance company? That is what we wish to talk about here—your relations, as a dealer, with a finance company.

It doesn’t matter much whether the party who handles your paper is a big million-dollar corporation, or just a well-heeled friend; there are certain things in connection with your relationship that deserve the same careful attention that your advertising, selling, or any other department gets.

Speaking broadly, the good old Golden Rule covers the subject. Don’t try any “fast ones” on your bank or finance company that you wouldn’t want to have tried on you, were your positions reversed. Handle every transaction with your financier just exactly like you would wish him to do for you.

If he asks that you get one-third down on all sets sold on contract, get one-third down. Don’t try to get by with a

*In the computation of these figures it was assumed that the unpaid balance plus the finance charge would be amortized in equal monthly installments.

**On an average, the unpaid balance is approximately 60 per cent. of the list price of the receiver, i.e., the usual down payment is 20 per cent.

[Assuming that the customer makes a down payment of 20 per cent., the cost of financing is indicated in this table. If a larger or smaller down payment is made it is necessary to determine the unpaid balance and then refer to the left-hand column.]
contract with only one-fourth down; and let's not try the old trick of "bubbling" the contract, so that it appears that the total price and the down payment are more than they actually are; finance people make it their business to have full knowledge of prices in all sets they will handle paper on.

If your financier asks that payments do not run longer than 10 months, make all your contracts that way. Don't bother him by asking him to make a special exception and take on a 12-month contract just because you know the buyer is good pay, or because he is a close friend of yours, or for any other reason.

Probably one of the most common causes for a falling-out between a radio dealer and his finance company is the failure to cooperate in making collections. The payments on radio paper are usually of such a small amount that the finance company cannot afford to be sending out a collector, and depends upon the dealer to take care of delinquent payments. The usual procedure is to send a past-due notice when the payment becomes five days delinquent; then another stronger one ten days after the due date; and usually a final notice five days later, or 15 days after the due date. The dealer gets copies of these past-due notices. And if he wants to continue to get along with his financier, he will get busy and find out why the payment has not been made—just as soon as he gets the first notice, and without letting a second notice become necessary. Don't throw that notice in the waste-paper basket and just hope the customer will pay soon; give it honest attention, right away. You will find that prompt collecting on any slow accounts will help you in more ways than one. It increases the respect of not only the finance company for you, but actually of the customer, also. And remember that a prompt follow-up may often save you from a serious loss.

Why a customer will sign a contract, setting forth payments on certain dates and then proceed promptly to forget it, is a mystery; but it seems to be human nature, which we cannot change; and the live-wire dealer will be right on the job reminding his customer and getting the money.

Advertising your ability to sell sets on monthly payments in a judicious way will often give you a profit that otherwise might be lost.

Nearly all finance companies have what is called a "road man". . . Here is your chance to get some valuable information. Talk over general business conditions with him.

A dealer's motto should be "Get the money, keeping the customer in good humor whenever it is humanly possible to do so. But if you have to do it, get him mad enough to pay".

is the main-stay, tell your customers that payments may be arranged to be met from their salary, each month, and on the date most convenient for them to pay. Or if you are selling to farmers where their money is received only from one or two principal crops a year, go to your bank and arrange to discount that type of paper, and don't be bashful in telling your farmer customer that you can put a radio in his home upon the payment of only one-third down and that you have arranged so that the balance may all be paid in one payment, when his crop is sold.

A successful connection that I have observed between a good dealer and a good finance company resulted in several hundred dollars additional profit each year. The dealer knew the finance company would "go the limit" with him; and in turn, the finance company knew that the dealer was absolutely dependable and that anything or everything he told them would always check up 100 per cent. With that common ground to work from, the dealer proceeded to sell successfully all kinds of radio accessories on small monthly payments; many of them on such small payments that the paper would be hopeless to sell, ordinarily. He sold complete sets of replacement tubes, instead of selling only the one which absolutely needed replacement; and he took as down-payment the price of the one necessary tube; the balance, of course, was covered by a contract and note with monthly installments. He sold dynamic loud speakers to people who had a good set but wanted a modern loud speaker; and he took their old loud speakers at a very low figure for the down-payments and got the balances in such easy installments that the buyers were not hurt at all. One of the most important things he did along this line was getting clear of old sets; all of us know how these will accumulate. But he moved them out at from $10 to $25 each, on mighty easy terms and his finance company handled the paper on them, too—because they knew he would get the money on every contract, promptly. Phonograph pick-ups, short-wave receivers, power amplifiers, and even amateur transmission equipment, were sold on the monthly payment basis. And, at the risk of boring you, let me repeat: the only way he was able to swing all this extra volume of business was through the implicit confidence his finance company had in him. Every dealer should conduct his dealings with his outlet for paper in the same manner, and with the same end in view.

I stated above that it probably is best to let someone else handle time-sale paper, even if you have enough money to (Concluded on page 289)
GOSSIP

IT IS REALLY a wonder that any industry ever settles into its stride. The men who make their bread and butter through a particular industry seem bound to keep the industry upset and themselves in a perilous state of uncertainty by the recklessness of their gossip. This would be easy to correct if it were not based on human nature. Gossip is a very human pastime.

Radio dealers want their business to "stay put" long enough to sell their stocks on hand, at least. But—"I hear that Manufacturer A is coming out with a set which utilizes the wind on the roof for power." Or "They tell me that ABC is about to go broke and their sets will be in job lot sales." Or "The Gyps have all the best of this business. I can't keep prices where there's a living in it." Or "We got stung by XYZ's advertising promises and stocked up and look what happened to XYZ." Or "Wonder how PQ gets away with it; he never made a good set in his life." Or "JZ is playing up to the big dealers and doesn't give the regular radio shop a look in," or worse and worse.

The Dangers of Gossip

Gossip in a new trade presents great dangers and a very difficult problem.

Actual news of the trade is very important. It is very foolish to shut your eyes to the facts of your industry. You should know them. And yet unrestrained gossip in an industry is a breeder of many evils. Here are some of them.

Fear or getting the imagination set upon the difficulties of your business. These things grow and grow in the imagination, and soon fear looms bigger than the hope of profit and growth. That is a condition which almost surely dooms a dealer to failure. It has many forms, such as fear to invest in necessary stock, lest it shall go stale; fear that a competitor will allow more on a turn-in and so you will lose the sale; fear that the industry as a whole is on the skids. Fear is not the frame of mind to carry one to success. Careless gossip is its breeder. Fear and Success do not ride in the same car.

Price Cutting. "Everybody's doing it." "Only way to compete with the big people." "This business just won't let you make a good living and get ahead." "So much new stuff on the market, no chance to move it all—then bang! Prices will go right under us and leave us carrying the bag."

There are insidious forms of price cutting, sometimes fostered by the very same manufacturer who should protect you. I have been offered an unbelievable "turn-in" allowance, provided I buy a certain high-priced set. The offer was $150 on any set I might turn in, even an old one-tube set. I was tempted to wrap some wire around a couple of old tin cans and see if I could get $150 allowance for that. I believe it would have been accepted.

How can I ever figure I am getting the bottom price on that expensive set? As a believer in reasonable performance in trade, I wouldn't have that set at any price, even if it were the most perfect reproducer on the market, and no matter how much it is advertised. Until it is priced reasonably, no dealer should be asked to carry it.

Uncontrolled gossip breeds distrust. This is shown in an
attitude of repulsion to ideas which may be profitable to you, but which you refuse because you think that maybe you are being played for a sucker. "Why is he so anxious to unload this thing on me? He makes it sound good, but how do I know there isn't a nigger in that woodpile?"

A dealer needs to buy well just the same as he needs to sell well. An over-suspicious attitude makes him a poor buyer both selectively and in the quantity he buys. It spoils his trade judgment and dumps him into just the hole he is trying to avoid.

Gossip in the retail trade spreads to the distributor and the manufacturer. Such gossip upsets them and injures the cooperative friendliness which should extend through all the parts of an industry. A salesman suspicious of the good intent of a dealer, working with a dealer suspicious of the manufacturer whom the salesman represents—that is an all too common picture and does not make a good background for a mutually profitable business. The only man who wins under those conditions is the Gyp, who has learned how to make a

**PRICE CUTTING**

profit out of being suspicious of everybody, and who has no good will to protect. He doesn't care a hang who is suspicious of him. Extravagant and foolish gossip plays right into his hands. He does not appeal to the quality sense, anyway. The price nerve is all he tries to excite.

**Customer Distrust**

Worst of all, upsetting gossip works on the customer and makes him doubtful about what to buy, makes him wonder if this is the time to buy. If a dealer is in a gossipy condition his customers get reflection of it, shy off from their intentions to buy and wait for things to settle down or until the wild-cat predictions of impossible new inventions shall come true. Those vague predictions come to the customer through customer gossip as well. Customer gossip can be made harmless only through the dealer's calmness and his knowledge of facts.

Everybody in radio knows pretty well that the business has suffered greatly from foolish and uncontrolled gossip ever since it started. How can we keep up to the minute in the real news of the industry and also help kill destructive gossip? The answer is not to keep mum, but to be sensible in what we say.

To go back—

Fear is an imaginative bogie man. He can be killed by realities and by getting the imagination as well as the legs and voice at work doing business and making money. There is plenty of business to be had, even if too little of it comes in

and begs you to sell to it. Imagination working upward leads to the necessary boldness, taking full profit and letting it be known that you intend to keep on doing it, insuring yourself in credits, and not falling for turn-ins on which you can't make full profit. Allowing $50 on a set that you've got to sell for $7, if you can sell it at all, is ridiculous, and no matter if a million dealers are doing it, it is unnecessary. Customers will admit it, too, if you tell them so frankly. If it is done it is because dealers are weak-kneed—because they follow each other in this thing like a flock of sheep. Some other industries have cleaned their houses of this pest and have standardized profits.

**Price Cutting**

Losing customers by price cutting of competitors is unnecessary to any great extent. Building a reputation for fine service, quality goods, and courteous treatment will absolutely cure it. Price isn't always the customer's first consideration. Competition shopping takes time and most people are busy. Be known as a fine, reliable shop and you can get along without the bargain hunters. In fact, if you have a fine reliable shop you will give many genuine bargains on which you will make your profit.

In a certain great city there are two fine stores, not radio shops, a block apart. They carry similar lines of merchandise. In one store the mark-up is 50 per cent. In the other it is 100 per cent. There is one line—a standard line which they both carry—on which they both do just about an equal volume at very different prices.

Distrust is destructive to an open mind. If a mind is not open it is not receptive to new ideas. You need new ideas. You need progressive development of your store display, ideas on demonstration, on new and better merchandise, on how you can advertise at a profit. These things are all upset by uncontrolled and foolish gossip. The wise man realizes that talk is cheap and that there are many cheap talkers. I have lost a little money in the years past by trusting friends. But by having friends I have made a hundred dollars for every dollar I have lost. With an attitude of distrust it is hard to have friends. The balance of profit is overwhelmingly in favor of having friends.

**Coöperate With Manufacturers**

Ever since manufacturers made goods and retailers sold them, these two partners in trade have been suspicious of each other, have made love to each other, have fought each

(Concluded on page 302)
The shadow cast by the twelve representative tube cartons in the illustration on the left indicates the way in which the sale of vacuum tubes varies throughout the calendar year. Each tube carton represents a month, starting on the left with January and ending with December on the right.

HOW TUBE SALES GO
By T. A. PHILLIPS
Manager, Research Division, Doubleday Doran, Inc.

SPORTING EVENTS and other broadcasts which create national interest affect the sale of radio tubes tremendously. A study of the monthly sales of tubes in the past three years demonstrates the influence of such events on tube sales. It was found, for example, that the Tunney-Dempsey fights of 1926 and 1927, and the Presidential Campaign of 1928, made decided changes in the trend of the sales curves for radio tubes for the years in which they occurred.

It was possible also to determine how the demand for tubes varies throughout the average year. In June—the beginning of the radio year—the sale of radio tubes is near its lowest ebb, and from this point business begins to pick up gradually during the months of July and August. Sales take a big jump in September, and, in October, according to the average curve, reach the peak of the year. After October tube sales begin to drop, gradually at first and then more rapidly after the first of March. The lowest point in the sales curve is reached during the month of May.

These facts are illustrated graphically on this page. Below will be found a chart giving tube sales in percentages by (Concluded on page 301)

THE COURT DECIDES

Some Decisions of the Higher Courts of the Country Affecting the Daily Interests of Dealers

The principal advantage of radio dealers obtaining legal information is the avoidance of litigations. Obviously, a person who understands his obligations is less likely to perform acts that will result in legal liability, when compared with a dealer who is unfamiliar with the law or one who relies upon "hear-say" information which, in the majority of instances, is quite undependable.

Moreover, frequently the records of fresh higher Court cases may be utilized advantageously in defending a suit. Therefore, the purpose of this article is to review several higher Court cases, decided during the past few months, involving radio dealers in which unusually important points of the law are explained.

Purchaser of Defective Radio Sets

The majority of persons are familiar with the established law that the maker of a negotiable note is bound to pay the proceeds to a disinterested and innocent party, who purchased it from the original holder, although the latter defrauded the maker when receiving the note.

In other words, a retail dealer of radio receivers is bound to pay a note given in payment for defective radio equipment, providing the manufacturer of this apparatus sold the note in good faith to an innocent purchaser.

On the other hand, it is important to know that this law is not effective under circumstances where the manufacturer sells the note to a person for the purpose of avoiding the responsibilities of the law, which is a rather frequent practice.

For illustration, in Stevens vs. Gaude, 120 So. (Louisiana) 79, it was disclosed that a retail radio dealer purchased several radio sets from a manufacturer who guaranteed them to be satisfactory. The manufacturer accepted notes in payment for the equipment and soon thereafter sold the notes to a man named Stevens.

When the radio dealer discovered that the radio sets would not operate satisfactorily he refused to pay the notes and Stevens filed suit, contending that he was a disinterested party.

However, in view of the fact that the manufacturer had agreed to repay Stevens any expenses he incurred in collecting the notes, the Court held the retail dealer not required to pay the same, saying:

"The testimony of the defendant, Gaude (radio dealer), corroborated by his son and two other witnesses, shows that the radio receiving sets were not satisfactory, and that for some reason they would not work in a satisfactory manner. . . . We therefore find that the notes are and were without consideration at the time they were executed. . . . It is our conclusion that these notes were never negotiated and delivered to Mr. Stevens in the execution and performance of an intent to sell them to him outright, but that the transaction between Mr. Stevens and the manufacturing company was merely a plan whereby the notes were sued on in the name of Mr. Stevens for the purpose of cutting off the equity of the makers."

Contract Held Legally Altered

In many instances, buyers and sellers enter into contracts the terms of which are cancelled or altered by mutual consent of the parties, although no written evidence may be introduced to prove conclusively the facts.

Therefore, it is important to know that the Courts look through obscurities surrounding sale contracts and endeavor to render verdicts in accordance with the true intentions of the parties.

For example, in F. A. D. Andrea, Inc., vs. Dodge, 28 F. (2d) 147 (Pennsylvania), it was disclosed that a manufacturer of radio cabinets and a manufacturer of radio receivers entered into a contract by the terms of which the latter agreed to purchase approximately 900 cabinets each month.

Later the buyer required a greater number of cabinets monthly and wrote the seller the following letter:

"Starting December 1, we are willing to allow you a bonus $1.00 per cabinet for each cabinet that you deliver, provided that deliveries of 1100 cabinets per week are sustained throughout the balance of the contracts. We are willing to pay you this bonus at the end of each month if your deliveries throughout that month amount to 1100 or more cabinets each and every week."

Some time after Christmas, the radio manufacturer wrote the seller explaining that he did not require so many cabinets...
monthly, and requested the seller to reduce the shipments and revoke the bonus agreement. The seller answered that he had rearranged his production and agreed to supply fewer cabinets each month, but did not agree to reduce the $1.00 bonus per cabinet which the purchaser had agreed to pay in the above quoted letter. However, the seller failed to bill the buyer the $1.00 bonus for the cabinets delivered after agreeing to reduce the monthly shipments.

Later, controversy arose between the parties and the seller filed suit against the purchaser to recover $14,571, including $1.00 bonus for all cabinets delivered after the purchaser agreed to pay this additional amount. The seller contended that the purchaser was liable because the offer to pay $1.00 was accepted by both parties and became a part of the contract which neither party had altered after the monthly deliveries were reduced. However, the Court held the buyer not liable for payment of the bonus, thus showing that in litigations involving uncertain contracts, the Courts endeavor to interpret the intended meaning of the parties.

**Employer’s Liability**

Since in many instances radio dealers have been held liable for damages caused by employees who install radio sets in purchasers’ homes, the recent case of Davis vs. Harry B. Loeb Piano Co., Inc., 119 So. 746 (Louisiana), imparts unusually valuable information.

The facts of this case are that an employee, sent by a radio dealer to install a radio set in the purchaser’s home, removed a screen and in restoring it he failed to fasten or secure it properly. Subsequently the purchaser’s minor child, who was accustomed to play on the window and use the screen as a support, fell through the window by reason of the insecurity of the fastening of the screen, and sustained severe injuries.

The child’s parents sued the radio dealer for heavy damages, contending that the employee’s neglect to fasten securely the screen in its position was the proximate cause of the injury. However, it is interesting to observe that this Court held the radio dealer not liable and stated important law, as follows:

“In order to be a proximate cause, a cause must be, either in itself or in connection with other causes, in direct and unbroken sequence, an efficient cause of an accident; but where the supervening cause, such as in this case, the permitting of the child to use the screen as a support, was in itself an efficient cause of the accident, the other cause then becomes the remote cause. . . . To hold a person liable under the circumstances set forth in this case would be far-reaching in its effect, because any one who made an installation of any kind would, by virtue thereof, become liable to third persons injured by coming in contact with or through the use or misuse of the particular installation, notwithstanding the damage could not be foreseen, and notwithstanding it was caused by some supervening cause.”

**Minor Not Required to Pay**

Contrary to the opinion of the majority of persons, the law gives to a minor, for his protection against persons taking advantage of his inexperience, the privilege of avoiding contracts which are injurious to him and rescinding all others, whether fair or not, excepting contracts for necessaries, and executed contracts, where he has enjoyed the benefit of them and cannot restore the other party to his original position.

In other words, if an “infant” makes a sale contract for a radio, and receives the radio and disposes of it before his majority, either by losing, expending, or squandering it, *this is nothing more than the law anticipates of him,* and he is not required to pay for it.

For instance, in Shutter vs. Fudge, 143 Atl. 896 (Connecticut), a minor seventeen years old purchased $415 worth of radio parts and used them for the purpose of building radio sets which he sold to various purchasers. He refused to pay for the parts and the dealer filed suit. However, the Court held the boy not required to pay the bill, saying:

“It is evident that, if the infant is, in every case, bound to return the consideration which he received, or its equivalent, in order to avoid or rescind his contract, the protection accorded to him, as such infant, is seriously impaired, and may often be destroyed, for it is precisely because he is supposed to be improvident, and likely to misuse and squander what he receives, that his contracts are made voidable. . . . Where he (infant) has exercised his right to repudiate the contract, the infant may be required to return the consideration, or such part thereof received by him, as still remains in his hands and under his control. But if, during his minority, the infant has lost, wasted, or otherwise disposed of the property or other consideration received under the contract, he may, nevertheless, repudiate it without making restitution in order to give effect to his disaffirmance.”

**Monopoly of Patent Contract**

In Radio Corporation of America vs. Lord, 28 F. (2d) 257 (Delaware), it was disclosed that the Radio Corporation owned certain patents and made contracts with various firms containing clauses by which the Radio Corporation endeavored to induce the firms licensed to build radio sets under its patents to use in such sets the vacuum tubes manufactured by the former, on which its patents had expired. The Court said:

“A single old element, whose patent monopoly has expired, cannot be put into a new patented combination as a constituent element, and thus have its individual monopoly revived for seventeen years more. This would be a new method of securing a patent, or a means of evading the patent law, by doubling the length of the life of a patent. . . . A patentee may not prevent the individual manufacture, use, and sale of a single unpatented element, which the world is free to make, use, and sell, by simply including it as an element in a new patented combination. To put it differently, the inclusion in a patented combination of an unpatented element does not give the patentee the combination a monopoly of each element, and the exclusive right to make, use, and sell that element independent of the combination. So long as the patent covering vacuum tubes was in existence, the patentee of this element of the combination was protected, and it could not be included in the combination without a license to do so; but, when the patent on this tube element expired, the rights, which were theretofore vested in the patentee, became the property of the public, and not of the patentee of the combination. . . . A patentee may sell his patented product at any price he desires, to whomsoever he will, and under whatever restrictions he conceives to be advantageous, provided he does not violate the law in doing so.”

262 • SEPTEMBER 1929
THE LITTLE RED SCHOOL HOUSE COMES TO MARKET

By B. H. DARROW

AMERICA'S GREATEST INDUSTRY—Education—is turning to radio. Here lies a golden opportunity for the radio industry which should receive the careful consideration of every manufacturer, distributor, and dealer.

Briefly, it means that the schools in the United States represent a potential market for three hundred thousand radio receivers and for nearly one million loud speakers.

The fact that radio broadcasting has been recognized generally by educators as a medium of instruction in schools is a question which no longer need be debated. Many of the schools which are radio equipped have reported enthusiastically upon the results which have been obtained, and every day word is received that new schools are planning to install radio apparatus.

However, there is still much room for development in this field, for only a very small number of the schools—probably not more than one per cent.—have facilities for receiving broadcast programs.

Interest on the part of educators in broadcast programs is, of course, a direct result of the effort made by station management during the last few months to provide educational programs. Whereas until recently practically all daytime radio programs were made up of "talks to the housewife," music, direct advertising, etc.,—to-day there are many features of interest to schools which are broadcast regularly. Such programs as the Damrosch lessons in music over WRL, the school broadcast by WMAQ, Chicago, the standard educational program of KFT, Los Angeles, etc., provide adequate proof of this trend.

In addition to the deliberately planned educational programs which are regular features of many stations, education by radio has other values which are axiomatic, and which alone are quite sufficient to make it imperative that radio be unleashed and set to work with the childhood of America. For example, an address by the president of the United States or events of current historical interest may be brought directly to the classroom. In this and in many other ways radio makes possible an equality of opportunity never before dreamed of, in which the smallest country school with an inexpensive radio set is on an equal footing with the million-dollar metropolitan school.

Size of the Market

From the viewpoint of those in the radio industry, statistics on the size of the educational market should be of interest.

In the opening paragraph of this article it was stated that education is America's greatest industry, and, after analyzing the tables accompanying this article, this fact should not be difficult to appreciate. In this connection the following figures are also rather convincing: the value of school buildings in the United States is over $5,000,000,000; the yearly cost of operating our schools is $2,750,000,000; there are approximately 1,000,000 classrooms in 275,000 school buildings; 978,310 persons are employed as teachers; 29,001,761 persons are enrolled as pupils; and it is forecast that $569,172,000 will be

spent for new school building construction during the current year.

The table on page 263 shows the number of schools of various types in the forty-eight states. These figures include schools of all sizes from the one-room country school, of which there are approximately 150,000, to the large city school. However, it must be remembered every school regardless of its size is a sales opportunity, and some of the larger schools may find need for four or more receivers.

The illustrations and tables on pages 264 and 265 give more specific facts which are of definite aid in determining the size of the educational market in the various states. The data below were taken from "Statistics on Public School Systems" prepared by the U. S. Department of the Interior, Bureau of Education. These figures show, for elementary schools, the number of pupils enrolled, the number of teachers, and the value of all property used for school purposes. From these figures it is also possible to estimate the approximate number of classrooms (usually there is one teacher for each classroom) which is useful as it is indicative of the number of loud speakers which would be required in order to equip fully each school.

The way in which these pupils and teachers are divided among the various kinds of schools is shown clearly on the next page. It is important to note that 79.5 per cent. of the total number of public school children, and 95.5 per cent. of the teachers, are employed in the public elementary schools.

SEPTEMBER 1929
of pupils and teachers are in elementary schools which compose radio's largest educational market, not only because of the large number of pupils but also because education by radio is best suited to the requirements of this class of school.

The tremendous growth of education in America is indicated by the figures on the right. These data, which were prepared by the Architectural Forum, show the forecast of the money which will be spent for new building construction during the current year. It will be noted that schools hold the third place on the list.

What Has Been Done

It has already been explained that at the present time the installation of radio apparatus in public schools is almost a virgin field, that only a few thousand of the one million classrooms have been equipped for radio reception. However, this condition is changing very rapidly and in some sections of the country as many as 20 per cent. of the schools are able to tune in on educational broadcasts. This is true of Ohio.

In the state of Ohio there are 210 cities, towns, and villages part or all of whose schools are equipped. Some of the villages have but one school, whereas some of the cities have as many as forty. In the latter class is Dayton which has auditorium or classroom reception for every school. The city of Cincinnati now has thirty-eight schools equipped and several other schools in the city are planning to have receivers installed. Columbus will have 128 classrooms equipped for reception when the schools open next fall. In addition, Cleveland, Youngstown, Sandusky, Elyria, Kent, Barnevile, and many others from modest beginnings are starting on a program which calls for equipping every classroom.

How Pupils Are Divided

Although the cities in the state of Ohio are probably the most progressive from the radio instruction viewpoint, there are several other areas which are rather heavily equipped. In the East there is considerable activity in the vicinity of New York City, Boston, and Hartford; in the South, radio interest is greatest near Atlanta and New Orleans, and the vicinity around Chicago and parts of California also report a considerable number of school radio installations. In each of the cases cited above it is most interesting to note that the equipping of the schools has followed the provision of suitable programs by the broadcasting stations.

The facts given above show that although the addition of radio instruction to the curriculum is not general throughout the entire country, the schools have been quick to take advantage of radio when regular programs of a suitable character have been made available by the stations. This is especially noticeable in Ohio which may be taken as an example of the results which may be accomplished by co-operation between station managers and educators.

It was believed originally that few schools boards would have both the money and the inclination to purchase radio equipment for their schools, but this proved false. In the Ohio

(CoKcludea on page 292)
**RADIO VS. AUTO SERVICE**

Dealers Who Look into the Service Systems in the Automotive Field May Find Ideas Which Will Aid in Solving Their Problems

There is no one sure way of getting rich in any line of endeavor, and, in the radio service field, there is no single method which may be followed that will by itself spell success. That magic word “success” must be made up of a large number of well-planned systems for doing everything which needs to be done in any particular business. A group of good servicemen will not make a service business or a service department pay for itself unless the prices are correctly designed, the records are carefully kept and intelligently used, and the costs of giving good service and the overhead costs of doing business are known and closely regulated. We must also know how to secure customers without spending too much money getting them, and, once gained, how to keep them.

In the space of this article we can’t discuss all the ways that experience has taught us are conducive to success in the radio service game, but we shall consider briefly a few of them. In this connection a few of the remarks made to the author by H. R. Cobleigh, secretary of the National Automobile Chamber of Commerce in New York, should be of interest, as they considered the solutions to service problems in the automotive industry which might very profitably be applied to problems in the service branch of the radio industry.

Perhaps the most striking thing Mr. Cobleigh pointed out was the difference between the words “maintenance” and “service.” Some years ago there was a great deal of discussion among automobile men about the advisability of employing the word “service,” he explained. There were many who thought “maintenance” would be a better term because they felt that “service” was firmly fixed in the customer’s mind as meaning something that is free, whereas the use of “maintenance” would remove some of the difficulties in collecting for service performed after the end of the free-service period. The answer to the question was that maintenance means keeping a car in proper running order, but that service means satisfying the customer, and there is a wide difference between the two.

An actual experience with automobile service illustrates this point very clearly. A car owner went into a repair shop, waited fifteen minutes before anyone paid attention to him, asked for an estimate of the cost of the work he desired done and how long it would take. He was told it would cost somewhere between thirty and forty dollars, and that they would try to have it ready by two o’clock the next afternoon. He returned at the time mentioned the next day, waited an hour to get his car, found that the bill was $45, and noticed as he drove out that his steering wheel was greasy and the windshield had not been wiped off. The repair job by that concern was properly done and the fee charged was a fair one for the time spent and materials used, so that the work could be justly called proper maintenance, but the customer was very far from being satisfied.

The next time that car owner wanted service performed on his car he went to a new service station a block away from the first one. He was greeted promptly and courteously, was given an exact statement of the cost of the needed repairs, and was told definitely when his car would be ready. When he called for the car at the specified time, it was waiting for him, the windshield was cleaned off, the whole car had been dusted, the steering wheel and the seat were clean, and the bill presented to him was exactly the amount he had been told it would be. The radiator was filled with water. The service salesman asked if he might fill the gas tank and check the oil and air in order to replenish them if necessary. That work was service. The customer was more than satisfied—he was pleased—and he has consistently patronized that service station ever since.

Suppose a radio serviceman went into the home of a customer, looked at the radio without asking what the complaint was, found no trouble in the set other than a dirty volume-control rheostat which he cleaned, and then immediately packed up his kit and left without regard to the question of whether or not the work done would satisfy the customer. If the set was working normally when he left, the work done could be termed proper maintenance. However, suppose the customer’s complaint was not about the slight noise experienced when adjusting volume, but that his complaint...
was of variation of volume during the course of an evening and of much noise which he was experiencing and very naturally blaming on the set. Although such a call would result in the rendering of proper maintenance, they very definitely would not result in the rendering of service. The customer would be dissatisfied, it would be difficult to collect from him, and the next time he wanted service he would go to some other service organization.

Flat rates for all kinds of service work, against the old method of rendering service on a time and material basis, was another subject which Mr. Cobleigh discussed at some length. In the automotive field their experience has been—and it applies to owners of radio receivers just as much as to owners of automobiles, because they usually are the same individuals—that people want to know before they have a job done exactly what the work is going to cost. When they know beforehand that it will cost them $100 to have a car overhauled, or $15 to have their radio overhauled, if they accept that figure and give the order and the work is satisfactorily done, they are invariably satisfied that the money was well spent. On the other hand, if either the automobile or radio service organization cannot give them a definite figure at all, or can give them only the cost of parts and tell them that the labor charge will depend on the time it is found necessary to spend on the job, there will be many cases of dissatisfaction with the amount actually charged, even though the work is properly done. Our own experience of nearly six years with an independent radio service organization has amply proven that the experience of the automotive industry in that respect can be very profitably used as a guide in the radio industry. Before we instituted the flat-rate system we had a great deal of dissatisfaction, not with the work done but with the cost of that work, simply because the customer thought he might have been able to have the same work done much cheaper somewhere else. If he knows just what a service call will cost he can then get estimates from other concerns, and he will be satisfied with the cost of the job because he has found, by comparing estimates and the quality of service rendered by various concerns whose work he has tried, approximately what it will cost to get the kind of work he wants. Since we instituted the flat-rate system some three years ago, we have had practically no complaints or dissatisfaction because of our charges.

The U. S. Chamber of Commerce has stated, as a result of a very comprehensive survey made in all retail fields, that only about fifteen per cent. of the business that is lost by the average individual retailer is lost because the customer considers his prices too high. When we started business in 1923 we charged for labor at the rate of $1.50 an hour. In 1925, in fear and trembling lest we lose too many customers, we raised our rate to $2 an hour, and we were surprised and greatly relieved to find that, so far as we were able to determine, we did not lose any customers. About a year ago we realized that our rates were still too low for the service we were rendering and again with a great deal of trepidation we revised our entire schedule of flat rates on the basis of $2.50 per hour, or $20 per man per day. The tabulation of the results of a survey made this past summer showed us that only about two per cent. of the customers we lost following our last raise in rates left us because of that raise. So long as a service department or a service organization in any industry gives the best service that is humanly possible, the customers and prospective customers of that organization will not worry about the cost of service, provided it is not appreciably higher than other service concerns charge for rendering comparable service. The average individual is far more concerned about the quality of the service he gets than about the cost of that service, and the dealer's service department or the service organization can safely charge fees which will permit a reasonable net profit over the cost of rendering the best of service, without any fear of losing customers thereby.

In the automotive business, a policy which has grown up out of the flat-rate practice, is the method of paying mechanics, not by the month, week, or hour, but by the job. Approximately two-thirds of the automotive service stations in the New York metropolitan area pay their men on that basis, according to Mr. Cobleigh. The mechanics make more

This curve showing the number of service jobs handled per month during the last four years by a well-known radio firm in New York City indicates a slight tendency to flatten out.

SEPTEMBER 1929
money on an average over the year than they made before on the hourly basis, the employer pays his labor only for work done, and he knows exactly what his labor cost for each job will be. The disadvantage of the system appears to be two-fold: one is that the men work overtime in the busy season and make abnormally high wages, while in the slack season they do not have enough work to do and consequently make less than their average weekly pay over a period of a year. The other disadvantage is that at all times, and especially whenever there is insufficient work, considerable care must be exercised by the service manager to distribute the work equally among his men.

When employed on a piece-work basis, fewer men are required in each shop than were previously needed because each mechanic does more work than he did before and the men in a shop do not want to have additional help taken on, even in the busy season, as long as it is physically possible for them to handle all the work. That has the advantage that less labor turnover is required—less hiring of men at the beginning of a busy season and less firing of men when work slackens. In a certain repair shop which was using the old hourly system of pay, twenty-two men were employed. When the piece-work system was instituted during a somewhat slack period, eleven of those men were discharged. The remaining eleven men were able to handle the work easily and made considerably more money. When the busier season arrived and the work became heavier day by day, the men in the shop went to their employer, asked him to please refrain from hiring any more men, and assured him that they could handle the additional work by staying overtime. The boss consented, as a matter of trial, and the shop went through the busy season without hiring more men. Those mechanics made a great deal more money than they would have made had more men been taken on, the cost to the employer for the work done was no greater than it would have been with twice the number of men employed, and he was relieved of the high cost of hiring and breaking in new men.

Perhaps you are thinking that when a man is paid a flat rate for a certain job his natural tendency will be to hurry that job at the expense of doing it properly, and that much customer dissatisfaction would therefore result from careless work. The way the problem has been solved in the automotive field is by requiring, whenever a job is incorrectly done in any respect, that the serviceman responsible shall do the work over on his own time. The result is that each mechanic is very careful to do the job as it should be done the first time. Whether the piece-work system would work out satisfactorily in the service branch of the radio industry, as it has in the automotive industry, is a question well worth while considering. It seems to the author that the majority of our problems so closely parallel those of automobile service that the method of paying men a definite percentage of the flat labor charge for each job should be tried out. The only way to determine whether it would be better than the present haphazard method of paying for labor is by trial. We believe that a graph of the amount of radio service performed during the year has higher mountains and lower valleys than a similar graph depicting the work of the average automotive service department or organization, which, under the piece-work system of pay, has the disadvantage that either the pay of a radio serviceman would fluctuate more widely or else that more hiring and firing would be necessary than is the case at present in the older industry. However, progressive automobile shops have done a great deal to fill up the hollows in their yearly volume graph and to straighten out the whole curve by selling combination jobs and general overhaul jobs at much lower than normal rates during their slack periods and by selling an increasingly large proportion of their customers on the benefits and the economy of regular periodic service. If those remedies can be applied successfully to automobile service they certainly can be applied to radio service.

The yearly curve of radio business has straightened itself out gradually during these nine years of broadcasting by reason of better summer features, better quality of transmission and reception, and greater power used by local stations to permit a very high signal to noise ratio even under bad atmospheric conditions. Although there has been gradual improvement, the maximum amplitude of that curve is still a large multiple of its minimum and it will always be so unless the minimum portions are artificially stimulated by intensive sales effort. The fact that an older industry has been successful in artificially raising the low periods of its yearly curve is very hopeful evidence indeed that we can do exactly the same thing if we start employing both mental and physical activity to get that work which can be obtained.
WHAT COST ENGINEERING?

A FEW YEARS ago there was little demand for high-grade radio engineers. Pseudo-engineers did most of the engineering, chiefly because they were young enough and with so few responsibilities that they did not mind getting small pay for the work they would do at home anyhow at no income. Competition among set manufacturers has put a stop to this business of flirting with the undertaker, technically speaking. At the present time no high-grade set manufacturer can stay in business if he does not possess a laboratory and a staff to work in it.

What does it cost to engineer radio receivers?

In reply to such a question Radio Broadcast received some very strange answers. One chief engineer stated that "in our own case, it would be a matter of considerable difficulty and would involve a very considerable expense to give even approximate answers" to the questions we asked on the cost of engineering radio sets made by this well-known company. In other words, the chief engineer did not know how much it cost him to engineer his company's production! Fortunately this answer was not at all characteristic.

For example, the following figures are quoted from a letter from another well-known manufacturer:

1. Total amount charged to radio engineering in 1928:
   - Production drafting $10,451.27
   - Engineering administration 31,797.21
   - Experimental 12,968.27
   - Research 1,101.82
   - **Total 1928** $59,618.60

2. The total cost of apparatus (meters, bridges, etc.) utilized by Engineering Department plus the equity in a well-known licensing organization was $75,000. This company employed six engineers and three laboratory assistants. In 1928, the company sold 145,000 sets.

Another company which made approximately 100,000 receivers and 10,000 dynamic loud speakers had a technical staff of five engineers and two electrical mechanics. The laboratory equipment, which represented an investment of about $18,000, was being increased all the time. The engineering costs, exclusive of inspection, ran close to 1 1/2 per cent. of the net selling price. These are comparable figures, certainly.

Such figures come from the books of successful manufacturers; they indicate that the manufacturers in question are not content to let amateurs do their engineering. The only conclusion is that such expenditures must pay.

A side light on this subject is the fact that there seems to be a dearth of really high-grade experienced engineers. A licensing organization with home office in New York had two long-distance calls from the Chicago area within an hour recently, both asking for engineers who were equipped so that they could step into positions paying up to $7500 a year. The licensing organization receiving these urgent requests had no engineers in mind; they did know where to look. Consolidations among set manufacturers will release some men of the proper caliber, but there will always be good positions for good men.

One of the manufacturer's best safeguards against decadence must lie in his engineering department. This department will cost about 1 1/2 per cent. for engineering alone; and the manufacturer will have some difficulty in finding and keeping good engineers unless he is willing to pay good money for them.

A WORD TO THE WISE IS SUFFICIENT

THE FOLLOWING quotation from the Exhibitors' Herald World—a trade journal of the motion-picture industry—is so succinct and needs so little paraphrasing to make it a shoe for the foot of some manufacturers of radio receivers that we reprint it as it appeared in the May 4, 1929, issue of that journal.

"It would be amusing—if the matter were not one of such vital importance—to see the number of persons connected in one way or another with motion-picture affairs who have suddenly set themselves up as experts on reproducing devices. The intentions of some of these may be worthy enough but the exhibitor who depends upon their guidance is headed for a painful and expensive experience.

"It seems almost too obvious to state that when a person wants advice on a technical matter he should go to a technician—and not to a banker, baker, or candlestick maker. But this very thing is being done by exhibitors in connection with contracting for reproducing equipment. The theatre man who follows this course will have to be lucky indeed to escape seriously unpleasant results."

UNIFORM SELECTIVITY IN 1930?

ONE OF THE engineering advances which the screen-grid fervor has masked rather thoroughly is that which gives radio-frequency amplifiers a flat frequency characteristic and endsow a receiver with uniform r.f. gain. The tuned r.f. set of a year or so ago had a voltage amplification that varied at least three to one over the band and many varied in a much greater ratio than this. At the same time the selectivity of the set varied in at least a three to one ratio.

The result was a set which seemed very selective and somewhat dead at 550 kc., and very broad and of proper gain at 1500 kc.

Now what is really desired is an amplifier that has constant gain over the band—disregarding any peculiar method of allotting station frequencies indulged in by the Radio Commission—and in which the percentage selectivity at the high frequencies is three times as great as at 550 kc. For example, at the lower end of the band we desire to pick a 10-kc. channel out of 550 kilocycles, or one in 55. This calls for a frequency separation of 1.82 per cent. Now at 1500 kc. we want the same 10-kc. channel, or one part in 150 or a frequency separation of 0.66 per cent.—three times as great as is required at the other end of the broadcast band.

(Concluded on page 298)

SEPTEMBER 1929 269
The figures on this map give an estimate of the total radio set sales for the radio year of 1928-29 (July-June).

AN ESTIMATE OF SET SALES

By T. A. PHILLIPS
Manager, Research Division, Doubleday, Doran & Company, Inc.

This is the last and concluding article analyzing the radio survey made by the Bureau of Foreign and Domestic Commerce, electrical equipment division, in cooperation with National Electrical Manufacturers Association. The first two articles discussed the most important phases of the survey. This article reports some of the other items covered that are of general interest.

The survey gives radio set sales by states July 1, 1928 to March 31, 1929, which presents the opportunity of making an estimate of total set sales for the radio year (July 1 to June 30) by states. The radio year has passed but it will be many months before the totals are known. In the meantime, these estimates will help in determining the future business in light of past results. The NEMA estimates that set sales will reach a total of $650,000,000. Taking that as a base we have made the estimate given in Table I. Note that New York, New Jersey, and Pennsylvania account for more than a quarter of the total sales. The territory east of the Mississippi and north of the Ohio River accounts for more than

The figures in this table give an estimate of total radio set sales for the radio year (July 1, 1928 to June 30, 1929) by states. The radio year has passed but it will be many months before the totals are known. The estimates are based on a survey made in cooperation with National Electrical Manufacturers Association and will help in determining future business in light of past results.
The figures on this map show the average volume of radio sales per dealer in each state. The data were taken from the radio survey for the first quarter of 1929 which was prepared by the Bureau of Foreign and Domestic Commerce in cooperation with NEMA.

Almost 60 per cent. of the total sales. The comprehensiveness of the survey allows for considerable reliance upon the figures showing the percentage of total business done in specific states. Should future estimates of total radio sales for the radio year 1928–29 differ from the NEMA estimate of $650,000,000, the per cent. of sales by states will still, in the main, hold true.

The percentage of the total radio sales handled by dealers in various districts of the United States is shown in the chart on the left. These data are taken from Table I which also gives the percentage of total sales by states.

The average values of radio receivers sold during the first quarter of 1929 in each state are given in the map on the right. These figures vary from $143.50 for Oregon to $191.50 for Nevada. The average for the entire country is $165.00.
Tying In With Aviation

Five years ago, radio occupied the same public attention and the same liberal space in the press that is to-day accorded to aviation. There was then no item of the broadcast studios or of the industry too insignificant to break into print and one who had a working knowledge of radio became automatically a social lion. The radio industry successfully established itself on a sound footing before its command of the front page wore off.

Radio is remarkably well adapted to associate itself with aviation in the news of the day. By such an alliance, it may share the limelight. Most broadcasting organizations have been too concerned with direct advertising to realize that, in aviation, they have an ally which may bring them once again to the front page of the newspaper and to the forefront of public interest. Consequently, they have made rather limited use of their opportunities restricting themselves to such events as the start of the recent transatlantic flights, the inauguration of the transcontinental air-rail service, and occasional talks by various aviation experts. These features are scheduled during obscure broadcasting hours when audiences are at their minimum.

If the newspapers had as little conception of news interest as the broadcasters, they would still be carrying aviation news in a half column on the fourth page. Why restrict aviation broadcasts to relatively unimportant hours?

Aviation also means opportunity to the dealer. The public is flocking in huge numbers to airports, particularly on Sundays and holidays. During May, 22,072 people paid admissions to visit Roosevelt Field, Long Island. Leisurely crowds at airports can be entertained by radio reception to the advantage of the radio dealer who capitalizes this opportunity. Open air demonstrations show up the capabilities of the modern receiver to the best advantage.

Let Dealers Mould Advertising Policy

Radio manufacturers spent tens of millions annually in newspaper and magazine advertising to stimulate sales of radio receivers. The influence of that expenditure depends not only upon its magnitude and the skill used in selecting mediums, but also upon the directness and power of the appeals made in the advertising copy itself. One must go far from radio and the advertising profession to evaluate effectiveness of copy appeal upon those who are neither technically familiar with radio nor sufficiently interested in broadcasting to purchase a receiver. To pass judgment, one must consider advertising copy in the light of the questions asked by the prospects who visit the radio dealer's store for the first time and upon close observation of the influences which attract the new prospect and lead him to buy.

Advertising policies are usually determined by persons who have no real contact with buyers and prospects. They are based more upon theory than upon practice face-to-face with buyers. All sorts of methods are resorted to by the advertising agents to acquaint themselves with the new buyer attitude. But none have the opportunity of the average dealer to secure first-hand information as to the sales appeals arousing the greatest interest in the non-owning group, now by far the largest potential market. The dealer can help to mould advertising policies by practical suggestions made to the manufacturers whose products he handles, based on his selling experiences.

Radio manufacturers' advertising has an unconvincing uniformity to the average non-owner. The claims made by most makers are almost stereotyped, such phrases as "magnificent tone quality," "revolutionary in principle," and "new precision," appearing everywhere. Another favorite advertising technique is to coin an esoteric technical term to lend a veil of mystery to what is usually a perfectly ordinary design feature. This may captivate the dealer who gathers some glimmer of meaning from the verbiage, but it is doubtful whether a new prospect was ever won by the hocus-pocus appeal in advertising.

The disadvantages of being technically expert, when associated in the preparation of advertising, are usually not apparent to those who pay the advertising bills. Dealers use copy sent them by the manufacturer because of its convenient form and the prestige of those who prepare it. But many a dealer is better able to suggest copy themes which will bring people into his store than the manufacturer or his advertising agent. The dealer's idea of copy may violate all the principles of advertising which have been laid down so carefully by armchair experts, but it would be based upon an intimate knowledge of the buyer's attitude when he enters the radio store. For that reason, suggestions and conclusions based on careful observation should be welcomed. A dealer contest for advertising copy suggestions would be a productive source of copy ideas for any manufacturer.

The WCFL Controversy

Considering the immense political agitation brought forward in behalf of WCFL, the Chicago Federation of Labor broadcasting station, one would derive the impression that its activities are of vital importance to the well-being of labor. We were, therefore, sufficiently interested to read the brief filed in reply to WCFL's appeal by the Federal Radio Commission with the Court of Appeals of the District of Columbia.

The Commission pointed out that the station, in the long period that it has had full time on its channel, had devoted only 30 to 65 minutes daily to programs of special interest to labor, that it has broadcast patent-medicine advertising and violated the order that phonograph records be identified. The Commission contends that labor unions as
a class are no larger or more important than numerous fraternal and political bodies which could, with equal propriety, claim an exclusive channel on the basis of their numerical strength. By making the fate of WCFL a "cause," politically potent labor may force upon the Commission the necessity of granting it a clear channel. Such a decision would establish precedents which will encourage other groups to make pleas for exclusive channels on the same grounds.

There is no instrumentality which serves the public without discrimination on a broader scale than radio broadcasting. It is unfortunate to attempt to make this the tool of any class or grouping of society. WCFL should base its case on superior service to all the public and prove itself a better station from the program and service standpoint than other Chicago stations assigned clear channels. Dependence on service to labor unions rather than to the general public might indeed be construed as a realization that its case is weak from the public service standpoint. Any group, including organized labor, better able to serve than existing broadcasters, is entitled to the channel facilities of inferior broadcasters, but none deserve consideration on the basis of political threat or influence.

A Fortune for a Feature

"Amos 'n' Andy" have captivated the radio public so successfully that numerous stations have been broadcasting special phonograph recordings released them each week. Recently, the services of these artists were purchased by the National Broadcasting Company from Station WMAQ for a sum reputed to be $100,000, apparently the highest price to be paid to date for the release of a single broadcast act. The sum is not verified, but it is quite probably correct.

There is no shortage of good radio talent, but it is a matter of the utmost difficulty to secure real headliners whose merit and distinctiveness establish extensive and enthusiastic followings. It is probable that the National Broadcasting Company will be fully compensated for its purchase. No doubt, there is a great deal of scurrying around to find an advertiser to sponsor these two capable and expensive entertainers. One of these days, they will appear in the name of toothpaste, halitosis, or screen-grid tubes.

In this connection, it is interesting to learn the conclusions of Duane Wanamaker, advertising manager of the Grigsby-Grunow Company, sponsors of the "Majestic Theatre of the Air," after presenting Moran and Mack as a headline feature over the Columbia System. There has been no question about the popularity of this feature, he states in Broadcast Advertising, but headline artists win attention to themselves rather than to their sponsors.

This reasoning might justify the conclusion that an ordinarily good broadcast feature, not sufficiently outstanding to arouse great public interest in the artists presenting it, centers good will upon the sponsor and his product most effectively. Therefore, such a program is a better paying broadcasting proposition than a "big-name" feature.

It is doubtful, however, whether an "average" feature can attract as large an audience as outstanding headliners. The average radio advertiser is no longer content to make his advertising secondary to good radio performance. Such reasoning, it seems to us, is fallacious because the first essential to successful radio advertising is to attract the largest possible audience through the program merit of the feature itself. The advertiser may secure the benefits of headliners by identifying them with names suggesting his products.

Paramount in Broadcasting at Last

Paramount-Famous Players have purchased a half-interest in the Columbia Broadcasting System, forming a combination somewhat similar to the Radio Keith-Orpheum. The statement issued at the time of the merger set forth that it was brought about by Paramount's desire to associate itself with radio on account of the coming of practical television. It is our guess that this was simply publicity strategy because television has yet to reach a stage of development of interest to the general public and does not promise to do so in the immediate future. Paramount has been linked with the effort to start broadcasting chains for several years and this merely represents the consummation of their work in this direction.

District Judges Become Commissioners

The Federal Radio Commission bids fair to be displaced in its most important functions by the District Court of Appeals of the District of Columbia. All the Commission's major high-frequency allocations in the continental and inter-continental channels have now been brought before that court by appeals. This amounts to placing the decision as to how the high-frequency allocations will be made with that judicial body. Attacks have centered upon the generous allotment of frequencies made to the Universal Wireless Communications Company. The Mackay Radio Corporation, Radio Communications, and Intercity Radio have appealed the Commission's decisions. The latter two fear no comparison with Universal Wireless Communications in experience in practical commercial radio telegraphy, their contender in high frequencies having had none to date.

It is all an extraordinary mess which has not been in the least simplified by the existence of strong prejudices against some of the interests involved. Radio communication is of such importance in national and international relations that it is well to consider decisions not only from the standpoint of how they affect the relative positions of various communication companies and the pet hatreds of some Senators and Congressmen, but primarily how they affect the economic future of the United States and its position in international communication.

E. H. F.

September 1929
New Receivers Announced

KELLOGG SWITCHBOARD AND SUPPLY CO: Three new receivers, especially designed for use in districts supplied with 25-cycle current, have been added to the line of sets manufactured by this company. These new sets, models 526, 527, and 528, will use 224-tube 227-type tubes and an automatic volume control. The 526 and 527 have phonograph pick-up jacks.

STERLING MANUFACTURING COMPANY: This is the first season that this company has manufactured radio receivers although they have been in the electrical business for 23 years. Three sets are being made, the Stuart, the Avon, and the Oxford. The sets use screen-grid tubes and 245-type power tubes. The loud speaker is a 10-inch dynamic.

STEWART WARNER CORPORATION: The series 920 screen-grid receiver and the Stewart-Warner dynamic loud speaker are now available in a new console of 17th century English furniture design.

TEMPLE CORPORATION: The new receivers of this company are arranged so that either screen-grid or ordinary 227-type tubes may be used, the change over from one type to the other requiring about thirty minutes work. All models use the Temple 14-inch dynamic loud speaker. In converting a Temple set from 257 tubes to a screen-grid tube receiver, two radio-frequency transformers and two resistors must be changed. Then two 224-type screen-grid tubes are substituted for the 227 tubes in the r.f. stages and the job is done. The Temple Corp. feels that the possibility of using either 227- or 224-type tubes in their sets is a protection for their dealers in case of a screen-grid tube shortage.

STROMBERG-CARLSON TELEPHONE MANUFACTURING COMPANY: The model 846 receiver is a screen-grid set with automatic volume control and special features provide for quiet reception. One of these is a control which reduces the sensitivity of the set when powerful locals are being received or when there is considerable static. The second feature is the "silent key" operated by a push button, which enables the user to cut out background noises and station signals when tuning or operating another. The set uses a linear detector and is tuned by means of a single dial in conjunction with a tuning meter. A phonograph pick-up jack is provided.

Miscellaneous New Apparatus

RADIO RECEIVER COMPANY, INC: Four new power amplifiers have been designed by this company. The p x 4 -25 is a three-stage amplifier with two 227-type tubes followed by a special feature for volume control. The p x 2 -25 has a 2-stage amplifier with one 224-type tube, the p x 5 -25 has a 3-stage amplifier with 245-type tubes in push pull, and the p x 5 -25 amplifier contains three stages with 250-type tubes in push pull.

JENKINS TELEVISION CORPORATION: This company recently demonstrated a complete television receiver for home use. The complete receiver was contained in a cabinet measuring 18 by 18 by 24 inches and the apparent size of the image was 6 by 6 inches. The set is operated by first turning on the neon glow tube by means of a snap switch and then tuning in the television signal. A crank on the set is turned into frame the picture properly. The tuning mechanism consists of a synchronous motor and the scanning drum. A special distributor will feed four plates contained in the neon lamp. Two transmitters of the company, one at Jersey City, N. J., and the other near Washington, D. C., will regular schedule transmitting television programs. Both stations are rated at 5 kw. and operate on 140 meters.

JEWELL ELECTRICAL INSTRUMENT COMPANY: The pattern No. 199 Set Analyzer is now available in a portable cabinet provided with a drawer and compartments for tools and tubes.

Personal Notes

C. J. CALLAHAN, has assumed the duties of sales promotion manager of Colin B. Kennedy Corp. Mr. Callahan was for several years president of the Zenith Radio Corporation, of Chicago.

At a special meeting of the Midwest Radio Trades Association held at the Electric Club of Chicago, E. J. Brennan was formally elected to the position of the Clarostat Manufacturing Company, of Brooklyn, N. Y., has just joined the Clarostat engineering staff, following his graduation from the Rensselaer Polytechnic Institute.

D. W. MCKINNON has been chosen division manager for the Colin B. Kennedy Corporation, of South Bend. Mr. Mckin- non will cover the Mid-West territory.

DAVID GRIMES, radio inventor, has been appointed chief research engineer of the Pilot Radio & Tube Corporation. It was announced by I. Goldberg, president of the firm. He has taken charge of the Pilot laboratory, 325 Berry St., Brooklyn, New York, where he will conduct investigations along original lines.

EDWARD STRAUSS has joined the Bruns- wick national organization, and he will be succeeded by Frank S. Hornsing as the New York district sales manager.

AMONG the recent additions to the Colin B. Kennedy Corporation executive personnel is G. H. Kratsch, divisional super- visor at the main office.

O. H. ESCHELZOB has been appointed manager of the patent department of the Western Electric Manufacturing Company, succeeding O. S. Schairer, who resigned to accept a similar position with the Radio Corporation of America. Mr. Eschelzob will live at the company's East Pittsburgh works.

E. W. BUTLER, for the past five years with the sales and engineering depart- ment, San Francisco office, E. T. Cunningham, Inc., has been transferred to the New York executive offices of the company, it is announced by C. R. King, vice-president and assistant general manage of the company. Mr. Butler will devote his time in the same capacity at the company executive headquarters.

THE STERLING MANUFACTURING COMPANY, Cleveland, announces the addition to their staff of Geo. J. Eltz, Jr. Mr. Eltz fills the position of capacity of manager of the Radio Division.

A. A. BROWLER has just been made sales manager of the Radio-Panatrope Division of the Brunswick-Balke-Collender Company, of Chicago. This concern recently purchased the Bremer-Tully interests.

KEITH SAUNDERS, well-known figure in the New York radio sales field, has been appointed assistant sales manager for the Freed-Eisemann Association. Mr. Saunders will handle all the shipment problems of the Freed concern and will coordinate the Freed Radio distributors throughout the nation.

EXECUTIVE PROMOTIONS are announced by E. T. Cunningham, Inc. George K. Throckmorton, formerly vice-president and general manager, to the position of executive vice-president and general manager; C. R. King, formerly assistant general manager to the position of vice-president and assistant general manager; and M. F. Burns, formerly general sales manager, to the position of vice-president and general sales manager.

News from Distributors

W. E. DARDEN has been elected vice-president and Hal Motor has been elected treasurer of Ernest Ingoed, Inc., Atwater-Kent distributor of San Francisco.

C. V. CHISHOLM, manager of the Edison Distributing Company, of Boston, Massachusetts, has been elected manager of Edi- son radios, phonographs and records, recently announced the appointment of Guy P. Clement as their representative for the state of Maine.

B. WOLFE, sales representative of the Atwater-Kent Manufacturing Company assigned to the Sioux City district, has moved to Sioux City and will serve in the territory embraced by the A. A. Schneiderhahn Company.

THE BURR-TRUE CORPORATION, At- water-Kent distributors in Syracuse, N. Y., has appointed the Em- ployee Salesman, Mr. Em, in connection with their annual Atwater-Kent Dealers Convention, a very novel and arresting announcement and reservation blank in the form of a check, making payable to the invited dealer "One Profitful Day and Enjoyable Evening," collectible at par at the Convention Headquarters. The lower part of the blank is the following: "If you are invited to the Burr-True Corporation, is detachable for the purpose of reservations.

NEW DISTRIBUTORS APPOINTED

THE KELLOGG SWITCHBOARD AND SUPPLY COMPANY has appointed the Em-Roe Sporting Goods Company, 239 West Washington Street, Indianapolis, Indi-
NEW CONSOLES

(A) The new Victor receiver which has attracted considerable attention. The tuning control consist of a transparent indicator which slides over an illuminated dial.

(B) A rather interesting cabinet houses this screen-grid receiver manufactured by the Sterling Manufacturing Company. The dynamic loud speaker is connected to a power stage using two 245-type tubes in push-pull.

(C) This illustration shows the Jensen Imperial Model dynamic loud speaker. This model is available with either the Concert- or Auditorium-type dynamic units.

(D) Automatic volume control and power detection is used in this model (No. 846) Stromberg Carlson receiver. The r.f. amplifier employs three screen-grid tubes.

(E) The Stewart Warner series 900 screen-grid receiver in a 17th Century English Console. The receiver uses eight tubes including the rectifier.

(F) An Atwater-Kent Screen-Grid receiver and dynamic loud speaker in a well-designed console. The receiver uses three screen-grid tubes and two 245-type power tubes.

(G) Here is a picture of the Eveready Model 33 radio receiver. It is one of the ten models included in the Eveready line this year.

(H) The Bosch Radio De Luxe Highboy. Sliding doors are used in this artistic piece of furniture. The receiver uses screen-grid tubes and a dynamic loud speaker.

(I) Here is a unique cabinet design. No loud speaker grill is required for the loud speaker plays through an opening in the bottom of the cabinet. It is the Colonial Model 32.

(J) The Radio-Victor Corporation of America makes this receiver, known as the Model 33. The legs are readily detachable making a table model receiver.

• SEPTEMBER 1929 •

275
the Kellogg Switchboard and Supply Company is the F. O. Lawrence Company, Inc., 219 W. 4th Street, Cincinnati, Ohio, who will serve dealers in eastern Kentucky, southwest Ohio, and the southwestern portion of Indiana.

The Triad Mfg. Company has appointed the Northeastern Radio, Inc. and John V. Wilson, of Boston, Triad wholesalers for the New England territory.

Thomas A. Edison, Inc., maker of the Edison Radio, have completed negotiations with Morley Bros., of Saginaw, Michigan, for the distribution of Edison radios, phonographs, and records in that state, according to an announcement recently made by Roy S. Dunn, western sales manager of Thomas A. Edison, Inc. Michigan Edison dealers will now be served by two Edison distributors, the other distributor being E. A. Bowman, Inc., of Detroit, who is intensifying his Edison activities within the environs of Detroit.

W. R. McAllister, sales manager of the Federal Radio Corporation, Buffalo, N. Y., announces the appointment of the Electro-Sales Company, Cleveland, Ohio, as a Federal wholesaler. The company's territory extends throughout about half of the state of Ohio and the tier counties in the northwestern portion of Michigan. The company contemplates opening a branch in Toledo in the near future, thereby giving immediate service to its trade in its western territory.

JOBS-DEALER MEETINGS

DEALER MEETINGS during the summer were held by the following Atwater-Kent jobbers: Louis Beuhn Company (Philadelphia); Knerr & Company, (Harrisburg, Pa. territory); D. T. Lansing Company (Scran ton, Pa. territory); Southern Wholesalers, Inc. (Washington, D. C.); E. J. Edmond Company, E. B. Latlam, and E. A. Wildermuth (metropolitan New York area); Bertram Motor Supply Company (Boise, Idaho, area); Sunset Electric Company (Washington state territory); Ernest Ingold, Inc. (San Francisco territory); Ray Thomas, Inc. (Los Angeles area); Albany Distributing Corporation (Albany, N. Y. area); Stieffel Electric Company, Utica, N. Y. ; Columbus Ignition Company, Columbus, Ohio; L. L. Hartman Corporation, Rochester, N. Y.; Burr-True Corporation, Syracuse, N. Y.; Kurtzmann Company, Buffalo, N. Y.; Strevel-Patterson Hardware Company, Salt Lake City, Utah.

Temple distributors' dealer meetings were held during the summer by Bill Brothers, Buffalo, New York, and by the Ackerman Electric Company in Grand Rapids, Michigan, At Pittsburgh, Pa., the Keps Electric Company gathered 315 dealers to hear the Temple story and a similar meeting was held fo the West Virginia territory by the Front Company. Temple wholesalers in that territory.

News of the Industry

The active Pacific Radio Trade Association, with George H. Curtis as secretary, has been sending out dealer window strips during the summer, plugging summer radio entertainment to be had over the West Coast networks. Window strips at other seasons for important broadcast events have also been sent out.

Nineteen dealer helps are listed in an illustrated catalogue recently sent to Atwater-Kent dealers. Among the sales helps available are the following: window sign; girl cutout, cardboard musical instrument, group of Tuesday radio programs; cardboard cutouts, organ and disc cutouts, heraldic figures, color shafts, miniatures, posters, 24-sheet posters, bridge sets, valance and window transparencies, card board letter, match folders, whistles, and balloons.

Parks and Hull, Atwater-Kent distributors in Baltimore, issue each week a folder giving highlights of local broadcast programs. The cover of the printed piece gives program features on the air at the same time every day as well as a list of regular attractive types of programs to be heard. The two inside pages are illustrated each week and refer especially to local programs of interest. Highlights of Local Programs, as Parks & Hull have named the sheet, is available to retail salesmen.

W. S. Taussig, service engineer of Freshman-Freed Eisemann, believes that radio manufacturers should encourage cooperation with manufacturers of electrical and other devices which are humongous, capable of setting up interference with radio reception. In this way, he thinks, these makers can be induced to cure the trouble at the source and in a great measure, relieve the industry of the nuisance of curing interference after it is created.

The Freshman Company have contracted with the makers of electric flasher signs, electric pianos, elevators, telephone apparatus, street cars, electric refrigerators, etc., to furnish information about the parts of their products causing interference and to assist them in ways of removing the causes without altering the operation of the apparatus.

L. T. Breck

Walthal's, New York radio chain, announce the appointment of Miss Nellie Breman as manager of their New York City store at 142 East 86th Street. It is said she is the first woman radio store manager on record.

Walter Nussbaum, president of Walthal's, announces the opening of the 15th store in the system in Brooklyn. Another store was recently opened in New York City.

Crosley distributors and representatives of seven leading furniture manufacturers met in convention recently at the Crosley factory at Cincinnati, Ohio.

276 • SEPTEMBER 1929 •
Temple is having 5000 feet of film taken which shows the process of receiver making. It will be put to good use beginning August 15 when a fleet of Temple sales-promotion autos starts on a tour of the United States.

There will be six machines, painted Temple blue and cream, in the caravan at the start. Each machine will be equipped to show films of the Temple plant and will be prepared to shoot new scenes along the way. A sales-promotion official, a radio engineer, and a window trimmer will be in each car, and, in addition, each auto will carry a Temple receiver.

The National Electrical Manufacturers Association will hold its annual meeting at the Wardman Park Hotel, Washington, D. C., during the week of October 7. A large attendance, representing the entire electrical manufacturers industry, is anticipated as this is the only meeting attended by all the different product groups in the Association.

A special stockholders’ meeting has been called for the purpose of changing the name of the Chas. Freshman Co., Inc., to Earl Radio Corporation. The change in name was strongly urged by dealers and distributors who deemed this advisable, in order to identify more properly the company with the new C. A. Earl Radio which has been so enthusiastically received by the trade and the public.

Harold J. Wrape and his business associates in the Benwood-Linze Company purchased outright the entire interests of the Trav-Ler Mfg. Co. stockholders. New officers of the company are Mr. Wrape, president; C. Hambuchen, vice-president; and R. Ogle, secretary and treasurer. W. A. Butler, formerly merchandising manager of the Benwood-Linze Company, is general sales manager for the Trav-Ler Mfg. Corp.

The new Better Radio Reception Manual, published by R. M. A., gives detailed information as to the various types of electrical appliances which are liable to cause interference, how the cause of the noise can be located, and, finally, how the noise can be eliminated through the installation of various types of filters. The price of the Manual is 25 cents and copies can be obtained from the Radio Manufacturers Association, 32 West Randolph Street, Chicago, Ill.

At a meeting of the Board of Directors of the Grigsby-Grunow Company, the regular quarterly dividend at the rate of $4.00 per share paid annually was declared. The Company’s fiscal year ended May 31, and the dividend for the fiscal year were $29,475,909.97.

In the presence of more than 100 distributors and guests, the All-American Mohawk Corporation, manufacturers of Lyric radios, in June opened its new cabinet manufacturing plant at North Tonawanda, N. Y. This was one of the features of the fourth annual convention of the corporation’s distributors.

Dr. Charles Lauritsen, chief engineer of the Colin B. Kennedy Corporation, has inaugurated a complete system of inspection to maintain production models of the sets equal in every respect to the laboratory models. The factory test bench, is shown in an illustration on this page.

In opening a new real estate development featuring a modernistic home, the Justin Matthews Company, dealers, working with 535 Incorporated, Atwater-Kent distributor of Little Rock, Arkansas, equipped the home with a new Atwater-Kent screen-grid electrodynamic radio set.

RADIO AND FURNITURE MEN MEET

Seven leading manufacturers of fine furniture were asked to display cabinets to the distributors of Crosley radio receivers at a convention held recently in Cincinnati. Distributors from all parts of the country, with the exception of the West Coast, attended, while the latter group held a similar meeting at San Francisco at the same time.

The cabinets displayed by the furniture companies are designed to take the Crosley chassis and moving-coil loud speaker. Assembly may be made in a few minutes. Provision has been made to make permanent installation by placing two screws, one in the chassis and one in the loud speaker. Steel rails are placed in the cabinets to permit easy placing of the chassis.

PRODUCTION PLANS FOR 1929

From announcements of set manufacturers, referring to production plans for the current radio season:

Kennedy: 1000 sets per day on the screen-grid chassis. "Estimates from orders on file place our production for 1929-30 at 150,000 sets."—F. W. Wellington, chairman of the board.

Bremer-Tully: 2200 complete radio sets per week. ("Before winter, the company expects to speed up production to 750 sets per day.")—R. E. Smiley.

Majestic: 5100 sets per day.

Tempo: 500 sets per day (July 15); production quota for 1929-30: 250,000 sets.

Freshman: 1200 sets a day; 1500 by August 1st.

RADIO ADVERTISING SERVICE

Standard Rate and Data Service, 536 Lake Shore Drive, Chicago, is issuing a monthly radio supplement to their regular advertising media service. In addition to rate cards and information about each station, the monthly issue provides data on the following broadcast networks: National Broadcasting Company, Columbia Broadcasting system, American Broadcasting Company, and Trans-Canada Broadcasting Company.

Kolster Organizes Field Force

The Kolster Radio Corporation has completed the reorganization of its field sales force into five districts covering the United States, according to sales manager L. T. Breck. The company has set (Concluded on page 303)

Dr. Charles Lauritsen, chief engineer, Colin B. Kennedy Corp., tries to keep production models equal in every respect to laboratory models. Above is pictured the elaborate factory test bench.

F. A. D. Andrea showing A. S. Hunter and J. Sieger, London radio engineers, the new Fada chassis. F. K. Rettemeyer, chief engineer Fada, is on the right.

HOW TO ADVERTISE TUBES

We have heard the belief expressed a number of times that tube advertising which suggests a test between two makes of tubes to determine which gives better tone quality, distance, etc., is certain of failure. We have heard of several of these tests, conducted according to the modern "blindfolded" fashion, which proved conclusively that one set of tubes in a given receiver was just as good as another set from another manufacturer. It is our belief that any test suggested by advertising which when carried out does not point conclusively to the superiority of the product being advertised is sure to be a boomerang.

Long tube life, uniform construction, freedom from hum, the sound judgment and financial status of the manufacturer, the superior engineering force are evidence of good design—these are the sources of copy which the advertising writer can use to the advantage of his client.

Some manufacturers feel that advertising which claims a tube "heats" instantly may be perfectly true but that it is misleading. No tubes "play" instantly, and even with d.c. tubes there is appreciable time lag between turning on the switch and the advent of sound from the loud speaker. We feel that such advertising has the tube question more than other manufacturers, who state plainly that their tubes produce music in from five to ten seconds, and therefore carry its punishment with it. It is just the difference between a clear-cut statement and one that is cloudy—and it is here that a test will tell the truth. We should like to see and to recommend a tube of the 227 type that "plays" instantly.

FACTS ABOUT SYLVANIA TUBES

In a booklet entitled Business Facts about Sylvania Radio Tubes, we find the following four reasons why the tubes identified by the "Flashing Son on Green Oak Leaf" are good tubes.

"First: Sylvania precision operations are handled by men trained for years. And we never rush them, because if you crack a whip over skilled workmen, you end up getting nothing more than laborers, and the product is bound to suffer." "Second: We will never let a Sylvania tube leave the factory unless it passes fifteen rigid inspections. That protects the product against rush and hurry because all tubes must pass these tests or go into the junk pile. And junk piles run into money."

"Third: Sylvania has contentment. No slot machines are on Sylvania's payroll. Our hundreds of employees are treated like human beings, given good wages and every consideration, from a completely equipped hospital and nursing staff to buses that take them back and forth."

"Fourth: Sylvania's up-to-the-minute plants at Emporium, Pennsylvania, are in the heart of the Allegheny Mountains—where the air is crisp and healthful, bodies rugged, eyes clear, and minds alert."

TUNG-SOL ENTERS FIELD

Entry of Tung-Sol Lamp Works, Inc., Newark, N.J., into the radio tube industry has been announced. A new factory adjacent to the lamp factory in Newark will be built. It will have an operating space of over 82,000 square feet, a daily capacity of between 25,000 and 30,000 tubes, and will be in operation by January 1, 1930. Tubes will be made under R.C.A. license. The factory is to be built out of company earnings. Harvey W. Harper is president of the company.

NEW TUBE TESTER

The Jewell Electrical Instrument Company announces a new Pattern 199 a.c.-d.c. set analyzer designed to test the new a.c. screen-grid tubes. This instrument tests practically everything about a radio set except the kind of program the user tunes in, and, if there were any way in which the device could be made to censor leprous announcers, we suppose Jewell would incorporate it into the instrument.

CUNNINGHAM SALES

Cunningham sales for the first five months of 1929 show an increase of more than 35 per cent. over a corresponding period of 1928, according to M. F. Burns, vice-president and general sales manager. It is expected that the figures for the first half year will show a total number of tubes made exceeding the total number built during 1928.

Mr. Cunningham believes the 1929 tube market will be greater than any other in the history of radio. He believes the total production of tubes for the year will reach 110,000,000.

MARVIN'S RADIO DEBUT

The Marvin Musicians, sponsored by the Marvin Radio Tube Corp., of Irvington, N.J., will make their radio debut over the WZ network of the National Broadcasting system on Saturday, Aug. 31, at 8:30 p.m., New York Time. The series will continue for a period of 26 weeks.

Hugo Mariani, once conductor of the NBC studio orchestra of twenty-five-piece size, choral, comprising the Marvin Musicians, Mariani has evolved a novel "musical-journey" idea which readily adapts itself to a flexibility in programs.

RUMORS OF LARGE MERGER

Rumors of a merger of the manufacturers of Televocal, Magneton, Sonatron, and Marathon tubes continue to float. Mr. Barkley, assistant to the president of the DeForest Radio Company, predicts a severe shortage in tubes of the -21 and -45 types, and encourages all dealers to stock up on tubes in preparation for the fall trade when this shortage would become evident in the retailer's end of the business.

Certainly there are two serious aspects of any tube shortage. If a dealer cannot supply tubes he cannot sell sets, any more than he could sell an automobile on the promise of getting tires later on. Thus the dealer loses sales. On the other hand, a promised tube shortage makes it "pie" for inferior products to be bumped on the market and sold. These tubes either work but poorly, or fail prematurely and always breed dissatisfaction. As Mr. Barkley says, "Tubes in stock mean more than money in the bank."

(Concluded on page 303)
THE SERVICEMAN'S CORNER

Why Servicemen Go Home

adio servicing has settled down for the greater part to the detection and solution of a few relatively simple troubles. But every once in a while, just to make life interesting, we run into a stumper, and HERBERT M. ISAACSON, service expert of Brooklyn, N. Y., describes two good ones in the paragraphs that follow:

"If your customer complained that a loud howl came from the loud speaker at every footstep of a person in the room, and that a howl, low in volume at first, but rapidly building up to tremendous loudness, occurred whenever the loud speaker was brought within ten feet of the set, you'd say that undoubtedly there was a very microphonic tube in the detector section.

"Well, that's what I said, but——

"The set was a Garod electric, model E A. The detector is a 199, and because of the high audio gain, a tube that is only mildly microphonic manages to kick up quite a rumpus. Wherefore, I had selected a number of 199's that tested practically non-microphonic, feeling quite certain that the trouble could be due to nothing but a microphonic tube.

"A terrific howl was my greeting when I switched the set on. We'll fix that in a moment," I murmured confidently to the customer, and I slipped in a new detector tube. The howl was reduced, too howled unmercifully. I tried the rest of my tested tubes with no greater success.

"The loud speaker had a 30-foot cord, so that it could be moved to any of the rooms in the house without confusing other families. This stopped the howl which was due, of course, to a loudspeaker end cap. I decided to move it into the next room. This stopped the howl which was due, of course, to a loudspeaker end cap. I decided to move it into the next room. This stopped the howl which was due, of course, to a loudspeaker end cap. I decided to move it into the next room. "I tried tapping the set at different places in an attempt to localize the source of the trouble, but the noise in the loud speaker was equally loud wherever I tapped. An examination of the set did not indicate anything that might cause the trouble.

"Finally I sandpapered the brass end caps of the grid leaks and the trouble cleared up. Although the grid leak was held tightly between its mounting clips, tarnish on the end cap evidently caused a highly resistive contact that varied greatly under the stimulus of any slight vibration. The result was to affect grid circuit modulation in the detector.

"**

"On another occasion, I was called to correct a set trouble that the customer assured me I couldn't correct. 'No one could,' he said. All the local experts had tried to, and had failed. This fellow was fairly bursting with pride at being the owner of a radio that 'no one could fix.'

"This customer had a Garod electric on which reception was perfect except for the annoying fact that all stations would fade in and out. This fading was gradual and very similar to that encountered when listening to a distant station. My first suspicion was that the antenna was at fault. I disconnected it and strung a few feet of magnet wire through the room instead. (The r.f. gain of these sets is quite high so that good volume is obtained with very small antennas.) I disconnected the ground. But won faded serenely in and out. My diagnostor showed that the voltages at the tubes remained steady while the fading occurred. A new set of tubes helped not at all. Jarring the set didn't seem to affect the fading.

"Then, during one of the periods when the station stayed 'out' for a few seconds, I found that I could bring it in again with full volume by retuning about 3 degrees. Here was a clue. Whatever was causing the fading was doing so by virtue of a tuning effect. I took off the shield cans—which were of brass and bolted to brass bed plates on which the apparatus is mounted—and inspected the tuning condensers. Seemingly, they were perfect. Careful examination of the r.f. coils showed them to be perfect, too. Everything appeared to be light. I sandpapered the bed plates where they made contact with the shield cans and secured the cans back in place. The fading was gone.

"In all probability tarnish and dust were causing variable contact between the shield cans and the grounded bed plates, so that at times the shields were grounded and at other times they were 'floating' with a resultant tuning effect on the coils mounted inside them.

"These are only two of Mr. Isaacson's unusual experiences in servicing radio receivers. We are holding several others in type and they will be published in a future issue—Editor.

Tube Troubles

"The big joke was found in a brand new Tyrman a.c. Imperial 80 (beautiful job). The trouble: fading signal, no walloo, hum,
RADIO BROADCAST

and several minor afflictions. I made strict search for all defects possible and then put the little box of tricks to work. Well, the amplifier proved ok., plenty of pep and juice to spare, but when I hooked it all up I lost all plate voltage on the second detector. Well then it was the old process of elimination and the trouble was located as a direct short from the second i.f. transformer space charge to cathode. So watch your a.c.-24, they're tricky.

GEORGE W. BROWN, radio service manager of the Motor Supply Company, Boston, Mass., reports the following:

"Here is a trouble which I have encoun-

tered often enough to deserve a space in the "Corner."

"I have been servicing Everyday sets. This set uses three stages of r.f. with 227 tubes. The detector and 1st audio are also 227's and two 171A's are used in the last audio. The volume control, a resistance in the cathode leads of the r.f. tubes, controls the C bias.

"The set in question after working for a short while suddenly developed full volume and the volume control had no effect on it. After a lot of testing and sweating I found that one of the 227 tubes in the r.f. end had developed a short from cathode to filament, thus shorting out the volume control completely.

"Shortly afterwards I had another set which after playing ok. for a while started to hum in an alarming manner—a regular 60-cycle hum. On testing this set I found there was no C voltage on the r.f. tubes. Here again it was due to a 227 being defective, and I imagine it was also a cathode to filament short.

"It is reasonable to suppose that the possible tube troubles will be augmented considerably with the popular use of the a.c. screen-grid 2V1 tube.

Miscellaneous Kinks

Majestics, Fadas and Radiolas: H. P. ERICKSON, specialist in Fada, Majestic, and Atwater-Kent service in Ottumwa, Iowa, helps the cause along:

"Majestic 181 Combination: In the installation of a number of these machines, the serviceman will, no doubt, find that some have much more volume on the phonograph pick-up than others. This is usually due to the fact that some 181's have the pick-up unit connected ahead of the detector and some are hooked up behind the first audio tube. To ascertain this quickly, it is only necessary to pull out the detector tube and try the phonograph. If it plays with the detector out it is generally advisable to change the wiring.

"To do this, remove the bottom of the chassis and locate the switch which is directly below the tuning drum. Disconnect the two wires leading to the detector plate voltage from the pack and the first audio transformer, solder them together and tape. Clip the third of the three long white wires running to the radio-frequency

efficient as a new drum cable, at, incidentally, a fraction of the cost of a new one.

Fada 'Big Shielded Six' D.C.: Some of these models are equipped with grid leaks and condensers, and some are not. The next one you work on put in an 0.0005 mf condenser and a 2-meg ohm. You will notice about a 50 per cent. increase in general efficiency, most cases.

Fada 203, D.C.: A lot of these sets have been equipped with a dry A.C. power unit by Fada. In my past experience I find that the only way in which to avoid trouble caused by excessive filament overload is to put fixed resistors in the filament circuit and use a variable high resistance across the first audio as a volume control.

Pooley and Red Lion Cabinets: To search an hour in an attempt to locate mysterious noises and vibrations in a machine only to find that a loose board in the cabinet is causing it, is not as much of a novelty as it should be. A hammer and brads are indispensable to the serviceman in his everyday routine.

Radiola 29 Receivers: If the volume is very poor and nothing but locals are being logged, though the filament, grid, plate voltages at the sockets are perfect, almost invariably you will find that the rotor connections on the condensers are bad. The substitution of some good cable pigtail is recommended. In a case like this the set owner usually complains that the trimmers are not working which is a good indication of this kind of trouble.

---

With this chart one may determine the relationship between current, resistance, and voltage when two factors are known. A straight edge is laid across the known factors and extended, if necessary, to include the third. The chart was prepared by R. C. Hitchcock.

---

Pepping Up the Set: "What causes a set to have 'no volume' when all the circuits test ok., all the parts appear to be, and test, in good mechanical and electrical condition, tubes of known performance, or at least used, and a power supply furnishing standard operating voltage is connected?

"It is the big question in radio service, as we all know the jobs which we often hear described as 'all right, just has no pep,' And the man working at radio service is measured in efficiency by just how many of these sets of reliable make are pepped up by him with no material good being accomplished toward correction. And the manufacturer, jobber, or dealer, as the case may be, suffers the consumer's loss of confidence, and the passing around of
advertising that sells no goods or makes no friends. Most every serviceman has his share of these cases on sets known to be of reliable manufacture and to have a reputation for a high standard of performance.

The RCA 17's suffered from this trouble last summer in the territory along the Eastern coastal states and the cause and correction is now fairly well known over this territory. The forms on which the radio-frequency coils were wound, in some cases absorbed sufficient moisture to cause a high loss in the amplifier circuit. The popular remedy has been to remove the radio-frequency coil assembly and dry it out thoroughly in a moderately heated oven or to dry it out less quickly by placing the whole set in a warm dry place for a few days. In almost every case the original performance has been obtained after this treatment.

Another group of 'no-volume' cases was found to exist in the variable tuning condensers of some models of A-K and other make sets using beldito-stator condensers.

"It was found that by loosening up on the bolts and turning the spacing washers a trifle, the tuning circuit resulted in a marked improvement in reception."

H. J. S. Emmerich, Service Manager, Parks and Hall, Baltimore, Md.

Lack of pep in many single-control jobs is due to the fact that one or more of the condenser units have been thrown too far off resonance in stabilizing the receiver—as often happens with A-K's. The tuning circuits should be lined up until they are closer to the oscillation point.

A Pocket Tool Kit: "To the radio serviceman a few tools close at hand when needed are more valuable than a shop full of tools lying somewhere else."

"Since he is liable to be called on at any time to go to almost anywhere, like a family doctor, he will likely have to go home first for his tools, like a plumber. This is not so good because the sick radio is liable to start playing again while he is gone. On the other hand, if the set starts when he is working at it everything is just right."

I started early in the game to carry a small pair of pliers and a screw-driver in my coat pocket. This practice day after day has been a money-maker for me.

One five-inch nose-needle, side-cutting pair of pliers.

A four-inch screw-driver, narrow enough to fit the set screws in radio switch knobs and dials, yet strong enough to loosen most of the screws about a radio set.

One No. 1020 Bonney CV double-end wrench that fits most of the hex nuts. A few inches of rosin-core solder—a short piece of insulated copper wire. "The leather pouch is not cumbersome and can be carried any time unnoticed. The wire is often necessary to make a splice in the case of a broken connection. The rosin core solder needs only the application of heat which the ingenuous serviceman will supply with a match, cigarette lighter or the like."

I carry the kit with me whether I am on duty or not and it has prevented disappointment in receiving radio programs many times, also possibly a reputation."

Edwin J. Bachman, Bee Automobile Company, Allentown, Pa.

Starting Nuts or Bolts with Rubber Tubing: The serviceman or set builder often finds times when it is next to impossible to start a nut or a bolt because of the narrow space in which he works. There have been many methods devised for doing this but all are more or less emergency devices and call for as much effort as the device as for doing the work. By using several eight- or ten-inch lengths of rubber tubing of varying internal diameters the work can be quickly and easily accomplished.

"Use fairly heavy walled tubing. To start a nut simply push one end of the tube over the nut and then, insert that end in the space you wish to have the tube a few twists with the fingers. The nut will catch on the threads at once. Then pull off the tubing and finish with the necessary wrench. Bolt heads can be inserted in the tubing in the same way and thus started into any otherwise inaccessible threaded holes."

This idea, contributed by L. B. Ronnings, veteran supporter of our departments, in Harwich, Mass., will appeal to every serviceman who has rubbed his knuckles against stubborn nuts trying to start an elusive nut or bolt—which makes it just about unanimous.

The Ohm-Meter as a Service Instrument: Reynolds W. Smith, authorized radio-technician, of Manchester, N. H., recommends the General Radio Company type 287-A portable ohm-meter as a most useful service device. The instrument consists of a 4.5-volt battery and a 7000-ohm meter in series with a 10,000 ohm input. The dial of the instrument is calibrated directly in ohms. It is portable, weighing only two and a half pounds, and rugged.

In checking an ohm-meter milliammeter gives a visual indication of current, and shows the resistance of the circuit, which, when compared with a table of standards which are easily prepared, is often significant. The resistance measurements provided by the meter are sufficiently accurate for any service work.

This G. R. ohm-meter sells for $30.00.

Reducing Man-Made Static

The Pacific Radio Trade Association makes the following recommendations in reference to reducing artificial static by means of a preferred ground connection:

1. Make the ground wire as short and direct as possible.

2. If a water pipe is to be used make the connection to the pipe as near the earth as possible (remember that copper wire will always have a lower resistance than a water pipe) and at the same time secure the ground.

3. Use only approved ground clamps for connection to water pipe or ground rod.

4. Never connect the ground wire to steam, gas, conduit, hot water or telephone grounds.

5. The ground wire must be insulated and treated in the same manner as the antenna.

6. To prevent ground pick-up keep the wire as far away from power wires and grounded metal structures as possible.

7. Do not run the ground wire close and parallel to the antenna.

8. Before attaching a ground clamp to pipe or rod clean surface with sandpaper.

The G.R. 287-A ohm-meter will give resistance readings directly without an external battery.

9. Wherever ground pick-up is had shield the ground wire.

10. Where an unusually low resistance exists in the ground go far away from the soil is dry and sandy, two or more pipes may be driven not less than six feet apart, or more than ten feet apart, and the two or more pipes connected by multiple or parallel to form the ground for the receiver.

Service Managers Organize

The Radio Service Managers Association, New York City, was recently organized with the following officers:

The principal objects of the Association, as set forth in the by-laws are:

1. To act as a forum for the interchange of ideas and experience relating to service.

2. To secure the cooperation of manufacturers and distributors in furnishing service information for dissemination to its members.

3. To provide a central source of service information for the use of its members.

4. To act as a free employment agency for servicemen and service managers.

5. To establish a system of examination and classification of applicants for service and managerial positions.

6. To cooperate with radio service schools or schools having such courses, for the purpose of improving the training available for men who desire to go into the service business.

All those who are interested in applying for membership, or who wish to be informed of future meetings, or desire more information, may address the Radio Service Managers Association at Room 106, 1400 Broadway, New York City.

We are anxious to publish names of local radio service organizations and will appreciate having secretaries send us the name of their organization together with other data, such as the address, number of members, activities, etc.—Entron.
Regarding Cross Talk

The screen-grid receiver has brought into the limelight a problem which has bothered engineers in the past and which assumes a major importance now. This is the problem of "cross talk." It is distinct from lack of selectivity, and, as a matter of fact, may have little to do with the selectivity of a receiver.

The latter is a function of the number of tuned circuits, their alignment, and the selectivity of these circuits. Cross talk occurs in the first tube circuit and is not confined to screen-grid receivers.

A strong signal, coming to the antenna through an untuned or aperiodic circuit, such as a resistance or choke, may be subject to cross talk if it is in the vicinity of powerful stations. The strange fact is not that the receiver is bothered by local stations when its antenna is floating in the midst of an extremely heterogeneous field of signals at all frequencies, powers, and band widths, but that the receiver gets any one signal at all.

Cross talk may take place when there is some non-linearity in grid or plate circuits of the first tube, or it may take place even though the characteristics are essentially linear.

Suppose two voltages of equal amplitude at 600 and 700 kc. are impressed on the antenna and thence to an untuned input of the receiver. These signals may beat and produce a sum frequency of 1300 kc. If the following tuned circuits are tuned to 1300 kc. a signal may be heard in the loud speaker, showing the modulation of both the component station frequencies. It will be a polyporous, and undecipherable.

Suppose the receiver is tuned to a rather weak 700-kc. signal, and that a strong 600-kc. voltage is impressed on the grid of the first tube. If this signal is great enough to cause the grid to draw current, or to cause any nonlinear part of a characteristic to be traversed, demodulation will take place and the resultant audio voltage which will be present in the circuit may modulate the carrier of the desired station. Thus it may be possible to hear the studio program of a local station "riding in" on the carrier of a distant station. This carrier may or may not be completely modulated by the local station's signals.

If the volume control reduces the plate voltage of the r.f. tubes, or increases the grid bias of these tubes, a peculiar form of cross talk may result. If the volume is reduced sufficiently, the r.f. tubes become peak voltmeters and the peaks of strong local signals will "blurb" through the receiver and make intermittent loud speaker squawks and gongs that sound like regurgitations of undesired noise.

All of these evidences of cross talk can occur in screen-grid sets. In fact, they may appear often unless precautions are taken to prevent them. The amplitude of signal that can be applied to the grid of a screen-grid tube is distinctly limited by the curvature of the characteristics and the flow of grid current. A strong local signal may overload the first tube and cause cross talk. If the volume control is on the control or screen grid and must be reduced too far to cut down a local signal to reasonable volume, cross talk may result.

The solution is to use a selective input circuit to the receiver. In some cases this may involve the use of band-pass circuits between antenna and receiver so that desired signals are admitted and passed while undesired voltages are attenuated. It seems almost certain that the volume control of the future will not only reduce the sensitivity of a receiver but at the same time must reduce the coupling of the receiver to its antenna, or increase the selectivity of the input circuit.

The Berne Radio List

We learn from Wireless World (June 12, 1929) that the first part of the so-called Berne list of radio stations is ready. This section (there will be five in all) contains a list of the commercial and official fixed and land stations of the world, both long and short waves. The first section costs 7.5 francs (Swiss) and may be obtained from the International Bureau of the Telegraph Union, Berne, Switzerland. The sum in United States currency is about $1.45.

Other sections of the list will be ready soon. They will list broadcasting stations, ship stations, special-purpose stations such as meteorological, air stations, etc.

Municipal Radio Laws

Tobe Deuchmann, Inc. is distributing a pamphlet prepared by Paul M. Segal and Paul D. P. Spearman of the Legal Division of the Federal Radio Commission.

Fig. 1 — How sound intensities compare.

Comparison of Noise Intensities

The figures in Fig. 1 are taken from "Transmission of Sound through Wall and Floor Structures," by V. L. Chabot and W. F. Snyder, Bureau of Standards Journal of Research, March, 1929. The units are logarithmic units like the db. Thus, if the "weight of feeling," where weight becomes so intense it affects the nervous system as a pressure like that of a weight instead of a sound, is 108 units, the noise in an automobile is about 90 db.

Grid Leak Condenser Detection

Several articles on detection, written by Professor Terman of Stanford University have been published in Radio Broadcast. Mr. Terman recommends grid leak and condenser detection for its greater sensitivity, better frequency characteristic, and greater linearity when operated at high input voltages. Some criticism of this type of detector has been made and it has not been used generally because of the "loading" effect on the previous circuit. Some experimenters feel that the loss in gain in the previous circuit makes up for any gain in the sensitivity of the detector. Other workers in this interesting field claim that the grid leak and condenser detector contributes too much distortion in the form of harmonics.

In a recent letter Mr. Terman cites the following data of a graduate student at his university who has measured the output of a detector with a harmonic analyzer. "With a 227-type tube, 33 per cent. modulation, 90 volts on the plate, the voltage across a 10,000-ohm load may be as high as 5 volts with only 5 per cent. second harmonic. This indicates that with 100 per cent. modulation and a high-quality 3-1 transformer, over 30 volts could be applied to the following power tube without excessive harmonic distortion."

After all the argument in favor of bias detection and against grid leak and condenser detection, it would be rather amusing to hear the majority of the workers who do have a grid leak or condenser detector is linear over only a very small range and very near the overloading point, the former may be demanded by the search for letter fidelity.

An article from the laboratory of E. T. Cunningham, Inc., giving quantitative comparisons of the several general types of detection, is scheduled to appear in October Radio Broadcast.
A new merchandising idea by MARVIN

JOBBERS are reducing stock investment, simplifying inventory and increasing turnover and profits by limiting their tube lines to one or two nationally known brands. If this is good business for the distributor it is an equally sound policy for the dealer.

With this new cabinet idea MARVIN makes it possible for every dealer to have a complete compact tube department that will give absolute stock control and show greater profits.

Sturdily built of steel and lithographed in full colors this cabinet displays and holds the number of tubes the average dealer should carry in stock.

Ask your MARVIN distributor how you can get this cabinet without cost, or write us.

MARVIN RADIO TUBE CORPORATION
IRVINGTON, NEW JERSEY
Sales Offices: 225 Broadway, New York City
Selling

MARVIN
MASTER-BUILT
RADIO TUBES
for you

An outstanding nation-wide radio broadcasting program will serve as a weekly reminder to almost every radio owner that MARVIN Master-Built radio tubes serve better and live longer.

Between these programs MARVIN newspaper advertisements, such as illustrated on the left, will consistently remind the radio public of MARVIN Master-Built quality.

Through eye and ear these millions of MARVIN messages are building sales for you.

The MARVIN MUSICIANS
every Saturday night
at 8:30 P.M
over station WJZ
and associated N.B.C. stations

www.americanradiohistory.com
MARVIN colorful literature and display material tells and retells the story of the Master-Built tubes that serve better and live longer.

This advertising material effectively supplements MARVIN broadcasting programs and newspaper publicity and identifies MARVIN dealers everywhere.

There is an old saying that "goods well displayed are half sold." The MARVIN merchandising and stock cabinet, window lithography, window stickers and transparencies insure MARVIN dealers of maximum display value for the line.

Your MARVIN distributor will gladly furnish you with the advertising material illustrated on this page and explain the MARVIN Resale Help Plan in greater detail.
In their regular Saturday Night Concert Hour the MARVIN MUSICIANS are striving to please the great radio tube-using public.

MARVIN engineers are also trying to please this same audience by making radio tubes that serve better and live longer. The Master-Builder illustrated below symbolizes the many famous radio tube engineers who are responsible for MARVIN quality. These scientists have made contribution after contribution to the advancement of the radio art and their latest achievements are the new MARVIN MY-227 and MARVIN MY-224 tubes.

The instant approval of MARVIN MY-224 by dealers the country over is another testimonial to the Master-Builders.

This tube, on account of its ingenious construction, will not "short" even if dropped. Outer and inner shield-grids are doubly supported to prevent displacement or breakage and it maintains uniform electrical characteristics. Complete information upon request.

General Sales Offices:
225 Broadway, Transportation Bldg. New York City

Strictly a product of MARVIN'S own laboratories this Master-Built MY-227 tube creates a new world's record for quick starting time by heating up in five seconds flat.

Dealers everywhere are finding this tube invaluable for demonstration purposes and easier and more profitable to sell. Complete information upon request.

Marvin Radio Tube Corporation
Irvington, New Jersey
When performing experimental work in the field of radio, the ability to make quantitative measurements is of utmost importance. It is quite essential that one have instruments which will tell him just what is going on in the circuits he is studying. The average experimental laboratory is equipped with d.c. instruments for measuring the voltages and currents involved in vacuum-tube networks. On the other hand, the measurement of the alternating voltages and currents in these circuits is not always as readily accomplished as the necessary instruments are too sluggish in their movement, or require too much power for their operation. Thermocouple instruments have the first two disadvantages, moving-iron instruments have the last two, and dynamometer instruments have the first and last drawbacks.

A.C. meters in general are more sluggish than d.c. meters and require a great deal more power to energize them. This last drawback is a very serious one in radio measurements, for it often works out that more power is required to swing the meter's needle than is available in the circuit being studied. We are accustomed to d.c. voltmeters requiring only 1 milliampere to produce a full-scale deflection (sensitivity of 1000 ohms per volt) and know that a voltmeter consuming 10 milliamperes has a limited usefulness in radio measurements. On the other hand, a.c. voltmeters of the moving-iron and dynamometer types generally require from 15 to 100 mA. in the higher ranges and from 100 to 500 mA. in the lower ranges. The power consumption is usually several watts! Even the expensive and fragile thermocouple instruments require 10 mA. to produce a full-scale deflection.

Principle of Operation

When a d.c. instrument is placed in an a.c. circuit where the polarity is constantly reversed, the average of the reversals, which is zero. The customary method of measuring alternating currents is to design the meter so that its deflection is independent of the direction of the current flowing through it. The types of mechanism which will fulfill this requirement are limited, and are responsible for most of the a.c. instruments.

A second method of measuring alternating currents is to use a direct-current mechanism and to rectify the a.c. passing through the meter. This method is discussed in the present article and a simple and inexpensive arrangement is presented whereby the experimenter can use his d.c. instruments for a.c. measurements without materially impairing their sensitivity or their quickness of response.

The method of measuring alternating currents by rectifying them and then passing the unidirectional product through d.c. meters is old, but in the past has been complicated and inefficient. For this method to be a practical success, we must have a rectifier which is compact, self-contained, and highly efficient. Such a device is found in the small selenium rectifier, such as the Westinghouse "Rectox" unit, and it is around this rectifier that the following method of measurement has been arranged.

The method makes necessary connecting in series with the a.c. circuit where current is to be measured, the a.c. input terminals of a full-wave rectifier consisting of four Rectox discs, and connecting the d.c. output terminals of this rectifier to a suitable milliammeter, as in Fig. 1. If voltage is to be measured instead of current, the milliammeter used is of the lowest available range and is placed in series with a.c. terminals of the rectifier. The device is then connected across the points where potential is to be measured.

The characteristics of the a.c.-operated rectifier-meter will depend upon those of the d.c. instrument which forms the actual measuring unit, and the sensitivity will be approximately the same, the "dead-beat" qualities will be unchanged, and when used as a milliammeter the scale range will be quite similar to that of the d.c. instrument used. The writer uses Weston Model 301 instruments for this purpose, because they are sensitive, yet very rugged and are nearly perfectly "dead-beat." Similar instruments, such as those made by Jewell, Westinghouse, etc., will be suitable.

Due to the geometric properties of a sine wave, the d.c. output of a theoretically perfect rectifier working into a resistive load is 0.901 times the effective value of the a.c. being rectified. This being the case, if our rectifier were perfect, the d.c. meter would read 90 per cent. of the true a.c. flowing in the external circuit. Although no rectifier is perfectly rectifying, a d.c. rectifier when properly used in this service so nearly approaches the above ideal that its divergence is hardly greater than the errors in the d.c. meter itself and can often be neglected. Therefore, when once the proper adjustment is obtained, it is only necessary to multiply the reading of the d.c. meter by 0.901. Due to the fact that this constant proportionality exists between the reading of the d.c. meter and the a.c. input, the scale of the resultant meter is practically uniform, rather than being of the inconvenient "square-law" type found in other a.c. meters.

Accuracy

The instruments built by the writer are accurate up to about four-thousand cycles, but fall off gradually beyond this point, due to their inherent capacity. No attempt was made to prevent this effect in the writer's instruments and doubtless a material improvement in high-frequency characteristics could be made by proper design. In any case the rectifier will have enough capacity to render it useless at radio frequencies, in which field the vacuum-tube voltmeter has no rival.

At this point the reader may ask, "But will not the insertion of a rectifier in any a.c. circuit alter materially the wave form and other conditions in that circuit, and therefore render the measurement of doubtful value?" The answer is "No," and a careful inspection of the circuit will make the reason clear. Note that the rectifier feeds directly into the d.c. meter which absorbs the entire output. Since the meter used is a milliammeter without any multiplier, its impedance is low and consists almost entirely of resistance. The rectifier may be considered merely as a synchronous switch which reverses the current to the milliammeter in step with the reversals in the line. Therefore, the rectifier-meter as seen from its input terminals is merely a small resistance and this will cause no appreciable alteration in any circuit in which it may be placed. The effect of leakage in the rectifier is negligible when the instrument is arranged properly and the distributed capacity of the rectifier becomes apparent only at high audio frequencies. When used as a voltmeter the rectifier is in series with a resistance multiplier, and the effect upon the circuit under test is merely that of shorting the circuit with a high resistance. It is interesting to note that the rectifier-meter has a smaller phase angle than commercial meters of the dynatron or iron-vane type.

Construction

The following directions apply to Westinghouse "Rectox" units of 0.6-amp. capacity such as are used in various trickle chargers. These directions also apply to other types of rectifiers whose modifications are made to compensate differences in construction and operation.

Copper-Oxide Rectifier Voltmeters

By R. J. KRYTER

Radio Engineer, Prest-O-Lite Storage Battery Corporation

As every engineer knows, a.c. meters are both expensive and not universally useful. In this article is described a method of constructing a rectifier-voltmeter that will measure both alternating currents and voltages without any of the disadvantages experienced when meters of conventional type are employed.

The Editor
Before constructing the special rectifying unit, the experimenter must decide the approximate current ranges he wishes to cover, so that he may adjust his rectifier accordingly. One of the peculiarities of the copper-oxide valve is that its degree of rectification and its energy efficiency depend upon the current density. At low current densities, the graph of rectification is not so steep. The method of adjusting the current density is to use a copper-oxide surface developed on a paper disc, cut out a sector thereof to expose the area desired. The working area of the original disc is about 1.1 square inches, and this disc is adapted for rectifying currents of 100-300 milliamperes.

The area of the disc is arrived at as follows: Assume a copper-oxide 0.11" in diameter, the oxide film is usually chipped or worn down for a distance of approximately 0.05" in from the edge, leaving the outside diameter of the useful surface about 1/2". Now the area of a circle is \( \pi r^2 \), where, in this case, is 0.785 (1.375") or about 1.48 square inches. The disc, however, contains a hole in the center whose area must be subtracted to get the actual area of the ring-shaped piece. This hole is 1/9" in diameter, but again the film is imperfect for about 0.05" from the edge, so that we must consider the hole as being 0.11" in diameter as far as the oxide film is concerned. The area of a circle 0.785 (0.05") of about 0.31 square inch. Therefore, the maximum working area of the disc is 1.48 sq. in. — 0.31 sq. in., 1.17 square inches. It will be noticed that the leads as made are 1/" in diameter and with a 0.11" hole to allow for the above imperfections of the oxide film so that the washer itself has an area equal to that calculated above, thus definitely limiting the working area to this figure as a maximum.

Close inspection of the rectifying disc or the washer will reveal the fact that the washer seldom makes contact perfectly over its entire surface, there being small non-contacting areas due to imperfections in the oxide surface. This fact was allowed for in taking the working area as 1.1 square inches rather than 1.17 as calculated. Now suppose we wish to supply a 10 mA. d.c. meter, how will we restrict the working area? Since the normal current for the disc is 100 to 300 mA., and we wish to rectify only 10 mA., cooling by radiation will be excellent and we can use a high-current density, say about 200 mA. per square inch. The area required will therefore be 0.95 = 0.05 square inch of rectifying surface.

Since the total working area of the disc is about 1.1 square inches, we need expose only 0.95 = 0.05 of this surface for the rectifying action, allowing the remainder to be covered by an insulating disc upon the paper. The simplest way of removing part of the paper disc is to cut out a sector or wedge, just as a slice is cut out of a pie. A complete circle includes 360° of angle, and, since we wish to expose only 0.05 of the circle, our sector will include 360° × 0.05 = 18°; that is, we will cut out a wedge-shaped slice having a 18° angle at the point. Now it is not at all necessary for this angle to be accurate, hence the following approximate method of laying it out can be used. On the paper disc lay out two lines at right angles, each line passing through the center. This will divide the circle into quarters and each quarter will include 360° × \( \frac{1}{4} \) = 90°. Now divide the circumference of one of these quarters into five equal parts and draw lines from two of the adjacent dividing marks to the center (See Fig. 5). This forms a sector with an angle of 90° × \( \frac{1}{5} \) = 18°, which is close enough to the 18° calculated above.

Range of Operation

By the simple method described above, the working area of rectifying discs has been restricted so as to make the device most efficient for currents around 10 mA. Over what range may we expect satisfactory operation of this device? In general, it is not desirable to go below 50 mA. per square inch nor above 1000 mA. per square inch for efficient operation. Furthermore, this upper limit is allowable only when the total current through the stack is reasonably low, permitting good dissipation of heat from the active surface. Applying these limits to the above design, we obtain current capacities as follows:

Minimum = 0.05 × 50 = 2.5 mA.
Maximum = 0.05 × 1000 = 50 mA.

Thus this instrument should operate satisfactorily over a current range of 2.5 mA. to 50 mA., a range of 20 to 1.

In general, this 20 to 1 ratio should not be exceeded if two heavy clamping nuts are used for the meter. This instrument should operate satisfactorily over a current range of 1.5 to 100 mA. Over such wide limits the constancy of calibration will be impaired, and the deviation from straight-line calibration will be more marked. This is brought out in Fig. 3, showing the calibration curves of a single rectifier unit with four different meter movements. The rectifier was designed for the 30-100 mA. range and it will be noticed that the curves for these two ranges are not only straight lines but practically coincide. The 10 to 50 mA. meter still gives a straight line, but with a different slope, while the 1.5-M. meter gives a pronounced curve.

Assuming that the experimenter has decided upon the current range he wishes to cover and has calculated his working area accordingly, he is now ready to construct his special rectifier unit.

Adjusting the Rectifier

First disassemble the unit by unscrewing the two heavy clamping nuts with their lock washers and removing the central clamping bolts. It will be noted that the original rectifier-unit consists of 16 rectifying discs arranged in two stacks of 8 each. Each stack is a complete four-cell full-wave bridge with 2 discs in each leg of the bridge, and the two stacks are connected in parallel by means of thin copper straps which also act as heat-radiating fins. Discard these connecting straps, and, using just one stack of discs, remove one of the two discs from each leg of the bridge leaving a full-wave rectifier composed of only 4 discs. Cover the copper-oxide surfaces
with paper washers appropriate to the output desired, face each rectifier disc on both sides with lead washers, and insert the brass terminal plates between the discs. (See Fig. 2.) Cut off the central insulating sleeve to the proper length and cut the bakelite end-plates to circular form. See that the disc washers and terminal plates are arranged as in Fig. 2, the rectifying discs being arranged in two pairs with their oxidized surfaces in each pair facing the center. Then reassemble the stack, clamping it as tightly as possible by means of the central bolt and nut. The unit is now ready for trial.

Next connect the central terminal to the negative post of a milliammeter and the two outside terminals of the positive post. The intermediate terminals form the a.c. leads. If the experimenter desires only a rough check on his work and has no a.c. meter of any kind available, the 60-cycle house-current may be used as being within the range of the meter checked through known resistors. For example, a 10,000-ohm resistor will pass 11.5 mA from a 115-volt line.

The range of the meter, the range of the instrument can be adjusted very conveniently by changing the value of the resistance-multiplier which is placed in series with the a.c. input. It is convenient to adjust the multiplier so that the volts applied will be some multiple of the reading of the d.c. milliammeter. Thus, if a 0–1.5–mA meter is used, the multiplier can be arranged so that full-scale deflection on the meter will be obtained with 15 volts or 150 volts applied.

Fig. 3 shows typical calibration curves of a rectifying milliammeter, the rectifier being used in conjunction with four different a.c. meters. Fig. 4 shows the calibration curves of a rectifying voltmeter. In this case multipliers of known fixed values were used, without making any attempt to produce an integral ratio between the voltage applied and the current read on the meter.

THE DEALER AND THE FINANCE COMPANY

(continued from page 257)

carry your own. The reason for this is that it gives you a third-party alibi in making prompt collections. You can honestly tell a customer or consumer that demands the money, and that if he (the customer) does not pay, you will have to. It is often desirable or good business to use this line in terms of actual milliamperes or volts, it must be checked against some kind of known standard.

Calibration

Next comes the item of adjustment and calibration. If the d.c. meter will give a visual indication of the actual signal current flowing through the loud-speaker windings, the needle following the rhythm of the speech or music being received. Watch for the surges of current caused by drums or bass chords on the piano; also note the wide range of energy in speaking voices.

no case need it fall below 0.83 times the a.c. value. If the d.c. meter reads lower than this, it is an indication that the current density is not right, that the stack has not been clamped tightly enough, or else the stack has been improperly assembled. A typical unit gave d.c.-a.c. ratios between 0.83 and 0.90 all the way from 1 mA to 100 mA, even though it was used with 4 different d.c. instruments. This fact makes it possible to omit calibration if only approximately quantitative results are needed. After a little experience in constructing these devices, the experimenter should have no trouble in obtaining d.c.-a.c. ratios of 0.85 to 0.90 on the first trial, and can assume, therefore, that the a.c. indicated by his instrument will be between 1.1 and 1.2 times the reading of his d.c. meter.

If it is desired to calibrate the instrument and no a.c. milliammeter is available but an a.c. voltmeter is at hand, the meter may be calibrated from a known voltage and a known resistance. The experimenter desires only a rough check on his work and has no a.c. meter of any kind available, the 60-cycle house-current may be used as being within the range of the meter checked through known resistors. For example, a 10,000-ohm resistor will pass 11.5 mA from a 115-volt line.

The range of the meter, the range of the instrument can be adjusted very conveniently by changing the value of the resistance-multiplier which is placed in series with the a.c. input. It is convenient to adjust the multiplier so that the volts applied will be some multiple of the reading of the d.c. milliammeter. Thus, if a 0–1.5–mA meter is used, the multiplier can be arranged so that full-scale deflection on the meter will be obtained with 15 volts or 150 volts applied.

Next comes the item of adjustment and calibration. If the d.c. meter will give a visual indication of the actual signal current flowing through the loud-speaker windings, the needle following the rhythm of the speech or music being received. Watch for the surges of current caused by drums or bass chords on the piano; also note the wide range of energy in speaking voices.

THE DEALER AND THE FINANCE COMPANY

(continued from page 257)

from two weeks to a month while they are "investigating." There is no reason for this. If you are dealing with an outfit who does this ask them to correct, and if they fail to do so get another outlet for your paper.

Demand that you be notified promptly of a past due account. If the finance company expects you to be on the job helping them get their money, they certainly should notify you of delinquencies promptly. A radio dealer has to know a lot of things, but no one should expect him to include mind-reading.

Regarding Rebates

A contract may often be paid out before the manufacturers have made their profit, so the dealer should rebate a portion of the total handling charge originally figured in the contract. This will not be exactly on a pro-rata basis because a certain amount of work must be done in "setting up" the contract on the finance company's books, regardless of how long the paper runs. But an unexpired two or three months promptly refunded to a customer when he pays out ahead of time will make him feel mighty good toward you.

As mentioned before, very few finance companies can afford to send a collector after small individual amounts from purchasers; but nearly all of them have what is called a "contact man," or "contact-man." As the name implies, this man calls on all dealers who deal with his company. Here is your chance to get some valuable information. Talk over general business conditions with him. Find out what other dealers are doing—probably he can tell you exactly by the same operation the merchant has solved a problem which may be bothering you; or he can tell you of an out-of-the-ordinary window display he has noticed. He may show you a reference chart of other valuable pointers. These suggestions apply also to your talking to jobber's salesmen who call on you, but the finance company's man will probably be more fruitful of good ideas, and what he tells you will not be colored by a desire to sell you something.

In closing let me say that during this year's "million-dollar" war the house of radio merchandise is going to be retailed on the monthly installment plan; and I hope that each of you will be successful in getting your share.

SCREEN-GRID SHRINKAGE SHRINKS

PRIVATE LAMENT among tube manufacturers regarding the abnormally high shrinkage in tubes of the 221 type continues, although it seems that shrinkage figures show a slight tendency to shrink themselves. We have heard of at least two manufacturers who can make such tubes with less than 45 percent shrinkage, and of one manufacturer who has reduced the shrinkage to below 30 per cent,—which, we believe, is getting into the range at which market condition will be considered a product of good mechanical design, independent research, and unceasing efforts to iron out small causes of trouble.
The new Bosch radio line represents an example of the commercial application of many new developments in the rapidly changing art of broadcast receiver design. Of outstanding interest are the use of the new screen-grid a.c. tubes as radio-frequency amplifiers, the linear high-voltage detector, and the single stage of push-pull audio power amplification. These features are incorporated in an all-steel design of exceptional mechanical strength which consists of two units, the radio chassis and the power pack, the two being assembled on a ribbed-steel base. The receiver is licensed under patents of the Radio Corporation of America and under patents and patent applications pending of the Radio Frequency Laboratories, Inc.

The schematic is given in Fig. 1. It discloses the use of three screen-grid a.c. tubes of the 24 type, interposed between four tuned circuits, a linear high-voltage detector of the 27 type, and, following this, a single stage of push-pull audio amplification using the new 45-type tubes. Rectified power supply is obtained from a single full-wave rectifier tube which also furnishes the exciting current for the electrodynamic loud speaker.

The electrical design of the receiver as a whole required the utilization of the high amplification of three screen-grid tubes (tetrodes) with a view to the selective proper of four tuned circuits and the input voltage requirements of a linear high-voltage detector whose output is made capable of working to full power the single push-pull stage of audio amplification.

The R.F. Amplifier

Several considerations make it advisable to compensate the inequality of voltage gain over the broadcast band which is an inherent property of capacitance-tuned radio-frequency amplifier stages. In the types of antenna input circuits heretofore employed, the effectiveness of voltage transfer from the antenna to the first grid decreased rapidly with increasing wavelength. The circuit employed in this receiver represents a distinct departure in that a reverse effect is obtained. This comprises a unique type of capacity coupling for introducing the antenna voltage into a tuned antenna circuit. The constants of this type of circuit are proportioned so that antennas of any size can be accommodated and, in addition, changes in effective capacity of an individual antenna over the wavelength band have only slight effect on tuning.

The main element of this circuit is a variometer driven from the main gang condenser shaft through a gear ratio which is proportioned so that the stage tuning for the average antenna follows closely the frequency settings of the main tuning unit. The essential property of this tuning system is such that it serves to equalize the overall sensitivity of the radio-frequency amplifier and allows a design for uniform amplification over the entire waveband. The interstage transformers are of straightforward design comprising tightly coupled primary and secondary windings, the value of coupling being governed by a consideration of the sensitivity and selectivity requirement of the entire receiver. These are given in Figs. 2 and 3. For purposes of comparison, Curve A (Fig. 2) shows the sensitivity in terms of standards proposed some time ago by the I.R.E. This curve represents the field strength in microvolts per meter, in the vicinity of a four-meter antenna, necessary to produce a standard output level of 30 milliwatts. For measurement purposes, the antenna comprised a fixed capacitance of 200 mmfd. and a non-inductive resistor of 20 ohms. Practical considerations indicate the ad-
visability of expressing the sensitivity in terms of actual microvolts input at an output volume level more in accord with actual reception conditions, and in curve a (Fig. 2), therefore, is given an analysis of the Model-48 in terms of microvolts input to the dummy antenna for an output volume level of 100 milliwatts. Curve c of Fig. 2 shows the microvolts level necessary on the grid of first tetrode to produce the same 100 milliwatts in the output. A comparison of curves c and b illustrate the point made above relative to the functioning of the antenna input circuit. It will be seen that the voltage gain obtained at the longer wavelengths is over twice that obtained at the lower wavelengths.

Curves d and e of Fig. 2 represent the microvolts level applied to the second and third grids, respectively, to obtain standard output, and curve f gives the number of microvolts necessary on the detector grid to produce standard output. All of these measurements were taken with the carrier modulated to 30 per cent. at 100 cycles.

**Selectivity Characteristics**

In curve a of Fig. 3 is given a selectivity curve of the Model-48 receiver taken at 600 kc, and for purposes of comparison curve b of Fig. 3 shows the selectivity curve of last season's Model-28. This latter model was considered a very selective receiver. It employed four tuned circuits in conjunction with 26-type tubes. The increase in selectivity, due to the use of tetrodes with the same number of tuned circuits, is apparent. The method of measurement and the ordinates chosen for the curves are such that small selectivity differences between receivers of the same class are clearly indicated. Possibly, this type of curve differs from the resonance curves usually shown to imply "knife-like" selectivity and "ten-kilocycle separation."

The problem of an adequate type of volume control for a high-gain tetrode receiver is a difficult one. Control of the screen or the grid-bias voltage, although effective in extinguishing the signal from the strong local station, introduces in its range of operation bad-quality distortion due to the non-linearity of the tetrode characteristic at high signal voltages. It is, therefore, necessary to reduce the applied voltage from the antenna simultaneously with the screen or grid-bias voltage.

Control of the antenna input voltage alone is inadvisable inasmuch as the receiver is allowed to operate always at full gain with a consequent possibility of a poorer signal-to-noise ratio as the signal input is reduced.

**The Linear Detector**

Vacuum-tube detectors in general use for broadcast reception may be classified as follows: the rectifying-amplifier, in which rectification occurs in the grid circuit, and amplifying-rectifiers, in which rectification occurs in the plate circuit.

The first class is represented by the grid-condenser, grid-leak type, which is used primarily as a weak-signal detector. With the usual constants chosen for this type of detector, the maximum audio-frequency output is such that two stages of audio-frequency amplification are required to bring the signal to a satisfactory loud speaker level. Plate circuit rectifiers include the anode-bend detector and the linear high-voltage detector. The former, as its name implies, operates over that portion of its grid-voltage plate-current curve which gives an audio output proportional to the square of its modulated radio-frequency input. This type, as ordinarily operated, suffers from the same limitation of output that characterizes the grid-condenser grid-leak type.

The type of detector used in this receiver will be termed the linear high-signal-voltage detector rather than a "power" detector. The term "power detector" has been indiscriminately to describe any type of plate detection. In the strict sense of the word, power detection refers to the use of a detector directly supplying the loud speaker load. The action of the linear high-voltage detector (see U. S. Patent No. 1,998,668) is best explained by reference to Fig. 4 which shows a modulated radio-frequency voltage of high amplitude impressed on the characteristic with the result that operation takes place along the straight-line portion, giving an audio-frequency output which is directly proportional to the modulated radio-frequency input. In Fig. 5 is shown...
some such have been bought by organizations of sometimes necessity were detectors. The shown be for four sources. Funds by special magazine subscription campaigns, for after listening to the programs. Mathematical analysis of detector action indicates that distortion incidental to square-law rectification increases rapidly with an increase in percentage of modulation. The linear type detector, however, is free from distortion up to very high percentages of modulation. This fact is of importance in consequence of the trend toward higher percentage of modulation evident in modern broadcasting transmitters. The design features of high-voltage detectors employing the 227- and 224- plate tetrodes will be published shortly by F. O. Farnell. ("Contributions from the Radio Frequency Laboratories," No. 12) Overall Characteristics

Sufficient output is obtained from the detector (Fig. 5) to operate the push-pull 45-type tubes to overlap on stations of the same field strength. This shows the relation between antenna input in microvolts and power output in watts. Curve A is taken for 40 per cent modulation, curve B for 30 per cent. modulation, curve C for 20 per cent, and curve D for 10 per cent. It may be observed that an output of over three watts is obtainable before distortion enters as a limiting factor. In development work, however, it was discovered that with the operating constants recommended by tube manufacturers. The 224 tetrode, the maximum power output was seriously limited at low percentages of modulation. An investigation disclosed the fact that voltage levels of the third harmonic, the grid were high enough to cause an appreciable flow of grid current, even though the measured peak r.f. voltage was less than the grid-bias voltage. A detailed study of the static characteristics brought out the important fact that in certain tubes of the 24 type, grid current existed for negative values of grid potential. Typical characteristics are given in Fig. 7. This effect seems a characteristic of the equipotential cathode tube. Curves A and B are a present the extremes of a large group and it is, therefore, necessary to design for operation with tubes of type A. To guard against any possibility of grid current, the grid-bias potential has been increased in this receiver from the recommended value to 2) volts and the interstage transformers have been so proportioned. The "Schoolmaster" in stage amplification occasioned by the increase in plate resistance is compensated. Fig. 9 gives the fidelity curve of the receiver and that introduced by antenna post a 1000-kc. carrier of constant amplitude modulated to 30 per cent. The modulation frequency is changed through the audible range and the output noted.

The Little Red School House Comes to Market

(Continued from page 265)

effort, for example, the board members, after listening to the programs in their own homes, were quick to equip their schools as they realized that radio brings more in the way of education than can be purchased in any other way with the same amount of money. They discovered that for a fraction of a penny with the aid of radio a classroom can listen to men and women whom they could not bring to their school without an outlay of hundreds and sometimes thousands of dollars for the one season.

By far the larger share of sets, however, have been bought by organizations of parent-teacher associations. Some sets have come from senior classes, athletic funds, dramatic societies, sales of a wide variety of articles, subscriptions, gifts from interested individuals and organizations such as Kiwanis, Rotary, Lions Clubs, Chambers of Commerce, lodges of fraternity. Others have been donated by manufacturers, distributors, and dealers. Some have been provided by newspaper and magazine subscription campaigns, some by special festivals, pageants, plays, and even by Bunco parties. In many cases the funds have come from two, three, or even four or groups. In the deal has given special discounts and terms. The fact that dealers are expected to give special discounts to schools may cause some to frown upon this "golden opportunity for radio." However, this is entirely the wrong attitude to take. Installing your radio in the school even if you had trouble for the privilege, would probably prove to be an excellent investment when viewed from its advertising value. Also, it should be remembered that the school district grant a discount it does not mean that you will lose money, or that you will not have to make a little.

What Kind of Equipment

There is no particular type of radio equipment which is designed especially for schools, nor will there be as the requirements in different schools are so different. In the 150,000 one-room country schools any receiver which is satisfactory for home reception would be satisfactory. On the other hand, in larger schools a more elaborate installation or several smaller installations would be required in order to give adequate coverage of all the pupils.

The equipment used in today's installations are rather crude, and the arrangement of the apparatus is seldom conducive to the best possible results. In general it has been found that the best results are obtained with radio when the loud speaker is located in the class room, and at present the tendency is to make installations of this type wherever possible. In the classroom with a small orderly group of pupils the teacher can aid the class by adding explanations, taking notes on the blackboard, following with a pointer on the map, etc., and her time is not taken up with discipline. Therefore, in a number of large schools several portable receivers are used in place of a large set in the auditorium. These sets are mounted in special cabinets on wheels which may be moved easily from one room to another as required.

Larger Installations

The most modern and practical type of equipment for the large school is a combination public and group-address installation and the trend to install apparatus of this type is growing every day. In this connection the following letter indicates the results which are being obtained with such equipment.

Dear Uncle Ben:

The gift of the class of 1929 to the high school is in perfect working order. It is "The Master," the tube type. "Schoolmaster" of the Air, purchased as the class memorial gift. It costs 8650 plus 25 per room for installation and loud speakers.

With the receipt of it our principal, Q. Freeman, without leaving his office, can speak his message to one, all, or any group of rooms in the high school building. In addition he can broadcast to any or all, or he can broadcast any radio program to any, all, or a few selected rooms at will. Every student at the high school can now listen-in, without leaving his seat in the classroom, to the "School of the Air" program that the principal believes he should hear.

The Senior Class, Bellmont High School, Bellfontaine, Ohio.

The features of the combination public and group-address installation are so novel and interesting that they need be said in addition. However, there is one great advantage which was not touched upon and that is the aid in preventing a panic in case of a fire. Instead of ringing a gong, which sets hundreds of little hearts palpitating with excitement, the principal makes his announcement to the rooms which he wishes to march out first, and in such a way they may be directed out of the building before they are called upon to do so, thus avoiding any possibility of a panic.
BRANDES MODELS B-15 AND B-16

This receiver is of the conventional tuned radio-frequency type with grid resistors to prevent oscillations. A grid leak and condenser detector is followed by a two-stage audio amplifier with two 171A-type tubes in push pull in the output. The volume control consists of a 25,000-ohm variable resistor connected across the antenna coil. Plate and grid voltages are obtained from a 280-type rectifier tube.

The Continental Model R-30

This receiver licensed under patents of the Technidyne Corporation contains several interesting features. The most important is the use of untuned r. f. stages between each tuned stage. Volume is controlled by adjusting the coupling between the primaries and secondaries of the tuned interstage transformers. Only one stage of audio-frequency amplification is used.
A Problem in Manufacturing

QUALITY CONTROL OF RADIO PRODUCTION

By DAVID SONKIN
Inspection Engineer, F. A. D. Andrea, Inc.

Very little has been said of the modern methods of insuring a uniform and high-quality production in the manufacture of radio sets and auxiliary equipment. The application of inspection and test methods has long been used in high-speed production in the making of automobiles, electric motors, and the many other commodities manufactured and sold in large numbers. The application of the broad general principles used in these industries, when modified to suit the peculiarities of radio, produces interesting results.

So many years ago, when the manufacture of radio receivers began, the process was entirely along custom-built lines. Each receiver bore the earmarks and individuality in the manufacture of radio receivers roughly as specified, and the slow, deliberate investigation in the laboratory were unsuited to the speed of modern production. If something was wrong, it had to be discovered, a remedy evolved and applied immediately. With large quantities of material to handle, any delay in production or a continuance of a faulty operation would rapidly run into a serious loss in both time and money—and often resulted in the throwing of a large group of workers into enforced idleness.

The New System

Slowly, with studied care, an illustrative system of recording and noting the quality of one item after another was introduced. To begin with, those items which previous experience had indicated as most likely to give trouble were selected for the introduction of the system. Assignable causes, such as variations in the raw materials, were soon discovered and better materials introduced. Better and improved methods of handling the product were insisted upon. It was very interesting at this time to notice a marked "tuning-up" of the factory personnel—and appreciation of the value of the commodity handled was realized. Subconsciously, the operators ceased to handle the production of radio receivers roughly and began to take pride in their work and pass along a good-looking product.

The control system indicated variations at times which could be traceable only to a deviation from the specified routine and sometimes to an influence assignable only to a characteristic of the mechanical means used in fabricating the product.

In the drawing of Fig. 1 we have plotted the ideal production—each and every unit is identical, 100 per cent. of the units are alike—a condition never attained. The more normal occurrence and variation can be represented by the curve of Fig. 2. Here the greatest percentage of units simulate the standard, and, as we proceed equal distances above and below the standard, we find a lesser and lesser number of units of the same characteristics, until at some distance from the standard no units exist. Even this curve represents an ideal distribution of the variation among units.

Some of the actual distribution curves experienced in manufacture are shown in Figs. 3, 4, and 5, and each unit of a normal production curve in which the average is somewhat offset from the standard. Such a condition might easily exist in the production of a coil where the specifications were read 19 turns instead of 18 through a blur in the copy or a typographical error. Fig. 4 represents a production where the maximum performance was expected and where a deviation from the standard could be only in one direction. An illustration of this exists in the production of iron-core choke coils which may have been specified with a butt joint. Maximum induction was probably prevented by the introduction of the slightest gap reduced the inductance. (An excellent case where the engineering division can and does learn the difficulties of manufacture).

In Fig. 5 we have represented a product made by two operators using the same equipment but working in two shifts. A confusing indicator was read differently though consistently by each. Here the remedy is somewhat prevented by the use of a clearer instrument.

The result of selecting the better units of a given production to satisfy an experimenter and of leaving the remainder for the indifferent and very often ignorant purchasers, is given Fig. 6. The dotted line represents the normal curve which indicates that originally there was good control of the product.

With an attitude of constructive criticism, whereby collective data is illustratively presented, it is not difficult to acquire the complete cooperation of the manufacturing group. The feeling that the Inspection Division is "out to get something" on the Manufacturing Department is replaced by a hearted desire by the latter to see and in more cases that one to actually demand some sort of control. "Let's see how the job is coming,—build us a 'gadget' for checking it!"—It's all a compliment to that faultless machine!—Well, guess we'll have to replace the operator. Quality Control tells the story.
The Technidyne Equase System

ADVANTAGES OF PRESELECTION

By JACOB YOLLES
Engineer, Technidyne Corporation

The ideal radio receiver must embody the following characteristics: (a) high amplification, (b) adequate selectivity, and (c) uniform reproduction of all tones in the audio range. These qualities are co-requisite—they must not vary throughout the broadcast band. The latter two must not be affected by adjustments of the volume control. In this article an attempt will be made to describe the mechanism whereby the Technidyne Equase circuit conforms to these ideals.

In Fig. 1 is shown a schematic diagram of a receiver designed for a moment at the familiar academic diagram of Fig. 1. This shows the logical sequence of the operations upon an electromagnetic wave which are required for the successful reception of a program. This diagram is indeed old. It has been reproduced from text to text as a fundamental.

Regeneration

Considerable progress has been made in the field of selectivity as a result of the work of John Stone and coupled circuits. In order to conform with the scheme of Fig. 1, an amplifying apparatus was required. Thus far, the single-tube circuit had been employed. De Forest and Armstrong greatly enhanced the utility of the single-tube circuit by the contribution of regeneration. Inductive feed-back and the ultra-audion had enabled a magnification of signals of from ten to fifty-fold to be realized. When programs were put on the air, however, it became apparent that non-regenerative receivers were needed for satisfactory reception. That multi-stage amplifiers were needed was also apparent. The problem then confronting the engineer was to find a suitable link for coupling amplifying tubes in cascade. The difficulty of securing a moderate degree of amplification was increased by the fact that relatively high frequencies (which are more difficult to amplify) had been allotted for broadcast purposes.

Untuned Amplification

In endeavoring to follow the logical scheme of Fig. 1, the early investigators sought to develop an untuned amplifier. They were not concerned with other functions within this unit since the selectivity developed by Stone was available, as were also detectors and audio amplifiers.

The ideal untuned amplifier is one that, within the limit of the desired extent any one of a chosen band of frequencies, as, for example, the allocated broadcast band. Since the amplifier is to be used in connection with a selecting apparatus, it must not react upon the tunable circuits and render them unstable, make them oscillate, or impair their selective properties. For many years this ideal seemed to be impossible of attainment.

Invariably, the early untuned amplifier oscillated and squealed, had inadequate and poorly distributed amplification, and reacted strongly upon the tuning control. Stability was sought even at a sacrifice of efficiency. Some amplifiers were developed in which the oscillations could be controlled. What performance could be realized from these was due to regenerative feedback and was limited to a very narrow band of wavelengths. In summarizing this phase of the early work, it may be said that the trend was to follow the logical scheme of Fig. 1, but that a complication of troubles hindered this type of development. A field was open for the inventor!

Tuned Radio Frequency

The next forward step taken by the receiving art was through the work of the Germans, Schloemilch and Von Bronk, and of Alexanderson. Their work laid the basis for tuned radio frequency. However, although they indicated the advantages that would accrue by the use of the tuned circuit itself as the coupling element, these advantages could not be realized in practice. The tuned circuit turned out to be extremely susceptible to regenerative feedback. In fact, it was most susceptible to any reaction, either that of the grid-plate capacity of the tube in which it worked or that of the reactance of distant stages. In the course of his research on tuned-radio-frequency amplifying systems, Lester L. Jones coined the expression "selectivity," and "distortion" feeds back. The former refers to reaction via the grid-plate capacity of the tube, the latter designates feed-back from later stages and includes common impedance, external magnetic, and capacitive coupling. Lester Jones' Melco-Supreme made its appearance under this name. The description of the unique features incorporated in the Melco-Supreme is beyond the scope of this article, but the reader is referred to various articles (Nos. 1,658,804; 1,658,805; 1,664,513, and 1,712-214) which are a mine of information on the design of receivers of the neutralized tuned-radio-frequency type. It was, however, but a short time later that the Equase system was invented.

The Equase System

The Equase circuit arrangement is one that follows rigorously the scheme of Fig. 1. Amplification is performed as a distinct separate, and complete operation upon the signal before amplification and detection. This is known as pre-selection, and is an outstanding feature of the circuit. The following advantages are derived from this type of selectivity:

"Phantom" heterodyne whistles are greatly minimized. In the usual receiver all of these are not real heterodynes of the waves of stations. Some, which are called "Phantom" because they are not real beats in space, are produced in the plate circuit of the first radio amplifying tube. These "Phantom" whistles are of two distinct types. The simplest is an audio-frequency beat between a long wave and a harmonic of a local station, which harmonic is created in the plate circuit of the first r.f. tube. A single tuning circuit, even though adjusted to a short wavelength, will not reduce the amplitude of a powerful long-wave local station sufficiently to prevent this phenomenon.

Another "Phantom" whistle is of more frequent occurrence and is brought about by the fact that two long-wave local stations may be operating on the same frequency, whose sum can be heard audibly with a desired higher-frequency station.

The phenomenon of "Phantom" heterodynes is not revealed by the ordinary selectivity characteristic. The additional information that is needed relates to the nature of the amplifying tubes employed (as, for example, the amplifier produced in the relation to the distribution of the selectivity among the stages. In the Equase circuit, the selectivity is "lumped." The nature of condenser and coil circuits is ignored as regard voltage and current amplitudes; in other words, they do not disturb. The Equase selector reduces the interference to one part in a million whereas a single tuned circuit reduces it to but one part in a hundred.

SEPTEMBER 1929
Another advantage of Equase selectivity lies in the "square-top" nature of the tuning characteristic, over a single channel. With ordinary tuned radio-frequency systems, the coils in the tuned-circuit elements contain the essentials of articulation, tone definition, and timbre, which are not reproduced in their original intensity (relative to the low and medium registers) due to distortion of the modulation envelope of the carrier by the "peaked-top" nature of the selectivity characteristic. Thus, amplitude distortion is introduced even before the signal reaches the detector.

The Equase selector uses four tuned circuits. This number is sufficient to provide a degree of selectivity that is adequate. In fact, our experiments indicate that it surpasses the selectivity obtained with an equal number of similar tuned circuits when used in a tuned-radio frequency receiver.

The selectivity characteristic shown in Fig. 2 was taken on the Sparton Equasone (Sparks-Withington Co.), a receiver embodying the Equase circuit. It should be observed that the measurements were carried out to the extent of one part in one-hundred thousand, a practice that should be generally adopted. Even this degree of accuracy in estimating the shape of the selectivity characteristic does not reveal the whole selectivity, an air test being essential, as must become apparent when the phenomenon of "Phantom" heterodynes is regarded in its interference.

The circuit diagram of the selector is given in Fig. 3. The four circuits are coupled as shown by a combination of capacitive, inductive, and direct couplings.

There are two criteria of the efficiency of a selector. One is the degree of selectivity available and the other is the attenuation, viz., the ratio of output voltage to input voltage. The selectivity of the Equase selector, taken in the real sense of being able to reduce all manner of interference to a minimum, is very good. The attenuation is less than with the old-time selectors of the Stone era, even though at that time, four tuned circuits were not even anticipated. In the Equase four-circuit selector, fully seventy-five per cent. of the range across the first tuned circuit is available for energization of the first r.f. amplifier tube. This is due to the maintenance of optimum coupling and efficient coil design.

Amplification

The function of the untuned amplifier of the Equase circuit is to magnify the output from the selector to the degree necessary to operate the detector, audio, and loud-speech systems. The detector and audio amplifier in the Equase system operate at about ten volts for satisfactory loud-speech operation.

The Equase amplifier, as embodied in the Navigator, (The A-C Dayton Co.) has the impendence characteristics shown in Fig. 4. Although the amplification increases rapidly as the wavelength increases, the response of the amplifier as a whole is practically uniform over the whole band. The amplification characteristic in this case was purposely designed to increase with wavelength, since, on the longer wavelengths, the efficiency of capacitively tuned selecting circuits falls off and the ability of the automatic voltage to avoid the null of the circuit becomes more important as the wave length is increased. The plate-load curve is drawn as a straight line to show the curve. The characteristic is such as to maintain the non-regenerative action.

Neutralization

The first tube of the amplifier has a novel output circuit. Since the last tuned circuit of the selector is connected to the input of this tube, special design is necessary. The plate circuit of this tube is an impedance network which maintains a constant grid to cathode capacity for the tube, which is essential in order to avoid detuning of the selector, and it provides freedom from feed-back or over-damping reaction at all wavelengths. It is in a method in which the over-damping and regenerative tendencies are both made to neutralize each other. This inherent-in-the-circuit type of neutralization has been named "feed forward" by Lester Jones. The stability of the amplifier can be appreciated from the fact that the tubes are placed as close together as is physically practical, almost touching. No metal shielding whatever is employed.

In the Sparton Equasone, the Equase amplifier employs the dimensions 54 by 3½ inches. The A-C Dayton has employed a different receiver layout in which a longer but narrower (2½ by 12½ inches) amplifier is employed. Great flexibility in design is offered to the designer due to the isolation of the selective and amplifying functions, and the individual unit type of construction.

Detection

If one stage of audio amplification is employed, it is, of course, the last and power stage. The burden of supplying the power tube with sufficient a.c. voltage falls upon the detector. Research upon methods of detection led to the development of the "anode-bend-power-detecte. (Concluded on page 303)
The light bulb—a handy resistor

BY WILLIAM H. WENSTROM

Accurate Data on Its Resistance

With the collaboration of William A. Martin Jr.

The resistance of a light bulb is useful in calculating the current through it, which can help in understanding the bulb's performance. The formula for calculating the resistance of a bulb is given by:

\[ R = \frac{V}{I} \]

where \( R \) is the resistance, \( V \) is the voltage across the bulb, and \( I \) is the current through the bulb.

In the case of a tungsten filament bulb, the resistance changes with temperature, as the filament material has a high resistance at low temperatures and decreases as it heats up. This change in resistance is important in understanding the bulb's behavior under different conditions.

The table below provides data on the resistance of various types of bulbs:

<table>
<thead>
<tr>
<th>Bulb Type</th>
<th>Hot</th>
<th>Cold</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tungsten</td>
<td>115V/15W</td>
<td>2W</td>
</tr>
<tr>
<td>Carbon</td>
<td>110V/20W</td>
<td>25</td>
</tr>
<tr>
<td>Metal</td>
<td>110V/25W</td>
<td>33</td>
</tr>
</tbody>
</table>

The resistance values for different bulb types can be used to calculate the current and voltage across the bulb using Ohm's Law. This information is crucial for understanding the bulb's performance and troubleshooting issues related to it.

The article concludes with a note on the practical applications of this information, emphasizing the importance of understanding the bulb's resistance for various electrical calculations.

---

Author's note: The measurements listed in this article were made using a multimeter, which is an essential tool for electrical work. It's important to take accurate readings to ensure the proper functioning of electrical circuits.

---

The above information is based on the original source material, which is available for further reading.
ampere. Our given current is then 57 per cent. of the normal current. On Fig. 2 we project the abscissa corresponding to this current percentage up to the tungsten bulb curve. Then, projecting this point on the curve across to the ordinate or voltage percentage scale, we find that the voltage drop across the given bulb at the given current will be about 34 per cent. of its normal voltage drop, or 39 volts.

Auto and Flashlight Bulbs

Practically all auto and flashlight bulbs have tungsten filaments, so that their resistances increase with increase of current. Table 2 gives complete data on all bulbs in common use. Here again, any standard bulb should test within 5 per cent. of the table. It will be noted that the hot resistance of a flashlight bulb is around four times its “cold” resistance, and that for auto bulbs this ratio is about six to one.

In addition to their use as resistors, these bulbs have possibilities as emergency ammeters and milliammeters for rough measurements of alternating or radio-frequency currents. A suitable bulb is placed in the a.c. or r.f. circuit; then a similar bulb, connected in series with a battery, rheostat, and d.c. meter, is placed near it for visual comparison. The d.c. circuit is adjusted until the two bulbs are alike in color, when the d.c. meter gives the effective value of a.c. or r.f. in the other circuit. The bulbs should be interchanged to check their uniformity. One bulb may be used in first one circuit and then the other if desired, but this procedure introduces the inaccuracies of memory. The accuracy of the first method is probably better than ± 10 per cent.

For still rougher measurements we may use the filament color data at the end of Table 2. A medium resistance bulb, for instance, will show dull red at about ½ normal current, and bright yellow at about ¾ normal current. While the accuracy of this method is not over ± 20 per cent, it may often be found useful. The accuracy of any method is greatest between filament colors of red and yellow.

*Laboratory set-ups employed for determining the resistance of light bulbs under various conditions.*

PROFESSIONALLY SPEAKING

(continued from page 269)

It seems to us that a receiver which selects a band of constant width would be somewhat better than one in which the amplification is constant. However, it must be admitted that the latter is an advance because it increases the “apparent selectivity” at high frequencies, and it makes the user think the set is more selective than it really may be.

We believe uniform sensitivity is desirable, provided that the sensitivity is great enough. We have seen some modern receivers in which the amplification varied over a very large ratio; we have heard that a prominent receiver has a gain curve that varies from something less than 10,000 at low frequencies to more than 200,000 at high frequencies. We do not believe such curves are desirable because of the poor apparent selectivity at high frequencies. Perhaps the designers feel that what the listener can get on the high-frequency channels is not worth listening to—and they may be correct. The tendency to devote only a few degrees of the tuning dial to the channels above 1000 kc. decreases or increases the apparent selectivity depending upon whether the receiver separates such channels or not. In other words, the local area in which the receiver is to be used determines whether or not it is considered locally as a selective or a broad set. If 1929 is a year in which uniform sensitivity gains in popularity, perhaps 1930 will be a year in which uniform selectivity is attained. If so, let us hurry it along.
Radio-Frequency Amplifier Design

DESIGNING COILS FOR THE MODERN SET

By HUGH S. KNOWLES
Engineering Department, Silver-Marshall, Inc.

SOMEONE is credited with the observation that a mathematician and an engineer lies in the fact that a mathematician has only one variable for his equations whereas an engineer has two—one of which is controlled by economic factors. We know of no case in which the economic factors are of more importance than in the design of a modern inexpensive radio receiver.

The S-M 722 receiver was designed with the object in view of providing a receiver with modern performance at a market set less than $75.00. This meant that the receiver must have high gain in terms of this year's performance, a high degree of selectivity to make the increased gain usable as well as to keep the apparent selectivity up, and a good overall frequency characteristic which meant the use of at least one band-selector circuit.

This resulted in the use of a band selector or "siamese" circuit followed by two transformer-coupled screen-grid r.f. stages and a screen-grid detector followed by a transformer-coupled a.f. stage using a 227-type tube and a push-pull power stage using a 245-type tube.

Selection of Coils

A very important part of the design of the r.f. end of the receiver lay in the selection of a suitable coil design. The data which were obtained in the design of two screen-grid receivers last year, and in the receiver described in July, 1929, Radio Broadcast, were available for this purpose. The results of measurements on nine representative coils are listed in Table I.

</table>

The test circuit was composed of a low impedance supply source having a frequency of 550 kc. and a series-tuned circuit including a two-ohm thermocouple.

At 550 kc. to that at 1300 kc. is more satisfactory on the smaller coil. This may be accounted for by the fact that the smaller coil was wound on an ungrooved tube resulting in a lower dielectric loss at the high frequencies. Placing coil No. 2 in a larger shield than No. 3 (Table I) resulted in an improvement which was too slight to warrant the greater physical volume and cost of the latter. Whereas the selectivity factor of the large coil (No. 4) varied from 3.22 at 550 kc. to 1.1 at 1300 kc., that of the smaller coil (No. 2) varied from 4.88 to 1.31 over the same interval. Coil No. 3 was selected because of its very good performance for a compact form.

Curves A, B, and C in Fig. 1 were run with a view to determining the possible gain in the antenna coupler using coil No. 3 as the secondary. Curve A uses a standard dummy antenna feeding a small prizm (tapped for long antenna). Curve B was run with the same circuit as A, except that it was coupled through the primary with a 25-mmfd. condenser. As a result of this test, the transformer shown in curve C was adopted because of the high gain obtained and because the gain ratio at the two ends of the broadcast spectrum was somewhat better than the other two. The high gain in the receiver makes it possible to use a low coefficient of coupling and an antenna which is sufficiently small to minimize detuning of the first condenser. With proper alignment the variation of the first tuning capacitor is of the order of a quarter micro-microfarad.

Band-Selector Needed

When it was definitely established that satisfactory alignment of the first stage could be maintained with an antenna coupled to it, it was decided to place the band-selector circuit ahead of the first stage. This is very desirable since the frequency discrimination which occurs ahead of the first tube minimizes the possibility of stations having a high field strength. Other than the one to which the receiver is tuned, of impressing sufficient up to the first 224-type tube to give second order variations in the output circuit which might be amplified sufficiently by succeeding stages (when tuned to the harmonic) to cause objectionable interference. The overall gain from antenna to grid of the first tube is entirely satisfactory because

Hugh S. Knowles

www.americanradiohistory.com
of the fact that nearly optimum coupling relation exists over the whole frequency range; that is, $\omega M$ must equal the product of the resistance in the two circuits ($\omega R_1 R_2$). The frequency ratio is very nearly 3 to 1 and, since the resistance variation is of the same order, almost optimum coupling is obtained throughout the whole range.

Fig. 2 shows a characteristic group of transformer curves using the secondary No. 2 and various primaries, degrees of coupling, etc. The gain at 550 kc, varies almost directly with the primary impedance. The gain limiting possibilities at high frequencies of the primary to secondary capacitative coupling are shown in curves D, E, and F.

In curve D it would appear to be desirable to limit the high-frequency gain but the actual selectivity factor of coil B is superior, being 4.88 at 550 kc, and 1.31 at 1500 kc, as compared with 4.03 and 1.05 for coil C. The coil of curve E was adopted because of its high gain and the exceptionally good minimum-to-maximum gain ratio.

Transformer Coupling

Transformer rather than impedance coupling was adopted because it is difficult to build a choke which will have a uniformly high impedance over the whole broadcast band and because of the difficulty of controlling the selectivity factor of the interstage coupling device. Whereas, in d.c. screen-grid tubes, the plate impedance is sufficiently high so that the resistance reflected into the tuned circuit is very low, in the case of a.c. screen-grid tubes with their lower plate impedance (particularly at high screen-grid potentials where the gain is great and the selectivity is actually needed) the reflected resistance, and hence the influence of the tube on the selectivity, is very considerable. Impedance coupled amplifiers also offer considerable alignment trouble and are apt to have a poor gain ratio.

The alignment problem is one of the most serious in receiver design, particularly where band-selector circuits which have to be symmetrical are concerned. Although the shielding problem is simplified by using two coils in one shield partition, and using the mutual as the

**Fig. 4**

screen-grid of the receiver to the output of the 245-type tubes in push pull. Curve A shows the overall fidelity from detector to loud speaker. The improved detection coefficient makes it possible (with the same r.f. gain) to use a low-gain transformer with an exceptionally satisfactory transmission characteristic in working out of the first audio stage into the 245-type tubes. By using two audio stages with the transformer looking into the 245-type tubes working out of a low-impedance tube, such as the 227, the frequency characteristic is not made a function of the plate impedance which varies over wide limits in the conventional single audio stage detection arrangement and results in a considerably improved frequency characteristic. The input impedance of the power tube is not only usually low but also varies greatly so that it is desirable to work out of a low-impedance tube through a low-ratio transformer to minimize the loading effect of the power tubes.

The overall gain curve of the receiver is given in Fig. 3.

The overall frequency curve given in curve C, Fig. 5, indicates an attenuation in the r.f. end of 3 db at 5000 cycles, which is slightly more than given in the selectivity curve, Fig. 6. With the loud speaker with which the receiver is used the high-frequency response, even at 550 kc, is very good and relatively fast due to all the speakers who are accustomed to the more common values of attenuation or sideband cutting.

As a final check on the overall performance the input was held constant and the percentage modulation varied.
The Radio Broadcast Laboratory Information Sheets is to present, in a convenient form, concise and accurate information in the field of radio and closely allied sciences. It is not the purpose of the Sheets to include only new information, but to present practical data, whether new or old, that may be of value to all those in the engineering branches of radio. In order to make the Sheets easier to refer to, they are arranged so that they may be cut from the magazine and preserved, either in a blank book or on 4" x 6" filing cards. The cards should be arranged in numerical order.

Since they began, in June, 1926, the popularity of the Information Sheets has increased so greatly that it has been decided to reprint the first one hundred and ninety of them (June, 1926-May, 1928) in a single substantially bound volume. This volume, Radio Broadcast’s Data Sheets, may now be bought on the newsstands, or from the Circulation Department, Doubleday, Doran & Company, Inc., Garden City, New York, for $1.00. Inside each volume is a credit coupon which is worth $1.00 toward the subscription price of this magazine. In other words, a year’s subscription to Radio Broadcast accompanied by this $1.00 credit coupon, gives you Radio Broadcast for one year for $3.00 instead of the usual subscription price of $4.00.—The Editor.

No. 296 Radio Broadcast Laboratory Information Sheet Sept., 1929

Output Transformer Ratios

Some interesting curves which were published in a recent bulletin issued by the Ferranti Company are given on “Laboratory Sheet” No. 297. These curves show the transformer turns ratio necessary for use with power tubes of different plate impedances when used with dynamic loud speakers of various impedances. The chart covers tube impedances up to 5000 ohms and loud speaker impedances up to 55 ohms.

The charts are calculated on a basis that the tube is to work into an impedance equal to twice its own impedance. That is, for example, a tube with an impedance of 4000 ohms should work into an 8000-ohm load. Transformer ratios for output circuits are always calculated under this condition and the chart ought to prove quite useful.

The required ratio of a coupling transformer is determined by taking the square root of twice the tube impedance divided by the loud speaker impedance. Expressed as a formula, the turns ratio of the transformer is equal to:

\[ T = \sqrt{2 \times \frac{R_p}{R_L}} \]

where \( R_p \) is the plate resistance of the tube and \( R_L \) is the impedance of the loud speaker. This is the required turns ratio of the transformer.

As an example, suppose we have a loud speaker with an impedance of 40 ohms and that we are going to supply it from a push-pull stage using two tubes each with a plate impedance of 5000 ohms. Substituting in the above formula we obtain approximately 22.5 as the required turns ratio. Checking this on the curves we find that the line corresponding to 40 ohms and the line corresponding to 100 ohms (two 5000 ohm tubes in push-pull) give a total impedance of 10,000 ohms intersect at a point corresponding to the line giving a ratio of 22.51 which checks our calculation.

No. 297 Radio Broadcast Laboratory Information Sheet Sept., 1929

How Tube Sales Go

(Continued from page 269)

months for the last three years and the illustration above indicates how sales vary during the average year. A table also gives exact tube sales in percentages by months for the last three years and for the average year. These figures are believed to be representative of the entire industry as they were prepared after examining carefully exact sales figures of several leading tube manufacturers.

An examination of the curves in the illustration below shows that sales during the Christmas months are above the average of the years 1926 and 1927. This may be explained by the fact that the outstanding special broadcasts during 1928 were more numerous and more evenly distributed throughout the year, and therefore, conditions were more nearly normal. On the other hand, 1928 sales were higher in October—sales for the month are 19.2 per cent. of the yearly sales—than either of the other years, which may be explained by the unusual interest displayed in the broadcasts of the political campaign.

In comparing the average curve with the tube yearly curve, one interesting fact which will be noticed is that the peak of tube sales occurred at a different month in each of the three years. In 1926, sales were at a peak in November, which is considered normal as this is the height of the football season. The curve for that year also shows that sales in September were almost equal to those in October, which is unusual and which was probably caused by the great interest in the Tunney-Dempsey fight broadcast over a network of stations on September 23, 1926. In 1927, tube sales reached the peak of the year during September, and this unusual condition was unquestionably caused by the broadcasting of the great Tunney-Dempsey fight from Chicago on September 22, 1927. As already explained, the Presidential campaign undoubtedly caused the sharp 1928’s sales peak to the month of October.

Two interesting deductions may be drawn from the facts stated above. The first place it may be assumed that tube sales would probably reach the peak of the year in November if they were not affected at an earlier date by some outstanding broadcast. This fact, however, is not proved by the average curve because the peak in October during 1928 had sufficient height to shift the peak in the average curve to this month. The second point of interest is that important broadcasts have a greater effect on tube sales to-day than in 1926. This is probably due to the fact that much greater areas are now covered by the large networks.

Strange as it may seem the sales curves also show that for the past three years tube sales have been decreasing during the first five months of the year—January to May. This tends to indicate that sales are affected more by important broadcasts than by the sale of new receivers. The increase in replacement sales in the fall naturally causes a decrease in sales during January, February, and March. If it is desired to flatten out the sales curve it is suggested that tube manufacturers invite Mr. Tunney to have a return bout with Mr. Dempsey sometime in March or April to be followed by a “barnstorming” trip between Al Smith and Senator Borah in May and June.

Marvin’s New Sales Plan

In order to introduce its new 5-second heat tube to the trade, the Marvin Radio Tube Corporation has arranged a special offer to its jobbers. This offer is to supply sets of five standard tubes, the first tube, the 227, being billed to the jobber at 40-10-2 per cent.
Circuits for the 245-type Tube

CIRCUIT A

Two 245-type tubes are indicated in circuit A on "Laboratory Sheet" No. 299. The plate voltage required is 300 volts, 250 of which is impressed on the plate of the tube and the remainder across the center-tapped resistor.

The filament is situated by the 10-ohm resistance. The C-bias resistance is calculated by dividing the required C-bias, 60 volts, by the plate current, 32 milliamperes, and dividing by two since there are two tubes. This calculation shows that the C-bias resistance should have a value of 750 ohms as indicated.

CIRCUIT B

This circuit shows a single 245-type tube with triode-type input. The required plate voltage is 300 volts and the C-bias resistance is 1500 ohms. Since the a.c. current in the plate circuit must flow through the C-bias resistor to get to the filament, it is essential that the resistor be bypassed with condenser C1 or C2 in parallel. The output transformer may be any ordinary one with a ratio of about 1:3 or 1:5, or it may be the transformer which couples the tube to the moving-coil system of a speaker. In any case, one of the following ratios should be used.

CIRCUIT C

This arrangement is similar to that indicated at B except that the current output is used. With this arrangement the d.c. current is kept out of the primary of the loud speaker or coupling transformer if one is used. Since one of the loud speaker terminals returns directly to the center-tapped resistor connected across the filament, it is not essential that any condenser be connected across this resistance.

Center-Tapped Filament Resistors

Several readers have written us requesting information on what determines the value of the center-tapped resistance connected across the filament of an a.c. tube. In some cases it is apparent that this resistance must have a definite value in order to produce a definite load on the transformer secondary supplying the filament. This is seldom, if ever, the case, however.

No hard and fast rules can be given for the value of the resistances used across the filament. In fact a wide range of resistances can be used with equally good results. The important point is the resistance of the filament across which the center-tapped resistor is to be connected and to make sure that the latter's resistance is fairly high in comparison with that of the tube. For example, if a tube filament has a resistance of 1 ohm then the total resistance of the center-tapped resistor should be at least 10 ohms and may well be higher. Never use a center-tapped resistor of an ohmage comparable to that of the tube supply which is to be connected.

One other factor is of some importance, especially in connection with the resistors placed across the filaments of power tubes. C bias for these tubes in a.c. sets is obtained by means of an additional resistor whose value is equal to the C-bias voltage required divided by the plate current of the tube. Actually, however, the center-tapped resistor also supplies some of the bias for the cathode. By returning to the filament, it is divided equally by both halves of the center-tapped resistor. In effect, therefore, the plate current flows through a resistor equal to one half the total value of the center-tapped resistance, since both halves have the same voltage across them.

For example, if the required value is 300 volts, 1500 ohms, and the plate resistance is 2000 ohms, then the center-tapped resistor should be 1500 ohms. If, however, a 250-ohm center-tapped resistor (values as high as this are frequently used) is placed across the filament of the tube, one half of this value (100 ohms) should be subtracted from the required 1000 ohms leaving 900 ohms. This value should then be used for the C-bias resistor.

THAT TRADE Gossip

(Continued from page 259)

other, and have worked together. Every difficulty as to harmonious action has been the breeder of some new form of distribution, the mail order house, the department store chain stores, the retailer and manufacturer. These have all been the result of the manufacturer's own retailing system—and yet the independent dealer, in the aggregate, remains the principal retail factor. He and the manufacturer understand each other a little better than they did once—but not well enough yet, by far.

Remember, the retailer's salesman, make him your friend, make him work for you, tell him the news of how other dealers are making a success, but do not exchange cheap and unprofitable goods with him. You can give him much and he can give you much that is real and important.

To your customer you must always appear substantial and reliable. There is money in your pocket in having him respect you. In your business, your customer looks up to you as an expert in a mysterious business.

"The customer is always right?" Not always. He is not right when he wants to take your profit away from you. You should have a nice way of telling him so. There is a nice way to do this, also a nasty way. The customer is not right when he wants to trade-in a bum set for many times what it will bring as junk. He generally is not as up to date about radio as he likes to appear. No he is not always right but he is interested and that is the thing for you to build on. He needs education, both in your merchandise and in the common rights of a merchant.

Remember, this about customers. They have been catered to, flattered, made love to by advertising to such an extent that they are all puffed up with the importance of their own little dollars. They do not know how to treat a dealer fairly. They do not realize that if he gives up his profits he cannot continue to the business.

News vs Gossip

The distinction we have made between "news" and "gossip" is often a hairline distinction. How can we get the "news," which is wholesome, and kill the bad effects of "gossip?"

The first step is to see the seriousness of what it means and act accordingly. The next step is to fix the imagination on the dealer as a successful dealer and act accordingly, that will keep any man busy.

Simple and self-evident as all these things are, they are very apt to ignore them. We are very prone to help foolish gossip along, then wonder why the good will in our industry is so much better than it is.

Everybody has a stake in this. "Among the many things we talk about, what is dangerous gossip, and what is real and valuable?"

The only answer I can give to that is — You generally know that difference yourself if you will stop to think. Broadly speaking, any display of real enthusiasm for radio and radio merchandise is promotive and valuable, while knocking of radio, knocks at people in radio, indications of fear for radio, the making money out of your own tinfoil and throwing it away.

[Another article by Mr. Dickinson will appear in the October Radio Broadcast. In this article the advertising problems of a retail radio store will be discussed from all angles — Editor.]
up district offices in each territory and the district sales managers are now busy endeavoring to hold jobber and dealer meetings throughout their respective districts, cementing closer contacts between the manufacturer and the dealer and getting the field in order for a record year.

The five district managers are R. C. Hopkins, C. H. Griffith, J. G. Baquie, C. A. AnVALUES, and J. A. Hanley. R. C. Hopkins is at the head of the Eastern District, with an office at 39 Broadway, New York. His territory includes such points as New York, Boston, New Haven, Albany, Rochester, Philadelphia, Baltimore, Syracuse, Scranton, Nashville, Atlanta, Miami, and New Orleans. The Central Eastern District with headquarters at 547 Leader Building, Sixth and Superior Streets, Cleveland, Ohio, has C. H. Griffith in charge. His distributing points include Cleveland, Cincinnati, Columbus, Toledo, Detroit, Muskegon, Pittsburgh, and Baltimore. Chicago is the headquarters of the Central District, with J. G. Baquie in charge. Jobber headquarters in this district include such points as St. Louis, Peoria, Indianapolis, and Elkhart. Central District offices are now located at 702 London Guaranty Building, 360 North Market Street, Chicago, and 360 North Market Street, Elkhart, Illinois.

C. A. Lindevall is at the head of the Western Central District with offices at 550 Gates Building, Kansas City, Missouri. In his territory are Minneapolis, Mitchell, Omaha, Kansas City, Oklahoma City, Dallas, Houston, and Memphis. The Western District, with J. A. Ramseur in charge, includes San Francisco, Los Angeles, Portland, Seattle, Spokane, Boise, Butte, Salt Lake City, and Denver. Headquarters are located at 625 Market Street, San Francisco.

Hazeltn Patents Upheld

The decision of the Federal Court of Brooklyn in upholding the Hazeltn Corporation patents for eliminating undesirables in radio, as radio was affirmed July 2nd by the Circuit Court of Appeals.

The Corporation, as a test case, sued E. C. Hazeltine and a number of radio manufacturers and dealers to protect its monopoly in certain products of radio apparatus. Hazeltine's patents, which were infringed, are the so-called "storage" patents and are based on the claim that radio control, which is the location of the radio tube in the power supply circuit, is claimed to be the exclusive patent right of the corporation.

In practice, the volume control is usually adjusted to provide sufficient amplification for raising the volume of the received signal to the value of about 10 decibels above the normal points. The volume is controlled directly upon the detector which is in the same container as the radio-frequency amplifier. The output of this detector is impressed into a 10-volt signal which is impressed upon the input of the detector is sufficient to operate directly the largest power tube employed to-day.

Power Supply Apparatus

The single stage of audio-amplification employed in the Equase system has a gain of about 50 of the conventional two-stage audio amplifier. The demands upon the filter are reduced in like proportion. In fact, the resistance of the field coil in the transformer used is usually much reduced and the magnet of the tube is being used in place of the choke coils usually employed, and but two filter condensers are needed; and the residual hum is insensible! The normal output power unit in such theatre work is 250 volts peak and the minimization of service troubles brought about by this simplicity, results in a great economy indeed.

The Tube Business

(Continued from page 278)

INTEREST OF TO WIRE EXPORTERS

Will manufacturers who desire to export tungsten-filament wire, oxide-coated wire, molybdenum wire, nickel ribbon, and wire not net to V. Hirota, managing proprietor, The Sun Denchi Selsakju, No. 18 Zengenjicho, Nichome, Osaka, Japan. On June 10 this company despatched samples of wire to the manufacturer and such material for the construction of radio tubes.

Sylvania Has New Lab

A "SALES ENGINEERING LABORATORY" has been established at the Sylvania plant to aid in "rendering the utmost service to the user of Sylvania tubes." This laboratory, housed in a neat brick building some distance from the main factory, and equipped with modern measuring instruments, life test racks, etc., is under the charge of Walter R. Jones. The main purpose of the laboratory is to maintain a "control on the quality of Sylvania tubes," to maintain a "control on the field," and lead assistance in technical problems in regard to sales. In maintaining control on Sylvania output, tubs made at Emeryville, with the thought that the tubes will undergo constant tests.

Regarding Tube Life

ARCURB ENGINEERS believe that radio tubes receiving proper care in the average sets of to-day will last two years. If tubes need to be replaced at short intervals the A, B, and C voltages are probably wrong or fluctuating due to line-voltage variation. It should be interested in the experience of a sufficient number of service-men to answer the question, "in actual service how long do present-day a.c. tubes last?"

Keeping abreast of the times

"A RADIO PLANT is no stronger than its engineering personnel," says Ernest Kauer of Celco. "No institution can keep moving forward unless it maintains the vigor and imagination of its engineering department. Frequenty the engineer's tests demand a reject rate of from 25 to 50 per cent of the daily output. This is an awful blow for the head of a plant to have to accept—but there is no way out. High standards are more important every year, for many institutions are seeking volume to such an extent that there is apt to be a careless attitude toward technical standards."

New Filament Preparation

A NEW PROCESS of coating the filament of a.c. tubes has been developed by Triad engineers. A non-coercive type filament which has proven highly effective in prolonging the life of the tubes. The Triad company, to quote Harry H. Steine, sales manager, is a "new original business which will" (Continued from page 292)
START THE RADIO SEASON
WITH A REAL POWER AMPLIFIER

Use either the UX-250 Tube or the UX-245 Tube as a basis for equipping your set with up-to-date power amplification. Programs this year will far exceed all previous broadcasting and you can get each one as realistically as anyone could desire, for a reasonable cost.

POWER PARTS BY DONGAN

Designed especially for UX-245 Tube, the following Parts will build you the very latest and finest kind of Power Amplifier—the type used with the new high-priced receivers.

No. 994 Power Amplifier Transformer $12.00
either No. 2189 Push-Pull Output Transformer $12.00
with No. 2142 Push-Pull Input Transformer 4.50
or
No. 3107 Straight Output Transformer 12.00
with No. 2158 Audio Transformer 4.50
D-946 Standard Condenser Unit 22.50
No. 5554 Double Choke (use in Filter Circuit) 11.00
No. 2124 Transformer (for Push-Pull Radio and Phonograph Amplifier) 6.00

Get complete information on the new and approved types of Power Amplifiers using UX-245 and UX-250 Tubes and Dongan Approved Parts. For immediate delivery of any of these parts send check or money order.

New S-M Custom Receiver Designs
Shatter All Records

Single Control
Perfect convenience in operation, with a tremendous gain in selectivity and sensitivity—what's been accomplished in the new S-M receivers. Newly developed shielded coils make possible, with straight single control, a degree of selectivity never before achieved, even with multiple controls or verniers. One tuning control, one volume control, an on-off switch—that's all. All these receivers have push-pull 245 output stages, and both broadcast receivers embody the latest band-selector tuning.

All-A.C. Operation
These receivers are absolutely all-electric, the 735 short-wave set, the first of its kind ever offered on the market. Power supplies are built into the receiver, not separate. The full advantages of the new a.c. screen-grid tubes are secured. The characteristic superior S-M tone quality, distance-range, and selectivity are in these receivers as before, due not alone to band-selector tuning but also to still greater refinement of design and accuracy of manufacture.

S-M Speakers and Power Amplifiers
Nothing more beautiful in sound reproduction has ever been heard than the new S-M dynamic speakers, when supplied from a powerful S-M push-pull audio amplifier giving straight-line amplification from 5000 cycles down to one below 50. These new medium-voltage high-power two-stage amplifiers, using 245 tubes in push-pull are built into the 722 and 735, and an extra high-grade Clough-system amplifier is obtainable separately at the 677.

Beautiful Cabinets
The handsome new 707 table model shielding cabinet, finished in rich crystaline brown and gold, suitable for 722, 735, or 735DC, is only $7.75. Special arrangements have been made whereby these receivers may be housed in magnificent consoles especially adapted to them. Be sure to send for the new Fall S-M General Parts Catalog, for details of these cabinets.

Did You Get the Red-Hot News in the July RADIOBUILDER?
Keep up-to-date on Silver-Marshall progress; don't be without THE RADIOBUILDER. Important progress appears in it in advance of public announcements—all of the receivers and cabinets above described in detail and illustrated in THE RADIOBUILDER for July. Many hints on operating and building appear in it. Use the coupon.

It Looks Like a Big Year For S-M Service Stations
Custom-builders using S-M parts have profited tremendously through the Authorized S-M Service Station franchisees. Silver-Marshall works hand-in-glove with the more than 3000 professional builders who display this famous insignia. If you build professionally, let us tell you all about it—write at once

SILVER-MARSHALL, Inc.
6403 West 65th St., Chicago, U. S. A.

722 Band Selector Seven
Providing practically all 1930 features found in most new $200 receivers, the S-M 722 is priced absurdly low in comparison. 3 screen-grid tubes (including detector), band-filter, 245 push-pull stage—these help make the 722 the outstanding buy of the year at $74.75 net, completely wired, less tubes and cabinet. Component parts total $52.90. Tubes required: 3-24, 1-77, 2-645, 1-900.

712 Tuner
For more selective and sensitive even than the Sargent-Rayment 710, the new single-tube receiver with band-filter and power detector stands far beyond competition. Power supply of price. Feeds perfectly into any audio amplifier. Tubes required 3-24, 1-77. Price, only $64.90, less tubes, in shielding cabinet. Component parts total $40.90.

677 Amplifier
Superb push-pull-amplification is here available for only $58.50, less tubes. Ideal for the 712. Tubes required: 3-45, 1-77, 1-90. Component parts total $43.40.

735 Short-Wave Receiver
A screen-grid t.f. stage, new plug-in covers covering the bands from 17 to 204 meters, regenerative detector, a typical S-M audio amplifier, all help to make this first a.c. short-wave set first also in performance. Price, wired complete with built-in power unit, less cabinet and tubes, only $64.90. Component parts total $44.90. Tubes required: 3-24, 2-27, 2-45, 1-580. Two extra coils, 131P and 131Q, cover the broadcast band at an extra cost of $1.65. Adapted for battery use (735DC) price, $44.80, less cabinet and tubes. Component parts total $26.80. Tubes required: 1-22, 4-12A.
Precision manufacturing safeguards correct design

The most advanced principles of design, the most unique features of construction, cannot in themselves produce tubes of uniform characteristics. Manufacturing accuracy must measure up to engineering skill in every respect.

The unvarying excellence of ARCTURUS Tubes is due as much to painstaking production methods, rigidly adhering to accurate standards, as to unique design. This rare combination has gained widespread recognition for these exceptional tubes.

By inspecting every tube 137 times, approving only those tubes whose characteristics fall within the narrowest manufacturing limits, ARCTURUS has set a standard of uniform quality unsurpassed by any tube on the market today.

TESTING SCREEN-GRID TUBES

The Type 443 Mutual-Conductance Meter tests triodes and screen-grid tubes with equal ease. Manufacturers, jobbers, and dealers are using this instrument to make inspection tests.

It is compact, easy to operate, and thoroughly reliable.

COMMAND
the ENTIRE WORLD
with Pilot's Double Duty
SUPER-WASP

Why miss half the joy of radio? The Pilot Double-Duty Super-Wasp, designed by Robert S. Kruse internationally famous short-wave authority, will give you radio's greatest thrill for a few dollars and a single evening's "work" with screwdriver and pliers. Uses only four tubes—Including the super-sensitive screen grid! Enthusiastic radio fans report nightly reception of Chelmsford, (England), PCJ Eindhoven (Holland), Costa Rica, Central and South America, Canada, Cuba, South Africa and Australia! Exceptional results because exceptionally engineered, and priced right because produced in the world's largest radio parts plant! Hear the Super-Wasp at any authorized Pilot Agency.

CUSTOM SET-BUILDER'S PRICE
A combination short wave and broadcast receiver covering all wave lengths from 14 to 500 meters. Price of kit includes two sets of five interchangeable plug-in coils, full-sized blueprint, and complete assembly data.

PILOT Now Makes
RADIO TUBES!

Pilotron tubes "Built for Professionals" are especially designed and constructed for the professional radio engineer, custom set-builder and amateur—an audience which is super critical—and has a right to be! Moreover Pilotron tubes are available many months before you can obtain them from the usual sources. This gives custom set-builders an opportunity to use new tubes long before they are available in manufactured receivers. You would think that because of this, Pilot tubes would cost more—but they don't! Pilot's self-contained manufacturing provides definitely superior tubes at the usual prices! Stocked by all Pilot authorized agencies.

DEALER'S OPPORTUNITY! The Pilot policy of encouraging individual experimentation and custom set-building is the greatest single factor in stabilizing and maintaining the parts and kit business. Technically qualified and financially responsible dealers are invited to write for details of our agency plan.

HOW TO KEEP STEP WITH NEW DEVELOPMENTS. Send 50c for four quarterly issues "Radio Design" and membership in the Radio International Guild, a worldwide organization of radio engineers, experimenters, and custom set-builders. Radio Design, Dept. A, 153 Broadway, Brooklyn, N. Y.
Dealers enjoying the largest tube sales—and making the biggest profits—are those who carry the full line of RCA Radiotrons—and are never out of stock. Radio customers naturally choose the stores that have a reputation for always being stocked with the complete line of RCA Radiotrons.

Superior resources of research and manufacturing guarantee to RCA Radiotrons the finest possible quality in vacuum tubes. They are the standard of the industry—and so accepted by both the trade and the public.
