Maximum Service in Minimum Space

TRIPLETT Thin Line INSTRUMENTS

Precision performance by new thin instrument with standard Triplet movement housed in either metal or molded case. No projecting base; wider shroud to strengthen face; simplified zero adjustment; balanced bridge support; metal bridges at both ends; doubly supported core. For "Precision in limited space" write for Triplet Thin Line Bulletin.

The Triplet Combat Line

New Answers to specialized needs of War: Production Speed-up and Standardization; Performance under the Stress and Vibrations of Combat Service.

Model 437 J P—A rectangular line of meters to meet dimensions shown (see diagram). Wide-open scale for maximum readability. Complete coverage AC-DC Voltmeters, Ammeters and Wattmeters. Magnetic or static shielding provided on order. Molded Plastic Case for maximum protection in high voltage circuits. Pivots, Jewels and other component parts designed to meet severe vibration requirements.

Model 372—Frequency Meter—"All-American make" Vibrating Reed Frequency Meter. Maximum readability by grouping of Reeds. Range—Frequency-Voltage to meet specific requirements. Protected against excessive panel vibration. In standard 3 inch mounting or on special order in any cataloged Triplet Case.

A WORD ABOUT DELIVERIES

Naturally deliveries are subject to necessary priority regulations. We urge prompt filing of orders for delivery as may be consistent with America's War effort.

MAILBAG

Dear Editor:

As a regular reader of Radio-Craft, I have picked up a number of tricks that are quite a help at times. To get the best out of each issue I have to read from cover to cover because I can never tell where I might find something useful.

In many of the articles the writer, in my estimation, does not go far enough. In these times of priorities and lack of radio men, there are many newcomers to the field who are not thoroughly acquainted with all the intricacies to be encountered.

All this discourse is brought out by two articles. On page 125 of the November issue there is a short article by Thomas D. Bigelow. Now the idea is quite all right but don’t you think that Mr. Bigelow should have taken care of the problem of using meters which are not sufficiently damped to prevent too great overshooting?

If the service man likes to use a scale where the readings are close to the maximum point of the scale and using a meter with no damping, in time it will injure the meter. The question of a resistance in series with the meter and shunted by a momentary contact switch of the push-button or toggle type will protect the meter against this trouble. The value of the resistance should be such that with the resistance in the circuit, the meter will read about 75% of the actual voltage when the resistor is shorted the meter will swing gently to the point of actual value.

Well I guess that gives everything off my chest.

By the way, how about getting Radio-Craft when one is in the army? I expect to be there soon.

DAVID LEBAHRE
Detroit, Mich.

D.C. variations in primary have no effect on secondary, but A.C. variations do. When using crystal phones it is always advisable to put a volume control in series with it.—(Editor)

HELPs BEGINNERS

Dear Editor:

I would like to thank you for the “Gernsback Educational Library. Recently a scout leader asked me to teach some of the boys enough about radio to enable them to get merit badges, and I was swamped until I thought of your books. The kids “ate ‘em up” and our town has a whole new crop of budding “super-bloopers” (and De- Forests, I hope).

I depleted my junk box building three tube A.C.-D.C. shortwave sets for them. A lot of them wanted B.C.L. coils, but I told them the first time I found them containing a repairable set that tuned almost 160 meters to an aerial it was curtains for the whole program.

Most of the kids wanted bread-board models, with all the works out in the open to be admired, and we were going broke buying top-of-panel mount sockets until I thought of using wafer sockets, with 1/2 inch brass spacers to raise them up for base-board wiring.

I lad in a gross of Fahnstock clips and plenty of soldering lugs and short wood screws, and now we’re in mass production. I also use 40-lamps in series with the 0.3 amp. tubes to drop the voltage for the heaters, its cheaper than 50-watt resistors or line cord resistors and involves no calculations. I’ve connected two 70’s, three 76’s, or a 6D6, 43 and 2525 up, and using the 40-watt tube, a very satisfactory arrangement with equally good results.

I find that for a beginner with little money to spend on radio, the A.C.-D.C. circuit is best in the long run; batteries come high. Hum is sometimes a little bad with phonics, but I have thought of a solution. How about hooking up a 6SK7 and 6SJ7 in parallel, then wiring them in series to a 2525 EF amplifier and 2525 rectifier? The 0.15 amp. tubes in parallel should work in a series arrangement with the 0.3 amp. heaters, and the tubes which are most critical to hum would be at ground potential.

I’ll try it as soon as I can get a couple of the 0.15 amp. tubes. NEIL EPLIN, Alberton, Mont.

(We are glad Mr. Eplin found the Gernsback Educational Library of such great help. It has helped thousands.

His idea to reduce hum sounds interesting, and ought to work out, if chassis is connected through a condenser to a good ground.—(Editor)

SIGNAL TRACER WORKS FINE

Dear Editor:

With reference to Mr. Olson’s article in a previous issue, presenting the project of a signal tracer I am sorry to say that I have made such a device myself with good results.

As I considered it more practical, the outfit was built in a large ex-tester box which I bought for the purpose, and I have now to complete a tester which will work in the same box along side the former, but in this country there is a very great shortage of milliammeters so that I will have to wait until the war is over.

ANNALDO E. ROBERT
Oncativo 4563
LANUS, F.C.S., ARGENTINA
LIKES CIRCUIT DIAGRAMS

Dear Editor:
I have been a steady subscriber to your magazines for the past four years. These magazines have been read many, many times.

This year I purchased a large looseleaf "radio scrapbook" and pasted in all diagrams of interest to me. Looking over this scrapbook there is no doubt that the chief diagrams are of amplifiers. At this time transformerless ones are of special importance.

The scrapbook is also strong on T.R.F. circuits and detroit of television and "ham" articles.

Many times I have seen only one diagram of interest to me in a magazine, but felt it worth the thirty cents.

It makes me smile to see a diagram using a two cent resistor instead of a ninety cent choke which would cost us Canadians $4.50 and which at the present time is unavailable.

I would appreciate seeing a diagram of a three-stage T.R.F. tuner, preferably 6SK7, 6SK7, 6SJ7 or 6CS5. So—more circuit diagrams, please!

GILBERT MILLER,
Toronto, Canada.

(We are glad Mr. Miller likes the diagrams, and regret that due to the war, circuits on television and ham rig are unavailable or are obsolete. We look forward to a tremendous return to this type of data when the victory is won. As for the T.R.F. tuner, a future issue will give information on this.—Editor)

WANTS EXPERIMENTAL ARTICLES

Dear Editor:

One reason why Radio-Craft is the best radio magazine is because of its many interesting features.

Of main interest to me are the Experimental Departments and the Mailbag section. I would like more articles on experimental effects and especially on communication by induction.

MELVIN SMITH,
Los Angeles, Calif.

(We are glad Mr. Smith likes our magazine. We expect to have articles on experimental effects, communication by induction for example, real soon.—Editor)

LIKES FILM RECORDING

Dear Editor:

An article written by H. W. Knettel in Radio-Craft Magazine interested me tremendously.

The article entitled "Wide Range Film Recording for Home Use" at once aroused (up till now) "sleeping" interest in sound reproduction. "A long interest" brought on by current events!

However being a former sound man and amateur home recordist, and that coupled with the simple fact that I love music of every type, naturally I'm vitally interested in any and every advance in sound reproduction.

Can you give me any further information on this new instrument direct from the manufacturer? I would appreciate it if I might learn a bit more about it.

DAN H. OHLSON,
(No address given)
(Oraloid Products Division at Johnson City, N. Y. should be able to give Mr. Ohslien the required information.—Editor)

INTERESTED IN AUDIO DATA

Dear Editor:

In the October issue of Radio-Craft there is an article by Fred Sligerman entitled "Practical Transformer Design" which was very interesting, instructive and valuable. This is especially so at the present time because certain types of transformers are unobtainable without a priority and no household radio service man can obtain one.

For this reason I am glad to hear of having to wind some when the set is won and the owner is willing to pay the cost. Wire of the sizes and quantity needed will be a bottleneck although I happen to have a small quantity.

At the end of the article the author states that in the event that the readers of Radio-Craft would be interested in a future article on output and audio transformers, it will be printed. Practically no articles have been published in this subject to my knowledge and I believe it would be of a great deal of interest and value. Please consider it seriously.

Another article which I believe would be of interest and value is an A.C.-D.C. V.T.V.M. and ohmmeter such as RCA's voltohmyst. But sensitive microameters such as are used in the RCA arrangement are not only unobtainable, but are not in the service man's possession. So, while I have not gotten around to it as yet and the work is now, may not get the time, still I wish to do it. That is, to utilize a direct-coupled amplifier similar to the audio amplifiers you have published articles about.

It would appear as if an 0-10 milliammeter could then be used and yet have the circuit sensitive without grid current flowing to render the low readings inaccurate.

A great many servicemen have basic milliammeters with scales of 0-1 and 0-10 milliams.

C. D. HEWITT,
Hamden, Conn.

(We plan to have something soon on audio frequency transformers, and later something on vacuum tube voltmeters and ohmmeters.—Editor)

SHORT WAVE FAN

Dear Editor:

I just got acquainted with your magazine. In the June, 1940, edition I found a list of short wave stations which I found to be very good.

I am an ardent radio amateur, especially a DX fan. I saw the notice about a more complete list of short wave stations. I have a six tube set which I am using for DX work.

I'll be very appreciative of your cooperation to help me by sending me the short wave list.

ANTHONY LASCKOWSKI,
(No address)

(Since reader Lasckowski gave no address we were unable to answer him. However it might be stated here that all lists of stations of course are now rendered obsolete by the war and will probably be revised when its over.—Editor)

COOKE'S SLIDE RULE

Dear Editor:

In the October issue of Radio-Craft I noticed an inquiry regarding the Cooke Slide Rule.

This slide rule is listed in the Keuffel and Esser Company catalog but at present is a priority article and cannot be obtained without a preference rating.

L. E. COOKE,
Lient. (jg) USN
Anacostia Station,
Washington, D. C.

Felix the Cat had a bewildered look on his face in 1929 when he swung around for hours on a phonograph turntable in front of television’s early scanning disks. Felix’s image was slashed into 60 horizontal lines—60 streaks of light and shade. Engineers of RCA watched the antics of Felix as he was tossed through space to receiving screens. They realized that all streaks and flicker must be removed.

Scientists of RCA Laboratories abandoned mechanical scanners and developed an all-electronic system of television, featuring the Iconoscope and Kinescope, electronic “eyes” of the radio camera and the receiving set. Motors and high-speed disks were eliminated both at transmitter and receiver. Electronic television became as quiet and fool-proof in operation as a home radio set.

By 1936, the number of lines per picture had been increased to 343, with marked improvement in quality. But the research men still were not satisfied. They continued to experiment, and to develop new equipment, for finer pictures of 441 lines. Before Pearl Harbor, 525-line television pictures were on the air from the NBC station atop the Empire State Building.

The streaks had vanished. Television at last had the texture of rotogravure. Now, faces and scenes are photographed directly from television screens without betraying the presence of scanning lines.

Brought to life by electronic tubes, and given wing by radio, television emerged from RCA Laboratories to reveal its practical usefulness. Today, knowledge gained from years of television research is contributing vitally to the war effort.

Recognizing the importance of television as a post-war industry and useful public service, RCA is continually pioneering in the science of radio sight. Television’s album of progress has only begun.

**RCA LABORATORIES**

*A Service of Radio Corporation of America, RCA Building, New York*

**PIONEER IN RADIO, ELECTRONICS, TELEVISION**

*Other Services of RCA: RCA Manufacturing Co., Inc. * Radiomarine Corporation of America

THE present war, which is changing everything on the face of this globe, will leave a strong imprint on post-war radio receivers. There will be revolutionary changes not only in radio sets, but in everything connected with radio.

By the time the war is over, the majority of radio receivers now in use will be outdated. In a radio sense, they will be antiquated. Behind locked doors in our radio and research laboratories, there is tremendous activity today. Great advances and many new discoveries have been made in the radio and allied fields and the end is not in sight.

All authorities are agreed that right after the cessation of hostilities, Radio Broadcasting in the United States will swing almost immediately into FM (frequency modulation). If the war had not intervened in 1941, there would now be in operation many hundreds of FM transmitters throughout this country. Only the scarcity of materials and labor, as well as the necessities of war cut all FM expansion down to almost the zero point. Inasmuch as television is explicitly linked with FM, there can be little question that frequency modulation will be the order of the day after the war.

War production, war fabrication and assembling technique will no doubt carry over when peace returns once more. For this reason, radio sets of the future will not only be constructed by entirely new methods, but the materials in these sets will vastly change, too.

Plastics, for instance, will be strongly represented in post-war sets. Ordinary wood and similar materials will almost disappear, except perhaps in the larger console sets—and even here it will be superseded by plastic-laminated wood which does not shrink nor warp; it is in some respects stronger than steel. When I say "plastics," I mean a variety of plastics. The pre-war plastic cabinet, for instance, is only one type. I just mentioned wood-plastics, but we also have today fabric-plastics—that is, fabrics impregnated with plastics; and the new paper-plastics—paper impregnated with plastics. So strong is this new substance that it is already being used in airplane wing-tips.

Manufactured radio sets will probably no longer have the hundreds of different soldered connections. Soon the soldered connection will be out-dated. We will have a good deal of instant-spot welding in most of the wire and other connections in radio sets. But I can foresee the day when even this will be outmoded. I can imagine commercial radio sets without a single soldered or welded connection. It is quite possible to do so and still have excellent electrical connections. Radio tubes, for instance, have never had soldered connections, because the tube must be taken out and replaced. It is conceivable that post-war receivers will have many of their components arranged in such a manner that each one can be taken out without unsoldering. We will have wires fabricated of tough metal, yet good conductors. Each one of these wires will have a mechanical connection at each end, which will make positive contact with other connectors or components.

Instead of having as many condensers and resistors as we have today, radio circuits, due to a new variety of tubes, will be simplified to such an extent that all of the smaller condensers will be assembled in a single block, as will most of the resistors. We will have resistor blocks and condenser blocks to which all connections are made. These blocks will have the individual condensers or resistors, as the case may be, mechanically fitted in such a way, that each one can be pulled out and a new one inserted without any tools, yet the contacts will all be perfect.

All this will help tremendously not only in assembling the receivers but, more important, in servicing radio sets.

The major trouble with pre-war radio sets was, that it is often a hopeless job to try and find out what is wrong in a set and too much time is wasted in finding defective components.

I maintain that in the past, there has been entirely too much radio engineering and too little physics. May I recommend to the radio industry that the physicist has a tremendous job to perform in our post-war radios. All of our sets are much too complicated and they need to be simplified; in the process they will automatically become more efficient and better than ever before.

When I put such emphasis on physics, I say so for the following considerations:

There exists a tremendous amount of misinformation and blind groping in many phases of radio today. The old-time radio man, when he thinks back to the crystal days, will remember having heard reports of singing and talking water faucets, talking tea kettles and frying pans—in the vicinity of radio transmitters. These are important clues which have never been followed up by any physicist. Have you ever heard of the speaking and talking arc lamp? Did you know that an ordinary incandescent lamp can be made to emit music? Have you ever heard a talking transformer or a singing motor or dynamo? All of these things are well known in physics but the radio engineer has not worried his head about it. What I am trying to say is, that our present loud speakers are woefully inadequate and that the future sound reproducers, will bear no resemblance to our present infantile types.

Physicists are well acquainted with molecular sound emission. The radio designer knows little about this. Finally, every scientist knows that the cricket is the most efficient sound machine known. By rubbing his legs against the wings, a relatively tremendous sound is generated—a feature which we never have been remotely tried to reproduce or make use of.

You can hear a cricket on a clear night over a good distance. The power that is used to generate that sound is of astronomical minuteness when compared to the sound reproducers which we use in our radio sets today.

The post-war radio receiver will have many of the above features incorporated in it. Twenty years hence we will look with amusement upon pre-war radio receivers. They will make us laugh—the same as we laugh or smile at the old crystal receiver today.
A Digest of News Events of Interest to the Radio Craftsman

NEW RECORDING STUDIOS

The new WOR recording studios, representing the last word in recording facilities, started operation last month.

Two new Scully recording lathes are used for cutting masters on lacquered glass discs. These recording machines represent the utmost in craftsmanship and precision, thereby enabling the production of the finest recordings obtainable.

Recordings can be taken "off the air" or "off the line," through some fourteen channels, with all channels interchangeable. Special recordings can be prepared in the cutting room; any desired combination of program or effects is possible.

INSTRUCTOR POSITIONS OPEN

The Civil Service Commission announced last month that it is seeking Student and Junior Instructors for the Army Air Forces Technical Schools and the Navy Aviation Service Schools. Student Instructors receive $1620 a year; Junior Instructors, $3000 a year.

Student Instructors will be given training in radio operating, engineering, airplane mechanics, and shop work, for a three to six month period. Graduates of the course are promoted to Junior Instructor.

Student Instructors not subject to early draft, can qualify through completion of one year's college study; through the possession of a Civil Aeronautics Administration ground instructor's certificate, airplane mechanic's certificate; or experience as a machinist, camera repairman, radio repairman; through completion of a six-month course in a radio school.

No written test is required. Applicant's qualifications will be judged from record of training and experience. Age limits are 20 years old and up.

Applications should be filed with the Secretary, Board of Civil Service Examiners, Chanute Field, Rantoul, Illinois.

U.S. ARMY IN AFRICA BROADCASTS

When the American Army landed in Morocco November 8, they had with them a powerful long-wave transmitter.

Technical details of course are secret, but it may be stated that it was a powerful aid in the landing operations.

Operating on the same wavelength as the local station—Radio Morocco—IT broadcast to the population President Roosevelt's message to the French people. Then Lieut. Gen. Dwight D. Eisenhower's orders to those of the French troops who were willing to act cooperatively with the U. S. landing forces, was broadcast, followed by General Henri Giraud's call to the French soldiers that the hour for them to restore themselves had come.

Radio Morocco (whose sponsorship and reliability has been questioned for some time) attempted to drown out the Army broadcasts by attempting "jamming" instead of broadcasting its usual material.

It tried to warn its listeners that a "clandestine" transmitter was operating on its wavelength, but to no avail. In the meantime the members of the German Armistice Commission were furious and fiercely demanded of the French authorities that they locate and smash the "clandestine" station.

But the Army station crashed through just the same and dramatically announced, "This is the transmitter of the American armed forces."

These soul-stirring broadcasts were heard even in London, and were rebroadcast by the British Broadcasting Corporation.

There is no doubt about the heartening effect such a broadcast by the Allied nations had upon the populace of the invaded country.

It certainly is to be expected that this will be one of the instruments of modern warfare, and one way in which the Allied nations can give mass intelligence to the citizenry of a country they are wresting from the Nazis.

AMATEUR "WIRED" RADIO

Use by Prince George county (Md.) amateur radio operators of electric light and power lines instead of air waves may revise civilian defense communications nationally, it was learned last month.

Under the system, any house radio equipped with a microphone may be set tuned to the frequency used by the amateurs to receive civilian defense messages when plugged into a wall socket.

Thomas F. McNulty, chief of the War Emergency Radio Service of the Maryland Council of Defense, told of the system now being used by amateurs in the county, and said that the system, already viewed by Washington civilian defense officials, may revise communications systems nationally.

Two sending stations, one in Hyattsville, are in operation now, sending waves over ordinary electric light wires instead of through the air.

It was pointed out that enemy planes could not use the messages as a beacon to locate objectives.

Seven transmitting stations are planned for the Prince George county network, and receiving sets will be placed in homes of all air raid wardens in the county. McNulty said OCD officials in Washington were "very interested" in the system, (dubbed by the amateurs "wired wireless") and indicated it might be used for international communication in case of telephone breakdown.

The battery of recording machines in the reference recording room of WOR's recording studios. Note the microscopes for examining the grooves, and the hoses of the exhaust system which takes away the minute chips and cuttings. Fourteen channels are available at all times, for "off-the-line" or "off-the-air" recording.

The student's view of the recording room at WOR. "Off-the-air" recordings are made here.
NEW CIRCULAR FM ANTENNAS

RADIO ON "HOME FRONT" IS WAR NECESSITY

The American Standards Association is starting a "Victory" repair standardization at the request of WPB and the War Production Board. "The radio receiver in nearly every American home has become an indispensable home front in the maintenance of civilian morale and in the enlightenment of every American citizen on the conduct of the War, both at home and abroad," Dr. O. H. Caldwell, former Federal Radio Commissioner, said last month when he revealed that the American Standards Association has, at the request of the Office of Price Administration and the War Production Board, undertaken a program of standardization and simplification of radio replacement parts.

Dr. Caldwell is chairman of the War Committee on replacement parts for Civilian Radio. As soon as the committee which he heads has completed its work of standardizing the repair parts chosen, these parts will be available to the radio receiver owners, WPB and OPA are expected to allot materials for manufacture of the standardized replacement parts and to issue limitation and price orders. The ASA standards will thus serve as a basis for assurance of continued operation of all modern home receivers for the duration of the war.

Considerable care is being exercised by the ASA committee to make sure that the quality of the standard repair parts chosen will be suitable from the set owners' standpoint. The "Victory" line of repair parts will be fully defined as to performance, dimensions and construction in the standards now in preparation. Sufficient parts of each type will be included in the standards to adequately service almost all of the modern home receivers in use today. Parts are not included in the project.

In the design of these standard parts the ASA War Committee is making every effort to provide units that will be mechanically interchangeable with present parts with a minimum of difficulty. In addition, non-essential or less critical materials, such as these materials, will be used wherever possible in these parts as compared with their peacetime prototypes.

Through simplification of the number of variant ranges now in use and the use of multi-purpose units when practicable, the actual number of parts will be held to an absolute minimum in the forthcoming standards. This will further serve to reduce the amount of materials kept in inventory by minimizing the stock of parts held by jobbers and service men.

For example some 62 standard volume controls have been proposed to serve as replacements for the overwhelming majority of the thousands of different types used in home radio receivers, the WPB and OPA are expected to allot materials for manufacture of the standardized replacement parts and to issue limitation and price orders. The ASA standards will thus serve as a basis for assurance of continued operation of all modern home receivers for the duration of the war.

S.W. STATIONS CLOSE

In the interests of national security and defense, and the successful conduct of the war, the Board of War Communications has ordered that the international radio broadcast stations WRUL, WRUK, and WRUW to cease operation.

In the meantime the Office of War Information will take over these stations and utilize the equipment for the best interests of the United States.
WHAT IS AHEAD IN ELECTRONICS?

Dr. De Forest in his laboratory working on one of his latest devices.

er level, remove slate from coal at the mines, sort the pure crystals of rock salt, level elevators, open doors, control punch presses, detect smoke and fumes, measure vibration and thickness.

X-ray, priceless electronic tool of the doctor, now examines heavy steel castings for imperfections, detects porosities in welded seams, see hidden defects in automobile tires, searches candy bars for foreign materials, picks good oranges from bad, analyzes metals and alloys in terms of diffraction patterns.

And now the intensive development of Electronics, demanded by the necessities of modern warfare, has multiplied a hundredfold the ingenious applications of the electron tube to uses and needs heretofore unpredictable. Foremost of these in the popular mind are the several applications in war work. These new principles, will, after the war, be equally useful applied to transport and private planes in the air, and at sea render collision in fog with ship or iceberg forever impossible.

Radio direction-finding devices, automatic homing systems, simplified blind landing beams, absolute altimeters, multifarious radio communication while in flight—all these advances have been greatly accelerated by war's demands. The future years of peace will immeasurably benefit by this enforced, often frenzied activity to make of modern aviation a science of safety. Modern aviation, as it is today, would be quite impossible without the generous aid of radio in its every department.

Frequency modulation has been taken from the commercial laboratories and been redesigned for practical use in Signal Corps work, tank warfare and military uses. Thereby its later application to police requirements has been vastly improved—a field where its peculiar properties of static avoidance will be of far greater value than merely to transmit the ultra-sonics of broadcast music, unappreciated or unheard by the average human ear.

Television, laid away in mothballs for the duration, will most certainly burst into full bloom within a short time after peace has been declared, and the author predict that within 2 years thereafter, we will have sale, practical screen projection receivers for the home, giving us large size images which will be easy on the eyes, adequate in detail, and abundantly bright, and at prices within reach of the many, if not quite for the multitude.

A little later we are going to see 3-color television as optional with the black and white of today. The possibilities lying hidden in the crystalline materials of fluorescent surfaces are as yet but dimly appreciated. Therein lie fallow fields for research by the physical chemist. It is conceivable that surfaces may be discovered which, chameleon-like will change their vivid colors of fluorescence depending upon the degree, or wave length, of ultraviolet light flooding them, so that from the same screen may be obtained in proper sequence the blue, the green, and the magenta to translate the electron stream into the true colors of the distant scene's reproduction.

Here again we will witness a sudden upsurge of television development and refinement, duplicating in form, if not quite in degree, the phenomenal rise and popular acceptance of the Radio Broadcast following the close of the last war.

For the intensive development of simplified, manufacturing processes and mass production methods which today's large radio manufacturers have been compelled to develop, will directly serve to equip these for economical quantity production of the new, improved television instruments and cathode beam tubes.

The genetic effect of electronic X-rays has already produced new kinds of flowers, many well improved strains of fruits, vegetables, and grains as seeds are bombarded with millions of volts. The electronic microscope has revealed to biologists the character of the tobacco mosaic virus, a deadly crop disease that has cost growers millions of dollars a year.

Biography today discloses when broken bones are mending, when teeth are decaying, how to treat a sinus condition; it shows the presence of tuberculosis and silicosis. Then comes therapy, as X-rays treat skin disorders and infections and wage war against cancer, gangrene and gas bacilli. By inducetherapy, another electronic application, heat is safely generated in living tissues. The electro-cardiograph amplifies the faint voltages of the heart muscle and records action on photographic paper for the guidance of the physician.

Radio is no longer jazz, jive, "hi-music," or even music fit to hear, sandwiched be-
VARIOUS APPLICATIONS OF ELECTRONICS IN INDUSTRY

1) Electronic tubes of various sizes and types as used in televisions and transmitting. (2) The most powerful X-ray machine in the world at the National Bureau of Standards, has 1.9 megavolt capacity. (3) Phototube system installed in cement kiln for temperature detection and control. (4) Water-cooled tube used in television transmitter. (5) Thyratron control panel controlling spot welder. (6) Herbert Duval, G. E. engineer, with model of new circular-type antenna for portable use. (7) Thyratron motor control alongside cable-stranding machine. These are only a few of the myriads of applications of electronic tubes and devices in modern industry. The art is growing by leaps and bounds and will open up unknown worlds for man’s inventive genius.

—Photos courtesy of General Electric Company

Air transport pilots will have constantly before them, on the screen of a cathode-ray tube, clear warning of any obstacles ahead, so that mountains will lose their terror in darkness, and thick weather, and blind landings will be facilitated. At sea the ship’s pilot will detect nearby shipping or icebergs through fog and darkness as plainly as in clear weather by day.

Today, with that magical Aladdin’s lamp, the electron tube, the engineer can command electrons so that they will do his bidding. For the first time he has hold of electricity itself—not just its manifestations. All that has gone before is only a preparation for a new and greater adventure in living.

In the early days of the electrical application, the Morse Telegraph monopolized, almost alone, the stage of commercial development. Then came Edison, Tesla, Elihu Thomson, and Sprague, to lead this communication agent out into the streets, the factory, the far-reaching trolley lines. Thus modern industry blossomed gigantically through the stimulus of electric power. And

OPTICS AND ELECTRONICS

By JOHN R. KEARNEY

T\textsc{hose} interested in electronics find it essential to have a good understanding of the basic principles of physics which apply in this field. Ordinary light, as an example, is familiar to all of us and we take it for granted. Yet, if you go into the subject, you will find more than enough to occupy your attention for hours on end. But we are interested chiefly in its practical aspects.

Let's examine some of the properties of ordinary light. We may define light as the agent which produces vision. In a dark room we cannot see, but where there is light we do see, and the degree of vision depends on how much light is present.

\textbf{LIGHT}

Light must be present upon the object which is to be seen. If we have a light in our eyes produced by the glare of a lamp in a street car and look out into the dark street, we cannot see objects in the street because the light on them is not sufficient. Light must be present on the object to be seen. The light must pass from the object to the eye, and in some cases light can be seen at the edges of an object behind which a light is shining. Under such conditions, \textit{diffraction} may occur. This being the elevation of the light rays from a straight course when partially cut off by an obstacle.

When passing through an opening or near an opening, light rays may be diffracted and will be accompanied by \textit{prismatic} colors due to interference of the light waves. The word \textit{prismatic}, in case you had forgotten, means refracted or formed by a prism, or exhibiting rainbow tints as the result of prismatic action.

The word \textit{refracted} meant that the light ray is bent or turned aside, deflected from its straight course, as the result of the section of the light wave-front having different velocities in a non-homogeneous medium. That is, in Fig. 1, the velocity of particle number one might be different from that of particle number two, and as a result the wave shape would be bent by the action of the medium.

Ordinarily, all parts of the wave would travel at the same velocity. However, in oblique passage of the wave from one medium to another, or in a medium whose density is not uniform, refraction occurs. As an example, an electron moving in a non-uniform electrostatic or electromagnetic field may be bent or refracted, as in a television tube.

The word \textit{homogeneous} means of the same composition or structure throughout. Substances such as paper or muddy water may transmit light, without allowing objects to be seen clearly, and are termed \textit{transparent}. They are not homogeneous bodies, but light in passing through them is scattered in all directions at the surfaces of the innumerable little particles throughout the mass. Even transparent bodies, such as glass or water, reflect at the surface, a part of the light that falls upon them. Bodies may be transparent for some kinds of light and opaque to others, which is caused by the body colors. Electronic apparatus may use light filters on lenses to exclude various kinds of light and to permit entrance of infra-red or some other special kind of light, giving the system a selectivity character.

\textbf{INTENSITY OF LIGHT}

An important principle is that light travels in \textit{straight lines} in a medium of uniform character. Like radio waves and other forms of radiant energy, light energy varies inversely as the square of the distance from the source. If the light on an object is 2 foot-candles at a distance of 4 feet, the light intensity at 8 feet will be

\[
I' = \frac{I \cdot d^2}{d'^2} = \frac{2 \cdot 4^2}{8^2} = \frac{32}{64} = 0.5 \text{ foot-candle}
\]

The foot-candle is the standard measure of light. An idea of values of light intensity in foot-candles can be gained by consideration of the following arbitrary ratings:

- Good illumination for reading—4 foot-candles; poor illumination for reading 1 to 2 foot-candles; full moonlight 0.02 foot-candles.

\textbf{VELOCITY OF LIGHT}

The velocity of light is practically instantaneous, being about 186,000 miles per sec. This is roughly equivalent to a billion feet per second. Or, in one billionth-of-a-second light travels 1 foot of distance, approximately.

Aberration is the displacement from the mean position, as the result of velocity of the object or of the source. As an example, consult Fig. 2. The telescope is pointed at a star, but the earth is moving in its orbit with a velocity of 18.51 miles/sec, so the eyepiece moves a distance "d" between "a" and "b" at a velocity V=1. The tangent of the angle is:

\[
V = \frac{d}{r} = \tan \theta
\]

where V-2 is the velocity of light. Recent aberration observations give the constant of aberration as 20.492" and the velocity of light then is:

\[
V = 186,000 \text{ miles per second}
\]

An ultra-high-frequency radio wave may have a length of 1 meter, (equivalent to 3.28 ft.), while a light wave has a length of one billionth of a foot, roughly.

\textbf{REFLECTION OF LIGHT}

Like radio waves or heat waves, if the light waves strike a good reflector they will be turned back at the same angle and with little loss of energy. The requirements of the light reflector differ in many respects from those of radio wave or heat wave reflectors, but in general the light reflector should be smooth, highly polished and clean. An accumulation of dust, grime and dirt cuts down the efficiency of a reflector or of a lens in an electronic device. In the same way, fog or snow will cut down such signals. An idea that does not seem to have been exploited is to use super-sonic frequencies or ultra-sonic waves for electronic alarm systems, such waves having short lengths which are less affected than light waves by changes in the air mass. If sound

\textbf{ELECTRONICS}

Many of our readers are interested in electronic applications of radio circuits, etc., and this article should be of interest to them, as it discusses light and lenses, the theory of which is so important to phototube applications.
is assumed to have a frequency of 1100 ft./sec., the wavelength at 30,000 cycles would be 0.036 meter, equivalent to about twelve hundredths of a foot.

REFRACTION OF LIGHT
When light strikes a perfect reflector, the angle of incidence is equal to the angle of reflection. In Fig. 3, the angle \( \theta_1 \) would be the same as \( \theta_2 \) under such conditions. The action is different when the light wave passes through a medium having a different density or structure than the original medium. As shown in Fig. 4, if light strikes the surface in the horizontal plane at an angle \( \alpha \), with the vertical it will not continue in the original direction but will follow a new path. This path will have an angle \( \gamma \), with the vertical and Snell's law states:

\[
\sin i = \mu \sin r
\]

where \( \mu \) is the index of refraction. The ratio of velocity of light in vacuum to that in the substance is called the "index of refraction" of the substance. Some indices for sodium light are:

<table>

LENSES
Lenses are pieces of glass or other transparent substance usually bounded by spherical surfaces, and are used in forming optical images. The line which passes through the center and joins the spherical surfaces is called the "principal axis." If the light waves are convergent, the lines are drawn inward toward the lens, and if divergent, outward. The "principal focus" of a lens is the point on the line of sight to which parallel rays of light pass. For convergent lenses, \( f \) is positive, and for divergent lenses, \( f \) is negative.

In Fig. 5, the conjugate foci are points "A" and "B." The focal length of the lens is \( f \). For convergent lenses, \( f \) is positive, and for divergent lenses, \( f \) is negative. When light from any point \( P \) passes through a lens, upon emerging from the lens it is either directed toward or away from some other point \( B \), these points being the conjugate foci. If the lens is thin, the line joining the points will pass through the center of the lens, but when the line does not coincide with the principal axis of the lens, the line between \( C \) and \( D \) is called the secondary axis.

Where transmission of light over a long route is necessary, a lens system permits more efficient operation than can be obtained without some form of focusing of the light rays. In Fig. 8, a light bulb sends out a beam which is picked up by a photoelectric cell. The filament of the lamp bulb has a height \( d - 1 \) and the height of the object, or its diameter, is \( d - 2 \). The relationship may then be expressed:

\[
\frac{A}{B} = \frac{d - 1}{d - 2}
\]

In a practical problem, it might be known that distance \( B \) is to be a certain value and the proper value of focal distance \( f \) and of distance between lens and bulb is to be determined. The diameter of the object and lamp filament height would be known factors. Then,

\[
B = \frac{(A) (d - 2)}{(d - 1)}
\]

and \( f = \frac{1}{A} + \frac{1}{B} \)

All dimensions, it should be observed, must lie in the same units; inches or feet, not both. For that matter, the metric units can be used.

REFLECTORS
The amount of light reflected depends not only on the material of which the reflector is made, but upon the color and wavelengths of the light. The wavelengths are given in microns. A micron is a millionth of a meter. A table showing these wavelengths and the per cent reflection for various mirror or reflector surfaces is given below:

<table>
<thead>

</table>

Various forms of reflectors have been used. As the result of experience in the practical work of building headlamps, motorlamps were given efficient lamps employing a double convex lens and an elliptical mirror reflector, the bullet shaped type often seen. This development of the automotive engineers could be applied equally well in electronics to secure a strong beam for long distance transmission within line of sight.

PRACTICAL APPLICATION OF ELECTRONIC CONTROL
For any specific application, it is well to consult the companies specializing in this field. Names and addresses may be obtained from any trade directory. In this field no bungling or half-done jobs are tolerated. In many cases electronic control is not

NEW ELECTRON MICROSCOPE

A new electron microscope, small enough and inexpensive enough to be available to industrial, medical and research organizations, has been developed by RCA Laboratories, it was announced last month, by Dr. V. K. Zworykin, Associate Director of RCA Laboratories, and Dr. James Hillier, inspecting the new mobile electron microscope which they developed, which can magnify up to 100,000 times. (3) Bacterium vibrio shuyl-kilienne (commonly found in streams), as micrographs by the electron microscope.

NEW ELECTRON MICROSCOPE

1. Magnification up to 100,000 diameters are obtainable which are 50 to 100 times more powerful than the strongest optical microscope.
2. Through the high resolving power and large depth of focus of the instrument, accurate calibration of magnification is possible and particle size and distribution determined.
4. Film of tobacco mosaic virus, and the study of anti-serum in the control of plant viruses.
5. Discovery of the fact that virus particles have internal structures, as found in the vaccinia virus.
6. Recording the action of germicidal agents on individual bacteria.
7. Investigation of smokes and dusts, both beneficial and harmful types.
9. Magnifications up to 100,000 diameters are obtainable which are 50 to 100 times more powerful than the strongest optical microscope.
10. For instance, a blood corpuscle is magnified to a diameter of a 2-foot sofa pillow. A dime thus magnified would appear more than a mile in diameter; or a human hair would appear as large as a giant red-wood tree.
11. To accomplish such magnifications the electron microscope uses electrons—infinitesimal bits of electricity—instead of light rays; and magnetic or electrostatic fields instead of glass lenses.

ELECTRONICS

These photos give some idea of the value of the electron microscope today. (1) is a micrograph of mercurochrome. (2) Shows Dr. V. K. Zworykin, Associate Director of RCA Laboratories, and Dr. James Hillier, inspecting the new mobile electron microscope. (4) Face powder magnified 54,000 times. Bear in mind that these micrographs show "depth", owing to the three-dimensional photographing ability incorporated in the electron microscope; a valuable aid in research.
A VERSATILE SQUARE WAVE AND PULSE GENERATOR

PART 1
By WARREN MILLER.

THE instrument which will be described is easily constructed and in its application is one of the most useful instruments for the experimenter, technician and engineer. When the instrument is operated as a square-wave generator it can be used for complete audio measurements such as transmission line measurements, audio-frequency amplifier checks, filter checks, pad or network checks, and a number of other uses where a quick observation of the frequency response characteristic of a particular system is required.

NATURE OF MEASUREMENTS

Due to the nature of square waves (exact details are omitted since they are highly technical), that is, as they are generated, the transmission of same through any form of apparatus, will show the defect or the perfection of said apparatus, because perfect reproduction requires perfect response over a wide band. For it must be remembered, a square wave has, besides its fundamental frequency harmonics of the fundamental wave in its character, and the number of harmonics present usually run up to the tenth harmonic of the fundamental.

For example, if we have an amplifier whose frequency response is to be observed, the following setup is required, (see Fig. 1).

![Diagram of setup](image)

A dummy lead, pure resistive, equal to the load the amplifier normally works into, is connected across the output terminals. The vertical deflecting circuit of an oscilloscope is connected across a dummy lead. The output of the square wave generator is fed into the input of the amplifier. After turning all the necessary power switches on, a 60 cycle square wave is used for the first check. Now, referring to the previous mentioned fact of multiple harmonics, besides the 60 cycle wave also the second, third, fourth, up to the tenth harmonics, or a 600 cycle wave is passed through the amplifier. If the frequency response is good the observed wave will be the same as the input wave form except amplified. Figure 2 shows input 60 cycle wave and output 60 cycle wave.

Suppose, now, that the output looks like Fig. 3a, Fig. 3b or Fig. 3c. We see immediately that the amplifier is not operating correctly, but is causing distortion. The distortion present may be due to several reasons, for example, in Figure 3a, lack of high-frequency response; Figure 3b, excessive high frequency-response; Figure 3c, improper grid bias in one of the audio stages, third low-frequency errors, etc.

VALUE OF MEASUREMENTS

So we can readily see how quick and easy we can check the frequency response of almost any audio device. If we would go up higher in frequency, say up to 1000 cycles, assuming that the low frequency response was good, the amplifier to be perfect would have to extend up to 20 kilocycles for reproduction of a perfect square wave, for the same patterns observed for the low frequencies, hold good for the higher frequencies.

The form of the patterns, with few variations holds fairly true for all measurements. If one were to make the same test with a sine-wave oscillator, the task would be far greater and much more difficult. Thus the time used for making an accurate and true measurement with a square wave generator is very small, compared to a sine-wave measurement and also is far more accurate. SPEED AND ACCURACY ARE THE BYWORDS OF THE SQUARE WAVE GENERATOR IN

THE RESPONSE MEASUREMENTS OF AUDIO DEVICES.

Although the generator, whose description follows, is not an absolute laboratory standard, its performance for average use is excellent, the writer using the same instrument for frequency measurements of wideband amplifiers. A more elaborate instrument with high accuracy will be described at some future date.

CIRCUIT DETAILS

As can be seen, only three tubes, oscillator, squarer, and a cathode follower are used besides the rectifier. The fact that only three tubes are used shows the efficiency of the circuit. The average laboratory instrument uses up to six tubes with slightly better performance.

For the experimenter’s purposes this three-tube unit will be an excellent boon. A short description of individual functions of the various tubes will now be given. A 6SC7 twin triode (any other twin high-mu triode will do also), (low-mu triodes are not recommended because they require a small feedback condenser from second output plate to No. 1 input grid), is used in a multivibrator circuit. Feedback so as to cause oscillation is readily available without resorting to any additional capacities.

(Continued on page 249)
RADIO FREQUENCIES
SPEED TIN PLATING

Westinghouse engineers announced last month a process which does a better job, faster, with great saving of time and material, in the electroplating of steel.

This is accomplished by using a high-frequency oscillator and having the tin strip pass through the oscillator coil. The coil induces eddy currents in the strip, and due to skin-effect, concentrates the heat in the tin layer where the metal fuses, and smooths out to a glossy desirable finish.

Then the strip is submerged in water to cool and end the fusing process. The advantage of this process lies in the fact that whether the plating is done in a molten bath or by electroplating, the smooth finish can be obtained at low cost and with high efficiency.

The radio oscillator used delivers 200,000 cycles per second. Alternating current is converted to direct current by means of a high voltage transformer and electronic rectifier.

The D.C. power applied to the plates of a tank of 3000-K.W. vacuum tube oscillators, similar to those used in a broadcast transmitter, is converted into high-frequency power. The resonant frequency of this power is determined by the tuned circuit consisting of the oscillator tank coil and the tank condenser.

Water-cooled copper tubes conduct this high-frequency energy to the inductor heater coil which surrounds the tin-plated steel strip. By means of electromagnetic induction, energy flowing in the electric circuit is transferred to the rapidly moving strip where it is converted into heat. The strip acts as a 1-turn closed circuit. This process is another step in the application of modern physics to industrial process; an inking of what will be more widespread after the war.

Granular tin deposit refloowed at 452 deg. Fahr. The electrolytically plated strip, dried by hot air, enters the inductor heater coil at 120 deg. Fahr. Here it is heated by high frequency current to the melting point of tin, 452 deg. Fahr., after traversing about 90% of the coil length. At this temperature the rough tin deposit flows into a smooth surface. The strip then runs through the water quenching bath where the tin is hardened and the temperature reduced to about 100 deg. Fahr.

The oscillating frequency at which the process lies in the application will be found in the next issue of this journal.

THE ELECTRONIC COP

If you're driving over the speed limit, at night, a flashing sign will tell you so. This is the recent application of the photo-electric cell and its associated circuits, as developed by the General Electric Company. A community can do itself and the motorists a service, and at the same time collect some kind of revenue, indirectly by way of taxes, on illuminated signs bearing advertising, as shown in illustrations.

Of course you are not supposed to be going over 35 miles an hour these days, but the idea is presented at this time because it was developed during the past year, and will probably find widespread application after the war.

Here is how it works. A section preceding the sign is marked off by two light beams. Suppose only one car enters the section. It breaks the first beam and the timer is started and the circuit "sealed-in." As the timer operates, it closes successive circuits, depending on the time it takes the car to pass through the section.

When the car breaks the second beam, the timer is stopped, and the circuit to the sign is closed (through the contact which was in position when the timer stopped) and the sign flashes the warning if the speed through the section exceeded the limit.

The sign remains lighted for a definite time, independent of the first timer, and then (Continued on page 254)
A NEW FREQUENCY DIVIDER
FOR OBTAINING REFERENCE FREQUENCIES

By F. R. STANSEL

For the tuned circuit.

Assume, for example, that the input frequency is 100 kc, and that the output is 20 kc. Part of the output is fed back to the harmonic generator, where its fourth harmonic, 80 kc, will be selected by a tuned circuit for the output.

This 80 kc current and the 100 kc input will result in a difference of the modulator, and the fundamental output frequency will thus be one-fifth of the control frequency.

MULTIVIBRATOR CIRCUIT

Multivibrator circuits have been widely used for frequency division but they have a number of disadvantages. Inherently the multivibrator is a self-oscillating circuit, which is unstable when no control frequency is applied.

By introducing a small amount of control current, however, either by the method indicated in Figure 1 or in any one of a number of other possible ways, the saw-tooth oscillations may be locked in step with the control frequency, which may either be the natural frequency of the system or some multiple of it.

With a 1,000-cyc multivibrator, for example, and a 5,000-cycle control frequency, the multivibrator will lock-in on every fifth cycle, and the fundamental output frequency will thus be one-fifth of the control frequency.

MULTIVIBRATOR CIRCUIT

Multivibrator circuits have been widely used for frequency division but they have a number of disadvantages. Inherently the multivibrator is a self-oscillating circuit, whose only merit lies in the ease with which its frequency can be controlled. Once this control is lost the device becomes worse than useless since an output is obtained which is entirely unrelated to the original controlling frequency.

Because of this there is always the possibility of a reference frequency generated by a multivibrator being "off frequency." The danger of "off frequency" operation is further enhanced in some cases by an occasional annoying tendency of the multivibrator to jump from one submultiple to another.

Although the stability may be improved by modifications of the circuit of Figure 1, and by careful design, this likelihood is a fundamental defect which can never be entirely eliminated.

This defect applies also to the multivibrator's first cousin, the controlled oscillator, another device which has been used at various times for frequency division.

Another disadvantage of the multivibrator is its wave shape. For some types of work its saw-tooth wave shape with high harmonic content is a definite advantage, but for most uses in laboratories, particularly for frequency standardization by means of Lissajous figures, a much purer wave shape is required. Because of this, when the predecesor of the present reference frequency equipment was installed in 1931, a series of special output filters was required to clean up the output of the various multivibrators.

FREQUENCY DIVIDING CIRCUITS

In recent years several new types of frequency dividing circuits have been developed. Of these probably the most successful is the regenerative frequency divider, which has today entirely replaced the multivibrator in the reference frequency system at our laboratories.

The basic form is shown in Figure 2. It consists essentially of three elements: a modulator, an output circuit tuned to the sub-multiple frequency to be produced, and a harmonic generator.

Once this circuit is in operation, its action is easy to understand. Assume, for example, that the input frequency is 100 kc, and that the output is 20 kc. Part of the output is fed back to the harmonic generator, where its fourth harmonic, 80 kc, will be selected by a tuned circuit for the output.

This 80 kc current and the 100 kc input will result in a difference of the modulator, and the fundamental output frequency will thus be one-fifth of the control frequency. In some regenerative frequency dividers this is supplied by a pulse applied from a starting circuit, but in more recent circuits it has been found possible to omit the starting circuit, and to depend on the transient voltages normally present in the circuit for this starting pulse.

In general, when the "nth" submultiple frequency is desired, the harmonic generator is tuned to the (n-1)th harmonic. An interesting case arises when the output frequency is to be half the input frequency. Under these conditions (n-1) is equal to 1, and no harmonic generator is required. Part of the output is fed back directly to the modulator.

Unlike the multivibrator, the regenerative frequency generator cannot operate without an input frequency. Should the input frequency fail, the output drops to zero, and thus off-frequency operation does not occur. In addition, the output current of the generator is a relatively pure sine wave, and additional "clean up" filters are not required for the earlier multivibrator when a sine wave is desired.

These and other advantages led to the adoption of a circuit of this type for the reference frequency equipment recently provided for the Western Electric Company. A schematic of the circuit is shown in Figure 3.

A pentagrid-mixer tube is used for the modulator and a pentode for the harmonic generator. With a modulator tube having two shielded input grids, it is possible to eliminate the balanced modulators and transformers required for the earlier regenerative frequency dividers; and with the increased modulator gain obtained, not only is it possible to eliminate the starting circuit, but the frequency division as great as 1 to 1 is obtainable in one stage.

Hence, two dividers in tandem would have been required for a 10 to 1 division, one giving a 5 to 1 reduction and, followed by a two to one reduction stage.

A SIMPLIFIED ELECTRONIC VOLTMETER

By HAROLD DAVIS

PART I

While the use of an electronic (VTVM) volt-meter are many and varied, the instrument is known best for its ability to check A.V.C. and grid bias circuits. For this purpose, the conventional one mil, 1000 ohms per volt meter is useless because of the comparatively low resistance = 5000 ohms on the 5-volt scale.

Even the 20,000 ohm-per-volt jobs have too low a resistance to simulate a high resistance A.V.C. and grid bias. The voltage on these is often exceed a megohm and nothing under several megohms can be shunted across them without seriously affecting the A.V.C. voltage.

Few servicemen know much about A.V.C. circuits as they would like. This is due to the fact that without some form of electronic meter, they have had nothing with which to measure and trace A.V.C. and accordingly get a first hand idea of what it was all about.

GOOD A.V.C. CIRCUITS

There is nothing complicated about A.V.C. circuits. They are simple resistor circuits and perform exactly the same function as the power rectifier in the set. The diode or second detector tube rectifies the R.F. carrier which is filtered and fed back to the converter and I.F. tubes as a bias voltage, which accordingly rises and falls in direct proportion to the radio signal being received on the antenna.

The difference between the A.V.C. circuits and the power rectifier is in the size of the components. Due to the difference in frequency, 0.0001 and 0.00025 condensers will filter the R.F. voltages, as well as the 8-ohm, will filter 60 cycle current.

The exact size of the components are not critical. The resistors are governed by the diode load requirements, most manufacturers recommend not less than 100,000 and not more than 1/2 meg. The condensers must be so chosen that they will by-pass R.F. and block audio signals. This value is usually about 0.00025 mid.

A typical A.V.C. circuit is shown in Fig. 1. Here the diode load consists of R1, R2 and R3. R1 is a 50,000-ohm resistor that feeds the audio load. This resistor decreases the audio load, which in turn enables a higher audio load resistor to be used. And, due to the fact that the other resistors are so high compared to R1, the audio drop across it is not appreciable. R2 is 200,000 ohms, which serves as a filter, and R3 is 250,000, completing the load.

This particular circuit is used only in the better class receivers where the signal that reaches the diode is large due to the R-F amplification ahead of it.

The by-pass condensers pass the R-F component but are not large enough to affect the audio signals. However, C3 is large enough to pass all signals, R2 serving as an isolating resistor between it and the audio circuit.

R4 is one megohm and has a value of 2 meg or more in some circuits. It prevents any retracece between circuits. Besides this main isolating resistor, each grid circuit is further isolated from the other by another resistor, usually 100,000 ohms.

To check this circuit it is necessary only to follow the a.v.c. voltage along the network, to the grid of the tubes controlled by the A.V.C. voltages. Practically the only things that can happen is a resistor might open or a condenser might short. But a leak in the 1 megohm resistor will seriously affect the voltage.

Should the by-pass condensers open, it will permit R.F. to feed back to the tube grids, causing distortion.

A.V.C. IN CHEAPER SETS

In the cheaper sets, the circuit in Fig. 2 is often used. The diode is connected through a 50,000 ohm-resistor directly to the volume control, which becomes a part of the diode load. The grid of the first audio is fed through a coupling condenser and is automatically biased by a 10 to 15 megohm resistor to ground.

In this particular circuit this coupling condenser must be kept comparatively small, 0.005 being a good value, or over-loading will occur on high volume. The insulation must also be good or it will furnish a path for the A.V.C. voltage to reach the audio grid.

DELAYED A.V.C.

Sets using Delayed A.V.C., while becoming increasingly fewer, might require special mention. Delayed A.V.C. does not mean that the A.V.C. waits until the signal gets through the tubes before it grabs it, but does mean that it waits until the signal reaches a certain level before it becomes effective.

The purpose of delayed A.V.C. is to permit greater sensitivity on weak signals. If A.V.C. begins to function as soon as a signal hits the diode, regardless how small the signal is, it will still reduce the sensitivity of the set accordingly. If, however, the A.V.C. action is delayed until the signal reaches a given proportion, the set will respond much more readily to weak signals.

Delayed action is often accomplished by biasing the diode that furnishes the A.V.C. voltage, the amount of bias being 1.5 to 3 volts. This can be done easily when a tube such as the 6H6 is used, by simply using a resistor in the cathode of the proper size. The diode coupled to the audio load cannot be biased, naturally.

BIASING A.V.C.

Other methods of biasing the A.V.C. diode are accomplished by returning the diode to a negative spot on the voltage divider, or by utilizing the drop across resistors in the plate and cathode circuits.

A.V.C. VOLTAGE

The amount of A.V.C. voltage to be expected varies with the particular set, but it is usually 5 to 10 Volts on local stations. On large sets it will reach 15 volts on strong signals, and is often only a volt or two on cheap models.

Measurements are made from the electrical ground of the set to the diode, or anywhere along the A.V.C. network, even at the grids of the controlled tubes. The idea is not to find out, "how much" voltage is present, but rather if it is being distributed evenly. However, weak A.V.C. could mean a weak detector tube, as the A.V.C. voltage is a pretty good indication of detector action.

OSCILLATOR ACTION

The electronic volt-meter can be used to check oscillator action of a superhet. When a tube oscillates, grid current flows. This amounts to 0.25 to 0.4 milliamperes in the case of the 6A8. A grid leak resistor of approximately 50,000 ohms usually is used. If 04 mils flows through 50,000 ohms, 20 volts will be developed across the gridleak with the electronic meter. Actually, this voltage is less than 20 volts, due to reduced plate voltage and smaller grid leaks. However, it is enough, because the set is oscillating and reads negative from ground.

When the tube is not oscillating, the voltage will be positive or zero. The grid-leak voltage will vary slightly with frequency.

AUDIO MEASUREMENTS

The electronic meter reads audio voltages without rectification. Audio signals are not A.C., but instead pulsating D.C. The only megohm coupling resistor serves as a filter. A blocking condenser should be used in series with the probe resistor if the points to be contacted contain any D.C. voltage.

As an audio indicator, the meter may be used as an output meter by contacting any point in the audio system. To prevent fuzzing around finding a contact point and make...

(Continued on page 243)
HUNDREDS of young men, without previous knowledge or experience in radio are learning the fundamentals of electrical theory, radio design, repair and maintenance, in the space of a few months. That is the record of the civilian training unit at 63 Park Row, New York City.

Shattering the traditions of the past, and all of the pet theories of the pedagogues, an intensive course is given which enables an expert radionian to be produced in about one eighth the time that it took in pre-war days.

Young men, and even oldtimers, learn how to design filters (high, low, bandpass, 120 cycle, etc.). They know how to calculate voltage, current, impedance and power induced and transferred, in R.F. and I.F. coils, output transformers, etc.

They tear down old radios and equipment of 1930-to-1940 vintage, and re-assembly the material into units of 1-tube stages, or revamped on suitable chassis.

They can take apart then build up and operate a gasoline-engine-driven generator set in 100 minutes.

When the school had trouble finding new equipment, it bought up all the derelict radios and equipment it could find in the New York Cortlandt Street second-hand mart, tore them down completely (giving the heavy metal chassis to the salvage campaign) and used the components to make breadboard layouts.

The student thus builds up a 1-tube unit to a superhet; or a 1-stage amplifier to a full power amplifier with power-packs.

Nothing is left to guesswork. Each man is enthusiastic and eager to learn and does his utmost to grasp every detail of practical work and theoretical explanation.

Serving with the oscilloscope is another valuable experience. Alignment, examination of output for distortion, measuring modulation percentage—all these become second-nature to the student.

All students are well-grounded in mathematics including algebra, trigonometry, and the use of the slide rule. Math is not so hard when you have a definite use for it, and the boys take this in their stride.

With a course like this, these men are thoroughly prepared for immediate acceptance into the Signal Corps as maintenance and repair men for field, tank, and aircraft radio.

Those who excel will be considered for candidacy in more advanced schools, or in transmitter construction, repair and maintenance.

Those who cannot complete the stiff theoretical part of the work, concentrate on developing skill in repairing radio equipment.

SCOPE OF COURSE

The course consists of two sections, of three months each. During the first section, the student (who is a mechanic learner) receives $1020 per year. (All students must enter on this basis.)

Successful completion of this section automatically leads to the position of Junior Radio Repairman, at $1440 per year.

The use and care of essential tools, basic shop practices, study of basic mathematics and electrical fundamentals, and the reading of electrical circuit diagram is included in the first section of the course.

The second section takes up advanced work in the field of radio. Upon completion of the course the trainees are well equipped to handle, maintain and repair almost all types of Signal Corps radio equipment.

QUALIFICATIONS FOR ADMISSION

All applicants must be men 18-44, in good physical and mental health, certified by the Civil Service Commission to the Signal Corps representative. The applicant must pass a mechanical aptitude test as given by the Civil Service Commission.

If successfully interviewed, the applicant must then enlist in the Enlisted Reserve Corps of the Signal Corps. By so doing the applicant is completely released by his selective service board, and is permitted to attend school for his pre-service training.

During this period, the reservist maintains his civilian status. Upon completion of the course, the reservist is called into active service as a private. However, with the training that a man receives in the school, he should advance in grade much faster than a man who has not had this training.

Furthermore, if a man shows possibilities as officer material he may have the opportunity to apply for Officers' Candidate School after completion of his basic training. Upon his graduation from O.C.S. he will be commissioned a Second Lieutenant in the Signal Corps of the Army.

HOW TO APPLY FOR ADMISSION

Obtain Form No. 4900-ABC from nearest U.S. or 2nd class post office: the Civil Service Commission at 641 Washington Street, New York, or from the Secretary, Civil Service Commission, 63 Park Row, New York, N. Y.

Under the heading of the application which reads: "Exact title of the examination for which you are applying," the applicant should fill in the following words: "Mechanic Learner (Radio)."

When the form has been filled-out, those applicants who wish to take the examination in New York City will mail the application to the Secretary, Civil Service Commission, 63 Park Row, New York, N. Y.

All other applicants must mail their applications to the Civil Service Commission, 641 Washington Street, New York City. Thereafter the applicant will be notified as to where and when he should report for examination.

RADIO CODE OPERATORS SCHOOL

A shorter, twelve-week course, is also being given by the Civilian Training Section, to men who are interested in learning the International Morse Code and radio code procedure as used in the Army Signal Corps.

At the present time this course is given only in New York City, and the qualifications for admission are the same as for the Radio Mechanic Course.

If an applicant is interested in this course, he must apply for the training exactly the same as for the Mechanic Course, except that under the heading of the application where it asks for "Exact title of examination for which you are applying," he should fill in the words: "Mechanic Learner (Code)."

So you young men who want to do your bit and at the same time learn a skill which can always be used, get busy and sign up. It is never too late.

**ALIGNMENT**

- **Cathode-Ray Alignment** is the preferable method. Connections for the oscilloscope are shown in the chassis drawing.
- **Output Meter Alignment**—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.
- **Test-Oscillator**—For all alignment operations, connect the low side of the test-oscillator to the receiver chassis, and keep the output as low as possible to avoid audio action.
- **Calibration for Alignment**—The proper dial calibration for alignment purposes can be set up in two ways:
  1. The dial may be removed from the cabinet by sliding out the two spring pieces which clamp it in its mounting position. The condenser plates should then be turned into full mesh, the pointer adjusted to the scratch at the left end of the dial backplate, and the dial aligned under the pointer so that its extreme limit calibration mark coincides with the pointer. The dial may be held in place with spinch take. In this manner the actual receiver dial is used for alignment. When alignment is finished, the scale should be replaced including the fibre light shield which are folded under the ends of the glass scale.
  2. A calibration scale is attached to the tuning drum. The correct setting of the gang, in degrees, for each alignment frequency is given in the alignment table. Check the gang, if the drum, making sure that the 0 degree scale mark is horizontal with the gang in full mesh.

**Point source Calibration Scale**—If method (2) is used, improvise a pointer for the calibration scale by fastening a piece of wire to the chassis, and bend the wire so that its point to the 0 degree mark on the calibration scale when the plates are fully meshed.

**Details of Alignment Procedure**

Step No. 1—Connect the high side of the test oscillator to 6SK7 I.F. grid in series with 0.01 mfd. Tune test oscillator to 455 kc. Turn radio dial to "A" band to a quiet point between 550 and 760 kc. Adjust L-21 and L-22 (2mL. I.F. Transformer) for maximum peak output.

Step No. 2—Connect the high side of test oscillator to 6AG7 grid in series with 0.01 mfd. Tune test oscillator to 455 kc. Turn dial to "A" band to a quiet point between 550 and 760 kc. Adjust L-18 and L-20 (1st I.F. transformer) for maximum peak output.

Step No. 3—Connect the high side of test oscillator to the antenna terminal in series with 0.01 ohms ("A" antenna trimmer C-1) should be ½ turn-out. Tune test oscillator to 15.3 kc. Turn radio dial to 15.2 mc. (140') "C" band. Adjust C-24 (Osc.), C-15 (Det.), Rock switch, C-1 (R.F.), and rock switch for maximum peak output.

**Tune and Trimmer Location.**

Step No. 4—Connect the high side of the test oscillator to the antenna terminal in series with 250 mmf. Tune test oscillator to 2,444 kc. Turn the radio dial to 2,444 kc. (105') "B" band. Adjust C-27 (Osc.) and C-19 (Det.) for maximum peak output.

Step No. 5—Connect the high side of the test oscillator to the antenna terminal in series with 200 mmf. (preset "A" osc. trimmer C-28 ½ turn out.) Turn test oscillator to 600 kc. Turn radio dial to 600 kc. (30.5') "A" band. Adjust L-30. Rock gang for maximum peak output.

Step No. 6—Connect the high side of the test oscillator to antenna terminal in series with 300 ohms. Tune test oscillator to 15.2 mc. Turn radio dial to 15.2 mc. (140') "C" band. Adjust C-1 (R.F.) and rock switch for maximum peak output.

Step No. 7—Repeat step 5.

Step No. 8—Connect the high side of the test oscillator to antenna terminal in series with 300 ohms. Tune test oscillator to 15.2 mc. Turn radio dial to 15.2 mc. (140') "C" band. Adjust C-1 (R.F.) and rock switch for maximum peak output.

*Use minimum capacitance that can be obtained. Check to determine that C-24 has been adjusted to correct peak by tuning receiver to approximately 14.29 mc. where a weaker signal should be received. Note—Oscillator tracks above signal on all bands. To reduce sensitivity during R.F. Alignment connect a 15,000 ohm, ½ watt resistor across secondary of 1st I.F. transformer.

**Loop Connections and Trimmers.**
HOW TO HOOK UP RADIO RECORD PLAYERS

By JOSEPH A. INNESS

This article discusses the proper connections to be made to the more common types of radio circuits when hooking up record-players. While many servicemen know all the tricks, there are probably some who are not familiar with the methods used. It is for this latter group that the author outlines suggestions and recommendations based on his experience.

performance of radio and record player alike some thoughtful analysis of the situation is necessary. First let's classify the different types of radios in regard to record players.

1. The later model sets which either have a radio-record switch built into the back of the set, or in the record player switch at the front of the cabinet, either pushbutton controlled or knob controlled and usually found as one position of the band switch.

2. Sets which are provided with a terminal strip on the back of the chassis to accommodate record players.

3. Sets which have no accommodation whatsoever for record players.

Of the first group we are not especially interested, inasmuch as the set manufacturer (with some exceptions) has done a perfect job of making the proper provisions for phonograph. It is group 2 and 3 which requires our attention. Let's consider the second classification.

TERMINAL STRIPS

Look at Fig. 1a. Here we have the terminal strip scheme shown in the "radio" position. In Fig. 1b the "proper" connections for record players are illustrated. Evidently some set manufacturers never intended the shorting bar to be placed across contacts 1 and 2 but want it to be left out entirely; which is obvious in cases where considerable manipulation is necessary to get the shorting bar across terminal 1 and 2. It will be readily observed that Fig. 1c is the record player position, Fig. 1d shows the original player position, and Fig. 1e is the radio position. Of course, the shorting bar is omitted in Fig. 1e. So our analysis is now complete. As always, the final word is in the hands of the owner. One point to consider in making these changes is to see that the change is a permanent one and not subject to being changed back to the original condition.

Another instance was where the record player leads were fastened to the 3-contact terminal strip provided on the back of the chassis. Some sets with the shorting bar left in the dangling position, which meant that the set was tuned to a strong station radio reception would get through the audio system as well as the desired recorded music or speech. If the set was tuned to a station any noise which was amplified in the RF-IF section would likewise reach the speaker.

To correct such conditions it would be necessary to arrange the shorting bar in such a way as to limit short to the ground contact to eliminate radio reception.

ANALYSIS OF RECEIVER TYPES

Set owners who have the above conditions are not very well satisfied and are willing to pay for having their record players attached in such a way to obtain record reception without objectionable hum and without interfering radio stations or noise. On the other hand they do not want their record players to hamper their radio reception. In addition some means must be provided for quick change-over from radio to records or vice versa, whereby it isn't necessary to connect or disconnect wires, etc.

With the above ideas in mind it will be seen that for proper connections and for top

radio-craft for january, 1943

214

www.americanradiohistory.com
NO PHONO PROVISIONS

Let's consider the third classification—where no provision whatsoever is made for record players. It might seem at first that our problem is somewhat more involved since now we have no terminal strip with which to work. The terminal strip is the same.

This condition is the same as in Fig. 1c except that the terminal strip is omitted. The procedure of connecting the player is essentially the same.

In other circuit arrangements, a break must be made and return (that is, switching arrangement can be inserted).

ELABORATE CIRCUITS

There are of course many other types of circuits designed to perform the same operations as those circuits already discussed, but which are possibly more elaborate and appear more difficult. Most of these "elaborate" circuits can be analyzed as readily as the simple ones, and the record player connections attached accordingly.

It may be wise to recall that in many AC and 1st audio grid systems, fixed bias is employed whereby the grids of the RF-IF and 1st audio tubes are supplied by a voltage of negative potential from either the power supply or by those delicate little items called bias cells. These biasing methods should present no great problem when installing record-player attachments. However, it is the best plan to look up the schematic of the set before doing any wiring.

Where the RF-IF grids are biased thru the AVC system from the power supply it is permissible to short out this bias where the switch connections are made.

In regard to bias cells in the AVC system, these circuits are usually so designed that when the AVC is shorted at the normal point, the bias cells themselves will not be shorted. Where a diagram of the receiver is not readily available and any doubt arises as to the possible results of shorting bias circuits, the shorting should be done through a by-pass condenser of about .05 mid.

ANTENNA HOOKUP

We have discussed satisfactory ways of connecting record players in several types of circuits and have solved the problem of preventing radio reception from escaping into the audio section when playing records by the process of shorting out the audio channel from the diode detector. Our biggest task was then not so much as to make the radio-recorder player combination workable as to prevent unwanted radio reception. It is time now that we ask ourselves this question—Can this radio interference be eliminated by other means than those already described? Why not get rid of it before it ever reaches the 2nd detector? Let us see what can be done.

If a receiver is tuned to a broadcast station and the antenna and ground connections are suddenly shorted, the program to which the listener is tuned will largely disappear. Why not, instead of shorting out the diode detector channel, make our switch connections to the primary of the antenna coil so as to short out any RF present when playing records?

Such a set-up seems to offer a simple solution to our problems; however, there are disadvantages to be considered. For example, some sets have a natural high noise level, and others are not so well shielded; and the possibility of picking up stations even with the ground grounded is very great. Also, in such sets, tube hiss, other internal noises and man-made static can be expected.

The chief advantage of the system is its simplicity. This type of hookup, moreover, can be used to good advantage in some receivers with favorable results. When considering this type of radio-recorder attachment it will be necessary to do a little experimenting, and in general use some discretion before making any final decisions.

CONNECTIONS TO I.F.

What we are really looking for is the simplest and most effective way to connect the record player. The above paragraph described a very simple process but does not always produce the desired results. The audio connections for the record player are quite satisfactory but the problem of eliminating unwanted radio reception is not entirely solved. So a few suggestions are in order.

The local oscillator could be made to cease operating. The procedure of doing this may not be a simple performance and the results would probably be disappointing. Why not block the I.F. amplifier? This seems more practical. Which circuit to work on is the next consideration. It would be folly to make any changes in tuned circuits, so that leaves us with untuned circuits.

On examination of a common I.F. system it seems logical that the cathode circuit of the I.F. tube could be opened. This is an easy operation and will make the procedure of connecting the record player a simple one. So much for simplicity.

The next question then is "Will this process prevent radio reception from reaching the audio system?" The answer is "It will."

BIASED CATHODE

In a case where the cathode is not connected directly to chassis but rather through a resistor-condenser combination the circuit would be open at the socket or in ground lead.

Incidentally, this "open cathode" in the IF amplifier is to be preferred to all other systems described in this article. The only disadvantage to this method is the fact that the cathode connections on the tube sockets of some sets may not be readily accessible because of being covered by wires, condensers, resistors and what not. Service men know only too well that the bottom of some chassis presents the appearance of an oversized can of sardines.

If such a condition is found it is perfectly feasible to open the cathode circuit of the converter tube to make the necessary connections, provided the receiver has only one I.F. stage. Should this tube socket prove to be as haphazard as the I.F., then make all connections in the audio section using the ideas already described.

AC-DC RECEIVERS

Up to this point all ideas and illustrations have concerned A.C. superheterodynes with dial selection. Attention is now given to B.C.receivers. As is well known (and sometimes temporarily forgotten) by service men, many AC-DC radios have a B minus network that is not of the same potential as the chassis. In other words the B-minus is separated from the chassis by a tubular condenser or a condenser and resistor in parallel. A condition such as this must be strictly observed when making record player connections. Be sure to make all ground connections, ordi-

narily made to the chassis of an AC set, to the B-minus of the AC-DC set and not to chassis. When installing the switch and socket in the back of the chassis it will be necessary to insulate the bared end of the switch socket from the chassis. Some AC-DC sets are equipped with a cabinet back made of wood; here a cardboard or other material and the units could be mounted here instead of in the chassis. If this is done keep these units as near the chassis as possible. The main thing to remember is the B-minus, for correct or incorrect connections will mean success or failure.

Of course all AC-DC sets do not have the B-minus above chassis and in a great many cases the B minus is a chassis wiring. In such an event the connections would be the same as for an AC set.

BATTERY SETS

Battery sets are as adaptable to record players as are the power line receivers, and many manufacturers have put on the market record players expressly designed for use with battery radios. These have a spring motor and the usual crystal pickup.

To make the correct phonograph connections the "open cathode" system is used to eliminate radio reception, and the audio connections are likewise the same. However, battery tubes have no "open cathode" filament itself acts as the cathode), so instead of opening an actual cathode we open the filament of the I.F. tube as in Fig. 2.

AC-DC-BA TTER Y PORTABLES

These sets are usually designed with the filament in series. The I.F. tube will be of the battery type with no cathode and we cannot break the filament circuit as this would cut off the filament supply to the other tubes. Therefore all wiring will have to be done in the audio section using the ideas outlined in the first part of the article.

POWER DETECTORS

Occasionally you will be asked to install a record player attachment on a superhet with biased detection, or a T.R.F. receiver with power detection.

In this instance an entirely different problem arises.

Here the problem is no longer: "How to get rid of unwanted radio reception?" but rather "how to connect the record player in the circuit and where?" If the grid circuit at grid is broken and

www.americanradiohistory.com
T HE OUTSTANDING feature of this inter-office communicator is its simple and foolproof design. The use of a design in which only 1 tube is necessary in each station, results in a unit of small size and few parts. Only 2 resistors are used in each unit!

ADVANTAGES OF "DIVIDED GAIN"
The construction of the unit is very simple, due not only to the few parts necessary but also to the stability of the design. The use of "divided gain" eliminates the possibility of oscillation which is often encountered in the high-gain type of inter-communicators. The 1-tube interphone also has other advantages over the usual type of system. The use of "divided gain" makes possible the calling of an unlimited number of stations without loss of either power or clarity. There are also unlimited possibilities as to multi-station break-in. That is, any group of stations may hold a conference without the use of additional switches, such as are necessary with the usual systems.

In order to understand the principle of operation of the 1-tube intercommunicating system, examine the 2-station type which is shown in simplified block diagram form in Fig. 1.

In Fig. 1A station No. 1 and No. 2 are shown in the "stand-by" position ready to receive messages from each other. In Fig. 1B station No. 1 has thrown its switch to the send position and is talking to station No. 2. When station No. 1 releases the switch, both stations are in stand-by position and station No. 2 talks to station No. 1 as shown in Fig. 1C.

Notice that during transmission, the 2 amplifiers are in cascade in order to give the required amount of amplification. The total amount of gain is "divided" equally between the 2 stations.

The total gain of the entire system is about 70 db. With the usual type of inter-communicator, to attempt to build a compact unit results in a design which is quite critical as to circuit oscillation. Any slight deviation from the original design in regard to placement of parts or method of wiring, may result in uncontrollable oscillation. However, by dividing the gain equally between the units, we have only 35 db gain to contend with. It is practically impossible to run into any trouble, no matter what the arrangement of parts. The method of wiring is also not critical, as long as the circuit is followed correctly.

It might be mentioned also that there are some disadvantages in the simplified system of the 1-tube intercommunicator. There is a slight hum when transmitting, due to the use of a power-type tube as the first tube in the amplifier. However this slight hum does not interfere with the clarity of the speech, and is not annoying. In the "stand-by" position the units are silent, without any background noise.

CIRCUIT ANALYSIS
The schematic circuit of a single unit of a 2-station system is shown in Fig. 2A. In installing the system, a 2-wire cable (with plug and socket connections) is run from one unit to the other. Each unit uses a 12A7 type tube which consists of a half-wave rectifier and a high-gain power pentode.

Note that the rectifier system does not use a choke for filtering. The 2,000-ohm resistor, R2, provides adequate filtering without causing excessive voltage drop. This is due to the fact that 12A7 draws only 1ma.

Switch Sw. 1 is a double-pole-double-throw unit of the press-to-talk type. This means that it should maintain a spring to return it to the "listen" position. Of course an ordinary D.P.D.T. toggle switch may be used, but this is more difficult to manipulate than the spring-return type.

Input transformer T1 is designed to feed from a 4-ohm line into a control-grid. The output transformer, T2, is of the universal type with the full whirling used as primary and taps 2 and 5 for the 4-ohm secondary. By shifting the taps of this output transformer, variations in tone may be effected.

In general, however, the 2 and 5 taps will be found best.

The basis for the 12A7 is obtained from the voltage drop across a 1,000-ohm resistor, R2, shunted by a condenser C2 which is a 10-mfd. electrolytic. Note that the "B"-minus return does not ground directly to the chassis, but is connected to a 0.1-mfd condenser, C3, which goes to the chassis. This serves to isolate the power line from the 4-ohm voice line. The resistor, R3, situated in the line cord, is 360 ohms. The speaker is a 3-in. P.M. (permanent-magnet) dynamic type. Switch Sw. 2 is a single-pole single-throw rotary switch.

7-STATION SELECTIVE OPERATION
When more than 2 stations are necessary, the circuit of Fig. 2D should be used. An examination of this circuit shows that a 7-switch, Sw.3, has been added. Also an octal-type socket has been substituted for the 3-prong socket. We can now install 7 of these units as a selective intercommunicator. The 7-point switch allows us to select any one of the other 6 stations with the last point used as an "off" or "stand-by" position.

The complete interconnecting wiring diagram of the 7-station intercommunicating system is shown in Fig. 3. The materials required consist of an 8-wire color-coded cable (of sufficient length to pass through all the rooms in which the stations are to be installed), and 7 octal-type plugs.

The best method is to install the cable all in one piece, all colored foot of slack at the points near where the units are to be installed. If splicing is necessary, the cable color code indicates the proper connections. If the colors of the cable do not correspond to those of Fig. 3, the correct colors must be noted on the diagram in order to prevent confusion.

The 7 octal plugs Pa, Pb, Pc, etc., of Fig. 3 are connected to adequate lengths of 8-wire cable as shown. The color code of all should be identical and are to correspond to that of the main cable to which the plugs connect. In connecting the plug cables to the main cable, simply skirt back the wires, make the proper connection (solder...
all connections), and tape each individually. These connections are made at the points where slack was left in installing the cable. For the sake of appearance the cable junction should be covered with a small box. Note that plugs Pa and Pg may be connected directly to the ends of the main cable. The next step is to insert the 7 plugs into their respective units and plug the line cords of the units into the A.C. or D.C. line. The system is now ready for operation.

The indication of the outlying stations position. When station “A” is finished talking, station “B” need only press Sw.1 in order to answer. This feature of the system saves much time because in the usual interphone, station “B” would have to know from what station the call had originated in order to reply.

THE "CONFERENCE" CIRCUIT
If station “A” wishes to have a conference with stations “B” and “C” simultaneously, he calls them each individually on each unit may be made by studying Fig. 2 and Fig. 3. Thus on station “A”, the point of knob of switch Sw.3 indicates as follows:

Point No. 1. "off" or "stand-by"
2. to station “B”;
3. to station “C”;
4. to station “D”;
5. to station “E”;
6. to station “F”;
7. to station “G”.

The dial markings of station “B” are similar, except that point No. 2 indicates station “A” instead of “B”, etc. The operation of the system is as follows: All stations are normally on point No. 1 or "stand-by". If station “A” wishes to call station “B”, the knob of Sw.3 is thrown to "B" position and Sw.1 pressed for the "call" and asks them to get on his line. A 3-sided conversation is then possible. This may be also arranged for any number of stations. Even while talking to all 6 outlying stations there is no loss in either volume or quality. This is due to the design whereby the voice is transmitted to a load which absorbs a very small amount of power. In the usual type of intercommunicator, the power delivered is inversely proportional to the number of speakers on the line.

While the system described was for 7 stations, any number of stations may be arranged for by means of slight changes. For instance, if a 3-station system is desired, only a 4-wire cable between stations is necessary. Only that portion of Fig. 3 which includes Pa, Pb, Pc, need be used. For more than 7 stations, the number of points of Sw.3 must be increased proportionately, and the cable likewise. Also binding post strips will be necessary instead of the octal sockets used. (The constructor may wish to try the recently-announced type 25AG, 25-V tubes—not as yet available to the writer—if increased amplification is desired.)

CHASSIS DETAILS, AND WIRING
In constructing the units, we first make the chassis as shown in Fig. 4. The main part of the chassis is formed from a piece of No. 16 gauge aluminum as shown in Fig. 4A. All holes are made with a No. 28 drill unless otherwise indicated. Next to, or in between the pairs of holes is indicated the (Continued on page 256)
THE "audio" scale, making it possible for the blind to weigh rapidly and accurately, and opening new industrial fields to them, was demonstrated last month at the American Foundation for the Blind in New York City.

The scale operates on the airplane radio beam principle, giving the audible signal "A" as long as the scale shows "under" the correct weight, and the signal "N" if it registers "over." Correct weight is signalled by an unbroken buzz.

The suggestion for such a scale was originally made by a blind woman in Buffalo, and the device was developed by the scale engineers with the encouragement of the Foundation.

In war plants, the scale has such uses as weighing out specific amounts of powder for fuses, medic for radio mechanisms, and bullets. (Continued on page 249)

OPTICS AND ELECTRONICS

(Continued from page 205)

practical, but where it is practical there is usually great demand for it and the electronic control under such conditions does the job better than any other method.

An example of real utility is the use of this modern method in conjunction with the welding process. In Fig. 9, if transformer TG should open circuit, T1 and T2 will be non-conducting. This is the result of having the large A.C. voltage (in phase with the anode) superimposed upon the D.C. bias potential. Anode output of the tubes, through the series power transformer, controls the power supplied to the welder transformer. When these tubes are non-conducting, there is a small exciting current flowing, but when the tubes are conducting a negligible reactance is presented by the transformer.

A bias is applied to the grids to make the vapor discharge tubes completely non-conductive, being secured (the bias) from the full-wave rectifier tubes, T7 and T8. Their output is filtered by the R3, C3 components, and resistor R7 limits the grid current when the grid is positive with respect to the cathode. The function of C2 is to increase the grid-cathode capacity. Condenser C2 and the resistance (with a negative resistance first characteristic) across the secondary of the series transformer assures that the tube will not lose its control of voltage surges and will not relinquish that control to the welder.

If the control over the welder is to hold satisfactorily, a necessary condition is that minimum current be drawn and not heavy transients in the supply line. Also, the D.C. components must not be allowed to saturate the core of the transformer, a requirement that dictates accurate timing and the employment of a timing device that cannot be connected directly to the power tube.

The control circuit uses the same principles used in the power tube arrangement, but without transformer coupling, for tubes T3, T4, are directly in the the A.C. supply lead to transformer TG. Tube T3 is a three-element type. Tube T4 is a four-element tube, selected for the reason that it can positively be controlled with minimum power. By using it, the limiting resistance (R) can be made high in value, which reduces the load on the timing circuit. A further advantage of this tube type (four element) is that its characteristics change very little with temperature.

In the event that timing could be introduced directly into the grid circuits of T1 and T2, without too great a power drain, the control circuit stage could be cut out. The timing circuit includes the elements TR4, T5, R5, R1, R2, R6, C1 and TR6. This circuit behaves as a limiting reactor, to limit the peak value of the discharge current of T5 and also acts as a part of the lockout circuit. The impulse circuit is regarded as an inverter and is used to perform the timing job for the welder. Controlled by the peak A.C. voltage the pulsating inverter is exactly synchronized at an even number of halfcycles of the A.C. power supply.

Length of the welding cycle is set by length of time required to charge C1, in the timing circuit, to a critical value, and the length of time that the current flows depends on what period of time the grid of T4 is positive during the cycle. The setting of resistor R1 determines the first, and the relative value of R2 determines the second. A simple system for adjusting the former operation is formed by R1 and R2. The (Continued on page 249)
REMOTE MIXER

In order to realize the most effective and most pleasant reaction by an audience to a P.A. system it must be constantly "monitored" from a point of vantage in the audience. This, of course, calls for a remote control system of "tailing" and "mixing" the input circuits of the amplifier. Until recently, however, such a system was impractical due to the difficulties introduced by the distributed capacity of the long cables, etc. Now, however, it is possible to accomplish this remote mixing, up to 2,000 ft. from the amplifier, through the medium of a compact portable unit small enough to be held in the hand. This of course is a highly desirable feature, seldom offered in P.A. equipment of any type. It has been adapted to the public-address systems of a well-known large manufacturer.

1612 TUBE AFFORDS CATHODE-CIRCUIT VOLUME CONTROL

The amplifiers with which this remote mixing unit is used have 2 separate input channels. Each channel has provision for phonograph and microphone input. Mixing of these input channels is not done in the signal circuits but is accomplished in the cathode circuits of the input tubes.

Circuit diagram of the remote mixer for P. A. work. Although it is simple and compact, it depends for its operation on a special type tube, the 1612. The illustrations show how the remote mixer is used.

The 2 potentiometers on the remote-control head are wired into the cathode circuits of the RCA type 1612 input tubes. Thus no losses in signal are introduced by the long, remote-control cables. Since the remote potentiometers are not in the signal circuits, remote volume control and mixing may be accomplished at any distance (up to 2,000 ft.) from the amplifier, and this may be done permanently or temporarily. The changeover to remote mixing is accomplished at any distance (up to 2,000 ft.) from the amplifier, and this may be done permanently or temporarily.

ARROW RADIO, INC.
82 CORTLAND ST., N. Y. C.
A development of the war, the author of this article demonstrates that it is possible to construct a radio set practically without the use of strategical materials. At the same time, a new radio principle—"CAPIND"-tuning—is introduced by the author.

While the present receiver has purposely been built as a "How to Make It" model, the author stresses the point that the new principle is certain to be used in post-war radio sets, as it does away entirely with variable condensers, used almost exclusively heretofore as a means of tuning radio receivers.

THE "SIMPLICITY—1"

The young lady is shown adjusting the throttle condenser. The other white cylindrical tube is the Capind, and the dark rod in the center is the filament switch. The headphones are connected to a pair of Fahnestock clips similar to the Ant-God clips, one of which may be seen projecting beyond the edge of the case. The front of the cabinet may be removed to change "A" batteries, the side for changing "B"s.

The values of all the lettered condensers and resistors in the above photograph may be found by referring to the schematic diagram printed on Page 243.

THE “SIMPLICITY—1”"  
By HUGO GERNSBACK

The "single wave length by means of a variable system, the correct wave length by means of a variometer.  
Still another tuning means is by using a loose coupler. This again is not very satisfactory for vacuum tube circuits because of the switching arrangement necessary to obtain the different wave lengths, as well as the inherent noises produced in the earphones or loud speaker when tuning the loose coupler.  
This brings us to the most recent means of tuning with which we are all familiar namely, the variable condenser. If a single circuit is used, only one condenser is employed. Where three tuned circuits are employed (such as in superheterodynes, etc.), a triple or ganged variable condenser must be used.

One of the newer recent developments is a (condenserless) tuning system whereby finely divided iron cores are used; by sliding such an iron core in and out of the inductance, tuning is achieved.

The new system which I am about to describe differs from all of the former methods. The "Capind" (a new word coined by joining the words "capacitance" plus "inductance") system, as its name implies combines tuning inductance and condenser, all into one component.

Let us see now how the "Capind" system works in practice.

We first have a long and rather slim inductance wound with fine wire. The wire may be wound on a cardboard tube or other insulator, or a solid wooden stick, such as a dowel, etc. To achieve tuning, we employ a sleeve which can be of cardboard, paper, plastic or any other suitable substance, which sleeve slides over the inductance. FOR BEST RESULTS, THIS SLEEVE MUST BE EXTREMELY THIN. On top of the sleeve, we have a slotted metal conductor, such as tin foil, wrapped around the sleeve. It is highly important to note that this metallic jacket must be slotted. It must not overlap, because the ensuing hysteresis effect will greatly weaken the signals. This then is not just a "losser" arrangement, because the electro-magnetic lines of force are not confined completely within the inductance when the metal jacket is slipped over the inductance, but some of the magnet lines of force still escape, as shown in the illustrations.

Final arrangements have not as yet been concluded to ascertain the exact theoretical
and practical width of the slot necessary for best operation, and quite a good deal of research work remains to be done. We did, however, experiment with a number of sleeves, and one selected in the present model of the "Simplicity-1" receiver seems to give optimum results for this particular inductance. The air slot of the metal sleeve is all important was quickly demonstrated when by mistake my original instructions had not been carried out correctly, for the first design had a spirally-wound tin foil sleeve which, even though it was insulated so that the metal edges did not touch, gave poor results, because there were no means for the magnetic lines of force to cut through the metal sleeve. "Capind"-tuning is accomplished simply by pushing in and out the movable sliding member which fits over the inductance, and the set thus tunes the same as other sets. As the "Simplicity-1" is a regenerative set, the means for regeneration are had by sliding back and forth a home-made type of variable condenser which can easily be made by anyone without special tools or machinery. This particular type of tubular slide condenser is not very new, as similar types of condensers have been used since the old days of wireless. It was selected simply for the "Simplicity-1" to keep everything as simple as possible, so that anyone could build the set with a few spare parts found almost anywhere.

Indeed, the purpose of the "Simplicity-1" radio set was merely my idea to demonstrate that even with the great scarcity of radio parts at the present time, it will still be possible for anyone with ordinary tools of the simplest kind to build a workable radio set that brings in the stations loud and clear.

With the exception of the radio tube and batteries, the rest of the radio material in the "Simplicity-1" costs less than $1.00—believe it or not. This again demonstrates what I have often said, that with a little ingenuity most obstacles can be overcome; and as necessity is the mother of all invention, it may be said that the "Simplicity-1" came to life just on account of this. Of course the "Simplicity-1" can also be built on a breadboard, if you do not wish to use the box arrangement shown in our illustration. It was thought best to incorporate the entire set in a box, as illustrated, and the glass window on top has been added merely so that the unusual tuning means can be followed visually.

The present set works well and brings in practically all stations with good volume, some of them strong enough to work a loud speaker on the nearer local stations. The calibrating is done as shown in the main illustration, stations being written on the outer paper sleeve where they pass the circular hole in the slotted wood panel. The first model is a portable battery-operated set. Due to the present scarcity of batteries, we will present in the next issue another model of the Simplicity receiver—electrified.

FUTURE CONSIDERATIONS
I am certain that the new "Capind" principle will be embodied in many receivers of the future. The reasons why I believe this to be so are the following:
1. The cost of the expensive aluminum variable condenser, or condensers, will be saved.
2. While in the first model the tuning method is, of course, crude in that it is necessary to pull the sleeve in and out, future factory-made sets will not be so hand-capped. The present motion can, of course, be translated by means of a simple lever arrangement so that an ordinary knob can be used for tuning; or, if desired, we can have a long horizontal scale, as is now prevalent in many radio sets—the tuning still being done by the knob method.
3. The "Capind" principle can, of course, be incorporated into a "gang," so that two, three or more Capinds are all moved simultaneously as it now done with ganged condensers, or ganged powder-iron cores.
4. The size of the Capind can be shrunk to very minute dimensions by using special bank wire-wound inductances or other forms of special inductance windings. Thus, for portable sets, such an inductance will shrink down to less than one inch in length, if necessary.
5. The usual assembly costs of a receiver are greatly reduced by using the Capind principle, and a great deal of valuable space is saved. This is especially important in portable receivers.
6. Finally, the weight of the radio receiver is reduced by using the Capind construction, as the set can be smaller in dimension. There are no condensers or heavy iron cores, the latter not being very practical in small portable sets anyway.

To sum up, it seems that there should be a very bright future ahead for the "Capind" principle.

I wish to express my thanks to Fred Shumanman who carried out my ideas incorporated here and who did a great deal of the preliminary experimental work. He also constructed the first model of the "Simplicity-1" receiver described on page 222.

RADIO-CRAFT for JANUARY, 1943
221
CONSTRUCTING THE "SIMPLICITY-I"

By FRED SHUNAMAN

ANY years ago—in 1922 to be exact—I was an ardent reader of the Gernsback magazines. The Gernsback editors were my favorite reading, and when about the end of 1923, Hugo Gernsback came out and predicted in a Radio News editorial that soon we would have "single-knob" receivers, the flame of my faith wavered and went out. (At the time I was toying with the idea of buying a Federal, a beautiful job with 11 controls.) The idea of a one-knob single-control set in 1923 was more than preposterous—it was downright idio
tic! The man must know that the constructors to whom Gernsback was manufactured for new entertainment. Nevertheless, his comings and goings, with a suspicion of eye—I had learned that the Editor was ready to sacrifice scientific fact for the sake of sensational prophecy.

Now that the single-control radio has become a reality, I make ready to believe that anything is possible in radio, so when Mr. Gernsback first asked me to carry out his idea on the "Capind" tuner, I was able to overcome my natural skepticism. It didn't look practical, and I felt that if there were anything in the idea, it would have been worked out in the 1922-26 period of experimental- tion. Nevertheless, I gave the plan a trial because of the curious trick circuits sometimes used in one
tube sets, and it is far more manageable and reliable than any of these.

NO MORE PARTS

The war has clamped down on the home radio constructor. Parts—even for essential jobs—are too expensive to obtain. No new ones are being manufactured for civilian use, and stocks are dwindling toward the vanishing point. Constructors boast of a job successfully completed "with the last 100-mm. variable in Kansas City." Yet there are many war uses for the small set. It may be used as an "alert" receiver for air-raid information. Constructed espe
cially for the job, it is less expensive to operate and wears out fewer valuable and unreplaceable parts than does the large broadcast receiver. As "alert" receivers are operated 24 hours a day, this is important. The small set may be used in makeshift ob
servation posts on roofs, etc., to keep in touch with local broadcasts. Tuned to the local police band for example it may serve the voluntary patrols.

The need for such sets challenges the ingenuity of the constructor to a level of difficulty created by the parts famine. They are far from inimitable. We are told that tubes—in certain standard types—will con
tinue to be available for the duration. As other parts become unobtainable, they must be made by the constructor himself. Old
timers were well equipped, and made their own book-type or slide-type vari
bles, copper-foil and mica fixed condensers, pencil-mark grid-leaks. Some tell tall tales of amateurs who constructed their own vacuum tubes!

With all this in mind, it was decided to construct a "Capind." Receiver would entirely dispense with the present type variable condenser (which is almost 100 percent constructed of aluminum, brass or other valuable defense metal), would use as few commercial parts as possible, and would make provision for substituting even these, with home-made components, as the supply of factory-made parts becomes de
pilated.

A number of ways of doing this comes to mind. The variable condensers may be sup
plied by the constructor, or by condensers with tinfoil-coated card or thin fiber plates and mica dielectric. Foil may be used for the tub
type condenser familiar in the early days of broadcasting, or even in the still more ancient tubular slide condenser.

Other specifications which the set should fulfill are: Use of as few tubes or other parts as possible; reliability, simplicity and compactness. A two-tube set is essential for good headphone volume on short tem
orary antennas.

Fortunately there is a double tube which will contain both a 1G6-GT and 6J5-GT. This gives us a 1.5 volt tube equivalent to two single-purpose tubes. The 1G5 would have been better for the purpose, but its manu
facture has been discontinued, and is hard to get.

The circuit chosen is the standard "re
generative detector one-stage audio," select
ed for its simplicity. A two-tube set is essential because of the trick circuits sometimes used in one
tube sets, and it is far more manageable and reliable than any of these.

MAKING THE "CAPIND"

The "Capind" whose theory is described in the first part of this article, was con
structed as follows: A tube was made by wrapping stiff writing paper round a cur
tain rod. The resulting cylinder, which was 5% inch in diameter and 5 inches long was soaked in melted paraffine wax, hot enough to drive out all moisture and leave an excellent low-loss form. Then a piece of thin tinfoil, six inches long and 1%/2 inches wide, was cut. A piece of cellophane 8 inches long and 1%/2 inches wide was cut, laid on a smooth desk, and covered with a very thin coating of coil cement.

The piece of foil—previously carefully smooth
d, was laid on top, 1/16 inch from the edge and 3/4 inch from one end, and rubbed from the center out, the pieces being turned over as soon as the cellophane adhered, and the squeezing continued to get all air bubbles out and make an absolutely smooth connection between the foil and cellophane. Figure 2 shows the sheet as it was before rolling.

The coil form was now wound for a length of 6 inches with No. 33 enamel cov
ered wire. (The number of turns totaled 750.) The ends of the winding were brought in two parallel leads, and the sides of the coil were taken to keep the winding even and smooth. Then the tin foil-cellophane sheet was wrapped snug
ly round the coil, cellophane side in." A little coil cement was applied to the overlap and the extra tinfoil wrapped on. We then had a cylinder which was foil outside and cellophane inside.

This tube was again wrapped with several turns of heavy writing paper, cut short enough to allow the tinfoil to project 3/4 inch at the end where the cellophane projects the shortest distance (1/4 inch). This is for connections.

A wooden plug was cemented in the other end as a hand-grasp. The tube was made to fit very snugly over the coil—experience showed that any looseness caused a great drop in capacity.

THE THROTTLE CONDENSER

A discarded tinfoil tube from an experi
mental radio was made into a tube from the "Capind" condenser. The inside tube was made by cementing a piece of tinfoil to paper, rolling it up and inserting it into the larger tube while the cement was still wet and expand

ing it with a knitting needle to fit the cello
phane inside wall of the outer tube. Of course the tinfoil of the inside tube was fixed up with a form, so that only one thin layer of cellophane separated the two metal sheets. Waxed paper was rolled up inside the inner tube while hot and expanded to the usual manner. When cool, the hardened wax gave the cylinder necessary rigidity.

There is no reason the condenser should not be built up in a more logical manner. Instead of cementing the tinfoil to the outer cylinder. There were a number of unsuccess
tul outer tubes from the "Capind" on hand that is why we chose this method used. Contact was made to the units by winding a thin strip of tinfoil around the bare end of the cylinders, then wrapping flexible lead around and into the tinfoil strips.

The tickler circuit had to be worked out to fit the peculiar shape of the "Capind." It started out as a regulation condenser feed-back circuit. Because of the length of the tuning coil, coupling was weak. If coupling was to be satisfactory, regeneration at the low-frequency end of the band, oscillation was uncontrollable at the higher end. The throttle condenser was made by taping the two coil forms with cellophane tape. The set was dead from 800 kc to the high-frequency end of the spectrum.

A compromise circuit was then worked out in which both throttle and feedback was used. The fixed condenser across the plate resistor assists regeneration at the high-frequency end of the band, where the throttle is most effective, in cutting down the outer, making control possible. The first experi
ment resulted in regeneration at both ends of the band and a dead spot in the center, but careful cutting and plating of tickler resulted in reasonably flat control over the whole band.

TICKLER CAPACITY

The tickler also influenced the tuning. Its effect on the tuning coil is similar to hav

ing another capacity at ground potential inserted inside it. In effect, it became an
other tuning condenser, and moving it in and out of the tuning coil seemed to give a greater change in tuning than an equal amount of movement of the condenser plate.

It was apparent that it would have to go at the end of the coil, and clear the winding altogether, if capacity effects were to be felt (Continued on page 243)

HOW TO MODERNIZE RADIOS FOR PROFIT

You can learn quickly to modernize all sets. Cash in by improving radio circuits, modernizing cabinets, adding fancy equipment, found in latest model sets. Practical job sheets, with schematics and photographs make the work easy. You are told how to obtain modernization work, what to charge, and how to complete the job quickly and efficiently. Large size, 8½ x 11 in. manual is priced at only $1.00

SIMPPLIED RADIO SERVICING

Revolutionary different COMPARISON technique permits you to expertly work on all radio sets. Gives practical pointers and suggestions. Covers every radio servicing and model. Handsy manual, form, size 8 x 11 inches, 112 pages. Over 1,000 practical service hints, 16 page trouble shooting blueprints $1.50

MOST-OFTEN-NEEDED RADIO DIAGRAMS

PRACTICAL RADIO MATHEMATICS

Introduces and explains the use of arithmetic and elementary algebra in connection with radio code, meter scales, Ohm's Law, alternating current, ohmmeter testing, wattage rating, series and parallel circuits, resistors, conductors, inductance, mixed circuits, vacuum tubes, curves, the decibel, etc., and has numerous examples. Net $2.50

RADIO-CRAFT for JANUARY, 1943

RAMAZING BARGAIN OFFER

Here is your chance to get practical training in radio almost free. In this single large course-manual you have the material covered by the best $100.00 radio correspondence course. All the lessons are included in this course-manual and cover every phase of modern radio work. Men with radio training are urgently needed in defense plants, service shops, Goering Secret jobs, and in the Army and Navy. Let the low priced course-book prepare you for a better job in radio or higher pay in the Armed Forces.

PRACTICAL TRAINING

These simplified, well illustrated lessons are interesting, easy to understand and apply. They early lessons explain to you the important radio principles and methods. The later lessons in the course-manual teach you advanced servicing practice. No special previous knowledge is needed. Everything you need is included in this one large-course-manual. You will find the material timely, up-to-the-minute, and of great help on the job.

LATEST DATA FOR RADIOMEN

Learn new speed-tricks of radio fault finding, ease histories of common troubles, servicing short-cuts, extra profit ideas. Included are many large lessons on the use of regular test equipment, explanation of signal tracing, television to the minute, recording dope. With this information you will have enough time on a single radio job to pay the special $2.50 price for the complete course of 22 money-making lessons. Many active servicemen used this reduced price radio training to brush-up and study of new servicing methods.

EVERYTHING IN RADIO

Every new development of radio is included in this complete course-manual. There are lessons on servicing instruments, signal tracing, interference, P.A., photo-cells, etc. Practical suggestions, service hints, repair methods. Thousands of the latest new-saving radio facts are packed into this complete course-manual available today for only $2.50, postpaid.

EASY TO UNDERSTAND

The practical lessons making up this course have been easy to follow and apply to actual radio jobs. Hundreds of radio facts that puzzled you will be quickly cleared up. You will find yourself doing radio repairs in minutes instead of hours, logically finding the faults or making needed adjustments. Get into radio for more important war work and better pay. The Armed Forces also need radio men and give higher rank and better pay. If you are already a radio man, improve your knowledge with this low-priced radio course.

10 DAYS' EXAMINATION

All the lessons of a high priced home-study radio course have been reprinted in a single large manual. The very newest data on auto sets, signal tracers, new tubes, etc., are included. You get a complete course of training at the unheard of price of only $2.50, nothing else to pay. And further, you risk absolutely nothing. You try the course for 10 days. If you are satisfied, the total price for the complete course is only $2.50. If you are not pleased, you receive a complete refund without a question.

SELF-TESTING QUESTIONS

The course-manual is supplied complete with all lessons, tube data, and supplementary material. Questions at the end of each lesson are used for self-testing and review. Order the course-manual on a 10 days' trial basis. You risk nothing. Don't pass up this remarkable offer.

LIMITED QUANTITY ON HAND

There are only a few copies of this 5th Edition on hand. We do not know if another edition will be permitted. Rush coupon for your course. Remember that the 10 days' examination period eliminates all risks on your part. Send today—begin to use the lessons this week.

"NO RISK" TRIAL ORDER COUPON

SUPREME PUBLICATIONS, 128 S. Jefferson St., Chicago, III.

Ship my copy of the complete Radio Course-Manual, including supplementary data and review questions. I must be entirely satisfied or you will refund my total remittance in full.

[ ] I am enclosing $2.50, full price. You pay the postage.

[ ] Send C.O.D. I will pay the mailman $2.50 and a few cents postage.

[ ] Also send other Supreme Publications as listed on attached paper.

PORTABLE RECEIVER POWER PACKS

By FRED SHUNAMAN,

NOW that portable batteries are difficult to obtain, servicemen all over the country are swamped with orders for electrifying portables. This magazine has been strafed with requests for power-pack hookups. Some remind us of a rash promise made by Radio-Craft long ago, "In a subsequent article we will give complete details for building a 1-tube power supply which will furnish both "A" and "B" power for any type of portable." Pressure is strongest from Canada, where batteries have long been unobtainable.

A supply "for any type of portable" is not as easy as it sounds. We find portables with 6-volt and with 1.4-volt filament supplies, and a few with 2-volt and 4.5-volt terminals. Tubes in a set may be all of the 50 MA type, or may be 50 MA and 100 MA mixed. The "A" supply may draw currents varying from 50 MA to 300 MA.

Serviceman's Advantage

The serviceman has one advantage over the manufacturer. Building his packs on a custom basis, he can vary each one to suit the set with which it is to work. For example, the manufacturer must put his packs out with at least three different sets of terminals—the serviceman can take his terminals off the customer's batteries, at a notable saving in time and expense.

The ideal pack would be one with a rectifying tube to supply the high voltage and a small dry rectifier for the filaments. Such a pack would have four terminals, with the A-minus and B-minus independent—an important feature in some portables. The disadvantage is that a rectifier for 6-volt supplies is not suitable for 1.4 volts and vice versa. A pack using tubes for both "A" and "B" supply can be adjusted to different types of circuits by simply changing the filament dropping resistor, a cheaper operation than changing the rectifier. On the other hand, a tube pack is essentially a three-terminal device, with a negative common to "A" and "B".

A Simple Circuit

The easiest set to electrify is one using a 6-volt "A" circuit and four 50 MA tubes. One of the best circuits for this purpose was put out by the Automatic Radio Mfg. Co. on their models P-57 and P-58, shown in...
In most cases it will be better to build a 1.4 volt power pack than to change the wiring of the set. This is also true in cases where 50 and 100 mA tubes are mixed in the same receiver, and in odd-voltage sets in which tubes are operated in both parallel and series, with shunts across some of the filament. Since both dry-plate and tube-type packs have their advantages and disadvantages, we decided to build and describe both kinds.

The pack shown in Fig. 2 uses a 11726G for plate power and a small copper-oxide rectifier for filament supply. A 20-ohm rheostat is connected in series with the output to bring the voltage down to an exact 6 volts. The 8-ohm resistor was a dropping resistor originally used to prevent heavy currents when the rectifier was used to charge a small storage battery. It was left on to provide "resistor input" to the filter, and because it was needed to drop the voltage to the required level. To use the pack on a 1.4 volt set it would be necessary to abandon the 8-ohm resistor and use a transformer and rectifier designed for 1.5 volt operation. The rheostat would still be necessary, as the condenser input would raise the voltage well above the 1.4 volt desired. According to figures from the Mallory catalogue, a rectifier designed to work at 1.5 volts with a resistive load will have a voltage of 2.5 volts when working into a capacitative load. These figures are based on the use of an extremely large input condenser, but are useful as showing the highest voltage to be guarded against.

The transformer was one built especially for this dry-plate unit, and has a secondary output of 10 volts with no D.C. load on the rectifier. The filter circuit is composed of the two resistors and the 30 and 100-mfd condensers. The connection of the resistors in the negative lead instead of on the positive side of the filament line was a mere case of convenience with the parts and layout at hand. The output filter condenser was found especially important in cutting down hum, which decreased exactly in proportion to an increase in condenser capacity. The orthodox method of filtering with this kind of rectifier results in a condenser with a capacity of several hundred microfarads capacity and a very low working voltage, but it was more convenient to use radio condensers at hand.

By changing the dry-plate rectifier, this pack may be used either for 6-volt or 1.4-volt portables. The plate supply is of course the same in both cases as it consists of the 11726G, a choke from a small A.C.-D.C. rectifier receiver, and the two 8-mfd condensers shown.

As the effectiveness of a filter condenser drops with the voltage, it will be necessary to use approximately 4 times as much filter capacity for 1.5 as for 6 volts.

**A VERSATILE PACK**

An attempt to build a more universal pack was made in the one shown in Figure 3. It can be used on 6- and 1.4-volt receivers, as well as odd-voltage jobs, without changing any parts. A variable resistor in the filament circuit and a special bleeder resistor make this possible.

The pack was constructed around three 25Z5's. The filament were all connected in series. The additional 40 volts line drop was secured by winding a 120-ohm resistor on a mica strip. This was then mounted on a piece of fibre—the mica clearing the fibre by the thickness of a couple of nuts on the mounting screws—and the whole stood up on a small bracket on the underside of the base. A line cord or any other 120-ohm, 50-volt resistor could have been used, of course.

All plates are connected in parallel, as are all cathodes. The conventional 0.5 ohm condenser across the line was forgotten till the pack was in its case, and since it seemed to make no difference, was not put in.

From the cathodes of the 25Z5's, the current follows two paths: The filament supply goes through R1 and the 100-ohm bleeder to the negative terminal. R1 is an old dictograph resistor obtained from Hudson Specialty Co., New York. It is a high wattage unit and can be adjusted from zero (Continued on page 235)
LET'S ALL PITCH IN!

WE CAN all help win this war by selling our government the communications receivers and equipment they need quickly and in sufficient quantities.

That is the reason I pay highest cash prices for used communications equipment.

When this war is over you will be in the market for new equipment and by taking advantage of my offer to purchase your present equipment at highest cash prices you will be in a position to buy new and better equipment than you now own.

Write, telephone or telegraph me description of your used communications receivers, transmitters and parts of standard make; you will be paid cash immediately without bother or red tape. I am particularly interested in Hallicrafters.

I also have a store at 2335 Westwood Blvd., West Los Angeles, Calif.

Bob Henry, W9ARA
HENRY RADIO SHOP
BUTLER, MISSOURI

PHOTO-ELECTRIC CELLS
Emby Products Co., Inc.
1800 West Pico Blvd.
Los Angeles, Calif.

THIS selenium cell is of the self-generating type with an output in excess of 450 microamperes per lumen, or 6 microamperes at an illumination of one foot-candle.

The cell is made permanently stable and can withstand temperatures up to 70 deg. C. Spectral response extends from 240 millimicrons in the ultra-violet region, up to 720 millimicrons in the infra-red. This makes it especially suitable for determinations requiring the selective ability of human eye.

The cell has no fatigue or "drift" effect, and for most practical purposes has no measurable time lag. Response is instantaneous and light changes of frequency exceeding 10,000 cycles can be recorded.—Radio-Craft

SOLDERS

ideal Commutator Dresser Co.
3067 Park Avenue, Sycamore, Ill.

is rated at 2,500 watts in intermittent operation. Two heats are provided, the low heat being 15% less than the maximum.—Radio-Craft

SOLDERING PLIERS

THE No. 10 Thermo-Grip is a plier type tool intended for large size soldering. It solders up to the 1650 ampere size, and can be used for sweating and unsweating threadless copper pipe and fittings, up to 2 1/8" diameter, and for heavy stator connections.

In intermittent soldering operations it can be used for pipe and fittings up to 4-inch diameter. Heating is more rapid and satisfactory by this method than by any other, because the pliers grip the work in two places and evenly heat the metal between them.

The unit operates on 117-volts, A.C., and

MIDGET RELAYS

Ward Leonard Electric Co.
Mt. Vernon, N. Y.

 THESE Bulletin 104 relays are used most frequently in small radio transmitters, aircraft control circuits, and other applications where available space is limited. The low overall height of 1 1/4 inches is made possible by the metal base and the short magnetic circuit.

All current-carrying parts are supported throughout by highest quality phenolic insulation.

In the energized position the relay is resistant to vibration up to ten times gravity.

—Radio-Craft

DECADE BOXES AND WHEATSTONE BRIDGE

Industrial Instruments, Inc.
156 Culver Avenue, Jersey City, N. J.

TYPE DR D. C. resistance decades are available in standard models with resistance ranges of .9 to 999,999 ohms total, and with guaranteed accuracy of plus/minus 1% and 0.1%, in two price classes.

All coils are of manganin wire, excepting the 100,000 ohm coils of nichrome. All coils are bifilar-wound on ceramic tubes,
oven-baked and protectively-coated. Switches have self-cleaning multi-blade phosphor-bronze spring wipers. The instruments are housed in rubbed walnut cases.

The Wheatstone Bridge Type RN-1 contains four resistance diodes with nine positions each, covering 9 x 1, 9 x 10, 9 x 100, and 9 x 1,000 ohms, with decade multiplying diodes. The ratio resistors have a guaranteed accuracy of plus/minus 0.5%, while the resistance coils in the decades of the bridge are guaranteed to plus/minus 1% tolerance.

Specifications for switches and cabinet are the same as for the decade boxes already described. The galvanometer is one of the well-proven moving-coil type with sensitivity of 1 microampere per division. Three standard flashlight cells comprise the 4½ volt battery in the cabinet, readily accessible without removing the panel. External battery connections are provided also.—Radio-Craft

NEW POLICE RADIO EQUIPMENT

NEW mobile FM police radio equipment, developed and manufactured for the radio reserve pool, by the General Electric Company, incorporates many new features, some of them suggested by police users in many parts of the country.

Iron-core, or inductive tuning (the closely controlled movement of an iron core in and out of a small form-wound coil) is used. This permits easier and more accurate tuning, and reduces the effects of car vibration on tuning adjustments.

Receiver battery drain has been reduced chassis is inverted for inspection or repair. A series of test jacks permits direct simultaneous readings of several functions at one time. All tube sockets and tuning controls are clearly stenciled on top of the chassis.

MOLDED PLYWOOD FOR RADIO MASTS

Bakelite Corp.,
New York, N. Y.

LIGHT, strong 15-foot tubes of molded plywood are being assembled into radio masts by the U. S. Army—thus saving aluminum previously required. This is just one of the many applications for which plywood, (bonded and impregnated with BAKE-LITE synthetic resins) is being used in war service today. Even more spectacular is the use of this material for the manufacture of plywood airplanes and gliders. For the giant cargo planes, too, plywood and laminated wood bonded with synthetic resins, figure in many vital parts. Even now big two-motor bomber-trainers are being made of plywood in this country and in Canada.

For non-war purposes the field of plywood bonded and impregnated with synthetic resins is expanding, at an encouraging rate.—Radio-Craft

FOR VICTORY TODAY
AND SOUND BUSINESS TOMORROW

Get This Flag Flying Now!

This War Savings Flag which flies today over companies, large and small, all across the land means business. It means, first, that 10% of the company's gross pay roll is being invested in War Bonds by the workers voluntarily.

It also means that the employees of all these companies are doing their part for Victory by helping to buy the guns, tanks, and planes that America and her allies must have to win.

It means that billions of dollars are being diverted from "bidding" for the constantly shrinking stock of goods available, thus putting a brake on inflation. And it means that billions of dollars will be held in readiness for post-war readjustment.

Think what 10% of the national income, saved in War Bonds now, month after month, can buy when the war ends!

For Victory today ... and prosperity tomorrow, keep the War Bond Pay-roll Savings Plan rolling in your firm! Get that flag flying now! Your State War Savings Staff Administrator will gladly explain how you may do so.

If your firm has not already installed the Pay-roll Savings Plan, now is the time to do so. For full details, plus samples of result-getting literature and promotional helps, write or wire: War Savings Staff, Section F, Treasury Department, 709 Twelfth Street NW., Washington, D. C.

RADIO—CRAFT
HOW SIGNALS ARE SENT

By C. W. PALMER

The beginner in radio while he is busy building a small receiver, probably is also interested in how radio signals are sent and received. To begin with, if you have a copy of the October issue of Radio-Craft, refer to the article in which atoms and electrons were explained. We will remember that each atom was made of a certain number of electrons and protons, arranged in "shells" or orbits very similar to the way in which the stars rotate around the sun. The electrons that move in this way are known as planetary electrons to differentiate them from the electrons in the nucleus. It requires the application of a force to move one of these electrons away from the atom, which then leaves the atom with an unbalanced positive charge. Each electron possesses a certain amount of attraction to the atom, depending on the distance separating it from the nucleus.

ENERGY

It is a well-known law of physics that energy can neither be created nor destroyed. It can, however, be transferred from one form to another. There are two kinds of energy—kinetic energy, which is energy in motion, as the force of a vehicle in motion—and potential energy, or the energy at rest, such as a large rock suspended at a height which becomes very powerful if released. See Figs. 1 and 2.

Now to return to the atom. If an electron is knocked from one orbit to another, some energy is either absorbed or emitted. If the electron is knocked from an outer to an inner orbit, for example, the difference in the attraction of the two positions must be given up. This energy is radiated in the form of electromagnetic radiations and for each electron moved, a certain definite amount of energy known as a "quantum" is radiated into space at the uniform speed of 186,000 miles per second. All this may seem rather far removed from radio transmission, but we will soon see how the two are connected. According to the theory of radiant energy, it is the agitation or radiating of these tiny units of energy through space that makes up the radio waves or rays. We are not certain whether the energy is transmitted by a sort of wave motion, as in the case of sound waves, which vibrate the air, or of groups of quanta move through space like bullets shot from a gun. To illustrate this, Fig. 3 shows two ways in which a bird may be killed, first by being struck by lead bullets and second by the concussion from large cannon being fired. It seems probable at this time that the facts may be best explained by the wave theory, although if we consider the transmission of energy, the quantum theory is necessary for a satisfactory explanation of the conditions. Energy can be transmitted from one place to another by one of two means; either by wave disturbances as illustrated by the cannon or by the motion of particles of matter from some source. According to the wave theory, an electromagnetic disturbance travels by a wave motion and as it is impossible for most people to think of waves without a medium (as the water for ocean waves, the air for sound waves, etc.) a hypothetical "ether" has been used as the medium to carry the magnetic wave motion.

ANOTHER EXPLANATION

If the above description of the radio wave is difficult to visualize, perhaps we can give another illustration that will make it easier. If we refer again to the first article of this series and read over the explanation of induction, we will find the explanation in just the same way as the current in one coil can start a similar current in the second coil, the current at the transmitter sets up currents in the receiver. If the two coils of the induction experiment are small, the magnetic field around the coils is small. On the other hand, if the coils are made larger, the field also increases in size.

To transport energy over a great distance, it would seem that enormous coils would be necessary. Such a conclusion is correct, but instead of having a very large coil generating the field, as pictured in Fig. 4, a long wire suspended high in the air is used. This wire, called an aerial or antenna, generates a large field that extends many miles and may induce a current in another wire, similar in construction to the first. Fig. 5 shows how this is accomplished.

FREQUENCY OF RADIATION

We will remember that the frequency of an alternating current flowing in a wire is the number of times that it changes its direction of flow, or in other words, the number of times the electrons change their direction back and forth. Frequency in radio transmission is similar to this, except that the energy is transmitted without the use of wires and instead of moving in a definite direction, it is carried in all directions away from the aerial of the transmitter, returning through the ground as it were.

If the wave reversals are between 50,000 and 1,500,000 times a second, we say that the waves are sent at a frequency of 50,000 to 1,500,000 cycles or more commonly 50 to 1500 kilocycles, which is the band of frequencies used for the regular broadcasting.

(Continued on page 248)
Beginners

The use of the type 19 tube, a twin triode, makes possible the battery operated version of this remarkable set. Full 2-tube performance is obtained by using both sections of the type 19 as separate circuits; one section as the detector tube and other as a stage of audio.

As you may see from the illustrations, the layout is as simple as can be. Two sockets, one for the tube, and one for the coil and the tuning condenser are the only major parts on the chassis. The regeneration control and the antenna coupling condenser are mounted on the panel. In the space of a few hours the set can be completely assembled, wired and set up for operation. Its smooth performance and easy handling are a pleasure even to the experienced ham. You will find the set brings in the nearby as well as the distant stations with unusual ease. All components are well insulated, and the parts are laid out so that all wiring (especially high frequency connections) are very short. Potentiometer type of regeneration control, though a little more costly, makes the operation of the set positive. The appearance of "dead spots" is eliminated by the use of a small variable coupling condenser in series with the antenna. The switch is attached to and is part of the regeneration control. A double-pole switch is used. One turns off the filament current, the other disconnects the "R" battery, thus removing all battery drain when the set is not used.

Coil Winding Data

The coils are wound on small 4-prong forms, 1/4 in. diameter, and 1 1/2 in. long. Coils A, B, and C are wound with No. 26 D.S.C. wire, and coil D with No. 30 D.S.C. wire. The bottom winding is put on first and connected to the two heavy prongs, and then the top winding to the two thin prongs. Turns: A—234-7/34; B—64-7/34; C—174-8/34; D—384-11/34. Accessories needed are a type 19 tube, a pair of sensitive phones, and an antenna. The antenna may be an ordinary single wire antenna, high and clear of nearby buildings, trees, etc., about 35 to 75 feet long. It should be well insulated so that there will be no possibility of the antenna wire or lead-in grounding at any point. Batteries needed are two dry cells and two 45 volt "B" batteries.

List of Parts

One 4-prong socket, 19
One 4-prong socket
50,000 ohm Potentiometer, with D.P.S.T. switch
One Harrison dial driver
One Harrison dial scale
One variable condenser, 140 mmfd.
Two 200 mmfd. condensers
One 5 megohm resistor
One .01 mf. condenser
One .1 mf. condenser
One 1 megohm resistor
Three knobs
One 100 mmfd. antenna coupling condenser
One speaker jack
One extruded washer
Two koulerted nuts

The circuit of the 2-in-1 all-wave set.

One-Tube All-Wave Battery Set

By W. Green

This month we present for the beginner a slightly more advanced receiver than the 1-tubers of the preceding two issues. This set is more sensitive and will produce lower signals—with a good aerial it should operate a small loudspeaker on local stations—yet it is little more difficult to construct than the earlier ones. Experimenter who have already built one of the 1-tube receivers can use most of their parts in changing over to this.

Use the Tube Manual

It cannot be too often stressed, not only for the beginner, but for the intermediate experimenter and constructor as well, how essential it is to have a receiving tube manual on hand at all times. It can be obtained for 35 cents at your radio supply store, or from RCA, Harrison, N. J., or Raytheon, Waltham, Mass.

It is folly to be without one. We are all familiar with the case of the luckless chap who starts out following a diagram, matching lead for lead, without regard to the difference of location of proper terminals on diagram and on the socket itself. He blithely turns on the juice, and zip! There goes another tube (or sometimes all the tubes).

All this could have been avoided of course if he had taken the time to look up the tubes in the manual. He would have found the tube element connections plainly marked, and he would have noted particularly that the view of the socket shown is the bottom view.

The reason the bottom view is shown is because most tubes are wired on the chassis, and the socket when wired up is looked at from its under side.

However, in the case of a bread-board layout, with the tube socket mounted on spacers on top of the board, the numbering order of the soldering lugs on the socket is just the reverse of that shown in the manual. Therefore the first thing the smart beginner does is to study the socket connections thoroughly, get familiar with the number of connections and their order. Then when he wires up he checks back and forth, and experiences no grief.

Another great use of the tube manual lies in the vast amount of solid usable technical information it contains.

It discusses automatic volume control, regeneration, power tubes and circuits, detection, oscillation, frequency conversion in superheterodynes, etc.

Tubes are listed and classified as to similar characteristics, filament voltages, power output, etc., so a proper choice of tubes can be made when making experiments.

(Continued on page 256)
MICROPHONES EXPLAINED FOR THE BEGINNER

THE 5 most common types of microphones used for P.A. systems and broadcast studio work are — the carbon, condenser, ribbon or velocity, dynamic or moving coil, and crystal. Each one has its advantages and disadvantages and so we shall consider each type in the order named.

CARBON MICROPHONES

The carbon microphone depends for its operation on the varying resistance of a carbon element when subjected to varying pressure.

The usual arrangement of this type unit, for best fidelity, consists of 2 carbon buttons one on either side of the diaphragm. This metal diaphragm—into a properly-built carbon microphone—is stretched and air damped so that the effects of self-resonance vibrations are negligible, giving a reasonably uniform output at all ordinary audio frequencies.

This unit has the disadvantage of a background noise called “carbon hiss,” which is caused by the passage of current through the granules. It has a high maintenance factor and must be handled with care. On the other hand it has the advantage of a very good power output level of ~30 db, together with low output impedance, making it possible to have the microphone some distance from the amplifier. See Fig. 1, A and B.

CONDENSER MICROPHONES

The diaphragm of the condenser microphone constitutes one of the plates of a variable air condenser, while the back plate, which is separated from the diaphragm by a film of air about 1/1,000-in. thick, acts as the other plate. See Fig. 1C. Capacity variations of this condenser series with diaphragm C, develop minute A.F. voltages which are then amplified by a 1- or 2-stage “head” amplifier. In actual practice, the condenser and head amplifier (or “preamplifier”) are all housed in the same case and the whole unit is called a condenser microphone. After the signal leaves the pre-amplifier, it has about the same output level as that of a double-cone type. The same principle of stretching and damping the diaphragm is applied to the condenser type as is used in the carbon microphone, therefore the “moving” or “sounding” part is the same. However, there is a noticeable absence of background hiss, and the ruggedness of the unit is a decided advantage.

RIBBON OR VELOCITY MICROPHONES

The ribbon-type microphone is so named because the armature is a light corrugated ribbon of aluminum alloy. See Fig. 1D. This type is also called a velocity microphone because the voltage induced in the ribbon is proportional to the instantaneous velocity of the air in the ribbon wave. The aluminum ribbon is suspended in the field of a permanent magnet and when sound waves penetrate the ribbon it vibrates, cutting the magnetic lines of force.

Whenever a moving conductor cuts lines of magnetic force, an electromotive force is induced in the conductor. Thus in this case we will have set up in the ribbon a small e.m.f. whenever it vibrates. Since the mass of the ribbon is extremely low, an excellent frequency response is obtained, extending well beyond the upper limits of the regular stretched-diaphragm-type microphone. This extended range of audio response is not very important as far as speech is concerned but does add brilliance to the reproduction of sound from musical instruments.

The output of this unit is approximately the same as that of a condenser-type microphone, so it also requires a 2-stage amplifier to bring the output level up to about ~30 db.

The velocity microphone is a low-impedance device, but it always has a coupling transformer mounted right in the microphone case. By matching the line impedance to that of this coupling transformer, the amplifier may be located some distance from the unit itself, provided the connecting cable is properly shielded. This type microphone is of a rugged nature and also possesses a very marked directional effect, the greatest response being obtained at right-angles to the plane of the ribbon; an “acoustical labyrinth” is sometimes provided to enhance the directional characteristic by absorbing ½ the backwave. The construction of the microphone is of such a nature that its operation is very quiet and free from noise or hiss.

DYNAMIC MICROPHONES

The operation of the moving coil or dynamic microphone, like the dynamic loudspeaker, is fundamentally that of a conductor moving in a magnetic field, thus generating an e.m.f. in the conductor. See Fig. 1E. The diaphragm is made of thin aluminum which— in a high-grade unit — is pressed into a dome shape for stiffness and to secure a piston action over the audio frequency range; improved frequency response is achieved by providing a “sweet passage” to afford outlet for the backwave. The moving coil is made from thin aluminum ribbon cemented to the diaphragm, and moves in the air gap between the pole pieces. The permanent magnet is composed of cobalt alloy steel, which will (Continued on page 238)
Although this article deals primarily with the servicing of the A.C.-D.C. type T.R.F. receivers, for which circuit diagrams are not obtainable, the procedures described apply equally well to these T.R.F. receivers when circuit diagrams are at hand, and will also prove of value in servicing A.C.-D.C. superheterodyne receivers.

The signal circuits of a midget T.R.F. radio set are extremely simple. Generally there is one stage of radio-frequency amplification using a 6.3-volt super-control pentode tube such as the 78, 6D6 or 6K7. The former two types have the same base and are interchangeable, while the latter uses an octal base.

The R.F. amplifier feeds into the detector, which uses a pentode tube having a sharp plate-current cut-off characteristic. Interchangeable, type 6G6 or 77 tubes, or the octal-base 6J7 tube will generally be found in the detector stage.

The audio output of the detector is fed by means of resistance-capacity coupling into the power output tube, which is generally a type 43 pentode. This tube in turn feeds the loudspeaker; although a dynamic loudspeaker is more often used, you will occasionally encounter a magnetic speaker.

In some sets one or more dummy tubes will be found, with only the filaments connected into the circuit. As long as the filament circuits is not open, the condition of a dummy tube is immaterial; in fact, defective tubes were often used by some manufacturer to keep costs down while making the customer think he is getting a larger receiver.

Typical circuit of a midget A.C.-D.C. receiver.

### Typical A.C.-D.C. Circuit

In Fig. 1 is shown the typical signal circuit arrangement of an A.C.-D.C. receiver. There are several peculiarities which should be noted; these are: (1) The chassis may not be an electrical part of the circuit, in which case the ground symbols simply indicate that the parts so marked are connected together; (2) the screen-grid of the R.F. tube gets the same potential as the plate; (3) an external ground connection is not used because one side of the power line (which connects to the receiver circuits) is grounded; (4) the small coils connected to the primary R.F. coil windings provide capacitative coupling in addition to the usual inductive, primary/secondary coupling.

The aerial for a midget set is usually a flexible wire, permanently attached to the set and connected to the receiver input circuit through a small tubular or mica condenser. This aerial wire may be grounded to a water pipe or other external ground, in which case the R.F. signals picked up by the ungrounded side of the power line will flow through the primary of the first R.F. transformer, then through the antenna condenser and the aerial wire to ground. The R.F. signals passing through the primary induce a signal circuit and the line cord plug is inserted in such a way that the chassis connects to the hot (ungrounded) side of the line; that is, you may get a shock when you touch the chassis if some part of your body is grounded.

If you get a shock, reverse the line plug; if the source is A.C.; this will connect the chassis to the grounded side of the power line. In the case of D.C. power you cannot reverse the plug, for that would make polarity incorrect; this makes a direct connection from the chassis to the aerial, and thus greatly increases the radio set's selectivity.

### Typical A.C.-D.C. Power Supply

Figure 2 shows a typical power supply circuit used for both T.R.F. and superheterodyne A.C.-D.C. sets. A 25Z5 tube is connected as a single half-wave rectifier, but where the loudspeaker field is externally independent of the receiver circuit, there will be a separate connection to each cathode and an extra filter condenser connected directly across the loudspeaker field, as indicated in the dotted circle at the right in Fig. 2.

The tube filaments are wired in series, with each filament requiring 0.3-ampere. The filaments of the type 25Z5 and 43 tubes require 25 volts each, while the 6D6 and 6C6 tubes each require 6.3 volts. This makes a total of approximately 63 volts, and means that the filament voltage-dropping resistor must drop 115-63, or approximately 52 volts. Since 0.3-ampere flows through this resistor, it will have a value of 52/0.3, or approximately 175 ohms.

If pilot lamps are used, they are usually placed in series with the voltage-limiting resistor. Each lamp is operated at about 4.25 volts, and hence the required voltage drop across the limiting resistor is reduced by this amount. Two pilot lamps connected as in Fig. 3A reduce this required voltage drop to 8.5 volts. (Although the lamps are rated at 6.3 volts, they are operated at 4.25 volts to prevent burn-out on surges.)

Pilot lamps are always shunted by resistors, for these lamps absorb much current as the tube filaments. The shunt resistance will be equal to the shunt current (the difference between the 0.3-ampere filament current and the pilot lamp current) divided into the voltage across the lamp or lamps.

### Pilot Lamp Color Code

On A.C.-D.C. sets, only 2 types of pilot lamps are ordinarily used; these can be identified by the color of the glass bead through which the filament-supporting wires pass. A magenta No. 40 lamp with a mating miniature screw base has a blue bead and has a brown-colored head. A magenta No. 44 lamp with a miniature screw base draws 0.25-ampere and has a blue bead, while a magenta No. 44 lamp with a bayonet base also draws 0.25-ampere and has a blue bead. This third type of lamp, having a white bead and drawing 0.20-ampere, is infrequently encountered. Replace burned-out lamps with new lamps having the same bead color and voltage rating (6.3 volts).

You will occasionally find 2 pilot lamps...
unshunt resistor across them. These will be 110-volt cheap lamps similar to those used on Christmas trees. They are connected in series to operate at half-voltage, thereby having longer life while still giving sufficient light to illuminate the tuning dial.

**TYPES OF HEATER RESISTORS**

Various types of filament voltage-dropping resistors are used in A.C.-D.C. sets. Many of the earlier models use ordinary wire-wound resistors mounted under the receiver chassis. The chief disadvantag of these is that the heat which they radiate causes deterioration of nearby receiver components, chiefly the electrolytic condensers. Line cord resistors, having the resistance wire embedded in asbestos and placed in the line cord along with the usual 2 copper wires, are now widely used because they keep the dissipated heat entirely out of the chassis. Line cords are easily identified by the fact that they have 3 leads instead of 2; the resistance is connected to one of the line wires, the connection being made directly to one of the prongs on the line cord plug. The line wire which connects to this same prong may be identified with an ohmmeter, and always goes to the rectifier plate. The other line wire will go to the ON-OFF switch which is mounted on the volume control of the receiver.

When a receiver which uses a line cord resistor in operation the line cord becomes quite hot, but this is natural and is no cause for worry. Never attempt to short-circuit these tubes in order to have a built-in resistance, for this would reduce the resistance value and affect the operation of the receiver.

Some tubes are even more satisfactory than line cord resistors for filament voltage-dropping purposes. These tubes came either in glass or metal envelopes, the metal envelopes being used well before the war. The resistance element is mounted inside the envelope and connected to prongs on the bottom of the lamp. Patents are provided, with connections to tube prongs to eliminate need for separate pilot lamp shunt resistors; an example of a ballast tube having one tap for this purpose is shown in Fig. 3B.

When a ballast tube burns out, always replace it with another having exactly the same number. This is necessary because the tubes are made with different ohmic values and with many different arrangements of prong connections. Ballast tubes become very hot while in use, but as the heat is above the chassis, critical parts in the receiver are not damaged.

Service men are sometimes asked to replace line cord resistors with ballast tubes; space limitations make it difficult to attempt this, but it can be done sometimes. Incidentally, an ohmmeter provides the quickest way of identifying the various prongs on a ballast tube.

**RECTIFIER CIRCUIT VARIATIONS**

A single triode rectifier or even a type 37 triode with grid and plate connected together may be found in a circuit arrangement like that in Fig. 4. Since supplying field excitation to a dynamic speaker would place too heavy a drain on the rectifier, you may expect to find a magnetic loudspeaker in a receiver having this power pack circuit. The 0.1- to 0.2-ohm resistor connected across the power line tends to prevent interference from entering the receiver by way of the power line. Oftentimes a 2,000-ohm, 1-watt resistor is used in place of the more efficient, but bulkier and more costly filter choke, as indicated inside the dotted circle in Fig. 4.

Sometimes you will find a circuit which uses two 1223 tubes connected in place of a single 25Z5; the circuit will be the same as that in Fig. 2 except that the 2 diode sections of the rectifier tube will be in separate envelopes. The filaments of the two 1223 tubes will be in series and will together be electrically equivalent to the filament of a single 25Z5 tube. This gave the set an extra tube and was therefore an advantage from a sales standpoint.

The 2 tubes supply sufficient power for loudspeaker field coil excitation, and hence a dynamic loudspeaker will usually be found. A single 1223 tube cannot, however, supply enough current for both the loudspeaker field coil and the receiver circuits and last a normal length of time.

Another power pack circuit using a 25Z5 rectifier tube is shown in Fig. 5. Here the filter choke is placed in the negative plate-supply lead, and the voltage drop across the choke is used as C bias for the control grid of the power tube. When the voltage drop across this choke is not correct for bias purposes, it can be inserted between points R and S in Fig. 3, and the control-grid return lead of the power tube is run to point X as indicated by the dotted line, instead of to the head of power tube. The insertion of the inserted resistor is so chosen that the voltage drop across the resistor equals the correct bias voltage for the tube. Notice that the cathode of the power tube is grounded, eliminating the need for a cathode bypass condenser and resistor. A decoupling resistor of sufficient value is used in the control-grid circuit of this tube, however.

A rather unique method sometimes used to secure a positive screen-grid voltage for the detector tube is shown in Fig. 6. Observe that here the detector screen-grid is powered directly to the cathode of the power tube, which is sufficiently positive with respect to the detector tube cathode for this purpose.

**FILTER CONDENSERS**

Filter Condenser Connections. When the filter choke is in the positive side of the power pack circuit, all electrolytic condensers will have a common negative lead. When the filter choke is in the negative side of the circuit, however, the negative side of the input filter condenser does not connect to ground (chassis) and consequently requires a separate lead. In this case the 2 filter condensers may have a common positive lead, as is the case in Fig. 5.

Failure of filter condensers is quite a common occurrence in A.C.-D.C. receivers. Oftentimes there will be no markings whatsoever on the old condenser block to serve as a guide in ordering a new unit; in a case like this, the following method of reasoning will allow you to order a satisfactory replacement.

Make a sketch of the old condenser block, showing which leads come out from it. Now trace each condenser lead and determine where it goes in the circuit. By this time you will be able to recognize the type of power pack circuit used. Label each lead on your sketch according to the point to which it connects, and indicate its polarity. Then when you replace the condenser with the type and value which was found, you will have no difficulty in determining the polarity of any point with respect to the "B-" lead and in drawing the internal connections for the condenser sections. Condenser block sketches for the power pack circuits given previously in this article are shown in Fig. 5.

Here are a few tips towards identifying the various leads. If the filter choke is in the positive side of the power pack circuit, as evidenced by a direct connection from one of the choke terminals to the cathode or cathodes of the rectifier tube, then all of the filter condenser leads in the block will have a common negative lead. You can identify this common lead by the fact that it connects to the receiver side of the ON-OFF switch either through the chassis or through a common lead. Once this is done, you can draw in the internal connections of the condenser block just as has been done in Fig. 7.

If the choke is in the negative side of the power pack circuit, as evidenced by the rectifier choke being electrically connected directly to the screen grid of the power tube without encountering any current-limiting or choking devices, you can locate the negative lead for the filter condenser by drawing a line from the filter choke coil to the negative side of the input filter circuit, where it will be the only filter condenser lead connected to the switch side of the filter choke. Where the loudspeaker field coil gets its

(Continued on following page)
current from a separate section of the 25ZS rectifier tube, there will be a condenser across the loudspeaker field coil with its negative lead also connected to the switch.

In most cases a single common negative lead is used for both condensers. The positive leads for these condensers are easily identified by the red or black lead of the loud speaker filter condenser will go to the same 25ZS cathode to which the speaker field is also connected, while the positive lead of the

The detector screen-grid obtains its bias from the cathode of the power tube.

input filter condenser will go to the other cathode of the rectifier tube.

Having located the leads and determined the value and capacitance of the electrolytic filter condenser block, you are ready to place on your sketch the approximate capacitance values for each section. Use the following general rules as your guide.

Input Filter Condenser—any value between 10 mf and 20 mf, rated at 200 volts D.C. working voltage; Output Filter Condenser—any value between 4 mf and 16 mf, rated at 200 volts D.C. working voltage; Loudspeaker Field Coil Filter Condenser—between 4 mf and 8 mf, rated at 200 volts D.C. working voltage; Cathode Bypass Condenser—5 mf, rated at 25 or 35 volts D.C. working voltage.

While condensers smaller than the minimum values given should not be used, the maximum values may be exceeded without impairing the operating qualities of the receiver. The voltage ratings can likewise be higher than the minimum values given.

Your electrolytic condenser block sketch

fully considered before attempting service work, in order to make sure that the owner's coil is not faulty, little rectifiers are designed primarily for reception of powerful local stations which are spaced well apart in the broadcast band. The receivers have little selectivity, so that local stations which are separated by less than 100 kc. may be expected to interfere with each other. The receivers likewise have poor capacity, and the reception of distant or even semi-distant stations will therefore be unreliable.

Where the complaint of the owner simply involves one of these factors, no service problem exists.

Likewise, good fidelity and freedom from blasting at full volume should not be expected from these receivers, particularly if they employ a magnetic-type loudspeaker. The owner making complaints which involve these factors is asking too much of his receiver and requires a better receiver to meet his needs.

Common Trouble, the simplicity of the circuits used in A.C.-D.C. T.R.F. receivers greatly limits the variety of troubles which may develop in them, which will, most often be encountered are: Set is dead; local signals are weak; hum is excessive; set distorts (squeaking) exists; set operates intermittently.

Servicing "Dead" Receivers. When the receiver is "dead," determine first of all if the tubes light or warm up. An open circuit somewhere in the series filament circuit is indicated if they do not. Take out each tube in turn and check its filament prongs with an ohmmeter for continuity or test the tube in a conventional tube tester. If tubes are OK, check the filament voltage-dropping resistor with an ohmmeter. If a ballast tube is used fit it from the receiver, and check its socket connections in order to determine between which prongs there should be continuity. If a line cord resistor is used, check with an ohmmeter between the line cord resistor lead and each prong on the wall socket plug in turn (the plug being removed from its outlet); with the power switch open, or one tube removed, there should be continuity

reversing the position of the line plug; proper polarity must always be observed on D.C.

A low rectifier-tube output voltage on A.C.-D.C. receivers is an indication of defective filter condensers. Check each condenser or condenser section in turn, by disconnecting one of its leads and then checking the condenser to see if leakage exists. If leakage resistance is lower than the normal value for a condenser of similar size, the condenser is defective and requires replacement. Even if leakage resistance is normal (check the leakage resistance of a new condenser of about the same size for comparison if you are uncertain), the condenser may still have deteriorated through dryness out of the electrolyte, with a resultant lowering of its capacity. Try a new filter condenser at each position in turn, while the old unit is disconnected. Separate 8-mf, 475-volt test condensers should be kept on hand for tests like this on any receiver. If the rectifier-tube output voltage comes up to normal when a new condenser is inserted, this is a sign that the old condenser was defective.

Even when only one section of the old electrolytic filter condenser is bad, a new one should be installed, for there is a good possibility that the other sections of the block will soon fail in a similar manner. The value of a test electrolytic condenser in this manner, you must, of course, observe polarity very carefully, for connecting an electrolytic condenser to a voltage source with improper polarity will in most cases ruin it.

If the rectifier tube output voltage of the "dead" receiver is normal, check the D.C. voltage between the receiver plug and each plate and screen-grid prong of each tube. Repeat this test for the corresponding tube socket lug; failure of the two readings for any one tube electrode to correspond indicates a break between the lug and the tube socket prong connection, making the installation of a new socket necessary.

Improper voltages on any tube electrode will point to the source of trouble, just as in the case of an ordinary A.C. receiver. The following diagrams in this article should give you an idea as to what voltages to expect; obviously the detector tube plate voltage and the control-grid voltage on the power tube will be quite low due to the high values of resistance in these circuits.

Simple continuity checks of various receiver circuits often prove the speediest way of locating trouble in a "dead" receiver. There should be continuity between the rectifier-tube cathode and the plate, as well as screen-plates, of all other tubes in the receiver, with the exact ohmmeter reading depending upon the sizes of the resistors in the various circuits. There should be continuity between the receiver power plug screw and the corresponding filter condenser, and the OFF power switch to the control-plates, as well as the cathodes of all tubes in signal circuits.

Rotor and stator plates of tuning condensers are sometimes shorted together; inspection will often reveal such a short, but if doubts exist, disconnect the coil lead from the stator of each section and check the rotor for shortness, either individually or with an ohmmeter. There should be no continuity between rotor and stator plates of a section.

To check the bias resistors in the cathode leads of the detector tube and the power grid, first disconnect the electrolytic cathode bypass condensers and then check the resistor with an ohmmeter. These condensers

PORTABLE RECEIVER POWER PACKS
(Continued from page 225)

The bleeder, B2, serves two purposes. It sets as a safety for the output condenser. Should the pack be turned on with the set turned off, the terminal voltage cannot rise higher than 10, while without it the terminal voltage would be around 100. It also makes it possible to operate 6-volt and 1.4-volt receivers within the range of the 1000-ohm variable resistor. The bleeder takes about half the current on 6-volt sets. On the 1.4-volt sets, where more current is required, the amount taken by the bleeder is very small. This resistor is rated at 2 watts.

The plate supply goes through the usual midget receiver choke, with a 20-mfd 150-volt (or higher rating) condenser on the output side. On the input side, one 20-mfd condenser is used for both plate and filament filtering. The output condenser in the filament circuit is a 100-mfd 25-volt unit. The hum level on a 6-volt portable was very low, though on 1.4-volt sets drawing heavy currents, where RI is set at a low value, it might be advisable to increase the input capacity to 40 mfd, and the output filament circuit condenser as stated in the description of the dry-rectifier pack.

A-minus and B-minus are common. Many portables bring these two terminals to ground. Others have a resistor in the B-minus lead to furnish "C" bias for the output tube. In sets of this type, distortion would result if a common A and B negative were used. Possibly the easiest way out would be to use a "C" battery in the pack, as shown in Fig. 4. Make sure the "on-off" switch breaks the circuit past the "C" battery doesn't discharge continuously through the resistor between A-minus and B-minus. If the switch doesn't break this circuit, take out the resistor.

Move cautiously when hooking the pack up to a set—1.4-volt tubes blow out on the slightest provocation. Set all resistors to their highest values, and put a voltmeter across the filament terminals. Then decrease resistance gradually till voltage is correct.

As will be seen from the photos, the packs were mounted on a plywood base. This was simply the experimental hookup—the original idea was to put them on a sheet of crackle-finished tin to match the case as soon as the final hook-up was arrived at. Thus we expected to gain a neat appearance and the underwriters' approval in one operation. The present plan, however, is to install the packs in cases the exact size and shape of portable batteries, to fit inside the radios on which they will be used. Probably the switch will be wired up to the switch on the set.

No parts list is given, as the values of all parts are marked on the schematics.

With these two types of packs, the serviceman should be able to power practically any type of receiver brought to him for electrification.

Radio-Craft would be glad to hear of any problems that may arise in converting portable receivers. Also—since many servicemen have no doubt worked out their own techniques—we would be glad to hear of any packs more efficient or versatile than those described, or possessing any other special features. No doubt you have run into problems different from those presented here, or have worked out simpler and more effective methods of solving them. Now is the time to let the world know what you have done.

Tell us about it, and give your fellow servicemen the benefit of your experience!

Any issue, prior to 1940, if in stock, 50c per copy.

HOOKING UP A MICROPHONE
If a crystal, use a lead direct from the mike itself. The other lead is grounded in both cases. If a crystal mike is used, a one-megohm resistor will have to be placed across it to provide a D.C. grid return.

A. The simplest method of hooking a microphone to your set is to remove the detector grid cap and replace it with one of the leads from the secondary of your microphone transformer if you are using a carbon mike.

The volume control may be used as this resistor.
This system is shown in 1A. Its chief disadvantage is that the cathode bias of a detector is usually too high for good reproduction of moderately strong signals.
Fig. 1B shows a second system, suitable for low-impedance pickups and microphone transformers. It brings the cathode bias down to a few hundred ohms, depending on the device shunted across the bias resistor. This is too low, especially if the detector has a high resistance in the plate circuit. Fig. 1C is the ideal hookup for this type of receiver. A double-pole double-throw switch makes it possible to insert the mike or pickup in the grid circuit at the best point, and at the same time change the cathode resistor to one suitable for amplification.
These three methods presuppose a volume control in the R.F. circuits of the receiver, so that when the mike or pickup is on radio may be cut out by turning down the control.

If radio signals filter through in any of these arrangements, break one of the I.F. cathode circuits, thus effectually killing the R.F. end of the set.

"PIGMY RECEIVER"

This circuit appeared in the issue of June, 1940, copies of which are no longer available. Herewith, the hookup and parts list. Note that a "Safety First" method of plugging in is used. Only one wire goes to the A.C. wall outlet, and the chassis is thoroughly grounded. If the plug is put in wrong, the set will not light—turn it around.

Parts List
1C-Mica trimmer, 1-35 mfd.
1D-19 plate 140 mfd. variable condenser
1E-Mica condenser, .001 mfd.
1F—Mica condenser, .003 mfd.
1G—Paper condenser, 1 mfd.
1H—Electrolytic condenser, 40 mfd., 150 volts.
R1—3 megohm, 1/2 watt fixed resistor
R2—75,000 ohm potentiometer
R3—10,000 ohm, 1/2 watt fixed resistor
R4—150 ohms, 1/2 watt fixed resistor
1-117L7 GT: 1-socket socket for same. 1-four-prong or six-prong socket, according to type of plug-in coils used. 1 pair headphones; phone jack, line cord and plug, knobs, dial, hook-up wire, etc., chassis and cabinet as desired.

Coil Data
Any set of standard plug-in coils may be used, or they may be wound to the following specifications:

For tone control, see circuits in Radio-Craft June, 1942, Page 608, and Aug.-Sept., Page 736.

[Diagram and schematic for Pigmy Receiver]
Input and Output Connections

Please explain input and output connections on the Push Pull Direct-Coupled 10-Watt Amplifier described in the July, 1939, issue and show how to add volume and tone controls to this circuit.—Several Readers

A. The two jacks are for three-conductor mike or phono leads, as from a double button mike, or an ordinary pickup with a shielded cable. The shield, or third conductor is grounded—the other two make connections to the grids of the first two tubes. The three points shown as "Output" are for connection to the primary of any push-pull output transformer suited to the 6L6's. Volume and tone control connections are shown.

Note that the 0.5 megohm dual volume control replaces the two 0.5 meg gridleaks of the first two tubes.

2-4 Tube Progressive Receiver

I am having trouble with the 2-4 tube Progressive Receiver (June and July Radio-Craft). I cannot get it to oscillate, and signals are very weak.

I am unable to get the set of plug-in coils and have wound my own. Would appreciate specifications of correct coils.

A. G. Verdun, Quebec

Several things may cause your set to refuse to oscillate:

1. Your coils, as you think, may be wrong. (See specifications for Pigmy Receiver coils in this month's Question Box).

2. Your tube may be poor. Have it tested at a reliable radio shop.

3. Tickler may be backward. Reverse the connections.

4. By-pass condenser may be defective. Try another, possibly a little bigger one. (00025)

5. Plate resistor may be too high. 50,000 ohms should be right. Check by substituting another.

6. Combination of circumstances—circuit wiring, etc.—may require tickler bigger than specified. Wind on a few more turns.

We trust that one of these suggestions may discover the fault in your receiver.

**Better A.V.C.**

Many radios do not have sufficient A.V.C. action, due to not enough voltage being produced across the diode-to-cathode load resistor.

Here is a circuit previously used as a voltage-doubling power rectifier utilizing a 2SK5 tube, but which can be adapted to the task of diode detection, using a 6146 in a voltage-doubling diode detector.

Due to the added bias fed back to the R.F. and I.F. tubes and the resulting decreased gain, the voltage across the diode load will not actually be doubled, but more uniform A.V.C. action will be had with increased A.F. output.

It would be well to reduce the minimum bias on the R.F. tubes to compensate for the increased A.V.C. bias applied to them.

Harold Gibson, Granger, Indiana
**Diagrams for The Radio Experimenter**

If you have a new Hook-Up, send it along; a pencil diagram will do. Be sure to include a brief description.

All diagrams and descriptions accepted and published will be awarded a year's subscription. Diagrams may be for receivers, adapters, amplifiers, etc. Send them to Hook-Up Editor, Radio-Craft, 25 W. Broadway, New York City.

**SELECTIVE OSCILLATOR**

Here is a diagram of an oscillator circuit (Fig. 1) that I have found to give remarkable selectivity, and extremely small drift.

It uses regeneration through the tuned circuit LC, and since the grid-plate capacity of any pentode (R.F. pentode) is very small, the detuning effect of it is negligible, and the frequency of oscillation is not changed by tube conditions.

Condenser C1 is needed to keep high voltage from the coil and condenser, and should be a small mica (.000025 or .00005).

Resistor R1 gives grid leak bias and should be about a megohm. R2 is a screen voltage dropping and decoupling resistor, along with C2.

C2 has no effect on oscillator frequency, but controls amplitude of oscillation and output.

**PHONO OSCILLATOR**

Here is a schematic diagram of an A.C.-D.C. Phono-Oscillator that I recently designed, and constructed almost entirely from parts salvaged from a late model midget broadcast receiver.

Although I used the output transformer and speaker from the broadcast receiver, with gratifying results, superior performance may be achieved by employing one of those special voice coil-to-grid matching transformers now available.

A type 1257GT tube was selected to amplify the output of the mike, since this tube (Continued on following page)

**MICROPHONES EXPLAINED FOR THE BEGINNER**

(Continued from page 231)

remain magnetized for a long period of time.

The moving coil microphone is quite rugged and is not affected by climatic conditions. Its output level is approximately 10 db higher than that of the condenser-type microphone, or about –80 db.

The low impedance of the dynamic microphone makes it possible to locate the preamplifier some distance from the microphone itself.

The frequency characteristic of the dynamic microphone is quite uniform from 35 to 10,000 cycles, so it has very good fidelity response to sounds in the normal audio range. This type unit has no inherent noise, and due to its very rugged construction can stand quite a bit of rough handling.

**CRYSTAL MICROPHONES**

Two types of crystal microphones are in common use today, to wit: 1st, the sound-cell type (See Fig 1G.) in which the sound waves act directly upon the crystal; and 2nd, the diaphragm type (See Fig 1F.) which uses a diaphragm to the center of which the crystal is attached by means of a mechanical link.

In either of these units, the principle of operation depends upon the piezoelectric effect or voltage produced in certain crystals when subjected to mechanical stress (bending, etc.).

The sound-cell unit is an assembly of 2 "linomorph" Rochelle salt crystal elements in a bakelite frame. The linomorph elements, in turn, are each made up of 2 crystal plates with electrodes attached, cemented together so that an applied sound wave causes a bending of the assembly, and produce a voltage. The mounting is such that mechanical shocks have little effect on the unit.

No diaphragm is used, the sound impulses actuating the crystals directly. An exceptionally wide frequency range, even into the super-audible band and down to zero frequency, may be obtained from this unit.

Of the 2 types of crystal microphones, the sound cell has the better frequency characteristics. Its output is very low, however, so it requires greater amplification. This type of crystal microphone is usually employed for full-range musical pick-up.

The diaphragm type will give much greater output, eliminating in most cases the need for a preamplifier, but it has the disadvantage of a limited frequency response. This type of crystal microphone is used mostly for voice work.

**HOW TO HOOK UP RADIO RECORD PLAYERS**

(Continued from page 215)

Phono connections made there, the results would be satisfactory for the player, but would defeat the radio. It will be seen that although the secondary of the last I.F. coil offers a high impedance to R.F., there will be negligible impedance to A.F., and we can therefore consider this coil as a piece of wire so far as A.F. is concerned.

With this in mind the circuit can be broken at the grid-return end of the coil and the proper connections made. Volume must be controlled from the control in the record player.

To make correct connections to T.R.F. receivers with power detection, use the same ideas as just described.
PHONO OSCILLATOR
(Continued from previous page)

provides much more overall stage amplification than any other type tube available. This was
considered necessary in consideration of the fact that the reversed speaker would provide small audio frequency
I first considered using a large inductance radio frequency choke in the plate
circuit of the mixer tube, but discarded the idea when it occurred to me that such an
arrangement would actually offer higher impedance to the second harmonic than it would to the fundamental frequency of 540
kilocycles. This would probably have resulted in the occurrence of an unwanted
signal in about the middle of the receiver dial. I therefore decided to use a tuned circuit in
the mixer plate circuit to insure maximum impedance to fundamental frequency.
A coil may be wound with No. 28 enameled wire on one inch by two and one-half inch coil forms. Each coil consists of 135 turns, but the oscillator coil is tapped 44 turns from ground end for the cathode lead.

The tuning condensers are of the trimmer type with maximum capacity of 500 mmf.
Because this set cost me only about $1.50
for parts I was unable to salvage from a broadcast midget, I would like to pass the idea along to other experimenters.

CODE PRACTICE OSCILLATOR

This diagram shows an "A.C. OPERATED CODE PRACTICE OSCILLATOR" made from old junk parts. The filament transformer is an old speaker output transformer.

When 115 v. is applied to the high impedance primary the secondary develops 2 to 3 volts. This takes care of the two 27's in parallel. In this way no voltage-dropping resistor is necessary for the filaments.

The unit I made was built on an inverted cheesebox with miniature jacks for the phones and key. The tone is very satisfactory.

If a filament transformer for 6.3 volts is available substitute 6C5's or 76's for the 27's.

If the oscillator doesn't perk, try reversing the audio transformer leads on the secondary.

The audio transformer, by the way, can be any ratio. It's an ordinary inter-stage transformer. If the audio note is too high a 0.0025 condenser in parallel with the grid circuit.

Changing the cathode resistor slightly will also change the tone. NOTE: Be careful not to ground the apparatus with a physical ground, since one side of the AC is used in the set.

DANIEL J. GNESIN
Grand Rapids, Mich.

RADIO HOOK-UPS

R.F.-A.F. AND POWER SUPPLY UNIT

Meet the 2X4! It is a combination R.F. and A.F. amplifier and regenerative receiver and power supply.

S3 is for switching the antenna from the regenerative R.F. amplifier to the receiver it is used with.

Coil forms used are 5-prong, to accommodate the tapped tickler which may be necessary because of different reactions between receiver and R.F. amplifier connections. R2 and C5 are mounted in octal tube base pins 2-8. Pins 1 and 5, 7 and 8 are shorted. R1 and C4 are mounted under the chassis on socket lugs 4 and 5. Other connections are as shown.

S1 and S2 are in position for R.F. amplifier connection and audio input connection. Throw switches and it is a regenerative receiver. R.F. output is shorted for receiver connections. S3 is antenna change-over.

LONGWAVE SUPERHET.

This is just the set for the short wave fan or ham who is tired of the regenerative set and wants something with more "pull-them-through" ability. The set is easy to build and is not very draining on the pocket-book, the cost being about $12.

The circuit uses a 6AK7 as mixer; a 6K7 as second detector; and a 6KG6 as output. Only one I.F. transformer is used, but this one has an iron core and has plenty of gain.

The usual building procedure should be used, making sure to have short leads to the plates and grids.

Either a single wire or a doublet antenna can be used; make sure to use a good ground. Tuning is done with the oscillator controls. The 15 mfd. variable condenser is used for bandspread.

Regular coils are used which cover from

(Continued on following page)
SUPERREGENERATIVE RECEIVER

The diagram below shows a receiver which I have tried, and found works satisfactorily.

When I first considered getting on 2½ meters I drew up a few diagrams and decided on the simplest form of superregenerative receiver. The results were not what was to be expected so I changed the circuit to its present state by adding a few parts and making coil changes. I feel sure that none of your readers will have difficulty in getting the set to operate.

When I was contemplating building the receiver I was under the impression that for 2½ meters one needed all high-priced doodads. I had all the parts in the junk box except the tube, so the set cost me a total outlay of 50c.

On 2½ meters I heard only one station as my location varies only about 20 feet above sea level, and the nearest active ham from my location on that band is 7 miles away.

On five meters I had good luck, having heard the W1, W2, W3, W4, and W9 call areas. I use a 4½ inch, vertical antenna about 50 feet from the ground. The antenna is coupled to the set by 50 feet of twisted line.

On the 9 meter police band the results were much more than I expected. I hear all the local and many distant police calls. The city of Linden transmits on 9 meters, and they come in on a loud speaker when hooked up to this set.

The volume control is needed for comfortable reception on the stronger signals. If the set has feedback, and bowls, a 0.1 mf condenser across the boxes will usually stop it. However, the 0.1 mf condenser cuts down the volume quite a bit.

The condenser on my set is insulated from the tuning dial by a 3-inch dowel. I am sure your readers will experience no difficulty in assembling the set.

Parts List

CONDENSERS
C1—30 mfd.
C2—6000 mfd.
C3—0.002 mf.
C4—15 mfd.
C5—0.005 mfd.

RESISTORS
R1—50,000 ohms
R2—10,000 ohms

MISCELLANEOUS
L2—B.P.C.—30 turns, 0.5 inch form. Dimensions for L1—2½ inches. 4 turns, 0.5 inch in diameter. Five meters, 10 turns, 7/16 inch in diameter. Seven to Nine meter police. 18 turns, 7/16 inch diameter. Ten meters, 20 turns ½ inch diameter. All coils should be No. 16 wire.

POWER SUPPLY CIRCUITS

Sometimes we want a power supply that need not be large and bulky, but just enough to give 45 to 65 volts. A great many portable radios, on which a lot of us are working lately, demands such an outfit.

It is possible to make such a power supply by using old transmitters or parts from B-battery eliminators, etc.

Fig. 1 shows how a 117-volt rectifier is used full-wave on an A.C.—D.C. hookup, to supply B-plus voltage.

Fig. 2 shows a power supply that can be constructed from an old Majestic type B-battery eliminator transformer, which has only the plate winding, and a 117-volt primary. Full-wave rectification is used in this also.

As can be seen in the diagram the circuit is very simple and inexpensive to construct.

CONVERTING AUTO RADIOS

With the production of new radio receivers stopped for the duration, the serviceman is given the opportunity of putting his ingenuity to work keeping the present receivers operating, as well as bringing the older sets up-to-date, where parts for doing so are available.

There will likely be a shortage of the small A.C.—D.C. sets that were so common as Christmas presents. There are a number of used automobile sets (especially those with synchronous vibrators) that can be converted into A.C.—D.C. receivers with little work.

The synchronous vibrators cost so much that a number of sets have been discarded. Yet the receiver and the tubes are usually O.K.

By replacing the vibrator transformer with a doorbell transformer and the vibrator with an S4 tube, the receiver can be changed over to A.C.—D.C.

The tuning condenser shaft will have to be lengthened, and a dial added—but that is not beyond the ability of the average experimenter.

WHILE THEY LAST

All of the attractive items here are brand new. ALL are IN PERFECT WORKING ORDER. In many cases, in brand new condition, better than the one you buy today. Terms in 30 days, no deposit, if full remittance accompanies order, deduct 2% discount. Send money order, certified check, new U. S. stamps, or C.O.D. in foreign currency.

ORDER TODAY  LIMITED QUANTITIES

ORDER FROM THIS PAGE. Use the convenient coupon below, include sufficient extra remittances for parcel post mailing (only if you order express, collect). Any check will be returned. In case of return, we deduct 20% deposit, if full remittance accompanies order, deduct 2% discount. Send money order, certified check, new U. S. stamps, or C.O.D. in foreign currency.

SERCING A.C.-D.C. MIDGETS FOR BEGINNERS

SERCING WEAK RECEIVERS. Essentially the same tests are made on a weak receiver as on a dead receiver. In addition, the dynamic loudspeaker field coil and its supply should be checked by applying a screwdriver to a pole piece; absence of pull indicates a defective field coil or no supply voltage to it.

The continuity of the aerial should be checked with an ohmmeter, and the trimmer condensers should be readjusted for maximum output. Weak reception can often be cured by moving the receiver around enough to secure a small amount of regeneration.

It is a good idea to check the line voltage in the customer's home when weak reception is the complaint; if this voltage is below normal, report the matter to the local power company.

Ordinarily there is nothing you can do to a receiver of this type to offset low line voltage. Excessively high line voltage is not serious in these small receivers; for the tube filaments and the pilot lamps are designed to stand up under all normal fluctuations in line voltage.

D.C. power lines in particular, the line voltage on peak loads may drop to a point where no reception is obtained, and again the trouble is not the fault of the receiver.

SERCING RECEIVERS FOR HUM. A certain amount of hum is to be expected in any receiver operating from an A.C. line. Many men forget that the telephone company line often drop 20 volts and spend hours trying to eliminate perfectly normal hum which they observe after correcting the original defect in the receiver. Hum, however, never to be so loud, however, that it becomes annoying when listening to the program from a local station. Excessive hum is often caused by a reduction in capacity of filter condensers, by a heater-to-cathode short in some tube, by an improper connection of a filter condenser, or by an open control grid return.

Curing Distortion. Improper centering of the loudspeaker voice coil is a common cause of distortion; the usual corrective methods apply here just as in larger receivers. Always try output tube when distortion is the complaint, for the great amount of heat dissipated by the heat in this tube often affects other electrodes in the tube. A leaky coupling condenser between the detector and the grid of the output tube is the most likely cause. You can measure a D.C. voltage across the grid resistor of the output tube when the positive voltmeter probe is connected to the grid and the negative probe to the resistor; a leaky coupling condenser is indicated; replace with a 0.05-mfd., 600-volt cartridge condenser if you cannot determine the value of the original part. Check the ohms values of the cathode bias resistors, and check cathode bypass condenser.
A SIMPLIFIED ELECTRONIC VOLTMETER

(Continued from page 210)

A circuit of the "Simplicity—1." A small toothpick was used as a form and the two discs were mounted on it three-quarters of an inch apart to make end pieces. Then the toothpick was put in the hard-drill and 600 turns of No. 38 wire were wound on it. (Had I built myself a cylindrical form, say of diameter not much smaller than the inner diameter of the tube, the chances are fewer turns would have sufficed.

The turns close to the toothpick are very small and have little inductance.

The coil was placed inside the ground end of the "Simplicity" tube in a position where it just covered the wound part. A socket seemed just another luxury in wartime. Therefore the leads were soldered directly to the tube prongs.

The switch was made of a small piece of curtain rod and part of a tin can. The writer was afterward shown how a much simpler switch which can be made from a paper-clip and a pair of screws—as illustrated in Figure 3.

The case was larger than originally intended. The first idea was to build it around a battery of 40 to 60 flashlight cells. Large-size portable batteries were still available at the time of construction, so they were used in spite of the somewhat greater size of the set.

It is our intention, however, to bring out an "Advanced Simplicity Receiver" shortly. This will dispense with practically all standard radio components except the condensers and resistors will be home-constructed, and the user will be able to choose battery operation, using "pen-lite" cells, or electric operation.

A certain amount of caution is necessary in tuning. Those experimenters who are not familiar with one-tube regenerators will be well advised to push the throttle condenser pretty well in, then slowly move the "Capind" in and out till a station is heard.

Then the throttle condenser can be pulled slowly out till the signal is just heard, and finally moved to a position where a maximum is obtained. The opposite method—pulling the throttle all the way out—will produce a series of whistles which make it difficult to tell anything about the station you are tuning across.

In addition, if you are using an outside aerial you will produce the same kind of howls and whistles in the sets of all your neighbors. The days of "blooping" are over, and any radioist who creates interference in a neighbor's receiver should be prosecuted for operating an interfering transmitter.

BYPASS CONDENSERS

Bypass condensers are in a circuit for just that purpose. While this particular meter cannot be used to check the bypassing action of R.F. condensers with a cathode bypass, R.F. amplifier, it can be used to check bias condensers and audio bypasses.

If the cathode bypass is open it can be detected in two ways; the bias will go up as will the audio signal drop across the bias resistor.

The first can be checked by measuring the D.C. voltage across the resistor, and the second by measuring the audio component with the D.C. blocked out with a condenser in series with the probe.

If the condenser is shorted or leaking, the opposite occurs. The bias will decrease due to the parallel resistance across the bias resistor. The audio signal will decrease if the leakage is great, but may increase if the condenser capacity is shorted but its D.C. resistance is high.

To check for leaky and shorted by-pass condensers, measure the D.C. across the resistor that is being bypassed. If a screen grid bypass, remove the tube which removes the current drain through the grid resistor.

The voltage should be the same on both sides of the resistor if the by-pass is not leaky. According, plate by-pass condensers can be checked by measuring the voltage across the plate resistor and transformers.

CURRENT MEASUREMENTS

While the instrument is not a current-measuring instrument.

A SIMPLE TRANSCIEVER

It has been the belief that "transceivers," even at very high frequencies, are merely make-shift affairs to serve only as substitutes for bona fide transmitting and receiving equipment. Therefore, I feel that any sciable investment should be concentrated in a transmitter-receiver combination rather than an elaborate transceiver.

However, I am aware of the desirability of compact, lightweight gear of this type for short range portable work. With all this in mind, I have designed a transceiver that requires an absolute minimum of space and parts, and still compares favorably with its more elaborate counter parts. High performance, even at 1 ¼ meters is made possible by the use of the inexpensive RCA 9002 UHF tube.

SENSITIVE P-E CELL AMPLIFIER

Following is a diagram of a circuit which was converted by me for use with the 117L7GT tube.

This outfit makes a fine emergency WERS receiver or transmitter.

The diagram is shown above.

JAMES D. ALEXANDER,
Terre Haute, Ind.

BREAK FOR REPAIR MEN

According to a recent announcement radio repair men whose service charges have been based upon the prices of competitors, may raise their prices if permission to raise these prices has been granted their competitors by the OPA.

There have been numerous complaints from radio repairmen and other service experts that OPA has allowed their competitors to charge better prices for jobs than they.

The new amendment to the services regulation is designed to eliminate this inequality.

Something like this has been needed for quite some time and it will no doubt help matters considerably, especially when dealing with customers who want to argue about costs.

A DIFFERENT TONE CONTROL

This tone control circuit is one of the simplest and most "bug-proof" I have ever used. The condenser should be one of good quality. The 50,000 ohm resistor need be no larger than ½ watt. The potentiometer should be a noiseless carbon. Any size potentiometer between 250M and 1 Meg. will do, with 500M ohms recommended. The .006 mfd. condenser is connected from the outer leg of the 50,000-ohm resistor to the center arm of the potentiometer. When the arm is at the ground side of the "pot" the highs are by-passed, giving best reproduction. When the arm is at the grid side of the "pot" the bass is attenuated due to the R/C pair (the .006 mfd. condenser offers higher resistance to the bass notes than it does to the high notes), and the reproduction is treble.

Intermediate positions of the arm will give different bass-treble response. Best position is determined by the listener's ear.

LEON A. WORTMAN,
Brooklyn, N. Y.

line cord resistor. All this makes possible a more compact and efficient unit. This circuit has sufficient power to work home-made relays. Strong sensitive relays can be made from old telephone ringers or cheap high-resistance milliammeters.

EUGENE HARMON,
Pittsburgh, N. Y.
HANDY LIGHT
While working in dark corners of a radio chassis, I wore out my flashlight cells. I tried an old output transformer from an A.C.-D.C. set as a step-down transformer to supply "juice" for the 2.5 volt flashlight. It worked so well that I decided to write and tell you about it. The transformer is so light it may be mounted right on the flashlight. The voltage on the primary is 110 V. A. C.
WM. J. CHERMAK, Hopkins, Minn.

CONVERTIBLE FLASHLIGHT
To convert flashlight into handy test light, drill a small hole in the back of light case, and cut an insulating washer to fit on bottom of back battery. Drill hole in washer to put test wire through, then solder one test wire to bottom of back battery. Run wire through washer and out through back of flashlight. Solder other test lead to shell of light. Ground the lead that is soldered to back of case and you can use as a regular flashlight.
RAY ATTWOOD, New Edinburgh, Ark.

DESK MIKE
Solder your carbon mike button to the part of the light socket that plugs into the light case. Then all you need do is to cut off the spoon part of a large beating spoon from your own kitchen, and put that into the frane that fits on the light case, and that makes a very commercial looking grille for your mike. (See Fig. 2).
Lastly, find the base from an old electric fan and fit that to the bottom of your automobile fender light, and the mike is complete.
As can be seen from the picture, Fig. 1, the carbon button can then be plugged in or out of the light case with just a turn of the wrist, and the button is held in place firmly by the spring in the light socket. The whole assembly makes a first-class, very neat and commercial looking, and very solid mike stand.
Those who do not have the funds to purchase an expensive mike stand will find this kink very useful. It is the most attractive and original stand that I have seen.
ROBERT W. L. MARK, Hanley, Pa.

DRE AND WET "A" CELL ADAPTER
Some of my customers with two-volt farm radios like to use dry "A" batteries on their sets while they have the storage cells recharged, keeping their set in playing order all the time. I solve this problem in the following manner:

HOW TO MAKE A GOOD ANTENNA

By FRANKLIN WILLIAMS, W6ULE

A GOOD antenna system should be:
1. Durable—strong enough to withstand a heavy wind.
2. Economical—should cost under $5.
3. High—at least 30 feet off the ground.
4. Versatile—in a position where it is easy to take down the antenna wire.
5. Easy to install.

The antenna described here has been in use for over a year, with great success. It was decided to mount two short poles on top of the house and garage. Each pole is 24' long and the roof where they are mounted is high enough to bring the total height to over 35 feet.

Six guy wires are used at each pole, two at the top and three half-way down (See Fig. 5.). The sixth is a safety guy and is run from the half-way point on the pole toward the other pole so that the pole will not fall over backwards in case the antenna wire snaps. No turnbuckles or guy insulators were used on the guy wires although it is better to use them. Retighten the guy wires every six months or so.

If the antenna is to be used for receiving purposes exclusively, a doublet is best, perhaps. This consists of a wire broken in the middle by an insulator with a twisted pair of wires going to it. The antenna will be most efficient when the frequency being received is equal to the resonant frequency of the antenna. A length of about 75' is about right for general short-wave purposes. If you do not want to go to the trouble of erecting a doublet, a single wire will serve almost as well.

When using this antenna as a ½-wave end-fed Zeppl on forty meters (See Fig. 7.), signals from every part of the world were received with good signal strength on a low-priced communications receiver.

As a transmitting antenna at W6ULE, the results were excellent. From here in California, with only a few watts on forty meters, code contacts were quite consistent with the entire United States.

A TINY P.A. AMPLIFIER

It is seldom that we run across miniature amplifiers, especially one designed for public address work, which will fit in the average man's overcoat pocket. For that reason, a unit like this is of unusual interest, and more so when we consider its design features.

In dimensions, it measures only 4 x 7 x 2½ inches, yet on this small chassis we find all components and tubes necessary to amplify the feeble output of either crystal microphone or phonograph pickup to a full output of over 2 watts!

This output is more than sufficient to drive any good 6 or 8 inch permanent-magnet dynamic loudspeaker, so that it will fill a decent-sized auditorium or home with a good quality of music or speech. To those who are not convinced, we wish to add that engineers estimate that 2 watts of audio output should be uncomfortably loud in a home.

The output of 2 watts, at least, is assured by the use of a 25L6 beam power, output tube. (See Fig. 1.) Sufficient voltage gain to drive this beam tube is obtained through the use of a 6J7 tube used as a voltage amplifier.

The 25L6 functions as a rectifier on both 110 volts A.C. and D.C. Since the types mentioned are all of the "all-metal" tube variety, it should be readily understood why the amplifier may be made so compact, since metal tubes are physically much smaller than equivalent glass types.

Concerning the layout and construction of this amplifier, little can be said about the best procedure, inasmuch as its compactness calls for crowded assembly and a certain nimbleness with the soldering-iron. However, it is reasonably possible for the average constructor to duplicate this unit. Since it is desirable to minimize hum pick-up and avoid possibility of audio feedback, it is recommended that all "live" audio (plate and grid) leads that are over 2 inches in length be enclosed in metal sheathing. Shielding of these leads is sufficient to reduce such detrimental factors.

The operation of the unit is very simple, since the power switch is ganged to the volume control. The input connections, it will be noted, are made directly to the grid of the 6J7 tube, and hence is of high impedance. Consequently, only high-impedance pick-ups or microphones should be connected to this source.

In other cases a suitable matching transformer is obviously necessary.

A simple good quality amplifier using 25L6. Anyone can build this who wants about 1 to 2 watts of output.
RADIO IN 86% OF HOMES

A BREAKDOWN of the 1940 Census of Housing by the bureau of census of the Department of Commerce reveals that 86.8% of the 30,721,944 white households of the nation have radios.

Only 43.3% of the 3,168,562 non-white households (mostly Negro) have radios.

Ownership of radios among the non-whites was greatest in the states where the Negro population is concentrated in the cities, and lowest in those states where the non-white population is in rural areas.

NEW JERSEY HAS MOST RADIOS

As a state-by-state summary of radio ownership from the Second Population series of the 1940 census:

FLAW DETECTOR SPEEDS RADIO TUBE PRODUCTION

INCREASED production of radio tubes for the armed forces, has been made possible by the development of a "thorium" detector that automatically sorts tungsten filaments by spectroscopic analysis, Westinghouse Lamp Division announces.

Government requirements call for the use of pure tungsten wire and thoriated-tungsten wire. If the tubes were made with any other kind of wire they burn out in a short period of time. Introducing a small amount of thorium into the tungsten wire increases electron emission and increases tube efficiency.

The thorium detector, with the aid of a spectroscope—the optical instrument used in observing visible images of the color spectrum—detects the presence of thorium in tungsten wire. The method consists of introducing a sample of pure tungsten or thoriated tungsten wire into an electric arc. As it burns completely, visible results are observed by means of the spectroscope. Two lines appear in the spectrum if the wire is pure tungsten; four appear if it contains any thorium.

TELEVISION GUIDES PLANES

A NEW invention of Dr. Alfred N. Goldsmith, the well-known radio engineer, will revolutionize plane landings in fog, rain or snow.

The new method eliminates the need for code and beam directors.

A film, similar to motion picture film, constitutes the central idea of the new device. The films, for several are used, comprise views taken from every possible elevation and angle and each frame is so marked. The television transmitter is located at one end of the air field and transmits in all directions. An incoming plane picks up the telecast and by charts and calculations the pilot gets his bearings.

At all times he has before him a picture of some sort, but of course all in one line. In other words the plane "sees" only those images that are in its line of sight.

The film is originally made in one of two ways. Either a model of the airport is made, and photographed on lines straight in, from several angles; or a plane is actually flown in on a straight line, and a motion picture taken all the while.

Thus there is a film for each solid angle of approach.

So no matter what line the plane comes in on there is always a set of frames that shows the landing at all times.
OPPORTUNITY AD-LETS

Advertisements in this section of the\nJune 7th edition must be included as the\nsame rate as those published in the\nrotation. Complete list of all classified advertisements\nwill be included at the time of issue. These advertisements\nwill be for less than ten words each. Maximum of one word\nper advertisement. Advertisements will be only for services\nObjectible or misleading advertisements not ac\ncepted. Advertising rates: One word $3, payable on\nreceipt. Inquiries must be received by June 10th, 1943;\ninsertion will be inserted as soon as possible.

HOW SIGNALS ARE SENT
(Continued from page 229)

of programs. The short waves are reversing even faster, from 1,500 kilocycles to 60,000 kilocycles.

WAVELNGTHS
We are all familiar with the term wavel\nlength. This is only another way to express the frequency. If we consider a single im\npulse of current that is sent out on the aerial of the broadcasting station, we find that it\ntravels a certain distance before another impulse is emitted. The distance between these impulses or reversals of current is the wavelength. This has been expressed in\nmetres instead of the more common feet or yards. A metre is about 39 inches in\nlength.

Radio waves travel at a speed of 186,000\nmetres per second. Suppose we consider a\nradio wave of a frequency of 1,000,000\ncycles. It takes one millionth of a second\nbefore the reversal of current starts. Then\nthe impulse travels at a rate of 186,000\nmetres per second, for one millionth of a\nsquare or about 0.18 metres. This can also\nbe expressed in millimetres instead of miles\nand when converted it becomes 29.98 metres.

An easy way to convert frequency to wavelength is to multiply the frequency in cycles\ninto 300,000 to find the frequency in K. C. and\ndivide the frequency in kilocycles into 300,000\nto ascertain the wavelength in\nmetres.

HOW RADIO RADIATIONS ARE\nPRODUCED
The electromagnetic radiations used in\nradio work are produced by generating\nelectric currents of the frequency to be used\nfor the transmitter and connecting the\nsource of these high frequency currents to\nthe aerial and ground. The high frequency\ncurrents are generated by large vacuum\ntubes known as 'oscillators,' which are\nmade on the same principle as the vacuum\ntubes in our receiver. In fact the receiver\ncan be used to transmit radio waves, if we\nperform the regeneration control to the right\nuntil the set starts to oscillate. Of course,\nthese waves are very feeble and do not travel\nvery far.

Vacuum tubes are used to generate the\ncurrents, as it is not practical to make gen\n erators of the usual rotating type employed\nfor generating the electric light current, for\nsuch high frequencies. Every broadcasting\nstation in the United States is assigned a\ncertain frequency, by the Federal Radio\nCommission. Practically all stations in one\nvicinity are assigned different frequencies

or wavelengths, so that we may select the\none we want without hearing any of the\nothers. This selection, as we know, is ac\ncomplished with tuning units.

The amount of energy picked up in an aerial is extremely small. It is interesting to note that it is estimated that the amount of energy picked up by the average receiving aerial, coming from a broadcasting\nstation 2000 miles away, if made con\n tinuous day and night for thirty years,\nwould be about equal the energy expended\nby a common house fly in climbing up a wall\nthe distance of one inch. The voltage in\duced in the receiving aerial of the nearby\ntransmitter of average power is in the\nneighborhood of 50 millionths of a volt—\n0.00005 volt.

If our eyes were capable of responding to\nthe radiations sent out from the aerials of\nbroadcasting stations, these aerials would\nappear like so many huge lighthouses flash\ning on and off, each one a different num\ber of times each second, corresponding to the\nspirit vibrations in the program being sent\nout. Since each station sends radiations of a\ndifferent frequency, these beams would all\nappear as lights of different colors to our\yes, which a sight would be truly fantastic\nand would enable us to understand more\nfully how these radio rays travel from the\nbroadcasting station to receiving sets.

A SIMPLIFIED ELECTRONIC\nVOLTMETER
(Continued from page 243)

measuring device, it can be used for that\npurpose very effectively by measuring the\nvolts across a known resistor, and then used\nin substituting this value in the formula. I = E/R.

For example, to determine the current\nthat flows through a 100,000 ohm plate\nresistor, measure the drop across this\nresistor, (which is usually 100 volts or more).\nIf it is 100 volts, divide this value by 100,000\nby pointing off five places to the left and\nit gives one milli plate current.
The entire D.C. load pulled by a set can be\nfound by measuring the drop across the\nfield or across a choke.

NOISY TRANSFORMERS AND RESISTORS
Noisy resistors and transformers can be\nlocated by connecting the meter across them\nand watching to see if its movement syn\nchronizes with the scratching noise heard in\nthe speaker.

REMOTE MIXER
(Continued from page 219)

complished by simply plugging the remote\ncontrol unit into an 8-ohm speaker jack on the\nfront panel of the amplifier chassis and\nturning the corresponding potentiometers\nsituated on the main amplifier to positions\nmarked 'R' on dial.

It is important to note however that an\namplifier using remote mixing must have 2\ninput circuits, each using the 1612 tube,\nwhich was designed expressly for this pur\npose.

The schematic circuit of one input channel\nis shown in Fig. 1. In Figs. B and C are illustrated both\nthe new and old methods of controlling the\ninput of a public-address system.\n
The remote control unit is available as a\nseparate unit and is connected to the main\namplifier by a cable and plug. This ar\nrangement is shown in section A of Fig. 2.

RADIO-CRAFT for JANUARY, 1943
A VERSATILE SQUARE WAVE AND PULSE GENERATOR
(Continued from page 207)

is perfect square wave generation.
The next tube is a 7C7 (or equivalent in older sets) and series of tubes 6J7, 6S7, 57, 24, 36, etc.) and is used as a clipper tube (the tube being operated so as to cause plate saturation). There is nothing complicated in this circuit except that resistance values must be adhered to for proper results.
The last tube is a cathode follower—meaning actually a tube that permits low impedances output without reflecting the load connected to this output, into the previous industrial application of a critical circuit, but it is important. The reasons follow:
If we terminate directly from the plate of the 7C7 into a load, a very peculiar situation will occur—namely, the output wave form will be affected, that is it will be distorted due to stray x distributed input capacities and impedances. To prevent this form of distortion the 7C5 (or any other beam power tube) is used to isolate the sensitive plate circuit of the 7C7 tube.
By terminating the plate circuit of the 7C7 tube into a high resistance, such as the grid of the 7C5, and the grid resistor 20 megohms a maximum load is reflected into the 7C7 plate circuit, and actually to be of any consequence at the given ranges.
The output is taken from the arm of R10, a variable control, large enough in wattage to dissipate the total plate current of the 7C5, through a large capacity. By thus terminating the output can be fed into any load and controlled from maximum to minimum without disturbing the previous circuit constants.

CONSTRUCTION HINTS
Chassis layout and wiring are not too critical, as can be seen in the photos. Of course wiring should be kept to a minimum. Excess wiring and wide spacing will introduce excess distributed capacity, which may be harmful in the final outcome.

CALIBRATION
To calibrate the frequencies a variable audio-generator of known values is made to "Zero Beat" against the square-wave-generator by using an oscilloscope and noting one position on the vertical and the other source into the horizontal deflecting circuits.
Using two frequencies are one single picture as shown in the figures, they "Zero Beat," and all one has to do is note the audio generator frequency and mark the dial on the square-wave generator correspondingly.

By doing this on a number of points the entire band can be calibrated.

A very important thing to operate the pulse with control, will be given in the next article.

OPTICS AND ELECTRONICS
(Continued from page 218)

lockout allows only a single impulse to be made by the tuning circuit, thus converting the welder into a spot-welding machine. Operating at high speed, the quick action of the lockout permits speedy spot welding, and synchronous timing control with moving parts. Production is thus increased and the reliability and smooth periodicity of the welder for welding of materials which could not be performed by any other method.
These welders represent the most outstanding industrial application of electronic control in the power field at the present time.

SERVICING A.C.-D.C. MIDGETS FOR BEGINNERS
(Continued from page 242)
devices for leakage in the manner already described, for these are also possible causes of distortion.
Distortion often occurs when the volume control is turned up too high when tuned to a strong local station, under normal conditions due to overloading of the receiver stages or of the loud-speaker, and the remedy obviously is for the customer to keep the volume level below the point at which distortion begins.
Adjusting Oscillation. A certain amount of oscillation is to be expected in these midget receivers when the volume control is advanced to its maximum setting, for the designer of these sets depend to a certain extent upon regeneration for high gain. Oscillation at low volume control settings can be due to open bypass or filter condensers, as well as to failure to use tube shields if they were originally provided.
Shielding of the control-grid leads of the R.F. and detector tubes, if these leads are over-exposed, or changing the positions of these leads are likely cures. Connecting the aerial to an external ground is sometimes effective in eliminating oscillations. Crawling the aerial into a small space will often cause circuit oscillation; keep this

AN EASY WAY TO SOLDER SMALL PARTS

It is easy to solder small, delicate parts without using the entire tip of a soldering iron. Take a short piece of No. 18 bare copper wire. Bend it around the tip of the soldering iron as shown in the drawing. (Fig. 1.) Be sure to tin the soldering iron tip well to form a good bond and heat conductor between the tip and the wire. The end of the wire serves as a very tiny soldering COPPER WIRE.

Fig 1

Fig 2

MAKING NEW CARBON GRANULE FOR MIKES

A carbon microphone that has become useless or broken down because of packing of the carbon granules can be re-used and put into use by repacking with new carbon. If the granules are not easily procured you can make your own as follows:

Open a medium grade lead pencil and lay the lead on a smooth surface. Then, with a sharp knife or better yet, a fine jewelers saw, cut off sections 1/16 inch long as shown. Glue pieces of No. 000 sandpaper to two pieces of board. Lay the bits of lead on one papered surface and then roll the other gently over the pieces with the other board, giving the top board a rotary motion as shown. In a short time the pieces will be reduced to a spherical shape and be rendered into perfect carbon granules for microphone use.

In most cases these will serve as well as the original granules, and in some cases, better.

L. B. ROBBINS, Harwich, Mass.

SOLDERING IRON HOLDER

This soldering iron holder has two principal advantages over other types which I have seen in your columns. All it consists of is the major plates from an old variable condenser. The iron should be in the position shown when it is heating. When it is hot, slide it back so that the tip rests on the plates. The advantages are that (1) the condenser plates will absorb short porcelain insulator. It was held at an upward angle on the inside with a wooden peg. The lead-in wire was then fed through the insulator into the room. The downward pitch prevented rain or snow from driving in from the outside.

This makes a good installation and, in the case of a small window light, does not impair room illumination. The light can be replaced at any time and the window restored to its former condition.

L. B. ROBBINS, Harwich, Mass.

SOLDERING IRON HOLDER

www.americanradiohistory.com
A New Type of Service Manual!

RADIO CIRCUIT MANUAL

The Only EDITED Manual
Ever Published!

DIRECTORY OF RECEIVERS MANUFACTURED IN 1940 AND UP TO JUNE, 1941

MORE INFORMATION IN HALF THE NUMBER OF PAGES

The value of a service manual is measured not by the number of pages but by the amount of useful information. Thus, in only 236 pages this Radio Circuit Manual covers over 200 receiver models. MORE than does any other competitor's manual in twice the number of pages.

NOW DID WE DO IT?

.... By increasing the size of our pages; by discarding non-essential data and editing the balance; by listing only those receivers which the Service Engineer will definitely have to repair (no communications or export receivers, no shortwave sets or amplifiers, no electronic devices, etc.); by many months of hard work based on a definite plan of procedure and a deep understanding of the actual requirements of the Service Engineer. There is no "dead weight" information to add bulk to this Manual. Every word counts. Every minute of reading time is well spent.

OUTSTANDING FEATURES

- Contains data on more than 1800 receiver models—more than any other radio service manual.
- Only 236 pages—less than half the bulk of any other manual and more than 1/3 lighter.
- All information is EDITED—all non-essential data deleted and the balance checked and correlated with the schematics and sketches.
- Each larger page permits listing of all information on one page. (A few unavoidable cases excepted.)
- I.F. peaks for all superhet circuits are boldly displayed in black type—none missing, all accurate.
- No space wasted on communications and export receivers, minifiers, electronic musical instruments, etc.—no 100% Service Engineer's Manual.

A "CUSTOM-TAILORED" MANUAL FOR SERVICE ENGINEERS

Here, at last, is a Service Manual deliberately PLANNED for the Service Engineer. Instead of a mere hodge-podge collection of service data, 80 manuals have been in the past, this Radio Circuit Manual is an orderly compilation of essential radio diagrams and service information, carefully edited and uniformly presented for the maximum convenience of the busy Service Engineer. All time-consuming, non-essential data have been weeded out, and the remaining information, vitally important to the rapid and efficient servicing of modern radio receivers, has been laid out in a logical, easy-reading style which cuts time from the day's work. Because of this and other features which are self-evident upon first observation, it has been possible to list all information pertaining to a given model on a single page. In 236 pages this Manual presents essential service data on over 1800 receiver models—more than any other existing service manual on the market!

ONLY ONE MANUAL PER YEAR!

The new technique used in compiling this Radio Circuit Manual—1941 makes it possible to include in a single book all the new receiver models which the radio industry can produce in a single year. This fact alone represents an important saving to all Service Engineers.

A PERMANENT INSTITUTION

This Radio Circuit Manual—1941 is NOT a one-year publication. Designed from the start to be a radio service manual for the next 20 years, it will be a "must" to every Service Engineer since 1942 and so an indispensible book for all those who are in the radio service field. By ordering now you will own the only work of the practicing Service Engineer.

ORDER YOUR MANUAL IMMEDIATELY—NOW!

Get your copy directly from us by filling out and mailing the convenient coupon shown at left. Send check, money order, or letter for your favorite edition.

10 BEST RADIO BOOKS 10 CENTS EACH

Radio Fans Everywhere—these fine ten cent text books give you an excellent foundation for the study of Radio. They are clearly written, profusely illustrated and contain over 15,000 words in each book. You'll be amazed at the wealth of information contained in these handy books. Excellent for reference—ideal for technical library.

1. HOW TO BUILD FOUR DEERLE SHORT WAVE SETS, No. 1
2. HOW TO MAKE THE MOST POPULAR ALL-WAVE 1- AND 2-TUBE RECEIVERS, No. 2
3. BEGINNERS' RADIO DICTIONARY, No. 3
4. HOW TO HAVE FUN WITH RADIO receiver, No. 4
5. HOW TO READ RADIO DIAGRAMS, No. 5
6. HOW TO BUILD THE "WIZZER" RECEIVER, No. 6
7. ALL-TUBE ELECTRICAL EXPERIMENTS, No. 7
8. SIMPLE ELECTRICAL EXPERIMENTS, No. 8
9. TELEVISION, No. 9
10. "THE ADVENTURES OF BERTIE" ALL TUBE RECEIVER, No. 10

BOOKS ARE ALL UNIFORM

Every book in the GENRE of ELECTRONICS and RADIO sends your money back if not satisfied. It's backed with the strongest possible guarantee. It's your money back if not satisfied. You can't lose.

WHAT IS AHEAD IN ELECTRONICS?

(Continued from page 203)

now, in exactly the same manner following the general pattern, the electron tube, conceived wholly for wireless communication, has already entered the doors of a thousand industries. Its future lies perhaps more grandly in its industrial applications than it does with broad spreading of the human voice, faces, music, and intellectual intercourse generally. Already steel makers control their Bessemer's with its aid and with unerring accuracy. Huge panels of plywood and plastic board are cemented together under hydraulic pressure and dried under the same time formerly demanded. The high-frequency bombardier is already a recognized factor in welding, soldering, melting, brazing, case-hardening operations, a quicker, neater job than the time-honored methods could ever perform. Tomorrow it will displace ten thousand furnaces. A self-balancing recording equipment registers data faster than 3 or more men with pads and pencils, and with infallible accuracy. The electron tube has already matured into higher mathematics, solving quickly intricate formulae.

Photo-cell and amplifier indicate combination efficiency by measuring density of spots on one-half of the retina, record it, and then automatically control the firing stokers.

The ubiquitous electron tube measures the thickness of oil on the inside of a plane's wings, and at the critical moment operates the devices. In the Police Court a lie detector, tube-operated, points the guilty finger where detection by eye and psychiatric methods have failed. In the refinery, the varnish factory, where high volatiles or explosives are concocted, the electron tube is an incalculable and dangerous heat is quietly announced, in ample time to avoid catastrophe.

In the hospital, and home as well, short-wave diathermy and improved galvanic devices are today proving their irreplaceable value, not only as healers, but as preventative of a host of dangerous ailments or maladies. A thousand other applications, scarcely 10 years old, marks only the threshold of a vast new medical science, where the old adage, "Electricity is Life," will indeed demonstrate its fundamental truth.

These, and a thousand other applications of Electronics to mankind's needs, comfort, and to the fulfillment of the "abundant life"—all as yet undeveloped—will characterize this Twentieth, as "The Electronic Century."

HANDY RADIO DATA BOOK

Every once in a while someone gets up a handbook or a data book that hits the bull's-eye, far as utility is concerned. Such a job has been done by Allied Radio Corporation of Chicago, in their new Radio-Formula and Data Book.

In forty pages and 5 diagrams, with numerous tables, the book contains the basic algebraic formula; the more common electrical formula; vacuum tube work; motors; wire tables; trigonometry; metric conversions; color codes for capacitors, condensers, transformer and speaker leads, logarithms, decibel tables, symbols and abbreviations, decimal equivalents and even the Greek alphabet.

It's a handy little booklet and ought to find thousand of users. It's worth the slight charge asked for it.

252 RADIO-CRAFT for JANUARY, 1943

www.americanradiohistory.com
SERVICING NOTES

Trouble in... ZENITH 85463
Squelch when volume control is beyond middle position is normally due to open 16 mf condenser No. C23 and not due to the volume control being worn.

LAURENCE ROESCHT,
Wilkes-Barre, Pa.

ATTENTION SERVICEMEN!

Do you have any Servicing Notes available which you would like to bring to the attention of the readers of Radio-Craft? If so, send them along and earn a one-year’s subscription to Radio-Craft for each one submitted.

... SPARTON MODEL No. 567
This model uses two pilot lights of the screw type base. The pilot light socket was found pushed against, or touching, the metal that holds the receptacle in place behind the dial, causing a short of the 6.3 volt winding. Clearing the pilot light allows all tubes to light and the set to play OK.

... ALL ZENITH MODELS USING A TWO-SECTION CANDOHM RESISTOR OF 40-200 OHMS
Replacements hard to obtain. Usually the 40-ohm section is bad. Shunt it with a "Zipolom," or other wire-wound resistor of proper ohmage.

HERBERT NOONES,
East St. Louis, Ill.

... PHILCO 1942 RECORD CHANGERS
In some models this motor is running is caused by bell drive shaft hitting frame at base. Some holes were found off center in respect with bearing. Reversing bearing clears up trouble.

LEONARD CHOMA,
Waterbury, Conn.

KINKS
(Continued from page 250)
Excess heat and the iron will be less likely to overheat and (2) the heat absorbed by the condenser plates will be radiated because of the large surface area.
In consequence, the holder will not harm your tubing work. The more plates in the unit, the cooler it will be.

GAYLORD ST. THOMAS
St. Paul, Minn.

MIKE AND PICKUP INPUT
A crystal and orthophonic phonograph pickup head is all that is needed for an improved mike. You simply extend a nail, with head cut off, from one needle socket to the other. The output of the crystal is wired to the input of the amplifier or whatever you have on hand.
The speech goes into the orthophonic head, from there the vibrations go to the crystal head making a perfect crystal mike. For certain experiments a lot of fun can be had; and in others some interesting observations made.

S. RUSTYAK,
Ihaca, N. Y.

UNUSUAL COIL WINDING ARRANGEMENT
I have been using reclaimed wire from small audio transformers, filter chokes, and speaker fields, which has a paraffin wax coating, instead of shellac or enamel. The diagram shows how I used the wire, passing it through a tray of insulated compound before winding into the form. Perhaps many of the radio fraternity can use this idea.

JAMES CALLAN,
Hamilton, Ont., Canada.

RADIO AMATEUR COURSE

RADIO & TELEVISION

148 PAGES 5 x 8 INCHES

OVER 150 RADIO DIAGRAMS and TECHNICAL PHOTOGRAPHS

Your Money Back—
If the RADIO AMATEUR COURSE does not represent the greatest book value ever offered to the radio "fans" for ...... 50c

To convince you that there isn’t a better book now today, the publishers of the RADIO AMATEUR COURSE make the sensational offer of a money-back guarantee on such a low-priced book. Stop in at any of the many dealers handling this book and examine it. See for yourself if the RADIO AMATEUR COURSE isn’t just the book you’ve always wanted.

Printed on the finest coated paper—well illustrated attractive 4-color covers—complete with radio information you must have. It contains a step-by-step program for obtaining a short-wave radio education.

THE INDUCTANCE AUTHORITY

By EDWARD M. SHIEPE, B.S., M.E.E.

1A NEW BOOK

The only book of its kind in the world. "The Inductance Authority" entirely dispenses with any and all computation or book work. It contains the construction of solenoid coils for tuning with variable or fixed condenser of any capacity, covering from ultra frequencies to the borderline of audio frequencies. All one has to do is to read the charts. Accuracy to 1 per cent may be attained. It is the first time that any system dispensing with calculations and correction factors has been presented.

There are thirty-eight charts, of which thirty-six cover the numbers of turns and inductive results for the various wire sizes used in commercial practice (Nos. 14 to 22), as well as the different types of covering (single silk, cotton-dyed silk, double cotton and enamel) and diameters of 1/8, 3/32, 1/16, 1/32, 1/32, 1/32, 1/32, 1/32, 1/32, 1/32, 1/32, and 1/32 inches.

Each chart for a given wire has a separate curve for each of the thirteen form diameters. The book contains all the necessary information to give the final word on coil construction to service men engaged in replacement work, home experimenters, short-wave enthusiasts, amateurs, engineers, teachers, students, etc.

There are pages of textual discussion by Mr. Shiepe graduate of the Massachusetts Institute of Technology and of the Polytechnic Institute of Brooklyn, in which the considerations for accuracy in attaining inductive values are set forth.

The book has a flexible binder cover, the present size is 9 x 12 inches of all curves (black lines on white field) is excellent.

WATTAGE AND CURRENT RELATIONS IN RESISTORS

The selection of a resistor for a specific application requires knowledge of not only the resistance required but also the wattage to be dissipated as the physical size of the resistor will be largely determined by the latter factor. Another point of importance is the degree of ventilation, as the nominal wattage ratings are based on free air mounting of the resistor.

The wattage to be dissipated in the resistor can be calculated readily by means of Ohm's Law when the resistance and current (or voltage directly across the resistance) are known. It is important to note that the wattage dissipated in a resistor varies as the square of the current, as stated in the equation: \[ W = 1/R \]

Non-technically stated this means that any change in the current causes a much greater change in the wattage, as graphically illustrated above. Thus, if the current is doubled, the wattage is multiplied by (2)\(^2\) = 4; if the current is tripled, the wattage is multiplied by (3)\(^2\) = 9. The importance of small changes in current is often overlooked, but it would be realized that if the current is increased by only 10%, the wattage is increased by 21%; and if the current is increased by 20%; the wattage is increased by 44%. Hence, the actual current must be used in figuring the wattage, and the increase in wattage due to apparently small changes determined, in selecting the proper size resistor.—Ohioite News.

**Electronic Cop**

(Continued from page 208)

extinguishes itself. The complete equipment then resets for the next car.

Regarding the possibility of more than one car passing through the section, the sequence would work out something like this:

Suppose two cars, A and B, one following the other, say within 50 feet, are in the section. Car B overtakes car A and passes the final beam before car A crosses.

The timer records the time the last car which intercepts the initial beam (car A), and seals-in the circuit. Since car B cuts the final beam first, the sign flashes the speed as the timer "saw" it, and the cutting of the final beam by car A has no effect.

In other words, the sign flashes virtually the "meshed" speeds of cars A and B. And so it would be for four, ten or 20 cars, the timer would be sealed-in by the first car, but would flash the meshed speed.

The extreme case would be a car travelling very slowly, cutting the first beam, and then just a split second before cutting the second beam, a faster vehicle passes it and cuts the beam. In this case the beams would cut two cars of extreme speeds, but the timer records the speed of virtually one car.

**FM Broadcasting Superior Survey Reveals**

In an effort to learn what the public thinks of FM broadcasting, General Electric engaged an independent research organization to make a survey in New York and other large cities.

During the hundreds of interviews, no mention of any manufacturer was made.

Names of FM set-owners were obtained from dealers in each of the 14 cities covered. Results of the survey follow:

Seventy-nine per cent of those interviewed are satisfied with the FM quality of reception.

Eighty-five per cent believe FM quality a decided improvement over regular broadcasts.

Seventy-five per cent tune in on FM stations more than once a week, over 50 per cent listen to FM at least once a day.

Ninety-one per cent would recommend a set equipped with FM to their friends.

Forty-five per cent believe that "improved tone quality" is the one FM advantage more important to them; 41 per cent think "freedom from noise and static" is the most important advantage.

Seventy-nine per cent said, "yes" to the question, "Have any of your friends listened to FM on your radio?"

Ninety per cent said their friends' opinions of FM radio are, "Favorable."

**JAM Proof Radio Transmission**

FRANCOIS CHARLES PIERRE HENROTEAU of Ottawa, Canada, has invented a new method of sending secret radio messages which cannot be "jammed."

As is well known, almost any frequency (except the ultra highs) can be jammed so that only howls and whistles emanate from the receiver.

The ultra highs of course are not so easily affected because of their short range.Henrotau's means of foiling the jam and still holding to secret transmissions is to use a plate, called a key plate, which distorts the frequency of the wave, as patterned on the plate.

A similar key plate is used at the receiving end and cancels the distortion pattern.

Should the enemy discover the pattern of the plate being used, a different plate may be used.

What prevents the enemy from jamming the desired signal is that he would have to vary his signal in exactly the same manner.

Thus he would be kept pretty busy trying to trace the pattern, and even if he found it, he would soon find a new one on his hands to contend with.
REPLACEMENT STOCKS AMPLE

ALTHOUGH much has been said about shortages of replacement parts—tubes, volume controls, condensers, etc., it seems that this is not always so.

The explanation seems to be that one replacement or dealer has run out of certain items and has not reordered (owing to priority difficulties of course), while another's stock is not depleted, or has been kept up, and certain common parts are available.

Also, through the WPB, there has come into the picture, what is called the "victory" list of parts for home radios, which is a big step toward simplification and standardization.

We are all familiar with the long list of volume controls for every type of set, running into thousands. On the victory list, it will be about 50 types. Likewise some 400 various types of condensers will be reduced to a list of about 11, for replacement purposes.

Transformers and chokes also, some 200 varieties, will be represented by 24 replacement types.

Altogether this is a wholesome picture and very encouraging, for it will mean easier replacing, fewer parts (that are better and cheaper than so many that are typical for each manufacturer and therefore a little more expensive), and less worry about getting exact components.

GROUNDED PILOTS

THE photos show (left) Miss Ruby Becker logging a flight traffic check and test of a Bell Aircraft Airacobra, while (right) foreman Harold Brundige gives a "quality check" to another Cobra in flight.

Many of these tests are handled by Miss Becker, who decided that this kind of work is more fun than teaching. She possesses a restricted radio telephone operator's license. For three years she trained for a teaching career, then suddenly decided that radio offers better opportunities. Shortly after she took a course in the Fundamentals of Radio Technology. Upon completing the course she passed the Federal Communications Commission tests and was prepared for her present job. The Bell Radio control room, besides maintaining ground-to-plane contacts is used to test every radio in every Cobra.
1-TUBE INTERPHONE ON A.C.-D.C.

(Continued from page 217)

part which is mounted there.

Before the main, mounted, flaps are bent down in order to form the chassis. The small front panel on which the switches are mounted is fastened to the main chassis with two screws.

The 3-in. P.M. dynamic speaker is mounted on the chassis by 2 small angle brackets.

In wiring the unit there are no special precautions except to note as already mentioned that the "B"-minus return does not ground directly to the chassis.

The cabinet is shown in Fig. 5. The dimensions shown are for the inside of the box. The front panel should be 3/4-in. thick, and the sides may be any thickness desired.

The speaker hole may be the simple circular type shown; or the grill type.

After the readers have reversed the line plug while one station is transmitting to the other. The best position as to minimum hum should be noted and maintained.

If the units have been wired up correctly there is almost no chance of trouble.

LIST OF PARTS
One Sylvania type 12AT tube, V (see text re 28ATC).
One Sprague dual electrolytic condenser, 8 mf.
200 V., C1.
One Sprague electrolytic condenser, 100 mf., 25 V., C2.
One Cornell-Dubilier paper condenser, 30 mf., 200 V., C3.
One Stancor input transformer, 4 ohms to grid, T1.
One Stanton universal output transformer, type A-2556, T2.
One 3-in. permanent-magnet speaker, P.M.
One "12AT9" type socket, S1.
One Centralab D.P.D.T. switch, Sw.1.
One Centralab S. P. 8-T. switch, Sw.2.
One I.R.C. resistor, 2,000 ohms, 1 W., R1.
One I.R.C. resistor, 1,000 ohms, 1/2 W., R2.
One resistor, 560 ohms, R3.
One 5-prong plug, P1, P2.
One chassis.
One cabinet.

Additional Parts for Multi-Station Type
One Centralab 7-point switch, Sw.3.
One octal socket, S3.
One octal plug, P.A. to P.G.
8-wire rubber-covered cable.

CORRECTIONS

In the "Simple 2½ Meter Transceiver" appearing on page 754 of the August-September issue the tube marked 558 must be a 928.

In the Economy A.C.-D.C. schematic shown on page 118 of the November issue one of our readers points out that resistors are never measured in microfarads. Therefore he claims the cathode resistor of the first tube should be 300 ohms.

In the article "Square-Wave Measurements and Their Future," page 156, December issue, the choke L1 in the 1852 cathode circuit should be omitted; and choking L3 and L4 in the 6F6 and 6C6 cathode circuits should each have a value of 150 to 500 microhenries, instead of a large value.

USE THE TUBE MANUAL

(Continued from page 230)

ments or following a diagram, etc.

Then if a man really wants to "dig-in," he will find the circuit diagrams showing some commercial applications of all the tubes, and a handy list of resistor and condenser values to use with tubes in resistance-coupled amplifiers.

LAWRENCE SLIDE RULES

With A, B, C, D, CI and K Scales

FEATURES: Nickel Silver Framed indicator with linear friction springs.
Scales calibrated directly on well seasoned wood.
Will retain accuracy regardless of temperature or humidity changes.
Instructive Illustrations and 3-hole punched pages clearly printed on back of rule for ready reference or teaching.
Each rule in a durable plastic case for protection. High-grade native.

The extremely low price of these slide rules and their absolute accuracy makes them ideal for the student as well as the working man who has always wanted to learn to use a slide rule.

LAWRENCE: 15 inch white-burnished type rule, 6 inch master. In black case. Price, including 30-cent literature book, $1.00.

38-page illustrated book of instructions, pocket size. No. 419, 5c.

RADIO-CRAFT for JANUARY, 1943

256 Printed in the U.S.A.
Thousands of Hallicrafters Sky Buddies gave faithful service... years of excellent performance! Sky Buddy owners will be amazed at how far-reaching the progress of research and new electronic development has been, even in the past year.

When Hallicrafters are again permitted to sell communications receivers for civilian use your new Sky Buddy will have so many improvements, comparison with the old models will be a difficult accomplishment.

Illustration (top) partial view of Hallicrafters Signal Corps communications equipment.
