You can sell MORE RCA Batteries because...

RCA BATTERIES give you a clear selling field—they're distributed primarily to the radio trade!

You have less competition from non-radio neighborhood stores. Sell RCA Batteries and repeat sales stay with YOU!

RCA Batteries are radio-engineered for extra listening hours. The completely rounded line covers virtually all renewal requirements.

Closely co-ordinated production meets seasonal demand, assures fresh stock always.

RCA provides the greatest array of battery selling aids in the industry—all geared to the radio trade.

Smart packaging, competitive prices and "the greatest name in radio" are compelling reasons why RCA Batteries are your best buy by far.

See your RCA Battery Distributor for fast, reliable service.
I'LL TRAIN YOU FOR YOUR FCC LICENSE

A Federal Communications Commission Commercial Operator’s License puts you in line for a good job in Radio or Television Broadcasting, Police, Marine, Aviation, Two-way, Mobile or Micro-wave Relay Radio. Mail coupon below for book and catalog (both FREE) about my NEW Communications course.

YOU BUILD THIS TRANSMITTER with parts I send. This low-power broadcasting transmitter shows you how to put a station “on the air.” You perform procedures demanded of Broadcast Station Operators, conduct many experiments, make many practical tests.

LEARN COMMUNICATIONS by PRACTICING at Home in Spare Time with MANY KITS of MODERN EQUIPMENT I SEND

Ever think HOW FAST Radio-Television Communications is changing, developing, growing? Have you considered what this amazing progress can mean to you?

In 1945, there were 943 Broadcast Stations. Today 2,694 are on the air! Result: THOUSANDS OF QUALIFIED MEN STEPPED INTO GOOD JOBS. Only 19 Television Stations were on the air in 1947. Today there are more than 50 and experts say there will be 150 in a few months, 1,000 within three years. That means thousands of well-paid jobs for trained Operators and Technicians. Then add development of FM, Two-way Radio, Police, Marine, Aviation and Micro-wave Relay Radio! Think what all this means! New jobs, more jobs for beginners! Better jobs, better pay for experienced men!

Are you a beginner who wants steady work in a growing field? My NEW course can help you get an FCC License and prepare for the job you want. Are you a man with some training in Radio or Radar, or a Licensed Operator? My NEW course modernizes, increases the value of your knowledge and experience!

Mail coupon now for facts about my NEW, intensely practical course in Radio-Television Communications. Let me send you FREE books. Read outlines of 78 lesson texts written for you by leading Communications experts, edited by my practical staff. See the nine big Kits of Parts I send that “bring to life” theory you learn. Read about the transmitter you build and operate, about the Electronic Multi-tester you get. All equipment yours to keep. My BRAND NEW course includes BOTH Theory and Practical Experience, with result-getting kits, in Radio-Television Communications. It’s backed by N. R. I.—the world’s oldest and largest home study Radio school.

Mail Coupon For Book FREE

Send today! See what my NEW course is like. Find out how I get you ready for a brighter future, better earnings, more security in Radio-Television. Send coupon now in envelope or paste on penny postal. NO OBLIGATION. NO SALESMAN WILL CALL! My books, sent to you FREE, tell the full story. J. E. SMITH, President, Dept. ON THE COVER: Technician John Flood checks the radio end of the installation described on page 38. Kodachrome by Averey Stack.

A SENSATIONAL NEW BOOSTER FEATURING A TURRET TUNER

The turret tuner is recognized as the most efficient television input tuning device yet designed because of (1) its exceptionally high gain and (2) its uniform bandwidth on all channels. It is used in today’s finest television receivers. Now, for the first time, National makes available all the advantages of a turret tuner in a truly sensational-performing new television booster.

COMPARE THESE FEATURES:

(1) Turret tuner with an individually tuned set of coils for each channel. (2) Removable polystyrene roll-mounting contact panels. (3) A single 6AKS for maximum usable gain. (4) A built-in power transformer (not AC-DC—no "hot" chassis). (5) Selenium rectifier for long life. (6) Channel selector and fine tuning in a single, easy-to-operate, dual-purpose control. (7) Pilot light illuminates selected channel.

MODEL TVB-2

$39.95

tist price

P.S. No other booster has a turret tuner!

Experiments with audio oscillators
Advanced trouble-shooting
... and many, many others

Complete Training by Practical Resident Trade School, Est. 1905

The same highly trained faculty, instruction materials and methods used here in our large, modern resident school, are adapted to your training in your own home. Shop Method Home Training has been proved by hundreds of successful graduates.

Both Resident and Home Study Courses Offered

YOU LEARN BY DOING

You receive special laboratory experiment lessons to show you how to build with your own hands various experimental units such as those shown at left, and how to conduct many tests.

You will find all lessons easy to understand because they are illustrated throughout with clear diagrams and step-by-step examples that you work out yourself. Every piece of the equipment and complete lesson material we send you is yours to keep and enjoy, including the multitester, experimental equipment, all parts of the Superheterodyne, tube manual, radio dictionary, and complete, modern Television texts. All parts are standard equipment.

Shop Method Home Training...

Earn While You Learn

With our practical resident Shop Method Home Training, you study in your spare time. You receive Spare Time Work Lessons, which show you how to earn while you learn. Service neighbors' radios and TV receivers, appliances, etc., for extra summer and year round experience. Many National students pay all or part of their training with spare time earnings!

DON'T DELAY! The Radio-Television Industry needs trained men NOW!

Now...a quality line of replacement speakers from one dependable source

Quality-engineered for dependable performance...and priced for replacement needs...the RCA line of standard speakers offers you a great selling potential.

From the superb 15" high-fidelity duo-cone to the 2" x 3" elliptical—each RCA speaker is designed with top engineering skill, made of the best materials, and mass-produced under rigid quality-control methods.

RCA's PM and field-coil types meet practically all replacement requirements. All 4", 4" x 6", and 5" speakers are supplied with a universal mounting bracket that saves time in mounting either clinch-type or strap-type output transformers.

Look to RCA—and your RCA distributor—as a dependable source for all of your replacement speaker requirements. For full details on the complete line, ask your RCA distributor for Bulletins 2F892 and 3F620.

Check these important features!

- Moisture-resistant voice-coil suspension—unaffected by humidity changes.
- Rugged mechanical construction with welded housing assembly.
- Exclusive clamping spring permanently locks Alnico V magnet in larger sizes of PM speakers.
- Mechanical filter ring in 12" speakers cuts needle scratch and 10-kc. whistle.
- Rugged—Dustproof resistant—Rustproof resistant.
- Adjustable voice-coil mounting in 12" speakers.
- Rim mounting designed to RMA standards.
If your answer is YES to most of these questions, CREI'S Home Study Course can help you get a BETTER JOB in Television

WHAT YOU DO to keep yourself abreast of new developments is what counts toward advancement in television. Obviously, everyone cannot qualify. Those who do are well rewarded. The television industry offers almost unlimited opportunity to trained engineers and technicians. CREI training helps all levels, from novice to experienced engineer, because its specialized individual instruction brings out the best in a man and takes him as far as his own aptitude and effort will let him go.

CREI is an accredited technical institute founded in 1927. Its home study graduates fill important jobs throughout the radio, television and electronics industries. Leading industrial firms—RCA Victor, Pan American Airways, United Air Lines, to name only a few—have CREI group training programs now in opera-
COLOR TELEVISION fully compatible with black-and-white standards was demonstrated by the Radio Corporation of America in Washington February 8. The color registry, or "color phasing," was controlled by a special development which prevents the "color drifting" that caused objects to change color gradually in earlier tests.

As explained by Dr. E. W. Engstrom, who conducted the tests, registry of the color dots is controlled by a pulse sent at the end of each line. Thus all colors start each line in perfect registry.

While the tests were conducted with standard RCA 3-tube experimental receivers roughly similar to those described in the January Radio-Electronics, Dr. Engstrom announced that RCA intended shortly to submit to the FCC for test a color receiver with only one cathode-ray tube to reproduce the three primary colors. This type of tube, he suggested, would probably be a prototype of those which will actually be used in future commercial color receivers, when such become feasible.

TAPE RECORDING standards are being submitted to the National Association of Broadcasters Board for approval. New proposals will include a recommended standard hub and flange for use with magnetic tape reels as well as a standard of fidelity and quality which will enable broadcasters to interchange reels and establish central tape libraries.

13,000 POLICE CARS have yet to be licensed for radio communications in this country according to a report made by the Marketing Services Division of the General Electric Company. The majority of these cars will be licensed within three years if the present growth of radio communications continues at the same rate.

Five thousand police radio licenses have been granted in the United States and the total number of licensed vehicles for two-way radio police radio now approximates 40,000. Currently eleven state police organizations are licensed to use over 300 mobile units in their respective systems.

SUBMARINE DETECTORS and other sound and ultrasonic equipment will be using barium titanate, a war-developed material with exceptional electrical behavior, instead of older types of crystals. This unusual compound shows a remarkably quick response to the slightest changes in pressure, temperature, or electric field. Even light shining on it will cause the molecules to rearrange themselves.

DIAL TELEPHONES for small cities will be made possible with a new electric brain developed by Bell Telephone Laboratories engineers. The new equipment lends itself to mass production methods, is easily maintained, and is more nearly self-checking than any previous dial system. Initial installations are now being made, and the equipment will be integrated with the nationwide communications network.

300,000 TRANSmitters are covered in non-broadcast authorizations by the FCC. Of these, nearly one-third are fixed stations, and the rest are portable or mobile units.

Most of these—over 250,000—are in the Safety and Special Services, which has some 94,000 land or fixed stations a'd 196,600 portable or mobile units. The common carrier services have nearly 26,000 transmitters of which 2,200 are fixed and 23,600 portable.

UPPER ATMOSPHERE showers large amounts of radio noise on us from all directions. These bursts of noise can be picked up by a sensitive radio receiver as increased background noise. This discovery was disclosed last month by Herman V. Cotton of the National Bureau of Standards.

This phenomenon was found when a solar radiometer, an instrument to measure the amount of radiation from the sun, was directed toward different parts of the sky on Nov. 23. On that day radio noise had increased to about six times normal, but the solar radiometer, when pointed toward the sun, showed no unusual disturbances. Dr. Cotton concludes that the exceptionally large amounts of radio noise are coming from somewhere in the outer atmosphere of the earth.

CHEESE can now be pasteurized by r.f. heating as a result of recent experiments conducted by scientists at Cornell University. The delicious cheddar flavor is best obtained by aging cheese made from raw milk, and it is much easier to pasteurize ten pounds of cheese than the 130 pounds of milk from which it is made.

The experimenters had hoped to be able to treat old cheese with this process, but so far, the radio frequencies pasteurize only very young raw milk cheese. The cheese is placed between two electrodes which carry a high-frequency current. The temperature goes up to 132° F. in about two minutes. This pasteurizes the cheese, yet leaves enough enzymes and bacteria to develop flavor.

Get Set for LAND OFFICE BUSINESS on the Astatic TELEVISION BOOSTER Soon to be Advertised Nationally on TELEVISION

OWNERS OF TV RECEIVERS, and their friends, the nation over, will soon see the Astatic Television Booster in operation ... and hear its exclusive advantages explained ... from their favorite TV stations. It doesn't take a crystal ball to forecast the impact of TV advertising on sales of Astatic Boosters. When set owners in your area actually see weak, washed-out pictures on a TV screen changed to bright, clear action by the Astatic Booster, the skyrocketing of sales will be automatic. They'll be asking — by the thousands — for the "four-tube booster" with "variable gain control," "dual-tuning," "handsome furniture-finish mahogany cabinet," and other exclusive features they've seen and heard about ON TELEVISION. They'll ask by name for the Astatic Booster.

If there is anything you don't know about the Astatic Booster, write for specifications and complete details. Get behind this surefire program to help you sell. Check your stock. Order TODAY for your needs.

Astatic Crystal Devices manufactured under Brush Development Co. patents

RADIO-ELECTRONICS
ROBERT D. HICKOK, president and founder of The Hickok Electrical Instrument Company, died January 23 at the age of 70. Since founding his company in 1910, Mr. Hickok had been actively interested in it and had supervised the development of many instruments used by electrical manufacturers and radio technicians. Some of his best known instruments are: an astatic uniform scale wattmeter, an expanded scale photoelectric exposure meter movement, and the original dynamic mutual conductance tube tester (known to technicians as the AC-47).

Mr. Hickok was an active RMA member and Fellow of the American Institute of Electrical Engineers.

KARL GUTHE JANSKY, radio research engineer known for his discovery of radio waves from interstellar space, died on February 14 at Red Bank, N. J.

An expert on radio transmission and on atmospheres and other types of radio interference, Mr. Jansky is credited with several basic discoveries and was recently awarded an Army-Navy Certificate of Appreciation for his work during World War II. He joined the Bell Laboratories in 1928 and concentrated on his research on shortwave radio-telephone transmission. He guided the development of special recorders and directional antennas with which he discovered interstellar radio waves in 1933.

RADIO PROPAGATION will be studied by the National Bureau of Standards at a new site near Boulder, Colorado. Laboratory facilities costing about $4,000,000 will be constructed on the 210-acre site during the summer of 1951. A research staff of about 300 people will be employed there.

This location was chosen because the Bureau's work is best carried out near a small town or city which is not congested by electrical and radio facilities. The site is near a major university which is expected to provide a source for competent new personnel and an opportunity for graduate training of junior staff members.

Mr. Gernsback receives Marconi Award. Pres. Wm. J. McGonigle is on the right.

MARCONI MEMORIAL Wireless Pioneer's Medal was awarded to Hugo Gernsback by the Veteran Wireless Operators Association at its annual Dinner Cruise held in New York February 25.

The award was made to the veteran technical publisher for "pioneering achievements in the radio art." It was recalled that Gernsback was the pioneer radio manufacturer as well as publisher of this country, having sold the first radio set to the public (a portable spark transmitter and receiver) in 1906. His Electro Importing Co. was during that period and later the Mecca of the radio experimenter. It manufactured The Pioneer's Medal.

and sold numerous radio parts (many of them invented by Gernsback himself) absolutely unobtainable elsewhere.

He published the country's first radio magazine, Modern Electrics, in 1908, and has continued as a publisher of radio magazines and books ever since that date. Gernsback was also one of the first to promote radio associations in 1909, and fostered the early amateur radio movement both personally and through his publications, parts of one of his editorials having been incorporated in the first law passed to regulate radio, which was enacted in 1912.

TV INSURANCE, covering service renewal contracts, is becoming a "necessary evil," in New York, according to several contractors and dealers. More and more customers are demanding insurance coverage of their second year service contracts, but dealers and contractors are not certain that they will gain by having coverage by a surety company.

Retailers and service firms seem to be confused as to whether the New York State Insurance provision is a law or merely the opinion of an Attorney General.

The New York State Insurance Department has announced that TV service contracts are definitely insurance contracts and that present rulings have had the status of law for some months.
RCA Engineering Products Department, Sound Equipment Section, has announced a newly engineered revenue-producing radio and sound distribution system for hospitals.

The new hospital equipment, designed to entertain patients in hospitals of 50 to 500 beds, consists of a basic four-channel AM-FM central station installation and special hospital reproducer equipment which requires no operating personnel.

There are several methods of distributing both radio and recorded music programs in the various hospital locations. Beds may be equipped with pillow speaker and plug selector switch assembly, allowing the patient to select his own program without disturbing others in the room or ward. Individual monoset earphone equipment provides the same individual reception for patients who are able to sit up or be out of bed, or wall speakers may be provided as reproducer equipment.

Sylvania Electric Products, Inc., radio division, is continuing to promote radio and television service technicians during 1950 in a new series of national ads in the Saturday Evening Post, Life, Look, Collier's, and Radio & Television Best, starting in January. The new campaign increases the size of previous Sylvania ads about repairmen from one-quarter to one-half page in black and white.

Sylvania is supplementing the ads with a cooperative campaign kit for technicians and dealers which includes four-color window posters based on the monthly ad, two-color streamers, three-color postal cards, free mats for local newspaper advertising, and radio spot announcements.

Emisoras Associadas, Brazil's largest radio network, plans to introduce television at the fast-growing business center of Sao Paulo. All equipment will be supplied by the Radio Corporation of America, it was announced by Meade Brunet, a vice president of RCA and managing director of the RCA International Division. The station is expected to be on the air in the summer of 1950.

Arrangements for the installation of the television transmitter, as well as associated studio and mobile pickup equipment, were begun in 1948 and concluded during the recent visit to the United States by Dr. Assis Chateaubriand, Director General of the Brazilian network, according to Mr. Brunet. He said the transmitter and antenna will be located atop Sao Paulo's highest edifice, the State Bank Building.

Erie Resistor Corp., Electronics Division, has created a Research and Development Department for the investigation of new principles, methods, and materials which may be applied to new and existing products. The department will be headed by J. D. Heibel as Director of Research and Development. Heibel has been with Erie Resistor for 13 years as chief electrical engineer, and has pioneered many engineering developments.

J. C. Van Arsdel, Electrical Engineer, has been promoted to the position of Manager of the Sales Engineering Department. He will work with the sales department in the proper interpretation of customers' specifications, as well as in the development of new products and of new applications for existing products.

General Electric, Syracuse, N. Y., has installed a two-way radio system to prevent the spread of forest fires in the area of Bar Harbor and Mt. Desert Island, Maine.

The residents of those areas, who suffered hundreds of thousands of dollars in damage in the great forest fires of 1947, purchased 10 mobile radio units and two remote control units from the General Electric Company in an effort to combat this ever-present threat of fire.

The ten G-E units are installed in such vehicles as the jeep patrol, which makes routine checks on forest fires, in the fire chief's car, in two pumping engines and in the county medical examiner's car.

Included in the two-way radio hook-up are Bar Harbor, Town Hill, South-west Harbor and Somesville. South-west Harbor also has ordered two G-E walkie-talkie radio sets to use with the mobile unit.

The American Gage & Machine Co. has announced its merger with the Simpson Electric Co. of Chicago, manufacturers of electrical and radio meters and test equipment.

Ray Simpson, founder of the Jewell Electrical Instrument Co., Simpson Optical Co., and the present Simpson Electric Co., will remain as chairman of the Simpson Electric Division. Herbert Bernreuter, meter and test equipment engineer, has been elected a vice president of the American Gage & Machine Co., and will act as operating head of the Simpson Division, with which he has been identified since its inception.

The Sightmaster Corp., New York, has announced the issuance of patent no. 2,492,524, covering its newly developed Sightmirror.

With the issuance of this patent, Sightmaster, according to Michael L. Kaplan, president, plans to make Sightmirror available for public use for any television receiver now in existence. Sightmirror, which serves as a filter to eliminate glare and the possibility of eyestrain and to soften the picture, is a decorative mirror when the set is turned off.

General Electric Company, Syracuse, N. Y., announces that the latest in G-E television transmitting equipment and techniques for alignment of television receivers will be demonstrated by R. H. Rudolph, G-E sales manager for equipment, in a tour of cities in the South and West.

The new G-E equipment, includes a five-inch oscilloscope, a marker generator and a sweep generator with a new balanced output adaptor.

The twelve cities Rudolph will visit are Oklahoma City, Tulsa, New Orleans, Houston, San Antonio, Fort Worth, Dallas, Albuquerque, Salt Lake City, Los Angeles, San Francisco and Seattle.

Radio Manufacturers Association reported that sales of communications equipment, radar and other radio transmitting apparatus to the U. S. Government during the third quarter of 1949 totalled $35,000,000. Sales of radar equipment amounted to $24,350,287 and government radio transmitting equipment purchases. Third quarter government purchases were slightly under the second quarter total of $40,140,586.

Sales of communications transmitters, receivers and transceivers during the third quarter totalled $4,752,306, and laboratory and test equipment purchases by the government amounted to $3,563,910. RMA member-company sales of radio navigational aids to the government accounted for another $2,620,816 and sonar apparatus sales for $595,037, while quartz crystals sales totalled $43,188.

Build and Keep 10, 12½ or 16 inch Picture Tube Quality TELEVISION RECEIVER as you prepare for a Profitable Future

Here is everything you need to prepare you at home for FASCINATING WORK, GOOD MONEY and a THRILLING FUTURE in one of America's most promising fields.

This includes the opportunity to build and keep the top quality Television Receiver shown above—with choice of a 10, 12½ or 16 inch picture tube that gives big, bright, sharp, steady pictures. Get the complete facts. This is an optional feature — available when you complete your training described below. See how D.T.I.'s wonderfully practical "BIG 5" method meets industry's needs. No previous experience needed. Mail coupon today!

16 Big Shipments of Parts — Plus Lessons

Work over 300 electronic experiments and projects from 16 big shipments of parts. This includes building and keeping all test equipment and radio set shown at left side of page. Modern easy-to-read lessons with handy fold-out diagrams simplifies your entire training.

You Also Use Home Movies

D.T.I., alone, includes the modern, visual training aid . . . MOVIES to help you learn faster, easier at home. See electrons on the march and other fascinating "hidden action"—a remarkable home training advantage that speeds your progress.

EMPLOYMENT SERVICE

When you complete your training, our effective Employment Service helps you get started toward a real future in Television-Radio-Electronics.

Modern Laboratories

If you prefer, you can get ALL your preparation in our new, Chicago training laboratories . . . one of the finest of its kind. Ample Instructors . . . modern equipment. Write for details!

APRIL, 1950
NEW 1950 Heathkit

Have all the Features

New 1950 Heathkit
Push-pull extended range
5" Oscilloscope Kit

Features
- The first truly television oscilloscope.
- Tremendous sensitivity .06 Volt RMS per inch deflection.
- Push-pull vertical and horizontal amplifiers.
- Useful frequency range to 2 1/2 Megacycles.
- Extended sweep range 15 cycles to 70,000 cycles.
- New television type multivibrator sweep generator.
- New magnetic alloy shield included.
- Still the amazing price of $39.50.

The new 1950 Push-Pull 5" Oscilloscope has features that seem impossible in a $39.50 oscilloscope. Think of it—push-pull vertical and horizontal amplifiers with tremendous sensitivity only six one hundredths of a volt required for full inch of deflection. The weak impulses of television can be boosted to full size on the five inch screen. Traces you couldn’t see before. Amazing frequency range clear useful response at 2 1/2 Megacycles made possible by improved push-pull amplifiers. Only Heathkit Oscilloscopes have the frequency range required for television.

New type multivibrator sweep generator with more than twice the frequency range. 15 cycles to 70,000 cycles will actually synchronize with 250,000 cycle signal. Dual positioning controls will move trace over any section of the screen for observation of any part. New magnetic alloy CR tube shield protects the instrument from outside fields. All the same high quality parts, cored electromagnetically shielded power transformers, aluminum cabinet, all tubes and parts. New instruction manual now has complete step by step pictorials for easiest assembly. Shipping weight 30 lbs. Order now for this winter’s use.

Conversion for Other Model Heathkit Oscilloscopes
A conversion for all 03 and 04 scopes is available changing them to the new push-pull amplifiers (does not change the sweep generator). Complete kit includes new chassis, tubes and all parts. For a small investment, add the latest improvements to your present oscilloscope (Except C.R. Tube Shield). Shipping weight 10 lbs.

Order 03 Conversion Kit No. 315
$12.50

The New Heathkit
HandiTester Kit
More Features Than Ever Before
- Beautiful streamlined Bakelite case.
- AC and DC ranges to 3,000 Volts.
- 1 1/2" Precision ceramic resistors.
- Convenient thumb type adjust control.
- 400 Microampere meter movement.
- Quality Bradley AC rectifier.
- Multiplying type ohms ranges.
- All the convenient ranges 10-30-300-1,000-5,000 Volts.
- Large quality 3" bulb meter.

The instrument for all—the ranges you need—beauty you’ll enjoy for years and you can assemble it in a matter of minutes—an instrument for everyone. The handiest quality voltmeter of all. Small enough to put in your pocket yet a full 3" meter. Easy pictorial wiring diagrams eliminate all assembly problems. Uses only 1 1/2" precision ceramic divider resistors and wire wound shunts. Twelve different ranges. AC and DC ranges of 10-30-300-1,000-5,000 Volts. Ohms ranges of 0-5,000 ohms and 0-300,000 ohms. Milliamperes ranges of 10MA and 100MA. Hearing aid type ohms adjust control fits conveniently under thumb for one hand adjustment. Banana type jacks for positive low resistance connections. Quality test leads included. The high quality Bradley instrument rectifier was especially chosen for linear scales on AC. The modern case was styled by Harrah Engineering for this instrument. The 400 microampere meter movement comes already mounted in the case protected from dust during assembly. An ideal classroom assembly instrument useful for a lifetime. Perfect for radio service calls, electricians, garage mechanics, students, amateurs and beginners in radio. The only quality voltmeter under $20.00. An hour of assembly saves you one-half the cost and quality parts give you a better instrument. Order today. Shipping weight 2 lbs.

$13.50

Note Handy Ohms Adjust.

The Heath Company
Benton Harbor 20, Michigan

Radio-Electronics for
The NEW V-4 Heathkit

VACUUM TUBE VOLTMETER KIT

**Features**
- Meter scale 17½% longer than average 4½" meter.
- Modern streamline styling.
- Burn-out proof meter circuit.
- 24 Complete ranges.
- Isolated probe for dynamic testing.
- Most beautiful VTVM in America.

The new Heathkit Model V-4 Vacuum Tube Voltmeter has dozens of improvements. A new modern streamlined 200 microampere meter has Alnico V magnets for fast, accurate readings. The new electronic AC voltmeter circuit incorporates an entire new balance control which eliminates contact potential and provides greater accuracy. New simplified switches for quicker assembly. New snap-in battery mounting is on the chassis for easy replacement.

The Heathkit VTVM is the only kit giving all the ranges. Check them—DC and AC full scale linear ranges of 0-1V, 0-10V, 0-50V, 0-100V, 0-200V, 0-1000V and can be extended to 0-3000V and 0-10,000V DC with accessory probe at slight extra cost. Electronic chinneter has six ranges measuring resistance accurately from .1 ohm to one billion ohms. Pointer readout is offset to zero center for FM alignment.

The DC probe is isolated for dynamic measurements. Has db scale for making gain and other audio measurements.

Order now and enjoy it this entire season. Shipping weight 8 lbs., Model V-4.

Accessory: 10,000V high voltage probe, No. 310, $4.50.
Accessory: RF crystal diode probe kit extends RF range to 100 Mc., No. 309, $6.50.

$24.50

New 1950 VERNIER TUNING R.F. Heathkit

SIGNAL GENERATOR KIT

**Features**
- New 5 to 1 ratio vernier tuning for ease and accuracy.
- New external modulation switch—uses it for fidelity testing.
- New precision coils for greater output.
- Cathode follower output for greatest stability.
- 400 cycle audio available for audio testing.
- Most modern type R.F. oscillator.
- Covers 150Kc. to 34Mc. fundamentals and calibrated strong harmonics to 103 Mc.

The most popular signal generator kit has been vastly improved—the experience of thousands combined to give you the best. Check the features in this fine generator and consider the low price $19.50. A best buy for any shop, yet inexpensive enough for hobbyists. Everyone can have an accurate controlled source of R.F. signal voltage.

The new features double the value—think of being able to make fidelity checks on receivers by inserting a variable audio signal. Internal 400 cycle saw-tooth audio oscillator modulates R.F. signal and is available externally for audio testing. The new 5 to 1 ratio vernier drive gives hairline tuning for maximum accuracy in scale settings. The coils are already precision wound and calibrated. Uses turret type coil and switch assembly for ease of construction. The generator is 110 V. 60 cycle transformer operated and comes complete in every detail—cabinet, tubes, coils, beautiful two color calibrated panel and all small parts—new step-by-step pictorial diagrams and complete instruction manual make assembly a cinch even for novices. Why try to get along without a signal generator when you can have the best for less than a twenty dollar bill. Better order it now. Shipping weight 7 lbs. $19.50

CONVERSION KIT FOR G-1 GENERATOR

Conversion kit for G-1 generators for vernier tuning and external modulation includes new high band coil for greater output. Gives all the features of new G-5 listed above. Order G-5 Conversion Kit No. 316 for $4.50

New Heathkit

IMPEDEANCE BRIDGE KIT

A LABORATORY INSTRUMENT NOW WITHIN THE PRICE RANGE OF ALL

Measures Inductance from 10 microhenries to 100 henries capacitance from .0001 MFD to 1000 MFD. Resistance from .01 ohms to 10 megohms. Dissipation factor from .001 to 1. "Q" from 1 to 1000.

Ideal for schools, laboratories, service shops, serious experimentors.

An impedance bridge for everyone — the most useful instrument of all, which heretofore has been out of the price range of serious experimentors and service shops. Now at the lowest price possible. All highest quality parts. General Radio main calibrated control. General Radio 1000 cycle hummer. Mallory ceramic switches with 60 degree indexing — 200 micro-amp zero center galvanometer — 1/2 of 1% ceramic non-inductive decade resistors. Professional type binding posts with standard 3/4" centers. Beautiful birch cabinet. Directly calibrated "Q" and dissipation factor scales. Ready calibrated capacity and inductance standards of Silver Mica, accurate to 1/2 of 1% and wired with every part — cabinet — calibrated panel — in one million. Provisions on panel for external generator and detector. Measure all you unknowns the way laboratories do — with a bridge for accuracy and speed.

All on a workbench, calibrated panel, trusted transformer, calibrated sweep. Husky 110V, 60 cycle transformer, large grey crackle condenser when you can read direct from the panel. NO CHARTS OR MULTIPLIERS NECESSARY. A condenser checker anyone can read without a college education. A leakage test and polarizing voltage for 20 to 500 volts provided. Measures power factor of electrolytics between 0% and 99%. 110V, 60 cycle transformer operated complete with rectifier and magic eye tubes, cabinet, calibrated panel, test leads and all other parts. Clear detailed instructions for assembly and use. Why guess at the quality and capacity of a condenser when you can know for less than a twenty dollar bill. Shipping weight, 7 lbs. Model C-2.

RADIO-ELECTRONICS for
all in HEATHKITS...

**Heathkit TUBE CHECKER KIT**

**Features**
1. Measures each element individually
2. Has gear driven roller chart
3. Has lever switching for speed
4. Complete range of filament voltages
5. Checks every tube element
6. Uses latest type lever switches
7. Uses beautiful shutterproof full view meter
8. Large size 11" x 14" x 4" complete
9. Checks new 9 pin pinatures

Check the features and you will realize that this Heathkit has all the features you want. Speed — simplicity — beauty — protection against obsolescence. The most modern type of tester — measures each element — beautiful Bad-Goos scale, high quality meter — the best of parts — rugged oversized 110V. 60 cycle power transformer — finest of Mallory switches — Centralab controls — quality wood cabinet — complete set of sockets for all type tubes including blank spare for future types — fast action geared driven roller chart uses brass gears to quickly locate and set up a type tube. Simplified switching cuts unnecessary time to minimum and saves valuable service time. Short and open element check. No matter what arrangement of tube elements, the Heathkit flexible switching arrangement easily handles it. Order your Heathkit Tube Checker today. See for yourself that Heath again saves you $5 and yet retains all the quality — this tube checker will pay for itself in a few weeks — better build it now.

Complete with detail instructions — all parts — cabinet — roller chart — ready to wire up and operate. Shipping Wt., 15 lbs.

**Heathkit SINE AND SQUARE WAVE AUDIO GENERATOR KIT**

Nothing ELSE TO BUY

$34.50

Experimenters and servicemen working with a square wave for the first time invariably wonder why it was not introduced before. The characteristics of an amplifier can be determined in seconds compared to several hours of tedious plotting using older methods. Stage by stage, amplifier testing is as easy as signal tracing.

The low distortion (less than 1%) and linear output (± one db) make this Heathkit equal or superior to factory built equipment selling for three or four times its price. The circuit is the popular RCL-swing circuit using a four stage variable condenser. Three ranges 20-200, 200-2,000, 2,000-20,000 cycles are provided by selector switch. Either sine or square waves instantly available at time switch. All components are of highest grade, cased 110V. 60 cycle power transformer, Mallory F.F. filter condensers, 3 tubes, calibrated 2 color panel, grey crankle aluminum cabinet. The detailed instructions make assembly an interesting and instructive few hours. Shipping Wt., 18 lbs.

---

**New Heathkit BATTERY ELIMINATOR KIT**

Nothing ELSE TO BUY

$22.50

Now a bench 6 Volt power supply kit for all auto radio testing. Supplies 5-71/2 Volts at 10 Amperes continuous or 15 Amperes intermittent. A well filtered rugged power supply uses heavy duty selenium rectifier, choke input filter with 4,000 MFD of electrolytic filter. 0-15 Volt meter indicates output. Output variable in eight steps. Excellent for demonstrating auto radios. Ideal for servicing — can be lowered to find sticky vibrators or stepped up to equivalent of generator overload — easily constructed in less than two hours.

Complete in every respect. Shipping Wt., 13 lbs.

---

**NEW Heathkit SIGNAL TRACER AND UNIVERSAL TEST SPEAKER KIT**

Nothing ELSE TO BUY

$19.50

The popular Heathkit signal tracer has now been combined with a universal test speaker at no increase in price. The same high quality tracer follows signal from antenna to speaker —locates intermitents—defective parts quicker—saves valuable service time—gives greater income per service hour. Works equally well on broadcast — FM or TV receivers. The test speaker has assortment of switching ranges to match push pull or single output impedance. Also test microphones, pickups — PA systems — comes complete — cabinet — 110V. 60 cycle power transformer — tubes, test probe, all parts and detailed instructions for assembly and use. Shipping Wt., 8 lbs.

BROADCAST MODEL BR-1
550 to 1600 Kc.

$19.50

Ideal AC operated superheterodyne receiver for home use or replacement in console cabinet. Comes complete with attractive metal panel for cabinet mounting. Modern circuit uses 12K8 converter, 12SK7 input IF stage, 12CR output IF stage and first audio 12AF beam power output stage, 5Y3 rectifier. Excellent sensitivity for distant reception with selectivity which effectively separates adjacent stations. The husky 110 V. cased power transformer is conservatively rated for long life. The illuminated six inch slide rule dial is accurately calibrated for DX reception. Enjoy the pleasure of assembling your own home receiver. Has tone, volume, tuning and phone-radio controls. Chassis size 2 1/4" x 7" x 12 1/2". Comes complete with all parts including quality output transformer to 3.4 ohm voice coil, tubes, instruction manual, etc. (test speaker). Shipping Wt., 10 lbs. No. BR-1 Receiver $19.50.

No. 335 Communications Type Table Model Metal Cabinet $4.50
No. 520 High Quality 5" PM Speaker for above 2.75

3 BAND MODEL AR-1
550 Kc. to 20 Mc.

$23.50

Enjoy the thrill of worldwide short wave reception with this fine new AC operated Heathkit 3 band superheterodyne—amazing sensitivity 15 microvolts or better on all bands. Continuous coverage 550 Kc. to over 20 Mc. Easy to build with complete step-by-step instructions and pictorial diagram. Attractive accurately calibrated six inch slide rule dial for easy tuning. Six tubes with one dual purpose tube gives seven tube performance. Beam power output tube gives over 3 watts output. Separately assembled coil turret with band switch eliminates difficult construction. Conservatively rated 110 V. power transformer supplies full operating voltages to all tubes for maximum reception. Has band switch, tuning, volume, tone and phone-radio controls. Chassis size 2 1/4" x 7" x 12 1/2"—supplied complete—punched chassis—tubes—controls—transformers (quality output to 3.4 ohm voice coil) —all small parts—hardware and instructions (less speaker). Shipping Wt., 10 lbs. No. AR-1 Receiver $23.50. No. 335 Communications Type Table Model Metal Cabinet $4.50. No. 520 High Quality 5" PM Speaker for above 2.75

RADIO-ELECTRONICS for
The GREATEST TELEVISION Buy!

A 18 TUBE Complete TV RECEIVER KIT
W ith 12 CHANNEL TUNER $34.50 less TUBES AND CABINET
Actually LESS THAN COST OF TUNER ALONE

Think of it. A beautiful factory engineered 18 tube television receiver with all parts (less tubes and cabinet) for the cost of the tuner alone, $34.50. Now you can afford to learn the fascinating secret of this new industry by actually assembling a high quality receiver. This TV receiver kit has everything, 12 channel Defiance tuner using 6BH6 RF stage and 6J6 as oscillator and mixer, all assembled and adjusted. Completely assembled 5000 Volt high voltage power supply ready to operate. A circuit incorporating the latest developments. The panel controls are station selector, volume, vertical and horizontal hold and contrast. At the rear are brightness, vertical and horizontal size, focus, vertical and horizontal centering. The circuit uses three stages of high gain I.F. with 6AG5 tubes, 12AU6 limiter, 6AL5 second detector, 12AU6 syn. separator, 12AU6 video amplifier, 12SN7 horizontal multivibrator, 50L6 horizontal output, 12SN7 vertical multivibrator, 12SN7 vertical output, 50L6 high voltage oscillator, 1B3 high voltage rectifier, 19T8 as FM detector and audio amplifier, 25L6 audio output.

The cadmium plated chassis is punched and formed ready to assemble - every coil, condenser, resistor supplied. Comes complete with large (18 x 24) pictorial and manufacturer's instruction manual.

BEAUTIFUL STYLING
This modern beautifully styled TV receiver will bring untold pleasure and entertainment to the entire family. The pleasant appearance compliments any living room while the steadily improving programs will please the entire family. There are excellent vaudeville programs to entertain your friends, excellent children's programs, Arthur Godfrey, United Nations programs for serious thinkers. A television set aids in the education of the family and by building it vast technical knowledge of this new profitable field is obtained.

Remember we have a limited quantity. Order now while still available.

Complete 7" Television Receiver Kit (less tubes and cabinet)..................................................$34.50
Complete set of tubes as outlined above with RCA 7JP4 picture tube (18 tubes for less than price of picture tube) 20.00
Beautiful piano finish mahogany cabinet for above TV set 20.00

Here's why top engineers and technicians use Model 630

Features like those shown above are what make this popular V.O.M. so outstandingly dependable in the field. The enclosed switch, for instance, keeps the silvered contacts *permanently clean*. That's rugged construction that means stronger performance, longer life. And tests show that the spiral spring index control, after more than 150,000 cycles of switch rotation, has no disruption or appreciable wear! Investigate this history-making Volt-Ohm-Mil-Ammeter today: 33 ranges, large 5½" meter.

ONLY $37.50 AT YOUR DISTRIBUTOR
ANOTHER HYTRON FIRST YOU'LL BE BUYING SOON

NEW HYTRON 12 BH7

does more for less

○ Ideal Sweep Amplifier
○ Higher-Perveance Twin Triode
○ Designed for TV
○ Permits Lower-Cost TV Sets
○ Another Hytron TV First

Here's another Hytron original you'll be buying soon. New 12BH7 twin triode is enthusiastically hailed as tops for sweep circuits by leading makers of TV sets. One half 12BH7 sweeps wide-angle 16-inch picture tube at 14 kilovolts. One section alone matches performance of: Paralleled 6SN7GT. Or equivalent single triode. Or triode-connected beam pentode. Other half of 12BH7 is free for other uses—such as blocking oscillator.

How does Hytron do it? Higher perveance (lower tube loss)? Yes. Also the Hytron 12BH7 is designed for TV. Rated for TV. Tested for TV. Again a Hytron TV first. Again a Hytron contribution to lower-cost TV for the mass market. Watch for the 12BH7. Write for Bulletin E-149.

AND NOW THE HYTRON

16TP4 Another Hytron 16-inch rectangular picture tube. Follows closely on heels of original Hytron rectangular tube, the 16RP4. Write for Bulletin E-150 for complete data. Watch also for early announcements of new Hytron 14-inch and 19-inch rectangular tubes.

MODERN LOW-COST 16-IN. DESIGN

A Hytron contribution to lower TV costs. All-Hytron: 1X2, 6BQ6GT, 6U4GT, 12BH7, 16TP4 or 16RP4. For application and circuit details, write for Bulletin E-151.
Throughout history, scouting parties have gone out ahead of man, ahead of settlements, ahead of civilization itself. Today, Bell System scouts are engaged in a new kind of exploration—charting a path for microwaves—using equipment specially designed by Bell Telephone Laboratories.

The portable tower shown is constructed of light sections of aluminum and in a few hours may be built up to 200 feet. Gliding on rollers, the “dish,” with its microwave transmitter or receiver, is quickly positioned for line-of-sight transmission, then oriented through electric motors controlled from the ground.

Test signals show how terrain and local climate can interfere with microwave transmission. Step by step, Bell’s explorers avoid the obstacles and find the best course for radio relay systems which will carry television pictures or hundreds of simultaneous telephone conversations.

A radio relay link similar to the one between New York and Boston will be opened this year between New York and Chicago. Later it will be extended, perhaps into a nation-wide network—another example of the way Bell Telephone Laboratories scientists help make the world’s best telephone system still better each year, and at lowest cost.
Wins 30% more business with SYLVANIA DEALER CAMPAIGN

"Last summer we obtained your coordinated campaign and mailed the postal cards to just certain sections. Then we kept track of service business, and found we received 30% more from the sections which got the cards.

"We're convinced... your campaign is the best-insurance against a summer slump in service business.

"This year, May, June, July, and August are going to be our big profit months."

Gale Radio and Television Lab., New Rochelle, N. Y.

You, too, will cash in BIG with this powerful, new summer campaign

Right now is the time to send for the new, complete advertising campaign that's bound to bring you extra business... all through May, June, July, and August.

Look at all the colorful, sales-making material you get! Everything from large 3-dimensional window- and counter-displays, to complete newspaper ad mats and postal cards. Even radio spot announcements to be broadcast over your local station. It's all yours... and it's all FREE... you pay only the postage on the postal cards, 1¢ for each card.

Written and designed to tie in with Sylvania's big national magazine advertising which your customers will see in the Saturday Evening Post, Collier's, Look, Life and other publications.

So, don't delay! Mail the coupon for full details TODAY!

Sylvania Electric Products Inc.

Please send me full information about the May-June-July-August Service Dealer Campaign.

RADIO-ELECTRONICS for
Unprofessional Servicing

There is still too much poor servicing in this country...

By HUGO GERNBACK

A SHORT time ago I was a house guest with some friends in a city on our Eastern seaboard, which now has several television stations. The television receiver had gone out of order and my friends had to call a service technician to fix it in a hurry. I was present when the service technician arrived. I ascertained that he was in business for himself; in other words he was his own boss.

I was immediately struck with his exceedingly seedy appearance. He wore an old frayed suit, badly in need of repairs. Unkempt, unshaved, he smoked a big cigar from which ashes continually dropped on the floor.

He looked at the receiver and after a few preliminary tests which showed that the audio seemed to be all right but there was no picture, he announced that he would have to take it out of the case.

Without much ado, he proceeded to put the televiser chassis right on an expensive oriental rug, much to the disgust of my host who stopped him and insisted that some wrapping paper be put on the rug before the televiser was placed on it. This request seemed to surprise the repairman.

The technician then went on with his work. He volunteered several disparaging remarks about the receiver, stating that he would not give such a set house-room and making other gratuitous observations of that ilk.

He never asked for an ashtray, but flipped his cigar ashes on the wrapping paper provided by my host.

The tool kit—if such it could be called—was a disgrace. He emptied it on the floor to find his tools, and I noticed that they were mixed up with resistors, by-pass capacitors, metal tubes, etc. He also had a roll of black adhesive tape which had acquired a coating of cigar ashes from previous occasions, bits of metal, stripped insulation, and assorted dirt.

The only good thing I can say about this individual was that he seemed to know what he was doing. It did not take him long to make his repairs, which included a burned-out tube in the high-voltage circuit and a loose connection which he soldered.

The soldering operation, incidentally, was the sloppiest I have ever witnessed. I still do not understand why the dropping hot globules of solder did not cause some trouble in the televiser.

When the receiver was tested, it seemed to work as well as ever according to my host. The service technician proceeded to put it back into the cabinet. In this operation some cigar ashes fell into the open chassis, which he cleaned out by blowing hard into it. This caused some of the ashes to fly all over the room, to which he also did not seem to object. My host grumbled about it loudly.

After the television set was back in its customary position, the service technician made out a bill on a scrap of paper, which was paid by my friends. He then departed, never even thinking of rolling up the soiled wrapping paper and cleaning up the mess which he had left behind. I walked over to the televiser and saw that his greasy fingers had left marks all over the beautiful mahogany cabinet.

One might think that I am putting it on pretty thick and that I exaggerate. I assure you I do not, and as a matter of fact I have left out a number of other incidents.

After he had left, my host told me that he had sent for this man because the card which he sent promised speedy repairs on the spot and reasonable prices. It was the first time he had serviced my friend's set, but the latter assured me that he would never have used a "disgraceful character" in the house again—even if his work was satisfactory.

After the mess which the so-called service technician had left behind had finally been cleared away, my friend wanted to know if all radio service people were of this particular type. He mentioned that he had dealings with several others, and they all seemed alike.

I assured him that this was not the case, but evidently some of the repairmen in this particular town did not care either for appearance or what they did to the houses where they made repairs.

The writer has spoken of these things before. While this particular case may seem exceptional, it is not. I have seen too many sloppy service technicians not to know that there is a high percentage of this particular tribe—an unhappy group who are forever bemoaning their fate that business is bad and lamenting that they cannot seem to get along.

What really prompted the writing of this article was that a few days ago I asked the telephone company to make a new telephone extension in my home. The excellent appearance of the telephone man, his neat kit, his courteous approach, the efficiency with which he worked made me furious when I compared him to some of the radio service technicians I have seen in the past.

When my telephone man was finished with his work, he asked for a broom to clean up the little dust that he had made in stringing his wires. He polished the instrument and asked me if there was anything that needed to be repaired on the existing telephone. He was all business, all unobtrusive courtesy. He was efficient and inspired confidence. When he left, there was not a speck nor a nor dirt, a scrap of wire left. He had removed it all. He did not smoke on the premises either!

The telephone companies train their men to work in just this manner. I have yet to see a telephone installation or service man who does not work in this efficient, businesslike way. Why can't the radio service industry take a hint from the telephone people?

A great many radio service technicians are a credit to their trade. But, unfortunately, the percentage of sloppy, careless, inefficient, garrulous radio repairmen is much too high today. These are the ones who send letters sprawled in pencil on scraps of paper, and then are surprised that when they write similar letters to big radio set manufacturers and others, they do not even get a reply.

Service technicians are judged not only by their appearance, but by their letters as well. People who have nice homes as a rule look askance at sloppy, businesslike service technicians and learn to avoid them. Not only that, but this minority group gives the entire radio servicing business a black eye.

Incidentally, it is the unprofessional type of service technician who never makes out well. He is always behind in his bills, and, because of his appearance, has a psychological handicap that prevents him from getting as well paid as his more efficient and better operating competitors.
MOST frequency-modulation receivers can be modified to improve greatly their interference-rejection capabilities. The adapter described was successfully used by the author in a Hailcraf ters S-55 receiver.

There are four important types of interference in a frequency-modulated system: impulse noise, adjacent-channel, co-channel, and multipath.

Impulse noise contains both amplitude and frequency modulation because of its random nature. There is amplitude modulation because two successive noise peaks rarely have the same height; frequency modulation results from the fact that the peaks are not uniformly spaced in time. A good limiter will take care of the amplitude modulation if it is provided with sufficient signal, but some frequency-modulation noise is bound to come through. The receiver itself contains a form of FM limiting, however, because of its relatively narrow bandwidth (perhaps 200 kc). As a result, frequency swings in excess of 100 kc are clipped; thus the noise is limited to a low value.

Adjacent-channel interference, which is usually troublesome when a station on the next channel is much stronger than the desired station, must be taken care of by the receiver's i.f. selectivity. Although the selectivity of the adapter could have been bettered by adding a couple of sharply tuned i.f. amplifiers, the consequent slight improvement might not have been worthwhile.

Reduction of co-channel and multipath interference is, however, quite another problem. Here is a possibility for real improvement in receiver performance.

Assume that there are two FM signals coming in on the same channel. These may be two separate stations carrying different programs (co-channel interference), or they may be two signals arriving at different times from the same transmitter (multipath interference). In either case, the two signals are picked up by the antenna, amplified, converted, and amplified again. Since the r.f. and i.f. amplifiers are linear and have sufficient bandwidth, the signals appear in their original form at the input to the limiter.

Here, however, the picture changes. Since the limiter is nonlinear, the signals combine, in much the same way that two signals combine in a detector to produce a beat note. There are no longer two separate signals with two separate frequencies. The one signal present, the resultant signal, depends on both the desired and the interfering signal. Since the discriminator is operated by the resultant signal, the audio output from the discriminator contains, in part, the interfering signal. The question is, what can be done about it?

Argiimbau has shown that even if the desired signal is only slightly stronger than the interfering signal, the average frequency of the resultant signal at the limiter output is exactly that of the desired signal. The instantaneous frequency of the resultant signal, however, may deviate very widely, as much as 1.5 mc if the interfering signal is 9/10 as strong as the desired signal. It is desirable, therefore, that the circuits following the limiter—and this includes the second limiter and the discriminator—have a bandwidth of at least 3 mc. The wide frequency deviations produced in the limiter will then be passed by the discriminator, and will appear as voltage variations at the discriminator output. The voltage variations can be smoothed out by the normal deemphasis circuit. Since this is, in a sense, an averaging process, the output of the de-emphasis network depends on the average frequency rather than on the instantaneous frequency. It is, therefore, a nearly undistorted replica of the desired signal.

Consider what happens in a normal FM receiver. The discriminator has the same bandwidth as the i.f. amplifier. The wide instantaneous frequency deviations are clipped, and the average output voltage of the discriminator (after de-emphasis) is no longer independent of the undesired signal. As a result, crosstalk will be noted when there are two stations operating on the same channel, and serious interference will be obtained under multipath conditions.

The two requirements for the proposed adapter are, then, the best possible limiter or limiters and a discriminator at least 3 mc wide.

The adapter

The photographs of the adapter show that it was constructed on a long, narrow chassis, 6½ inches wide, 5 inches long, and 1 inch high, modified to fit a positionning inside an S-55 receiver. In the schematic diagram of the complete unit, the first stage V1 operates at the normal 10.7 mc intermediate frequency of the receiver. The first tuned circuit T1 has a bandwidth of about 300 kc, which is sufficient because limiting has not yet taken place. The plate circuit of V1 is tuned to 10.7 mc by T2, a double-tuned transformer with a bandwidth of 3 mc. This great bandwidth is necessary because limiting takes place in the secondary circuit of T2.

Various types of limiters were tried in the breadboard model of the adapter. Although the ordinary pentode class-C amplifier-limiter is economical to use (it can give a fair amount of voltage gain) it is inferior in suppressing ignition noise. This is a result of the time constant necessary in the grid circuit to give class-C bias. When an ignition-noise pulse appears, a very high bias is built up. It takes

By PETER G. SULZER*

* Engineering Experiment Station, The Pennsylvania State College.
Schematic of the adapter. Novel double conversion system gives wide bandwidth.

an appreciable time for this bias to return to normal after the pulse disappears. Therefore, a large "hole" is punched in the signal, accentuating the effect of the pulse.

The limiter finally chosen, shown connected in the grid circuit of V2, consists of two 1N34 crystal diodes connected as a biased, full-wave clipper. Since there are no time constants important to the operation of the limiter, the grid voltage of V2 is a square wave whenever there is sufficient signal, and more constant output results. V2 is operated as a frequency doubler. Although it is unusual to find doublers in receivers, their use is recommended where a large amount of gain is necessary, especially an FM receiver. By having some of the gain at one frequency and the rest of the gain at twice that frequency, there is much less trouble with feedback or regeneration. V2 could be operated as a tripler with somewhat greater efficiency, since the input to its grid is a symmetrical square wave, which does not normally contain even harmonics. This would put the remainder of the system at 32.1 mc, which would be convenient for use with surplus i.f. transformers.

The third and fourth stages V3 and V4 respectively, operate at 21.4 mc. Since the frequency has been doubled, the deviation is also doubled, and T3 and T4 must have a bandwidth of 6 mc. There is another limiter connected in the grid circuit of V3. The use of two limiters has been found very helpful against ignition noise. The discriminator, which is really the heart of the unit, consists of T5 and two 1N34 crystal diodes. The circuit is of the Foster-Seeley type. Instead of the usual magnetic coupling between primary and secondary, capacitive coupling was used with the aid of C1, which unbalances the secondary circuit. The variable coupling obtained makes adjustment much easier.

As a result of the great bandwidth of the discriminator, its audio output is very low. For this reason, V5 was included as an amplifier to bring the audio level up to about 1 volt for driving the 5S-55 receiver. The de-emphasis circuit R-C2 is placed in the grid circuit of V5. The time constant is 68 microseconds, very close to the standard value, which is 75 microseconds.

The power supply includes a resistance-capacitance filter. Since the high-voltage requirement is only 120 volts at 45 ma, a choke filter was not round necessary.

**Construction**

The photographs show the parts layout, which is not particularly critical because the unit operates at comparatively low frequencies. The heater wiring should be kept close to the chassis, but the signal-carrying leads should be up in the clear to minimize stray capacitances.

The intermediate-frequency transformers are surplus items which happened to be available. Winding data for these transformers is as follows:

- **L1**: 100 turns No. 36 enameled, scramble-wound on ½-watt resistor.
- **L2, L3**: 30 turns No. 26 enameled, wound on 1-watt resistor.
- **T1**: 40 turns No. 30 enameled, close-wound on 3/16-inch-diameter slug-tuned form.
- **T2** primary and secondary: Same winding as T1, wound on 3/16-inch-diameter, double-slug-tuned form, with ⅛ inch spacing between windings.
- **T3, T4** primary and secondary: 28 turns each No. 30 enameled, close-wound on 3/16-inch-diameter double-slug-tuned form, with ¼ inch spacing between windings.
- **T5** primary: 22 turns No. 30 enameled, close-wound. Secondary: Two windings of 11 turns each, No. 30 enameled wire. One half of secondary is wound over the other. Spacing between primary and secondary is ⅛ inch. Both windings are slug-tuned.

Standard 10.7-mc transformers could be used for T1 and T2 without modification except for a slightly higher value of C3, T3, T4, and T5 could be television intermediate-frequency transformers, with a centertap added to the secondary of T5.

The grid wiring of V5 (and this includes the discriminator secondary circuit) must be kept away from the heater circuits.

After the wiring is finished, the power should be turned on and the heater and plate supply voltages checked. If these are satisfactory, the discriminator can be aligned by standard methods. Increasing the value of C1 will increase the coupling, making the discriminator broader. When adjusted properly, the discriminator characteristic should be linear over a range of 6 mc, with a spacing of 8 mc between peaks.

With the discriminator operating properly, the remainder of the i.f. amplifier should be aligned. Again, this can be readily accomplished with the sweep generator. Remember that the input to V3 and V4 should be at a center frequency of 21.4 mc, while the input to V1 and V2 is at 10.7 mc.

After the alignment is complete, the unit can be installed in the receiver. The adapter will work with any FM receiver having a 10.7 mc intermediate frequency. The i.f. input lead should be connected to the plate circuit of the last i.f. stage in the receiver. If a long lead is necessary, it should be shielded, and another 2-µf capacitor should be placed at the receiver end of the lead to prevent detuning.

The adapter cuts automobile ignition noise to the point where it is almost negligible. With an automobile running at a top speed of 20 feet of antenna, the noise is just barely noticeable. This is a decided contrast to the performance of the original receiver, which was useless under similar circumstances.

As far as co-channel interference is concerned, the new system exhibits very interesting properties. With fading, only the louder of the two signals is heard. As the louder signal fades, there is a sudden changeover, the original signal disappearing and the other one coming in without interference. This indicates that interference-free reception will be obtained if the desired signal is only very slightly stronger than the other signal.

With the original receiver, bad distortion was noted on some stations, whether they were weak or strong. The addition of the adapter reduced the distortion to a negligible amount.
Television Equipment Standards

Uniform standards insure reception regardless of transmitter or receiver designs.

By MATTHEW MANDL*

Final air-cooled power stage of Federal 5-kw television broadcast transmitter.

Of their frequency separation.

Fig. 1 illustrates how each television channel is subdivided. The amplitude-modulated picture carrier is 1.25 mc above the lower limit of the channel. Video-frequency modulation components as high as 4.5 mc are transmitted, but those above 4 mc are attenuated in the transmitter fairly sharply.

With effectively 4 mc as the top modulation limit, a symmetrical transmitter output would require 8 mc for the picture information alone. To conserve spectrum space, only 0.75 mc of the lower sideband is transmitted, with another 0.5 mc in the attenuation region. Since a part of the lower sideband is transmitted, that is, a vestige of it remains, the system is known as vestigial-sideband transmission, as distinguished from single-sideband transmission, where one sideband is almost totally filtered out.

The sound carrier (FM center frequency) is 0.25 mc below the top of the channel. Maximum deviation is 25 kc (.025 mc) above and below center, giving the signal a bandwidth of 50 kc. (This is one-third the swing of an FM broadcast transmitter, which is allowed ± 75 kc.)

Transmission standards

The center frequencies of both carriers are maintained within ±.002%. The picture transmitter is amplitude-modulated, the sound FM. Picture transmission is negative (a decrease in light intensity in the picture causes increased r.f. output). The advantage of this system is that interference impulses produce dark spots on the screen, which are considered less annoying than the white spots which are produced in a positive system, such as is used in Britain.

The level of the pedestal beneath the sync pulses—which corresponds as nearly as possible to the black level—is 75% of maximum peak carrier amplitude ± 2.5%. Sync pulses extend from here into the blacker-than-black region between 75% and 100% modulation. Maximum white picture elements bring the carrier level down to or below 15% modulation. The exact modulation percentage corresponding to maximum white during any frame depends on the average illumination of the scene at the moment. (This is what makes the d.c. restorer necessary in the receiver.)

The transmitter output varies approximately in inverse logarithmic relation to the brightness of the scene.

The number of frames per second is 30, each consisting of 525 horizontal lines. Interlaced scanning is used, with one field or half a frame transmitted every 1/60 second. The number of lines per second is 15,750, the product of the frame rate (30) and the number of lines per frame (525). This requires a 15,750-cycle horizontal sweep oscillator in the receiver. The vertical oscillator must operate at 60 cycles.

The aspect ratio of the transmitted picture is four horizontal units to three vertical units. The direction of picture scan is left to right and top to bottom.

Sound transmission

The FM sound transmitter must be capable of transmitting an audio range of 50-15,000 cycles. Since maximum deviation is 25 kc, the modulation index is 25,000/15,000 or 1.66. The peak radiated power of the FM transmitter

---

*Technical Institute, Temple University.

www.americanradiohistory.com
must be between 50% and 150% of the peak power of the video transmitter. Normally, the FM transmitter radiates less power than the picture transmitter. The signals radiated by both transmitters are horizontally polarized.

Fig. 2—Sound pre-emphasis curve.

As in FM broadcasting, the higher audio frequencies are pre-emphasized before reaching the modulator. This allows the receiver design to include a high-frequency roll off in the audio circuits, reducing noise but allowing the full sound range to come through. The 75-microsecond pre-emphasis curve is given in Fig. 2. The permissible error is about 3 db at all points except the extremes, where it is somewhat more. Every receiver should include a de-emphasis network complementing the curve of Fig. 2 to restore the higher audio frequencies to their original level.

Intermediate frequencies

There is no such thing as a standard intermediate frequency in receivers, though most of them are in the same general range. Table II shows the design trend in this respect. It lists the sound and picture i.f.'s of a number of representative receivers. Notice that almost all are in the 20-25-mc range, though one or two deviate. Where “all models” has been indicated under a manufacturer's name, there may still be deviations in some models, especially ones marketed since the table was compiled.

On practically all present receivers except those using intercarrier sound, the oscillator operates above the r.f. In intercarrier, it may operate above on the lower channels and below on the upper channels.

The picture i.f. channel of a receiver should have a bandpass of 4 mc to accommodate all the picture detail obtainable from the signal. Most of the better receivers are said to have this; but a few, especially those with 7-inch and smaller C-R tubes, pass only a 2.5-mc band. The smaller screen is unable, of course, to reproduce the same detail as the larger ones.

The minimum required bandpass for the FM sound i.f. channel is equal to the maximum frequency swing, which is 50 kc (25 kc each side of center). Almost invariably, however, the sound i.f.'s will pass 200 to 300 kc or more. The advantage here is that normal frequency drift will not wash out the sound completely or clip off some sidebands. Excessive drift of the oscillator will bring the center frequency of the FM far enough away from the discriminator frequency to cause distortion, and for this reason many sets must be retuned a few minutes after a cold start. Drift rarely affects the picture noticeably, due to the comparatively wide video band. Receivers containing a.f.c. require a wide FM i.f. band for correct operation.

**TELEVISION DX**

Additional letters reporting long-distance television reception have come in during the month.

John W. Hull, Fort Recovery, Ohio, reports receiving KLEE, channel 2, Houston, Tex., at various times under widely different weather conditions. His "travise dx" is WJAC, channel 14, Johnstown, Pa., which he received on the afternoon of September 3 with perfect picture and sound.

David C. Graves, Barnesville, Ohio, sent in a long list, mostly of stations within a couple of hundred miles. He received WTVJ, channel 4, Miami, Fla., dozens of times all summer and WMAL, channel 7, and WTTG, channel 5, Washington, D.C., once each. He reports consistent reception from WBAP, channel 2, Fort Worth, and the inevitable KLEE, Houston, Tex.

KLEE-TV, which we are about to dub the "nationwide station," was the cause of a letter from Lewis R. Christy of Lake Elsinore, Calif., though not one addressed to the editor. Receiver dx—receiving KLEE-TV was an unsolvable problem, as far as he was concerned. Mr. Christy wants to know how he gets KLEE-TV when he should be getting KFMB-TV in San Diego, which is not received in his area, though it goes over his head to Los Angeles.

Homer W. Snyder, Miami, Fla., sends along a lengthy log. Among the stations listed, most of them several times, are: WMV, channel 2, Baltimore, Md., WCBS-TV, channel 2, New York, WPTZ, channel 3, Philadelphia, WRGB, channel 4, Schenectady, N. Y., WBZ, channel 4, Boston, Mass., WNBW, channel 4, Washington, D.C., WJL, channel 5, Detroit, WBEN, channel 4, Buffalo, N. Y., WDTV, channel 3, Pittsburgh, WNBK, channel 4, Cleveland, WLW-T, channel 4, Cincinnati, and—surprise—KLEE-TV, Houston, Tex.

This KLEE-TV is beginning to intrigue us and we are going to write the station a letter asking just what kind of Wheaties they feed to the transmitter instead of electrons. KLEE-TV is responsible for about 50% of the dx letters we receive and it is among the stations received in almost all the others. We will pass along the reply as soon as we get it.

It is getting a bit monstrous but Dr. George B. Meyer of Oshkosh, Wis., is entitled to his day in RANto-KLE-TRONICS, so here he is. What station did he receive from way down in Texas? You guessed it! His list includes seven other stations more than 150 miles from Oshkosh.

WOAI-TV, channel 4, in San Antonio, Tex., was snagged during December by Clarence P. Miller of Portsmouth, Ohio. He remarked in his letter that he was using the circular antenna described by Noll and Mandl in the February 1949 issue of this magazine. He wants to know how to make the antenna directional. Directors and reflectors tried with it didn’t seem to have any effect.
**A DeLuxe Telesisor**

Part IV—Some additional features of sweep circuits and audio stage

By CHARLES A. VACCARO

The construction of this de luxe telesisor having been covered in the January, February, and March issues, we will now discuss its operation and circuit features. The i.f. strip is shown in Fig. 1 of the January issue, the tuner in Fig. 7 in the February issue, and the complete schematic in Fig. 17 of the March issue.

The tuner receives channels 2 through 7, and channels 8 or 9, 10 or 11, and 12 or 13. Its input circuit, designed to match a 300-ohm line, consists of a high-pass circuit in parallel with the cathode inductor of a 6AG5 grounded-grid r.f. amplifier. One triode of a T8 is a modified Colpitts oscillator tuned to the high side of the video and sound carriers, and the other triode is a mixer with its plate circuit tuned to 22 mc.

The video i.f. strip has four stages which are tuned to different frequencies to produce the desired over-all response curve. The constructor may use 6AC7's or 6AG5's as video i.f.s. The 6AG5's are interchangeable with the new 6BC5's which have a higher transconductance.

The last coil in the video i.f. stage is coupled to the video detector—half of a 6H6 diode rectifier. The detector output is negative and is directly coupled to the 6AC7 video amplifier. The 6AC7 on the cathode, the grid will never go more positive than —5 v with respect to the cathode. The grid will never draw current; therefore tube life will be longer.

One of the reasons for selecting this system of modulating the picture tube and of setting the intensity is the feeling that you have something "solid" in your hand when you are operating the contrast and intensity controls. Video modulation being applied to the grid instead of the cathode in some sets, the initial setting of the intensity control is such that the raster is not seen when the grid is unmodulated—contrast turned down or no signal from a station. Then when the grid is modulated, whiter or brighter as the picture becomes, signal strength increases. Thus when the contrast control (picture gain) is increased, you have the feeling that you might be turning the intensity control. This is because you are actually setting the black level and thus the maximum whites are determined by the maximum video signal.

With the system used here the setting of the intensity control actually sets the maximum white level and variations in signal will not increase it. Turning the contrast control increases the picture gain, driving the cathode more positive (the grid toward cutoff), so the blacks become a deeper black.

After the sound has been tuned in, set the intensity at the desired brightness level, then increase the contrast control until the retrace lines disappear. This eliminates glare which is a common fault in some circuits.

Returning to the 6H6 video detector, we see that the other half of this tube rectifies the 6.3-volt a.c. to obtain a bias voltage for controlling the gain of the first three tubes in the i.f. strip. The contrast control varies this bias between the limits of —8 volts near cutoff and up to —2 volts at full gain.

**Dual sweep circuits**

Two separate horizontal sweep control circuits—called d.s.c. and a.s.c.—are built into the set. The d.s.c. (direct sync control) circuit consists of a cathode-coupled multivibrator directly synchronized by the sync pulses from the transmitter. The a.s.c. (automatic sync control) system is conventional. It uses a 6F6 Hartley oscillator controlled by a d.c. voltage developed by the a.f.c. discriminator. A part of the video signal from the 6AC7 video amplifier is capacitance-coupled to a 6SH7 whose bias and plate voltage are adjusted so that the synchronization signals are clipped and separated from the composite video signal. Part of the output of this tube is fed directly to the 6SN7 horizontal multivibrator (MVB in the drawings) through a 47-μuf capacitor and across a 240-ohm resistor. This combination shapes the horizontal sync and attenuates it to a level just below that needed to synchronize the horizontal multivibrator. It also attenuates frequencies below 15,750 cycles so that they have practically no effect on the horizontal oscillator frequency.

The 15,750-cycle tuned circuit in the cathode circuit forms a pedestal for the sync signal to raise it to the level required to lock the horizontal multivibrator in sync. This circuit further attenuates other unwanted frequencies. The second half of the 6SN7 multivibrator contains the 150,000-ohm charging resistor, the 1,400-μuf capaci-

tor, and 15,000-ohm resistor forming the sawtooth horizontal sweep voltage which terminates at one of the d.s.c. terminals on the d.p.d.t. switch. When the switch is on d.s.c. the 6BG6-G horizontal output tube is driven by a sweep voltage synchronized directly from the transmitter sync signals.

In the a.s.c. circuit, a 68-μuf capaci-

coupled the horizontal sync signals into the centertap of the secondary of the sync discriminator transformer. Also coupled to the secondary of this transformer is a sine-wave voltage from its primary. This primary along with the 6F6 and associated circuits make up a Hartley oscillator circuit operating near or at 15.75 kc, the horizontal sweep frequency. Therefore on the plates of the 6H6 discriminator we have out-of-phase sine-wave voltages which have in-phase sync pulses superimposed on them.

If a difference in time (phase) exists between the 6F6 oscillator frequency and the incoming sync pulse, the pulse voltage may ride down near the negative peak of the sine wave on the top diode and up near the positive peak of the sine wave on the bottom diode as in Fig. 19-a. The larger output of the bottom diode will appear across its 470,000-ohm load resistor and the sum of the two readings may be positive. If we assume that the above condition existed when the sine-wave oscillator was faster than the sync pulse, then, when the oscillator is slower or a phase difference exists in the other direction, the sync pulse will ride up the slope near the positive peak of the sine wave on the top diode and down the slope near the negative
peak of the sine wave on the bottom diode as in Fig. 19-b. Now the output of the top diode will be larger and the total across the two load resistors will be 15,000-ohm resistor in series with it. As soon as the pulse is gone from the grid, the tube becomes nonconducting due to the bias built up across the 0.1-µf capacitor and the 220,000-ohm resistor in the grid circuit. The voltage now rises linearly to the value of voltage remaining across the 680-µf capacitor. The rest of the spiked waveform is now formed as the plate voltage rises linearly and slowly while the capacitor is charged through the 680,000-µmho charging resistor. This voltage drives the 6BG6-G horizontal output amplifier when the sweep switch is in the a.c. position.

Horizontal output circuit

The spiked sawtooth horizontal sweep is fed to the grid of the 6BG6-G output amplifier, which in turn is transformer-coupled to the horizontal deflection coils. At the end of each sweep the plate current of the 6BG6-G is cut off and the field of the secondary of the transformer collapses. This collapsing field induces a positive pulse in the primary transformer winding which is connected as an autotransformer to increase the output voltages to approximately 10 kv. This high-voltage pulse is rectified by the 1B3-G7, and the resulting pulsating d.c. is filtered by a resistor-capacitor filter, including the 5-megohm (minimum) capacitor between the internal anode coating and the external coating of the picture tube. The 300-megohm bleeder consisting of 15 20-megohm resistors in series provides safe means of measuring the anode voltage. It eliminates the danger of either of the capacitors retaining their charge and connecting the bright spot which is usually seen on the picture tube for several minutes after the set is turned off. This is useful, as the bright spot can burn the phosphor sufficiently to cause that part of the screen surface to last longer than the rest of the screen face.

The 6A7-G booster and damper is across the horizontal deflection coil. This tube is adjusted to permit a power gain of approximately two to the sweep while efficiently damping any oscillations which might persist after the retrace pulse—the first half-cycle of oscillation. Horizontal linearity control No. 1, in the cathode circuit of the 6A7-G, affects the linearity of the sweep by shifting the operating point of this tube along its characteristic curve.

The horizontal linearity control No. 2 varies the time constant of the grid circuit which controls linearity by controlling the portion of the sweep over which the damping action is most effective. The 55-250-µh coil shunted across a portion of the secondary winding of the horizontal output transformer decreases the width of the picture by shunting a part of the sweep current.

Vertical sweep circuit

A portion of the output of the first sync amplifier is fed to the vertical sync amplifier and noise attenuator through a resistor-capacitor network which attenuates the higher frequencies and passes the 60-cycle sync signals. The output of this amplifier passes through another network which further attenuates frequencies above 60 cycles and shapes the sync pulses which synchronize the 6SN7 vertical multivibrator. The 200,000-ohm vertical hold control varies speed of the multivibrator by changing the grid bias on one of the 6SN7 triodes. The plate voltage on pin No. 2 of the 6SN7 and the cathode voltage of the 6Y6-G vertical output amplifier have been adjusted so that the two stages can be directly coupled. The two 0.1-µf capacitors in series and the 1.8-megohm resistor are the charging capacitor and resistor, respectively. A tubular-type, dual, 0.1-µf capacitor was used here because of its mounting; however, a single 0.5-µf capacitor could be used. Vertical linearity control No. 1 changes the operating point along the characteristic curve of the 6Y6-G, making it possible to obtain good vertical linearity. Vertical linearity control for the amount of spike necessary to produce the correct waveform for a sawtooth current in the deflection coils. The height control varies the amount of voltage across the charging capacitor, changing the size of the spiked sawtooth coupled to the 6Y6-G.

Operating as a triode, the vertical amplifier is transformer-coupled to the vertical deflection coils which are shunted with 470-ohm damping resistors.

The audio circuits

Returning to the mixer plate coil, we find coupled to it the coil which is connected at 21.25 mc which carries the audio i.f. to the 6SG7 audio i.f. amplifier. This tube in turn is coupled to the following 6SH7 limiter by a slightly overcoupled i.f. transformer, resulting in approximate output i.c. bandpass limiting action is accomplished in this stage by the bias, which varies with the incoming signal due to the 51-µf capacitor and the 220,000-ohm resistor in the grid circuit and by plate saturation of the low plate voltage. The FM discriminator transformer is between this 6SH7 limiter and the 6H6 ratio detector. This type of discriminator circuit was chosen because it is easy to align, the transformer is easily constructed, the quality is good, and the possibility of using a tube with a single cathode allows, for flexibility in future changes. This will be discussed in a later installment.

The audio output is coupled to a 6SF5 audio amplifier through a de-emphasis filter consisting of an 82,000-ohm resistor and 330-µf capacitor and also through a selector switch and a bass-boosting volume control.

The de-emphasis filter used here only partially restores the original level. The 1-megohm tone control in the plate circuit of the 6SF5 then permits adjustment of the high-frequency audio to the same level, to a slightly higher level, or to a lower amplitude level with respect to the lower-frequency audio that resulted from the original sound.

The output of the 6SF5 is capacitance-coupled to the 6V6 audio power amplifier, which in turn is transformer-coupled to a 12-inch FM speaker.

When the TV-off radio selector switch is in the off position, it disconnects the a.c.-supply from the receiver. When switched to TV, the audio amplifier tubes obtain their heater, plate, and audio-input voltages from the rest of the television circuits. In the radio position, the a.c. line is switched from the TV power supply to jack J3. The radio line cord plugs into J3. The switch also disconnects the heater, plates, and audio input of the amplifier and connects them to a four-circuit female connector. This requires that four wires carrying 5.3 volts a.c., 250 volts d.c., and audio be brought from the radio through a four-circuit plug. This radio unit or tuner can be left out, as the audio output is all connected to the selector switch is in TV position, or the radio unit can be added at any time and be as elaborate as desired. It can consist of AM, FM, shortwave, and phono, or any one or combination of these functions, the important being that the power supply in the unit can stand an additional drain of 250 volts at approximately 40 ma and 6.3 volts at 0.75 amp.
A Revolution in Robot Radio Servicing

By MOHAMMED ULYSSES FIPS, IRE*

RECENTLY I inspected the huge electronic brain—the electronic computer designed and constructed by the International Business Machines Corporation. (For further data see Radio-Craft, May, 1948.) This almost human machine not only can actually "think," but also has a memory. Costing $760,000 to build, it has 12,000 radio vacuum tubes, 20,000 relays, 4,000 neon tubes, and tens of thousands of resistors and capacitors. This calculating machine can solve in a matter of minutes complex problems that would take a topnotch mathematician years to solve using ordinary calculating means.

What impressed me particularly was that this huge electronic calculator—which takes up a large room—"services itself." If one of the tubes burns out or some part in that tube's circuit goes out of order, a neon tube in that circuit flashes immediately, making it easy to discover any trouble whatever in that vast electronic network.

Other automatic means provided in these electronic calculators make it simple to locate trouble when the machine stops due to an internal breakdown.

You can feed the computer any problem, no matter how complex, and the electronic calculator will answer it. If you supply your own problem, the I.B.M. Corporation will charge you $300 an hour for the use of the machine. Usually it is fed a punched card which states the problem. From there on the computer does the rest. When it has finished all the calculations, it types the final answer to the problem on a special typewriter.

Service technicians waste a lot of useful time hunting trouble in radio and particularly in television sets. Why not simply hook up a defective television receiver to the electronic calculator, state the problem to the machine and let it find the trouble?

I talked to the chief engineer about this. He was of the opinion that the idea was quite feasible and that an electronic calculator could no doubt solve most servicing troubles in a few seconds, no matter what the failure in a given televiser might be. Thus encouraged, I proceeded at once to look into the possibilities of electronic brain servicing.

The price of $300 an hour for the use of the machine would be very low because each televiser would take only a few seconds to service. I envisaged a servicing assembly line on which defective televisers would roll along slowly on a moving belt. A girl would take out the diagnosis card from the special typewriter, then attach it to the corresponding televiser. Now the radio servicing technicians—knowing exactly where the trouble was—would repair the set within minutes.

Every service technician knows that it sometimes takes hours to locate a given fault, which, once found, can be cleared in a few minutes. So why waste the valuable time of a good service technician if we can have electronic brains?

The more I thought of the problem the more fascinated I became.

With the facilities of an electronic calculator in a large city, an electronic-brain servicing firm could get all the business, because it could work for so much less than the regular service house.

There was but one little problem that had me worried, but I solved this (in all due modesty, brilliantly). How could the electronic brain service a set in the owner's home? Naturally, you can't transport the electronic brain into a private home to do the servicing. (It takes up two freight cars.)

The problem was resolved very simply. I knew that it would be a simple matter to hook up a televiser to the electronic calculator. All you require is a heavy cable with a number of connections made to the strategic points in the televiser. Then in five seconds your answer is supplied by the computer.

This then led me to the invention of a special unit which I term the Tele-pulsor. This is shown in one of the photographs and works as follows:

Connecting defective televiser (1) to electronic computer. (2) is "Table Look-Up Unit." (3) shows a small part of the insides of the electronic brain, which has over 12,000 vacuum tubes, 20,000 relays and 4,000 neon tubes.

www.americanradiohistory.com
In the owner's home, the telephone handset is connected to an ordinary microphone as shown in one of our illustrations. Its cable is connected with the telepulsor, and the latter is connected with the televiser. The service technician now calls up the home office of the electronic calculator. At headquarters, an ordinary handset is placed on an amplifier which amplifies the sounds coming from the telephone of the handset. The amplifier in turn is connected with the electronic calculator.

Now the latter sends impulses over the telephone line which go to the televiser, thence by a cable to the televiser. The impulses sent by the electronic calculator via the telepulsor act exactly as if the televiser were connected to the electronic brain by direct cable.

The telephone line has become the diaphragm and the link and the computer works exactly as if a televiser were in the same room.

In a matter of seconds the electronic calculator has located the trouble in the televiser. Headquarters now tells the service technician by phone just what is wrong with his unit.

Inasmuch as it only takes a few minutes to set up the telepulsor and make the telephonic connection and as it takes only a few additional seconds to get the televiser on the line from the telepulsor in case of failure, you can see what a great advantage the radio technician has in servicing a set. In a very short time he will have remedied the trouble. While in some cases it might be necessary to remove the televiser to the service station, in most instances the receiver can be repaired right on the spot.

For this reason I figured a standard charge of $30 for all radio televiser diagnosing. This, of course, does not include replacements of defective parts. Electronic-brain servicing should prove a gold mine for those lucky enough to get in on the ground floor.

Furthermore, inasmuch as this electronic calculator cost $750,000, the original servicing firm shrewd enough to make contact with the computer's owners would not have to worry much about competition. Not many other servicing firms would be willing to spend the more than a million dollars which it would cost to manufacture a new electronic calculator at present high prices.

After I had made my preliminary trials and got all my facts together on paper, I sent out a lot of publicity releases to service technicians and others so they could see my new wonder under actual working conditions. I did this purposely as my big boss was away in Europe and I thought if there ever was a beat for a radio magazine, this would be it. My first public demonstration was timed to take place the day after the boss returned from Europe.

I sent invitations to all the newspapers and to various local radio service firms to bring their defective televisers and have them robot-analyzed free of charge for this demonstration. Nearly a hundred televisers were received to be analyzed and over 400 people were on hand that memorable morning when the first public demonstration took place.

I had reserved the best seat in the room for the boss so he could watch the whole demonstration with ease. He seemed puzzled at first because I had not told him exactly what the occasion was, but I had intimated that this was going to be the biggest journalistic coup ever undertaken by any radio magazine. Everything, down to the smallest detail, came off exactly as I had planned.

I delivered my lecture to the assembled audience, explaining to them how servicing was going to be completely revolutionized and how much the public would benefit by means of this new invention. I told them that most of the television receivers would not have to be removed at all from the premises and that they could be repaired and put into use again in such a very short period, that owners would not be deprived of their beloved televisers for more than a few short minutes at the most.

Next the television receivers were put on the servicing belt and slowly started down the line. It took only a few seconds to attach the special card that went to the electronic calculator—the electronic brain. A special card was fed into the hopper of the computer and within a few seconds the neatly typed answer came out. Then a pretty girl attached the card to the correct televiser.

I looked expectantly at the big boss—pride glowing in my eyes. I was, however, disturbed and puzzled by the ferocious expression on his face. He chewed his big cigar nervously and, slowly the color in his face changed from a pink to a sort of queer purple. This, I could not understand, but I attributed it to the fact that he perhaps was jealous of my accomplishment so I paid little attention to him. All went well till the fifteenth televiser was connected to the electronic brain. Then, something dramatically happened. An ominous growling noise came from the great vacuum-tube panels of the machine. The normal hum and click from the relays rose to a high-frequency staccato pitch. The relays clicked and clacked with frightening intensity. Neon lights flashed all over the big panels and suddenly smoke started to curl from some of them. Soon flames began to shoot from the table lock-up units (memory units). Some of the paper rolls began to burn. . . . Attending engineers of the electronic brain by this time were running around frantically. Some of them grabbed fire extinguishers and shot streams at the flames. Now the commotion became catastrophic and in a panic all the frenzied guests ran for the doors.

The boss had gotten up in a hurry too. I saw him snatch away the card on which the answer came out of the computer.

He next grabbed me by the collar and pulled me out to safety onto the sidewalk on 57th Street. Everything had happened so suddenly and with such speed that I was practically a nervous wreck.

We were still trying to catch our breath when someone approached the...
boss, quickly put a slip of paper in his hand and disappeared in the gathering crowd, which was augmented by the two fire companies who had already rolled out their fire hoses intent upon putting out the conflagration. The boss glanced briefly at the note, gave a nasty grunt, and pulled me by the arm into a nearby café.

As soon as we had settled down he bellowed:

"Fips, this is the end of all the crazy

You should also have thought of the fact that such a machine, if it became a reality overnight, would put out of business most of the servicing instrument makers, analyzer companies, etc., which after all are our bread and butter. How do you think the country's servicing trade would feel if this radioactive cock-eyed scheme of yours had become a reality overnight?

"Fortunately, one of the local radio servicing firms cooked your goose."

This is the "answer card" of the electronic brain. It has 800 spaces provided for 800 possible failures in a given television. Machine punches holes in card, which when translated gives the technical failure or failures in the television receiver.

After this jolt I bowed out to see if my friend could remember the "answer card" and when I returned he was still quaking in his shoes.

Sap stunts you have ever pulled. This one is the asinest of them all. You have the brain of a burnt-out vacuum tube, and your capacity for thinking is not equal to a blown capacitor. Every time I turn my back you go haywire with some of your electronic contraptions. Only an electronitwit could cook up such idiocies. While I do admit that some day in the future it will be possible to have electronic-brain servicing, you should have thought of what this would do NOW to the servicing trade to which your magazine caters.

Here the boss pulled out the slip which had been handed to him on the sidewalk. He read:

"Editor, RADIO-ELECTRONICS, If you don't fire that electronic ass Fips within 24 hours, we will take him for a ride and electrocute him in a lone spot in gratitude for his hare-brained schemes. Fortunately we 'gimmicked' one of the sets with a small battery-operated shocking machine for which we know the electronic brain was not prepared. We know this will fix you and Fips, but good!"

"The Electronic Servicing Avengers."

"So you see, my electronic imbecile," continued the boss, "they spiked you good and proper, much to my unbounded pleasure. When the gimmicked televiser was connected to the electronic brain, something totally unexpected happened. Instead of analyzing a number of dead circuits, the electronic brain was now connected with the televiser's powerful shocking machine which sent several hundred volts into the computer's totally unprepared brain. This was so unexpected that the electronic brain was completely shocked out of its routine. It went absolutely haywire and electronically berserk. In short, it had an electronic nervous breakdown, which in turn made it an electronic psychopath, the most dangerous robot we have as yet seen.

"Naturally everything in the machine went haywire too. There were thousands of short circuits, thousands of relays fused, wires started to heat up, and in only a few seconds the entire machine was in flames, as you yourself have seen.

"Now I will probably be sued for a million dollars or more, thanks to this little escapade of yours." In saying so, the boss' right fist shot out and closed my best left eye. In his anger he threw down a piece of cardboard as he went out, snarling over his shoulder:

"See what the electronic brain answered before it had its final psychic breakdown."

Completely stupefied by this time and rubbing my closed, swollen eye, I looked at the electronic-brain answer card in front of me. I sadly read:

"APRIL FOOL"

VELOCITY-MODULATED TV

An interesting method of producing an image on a television cathode-ray tube was described by M. A. Honnell and M. D. Prince in a recent issue of The Research Engineer, published by the Georgia Institute of Technology.

In the usual system, the rates of vertical and horizontal scan are kept constant, while the brightness of the spot is varied by feeding video to the C-R tube grid. In the velocity-modulation technique the brightness of the spot is kept constant, and the horizontal scanning velocity varies from instant to instant. When the velocity is high, almost no light shows on the screen; when low, the light is bright. It was found that details of a shaded image do not reproduce well but that the outlines of "line" material - silhouette drawings, printed matter, and other black-and-white images—are extremely sharp.

The method was investigated during research on characteristics of a military airborne TV system. Scanning circuits in the receiver and all the transmitter circuits are conventional. The video signal in the receiver, however, instead of being fed to the C-R tube grid, is superimposed on the horizontal deflection voltage.

The two photographs show reception of a printed letter group by the standard system on the right and the velocity method on the left. Notice that the velocity system produces very sharply defined printing. The appearance of relief modeling is particularly interesting. It is caused by a light band on the left and a dark band on the right each time the beam traverses a two-toned image. The additional contrast thus provided, which shows only the outlines of the image, enhances readability, especially for thin areas.

RADIO-ELECTRONICS for
Horizontal flyback
The return of the spot after each horizontal sweep. It is also known as horizontal retrace.

Horizontal frequency
The number of times per second the spot sweeps across the screen in the horizontal direction. It is also referred to as the horizontal repetition rate. In standard television practice, the horizontal frequency is 15,750 sweeps per second.

Horizontal resolution
That quality of an image which enables an observer to distinguish the individual picture elements in each horizontal line.

Ironsocpe
A television pickup tube in which the scene to be televised is optically focused upon the photosensitive mosaic. The mosaic consists of a rectangular plate of mica or other insulating material upon which a large number of individual globules of photosensitive selenium-silver have been deposited. The back surface of the mica is coated with a conducting film. A small value of capacitance thus exists between each globule and the metallic film. When light falls upon the mosaic, the globules emit electrons, thus producing a charge on the globule-capacitance. Each is charged in proportion to the intensity of the light falling upon it. The tube also contains an electron gun, and the electron stream is made to scan the mosaic. As the stream strikes each globule in turn, it replaces the electrons lost by photoemission and thus discharges the globule-capacitances. The discharge currents, taken out from a lead to the metallic film, constitute the signal currents.

Image dissector
A type of television pickup tube which converts the optical image to an equivalent electron image and then scans this electron image by allowing a small portion of it at a time to pass into an electron multiplier tube. (See Dissector.)

Indirect view
A type of television receiver in which the image is optically projected from the cathode-ray tube to a larger viewing screen.

Integrator
A circuit having an output proportional to the cumulative value of the input. It is the opposite of the differentiator.

Intensifier ring
The third anode in a cathode-ray tube. Consisting of a "painted" coating on the inside of the glass envelope, it is the element closest to the fluorescent screen. The application of a high positive potential to the intensifier ring increases the velocity of the electron stream, consequently increasing the intensity of the light.

Intensity modulation
The process of applying a voltage to the grid or cathode of a cathode-ray tube, varying the intensity of the spot as it sweeps across the screen. For instance, in the television receiver, the incoming video signal is applied to the control grid of the cathode-ray tube to vary the intensity of the spot and produce the dark and light portions of the image.

Intensity of illumination
The brightness of an illuminated surface. Intensity of illumination is normally indicated in foot-candles and is inversely proportional to the square of the distance from the source.

Interlaced scanning
A system of scanning in which only a fraction of the image is scanned during each field. In a standard interlaced scanning system, the odd lines and the even lines are scanned as separate fields. Each field therefore contains 256.5 of the total 512 lines.

Ion
An atom having more or less than its normal number of electrons. A balanced atom has an equal number of protons and electrons. If such an atom loses one of its electrons, it assumes a positive charge (positive ion). If the atom should gain additional electrons, it assumes a negative charge (negative ion).

Ion spot
An insensitive dark spot on the screen of a cathode-ray tube due to ion bombardment of that spot. This condition may be prevented by use of an ion trap which allows electrons to pass to the screen but obstructs the ions.

Ion trap
A coil or permanent magnet placed near the neck of the cathode-ray tube for the purpose of removing ions from the electron stream. The magnetic field is able to deflect the electron stream, but has little effect on the heavier ions. In this way, it is able to separate the electrons from the ions and to prevent an ion spot on the screen.

Keystone distortion
A form of distortion which causes the television image to take the shape of a trapezoid even though the mosaic in the pickup tube is rectangular. Keystone distortion is due to the fact that the electron stream does not strike the mosaic at right angles. This distortion is normally corrected in the transmitting equipment.

Kickback
The counter-electromotive forces produced in a coil when the current through it is stopped and the magnetic field collapses.

Kickback power supply
A type of high voltage power supply used extensively in television receivers. The horizontal sawtooth is applied to a transformer, and the high counter-e.m.f. produced by the inductive kickback is rectified.

Kinescope
The commercial name for television cathode-ray tubes manufactured by RCA.

Latent image
Stored picture information such as that contained in the charged globule-capacitances of the iconoscope. (See Iconoscope.)

Light
Electromagnetic radiations having wavelengths between 4,000 and 1,000 Angstrom units and therefore invisible to the eye.

Light flux
The total amount of light produced by a source. Light flux is usually measured in lumens. The term is sometimes used to describe invisible radiations such as infrared and ultraviolet rays.

Line
The picture information contained in one horizontal sweep of the electron beam.

Linearity
The uniform distribution of picture elements over the total area of the image. Such uniformity can be achieved only if the sweep waveforms are linear. (See Linearity control.)

Linearization
An adjustment in the vertical or horizontal sweep oscillator which controls the linearity of the sawtooth and consequently the uniform distribution of the picture elements of the image. If the sawtooth is not linear, the spot sweeps across the screen at a varying rate rather than at a constant rate, with the ultimate result that the image is spread out near one edge of the picture and crowded toward the opposite edge.

Luminous intensity
The term used to describe the candlepower of a source of light.

Magnetic focus
The process of focusing the electron stream in a cathode-ray tube by means of a magnetic field.

Magnetic sensitivity
The relationship between the current passing through the deflection coils and the physical distance by which the electron stream is displaced.

Mechanical scanning
The process of breaking down an image into a number of picture elements called scanning. If this scanning is accomplished by mechanical means such as a Nikprow disc, the system is called mechanical scanning. Electronic scanning used in modern television practice is far more satisfactory than mechanical scanning.

Microwave relay
A system of increasing the range of television coverage by reception and rebroadcast of the signal over a chain of towers located 10 to 25 miles apart. Each tower contains a receiver to pick up the signal from the preceding tower and a transmitter to rebroadcast it to the following tower. These receivers and transmitters operate in the microwave region, which extends from 3,000 to 30,000 mc.

Minimum resolving distance
The distance an observer may move away from a television image and still be able to distinguish the individual horizontal lines of the picture.

Monitor
A cathode-ray tube used at the studio or transmitter to enable the operator to judge the content and quality of the image.
THE safe current flow through an ordinary phototube is but a few microamperes, which is much too small to operate an ordinary relay directly. Most phototube relay circuits resort to thermionic-tube amplifiers. Such circuits, using heated-cathode tubes, always waste power unnecessarily. This article presents several simple and practical phototube relays which use cold-cathode tubes exclusively.

A gas-filled phototube consists of a central wire-rod anode, a large sheet-metal cathode with light-sensitive surface, and an atmosphere of some inert gas such as argon. The anode wire collects the electrons liberated from the cathode upon exposure to light and the additional electrons liberated by the resulting collisions with gas molecules. With the anode at a positive potential so that there is an electron flow between electrodes, the phototube can be considered as a resistance which changes its value with exposure to light. The resistance is high and the current passed is feeble, so electronic trickery is needed to make the ordinary relay respond.

The Cold-Cathode Diode

Fig. 1 reveals the first phototube relay circuit using two cold-cathode diodes. A 918, 921, 923, or 930 phototube is the first and an OA3 (VR75) glow-discharge voltage-regulator tube the second. With the selenium rectifier and the 40-µf electrolytic capacitor, a d.c. potential of well over 100 volts is developed. The voltage forces a trickle of current through the potentiometer and its series resistor to charge the 0.5-µf capacitor. The voltage across the terminals of the capacitor increases directly with the charge until a critical value is reached. At this point the gas within the OA3 tube, which normally serves as a good insulator, becomes ionized and passes a current which rapidly discharges the capacitor through the coil of the adjustable-contact relay. The cycle repeats itself, for the circuit is a relaxation oscillator.

The phototube controls the relay indirectly by regulating the capacitor's charge rate. With switch S2 in position A, the phototube is in effect connected across the glow-discharge tube and paper capacitor. With exposure to light, decreased resistance of the phototube tends to discharge the capacitor and by so doing slows down or completely stops the pulses through the gas tube.

In actual use, the potentiometer is adjusted so that no glow discharge occurs when the phototube is illuminated; then, upon extinguishing the light, the capacitor becomes charged so that a pulse occurs and the relay closes. Switching S2 to position B reverses the operation. Upon exposure to light, the charging current is increased; the potentiometer is adjusted for no discharges with no illumination. Upon exposure to light, a discharge takes place and the relay is energized.

At the time of a discharge, the sensitive adjustable relay is momentarily operated. This rapid closing and opening of contacts being unsuitable for most devices, a delaying arrangement is employed. The surge of current through the coil of the adjustable relay opens contacts which allow current to flow from the 40-µf filter capacitor through both relay coils in series. This new energizing current maintains the contact originated by the pulse and also closes the output-controlling contacts. With switch S1 closed, the 40-µf capacitor is kept charged and the relay contacts are held closed until the switch is opened or the power supply disconnected.

With S1 open, the 40-µf capacitor is connected to the rectified power source by the normally closed contact of the s.p.d.t. relay; when a pulse is received and the relays are energized, the supply connection is broken and the relays are held closed for only a few seconds by the discharging filter capacitor. After the contacts return to their normal positions, the capacitor is again charged by the power supply and the phototube circuit is ready to start a glow-discharge impulse at any time.

Ample constructional information is given by the schematic diagram of Fig. 1 and photographs. The potentiometer can best be adjusted for different lighting conditions with a piece of paper inserted between the normally open contact and the armature of the adjustable relay. This permits observation of the oscillation rate by the flashes within the OA3 tube. The reason for specifying an adjustable s.p.d.t. relay is to allow setting the contact spacing and spring tension for positive action on the first discharge pulse. With feeble illumination the discharge pulses may occur as far spaced as a minute and with ordinary lighting they may occur many times per second.

Relay constructed according to Fig. 1.

By BOB WHITE

Fig. 1—Pulses caused by OA3's discharge trip the adjustable 2-ma relay.
The applications for this device are numerous and, because of the difference in operating principle from the ordinary phototube relay, much more unusual. A typical use would be to operate a display window light; with the phototube controlled by the sun, during the night the contacts would close and open each few seconds and cause the electric sign to flash on and off. Another very suitable application would be as an alarm. A concentrated beam of light could be directed across a doorway or other open space to the phototube unit. Switch S1 could be left open, and any interruption of the beam of light would cause a bell to be operated by the output contacts for about 2 seconds. Or instead, if S1 were closed, an interruption of the beam would ring a bell continuously until S1 were opened. In such an operation involving a brief break in the light beam, it is vital to have illumination of sufficient intensity to allow setting the glow-discharge rate to complete one pulse cycle before light is restored.

The Cold-Cathode Triode

A change to a more conventional type of phototube-relay operation is made possible through the use of the OA4-G cold-cathode triode. The physical form of the elements within this tube differ somewhat with the manufacturer. In general, this triode consists of a glass bulb containing an atmosphere of an inert gas, a cathode in the form of a large metal disc or cylinder, an anode of a straight wire enclosed except for a short length by a glass tube, and a starter anode of a small wire. The starter anode is mounted much closer to the cathode than the anode because the required voltage between electrodes for ionization of the gas is much less with a shorter spacing distance. Once the discharge between the closely spaced starter anode and cathode has begun, free ions are produced which trigger the main discharge between the anode and cathode.

An interesting and useful action of the OA4-G tube is its ability to rectify alternating current. The current flow within such a tube is roughly proportional to the negative, electron-emitting electrode area. When the cathode element is made negative by the impressed a.c. supply, a much greater current can flow, because of the large area of influence, than when the anode wire is made negative. This action allows the use of d.c. relays with appropriate capacitors in shunt to filter the current. With an a.c. supply the applied voltage drops to zero many times each second and the starter anode is capable of determining whether or not the OA4-G should conduct each time. With d.c. the voltage ordinarily never reaches zero; and once a discharge is started, the starter anode has no control over it until conduction can be stopped by momentarily breaking the supply connection.

The cathode of such tubes as the OA4-G is coated with oxides of active metals which become partly reduced during manufacture and which continue to be reduced slowly during its conducting period. The gradual use up of the active metal gives the tube through its negative alternation.

This circuit was constructed on an aluminum chassis measuring 4 x 2 1/2 x 11/16 inches, and the complete unit with power cord weighs less than 1 pound. Components worth honorable mention are the 0.5-µf capacitor shunted across the relay coil to prevent chatter and the 500-ohm resistor to limit the conduction current to a safe value. The output terminal strip provides switching action through posts 2-4 or 2-3 and by joining 1-2 provides controlled line voltage from 3-5 or 4-5.

Fig. 2 shows another phototube relay. It is made in the form of an alarm system, but can easily be adapted for other uses. Without illumination the 5.1-megohm resistance maintains the starter anode above its critical value and causes conduction in the OA4-G tube; the relay is energized and the

Under-chassis view of the relay constructed from the schematic shown in Fig. 1. a definite length of life. For this reason it is only sensible, in the case of a great unbalance of the illuminated and unilluminated time, to choose the shorter period for the OA4-G to conduct. This is the reason for providing two circuits; the first conducts when the phototube is exposed to light, the other when it is removed from light.

Fig. 2 is the simpler circuit. Illumination has the effect of decreasing the resistance of the phototube and causing an increase in the applied voltage to the starter anode. Upon reaching the critical glow-discharge voltage, the starter anode enables the main discharge to take place and the relay to become energized. Absence of light lowers the control voltage below the critical value; the starter anode then fails to renew the conduction after the alternating current source has passed.

Photograph of the simpler unit. Note its compactness and placement of tubes.

Construction
Bell sounded continuously. Exposure of the photocell to light increases the current flow through the resistance and thereby decreases the starter-anode potential in respect to the cathode to below the lower critical value; the discharge is stopped, the relay is unenergized, and the bell is silenced.

The entire alarm unit can be housed within a small metal cabinet such as the surplus interphone amplifier box measuring 5" x 4" x 2½ inches shown in the photographs. This phototube relay was constructed to be mounted on one side of a doorway with a concentrated beam of light directed at it from a source on the opposite side. The bell sounds when the beam of light is interrupted.

An important characteristic of the cold-cathode triode is that a higher control voltage is needed to start a glow discharge than is required to maintain it. In Fig. 2 this means that a brighter light is necessary to start conduction than is actually required to continue it, once started. In Fig. 3 a brighter light is required to silence the bell than is actually needed to keep it from starting to sound. This behavior of the OA4-G in the alarm circuit can be put to practical use. By including a series rheostat or a tapped transformer in the light-source circuit, the intensity of the light can be made adjustable. At normal illumination the bell rings only whenever the source is being interrupted.

With dimmed illumination, at a momentary interruption of the light the bell sounds continuously until the light intensity is restored to normal. The dimmed burglary-alarm connection would conserve power and would be less easily seen.

The three phototube-relay circuits are given in decreasing order of sensitivity. Of interest in all three circuits is that no ground or electrical connection of any kind need be made to their chassis or cabinets.

**Sources of light**

For operating a device from natural daylight or darkness, good indirect sunlight is all that is required as a source. For applications involving such a function as opening a garage door upon exposure to headlights of a car, there is again no concern about a source of illumination.

An incandescent lamp located at the focal point of a good circular-paraboloid reflector makes an excellent source of illumination. The purpose of the reflector is to direct as much of the radiation as possible into a narrow beam.

A good and inexpensive source is provided by the lamp and reflector of a flashlight operated through a small step-down transformer. Where a great distance is to be covered, an inexpensive source such as a sealed-beam spotlight will be required. Ordinarily, as the shaft of light leaves its source, it diverges; the area illuminated increases greatly with distance. At the phototube the sensitized cathode is not large enough to benefit from all of the energy reaching the relay unit and for this reason it is sometimes advisable to employ a large condensing lens to collect part of the wasted light.

The plano-convex condensing lens is placed a short distance in front of the cell with its flat surface toward the cell so that the light is converged as uniformly as possible upon the cathode.

To make the relay insensitive to stray light, place a tube or hood over the opening in the front of the case. Coat the inside of the tube with flat black paint to reduce reflections.

**Connect TV Sound to Hi-Fi Amplifier**

A friend wanted to connect the a.f. output of his TV receiver to the audio system of a high-fidelity radio-phonograph console, with all controlling done at the TV receiver when it was in use. No additional controls could be added to either set. Furthermore, he wanted to be able to detach the TV set and use it with its own speaker at any time. The drawing shows how the problem was solved.

A small s.p.d.t., d.c. relay was mounted near the volume control on the combination and connected as shown. A four-prong male connector was mounted on the rear of the combination chassis and a connecting cable was made from a shielded lead and a length of high-voltage insulated wire. One end terminated in a male octal plug and the other in a four-prong female connector. The octal plug replaced the power amplifier, a 6V6, in the TV receiver. The shielded conductor was connected to the grid pin and the insulated line to the plate pin on the plug. An a.c. receptacle was connected across the primary of the power transformer in the combination and mounted on the chassis where the TV line cord could be plugged in.

Current for the relay is taken from the plate pin of the output tube socket. The relay used drew approximately the same current as the 6V6, however, if its resistance had been too low or too high, a limiting resistor could have been used in series with its coil or a shunt resistor across it. The relay should draw the same current as the 6V6 so that the focusing and other voltages are not disturbed.

The TV set is operated by first turning on the combination. This will operate normally until the TV set is turned on. When this is done, the audio circuit is excited and the a.f. grid in the combination is switched from its volume control to the audio line from the TV set. Both sets can be turned off at the console but the radio or phonograph will not play until the TV set is turned off.

If the audio output from the TV set is at too high a level, it will not be possible to get good volume control using the control on the TV set. This can easily be remedied by adding a voltage divider ahead of the relay in the audio line.—Ross H. Snyder

**Radio-Electronics** for
Portable Broadcaster

By OTTO WOOLEY, W9SGG

Built to provide fun and amusement for the family and friends, this tiny home broadcaster was so well received that we believe that others may care to duplicate it. As a source of amusement, its applications are limited only by the user's ingenuity and imagination. Solid construction insures frequency stability which permits the unit to be operated while being carried in the hands, so we named it Carry-Talky.

A very minimum of parts is required, and the little rig can be built in a pleasant evening's work. The schematic is shown in the diagram. The basis for construction is a Signal Corps BC-1366 Jack box. These boxes and the T-17 microphone are readily available in the surplus market. The box comes with a wafer switch, volume control, and phone and microphone jacks. All parts are removed except the microphone jack. The switch hole is enlarged to accommodate a seven-pin miniature socket for the 185 tube. A discarded i.f. transformer with one good winding was used for the frequency-determining circuit. An additional winding was placed on the form to provide a feedback coil. The i.f. can and the microphone transformer are mounted on top of the jack box lid, and the remaining components are wired in place on the bottom side of the lid. The midget 67.5-volt B-battery is secured to the back of the box by wires passed through holes in the rear wall.

The antenna post is a feed-through insulator mounted in the hole that originally held the phone jack. An antenna of 18 or 24 inches will give sufficient signal for use about the house. For more power, use a loading coil at the lower part of the radiator as shown in the photographs. Of course a longer piece of wire may be used as an antenna, but it will make the unit inconvenient to use when walking around.

The filament and microphone switches are built into the T-17 microphone, and all that is necessary to insure proper operation is to make the microphone jack connections as shown. There being no battery drain until the microphone button is depressed, the batteries should last a long time. The B-battery current is less than 6 ma. The unit will operate on only one 1 1/2-volt A-battery if a jumper is used between the A-plus terminals; however, fairly strong talking will be required for good modulation. The addition of the second A-battery in the microphone circuit allows very full modulation at low voice levels. The tone quality and modulation are good.

No trouble should be experienced in getting the rig to work. The feedback coil, 25 turns of No. 32 d.c. wire, is placed close to the i.f. winding with its turns wound in the same direction. It may be necessary to reverse the leads to this winding to secure oscillation. The rig is tuned by the i.f. trimmer capacitor. The model shown is tuned to about 550 kc. and the second harmonic may be heard at 1100 kc. It may be necessary to remove a few turns from some i.f. coils to permit tuning into the lower end of the broadcast band. It is possible to set the transmitter on the receiver's intermediate frequency so the signal may be heard regardless of the receiver dial setting. However, a receiver with a high-gain i.f. stage will be required for satisfactory reception.

With the exception of the filament voltage and the coil specifications, the component values are not at all critical and may be varied as much as 50% with no appreciable effect in performance of the unit.

Inasmuch as the total B-battery input to the tube in transmitting is approximately 0.3 watt, there is little likelihood of interference to nearby receivers. However, no attempt should be made to send a signal beyond the immediate premises. FCC rules are very strict regarding any unnecessary interference that might be intentional. But it may be pointed out that this rig operates on the same principle as phono oscillators (wireless record players) and similar devices, so the prospective builder need have no cause for concern when using the unit in the manner intended. It does in fact make a good phono oscillator if a crystal pickup is inserted in the circuit instead of the mike transformer secondary.

As an inexpensive source of enjoyable entertainment the Carry-Talky is hard to beat!
Custom Sound Installation

Profitable opportunities are waiting for capable sound technicians in the field of individually engineered home phonograph (and also radio) equipment

William Rivkin*

More and more owners and purchasers of radio and phonograph equipment are looking with favor on the idea of "built-in" radios and music systems. There are advantages both of style and economy. Custom sound installation is accounting for a continually increasing portion of our business, and a correspondingly larger share of the profits. The field offers an excellent opportunity for the average radio technician, particularly if he has ability and experience with sound. While he should generally confine himself to the electronic and acoustic angles of the installation, leaving the woodworking to a skilled carpenter or cabinetmaker, he should have a knowledge of what can be done, and what provisions must be made in the construction for housing the electronic equipment. Then he can act as a consultant to the customer, or to the carpenter or cabinetmaker who does the work. In many cases, alterations in bookcases or other existing construction can be made by anyone handy with woodworking tools—and the radioman may find himself capable of doing the complete job.

The illustration on this month's cover is a good example of one type of custom installation. The wall unit was built specifically to house a complete high-fidelity system and blend perfectly with the room decoration. Although the room was designed with the help of an architect, the construction was done by carpenters with materials commonly available at any lumber yard. The radio unit, matching bookcases along the other two walls, and the room and cabinet doors all are finished in combed plywood paneling. For the door panels the plywood was cut in pie-slice sections to form the corrugations into concentric squares.

The system installed in the radio unit consists of a Webster-Chicago three-speed changer, an RJ-20 Browning FM-AM tuner, a Lafayette high-fidelity amplifier, and a 15-inch Stephens speaker. The record changer, mounted on slide-drawer brackets, is housed in the upper left of the cabinet spaces. The door is hinged on the left side to allow easy access to the changer. On the right, also behind a side-hinged door, is the tuner unit. Both these units are placed at convenient operating height. The amplifier is mounted below the tuner unit so that its controls and the remote speaker jack can be brought up to the tuner control panel. All units are connected by plug-in cables and are easily extractable for servicing. This is an important feature. Proper provision for future servicing included in the planning and installation stage can save many headaches later on.

The large speaker baffle at the top of the unit has a Venetian-blind grille which blends well with the over-all design. Walls and sides behind the baffle are insulated with Tufflex sound-absorbing material to reduce vibrations. A portable speaker was also installed to bring listening pleasure to either of the two porches adjoining the room. It is rigged with a remote volume control on a T-pad hookup. Convenience features like these are often big selling points.

Another feature is a sliding shelf just above the generous and well-placed record spaces. Records and albums may be set on the shelf while making selections and loading the changer. The shelf slides back into the unit when not in use.

An installation may be improved almost without limit. For instance, in this case the lower-left cabinet section is not now being used, but perhaps it could be utilized to increase the convenience of the installation as a storage space for the remote speaker or for small items such as record cleaner.

A neat installation

In another recent installation, a complete system was housed within the wall itself (see Fig. 1), saving floor space and avoiding blocking a rather

*Manager High-Fidelity Sound Dept., Lafayette Radio, New York, N. Y.
narrow passageway. A deep wall was used in building this ceiling-to-floor unit which is directly opposite a set-in bookcase of similar design. The system includes a Radio Craftsmen RC-8 tuner and amplifier, an Altec 603B speaker, and a Webster-Chicago 356-27 record changer with G-E variable-reluctance cartridges, and a G-E pre-amplifier.

The controls and record changer are mounted at a convenient height for tuning and record handling, with the amplifier and preamp behind the tuner unit. This provides service accessibility to all three units at the same time and leaves more space for storage. The large storage spaces above and below the units will accommodate almost any record library.

Good results were obtained with the FM dipole and AM loop mounted on the side wall behind the amplifier. This eliminated the need for concealing lead-in wires from the outside.

The baffle for the 15-inch speaker is mounted behind the grille panel. It is a separate piece set at an angle to direct the sound down into the room. The grille panel opens on a piano hinge to provide access to the speaker. Varied effects and more flexibility in speaker arrangement can be obtained in this way.

### Demountable Custom Installation

Still another installation recently developed by the engineering staff of Lafayette Radio consists of rather simple bookcase sections set into a wall recess (Fig. 2) giving the effect of an in-the-wall job. The units included a Browning FM-AM tuner, an Altec amplifier, a Webster-Chicago 356-1 record changer, and an Altec speaker and cabinet. Due to room layout, it was decided to place the system in the recorded section at one end. But arranging the components presented a problem. The speaker cabinet alone was not wide enough to fill the wall space and the tuner and amplifier together were too wide for the top of the speaker cabinet.

The arrangement which finally proved satisfactory consisted of cabinets and bookcases built around the speaker cabinet in four separate sections. Convenient and sufficient record space was provided, the controls are readily available, the finished job is attractive and can be disassembled easily. This is an important feature for apartment dwellers, since the entire system can be removed whenever necessary. The front panels on the tuner and on the amplifier are also removable to permit easy servicing. Good results and short lead-in wires were obtained by mounting the FM and AM antennas in the cabinet closest to the left.

In this case the record changer was installed as a chairside piece to suit the owner's personal taste. This is another important point: the personal preference of the owner, where practi-
M ECHANICAL limitations of the disc recording medium have led record manufacturers to adopt a somewhat complex recording characteristic. At frequencies below crossover, a constant-amplitude recording characteristic is utilized to prevent cutting through the lands separating the grooves. Above the crossover frequency, recording is at constant velocity. At the highest frequencies, pre-emphasis is superimposed on the constant-velocity characteristic to minimize the surface noise of the record.

Phonograph pickups may be either amplitude- or velocity-actuated. Crystal and strain-gauge pickups are examples of the amplitude-actuated reproducer, which generates an output proportional to the stylus displacement. Magnetic and variable-reluctance pickups are velocity-actuated reproducers whose output is proportional to the stylus velocity. Because a single reproducer cannot be both amplitude- and velocity-actuated, equalizers are necessary to complement the recording characteristic.

Amplitude-actuated reproducers

Considerable variance exists between the recording characteristics used by the different record manufacturers. However, the NAB lateral characteristic may be used as an average for American-made records.

The NAB lateral characteristic utilizes constant-amplitude recording below a crossover of 500 cycles and constant-velocity recording between 500 cycles and 1500 cycles. Above 1500 cycles the use of pre-emphasis results in a return to a constant-amplitude characteristic. The idealized equalizer requirements for the reproduction of a record based on the NAB lateral characteristics by an amplitude-actuated pick-up are presented by the dashed line of Fig. 1. A suitable equalizer is diagrammed in Fig. 1, and the equalizer frequency response is shown by the solid curve.

The solid curve indicates the actual NAB characteristic. The dashed idealized curve is no longer used, even for reference, but it is useful for instruction.

The equalizer design is based on a constant-voltage source and an infinite load impedance. The latter may be had by connecting the equalizer output to the grid of a vacuum tube. The constant-voltage source may be approximated with a low-mu triode preamplifier or by using a plate load resistance of less than 50,000 ohms with a pentode or high-mu triode preamplifier.

British (London ffr) recordings differ from the NAB characteristic in the use of a 250-cycle crossover frequency and in less high-frequency pre-emphasis beginning at 3,000 cycles. The idealized equalizer requirements for the reproduction of British recordings with an amplitude-actuated reproducer are illustrated by the dashed curve of Fig. 2. The solid curve of Fig. 2 is the frequency response of the equalizer circuits shown. (The range of ffr's actually goes up to 14,000, with a sharper pre-emphasis after 12,000 cycles.—Editor)

A complete equalizer circuit for use with an amplitude-actuated pickup is diagrammed in Fig. 3. This unit may be constructed as a separate preamplifier or the design may be incorporated in a complete phono amplifier. The low-mu triode-plate results in a net equalizer gain of 20 db. A three-position switch permits selection of the NAB, British, or a flat curve. A variable treble-cut scratch filter is included. The dotted curves of Figs. 1 and 2 show the effects of the scratch filter when R2 = 0.

The input resistor R1 should be selected in accordance with the manufacturer's specifications for the particular pickup used. C1 must have a reactance, at the lowest frequency to be amplified, of less than one-fifth the input impedance of the amplifier following the equalizer.

If the plate supply is taken from the following amplifier stages, it will be necessary to insert a 10,000-ohm, 10-uf plate decoupling circuit in the B-plus line to prevent feedback.

The values of the components are not particularly critical, and small alterations in values may be made to complement the idiosyncrasies of the individual pickup. Decreasing the values of R3 and R4 will increase the amount of treble boost. Decreasing C3 and C4 will move the response curve to the right, raising the frequency at which treble boost begins.

Velocity-actuated reproducers

The idealized equalizer requirement for the NAB characteristic with a
magnetic or variable-reluctance pickup is shown by the dashed curve of Fig. 4. A bass boost of 6 dB per octave below a 500-cycle crossover and a treble roll-off of 6 dB per octave above 1500-cycle crossover are required. The two separate equalizer circuits presented in Fig. 4 are recommended. The solid curves represent the individual equalizer frequency response characteristics. The combined effect is shown by the dotted curve of the figure.

The circuits and curves for equalizing British ffr recordings with velocity-actuated reproducers are presented in Fig. 5.

Preamp for velocity pickup

A complete equalizer-preamplifier circuit for use with a velocity-actuated pickup is diagrammed in Fig. 6. Two three-position selector switches permit the selection of any combination of bass boost and high rolloff. A variable treble-cut scratch filter is provided for use with noisy recordings. Low-mu triodes provide a constant-voltage generator for the equalizer networks as well as provide a net gain in the order of 30 dB.

R1 should be selected to accord with the manufacturer’s specifications for the pickup. The reactance of C1 at the lowest frequency should be less than one-fifth the input impedance of the following amplifier. The values of the equalizer components may be altered to provide additional correction for the peculiarities of the pickup. Decreasing R2 will increase the amount of bass boost. Increasing C2 and C3 will lower the frequency at which bass boost begins. Increasing C5 and C6 will lower the frequency at which treble rolloff begins. Capacitor C4 and the 10,000-ohm resistor form a decoupling network to insure circuit stability by preventing any feedback through the high-voltage circuits.

Frequency test records

The over-all performance of the pickup and equalizer-preamplifier combination may be checked most conveniently with a frequency test record. The author recommends the Columbia 10003M and 10004M. The response curves obtained with these records should be substantially flat to the point at which high frequency de-emphasis begins. Beyond that point the frequency response should follow either the NAB equalizer curve in Fig. 4 or the British equalizer curve in Fig. 5, depending upon the particular equalizer settings.

Above all, do not be discouraged by deviations of your experimental curves from the ideal. At best, equalization is a compromise between recording characteristics and pickup response variations. The best criterion for the effectiveness of any equalizer is listening pleasure, and the optimum equalizer is the circuit which achieves the most realistic record reproduction.

APRIL, 1950
Kit manufacturers are now turning to television service instruments

Television Test Equipment Kits

Considerable interest in our February survey of sweep generators and oscilloscopes for television testing has been expressed by readers. A number have urged that we print a similar article covering the television test instruments sold in kit form.

At the moment of writing, it appears that only three manufacturers are selling kits for sweep generators or television-type oscilloscopes. Radio City Products was about to put kits on the market, but did not have complete specifications ready in time for the article.

The only two sweep generator kits offered are by Eico and Heath. Complete specifications for both are given in the table. Each uses a combination of fixed and variable oscillators to cover the wide band of frequencies required in such instruments. Eico’s model 390 uses a variable oscillator with a range from 54 to 114 mc and a 114-mc fixed sweep oscillator. The two oscillators produce difference and sum frequencies to cover the 0-60 and the 168-228-mc spectra. The second harmonic of the difference frequencies covers the range from 0 to 120 mc.

The Heathkit TS-1A has a variable sweep oscillator which provides the signal from 174 to 220 mc. The band from 0 to 46 mc is provided by beating the sweep oscillator against a fixed 174-mc oscillator, and the band between 54 and 100 mc is covered by beating against a 274-mc oscillator. The sum frequencies fall outside the television frequencies.

A loudspeaker-type motor supplies the FM (sweep) modulation in both generators. This method provides a sweep range 30 mc wide.

Both generators have internal provision for marker pips. The Eico generator uses half a 12AU7 as a crystal oscillator for use with external crystals, producing strong marker pips at the fundamental and at several of the harmonics of the crystal used. (The other half of the 12AU7 is a mixer tube for the output of the fixed and variable oscillators, providing a cathode follower output tube for the generator.)

The TS-1A has an ingenious absorption circuit—in effect a wavetrap tuned to the desired marker frequency. A sharply defined notch is cut out of the output wave at the frequency of the marker. The marker tuning capacitor is adjusted for calibration before shipment, and can be used for calibrating the generator ranges.

The most important special feature required in an oscilloscope for television use is wide vertical amplifier bandwidth. An ordinary “broad-band” scope

is useful for observing i.f. response curves where only the low-frequency modulation pattern is under observation. As the width increases, the scope becomes more useful in tracing troubles in the sync and sweep circuits whose steep-fronted pulses make wide frequency response necessary. The ideal would be an oscilloscope with a 4.5-mc response, which would show the complete modulation pattern. Unfortunately, such scopes are too expensive for the average service technician, and the practical service scope represents a happy medium between technical perfection and economic reality.

Three TV oscilloscope kits were on the market at the time of writing—the Eico 425, Feiler TS-7K, and the Heathkit O-5. The tendency is toward a bandwidth of about half a megacycle though the Heathkit is listed as “useful to 2.5 mc.” An interesting feature in the Feiler kit is provision for connecting headphones. In many cases, puzzling interference can be identified immediately by simply listening to it, and this feature is worth adding to existing scopes.

A real necessity, in the author’s opinion, for the service technician, this signal generator takes the place of ordinary variable-frequency generators, having greater accuracy on the frequencies most used for broadcast-receiver alignment, and is a terrific time saver, too, in lining up push-buttons on sets that have them.

The generator is entirely controlled by push-buttons. Crystal-controlled signals are provided for the four most common i.f.’s: 455, 460, 465, and 470 kc. The crystals were obtained on the surplus market. When you buy them, do not be misled by the white markings on the holders; these crystals were used in Signal Corps equipment on the 54th harmonic of the fundamental crystal frequency. Another i.f., 262 kc, and six broadcast-station frequencies are available by making the oscillator self-controlled.

The push-button feature is a product of the writer’s servicing experience. Re-adjusting station-selector buttons on large receivers ordinarily requires switching from manual to buttons and back again many times to make sure of getting the right button for the right station and tuning it on the nose. On i.f. alignment, the thought always crops up, “How many kc off calibration is my generator dial?” Moreover the switching and tuning are nuisances. All these items are time killers to the man whose time is his stock in trade. With the push-button generator, a single motion brings the desired frequency and (on the i.f.’s, where it is most important) with crystal accuracy.

The basis of the circuit is an electronic-coupled oscillator, which can be either self-controlled or crystal-operated, and a triode modulator. The power supply is “transformerless,” but to isolate the chassis from the line—an absolute necessity for test equipment—we included a pair of 6.3-volt filament transformers back-to-back, as the diagram indicates. The 6.3-volt windings supply voltage for the tube filaments.

Quick Tuning Generator

By M. RABINOWITZ

It would be much simpler to use a 1-to-1 transformer with a 6.3-volt winding, but the writer has yet to see one.

Two push-button assemblies were needed, one with a trimmer strip. All are RCA receiver replacement units, though surplus stores offer many suitable miscellaneous assemblies at rock-bottom prices. On this particular trimmer strip, one side of each trimmer is bonded to the support, so that was insulated from chassis by ceramic stand-offs.

The cabinet is a standard metal one 5x9x9 inches, with a hinged lid, allowing ample room for parts. The top row of buttons selects station frequencies. The left button on the lower row transfers control to the upper row, and the others in the lower row select i.f.’s.

The schematic diagram gives all the necessary information for the wiring. The photograph gives an idea of the front panel layout.

Adjustment

The first step is to see that the audio oscillator is working. Ground one lead from a pair of phones and touch the other, through a .05-µf capacitor, to pin 7 of the 6BJ6. If you hear no audio note, reverse the connections to the plate winding of the transformer. To change the pitch of the tone, replace the .05-µf 6C4 grid capacitor with a different value.

To determine if the r.f. oscillator is running, connect a high-resistance voltmeter or v.t.v.m. from grid of the 6BJ6 to ground. There should be a negative reading for all push-button settings.

Next adjust the station buttons on the top row. Press the lower left button to place them in the circuit. Six stations are allowed for, the larger trimmers being for the lower-frequency stations. To calibrate them, tune in the desired stations successively on a receiver and adjust the trimmer until you hear zero beat in the speaker. Adjust for the lowest frequency first. To adjust the 262-ke trimmer, plug a pair of phones into the closed-circuit jack. Couple the output of an accurate 262-ke generator loosely to the 202-ke coil with a few turns of wire placed a few inches from it, and tune the 262-ke trimmer for zero beat.

Two push-button assemblies are used. Crystals provide the most common i.f.’s.
Battery Signal Generator

Easily built portable test generator covers range of 130 kc to 16 mc in 5 steps

For the rural service technician and experimenter, this battery-powered, portable, all-wave signal generator tunes from 130 kc to 16 mc in 5 ranges. It has a 1N5-GT r.f. oscillator and a 1G4-GT a.f. oscillator that can be used alone or as a modulator for the r.f. generator. Power is supplied by a 1½-volt A-battery and a 45-volt B-battery. Most of the parts can be found in the junkbox or salvaged from old receivers.

This case makes the instrument portable. Batteries are inside and a handle is on the cover.

DEAL for the rural service technician and experimenter, this battery-powered, portable, all-wave signal generator tunes from 130 kc to 16 mc in 5 ranges. It has a 1N5-GT r.f. oscillator and a 1G4-GT a.f. oscillator that can be used alone or as a modulator for the r.f. generator. Power is supplied by a 1½-volt A-battery and a 45-volt B-battery. Most of the parts can be found in the junkbox or salvaged from old receivers.

By J. C. ANDERSON

The r.f. generator is a standard Hartley oscillator with the 1N5-GT connected as a triode. The grid is returned to the midpoint of two 100,000-ohm resistors across the filament supply. This places an initial bias of +0.75 volt on the grid. This tube is plate-modulated by the 1G4-GT when a modulated signal is desired. The range switch is in the center of the panel above the tuning control. The other controls are in a row across the bottom. From left to right these are the function switch, modulator switch, multiplier, and attenuator.

When the function switch is in position 1, the filaments of both tubes are lighted and the 1N5 generates a signal whose frequency is determined by the setting of the range switch and the tuning control. An unmodulated signal is obtained when the modulator switch is open. When it is closed, the signal is modulated at about 1,000 cycles. Moving the function switch to position 2 grounds one end of the transformer secondary, and the signal is modulated at about 400 cycles. The 400-cycle a.f. signal is available at the output terminals when the function switch is turned to the No. 3 position. The modulation frequencies are determined by the size of the capacitor across the plate side of the audio transformer.

Two r.f. output levels are available, selected with the multiplier switch. The low-level voltage is taken from the plate circuit of the 1N5-GT through a .01-uf blocking capacitor. When the signal is taken from the pickup loops, it is about

Instead of a standard chassis, author fastened metal strips to rear of panel.
10 times stronger than the low-level signal. The attenuator controls the strength of the signal at the output terminals.

If only a single output level is sufficient, remove the .05-μf capacitor from across the plate winding of the audio transformer. This will raise the level available directly from the r.f. plate coils almost to that obtained from the small pickup coils, which may then be omitted. There will also be some change in the audio modulation frequency.

The oscillator tuning capacitor is a standard two-section broadcast tuning capacitor with its sections connected in parallel. The low-frequency coil used in the 138-520-kc range is a three-pie coil salvaged from an old European receiver. We isolated one piece and used it as the tickler. A tap was made at the connection between the remaining pieces and connected to the range switch.

When this switch is in position A, both pieces are used and the tuning range extends from 130 to 520 kc. When the switch is in position B, a single piece is used and the tuning range is 230 to 680 kc. We used an old broadcast oscillator coil to cover the 550-1800-kc range.

The two high-frequency coils were wound on 1-inch forms. The grid coil of the 1600-5600-κc coil has 36 turns of No. 24 s.c.c. wire, and its tickler has 23 turns of No. 28 s.c.c. The coils are spaced 7/8 inch apart. The 5000 to 16,000-κc coil has seven turns of No. 18 wire on the grid winding and nine turns of No. 28 s.c.c. on the tickler.

The pickup coils for the two low-frequency coils are four turns each. Pickup coils for the 1600-5500-κc and 5000-16,000-κc coils have one turn and one-half turn, respectively. The ticklers are on one end of the coil forms, and the pickup coils on the other.

The low-frequency coil can be made from an i.f. transformer or r.f. choke. The broadcast and shortwave coils may be standard three-band antenna, r.f., or oscillator coils.

The simple circuit of this signal generator can be constructed by almost anyone who can follow a schematic diagram.

Construction

As shown in the photographs, the oscillator was built into a standard metal carrying case (often known as a "utility box") obtainable in radio parts stores. A standard chassis was impractical because of the shape of the case, so several strips of aluminum were cut up to support the components. There are not many parts in the instrument but nevertheless the constructor should be very careful to lay out the "chassis" in such a way that the batteries have plenty of room. The main point is to get the assembly as high in the cabinet as possible.

The batteries may be clamped to the removable rear panel with metal straps or angle brackets can be used to make brackets for them. They should be fastened down solidly so they don't rattle around.

A - 130-520 KC
B - 230-680
C - 550-1800
D - 16-5600
E - 5-16
CL - 365 μf EACH

Each range coil has three parts—oscillator tuning, tickler, and output coupling.

EXTENDING RANGE OF V.T.V.M.

Range and utility of an electronic voltmeter can be extended by adding two banana jacks and a s.p.d.t. switch. Mount the switch and jacks on the panel and connect them as shown in the diagram. Operation is normal when the s.p.d.t. switch is in position 1. To increase the resistance range of the meter, set the range selector to R x 1, throw the s.p.d.t. switch to position 2, then insert a suitable precision multiplier resistor in the jacks.

Care must be taken when using a soldering iron near the precision resistors in the ohmmeter, because overheating them is likely to change their values permanently. Two resistors can be matched by connecting one across the ohmmeter test leads and plugging the other into the jacks. They are equal when the needle rests in the center of the scale, having previously been zeroed with the jacks open.

The precise value of a resistor can be ascertained by connecting it to the resistance test leads and connecting a decade resistor box to the jacks. The unknown resistor is equal to the setting of the decade when the needle is centered. The accuracy will be as great as that of the decade resistors.—L. M. Dilley.
The author explains how waveforms and meter design can affect the accuracy of the technician's voltage measurements.

By IRVING DLUGATCH

A VOLTMETER is supposed to supply vital information about an electrical circuit. It can do its job well only when used for the type of measurement for which it is specifically designed. Too often, the technician is unaware of the narrow limitations of his meters.

In radio work, the instruments are usually correctly applied. In television servicing, one needs to know the frequency and waveform to interpret the strange results sometimes obtained with ordinary meters.

Let's begin with a conventional D'Arsonval-movement d.c. voltmeter. Current flowing through the meter's coil produces motion by reaction between the coil's magnetic field and a fixed magnetic field. It is the average value of the current which produces the deflection.

This is best illustrated by imagining the voltage of Fig. 1-a being measured by our voltmeter. The coil swings in one direction for the positive half of the cycle and in the opposite direction for the negative half. If both alternations are equal in amplitude, we have equal swings. The average of the two swings is, of course, zero, which is what the meter reads. The swinging of the needle is visible only if the frequency is very low. The meter reading is the average of the instantaneous motions of the needle, the average of the currents flowing through the coil over a short period of time. All d.c. meters are calibrated in average values.

Average and r.m.s. values

What is the significance of the average value? Vacuum-tube potentials and currents may vary with instantaneous signal level but proper operation is often determined by the average values. On the other hand, circuit components and the tubes themselves must be selected on the basis of the heating effect of the currents passing through them which depends on the effective or r.m.s. value. For Fig. 1-b, a d.c. "wave," the average, effective, and peak values are alike. The d.c. meter is designed to measure this type of voltage accurately for only then can it register the heating effect directly. Compare this with Fig. 1-a where the meter would read nothing, yet we know the effective value is as great as for Fig. 1-b.

Before going any further, it is necessary to understand how the average and effective values are calculated for any wave. We will then better appreciate the results that are to be expected in making pulse measurements with conventional meters. Step 1 in our calculations is to divide one cycle of any wave into a number of equal time intervals. The greater the number, the better the accuracy. In Fig. 1, the waves are divided into eight parts, though this is far too few for any accuracy. We will then note the amplitude at each of these intervals.

The direction of the current flow has no bearing on its heating effect. Both the negative and positive alternations of a current heat equally a resistor through which it flows. (Note that Fig. 1-g has the same effective value as 1-a.) In other words, polarity is ignored for r.m.s. calculations, but not for averages.

Step 2 is to calculate the average value by adding all the amplitudes and dividing the sum by the number of intervals. Table I lists the data for four of the waves illustrated in Fig. 1. The others are obtained similarly.

As a sample of the calculation of the average value, for Fig. 1-d, the sum of the amplitudes is 400 volts. Dividing by the number of points taken, 8, we arrive at an average value of 50 volts. For 1-a we get zero volts.

The effective value is next calculated. The heat produced by a current varies directly as the square of the current (P = I^2/R), or of the voltage (P = E^2/R). The term r.m.s. means "the square root of the average of the squared amplitudes." That is, the effective current is that whose square is the average of all the heating effects. For a sample calculation, for Fig. 1-d (see Table I), the sum of the squared values is 40,000. Dividing by 8, the average of the squares is found to be 5,000. The square root of 5,000 is 70.7 which is the r.m.s. value for the wave. Calculating for Fig. 1-h, we find the effective value is equal to the peak, and the average value to zero.

It is somewhat simpler to understand this last, if we imagine any a.c. wave as it would appear after full-wave rectification as in Fig. 1-g, compared with 1-a. This is in agreement with what has been said about the direction of the current flow being unimportant. The calculations are based on this "rectified"
wave. For 1-h we would get a straight line or pure d.c., which accounts for the peak, r.m.s., and average values being the same.

Coming back to our d.c. voltmeter, let's see what happens in the measurement of pulsating d.c. voltages. If Fig. 1-d were the plate voltage of a tube, the 50-volt average value would be used in determining the gain or power-handling ability of the tube. The 70.7-volt r.m.s. value would be needed to calculate the wattage of the load resistor. The peak value of 100 volts should be known to select tubes and capacitors that won't break down. The meter, however, is giving us only the average value of 50 volts. Usually a large safety factor is used in selecting components so that this is not too important. It does indicate, however, how little information a d.c. meter may supply about an electronic circuit. (Other effects may make the reading inaccurate even for the average values.)

Fig. 2—Circuit of a d.c. voltmeter.

The square wave of Fig. 1-d is formed by the addition of a great many harmonics. It is very possible that many of the harmonics will be lost due to bypassing capacitance in the meter circuits. Something like Fig. 1-c might result. Assume that the peak value remains as high as that of the original square wave. (This is very unlikely.) Then the average value of the effective value is 50 volts, as calculated from Table I. Our meter would read too low. This extreme case indicates what is to be expected and is not to be taken as a practical example.

There is yet another cause of error in using the meter on pulses. Look at Fig. 2, the electrical circuit for the d.c. voltmeter. R is the large value of resistance used as a multiplier and L is the inductance of the meter coil (usually small in value). Such a circuit is a differentiator. The voltage across the inductance might look like Fig. 1-e if the square wave were applied to the input terminals. It is easy to see that the average and r.m.s. values might be far different from those of the original square wave.

The inaccuracies noted above seem to be avoided by the use of a d.c. vacuum-tube voltmeter operating on peak values. From Fig. 1 it is obvious that, regardless of wave shape, the same peak value will be read for c, d, and e. Unfortunately, the meter is intended to be used with voltages such as Fig. 1-b where the peak value is also the average and r.m.s. value. This is not true with a new dial or a new multiplier, is not correct for any but sine waves.

For example, r.m.s. value = form factor X average value meter reading. For the sine wave of Fig. 1-a, meter reading = 1.11 X 63.6 = 70.7 volts.

Let us assume a waveform similar to Fig. 1-d with an average value of 63.6 volts. Then its meter reading would be 1.4 X 63.6 = 89.04 volts. However, the meter is calibrated on the basis of a sine wave's form factor. Therefore, we will read 70.7 volts instead of 89.04 volts for the square wave.

Where the multiplier is shunted with a capacitor, there is additional error due to the effect of the capacitor on the waveshape. It tends to block the low frequencies in the special wave. In addition, it is possible for resonance to occur at certain frequencies because of L and C in series (Fig. 3). Of course, shunt capacitances still exist to bypass higher frequencies. At high frequencies, many rectifiers will not operate. All of which stresses the fact that even a knowledge of the form factor of a wave is not sufficient to correct a reading obtained with such an instrument.

The solution seems to be the use of an a.c. v.t.v.m. Again calibration introduces error. Most v.t.v.m.'s operate on the peak value of a wave. This must be converted to an a.c. reading for usefulness. In other words, the needle deflection must be reduced by increasing the size of the multipliers or the dial must be marked with lower values since the reading is too high. For sine waves, the ratio between the peak and r.m.s. is 1.41. Compare this with 2.0 for Fig. 1-c, 1.41 for 1-d, and 1.72 for 1-e. It would be correct for the square wave but too low for the other two. The v.t.v.m., too, has the same faults as the rectifier instrument as far as waveshape changes, resonance, and shunt capacitance. In addition, for waves with unequal alternations, we may get different readings when the test leads are reversed. This does not take into consideration error due to poor grounding of the meter. Some of the troubles are avoided by using special probes.

All of this may frighten the technician away from the use of voltmeters for signal tracing in television sweep circuits. However, they are valuable for quick comparison checks on equipment with which the technician is familiar, or for determining whether the pulse is present. Interpretation of the meter reading should be attempted only with the assistance of an oscilloscope.

**APRIL, 1950**

www.americanradiohistory.com
THE last chapter discussed the common garden variety of power supply diagrammed in Fig. 1. While this supply does an excellent job, there are at least three things wrong with it from the point of view of the radio manufacturer: it is heavy, it is bulky, and—most important of all—it costs too much.

Fig. 1—A basic full-wave power supply.

All three of these complaints point accusing fingers at the bulky, heavy, expensive transformer and iron-core choke. To get rid of these two items—especially the transformer—was a must for compact, lightweight, cheap receivers. Disposing of the choke was easy. As we shall learn in the next chapter, many speakers have field coils that consist of thousands of turns of wire wound on an iron core. Direct current must pass through this coil to make the speaker perform as it should. If we replace our filter choke with this field coil, such a current will pass through its turns; furthermore, the ready-to-hand inductance of the iron-core coil will perform exactly the same filtering job that the choke has been doing. Thus, by making the field coil do double duty, we can discard the filter choke.

Getting rid of the transformer, however, is like trying to put on Uncle Tom’s Cabin without Simon Legree. It may be a villain, but it plays important parts in both the A- and the B-supplies. Radical changes must be made in both of these before the transformer out can be torn out by the roots and discarded.

Fig. 2 shows the first step in accomplishing this. The filaments of all the tubes and a ballast resistor are connected directly across the 117-volt a.c. line. As can be seen, the voltage needed across the string of tube filaments is the sum of the individual tube requirements. The difference between this voltage and the line voltage is accounted for by the voltage drop across the ballast resistor.

In Fig. 2, for example, are two tubes with 25-volt filaments and three using 6 volts on the filaments. That means that 68 volts is needed across the filament string. The ballast resistor, then, must be designed so there will be a 49-volt drop across it when the tubes are drawing their rated filament current.

The tubes used in the first a.c.-d.c. sets had filaments that drew 0.3 ampere. When this current is multiplied by the 49-volt drop across the resistor, the resistor dissipates 14.7 watts in doing its voltage-dropping chore.

This amount of heat being constantly released within the close confines of a small cabinet did the capacitors and other parts no noticeable good; so the ballast resistor was fabricated as a separate, asbestos-shielded resistance wire right into the line cord. This took the heat out of the cabinet, all right; but unfortunately the resistance wire did not take too kindly to the twisting, bending, and tying-into-knots that most line cords suffer.

Then the tube manufacturers came dashing to the rescue. They brought out sets of tubes whose total filament voltages were exactly equal to the line voltage; and, to reduce the heat dissipated by the tube filaments, they reduced the current requirements to 0.15 ampere. This got rid of the ballast resistor as well as the filament-heating portion of the transformer; and these tubes, with their various octal, loktal, or miniature bases, are the ones used in most a.c.-d.c. sets today.

There is only one flaw in the setup—it is hard on tubes. Any service technician knows that he will put three tubes into a transformerless receiver for every one he replaces in a set using a transformer. The fault is that the cold filament resistance is much less than the hot filament resistance. As a result, when the set is first turned on, a heavy surge of current passes

Here's the only complete Buying Guide to everything in TV, Radio and Electronics—packed with the world's largest selections of quality equipment at lowest money-saving prices! See the latest in TV, AM and FM receivers; radio-phonos; new Sound Systems and P.A. equipment; high-fidelity custom sound components; recorders and accessories; full selections of newest Amateur receivers and station gear; test instruments; builders' kits; huge listings of parts, tubes, tools, books, diagrams—all in stock for immediate shipment.

ALLIED gives you every buying advantage: speedy delivery, expert personal help, lowest prices, assured satisfaction—plus the most liberal Time Payment plan in radio. Get the 1950 ALLIED Catalog—it will save you time and money. Send today for your FREE copy!
2 Pages of TEST EQUIPMENT at prices every serviceman can afford!

OUR POLICY

MONEY BACK? Every unit we advertise is offered on a strict "money-back-if-not-satisfied-basis". No ifs—no buts—no maybe's. If you are not completely satisfied after a 10 day trial—return for complete refund. No explanation—you are the sole judge. Plain enough?

GUARANTEE? Every unit sold by us is covered by a one year guarantee.

KITS? We have discontinued advertising Test Equipment in kit form. After handling kits for a period of three months, we have come to the conclusion that it is impractical to successfully complete instrument kits at home without the expensive calibration standards and other equipment available when instruments are factory produced.

THE NEW MODEL 200

AM and FM SIGNAL GENERATOR

Specifications
- R.F. FREQUENCY RANGES: 100 Kilocycles to 150 Megacycles.
- MODULATING FREQUENCY: 400 Cycles. May be used for modulating the R.F. signal. Also available separately.
- ATTENUATION: The constant impedance attenuator is isolated from the oscillating circuit by the buffer tube. Output impedance of this model is only 100 ohms. This low impedance reduces losses in the output cable.
- OSCILLATORY CIRCUIT: Hartley oscillator with cathode follower buffer tube. Frequency stability is assured by modulating the buffer tube.
- ACCURACY: Use of High-Q permeability tuned coils adjusted against 1/10th of 1% standards assures an accuracy of 1% on all ranges from 100 Kilocycles to 10 Megacycles and an accuracy of 2% on the higher frequencies.
- TUBES USED: 12AU7—One section is used as oscillator and the second is modulated cathode follower. T-2 is used as modulator. 6C4 is used as rectifier.

The Model 200 operates on 110 Volts A.C. Comes complete with output cable and operating instructions.

$18.85

SUPERIOR'S NEW MODEL TV-10

TUBE TESTER

Specifications
- Tests all tubes including 4, 5, 6, 7, Octal, Lock-in, Peanut, Bantam, Hearing Aid, Thyatron, Miniatures, Sub-Miniatures, Novals, etc. Will also test Pilot Lights.
- Tests by the well-established emission method for tube quality, directly read on the scale of the meter.
- Tests for "shorts" and "leaks" up to 5 Megohms.
- Uses the new self-cleaning Lever Action Switches for individual element testing. Because all elements are numbered according to pin-number in the RMA base numbering system, the user can instantly identify which element is under test. Tubes having roped filaments and tubes with filaments terminating in more than one pin are tested with the Model TV-10 as any of the pins may be placed in the neutral position when necessary.
- The TV-10 does not use any combination type sockets. Instead individual sockets are used for each type of tube. Thus it is impossible to damage a tube by inserting it in the wrong socket.
- Free-moving built-in all chart provides complete data for all tubes.
- Newly designed Line Voltage Control compensates for variation of any line voltage between 120 Volts and 130 Volts. The Model TV-10 operates on 105-130 Volt 60 Cycles A.C. Comes housed in a beautiful hand-rubbed oak cabinet complete with portable cover.

RADIO-ELECTRONICS for
Superior's new model 770

AN ACCURATE POCKET-SIZE VOLT-OHM MILLIAMMETER

(Sensitivity: 1000 OHMS PER VOLT)

**FEATURES**

- Compact—measures 31/4" x 51/4" x 21/4".
- Uses latest design 2% accurate 1 Mil. D'Arsenal type meter.
- Some zero adjustment holds for both resistance ranges. It is not necessary to readjust when switching from one resistance range to another. This is an important time-saving feature never before included in a V.O.M. in this price range.

**SPECIFICATIONS**

6 A.C. VOLTAGE RANGES:

0-15/30/150/300/1500/3000 VOLTS

6 D.C. VOLTAGE RANGES:

0-7.5/15/75/150/750/1500 VOLTS

4 D.C. CURRENT RANGES:

0-1.5/15/150 MA, 0-1.5 AMPS.

2 RESISTANCE RANGES:

0-500 OHMS 0-1 MEGOHM

**PRICE**

$13.90

Superior's new model 670

SUPER-METER

A COMBINATION VOLT-Ohm MILLIAMMETER PLUS CAPACITY REACTANCE INDUCTANCE AND DECIBEL MEASUREMENTS

**SPECIFICATIONS**

D.C. VOLTS: 0 to 7.5/15/75/150/750/1500/7,500 Volts
A.C. VOLTS: 0 to 15/30/150/300/1500/3,000 Volts
OUTPUT VOLTS: 0 to 15/30/150/300/1500/3,000 Volts
D.C. CURRENT: 0 to 1.5/15/150 MA, 0 to 1.5 Amperes
RESISTANCE: 0 to 500/100,000 Ohms 0 to 10 Megohms
CAPACITY: 200 to .2 Mfd., 1 to 4 Mfd.
(quality test for electrolytics)
REACTANCE: 700 to 27,000 Ohms 13,000 Ohms to 3 Megohms

**PRICE**

$28.40

**ADDED FEATURE:**

The Model 670 includes a special GOOD-BAD scale for checking the quality of electrolytic condensers at a test potential of 150 Volts.

$28.40

The model CA-11

SIGNAL TRACER

SIMPLE TO OPERATE... BECAUSE IT HAS ONLY ONE CONNECTING CABLE—NO TUNING CONTROLS!

**FEATURES**

- SIMPLE TO OPERATE—only 1 connecting cable—NO TUNING CONTROLS.
- HIGHLY SENSITIVE—uses an Improved Vacuum Tube Voltmeter circuit. Tube and resistor-capacity network are built into the Detector Probe.
- COMPLETELY PORTABLE—weighs 5 lbs. and measures 5"x6"x7".
- Comparative Signal Intensity readings are indicated directly on the meter as the Detector Probe is moved to follow the Signal from Antenna to Speaker.
- Provision is made for insertion of phones.

**PRICE**

$13.50

through the filament wires. The strong magnetic fields that surround adjacent loops of the filament wire inside a cathode set upon each other, making the filament “wriggle” violently under the influence of this heavy current; and often the movement either fractures the filament or causes it to short out to the cathode sleeve.

The only reason the transformer is easier on tubes is that the regulation of the voltage delivered by the filament secondary is much poorer than that of the line. When there is a demand for heavy current, the transformer secondary voltages sag and so cannot deliver it; but the 117-volt line can and does put it out—much to the detriment of the tube filaments.

Fig. 4—Supply for three-way portable.

Just to show how radio engineering progresses in spirals, a new type of ballast resistor just introduced has a cold resistance several times its hot resistance. With such a resistor in series with the tube filaments, the initial current is quite low and rises slowly to the rated value as the filaments come up to their proper operating temperature. Since this arrangement is said to be even more gentle on filaments than a transformer, do not be surprised if we go back to ballast resistors.

But now let us look at Fig. 3, which is the essential power supply circuit of an a.c.-d.c. receiver, and see how the B-voltage is secured. All of the tube filaments are hooked in series directly across the line. The plate of the half-wave rectifier tube is connected to the top side of the line. The cathode of this tube is connected through the filter choke and the load resistance to the other side of the 117-volt a.c. main.

Outside of the fact that our rectifier has a cathode, this rectifier circuit is very similar to the half-wave transformer circuit described in Chapter XIII. In that circuit, however, the electrons that flowed to the plate from the cathode during the portion of the cycle when the former was positive, returned to the cathode by flowing around through the transformer secondary and the load resistance. In this circuit, there is no such apparent low-resistance return path from the plate to the “B-Minus” lead.

There is a return path, nevertheless, even though you do not see it. This path is through the windings of the generator producing the 117-volt a.c. fact that the generator may be several miles away from the point where the receiver is operating means nothing to an electron that cruises at a rate of about 186,000 miles a second!

The filter circuit operates just as did those described last month. The working stage of the filter capacitor does not need to be so high, because the rectifier puts out only slightly more than 100 volts of filtered d.c. Capacitors of 150 working volts are normally used. Quite often the filter choke is replaced by a 1,000-ohm resistor, while such a resistor is cheaper, it is not so good at filtering as is the choke; thus it is necessary to increase the size of the capacitors to around 50 μf each.

If this a.c.-d.c. radio were plugged into a 117-volt d.c. main with the positive side of the line connected to the plate, current would flow through the rectifier continuously instead of in pulses as it does on a.c. The d.c. would heat the filaments just as well as a.c., and our set would operate quite satisfactorily. A transformer set could not operate on such current, for the d.c. would quickly burn out the transformer primary.

That is why manufacturers call these transformerless sets “a.c.-d.c.” Of course, the possibility that the ordinary buyer will use the set on d.c. (except in a few large cities) is about equal to that of his winning the Irish sweepstakes, but it is much better sales psychology to talk about even the most useless “extra” your product may have than it is to mention what has been left out!

The three-way portable does still better. It will work on 117 volts of either a.c. or d.c., or on self-contained batteries. Fig. 4 shows the basic power supply of such a receiver. When the 8-amp switch is thrown to the battery position, the 7.5-volt A-battery heats the four filaments hooked in series, and the 90-volt B-battery supplies the plate and screen voltages.

When the switch is thrown the other way, the selenium rectifier permits the 117-volt a.c. across it to pass in only one direction. By chemical action, this compact little rectifier does the same job that a diode vacuum tube would perform—and does it without drawing filament current!

One branch of the rectified output flows through R1 and R2 and the filament string back to ground. The drop across the two resistors is such that just the required 7.5 volts of d.c. appear at the ungrounded end of the filament string. C1 and C2 work in conjunction with the resistors to filter the voltage used on the slender, battery-saving, 50-μa filaments. This pure d.c. is necessary to prevent hum with such tubes, because they are very sensitive to filament-voltage changes (so sensitive, in fact, that most of these sets go dead on a.c. if the line voltage falls below 100%).

R3 and R4 provide further filtering for the other branch of the rectifier’s output that supplies the plates and screens of the tubes.

(Continued on page 54)
The transformerless power supplies so far discussed have outputs roughly equal to the line voltage, but it is possible to secure an output voltage twice the line voltage without using a step-up transformer. This is done by a gadget called a voltage doubler, one form of which is shown in Fig. 5.

When the side of the line connected to the plate of the upper diode is positive, electrons attracted from the cathode leave C1 with a charge nearly equal to the line voltage. When this same side of the line swings negative, current flow ceases in the upper diode.

Fig. 5—A full-wave voltage doubler.

but as the cathode of the lower diode becomes more and more negative, electrons flow from it to the plate and charge C2 to the line voltage. C1 and C2 are connected so that their charges are in series and add together; therefore, twice the line voltage appears across the load resistance.

In practice, instead of separate tubes, a twin diode with individual cathodes is normally used. Probably voltage doublers would be more popular if it were not for the fact that the output voltage is very dependent upon the capacitance and condition of C1 and C2. Too, the output voltage falls off rapidly when the load current is increased.

Auto-radio supplies

The typical American cannot long enjoy doing anything unless he can do it in his car, so he began to demand an automobile radio. The first ones used the car battery to heat the filaments of the tubes and B-batteries to supply the other-electrode voltages. But the radio engineers began schem-
SAVE 25 TO 52% BY BUILDING YOUR OWN LABORATORY PRECISION TEST INSTRUMENTS!

NEW TV-FM SWEEP SIGNAL GENERATOR KIT

EICO
Model 360-K
$29.95

Crystal marker oscillator with variable amplitude. Covers all TV and FM alignment frequencies between 500 kc. and 228 mc. Sweepwidth variable from 0.5 to 360 cycles with mechanical inductive sweep. Extremely wide sweepwidth allows gain comparison of adjacent mc., 500 IN voltage wave frequencies. Complete with cables and case. Complete with STEP-BY-STEP INSTRUCTIONS and EASY-TO-FOLLOW DIAGRAMS.

NEW 5' OSCILLOSCOPE KIT

EICO
Model 425-K
$39.95

All-new laboratory precision scope has Push-Pull deflection and 0.5 to 1 volt per inch sensitivity. Wide range, built-in gain setting, useful to 25 mc. Wide-range, multivibrator, sweep circuit from 1 cps to 75,000 cps. Direct connection to plates of CRT available at rear of cabinet. 2 axis intensity modulation feature included. Size: 61/2" x 15" x 15" high. Complete with 3-6SN7, 2-6J5, 2 of SY5, BPI CRT, 110-125 v., 60 cycles AC, Shpg. wt., 30 lbs. IN KIT FORM.

VACUUM TUBE VOLTMETER KIT

EICO Model 221-K
$23.95

Triode tuned balanced bridge circuit. New features include Zero Center for TV discriminator adjustment. 1 Meg. DC input impedance. Accuracy 0.5% meter calibration. Complete with 41/2" meter case with crossed rubproof panel. 110-125 v., 60 cycles. Price $23.95

HIGH FREQUENCY RF PROBE KIT

EICO Model P-75K
$3.75

Germanium crystal probe for visual RF signal tracing and measurements to 250 megacycles. 61/2" long, 12" D.D. Shpg. wt., 10 oz. IN KIT FORM.

HIGH VOLTAGE PROBE

EICO Model HVP-1

$6.95

Measures up to 30,000 volts. Special HV Multiplier Resistor for all 20,000 shunt ohm voltmeters with 1000 volt scales and most VTVM's. Lucite handle, or 1000 volt scales and most VTVM's. Lucite handle, or a 1000 volt scale. In KIT FORM.

HAPPY 50TH ANNIVERSARY OF LAFAYETTE!
The new UNIVERSITY POWRMIKE opens a new field for sound distribution. Low in cost, requiring no amplifier, completely portable, POWRMIKE can be used in thousands of applications where power supply or high cost rule out sound amplification. POWRMIKE has a maximum output of 1.5 watts, reproduces speech with excellent fidelity and is instantaneously operated by handy press-to-talk switch. Additional speakers may be added for broader coverage and special switching arrangements.

POWRMIKE is the perfect answer for voice amplification in stores, carnivals, rallies, waiting rooms, auctions, outdoor markets, sight seeing buses and boats, school group activities, police and fire department work, etc. Get the complete story on sensational POWRMIKE, today.

MODEL PC-66 — For applications requiring portability. Includes: POWRMIKE microphone wired to loudspeaker, "Hot-Shot" type battery mounting bracket with volume control, and automobile current adapter.

MODEL PC-60 — For mobile operation and special installations. POWRMIKE microphone, loudspeaker, and automobile cigarette lighter adapter, supplied unwired.

WRITE DEPT. D FOR ILLUSTRATED CATALOG
$12.95 TAKES ALL 3 BIG BARGAINS

1. SENSATIONAL, FASCINATING, MYSTERIOUS SYLVESTER. Brand new original made by 0.000. Company. Two or more connected together work perfectly on all VHF & 120 VDC. Any number of the same or different sets connected together will rotate exactly as one. Never to be seen again. $12.95.

2. AC-DC POCKET TESTER

AC-DC Pocket Tester

For the owner of your own test lab at a fraction of the cost of a high-priced professional instrument. Complete with instructions and operating manual. 

Deluxe AC-DC Radio Kit

High quality standard production line radio in kit form with complete instructions. Features 2-conductor output, 2 input jacks, transformers, and high-quality transmitting coils (inductive or self-oscillating). Tubes include U-634, 14, 24, 30, 121, 127, 127 and 127. Total retail $7.95 or $2.50 framed.

Phono Scratch Eliminator

Consists of 2 resonators and patented stop noise connected in series and designed to eliminate noise in any phonograph. Complete with instructions and operating manual. 

New G.T. Transmitter

Ideal 1956 General Electric UC-355, UC-310 transmitter, including 12 and 24 - V. transformers, complete with instructions and operating manual. Complete use of 12 and 24 - V. transformers. Total retail $5.95.

Sodium 64 Portable

6, 13 and 24 volt, crystal-controlled transmitter receiver with built-in microphone or you receive, no extra charge.

AC-DC Pocket Tester

This analyzer, featuring a sensitive repulsion type meter housed in a bakelite case, is the result of 15 years achievement in the instrument field by a large company specializing in electronic test equipment. Specifications of the AC-DC Model Volt-Ohm-milliammeter: AC and DC volts 0-10, 0-15, 0-30, 0-150, 0-300, 0-600, 0-1200, 0-1500, 0-6000. Ohms Full Scale - 100,000. Ohms Center Scale - 1200. Capacity 0-15 Mfd. Total price prepaid any where in the USA $7.50. Similar DC Meter, lacking AC operated ranges of above, $5.50 prepaid.

PORTABLE AIR COMPRESSOR $14.50

Portable air compressor and air line. Hermetically sealed, using lifetime belt sealed ball bearing on connecting rod and anti-moisture rubber sealing on shaft. Unique design. Ideal for spraying paints or lacquers, disinfectants, insecticides, etc.

"DRILLMASTER" ELECTRIC DRILL

Ideal for hobbyists. Complete with sanders, buffers, grinding wheels, etc. Only a few are available. Sensational bargain at $9.95. Satisfaction guaranteed or money refunded if returned prepaid within 3 days.

3 gang broadcast band PERMEABILITY TUNER

was $3.50, NOW $1.50

SENSATIONAL BUT

SOS EMERGENCY TRANSMITTER

Famous Gibson-Girl Transmitter that saved lives of thousands of people. Sensational bargain at $9.95.

DELUXE AC-DC RADIO KIT

High quality standard production line radio in kit form with complete instructions. Features 2-conductor output, 2 input jacks, transformers, and high-quality transmitting coils (inductive or self-oscillating). Tubes include U-634, 14, 24, 30, 121, 127, 127 and 127. Total retail $7.95 or $2.50 framed.

PHONO SCRATCH ELIMINATOR

Consists of 2 resonators and patented stop noise connected in series and designed to eliminate noise in any phonograph. Complete with instructions and operating manual.

NEW G.T. TRANSMITTER

Ideal 1956 General Electric UC-355, UC-310 transmitter, including 12 and 24 - V. transformers, complete with instructions and operating manual. Complete use of 12 and 24 - V. transformers. Total retail $5.95.

SCRA10 PORTABLE

6, 13 and 24 volt, crystal-controlled transmitter receiver with built-in microphone or you receive, no extra charge.

BUFFRAID SECTIONAL TOWER

This addition to the famous line of BUFFRAID antenna products makes up to a hundred foot tower from any number of strongly welded tee sections, which are shipped assembled and painted. Erection is a matter of minutes, and change to any other antenna is accomplished by standing up the completed portion of the tower with the next 25 in section to be installed. Bases and foot-holds are provided for safety and ease. Cap at top of tower provides bearing surface for revolving, and prevents water from entering tubes. Useful for police or amateur transmitters. In addition, tower provides satisfactory TV reception where otherwise impossible. Bases for supporting temporary or permanent power lines, wind generators, stadium lights, radio or voice transmission equipment, etc. "B" and "C" sections together cost a total of $15.75 and total 86 ft. A section, which makes up the entire tower top, are each ten feet long and each cost $12.75 apiece. Base base test shown is obtainable for only $6.00. Base is especially useful when erecting tower on a silo or roof.

PORTABLE AIR COMPRESSOR $14.50

Portable air compressor and air line. Hermetically sealed, using lifetime belt sealed ball bearing on connecting rod and anti-moisture rubber sealing on shaft. Unique design.

"DRILLMASTER" ELECTRIC DRILL

Ideal for hobbyists. Complete with sanders, buffers, grinding wheels, etc. Only a few are available. Sensational bargain at $9.95. Satisfaction guaranteed or money refunded if returned prepaid within 3 days.

Radio Repair Licensing:
Pedro Takes A Dim View

BY GUY SLAUGHTER

"How many lectruns in the orbutts of a merkry adam?" he stumbles

I, Pedro," I chirp, walking in and flinging my hat toward the rack in the corner. "You're early this morning."

"Yeah," he responds distastefully, shoving the push-broom across the floor. "You guys sure can be messy sometimes."

"Messy?"

He jerks his thumb at the litter of cigar and cigarette butts scattered over the floor.

"Oh that! Technicians' Association meeting last night."

"Yeah," Pedro mutters glumly, making with the broom. "I can tell. Must have been a hot discussion."

"It was." I riffle through the pickup cards on my desk, and deal them into piles according to their respective neighborhoods. "We decided to ask the City Council to start a licensing program."

"Humph?" Pedro stops sweeping, and leans gratefully on his broom. "For what?"

"For radio technicians," I explain. "Every repairman has to pass an exam before he gets a license. No license, no business."

"You're kidding, huh?" Pedro asks hopefully.

"No, I'm not kidding. There's too many screwdriver mechanics in town. They gyp the public and the public gets it in for all of us."

"So?" Pedro asks sarcastically.

"So if a guy don't know enough radio to pass the exam, he gets no license," I declare smoothly. "Just as simple as that!"

"How about crooks?" Pedro wants to know, still leaning casually on his broom.

"Guys that know radio, pass the exam, and still gyp people."

"We thought of that," I elucidate.

"If the City Council's licensing bureau gets too many complaints on a technician, then they go ahead and revoke his license."

"Won't work," Pedro says complacently. "Some people complain all the time."

"True," I admit, feeling a little irri-
tated. "But our Technicians' Association will act as an advisory board. we can tell whether complaints are justified or not."

"I get it." Pedro nods his head, and stares at me accusingly. "The old freeze-out, hunh?"

I think I see what he's driving at, but I choose to play dumb.

"Freeze-out?"

"Freeze-out," he repeats. "If a guy belongs to your club, you protect him. But if he doesn't, you get his license revoked and freeze him out of business."

"Pedro," I command, my plate current zooming, "you start shoving that broom instead of leaning on it, and I'll take care of the thinking around here." I go back to my bench, muttering to myself, and dig into a TV set that some amateur repairman has tinkered up. The audio is dead, and the video i.f. has been misaligned.

"Look here, Pedro," I yell. He drags his broom up to the bench, his face an emotionless mask. His feelings are hurt. "See what I mean?" I query. "Some screwdriver mechanic tried to fix this set, and just messed it up."

"Yeah," Pedro says. "Uh-huh."

"Not only couldn't he fix it," I continue, "but he jimmed up all the tuned circuits to boot. Now the owner'll have to pay for a complete realignment on top of the original repair."

"Too bad," Pedro murmurs. "And he'll probably jump me for charging him too much."

"Licensing would keep such tinkerers out of the business," I argue, pursuing the point.

"It doesn't take licensing," Pedro shakes his head. "The bum is all through in that neighborhood. The set owner'll tell his friends and they'll tell their friends, and that's that. A few jobs like this one, and he'll be out of business."

"I guess that's right. But the customers have to learn the hard way."

"Advertise," Pedro suggests disinterestedly. "Can I get back to my sweeping?"

He waltzes off with his broom, and I go to work on the TV set. When it is finished, I gather up my tools and get ready to start my pickups and deliveries.

It's almost closing time when I get back. Pedro is sitting at my desk, his feet resting comfortably on its top, talking on the telephone. He hangs up hurriedly when I walk in, and jumps to his feet self-consciously.

"Hi, Herk," he greets. "How did it go?"

"Okay," I say wearily, heading for the bench and setting down my tool box. "There's a bunch of chassis in the truck. Want to lug them in?"

"Sure," he answers cheerfully, disappearing out the door.

**It Pays to Advertise?**

I check the "to-be-repaired" rack to see what's come in during the day, and then go out front to look over the call cards on the desk. I find a sheet of paper rolled into my typewriter, and read it curiously. "Wanted!" it says.

"Information concerning gyp-artists. The Sequin Radio Technicians Association will welcome the opportunity to investigate any complaint you, the public, may wish to lodge against any of the local radio shops. Excessively high charges or inferior workmanship..." It ends there, and just then Pedro bustles through the door with an armload of chassis.

"Hey, Pedro," I demand as he lugs them through the door to the service bench. "What's this all about?"

"What, Herk?" he asks innocently, reappearing without the sets. Then he sees what I'm looking at, and starts to color a little. "Oh, that," he shrugs, trying to be nonchalant. "Just an ad I was working on."

"For what?" I ask, mystified.

"Well," he says, leaning on the counter and staring out the window self-consciously, "I figure if your association ran an ad like that in the paper and listed all the member shops, the..."

VEE-D-X TWIN LEAD
LIGHTNING ARRESTER

1. For outdoor or indoor use
2. High frequency - low loss
3. Easy to install
4. Unnecessary to cut transmission line for installation
5. Unnecessary to change spacing of transmission line
6. Does not vary impedance
7. High dielectric - low loss plastic material. Will not absorb moisture.

$2.00 list

public would steer clear of the other outfits.”

“Oh?”

“Sure,” he continues. “And the ad would make the nonmembers sit up and take notice, specially the crooked ones. They’d probably straighten up and want to join your association.”

“Yes,” I say patiently. “And I suppose you have some other ideas on the subject, too?”

He nods vigorously.

“If your outfit would hold classes for the guys who don’t know enough radio, you could help them and the public.”

“Pedro,” I tell him, smiling broadly.

“You’ve got an idea there!”

His face lights up like a 6-volt pilot bulb across the a.c. line, and his grin touches his ear lobes.

“Only,” I continue, “we’ve already voted for the licensing program, and that makes all your suggestions unnecessary.”

His grin fades like a scanning raster when the high voltage breaks down.

“It’s not too late, is it, Herk?” he asks breathlessly. “You can still call an emergency meeting and change it, can’t you? You’re the president.”

“Yeah,” I gloat, grinning at his discomfort. “I could, but I’m not going to!”

“It’s a mistake, Herk,” he waives.

“Once you get this license thing started, you can’t stop it!”

“Yeah! So it is.” I dig deep and pay him off. He starts for the coor, but he stops with his hand on the knob.

“Herk,” he says apologetically, “I can’t come in after school Monday.”

“Why not?”

“I’m student mayor for the day. Got to run the city.” He opens the door, and starts out.

“Congratulations, Pedro,” I answer with a laugh. “Don’t take any ribes.” I go back to the bench, and knock out some work.

Up Against the Law

Monday morning I’m plugging away at the bench, and the gong rings for the eleventh time, announcing a customer. Only this time it’s just a kid, maybe fifteen or so, and he’s looking very tough. His police cap sets down around his ears, and he’s not too clean.

“Hi, chum,” I greet him cheerily.

“What’s on your mind?”

“Ya Hercules Newton?” the kid growls.

“Yeah,” I acknowledge, surprised.

“Who’re you?”

“Chief a piece,” he snarls. “Where’s ya license?”

“License?” I ask, remembering Pedro’s remark about being mayor for the day, and deciding this kid’s playing cop in the same game.

“Ya. Technical license,” the kid snaps, putting his hands on his hips belligerently. “Have ta close ya up if ya ain’t got one.”

I decide to humor him.

“I don’t have one yet, chief,” I say.

“But I’ll be happy to apply for it. What do I have to do?”

The kid whips out a piece of paper, and reads it to me. It’s copied right out of a physics book, apparently, and the kid has trouble reading it.

“How many lecruits in the orbit of a mercary atom?” he stumbles.

“Sure, how many electrons in the orbit of a mercury atom?”

“At what I said.”

“I haven’t the faintest idea.”

“Too bad,” the kid declares, stuffing the paper back in his pocket. “Ya thunked the exam. No license. Gotta close ya up.”

$1,200.00 PRIZE CONTEST—
RADIO-ELECTRONICS IN THE HOME

Midnight of May 1, Eastern Standard Time marks the closing of the second month’s Radio-Electronics in the Home contest. Entries for the May contest must be postmarked before this date. The closing date for the April contest is midnight, April 3.

FIRST PRIZE . $50
SECOND PRIZE . $25
THIRD PRIZE . $15
FOURTH PRIZE . $10

Monthly prizes totaling $100 are given for the best ideas on applications of radio-electronics in the home.

Prizes will be awarded in accordance with novelty, general importance of the application or device, smallness of cost involved in building it, and practicability.

Any ideas may be submitted. Highest prizes will be awarded to contestants who have actually built the device and submit photographs to prove it. Lesser prizes will be given for "idees" and entries not accompanied by photographs.

For complete details and rules of the contest see page 35 of Radio Electronics for March.
The electron tube that rivals the human eye

Invention of the iconoscope—
TV’s first all-electronic “eye”—led to supersensitive RCA image orthicon television cameras

No. 3 in a series outlining high points in television history

Photos from the historical collection of RCA

Had you attempted to invent a television camera from scratch, odds are you’d have followed the same path as early experimenters—and tried to develop it on mechanical principles.

Illogical? Yes, in the light of what we now know about electronics. But electronics was young in television’s infancy. At that time the best way to take television pictures was with a mechanical scanning disk, invented in 1884.

Revolutionary was the invention of the iconoscope by Dr. V. K. Zworykin, now of RCA Laboratories. Here was an all-electronic “eye” for the television camera...no moving parts, no chance of mechanical failure!

Carrying forward the development of television pickup tubes, RCA scientists have developed the image orthicon—eye of today’s supersensitive RCA image orthicon television camera. So keen is this instrument’s vision that it sees by candlelight or by the faint flicker of a match.

Despite its simplicity of operation, the RCA image orthicon tube is a highly complex electronic device. Integrated, within its slim 14-inch length, are the essentials of 3 tubes—a phototube, a cathode ray tube, and an electron multiplier!

The phototube converts a light image into an electron image which is transferred to a glass target, and scanned by an electron beam to create a radio signal. The electron multiplier then takes the signal, and greatly amplifies its strength so that it can travel over the circuits which lead to the broadcast transmitter.

Inside the tube itself, more than 200 parts are assembled with watchmaker precision. For example, a piece of polished nickel is pierced with a hole one-tenth the thickness of a human hair...a copper mesh with 250,000 holes to a square inch is used...and the glass target is bubble-thin! Yet all are assembled and made to work—at RCA’s Lancaster Tube Plant—with precision.

Actually 100 to 1000 times as sensitive as its parent the iconoscope, RCA’s image orthicon pickup tube literally rivals the human eye. And when an outdoor telecast may start in daylight and wind up in the dim light of dusk—that’s a necessity!

Radio Corporation of America
WORLD LEADER IN RADIO—FIRST IN TELEVISION

Dr. V. K. Zworykin of RCA Laboratories with his iconoscope tube. Its successor, the image orthicon, has been developed by RCA scientists to have up to 1000 times greater sensitivity.

Mechanical scanning equipment, used at RCA-NBC experimental television station W2XBS in 1928, long before the present RCA image orthicon camera came into existence.
“Wait a minute,” I argue. “What difference does it make to a radio man how many electrons there are in any atom?”

“Ya oughta know,” the kid snarls.

“Can’t have no dummies in the bizness ta gyp the public. Wanna try the other exam?”

“Sure,” I say, smiling in spite of myself. “I’ll give her a whirl.”

He digs out another scrap of paper.

“What’s chums law?”

“Ohm’s law,” I translate. “That’s more like it. I equals E over R.”

“Don’t tell me about it,” the kid growls. “Fer this exam ya gotta write yer answers.” He pauses and scowls at me. “On a hunderd dollar bill!”

I go to the telephone and call the city hall, not quite sure whether I should laugh or get mad. I ask for the mayor, and sure enough, Pedro answers.

“Pedro,” I say. “This is Herk.”

“Hi, Herk. Call me Your Honor.”

“Okay, Your Honor. Your chief of police is trying to shake me down,” I say, eyeing the kid in front of the counter. He is still glaring at me, but not in the least perturbed otherwise.

“He wants me to write my license exam answers on a hundred dollar bill. Bribery.”

“No, Herk,” Pedro says calmly. “Not bribery. That’s to defray the cost of operating expenses in this licensing procedure. Perfectly legitimate. Better do like he says if you want your license.” He hangs up on me. I sit there a minute with a dead phone, and then I slam it down on its cradle.

“Look, chief,” I falter, facing the kid again. “There’s some cheaper way for me. What is it?”

The kid gives me a long look, and then whistles shrilly. Another boy about the same age answers the call by walking in the door, planting his feet wide apart in front of the counter, and winking solemnly at the chief of police.

“This here guy,” explains the chief, “has got a technician license. If ya hire him to run yer store for a fin a week, we won’t hafta close ya up.”

“Hi,” I ask the newcomer. “You know any radio?”

“Nope,” he says cheerfully. “Don’t know nothin’ about it.”

“Then how,” I ask him, “did you manage to get a technician’s license?”

“Politics,” the squirt replies, in a confidential tone of voice. He leans an elbow on the counter, spits on the floor, and whispers at me. “Me cousin’s a salverman.”

“Here’s a buck for you guys,” I say, suppressing a smile. “Now beat it and leave me alone.” They both grab the bill I hold out, and run through the door together, clutching the money between them.

I stand there at the counter a minute, scratching my head, and then I reach for the telephone again.

“Pedro,” I say when my connection is completed. “I mean, Your Honor.”

“Yes, Herk,” he says sternly. “Speak...
up, please. I'm a busy man."
"I'm convinced," I confess humbly.
"It could happen. You write that ad for me, will you?"
There is dead silence for a minute.
Then a little laugh sounds in my ear.
"Sure, Herk," he says happily. "I'll do it right away."
"That's swell, Pedro. Because I'm going to call an emergency meeting of the association for tonight. I'd like to read them your ad."
"Okay, Herk."
"And I'd like you to give your views on licensing at the meeting, too."
"Me?" Pedro gasps. "I'm just a kid."
"I'll have a ten dollar bill here with your name on it," I say softly."
"But there's one thing," Pedro continues hurriedly. "I'm awfully old for my age."

**UNIQUE CRYSTAL PROBE**

Many owners of such d.c. vacuum-tube voltmeters as the RCA Volt-Ohmyst have constructed a.c.-r.f. test probes for their instruments, using 1N34 crystal diodes. These probe circuits are peak-operated and are of the shunt-diode type.

The probe circuit shown in the accompanying circuit diagram is unusual in that it has an a.f.-r.f. voltage-quadrupling arrangement. Voltage stepup is obtained without a transformer. The d.c. output voltage of this probe is equal to approximately 5.66 times the r.m.s. value of the input voltage. This results in a much increased meter sensitivity. For example, the full-scale deflection on the 0-3-volt d.c. range of the VT voltmeter will indicate an a.f. or r.f. input voltage of only 0.53 volt r.m.s. when this probe is used.

Although the voltage-quadrupling probe uses four 1N34 crystals and four 0.01-μf postage-stamp mica capacitors, it may be built into a small-sized container. The crystal polarities indicated in the schematic must be followed exactly or the circuit will not multiply correctly.

It is advisable to make an individual voltage calibration after the probe has been completed and plugged into the d.c. vacuum-tube voltmeter, since the rectification efficiency of production-lot crystals varies and the 5.66 multiplication factor might not hold exactly for a particular quartet of crystals.—Rufus F. Turner

Static Troubles in Aircraft Radio

By THERESA M. KORN

Radio interference can be so destructive to communications in modern aircraft as to result in crashes. This is true, in particular, of aircraft navigated by radio. Visual indications of radar and other navigational devices can be obliterated by radio noise.

The air force and commercial services are keenly aware of the effect radio noise has upon the morale and efficiency of air crews. They have found that even small quantities of radio noise can become so annoying that, to escape it, crews turn down receiver sensitivity to such dangerously low levels that communication is unreliable.

Radio noise includes periodic corona discharges produced by electrical discharges, and man-made noise.

Corona discharges produce precipitation static, which resembles frying, crackling, and musical "crying" sounds together with rumbling background noise.

Precipitation static results when large electrical charges on propeller tips, antennas, and other aircraft extremities discharge into the surrounding atmosphere. These large charge densities are produced by the rapid impact and friction of rain, snow, sleet, hail, or dust upon the aircraft skin.

Another type of precipitation static, external field static, occurs during flight through the strong electrostatic fields of thunderstorms. By induction, large concentrations of positive or negative charges accumulate on some portions of the aircraft while other portions acquire an opposite charge, as shown on the Curtiss P-40 in the photo. Radio noise results when the charge concentrations reach the critical breakdown point of the adjacent atmosphere and corona discharges occur.

Corona discharge, or St. Elmo's fire, is sometimes visible to the occupants of the aircraft as streamers of bluish flame up to 6 inches long. To prevent such corona discharges, ten to twelve dry-wick dishantlers are mounted on aircraft extremities to drain off electrostatic charges to the surrounding atmosphere as they accumulate. The use of dielectric-covered wire in the new antistatic antennas also greatly reduces precipitation static.

Atmospheric static occurs in receivers as random bursts or crashes of varying amplitudes during the lightning discharges of thunderstorms. The intensity of this radio noise depends on the geographical location, season, and weather. It is most severe in the tropics during the rainy season.

Man-made noise

The most troublesome sources of man-made noise are the electrical transients caused by electrical rotating machinery, ignition systems, and other current-interrupting devices.

Of these, the worst radio offender is the ignition system. Each time a spark...
plug is fired, a steep-wavefront voltage, rich in harmonics, is set up. This interference may be severe unless the entire ignition assembly is effectively shielded to prevent radiation to receivers.

Ranking close to ignition noise in production of radio interference are various pulsed electronic devices, including radar equipment, which produces periodic pulses of high amplitude. Adequate shielding and placement of these units as far from receivers as possible is absolutely necessary.

Machinery with moving contacts (vibrators, relays, and voltage regulators) can produce clicks in receivers each time they make or break contact. These current interruptions cause transients that are not usually serious unless they are repeated frequently.

Less-important sources of man-made noise are industrial areas on the ground, electrical equipment in nearby aircraft, and interfering transmitter signals.

Although some hash may occur in receivers in the vicinity of large industrial areas, it is not a serious hazard since the intensity is usually low and the duration short. This is also true of radio noise from nearby aircraft, but this source can be very troublesome if the noisy aircraft is one of many other planes flying in close formation.

Radiation from other transmitters presented a special problem to military aircraft during the last war. Although some of these signals were from friendly transmitters, others were jamming signals from enemy sources that required special remedial action.

Receiver internal noise appears as a random sizzling, hissing, or crackling sound. In visual output devices, it causes the spurious indications called hash or grass. This background noise, inherent in the circuit components, is caused by thermal agitation in the receiver input resistance, tube hiss, and shot effect in radio-frequency stages. Leaky capacitors, defective batteries and tubes, poor contacts, and noisy carbon resistors are also noise sources. A periodic check of the equipment will help to keep these effects at a minimum.

When radio noise enters a receiver,
**General Industries**

**PHONOMOTOR MARKET**

"A motor for every phonograph requirement"... this General Industries slogan is as true today as it was thirty years ago when it was first introduced. Today General Industries manufactures a complete line of single-speed, dual-speed and three-speed motors for use in every type of record player and automatic record changer.

General Industries offers you the popular belt-drive Model TS 3-speed motor for both automatic record changer and manual use, and the turret model 3-speed motor illustrated for automatic record changer applications. Write today for complete details.

Electronics

it does so by either conduction, induction, or radiation.

Man-made noise, for instance, reaches the receiver through the common bus of the electrical system by conduction. Conductive coupling occurs only in circuits close to the noise source, since its effectiveness decreases as the square of the distance from the source.

As currents flow through the conductors, electromagnetic fields are set up around them. These fields are capable of initiating interference currents in the receiver. Parts of the fuselage, compartments, and bulkheads can be used as shields against inductive coupling.

Some of the electromagnetic fields about conductors of radio noise are radiated at the speed of light, just as radio-frequency energy is radiated from a transmitting antenna.

Paths of entry to the receiver for noise energy include the antenna and its lead-in, the receiver power and control wiring, as well as the receiver case and output leads. Radio noise energy can be kept out by suppressing it at its source, by adequate shielding and filtering, and by wisely selecting installation locations.

Extensive experiments have been conducted to determine the thresholds of intelligibility of speech under various noise conditions. The threshold of intelligibility is that speech-to-noise ratio at which the listener is just able to follow the gist of conversation through electrical noise. A speech-to-noise ratio of 4 to 1 is generally accepted, although then a listener misses almost 10% of the single, isolated words spoken. For reliable communication, a speech-to-noise ratio considerably greater than 4 to 1 is essential.

Ambient acoustical noise is not radio interference in the strict sense of the word, but it has an important bearing on the problem. A sufficiently large speech-to-noise ratio must be maintained despite the noise generated by the engine, propellers, exhaust, and slipstream. To do this, the receiver output must be greatly increased. However, increasing the receiver output amplifies the electrical noise as well as the signal. The resulting din is very annoying and lowers the crew's efficiency.

Until just a few years ago, the task of radio noise elimination amounted to merely attaching a filter here, adding a bit of shielding there, and assuming the remaining noise was an insurmountable evil. Today extensive research and experimentation show that a surprisingly large amount of radio noise can be eliminated on the designers' drafting boards even before the airplane or its components are built. The responsibility for low-noise design in aircraft lies with three key men: the radio and electronic equipment designer, the electrical equipment designer, and the radio installation designer.

Even with good design, however, there is sometimes a certain amount of radio interference that must be eliminated. The amount of this noise can be measured only by testing the completed installation under flight conditions.

RADIO-ELECTRONICS
GEIGER TUBE FEEDBACK

RESPONSE amplitude of many Geiger-Muller-counter amplifiers may be increased, sometimes spectacularly, by adding surge-type feedback to the circuit. Click amplitude increases greatly, and very little is added to the weight of the equipment.

One method of introducing very effective feedback is to insert the primary of a small interstage transformer (approximately 1:1 ratio) into the E-plus lead of the amplifier tube, and to connect the secondary in the grid return, as in the diagram. The secondary is so polarized that an increase in plate current makes the grid positive momentarily. When an incoming pulse from the G-M-tube circuit puts a small negative pulse on the grid of the IT4, the plate current decreases slightly. This reduces current in the secondary of the transformer, which continues to drive the grid more negative as long as the plate current decreases. The resultant plate current is very strong, surging, producing a loud click in the headset.

This circuit is very effective in portable equipment, but will respond to any impulse anywhere in the circuit; therefore, a "clean" plate supply is essential. The amplifier will respond to plate circuit "hash" just as effectively as will a G-M-tube discharge.

The same principle is applicable to stationary equipment, but usually requires limiting resistors in the circuit so that a really good surge will not melt plates in the amplifiers, with accompanying pyrotechnics and shutdown for repairs.—Ronald L. Eves

Another method uses a 1US for the amplifier, coupling the diode section plate to the amplifier plate with a small trimmer and to the grid through a 5-megohm resistor. Electrons drawn by the diode plate go to ground through the resistor, thus adding to the impulse on the grid.—Editor

TRANSMITTING TUBE CHECK

Only very large commercial tube users have equipment to test transmitting tubes. However, a simple and satisfactory check can be made as follows.

Determine the final or multipactor circuit in which the tube is being used, noting the plate current. This current rises at either side of resonance. With a new tube the rise will be much higher than with a much-used tube. Emission drops with use; therefore the rise is more limited in a tube that needs replacement.

If the operator takes periodic off-resonance readings, he can judge the condition of his tubes. No circuit should be left detuned longer than necessary, of course.—I. Queen

THE HICKOK ELECTRICAL INSTRUMENT CO.

10531 Dupont Avenue - Cleveland 8, Ohio

Features

- High output to 5,000 microvolts.
- Checks relative receiver sensitivity; horizontal and vertical deflection circuits.
- Permits alignment of linearity, drive, width, height, hold and horizontal AFC controls.
- Connects to receiver antenna.
- Blue hommetex portable steel case.

SERVICE MAN'S INCOME BUILDER...

Provides Stable Pattern for Aligning TV Anytime ... Anywhere HOME OR SHOP

- Here is the instrument for television trouble-shooting that is completely independent of station operation.
- A new portable instrument especially designed to make TV Warranty Servicing simpler and more profitable.

Now you can prove to any customer in his home, by an electronic instrument that his set is properly aligned. Then, if reception is still faulty, you are able to show the receiver is not at fault. Perhaps a better antenna installation is needed.

Model 620 is a compact, portable instrument built to the high HICKOK standard. Technicians who seriously considered dropping warranty servicing now use the 620 and profit by it. Ask any technician who owns one. See your jobber for complete information.

BROOKS RADIO DIST. CORP. 80 VESEY ST., DEPT. A • NEW YORK 7, N. Y.
A Simple Electronic Key

Construction problems eliminated by using bug in an electronic key.

By JACK D. GALLAGHER, W5HZB

The electronic key, a compact assembly.

An electronic key based on a multivibrator circuit was described in "A Deluxe Electronic Key," by Wilbur R. De Hart, in the September, 1946, issue of QST. Such an arrangement is well worth consideration if good results are to be obtained from the multivibrator circuit. Other circuits may perform just as well, but most of them require more than one adjustment to change speed, while others are less dependable in operation. In both keyers described in this article, the basic multivibrator circuit and speed-switching arrangement have been followed. The mechanical construction has been simplified by utilizing the keying mechanism of a regular bug instead of a separately constructed mechanism, which would be a tedious job without proper tools and other equipment.

Since the keyer diagrammed in Fig. 1 was constructed with a semiportable feature in mind, such space-consuming items as a vacuum-tube keying arrangement and an audio oscillator were purposely omitted. The second unit (Fig. 2) contains an audio oscillator used for monitoring purposes.

The smaller unit is assembled in a small metal box that is mounted on the back of the base of the bug. A minimum of drilling is required for the mounting, and the result is a very compact unit that is easy to handle. As shown in the circuit diagram of Fig. 1, the keyer will function as a multivibrator if the cathode resistor of V1-b is shorted out by pushing the key lever either to the right or left. In the multivibrator circuit it is necessary to establish both equal and unequal conducting periods as well as a neutral position for keying. These requirements can be met by making the grid resistances of V1 equal, C1 and C2 equal, and C3 twice the value of C1. When C3 is connected in parallel with C2, as it is for producing dashes, the total capacitance becomes three times that of C1 and the conducting period is three times as long as when dots are produced. However, in order that the first dash be the correct length, C3 must be charged to the correct potential just before the dash is made. This is achieved by leaving C3 paralleled with C2 except when dots are made.

The combination of the speed selector switch and its resistors is a very useful part of the keyer, because almost instantaneous speed changes can be made with minimum adjustment. Many keyers have used potentiometers for speed control, but unless these potentiometers are properly matched for all positions of adjustment, the dots and spaces will not be the same length.

The circuit of Fig. 1 or Fig. 2 will produce dots and spaces or dashes and spaces, depending upon the position of the lever arm of the keying mechanism. These dots and dashes are transmitted to the keying amplifier V2-a through the coupling capacitor C4. V2-a conducts with the key in the neutral position. Due to the voltage drop in the V1-a plate resistor, a negative potential is applied to the grid of the keyer tube V2-b, causing plate current cutoff in the keyer tube.

When a dot or a dash is made, the following events take place: The negative voltage applied to the grid of the amplifier tube is sufficient to drive the amplifier grid beyond cut off. At this point the amplifier tube stops conducting, and a positive voltage with respect to the cathode is impressed on the grid of the keyer tube. The keyer tube then conducts and produces dots or dashes which operate the relay.

In both units (Figs. 1 and 2), V2-b serves to actuate the relay, which keys the transmitter (and keys the audio oscillator in Fig. 2). The neon bulb in Fig. 1 is simply an indicator which glows when the relay operates;
the relay armature removes the ground and allows positive voltage to be placed across the lamp. At slow speeds this system can be used as a good visual monitor.

Several types of audio-frequency keying oscillators were tried before the circuit shown in Fig. 2 was used. The multivibrator type keyed well but had a disagreeable tone. The feedback type had the disadvantage of slow starting when keyed. The circuit of Fig. 2 allows the oscillator to operate at all times, but it is cut off from the grid of the amplifier tube V3-b by the ground on the relay armature. This arrangement provides clean, fast keying and a desirable tone. Any pitch may be produced by selecting the proper values of C6 and C7. The values shown in Fig. 2 produce a frequency somewhat less than 1,000 cycles.

The transformer T was removed from a 274-N surplus receiver and is suited for its purpose in the oscillator because of its size, but almost any i.f. transformer can be used. The terminal numbers given are for the 274-N unit.

Construction
Ordinarily the key mechanism would probably be the most difficult part of the mechanical construction; but if a standard bug is used, no mounting problems are encountered. The drilling consists of making one hole through the rear arm and reaming out two holes on the rear of the main support so that two thumbscrews can be inserted. It is also necessary to remove everything on the bug base from the rear arm back so that the 4 x 6 x 6-inch metal box can be mounted on the base. In Fig. 2, the metal box measures 6 x 6 x 6-inches.

As shown in Fig. 1, the key mechanism must short out the V1-b cathode resistor for either dots or dashes. Disconnecting C8 for producing dots. In the neutral position, C3 must remain paralleled with C2 to keep C3 charged to the correct potential for making the first dash the right length.

Each key contact in the diagram can be seen in the photograph with the exception of the regular dash contact, which is just forward of the main sup-

Note contact spacing for the plate relay. Surplus relays can be adapted easily. The closed-circuit jack is insulated from the metal box and is installed for the purpose of keying a relay which is mounted on the back of a receiver for break-in operation. This relay is the same type as used in both of the keyer units.

The power supplies of Fig. 1 and Fig. 2 provide both positive and negative voltages for each keyer. Two 6.3-volt filament transformers are used in each supply to prevent the a.c. line voltage from being connected to the framework.

Fig. 2—This keyer is like that of Fig. 1 except that it includes an a.f. monitor.

The contact represented in Fig. 1 by point 2 is shown on the left side of the rear arm and is soldered to a copper strip, which in turn is soldered firmly to the rear arm. The thumbscrew on the left side of the main support is insulated from the main support and is represented in Fig. 1 by point 3. Point 1 in Fig. 1 is the regular dash contact; it is connected to point 3. Connections to the insulated thumbscrews on either side of the main support from inside the box can be seen in the closeup view of the key.

The description of the key mechanism applies to both units, but the photograph was taken of the unit shown in Fig. 1.

A relay used for keying a transmitter is usually considered untrustworthy, since adjustments must be made and contacts must be kept clean. However, very satisfactory performance has been obtained with the relay found in the surplus aircraft beacon receivers. The relay may be purchased from some radio surplus stores for less than $2. It has a d.c. resistance of about 13,000 ohms, and it will work very satisfactorily on 500 µa.

Since the relay does not have a contact on the back-stop thumbscrew, it is necessary to provide one for clean-cut keying of the audio oscillator in Fig. 2. Such a contact was found on a surplus relay taken from a BC-459 transmitter. The back-stop thumbscrew of the relay in Fig. 2 was removed and the end was filed to a flat, clean surface and tinned. Then the contact spring from the relay in the BC-459 was cut off about 1/4 inch from the contact. The back side of the contact was tinned and soldered to the tip of the back-stop thumbscrew. When the thumbscrew had cooled, the remaining part of the contact spring was cut off and the edges filed down to a smooth surface. The surface of the contact was cleaned and the back-stop thumbscrew was screwed back into the screw mount.

The contacts which are already on the relay, and almost any contact found on other surplus relays, are quite suitable for keying oscillator and light buffer stages; but if heavy currents are keyed, an additional spark filter should be used across the armature contacts to eliminate sparking.

Many small parts can be found in surplus receivers and transmitters; the compact capacitor units, such as those found in the 274-N surplus receivers, proved most useful because of their size and the fact that they were so easily mounted. There is no reason why 12AU7's cannot be substituted for the 6SN7's.

Adjustment

The fact that there must be both equal and unequal conducting periods if dots and dashes are to be produced must not be overlooked. Since these conducting periods depend upon the V1 grid resistors and the values of C1, C2, and C8, it is important that the grid resistors in both sections of V1 have equal values. They do not have to
This heavy gauge, all-metal Kit that has almost 101 uses. Worth twice-as-much, SWEDGAL's usual low-price would be $2.49 if you order it Alone. For a limited time only, we are including this sturdy reinforced, metal kit FREE with any purchase of $20 or more.

Just a few of its uses: this kit gadget box, spare parts box, protects valuable papers, strong box. "SUCCESS STORY OF THE
MAGIC WAND ANTENNAS"

More than a thousand power lines snapped! Street car service disrupted by broken trolley wires! Thousands of tree branches crashed to the ground!

But the Chicago area's worst ice storm did not affect a single Ward Products "Magic Wand" TV antenna.

"Magic Wand" antennas are made of Perma-Tube, a special alloy expressly developed for Ward Products by the Jones & Laughlin Steel Corporation. Perma-Tube is a rugged alloy designed to withstand the harmful, corrosive effects of ice, sleet, snow, wind, and rain.

In good weather or bad, your TV set will give you the best reception if you have a Ward "Magic Wand" antenna. Tests have proved a medium-priced TV set with a good antenna performs better than an expensive set with a cheap antenna.

Write for our free booklet, "The Story of the Magic Wand." It contains interesting, authoritative information about TV and FM antennas.

AMATEUR

A RADIATIONLESS METHOD
FOR TRANSMITTER TUNING

By PHILIP JOHNSON, W7MHU

Good operating procedure requires that radio transmitters should not radiate energy during tuning operations. A dummy antenna may be used in making adjustments on the transmitter itself. It is commonly believed, however, that transmitting antennas cannot be tuned and adjusted properly without being energized. Thus, interference is produced, and one of the rules of good operating technique is broken.

Fig. 1—Setup for radiationless tuning.

But there is a way in which transmitting antennas may be tuned without energizing them. Devised by U.S. Navy radio technicians to tune antennas during periods of radio silence, the method is easy to understand and apply.

The antenna is tuned to resonance and the proper coupling determined by utilizing the static noise voltage picked up by the antenna.

Only three items of equipment are required: a good receiver, a fairly high-impedance a.c. voltmeter having a 1- or 2-volt scale (or other output meter), and a 1/4-watt carbon resistor.

The circuit connections are shown in Fig. 1. The receiver is loosely coupled to the plate lead of the transmitter tank circuit by capacitor C, which consists of approximately 1 inch of insulated wire wound around the plate lead. The receiver is tuned to the operating frequency of the transmitter, and the static noise voltage picked up by the transmitter antenna is read on the output meter.

Antenna resonance is indicated by adjusting the antenna tuning controls for a maximum reading on the output meter.

Correct antenna coupling is determined by adjusting the coupling controls until the received noise voltage, as indicated by the output meter, drops to about one-half its peak value when a resistor equal to the load resistance required by the transmitter output tube is connected from the plate of the transmitter output tube to ground. Resistor R1 in Fig. 1 is the load resistor used for this purpose. It is the 1/4-watt carbon resistor previously specified as required equipment.

The method can be used for adjusting any type of tuned antenna, irrespective of the type of coupling to the tank circuit. For antennas with un-
tuned feeders, only the coupling need be adjusted.

**Theory of operation**

The action is simple, and for the tuning adjustments is obvious. No amateur requires any elaboration of the point that, when transmitter antenna and tank circuit are both tuned "on the nose," a maximum noise voltage will be induced into the receiver, which is tuned to the operating frequency.

The coupling principle is equally simple, though not so obvious. Every amateur also knows that tuning an antenna neutralizes or opposes its reactive components, so that at resonance it appears as a pure resistance. The tuned tank circuit also looks like a pure resistance; therefore, a perfectly tuned output circuit looks to the output tube like R2 in Fig. 2. (E is the noise voltage generated in the antenna, used to obtain the indications on the a.c. output meter.)

![Diagram of a circuit](image)

**Fig. 2—A perfectly tuned output stage.**

If the circuit is properly coupled, the output tube will see R2 as a resistor of the correct value for proper tube loading. Now, if this resistor is shunted by another of the same value, the voltage indicated on the a.c. voltmeter will drop to one-half its former reading, by Ohm's law. The switch makes comparison between R1 and R2 easy.

**Tuning procedure**

1. With the transmitter operating, properly tuned, and feeding into a dummy antenna, tune the receiver to the operating frequency of the transmitter.
2. Shut down the transmitter plate supply, leaving the filaments of the transmitter tubes energized.
3. Couple the receiver input to the plate circuit of the transmitter final amplifier tube as indicated in Fig. 3, a simplified form of Fig. 1. (As previously stated, capacitor C, the coupling unit, consists of approximately 1 inch of insulated wire wrapped around the plate lead. This is quite sufficient for the frequency ranges used for amateur communication. The lead from C to the receiver antenna terminal should be a shielded wire not over 4 or 5 feet long. The shield must be grounded.)
4. With the receiver a.c. off, retune the transmitter tank circuit until maximum noise output is indicated by maximum reading on the a.c. voltmeter.
5. Couple the antenna to the transmitter, and adjust the antenna tuning capacitor until maximum noise output is again indicated on the a.c. voltmeter. This indicates antenna resonance. It may be possible to increase the resonant voltage reading by retuning both the transmitter tank capacitor and the antenna capacitor a trifle. The receiver should not be retuned.

Next adjust the antenna coupling.
This adjustment is entirely independent of, and does not affect, the previously made resonance adjustment.

1. Adjust the receiver output sensitivity to 1 volt or some other convenient value on the a.c. voltmeter.

2. Switch R1 into the circuit and observe the receiver output voltage. If the receiver output voltage is about one-half its former value, the antenna loading is nearly correct. If the value is less than one-half, R2 is greater than R1 and the coupling must be increased if the value is greater than one-half, R2 is less than R1 and the coupling must be decreased.

**Determination of R1:**

The value of R1 is very easily determined either by calculation or experimental work.

To determine the value of R1 by calculation, use the formula:

\[ R1 = \frac{P}{I^2} \]

In the above formula, I is the current input to the plate of the final r.f. amplifier, and P is the power consumed by the tuned tank circuit of the transmitter.

**Experimental method:**

If tube data is not available, R1 may be determined experimentally by using an actual antenna.

1. Tune the transmitter and the antenna by one of the above methods.

2. Tune the receiver to the operating frequency of the transmitter; shut the transmitter down, but leave the transmitter filaments energized.

3. Couple the receiver to the transmitter plate circuit and adjust its output to some convenient value.

**Guaranteed Pre-tested RADIO TUBES for QUALITY, PERFORMANCE and DEPENDABILITY**

Every individual tube must undergo rigid tests before it leaves the Le-Hi plant. This guarantees of pre-testing is but one assurance of the BEST BUT FROM Le-Hi. Rugged construction, dependable performance and economical service at LOWEST PRICES makes our tubes even MORE DESIRABLE. Compare performance, quality and price with any standard tube—and remember EVERY Le-Hi Tube IS FULLY GUARANTEED.

Fig. 3—Circuit showing tuning method.

**To Tank, Ant Circuit, Etc.**
4. Connect different values of resistance from the plate lead of the transmitter final amplifier tube to ground until the audio noise voltage reading of the a.c. voltmeter is about one-half the noise voltage reading obtained without the resistor. This is the value of resistance R1.

With this method, the antenna need be energized only once—all succeeding tune-ups may be made without radiating any energy.

Irrespective of whether R1 is found by calculation or experiment, its value will vary with the frequency of operation and the transmitting tube in use. With most transmitting tubes operated on the common shortwave frequencies, R1 ranges from 1,000 to 5,000 ohms.

Operating suggestions:
Static noise voltage is often very erratic, especially in large metropolitan areas. Under such conditions, tuning by this method is very difficult and often quite unreliable. A slight modification eliminates the difficulties and improves the accuracy of the system.

The modification consists of tuning a small signal generator to the transmitter frequency and inducing its signal into the transmitting antenna. This can be done by feeding the signal generator into a wire mounted close to and parallel with the antenna leads. The signal so induced in the antenna circuit is larger than the static noise voltage, but small enough that it cannot radiate more than a few feet from the antenna base.

Considerably greater accuracy can often be obtained if the receiver speaker is not disconnected during tuning operations. Ease of adjustment is increased when it is possible to hear the signal as well as to see it on the a.c. voltmeter.

**NEW Cletron**

**safe**

**approved**

**TV-FM**

**LIGHTNING ARRESTER**

**Outstanding Features**

- Quickly—easily installed without cutting line.
- Universal Base—Accommodates all types of lead-in cable.
- Absolutely does not affect signal strength on any channel.
- Prevents static build-up in antenna.
- Maintains constant antenna potential relative to ground.
- Acts like a switch in bypassing high, harmful voltages.
- Thoroughly insulated—Underwriters Lab. approved.
- Weatherproof—Built to last. List Price $2.25

**Combination Bleeder and Gap Design**

- The first arrester to successfully combine bleeder and gap principles for FM-TV.
- Electrically balanced to ground—The balanced bleeder resistors prevent any static build-up in the antenna.
- Keeps the antenna and all surrounding conductors, reflectors, directors and masts at a constant potential relative to ground. Momentary, high and harmful voltages break the gap and are by-passed harmlessly to ground.

A lightweight unit, easily mounted or installed by hanging on the lead-in cable.

With a Cletron Arrester, any antenna installation is safe.

Order out a stock today—Build more satisfied customers.

25 West Broadway, New York 7, N. Y.
**New Devices**

**LIGHTNING ARRESTER**
Cleveland Electronics, Inc.,
Cleveland, Ohio

The new Cleveland lightning arrester for television and FM antenna transmission lines is a combined blinder and gap design. It has a universal base to accommodate all types of cable. It may be installed quickly without cutting the cable and does not effect signal strength. Approved by Underwriters Labs, the arrester keeps the antenna and conductors at a constant potential with respect to ground. The balanced blinder resistors prevent any static buildup in the arrester. Momentary high voltages bypass the gap and are bypassed to ground.

**DISC CAPACITOR**
Erie Resistor Corp.,
Erie, Pa.

A new 0.01 uf disc Ceramic is only 19/32 inch in diameter. Capacitance is held to within ±0.05%, and ±0.05%. Voltage rating is 400 volts, based on a life test of 800 volts d.c. at 85 degrees Cent.

**PAGING SPEAKER**
Raco Electric Co., Inc.,
New York, N. Y.

Since each PA installation requires an individual solution, for a long time sound technicians have had to carry a large inventory of loudspeakers. To simplify selection and help reduce the sound technician's inventory, Raco now has in production the new model MN-155.

This one speaker handles 65% of all paging requirements. The greater efficiency is due to its incorporation of true exponential design for its complete length—for the tone arm, the reflector and the bell. The advantage of this construction is that it assures uniform response throughout its entire transmission range.

The low-frequency cutoff provides a rising response characteristic for greater intelligibility in high-noise level areas. The lowered mass of the special aluminum-wound voice coil assures greater efficiency of the loudspeaker, especially where increased diaphragm sensitivity is needed for talk-back.

Specifications are: 20 watts continuous capacity, 35 watts peak capacity, frequency range 450–6,000 cycles. The speaker is available in 8, 15 or 45 ohms.

**HIGH-VOLTAGE PROBE**
Electronic Instrument Co.,
Brooklyn, N. Y.

A new Eico high-voltage probe, model HVP-I has a special helical-film, steel-tube-red-type multiplier resistor, which may be removed and replaced with different resistance values. As is, the probe matches most 20,000-ohms-per-volt meters and v.t.v.m.’s. Safety features of the probe include a plywood baleite handle and large flashguards.

**NEW INPUTER**
Allen B. Du Mont Laboratories, Inc,
Passaic, N. J.

The new four-section Inputuner incorporates the latest Mallory-Ware spiral-type Inductor. It has much greater gain than previous Inputuners and more selectivity. The tuning range is continuous from 94 to 216 mc, covering both TV bands and FM broadcast.
ALIGNMENT TOOLS
Insulin Corp. of America, Long Island City, N. Y.
Nine kinds of stock and television servicing tools are included in the new TV Handi-Kits. They are furnished in a pocket-size leatherette carrying case. The tools will fit the adjusting screws of all types of L and U, transformers, paddler and trimmer capacitors, etc., found in current TV receivers. With their assistance, a service technician can align circuits in a minimum of time.

TELEVISION TUNER
Standard Coil Products Co., Inc., Chicago, Ill.
Model TV-250 is the same electrically as the models TV-101 and 201, used in many receivers but has a longer shaft. The shaft is concentric, controlling coarse and fine tuning. Both sections are fluted along their lengths so they may be cut to any desired measurement.

HIGH-VOLTAGE TESTER
Oak Ridge Products, New York, N. Y.
The new model 102 miniature TV high-voltage tester checks all high voltages in any television receiver. It has three 10,000-ohms-per-volt scales: 5,000-10,000-20,000 volts, and comes with a special high-voltage test lead, 1/4-inch pocket-case size measures 5 1/2 x 2 1/4 inches.

TELEVISION TOWERS
Teletowers are triangular steel masts for mounting television antennas. They are composed of 18-gauge steel tubing welded together with 1/4-inch steel flanges, which also serve as climbing ladders. The towers come in 10-foot sections weighing about 20 pounds each, which may be put together for heights as great as 100 feet. Fittings of various types are available for busing, gaving, and supporting mast androtating motors at the top.

ANTENNA ROTATOR
The Radiart Corporation, Cleveland, Ohio
The Radiart Tele Rotor will handle up to a 150-pound load with ease, and takes any size mast from 3 1/2 inch to 2 inches. Control boxes for the Tele Rotor come in two models. Model TR-1 has an "end all rotation" light and uses a 6-wire cable. Model TR-2 is the compact control rotator with the illuminated "perfect pattern" dial control unit. The face is two-tone, reproducing an illuminated TV test pattern and giving instant indication of antenna position as it is rotated by the fingertips control. It uses an 8-wire cable between control box and rotator.

CROSSOVER NETWORK
University Loudspeakers, Inc., White Plains, New York
Model 440 is a new filter network of the LC type for use with co-axial or double loudspeaker systems. It provides a proper attenuation rate at a cross-over of 600 cycles. The filter is housed in a cast aluminum container. A high-frequency attenuator is supplied for balancing the highs and lows to suit acoustic conditions and the listener's pleasure. A matched cable permits mounting the attenuator in any convenient location remote from the speaker.

INSULATORS
Hot Nails, Inc., New York, N. Y.
These specially shaped nails of high-carbon steel may be driven into brick and masonry or into steel and aluminum. Each nail is equipped with a specially slotted piece of polyethylene which holds any type of transmission line commonly used for television. The nails are especially designed for antennas, but have many other uses.

NEEDLE CLIP
Mueller Electric Co., Cleveland, Ohio
The new solid-brass needle clip makes quick electrical contact by piercing the insulation of wire. A sharp needle is a part of one jaw. The non-corroding clip has a brass screw for connection. The Mueller No. 49 Insulator may be slipped over it.

CRYSTAL DIODES
General Electric Co., Syracuse, N. Y.
A low-priced, ultra-high-frequency germanium diode and two new types for use in v.h.f. television receivers have been announced. The v.h.f. germanium diode is self-healing under temporary overvoltage conditions, and requires no special handling. New snap-in construction eliminates the need for soldering and speeds installation. The only germanium diode currently available for use in the ultra-high frequencies of 300 to 1,000-Mc range, it is designed for use as a converter.

TWEETER UNIT
Mark Simpson Mfg. Co., Long Island City, N. Y.
The Massco model HT-100 high-frequency tweeter is designed to provide wide-range frequencies recorded in the upper register to 15,000 cycles. Installation is simple and requires no additional space. The existing cone speaker is unscrewed, the screen with high-frequency unit attached placed over the corresponding holes of the cone speaker, and the assembly screwed back in place. The two speakers are then series-connected.

ATTIC TV ANTENNA
Tri manufactures Co., Griswold, Ill.
This all-channel television antenna can be installed in attic, on roof, on rafters, floor joists or on the floor itself. It gives better reception than the average indoor antenna and meets with the approval of landlords who object to bad installations or owners who prefer not to encumber their buildings with outside television antennas.

The two new diodes for use in present v.h.f. television receivers are the IN84A designed and selected for optimum efficiency in video detector circuits, and the IN45 which is for use as a d.c. restorer in TV circuits and is especially selected to provide high back-resistance.
CONSTRUCT A PICTURE TUBE HOLDER
Complete Plans and Instructions in the APRIL Issue of:

Radio Television Maintenance

the APRIL issue is on sale at your jobbers' counters

No more problems of what to do to safeguard the picture tube that must be removed from cabinet in order to service some TV sets. Here now is presented a complete working drawing and detailed instructions for a radiation, stable and safe holder for TV picture tubes. Designed to fit any and all CRT's in current TV sets, this holder will save you time and money, makes your work easier and put your mind at rest—no worrying about breakage!

This is another in the series of valuable construction articles appearing in Radio & Television Maintenance magazine in addition to the regularly featured technical articles and news about AM-FM-TV. Get your copy today and subscribe now by sending in the coupon below!

DON'T MISS ANY OF THE FORTHCOMING ISSUES!
Here is a list of future construction articles:
How to make receiving dollys for incoming radios
How to construct a truck interior for efficient field work
Building an auxiliary bench for testing, minor repairs, operating observation, etc.
Shop planning and layout for steps, time and money saving.
Auxiliary HV power supplies for operating tests on picture tube
Designers arrangement of a portable parts, tool and test box for servicing
Design and construction of TV antenna location tester

There are in addition to the regular content of technical articles on TV-FM and AM receivers, test equipment tools, etc.—news articles on current happenings, trends of the industry, new products and new literature—sales methods and advertising programs—business methods

35,000 radio servicemen read RADIO & TELEVISION MAINTENANCE regularly—PROOF of its value to the trade!

FIELD INTENSITY CALIBRATOR
Patent No. 2,489,908
Charles V. Larrick, Richland, Wash.
(assigned to General Electric Co.)

Field-intensity measurements are required by the FCC and are necessary for correct design and adjustment of radio apparatus. The measurements are often made with portable instruments previously calibrated at a laboratory. However, there is danger of upsetting the calibration when the instrument is moved from one location to another, which is jarred, etc.

This circuit carries its own calibrator so it may be checked every time it is used. It contains an oscillator, voltmeter, potential divider, and receiver.

The receiver picks up a signal either from the antenna or from the calibrated oscillator. The signals are, of course, equal when they produce equal outputs.

The input impedance across the receiver coaxial cable should equal the sum of resistors R1 and the antenna resistance, which is approximately 75 ohms. If the input impedance is known, the value of R1 is fixed. This impedance should also equal the sum of R4 and resistors R2. R4 may be fixed arbitrarily at some small value such as 5 ohms, in which case R3 is known.

The small resistor R4 together with resistors R3 form a voltage divider to reduce the voltage at V to the much smaller potential received from the antenna. Therefore R3 will depend upon the voltage output of the oscillator.

The value of R5 is such a value as to make the resistance of the attenuator network equal to the surge impedance of the line from the calibrated oscillator.

The calibrated oscillator may be checked for accuracy with laboratory equipment at frequent intervals to insure accuracy. No other laboratory calibration of the equipment is needed.
with purchase of
100 Sylvania Receiving Tubes...
or 3 Sylvania TV Picture Tubes

The clearest
and most complete
Television Servicing Book
ever printed

FREE
during April, May, June, July and August

HERE at last is a guidebook to help simplify TV set service for you. You’ll be amazed how it will enable you to quickly identify trouble...solve tricky problems.

Contains more than 100 pages with scores of actual photographs and easy-to-read diagrams, to help you increase and improve your TV set repair business.

Not for sale...it’s FREE!

This valuable book is yours absolutely free, from your regular Sylvania distributor, with your order of 100 Sylvania receiving tubes...or just 3 TV Sylvania picture tubes. Spirally bound with a sturdy board cover to stay open and lie flat on your bench.

NOTE: This important booklet offer is open for a limited time only. So don’t delay. Send your order for the tubes you need today to your Sylvania distributor and he’ll mail this free, helpful guidebook to you immediately.

SYLVANIA ELECTRIC

RADIO TUBES; CATHODE RAY TUBES; ELECTRONIC DEVICES; FLUORESCENT LAMPS, FIXTURES, WIRING DEVICES, SIGN TUBING; LIGHT BULBS; PHOTOLAMPS

APRIL, 1950

Here are 2 sample pages from “Servicing Television Receivers.” Note the easy-to-read type arrangement and the simplified photographic instructions.

Quickly answers scores of questions

- Shows more than 80 actual photos of screen test patterns. Shows how to identify trouble by pattern behavior.
- Gives simple, concise instructions for making repairs, proper adjustments.
- Contains complete circuit diagrams of typical television receiver.
- Explains latest television developments such as “Intercarrier sound.”
- Tells about television test equipment and what each instrument will do.
- Provides a practical dictionary of television set trouble.
CAMERA SHUTTER TIMER

If your oscilloscope has a calibrated driven sweep, use it in conjunction with a photoelectric cell to check the speed of your camera shutter. A typical setup is shown in Fig. 1. The auxiliary lens is not needed if the camera is focused on the lamp and the emissive surface of the cell is in the plane of the film.

Fig. 1—Setup for shutter speed check.

When the shutter is tripped, the cell generates a pulse which triggers the sweep on the scope. Applied to the Y plates of the scope, the pulse bends the horizontal trace in a vertical direction. A typical trace for a radial shutter is shown in Fig. 2-a and a focal plane shutter in Fig. 2-b. Because the sweep is linear, the length of the sweep can be measured with a rule and compared with the length of the shutter trace.

A camera with a fast lens and high-speed film is used to photograph the trace on the C-R tube. It may be possible to record the trace by fastening a piece of high-speed pack or cut film...

THE FINEST 16" TELEVISION SET EVER DESIGNED!

With Automatic Gain Control (AGC)

Now you can have the finest 1950 model VALHALLA Double Giant Screen Television. Each is designed Custom-built and improved with unusually high brilliance and detail. RCA designed 628 type chassis. This identical type TV set is used by many Radio & TV Engineers than any other set ever manufactured.

The 30 tube circuit is more sensitive than any of the cheaper sets having less tubes and the new standard Tuner has a heavy-duty stage which acts as a high-gain built-in Television Booster on all channels. It is guaranteed for an automatic frequency control system that keeps the picture steady and makes tuning easier.

Factory wired and tested, ready to operate, shipped complete with tubes. 16" picture tube...$149.50
Extra-Clear 16" glass picture tube—guaranteed for one year...$39.50

SPECIAL!

Super-Giant 19" Television Sat. 630 type similar to above, but modified to provide a whopper-sized picture. Ready to operate. Shipped complete with tubes, 19" picture tube, Price...$199.50
Extra-Clear 19" glass picture tube—guaranteed for one year...$79.50

12½" 630 chassis...$149.50;
12½" tube—1 year guarantee...$24.95

DE LUXE TELEVISION CABINETS

Beautifully designed to match the 630 chassis without any cabling or construction like the finest furniture with a satin finish. Shipped complete with mask and protective glass windows.

16" Table Model—Mahogany or Walnut...$39.95
19" Table Model—Mahogany or Walnut...$44.95
16" Console—drop panel to conceal knobs when desired. Mahogany or Walnut...$89.50
Blonde...$79.50
19" Console—with drop panel as above—Mahogany or Walnut...$97.50
Blonde...$89.50

4-TUBE AC/DC TELE-BOOSTER

CHECK THESE FEATURES

Uses type 6AX7 in an extremely stable and efficient wide-bander amplifier circuit. Self-contained power supply covers all television channels in use. Eliminates need for outdoor antennas in many locations. Will actually make difference between "Flat" and very bright pictures on weak stations. Improves receiver immunity to off-channel interference. Can be tuned to boost weak station or turned off to provide normal reception. Simple to install and operate, requires only external connection to receive. Operates on 110 volts AC or DC. ONLY $16.95

TUBE SUBSTITUTIONS

When a 6H6 goes bad and a replacement is not immediately available, check the circuit. If only one diode is used or if both diodes are connected in parallel, a 6C6, 6J5, or 6P5 can be used as a replacement.

Connect one jumper between pins 3 and 5 and another between pins 4 and 8 on the base of the triode. The jumpers make it possible to use any of these triodes as replacements.

The replacement triodes may be those which would normally be discarded because of microphonicism or grid-to-plate shorts. —Charles Erwin Cohn

www.americanradiohistory.com
SIMPLE S-METER CIRCUIT

An S-meter can be added to the average superheterodyne receiver merely by adding three resistors and a 1-ma d.c. meter. Two 47,000-ohm resistors and a 50,000-ohm potentiometer are connected as a bleeder across the high-voltage supply. The meter is connected between the arm of the pot and the screen grid of an i.f. tube controlled by the a.c. voltage. The circuit is shown in the diagram.

The arm of the pot is adjusted until the meter zeros with the r.f. gain control on full and the antenna terminals shorted. If the meter is too sensitive, a variable resistor may be shunted across it.—John A. Bishop

WIRELESS INTERCOM

I live on the floor above a store which I operate. Being unable to remain in the store at all times, I rigged up a wireless intercom which enables me to listen in on any thing that happens in the store. I used a battery-operated set as a transmitter. The primary of its output transformer was disconnected from the output tube and one lead was connected to the arm of the volume control and the other to ground. Another output transformer was installed with its primary in the output circuit and its secondary connected between ground and the grid cap of the 1A7 mixer-oscillator. A short antenna was connected to the 1A7 plate through a small capacitor. This set was then tuned to a spot on the low-frequency end of the broadcast band. A standard receiver upstairs was tuned to the oscillator frequency of the transmitter.

The speaker on the transmitter picks up sounds in the store and feeds them to the a.f. circuit where they are amplified and used to modulate the 1A7.

Adjust the transmitter so its signal falls on a quiet spot on the band. Keep the antenna as short as possible for good results, and above all, don't try for distance records with this unit or the FCC may have a few things to say about it.—John W. Graves

BATTERY CONNECTORS

The next time you need connectors for a 6-volt storage battery when servicing an automobile radio, try the sliders from a 50-watt adjustable resistor. These sliders are inexpensive and fit the terminals on most vehicular storage batteries.

Another connector useful for the workbench is made by drilling 3/16-inch holes about 1/16 inch into each post. Tap in 8-32 screws and saw off their heads. Then screw on nuts from ordinary dry cells, making very convenient terminals.—W. M. Finley, Jr.

APRIL, 1950

Four channels from 40 miles clearly
with new low-cost C-Series

Tel-a-Ray

Here is the antenna you want — for sharp images — wide range — easy assembly — low cost! Tel-A-Ray's C-Series is new . . . designed after extensive tests to give you the best performance possible at the lowest cost.

Tel-A-Ray antennas are durable . . . made from Dural with stainless steel fittings. The C-Series can be assembled and erected in a few minutes, yet its electrical efficiency in simple arrangements is superb. Available in a complete Hi-Lo Channel Kit with mast, guy wire lead-in, and mounting for $24.50 list.

& ELECTRONICS CO. INC.
127-C DUANE ST. • NEW YORK 7, N.Y.
2 Blocks North of Chambers St.
BARCLAYS 7-1840

These pictures were taken of a 10" Crysler screen in Aurora, Ill., 40 miles southwest of Chicago. A C-Series antenna on a 15-foot mast was in use . . . bringing in clearly the four channels pictured above. No booster of any type was used. (All photos unre touched. Documented evidence on file.)
Radio-Electronic Interval Timer

Various on-off interval timers have been described for use on welders, photographic printers, and enlargers, and other industrial devices. This unit, described in an RCA Application Note, is unusual in that it automatically repeat a sequence consisting of adjustable on and off intervals. Such a device can be used to control animated window displays, mechanical toys such as electric trains, or many types of electric and electronic devices which are repeatedly turned on and off for definite periods. A pair of thyristors are connected in a multivibrator-type circuit. The

CRISTAL DIODE CIRCUITS

Germanium diodes such as the 1N34 have been used to replace vacuum tube diodes in many interesting applications. Their use as video detectors in

Unlike the more conventional circuits, load resistors R1 and R2 are in parallel with the diodes instead of being in series with them. Because the resistors shunt the diodes, variations in back resistance are swamped out and the static balance of the circuit is maintained.

Fig. 2 shows how the 6AL5 or 6H6 horizontal sync discriminator may be replaced by 1N34's in the a.f.c. circuit of a popular type of horizontal sweep circuit. It is claimed that the use of germanium diodes in the discriminator makes possible a more completely balanced and stable circuit. This circuit also eliminates the possibility of the 60-cycle hum sometimes present in vacuum-tube discriminators because of heater-to-cathode leakage. If the hum is strong enough, it will frequency-modulate the oscillator and produce non-linearity or a distorted raster.

Values for C1, C2, R1, R2, and R3 are critical and should be as shown on the diagram. The unmarked values and their exact circuit arrangement may vary in different makes and models of TV sets.

Besides eliminating a possible source of 60-cycle hum, the germanium diodes have a very low shunt capacitance of about 3 µf when mounted in a chassis as compared to about 15 µf of a 6H6 diode in a rectifier circuit. This low capacity makes them useful in circuits

and operate up to several hundred megacycles.

The 1N34 is rated at 50 volts maximum peak inverse voltage and the average current rating is 22.5 ma. The forward resistance is about 50 ohms and the back resistance is about 1/2 megohm.
CROSSOVER NETWORK
The crossover network shown in the diagram was taken from a bulletin published by Racon Electric Co., Inc. It is designed for a crossover at 1,000 cycles. The table gives values for the capacitors, tweeter level control, and inductors as well as winding data.

The inductor design is based on a nonmagnetic winding form 1 3/4 inches in diameter with ¾ inch winding space. The inductors are wound with No. 16 enamelled wire with approximately 13 turns per layer. The form may be a ¾-inch length of 1 3/4-inch wooden dowel with 3-inch squares or circles of stiff cardboard or Masonite nailed to the ends.

For the inductors in the 4-, 6-, 8-, 10-, and 12-ohm networks 1 pound of wire will be sufficient. The 16-ohm network requires 1 3/4 pounds of wire. The capacitors should be of the nonpolarized type (paper). Their voltage ratings may be as low as 25.

All Conicals Look Alike, but
only OAK RIDGE Fringemaster

GIVES YOU: LOWEST COST AND HIGHEST QUALITY FOR GREATEST PROFIT!
HIGHEST GAIN FOR LOCAL AND FRINGE AREAS!

Here's why you get lowest installation cost, fastest call-backs, best performance—and highest profits—with the new Oak Ridge FRINGEMASTER Conicals:

for Metropolitan Areas:
The X-66 gives you the highest gain and lowest cost for its type on the market! 6 forward and 6 reflector elements.

for Fringe Areas:
The superb sensitivity of the X-66 is unmatched by any other conical! Lowest-priced! 6 forward and 6 reflector elements, double-stacked.

- Highest gain conical beam
- Highest signal-to-noise ratio
- Major lobe in line of frequencies
- Highest front-to-back ratio
- Matched to 72, 150 or 300-ohm transmission lines
- Supplied with any combination of antenna or reflector elements

BIG MONEY IN RADIO and TELEVISION NOW!
See COYNE'S Brand New 7 Volume Set
APPLIED PRACTICAL RADIO-TELEVISION

A BRAND NEW Set of books written for men who want to "go places" in TELEVISION and RADIO...men who know how a PRACTICAL working knowledge helps to make the BIG MONEY. Over 2,500 pages of the latest Radio and Television "know how"; easy to understand with hundreds of crystal-clear illustrations. It's ALL here! EVEN COLOR TELEVISION AND UHF. How to install, service, align, balance ALL radio and TV sets...how to use new and old testing instruments for TV service...latest data on adapters, converters and MORE. Complete volume on Electronics and handy Radiomen's Handbook included. You name it and COYNE'S GOT IT, in this amazing new money-making 7-Volume Radio-Television Library.

7 fact-packed volumes — 1400 illustrations and diagrams with step-by-step photographs which "break down" the equipment to show what makes it "tick." Up-to-the-minute, complete, easy to follow.

Send Coupon — See Set Free for 7 Days

You must see these new books to know how easy it is to prepare for the big jobs in radio and television. Here's our special offer: We'll send the complete 7-volume set for your 7-Day FREE Examination. And with it, we'll include our valuable, new guide for all radioamateurs, "150 New Radio-Television Diagrams Explained," absolutely FREE! If you keep the 7-volume set all you pay is $3.00 within 7 days after the books arrive and $3.00 per month until $23.50 is paid — or you can pay $22.60 cash price. If you don't want the set, return it and you OWNE NOTHING. But either way you keep "The Radio and Television Diagrams Book" as a gift. That book is ABSOLUTELY FREE!

**PENNSYLVANIA MAKES ANNUAL AWARD**

The plaque awarded annually by the Federation of Radio Servicemen's Association of Pennsylvania was given to the Sylvania Electric Products Corporation at a banquet luncheon held February 19 at Harrisburg.

The plaque, which carried the wording: For consistency in promotion and advertising to the public in effort to promote public confidence and to assist the radio-television technician was presented by Richard Devaney of the Philadelphia organization and accepted by Mr. R. H. Bishop on behalf of the Sylvania organization.

More than 30 persons, representing eight of the Pennsylvania local organizations, the New York state radio technicians federation (ESFETA) representatives of the technical press and visitors from Sylvania and a number of radio technicians' associations, were present at the presentation.

Holding the award is R. H. Bishop. At his left, Dave Krantz, the Federation's president, and between them (rear) T. L. Clarkson of the Mid-State Association.

**OKLAHOMA CITY ASSOCIATION ACTIVE**

The Oklahoma City Radio Service-men's Association elected R. B. Cherry as its president for 1960. Vice-president is Walter Cox, secretary-treasurer L. G. Deering, program chairman E. J. Snyder, and publicity director James H. Jackson.

A campaign to publicize and stress the decals of the organization was planned at the annual meeting, and arrangements made to have technical speakers address the group throughout the year, a committee being entrusted with the work.

**PHILIPPINE AMATEUR ASSOCIATION**

Photo above is of a Philippine hamfest, held at the home of Jess Escalante, DU1VS, of Cavite City. The hams in the front row (kneeling) are Pedro Auguinoido, Jr., DU1ID, and Gregorio Orlbta, DU1AW; the second row, left to right: Jorge Ilenberger, DU1JI, David K. Pope, W3IJW, Mary E. Pope, Rose Ilenberger, Celstina Marcelo Ilenberger, Mrs. Jess Escalante, Lita Contreras, Nunilon Lim, DU1NL, and Jess Escalante, DU1VS. In the back row are Jack Sartoromana, DU1JS, Gregorio Trinidad, DU1GT, Fred Hashim, Miguel Contreras, DU1MC, Victor Valenzuela, DU1AQ, Emmet M. Johnston, W7CEV, and Frank Tunison. We thank Mr. Elpidio de Castro, secretary of the Philippine Amateur Radio Association, for the photograph.

Review of Recently Issued Tubes

This month’s crop of new tubes includes the shortest 3-inch electrostatic cathode-ray tube ever manufactured commercially, a group of “ruggedized” tubes, and an improved photo-tube. The little 3M1 tube was originally designed for use in small industrial oscilloscopes, but its manufacturer, General Electric, reports that it is expected to find numerous applications in television servicing as well as testing industrial equipment.

Maximum ratings of the new tube are: anode No. 1, 1,000 volts; anode No. 2, 2,500 volts; maximum negative bias 200 volts, and maximum positive bias 2 volts d.c.

“Ruggedized” tubes are standard types designed to give reliable service under conditions of severe vibration and shock. Five out of a proposed total of 20 have been announced by Sylvania. These are the 6SN7-WGT, 6X5-WGT, 26D7-W, 5L6-WGA and 6SL7-WGT. Characteristics of the tubes are identical with their standard equivalents.

Sylvania also announces a new all-glass 16-inch picture tube. The tube, the 16LP4, which is 22.4 inches long, employs an ion trap for use with an external magnet. Deflection angle is approximately 52 degrees. Anode voltage is 12,000, No. 2 grid voltage 900, No. 1 grid voltage (for cutoff) -33 to -77. Heater voltage is 6.3 and current 0.6 amperes. Focus coil current is 110 ma and ion trap magnet current 120 ma. A smaller tube, the 8BP4 has electrostatic focus and deflection, and is designed to replace the 7JP4, with which it is directly interchangeable. Its useful screen area is roughly 50% greater than that of the 7JP4. The deflection sensitivity provides full scan in circuits designed for 7-inch tubes. Operating voltages are 6,000 on anode No. 1, 1,620 to 2,400 on anode No. 2, and zero to -72 to -168 on grid No. 1.

Another Sylvania contribution of the month is a miniature high-voltage rectifier for television receiver high voltages. The 1X2 may be used where d.c. voltages up to 15,000 are required. Filament voltage is 1.25, filament current, 200 ma. Peak plate current rating is 10 ma, and maximum load current, 1 ma. It is designed for a supply frequency of 300 kc maximum when used in r.f. power supplies.

Improvements in multiplier phototubes have been announced by RCA. The 1P21, already a useful tube of this type, has been improved by reducing its “equivalent noise output” about six times, to permit a corresponding reduction in the lower limit of measurable light intensities. This extension of range makes the tube of great value to astronomers studying light intensity of distant stars, to nuclear scientists studying atomic radiation, and in other research work requiring low intensity light measurements.

Further information (technical data sheets) on any of the tubes described above may be obtained by writing direct to the manufacturer.

Now you'll really know HOW TO USE AN OSCILLOSCOPE

Don't let the oscilloscope "stump" you!
Learn to use it fully — and watch your efficiency soar.
This easy-to-understand book by an expert gives you the facts and helps you use the data you've been wanting.

MODERN OSCILLOSCOPES AND THEIR USES

by JACOB H. RUIER, Jr.,
of Allen B. Du Mont Laboratories, Inc.
326 pages, 370 illustrations, $6.00

This big book gets right down to earth in explaining oscilloscopes (cathode ray oscillographs) and showing exactly how to apply them to specific A.M./F.M./TV service jobs. No involved mathematics! First the author explains oscilloscopes fully. Then, in easily understandable terms, he tells exactly how to employ them on specific jobs—from locating receiver troubles to aligning and adjusting the most complicated circuits.

WHAT IT IS—HOW IT WORKS

HOW TO USE IT ON THE JOB

MAKES THE OSCILLOSCOPE EASY TO UNDERSTAND
Each operation is carefully explained including the making of connections, adjustment of circuit components, setting the oscilloscope controls, and analyzing oscilloscope patterns. About 400 illustrations, including literally dozens of pattern photos, make things doubly clear.

Besides its radio and TV uses, you learn about many oscilloscope applications in industry and teaching. Send coupon today for your copy of MODERN OSCILLOSCOPES AND THEIR USES. If not more than satisfied, return it after 10 days and we'll gladly refund the purchase price.

The 40-inch focal length lens is no longer than other standard TV camera lenses.

New TV Lens Has Mirrors

A NEW kind of lens for television cameras made its debut several months ago in a CBS football broadcast. The lens has a 40-inch focal length and will make the figure of a man more than a block away from the camera completely fill the television screen.

The new device, known as the Video-Reflector, was invented by Dr. Frank G. Back, whose company, F. G. Back Video Corp., is producing it.

Increased focal length is achieved by the use of mirrors. Note path of light rays.

Resolution was poor.

The total length of the new lens, from mounting to tip, is 16 inches. The 40-inch focal length is made possible by the technique of passing the light several times through the same space.

As the photo shows, the Video-Reflector looks more like a stereopticon than a lens. It is shown mounted on a standard TV camera lens turret with three other standard lenses.
**ELECTRONIC LITERATURE**

Any or all of these catalogs, bulletins, and periodicals are available to you if you write to us on your letterhead (do not use postcards) and request them by number. It is necessary to send only the number of item you want. We will forward the request to the manufacturers, who in turn will send the literature directly to you. This offer void after six months.

**A-1—TRANSFORMER CATALOG**

The 15-page Catalog No. 49A, published by Audio Development Co., describes power and audio transformers, power-supply, bandpass, and sound-effects filters, patch cords, and plugs. Electrical and mechanical specifications are given where necessary.—**Gratis**

**A-2—SHIELDING INFORMATION**

Mechanical Aspects of Electronic Assemblies, a reprint from Product Engineering issued by the New York University Bureau of Public Information. This 4-page folder deals with parts placement, wiring methods, grounding, sub-assemblies, etc., but most particularly with shielding problems. A table of recommended shielding, wiring, and grounding practice for 25 types of electronic equipment and a chart showing thickness of shielding required for frequencies from 10 kc to 10 mc form part of the presentation.—Price 10 cents

**A-3—MAGNETAPE RECORDERS**

A publication of the Amplifier Corp. of America describes their 1950 line of magnetic-tape recorders. Two introductory pages are devoted to a technical discussion of the features of Twin-Trax recorders, illustrated with mechanical drawings and schematics.—**Gratis**

**A-4—MULTI-ANTENNA SYSTEM**

Catalog No. 149 of the Jerrold Electronics Corp. describes their Mul-TV Antenna System, also accessories and associated equipment. 8 pages.—**Gratis**

**A-5—SERVICE EQUIPMENT**

The Superior 1950 test equipment catalog covers the complete Superior line. Besides a complete line of radio test equipment, an industrial analyzer, with ranges up to 6,000 watts, 5,000 volts a.c. and d.c., and direct and alternating current up to 30 amperes, is described.—**Gratis**

**A-6—AMPLIFIER CATALOG**

The latest Bogen catalog contains 19 pages, listing public-address amplifiers and accessories—microphones, speakers, matching transformers, and so on. Two of the amplifiers have the anti-feedback control which "tunes out" acoustic feedback from loudspeaker to microphone.—**Gratis**

**A-7—TRANSFORMER REPLACEMENT GUIDE**

Stancor replacements for the transformers used in 108 popular television receivers are listed in this four-page reference. Power and audio transformers, filter chokes, deflection yokes, and focus coils are included.—**Gratis**

Four Stores To Serve You

6205 Market St., West Phila., Pa.
6th & Orange Sts., Wilmington, Del.
4401 Ventnor Ave., Atlantic City, N.J.

---

A Brooklyn television dealer cuts down nuisance service calls by running free television classes for his customers, teaching them to distinguish between real faults and bad reception conditions.
Question Box

SURPLUS A.F. TRANSFORMERS

? I have the driver and modulation transformers from an ART-13 transmitter. I want to use these to modulate an 813; however, I do not have sufficient information on the transformers or the conditions under which they were designed to operate. Please prepare a diagram of the ART-13 speech amplifier and driver and show the terminal numbers on the transformers.

—W. W. W., Bronx, N. Y.

A. The diagram shows a speech amplifier, driver, and modulator much like those used in the original transmitter. The modulation transformer is designed to match the 15,000-ohm plate-to-plate impedance of push-pull 811's to an 813 with 1250 volts at 170 ma on the plate. An additional secondary winding is used to modulate the screen of the final amplifier. Because the modulation transformer is small, the 811's are held down to a little more than 100 watts output—sufficient to fully modulate a 200-watt final.

The driver is a 6V6 with inverse feedback to lower its apparent load impedance. A single 6SJ7 or similar speech amplifier will drive the 811's to full output when fed by a microphone having high output. A speech amplifier stage is needed in front of the 6SJ7 shown on the diagram if a low-output dynamic or crystal microphone is to be used.

CRYSTAL-CONTROLLED CONVERTER

? Please print a circuit of a crystal-controlled converter for use with my automobile radio for reception of 39.42 mc signals. I would like to be able to turn the converter off and switch the antenna to the receiver at the same time.

—J. V. D., Brooklyn, N. Y.

A. The converter is shown. Its tube line-up consists of a 6AK5 r.f. amplifier, 6J6 mixer, and a 6J6 crystal oscillator and tripler. The input and output circuits of the 6AK5 are tuned to the same frequency, so take care in laying out the circuit to prevent oscillations. Use a shield between the antenna and the mixer grid circuits. R.f. stability is insured by tight coupling to the antenna and through the use of the r.f. gain control.

A 12.64-mc crystal oscillator is followed by a tripler tuned to 37.92 mc. There may be sufficient coupling between the tripler plate and the mixer grid circuits for good mixer performance. If not, then connect a lead to the tripler plate and couple it to the mixer grid through a two- or three-turn twist of wires to form a capacitor.

If the broadcast antenna is found to give good results on 39 mc, it may be used for high-frequency and broadcast reception. A three-pole, double-throw switch transfers the antenna from receiver to converter and controls the filament circuit of the converter. If a separate high-frequency antenna is used for 39-mc reception, then a d.p.d.t. change-over switch can be used. One section will switch the receiver input circuit to the broadcast antenna or to the output of the converter, and the other controls the converter filament circuit. The 39-mc antenna may then be connected permanently to the converter. Shield all leads to the receiver's input circuit to prevent stray 1500-ke pickup when the converter is in use.
L2 and L3 are 10 turns of No. 12 enameled wire, 1/2 inch in diameter and approximately 2 inches long. L1 is 6 turns of No. 14 d.c. wire wound with the grounded end of L2. L4 and L5 are primary and secondary of a standard 120-1500 converter output transformer. The primary is tuned by capacitor C.

L6 is 10 turns of No. 18 enameled wire, 3/4 inch in diameter and approximately 3/8 inch long. L7 is 5 turns of No. 18 enameled wire, 3/4 inch in diameter and 5/16 inch long. L6 and L7 may be cut from a 2-inch length of B & W type 3011 Miniductor.

A grid-dip meter or sensitive wavemeter is used when tuning the oscillator and tripler circuits. Tune L5 and L7 for maximum indication on the wavemeter at frequencies shown in the diagram. Adjust the mixer plate circuit to resonance by connecting the converter to the antenna post on the receiver. Tune the receiver to 1500 kc. Set a modulated signal generator to 1500 kc and adjust C for maximum output from the receiver. If a signal generator is not available, connect an antenna to the mixer grid and tune in a 1500-ke broadcast station. Peak the output circuit as described for the signal generator.

Adjust L2 and L3 with a 39.42-mc signal from the transmitter or signal generator. Adjust the tuning capacitors for maximum signal.

Plate and heater voltages may be taken from the automatic automobile receiver. It may be necessary to use heater and plate chokes in the leads.

**SUBMINIATURE TUBE TESTER**

I would like to construct a simple battery-operated tester for Raytheon subminiature hearing-aid tubes having 5J-type base connections.—W. T., St. Catherine's, Ont.

A. An emission-type tube tester which should meet your needs is shown in the diagram. A five-prong subminiature socket is used for checking all tubes having 5J base connections. A 1.5-ma meter is used to read filament voltage and cathode current directly. When the switch is in the FIL position, the 1K resistor is in series with the meter to make it read the filament voltage.

Adjust the setting of the rheostat for correct filament voltage before inserting the tube in the socket. The meter may be calibrated for various tubes by testing new ones.

Jerome R. Steen, director of quality control for SYLVANIA ELECTRIC PRODUCTS, INC., has been elected to grade of Fellow by the board of directors of the INSTITUTE OF RADIO ENGINEERS. He will receive a Fellowship Award during the institute's National Convention in New York for his work "in the introduction and development of statistical quality control techniques in electron tube manufacturing."

R. L. Grove has been appointed chief engineer of CORNELL-DUBILIER'S Ceramic Division in New Bedford, Massachusetts, according to announcement from OCTAVE BLAKE, president. This new activity includes setting up the manufacture of a line of ceramic capacitors and the establishment of a ceramic research and control laboratory.

Dr. William F. Meggers, Chief of the spectroscopy section of the NATIONAL BUREAU OF STANDARDS, has been elected President of the OPTICAL SOCIETY OF AMERICA at the Society's thirty-fourth annual meeting. The Optical Society serves as a common meeting ground of physicists, chemists, physiologists, psychologists, engineers and mathematicians in the general field of optics. Election to the presidency is the highest honor the Optical Society of America can render to a scientist in this field of optics.

Dr. Dayton Ulrey, chief engineer of the Lancaster, Pa., plant of the RCA Tube Department, has retired, but is retained as consultant to the company.

An early researcher into vacuum tube design whose life's work has paralleled the development of the radio and television art, Dr. Ulrey is also well known as an administrator and teacher. In this capacity, he was instrumental in securing needed facilities for many young scientists engaged in radio and television research, some of whom are the leaders of the industry today.

Joseph A. McDonald, vice president, general attorney and secretary of the AMERICAN BROADCASTING COMPANY, has been elected a member of the Board of Directors of the TELEVISION BROADCASTERS ASSOCIATION, INC. He succeeds ROBERT E. KINTNER, ABC president, who has resigned.

McDonald is a veteran of the radio industry. Between 1932 and 1945, he served on the legal department of the NATIONAL BROADCASTING COMPANY in New York and Chicago, becoming assistant general counsel of NBC in 1943. In February, 1945, he was named vice president and general attorney of ABC.

John Bentia, sales manager of the ALLIANCE MFG. Co., has been given direction of the company's greatly expanded 1950 Tenna-Rotor advertising campaign. Mr. Bentia reports that over 50 radio stations will be used for chain-break spot announcements and that distributors throughout the country's TV trading area are tying up with the campaign through point-of-sale promotion for the Tenna-Rotor.

Robert D. Hickok, Jr., has been elected president of the Hickok Instrument Co., succeeding his father, who died January 23. WALTER WEISS was made vice president in charge of engineering at the same time as the younger Hickok was elevated to the presidency of the company.

The new president has been a vice president and acting general manager of the company for the last ten years.

Dr. John McElhinney has joined the staff of the Radiation Physics Laboratory of the NATIONAL BUREAU OF STANDARDS. He will use the Bureau's new 50-million volt betatron to carry on investigations of nuclear reactions and high-energy X-rays.

Antony Wright has joined CAPEHART-FARNSWORTH CORPORATION, Fort Wayne, Indiana, as chief engineer for the Consumer Products Division. For the last two years, he has been chief engineer for the MAGNAVOX COMPANY.

RADIO-ELECTRONICS
PHILCO UN6-400

Intermittent noise and loss of sensitivity were traced to shorted capacitor C-407 between the plate of the 7A7 and the control grid pin (No. 6) of the 7B8. The shorted capacitor (250 µf) was discovered when a v.t.v.m. showed positive voltage on the 7B8 grid.—T. Horiuchi

HUM IN A.C.-D.C. SETS

If hum cannot be eliminated in a.c.-d.c. sets using the volume control circuit shown in Fig. 1, C2, R1, or the grid of the tube may be picking up hum from adjacent a.c-carrying leads. If this is the case, the hum level is not controlled by the setting of the volume control.

TO DET LOAD RES

Fig. 1—Components in this circuit may pick up hum which is hard to eliminate.

This trouble can be eliminated or at least considerably reduced by removing C2 and R1 and connecting the grid of the tube directly to the arm of the control as shown in Fig. 2. In this circuit, hum picked up by the control grid of the tube will get louder as the control is advanced. In most cases, the signal is loud enough to mask the hum.

TO DET LOAD RES

Fig. 2—Changing Fig. 1 to this circuit may reduce hum to a tolerable level.

This conversion can be made on sets having the volume control in the diode load circuit. C1 in both circuits decouples the volume control from the detector load.—James W. Essex

RCA 630TS

Horizontal distortion could not be corrected with the linearity control. This component, L-201, was found defective when checked with an ohmmeter (its normal resistance is 37 ohms). A factory replacement restored the set to normal operation.

When horizontal nonlinearity is not caused by a defective control, check capacitors C-186 and C-188 on a capacitance bridge. Their values should be .05 and .035 µf, respectively. These capacitors are connected between the ends of the control and the high-voltage center tap.—Wilbur J. Hantz

THE AMATEUR ALIBI

Dear Editor:

Re “TV Interference Problems” by William L. Kiser in your January issue, I say Amen, brother! To the paragraph, “The Amateur Alibi.” Being both a ham and a serviceman, I can truly vouch for what he says. Sad as the fact may be, the amateur alibi used by many service technicians is merely a manifestation of incompetence.

PETER N. SAVESKIE

Baton Rouge, La.

RMA COLOR CODING

Dear Editor:

Under “Electronic Literature,” item D-8 on page 89 of the December 1949 issue of RADIO-ELECTRONICS, it stated that the Aerovox Duranite Decoder Chart lists “RMA color coding for molded tubular capacitors.” This statement is incorrect. There is no RMA standard for molded tubular capacitors, nor any color coding for them.

In checking over the subject chart very carefully, I can find no reference made on it nor any of the Aerovox literature to the effect that this color code is supposed to be “RMA standard.” The same observation pertains to Syracuse literature on molded tubulars. This color coding is a development of the manufacturer and though based on similar RMA coding for molded composition resistors, cannot rightfully be called RMA standard.

This is for your information. I doubt whether there would be any point in retracting the statement, but should similar reference recur you will be in a position to avoid a misstatement.

PAUL S. SMITH
Chairman, RMA R15 and CC Committees on Color Coding
Motorola, Inc.
Chicago, Ill.

INVENTORS

IF YOU WISH TO PROTECT YOUR INVENTION
YOU SHOULD TAKE STEPS TO PROTECT IT BY A U. S. PATENT

Whether an invention is patentable can be substantially determined by a search of the U. S. Patent records. Without obligation, write for information explaining the steps you should take to secure a patent.

GEORGE B. OUJEVOLK
Registered Patent Attorney
505 FIFTH AVENUE NEW YORK 17, N. Y.
ON THE EUROPEAN TV SITUATION

Dear Editor:

We read with interest the European Report in your January issue but cannot compliment your correspondent on his knowledge of the TV situation in Europe. He states that "Holland is developing 449 lines, the Iron Curtain countries 625, Italy 441 and Denmark 697." This is definitely incorrect!

The facts are as follows. Britain has chosen 405 lines as their definition for the next ten years; France has done the same with 455 lines while at the same time beginning with the new French standard of 819 lines which nowhere met with a favorable reception, not even in France.

The other European countries tend towards a “European” definition of 625 lines (which at 25 frames per second corresponds to the American standard of 525 lines at 30 frames per second). Holland adopted that standard for a period of ten years and other countries such as Switzerland, Denmark, Sweden, Czechoslovakia and Western Germany had already done the same thing. It is believed that Spain, Portugal and Italy will also adopt the “European” definition. Thus there is a majority in Europe for the 625 lines, opposed only by England and France because they already have committed themselves to other definitions either higher or lower.

In Belgium the general feeling is that the 625 lines definition is the most businesslike which can be realized at once. However, our country has not yet made a decision but will try to mediate at a conference to be held in London on January 10.

CTI COLOR TV USES
SEQUENTIAL LINE

Dear Editor:

There is an apparent misunderstanding of the CTI color system in Dr. de Forest’s article on color television on page 24 of your January issue, where he likens the CTI to the RCA system.

Color Television, Inc., of San Francisco, employs a sequential color line system in contrast to the sequential color dot system of RCA and the sequential color field system of CBS. CTI utilizes a single pickup tube in the camera with a single electron beam which scans the three optical images focused on its photocathode. In reproduction at the receiver it utilizes likewise only a single cathode-ray tube with a single electron beam. The beam reproduces three images on its fluorescent screens—one image falls in the red phosphor area—the next image falls in the green phosphor area and the third image falls in the blue phosphor area. The three images are superimposed into the final color picture by means of an optical system on a projection screen.

Black-and-white programs as now being transmitted may be received on CTI color receivers without any change as well as their receiving any CTI color transmissions. Also, the present black-and-white receivers owned by the public can pick up CTI color transmissions as black and white without any modifications. The unique characteristic of the CTI system is that it accomplishes 100% compatible color television with the present black-and-white standards and it is far less complex than the other fully electronic system—that of RCA.

I take the liberty of passing this information on since there is not much data available on the CTI system outside of the FCC record of hearings. My information comes to me as a stockholder in CTI and I hope it will be of interest to your readers.

Enter a dynamic profession! Become an ELECTRICAL ENGINEER

- MAJOR IN POWER OR ELECTRONICS
- B.S. DEGREE IN 36 MONTHS

Look at the powerful trends which influence your future in these fields.

Men specializing in Electronics enter a science of tremendous, growing value—in communications, radio, television, broadcasting, high-frequency heating, power system control, printing, and other fields.

Men specializing in Power become equipped to serve the electrical power industry, which must face an 80% expansion of its generating capacity by 1960.

This 47-year-old Technical Institute and College offers important advantages to the young man preparing for these opportunities. He saves a valuable year by gaining his B.S. degree in 36 months of continuous study. He receives extensive technical laboratory experience on modern equipment. This is integrated, in each successive term with fundamental education in engineering and the humanities.

The World-famous course in Power covers 24 technical specialty subjects in Electrical Power, including 8 in Electronic Design.

MILWAUKEE SCHOOL OF ENGINEERING
Founded 1903 by Owen W. Wernau

Over 35,000 alumni and 1,555 students. Faculty of 85 specialists.

Practical, military or academic training evaluated for advanced credit. Preparatory programs also available.

Sturdy shelled pole A.C. induction motor. Mounts easily. 3.2" x 2.5" head. 110 volt, 60 cycle A.C. Only. Weight is 5 lbs. This motor easily provides up to 1 HP. Can be used for a Flywheel, Generator, etc. Can be operated from 120 volt, 60 cycle A.C. Can be connected to a 12 volt D.C. battery. Ship. wt. 6 lbs.
ITEM NO. 147 UNUSUAL BU...

This second edition of a standard work (reviewed in Radio-Craft May 1944) has 80 more pages and 25 more diagrams than the first edition. The chapter on receiver noise has been entirely rewritten and the space given to negative feedback greatly expanded. Other revisions appear throughout.

WHO KNOWS—AND WHAT. Published by A. N. Marquis Co., Chicago. 73 x 10 1/2 inches, 796 pages. Price $15.75.

This unusual book lists the names and addresses of 16,000 men and women who qualify on 35,000 subjects as experts. Each name is followed either by a short biography or by a symbol indicating that a biography appears in Who's Who in America. Another symbol tells whether the person is available for consultation.

The fourth edition of this complete listing of shortwave broadcast stations of the world, together with long- and medium-wave stations of most countries (the United States is the notable exception), is dated October, 1948. The handbook is now coming out as an annual, with the next edition to be published late in 1950.

The arrangement of earlier editions is followed. Stations are listed according to political divisions, with frequencies, wavelengths, power, main programs and the names and addresses of the companies or administrations responsible for their operation; even the names of the leading personalities are included. A list of long- and medium-wave stations of Europe, North Africa, and the Near East, and a list of the shortwave stations of the world, both arranged by frequencies, is included.

HERE IS THE LONG SOUGHT ANSWER IN TELEVISION TRAINING FOR THE MAN ALREADY IN RADIO! TRAIN AT HOME—FULL PROGRAM—4 TO 8 WEEKS!

Low Cost—Monthly Payments. Everything You Need to Learn...

TELEVISION

I Send You NOT JUST an Ordinary TV Kit—But a Complete Training System Including TV Test Equipment

Here is the NEW Combination Sprayberry Television Training System

Out of my laboratory has come an entirely new Television Training... cutting months off the time required in old methods. I give all the knowledge and experience you need in weeks instead of months. I start where your present radio experience ends. The same day you enroll with me, I rush the first of many big Televisions kits that I will send you for training. From the first hour you are experimenting and testing practical TV circuits... and you keep right on from one fascinating experiment to another. You build the remarkable new Television Receiver-Tester illustrated at the left and useful TV Test Equipment. I give you theory, too, but it's 100% practical stuff that will make money for you in Television.

YOUR CHOICE OF 7, 6½ OR 10 INCH TELEVISION PICTURE SIZE

Exclusive THREE-UNIT Construction

You build my Television Receiver-Tester in three separate units—one unit at a time... each complete and self-contained within itself. With each unit you perform dozens of important experiments—and each unit may be used in actual Television receiver servicing. In this way my training may save you many dollars by eliminating the need for costly TV Test Equipment. With these three units you can locate most TV Receiver troubles quickly and easily.

BE READY FOR TOPE PAYING TELEVISION JOBS

If you are a radio serviceman, experimenter, amateur or advanced student... YOUR FUTURE IS IN TELEVISION. Depending upon where you live, Television is either in your town now... or will be there shortly. This is a vast new industry that needs qualified men by the thousand to install and service TV sets. There's really big money in Television, but you MUST know what you are doing to "cash-in" on it. I will train you in a few short weeks if you have had previous radio training or experience.

VETERANS—Radio portion of training available under G. I. Bill

The quality of RCA tubes is unquestioned.

Higher Quality Standards
for TV, FM and AM

The quality level of RCA miniatures has been continually advanced in step with circuit progress. Improved design . . . more rigid control over manufacture and inspection . . . and more exacting tests, including rigid re-test before shipment, are the reasons why RCA miniatures have unusually uniform characteristics, so important to tubes for television receivers in particular, and also for FM and AM receivers. Their dependability in critical circuits cuts down costly service call-backs.

And now . . . this extra quality of RCA miniatures is "packed in so it can't be shaken out." A new type "snug-fit" carton protects tubes against damage by holding them securely in place during transit.

RCA's engineering leadership adds value beyond price to the RCA tubes you sell. Your customers know about this advantage too.
