

# The Concise HOUSEHOLD ENCYCLOPEDIA 

A Practical Guide Written by the Leading Experts in all Branches of Homecraft

6,000 ILLUS'TRA'IONS

Complete in One Volume

> LONDON

The Amalgamated Press Ltd. The Fleetway House

## THE EDITORS FOREWORD

AI no period of our modern social history has the need been more pressing for such service as the Concise Household Encyclopedia provides. The high cost of labour, arising from post-war conditions, has so increased every item of domestic expenditure that even in houscholds where formerly economy was little studied it is now usual to avoid calling in outside assistance on all sorts of repairing jobs that can be done by members of the family with such guidance as may be given by printed instructions.

The practicability of written instruction has long been recognized, but never so effectively proved as by the subscribers to the original six-volume Household Encyclopodza, now out of print for some years. The editor has received from numerous subscribers the assurance that by following its instructions they have saved its total cost several times over. No wonder, for the work contains the greatest body of practical information on every aspect and detail of domestic life ever brought together.

The Concise Household Encyclopedia is a completely revised and condensed version of the original, produced under the same editorship and, in the main. by the same staff of experts. It has the great advantage over the parent work that all the practical information has been retained unimpaired, improved indeed, by being reduced to that conciseness of statement
which has made it possible to embody in one large but not inconvenient volume the essential text and illustrations of the whole six volumes.

Wherever newer methods than those described in the original work have been devised they will be found in this Concise edition; and recent years have seen great advances in the perfecting of household appliances as well as many ingenious inventions that render the task of the housewife more pleasant and the results of her work more efficient. All these, and most of the approved devices, old or new, that help in a practical way to the increased comfort of the home, are hare recorded and illustrated in some ten thousand clearly written articles.

THis immensely valuable treasury of information and advice for the housewife and the handyman-be the latter's bent towards woodworking, decorating, gardening, poultry-keeping, or amatear mechanics-arranged as it is in alphabetical order, is instantly accessible for consultation when the need for the specific information arises. No other work of the kind exists.

In order to give the reader some idea of the comprehers sine nature of the Concise Household Encyclopedia we print below the synoptical table which was framed as a guide for its departmental editors in preparing the contents of the work. These editorial divisions do not of course, appear in the printed pages.

## THE CONCISE

HOUSEHOLD ENCYCLOPEDIA

ARERDEEN TERRIER. The Aberdeen or Scotch terrier is an excellent house. dog, a good ratter, and readily teachable. From 9 in. to 12 in high, it las a short, hard, wiry coat of iron-grey, brindle, black or sandy, and soft under-fur. A white variety should have no admixture of other tints. The outer coat is of uniform density, about 2 in . long, end without silkiness or curling The dog is short-hacked and rather fint-sided, with strong hindquarters; short legs, and small, short-hajred feet.

The head is rather long and domed, with a drop between the eyes to the muzzle, which tapers to the broad, black nose projecting over level jzws. Neck short and muscular, shoulders slopins, chest broad and deep : amall, pointed, velvety ears See Dog.

Aberdeen or Scotch Terrier, prize-winning apecimen

ABSCESS. This name is given to a collection of matter or pus, of which there are two distinct kinds, acute and ohronic.

Acute Abscess. The entry into the body of germs which cause suppuration may give rise to an acute abscens. If an ahscess occurs the regult is the collection of a thick yellowish Huid sarrounded by a thickened layer of tissue which consticutes the wall of the ahscess. This may occur anywhere; it may be superticial or it may be deep. The lluid is always under pressure, and this fcrees it along the path of least resistance, usually to the surface.

An :cute abscess produces pain and tenderness. There is also swelling, at first hard and biawny, but later soft, particularly in the centre. The pus is finding its way out, and is said to point at the spot where it will reach the surfact, indicated by a deeper redness. The akin becomes very thin, with an increase of pain, and finally the abscess bursts. The patient suffers from fever, not very much, perhapis, in the case of small abscesses, and may have a rigor-that is, feel cold, even to the extent of his teeth chattering. Then he will feel hot, and finally his skin, which has lreen bot and dry, will be covered with profuse perspiration. There will be sevcral fits of this alternute heat and coldness, but the discomfort will subside as the abscess gradually ceases to discharge.

Treatment is a matter for a surgeon. While the abscens is forming, relief may he afforded by resting the part; and it will usually be found that if the afflicted member be raised (e.g. with a sling) the pain will be less. Fomestations may aiso be useful, and these can bo wrung out of hot water in which boracio acid has been dissolved (l oz. to the quart) and covered over with gutta-percha tissue or jaconet. But when pus is definitely present it must be let out.

Chronic Abscess. The second kind of abscess, which is generally painless and may dry up without hursting, is a form of tuberculosis (q.v.), heing caused by the tubercle bacillus.

ABUTILON. Evergreen shrub with bellshaped flowers and handsome lea ves, a desirable climber for raftera or pillars, or planting out. The best varieties for growing under glass to flower in Aprilare: Darwini, orange ; fleur d'or, orange and red; canary bird, yellow : houle dc neige, white; Princess Marie, rose lake.

Propagation is lyy cuttings of young wood struck in a temporature of $60^{\circ}$ in summer. Also from seeds in a propagator or over bottom heat. They are generally $80 \times \pi$ in spring. Pron. A-bu'ti-lon.

ACACIA. One of the acaeias is commonly known as the wattle or mimosa (q.v.). The so-called acacia tree of suburban gardens is Robinia, or false acacia (ๆ.v.).

ACANTHOLIMON. Dwart cvergreen plants, somewhat resembling thrilt, but with stiff, spiny leaves, suitable for the rockery. A popular species is glumaceum, which hears a profusion of rose-colourcd flowers in summer. Venustum also has a rose flower.
Those sea lavenders thrive in warm. gritty, well-drained soil. They are propagated by cuttings or layers taken in the late summer. The slipe must be wintered in a cold frame, and do not make good plants until the second year Pron. Ak-an-tho-li'-rnon.

ACANTHUS. Of the two species of acanthus, spinosus is so called from its spiny leaves; mollis, or bear's breech, is characterised by large, deeply out leaves, with soft spines. The plant grows about five feet high, flowering in summer, and is well adapted for herbaceous borders. Latifolius, a form of mollis with heart-shaped leaves and white or pink flowers, is unsuitable for small gardens.

The best way of raising a stock is to sow secds in a warm frame or greenhouse in spring. Further increase can be effected by division in autumn or spring. See illuatration below.
ACCELERATOR. This is a mechanical device, used in connexion with petrol motors, gas and oil engines, by ineans of which the speed contmler nay be rendered inoperative. See Governor; Motor. car: Thmotle.
ACCIDENTS. There aretwo senses in which the word accident is used in speech and by lawyers: (1) An occurrence which happens neither by negligence nor design; and (2) an untoward event which causes in. jury or damage, even though it may be caused by somebody's negli. gence or design this we speak of a man being in. jured by nn accident if he is knocked down by a motor-car, the fault of the
 of a common variety
driver or the fault of the injured man himself Householders should always insure against liability under the Workmen's Compensation Act. hecause under it an employer is liable to compensate a servant who meets with an accidental injury arising out of and in the course of the employment Accidental is here used in the wide, popular sense
For accidents caused by a person's negligence, he is resimonsible For accidents caused by a wife's negligence. the husband is responsible. For accidents caused by a servant in the course of his work, the employer is re. sponsible; for example, if a house maid, cleaning the windows, negligently drops the bucket on the head of a passer.by, her master is responsible Alower spray, showing
drooping blossoma and vine-like leal responsible for the accident. A parent is not responsible
for accidents caused by the negligence of his child-unless, of course, the child is in the parent's employ and the accident is caused by something done during the employment

Accident Insurance. Insurance of this nature is a wise precaution, and is generally effected through an agent. Owners of motorvehicles are now compelled to insure against accidents causing hodily injury to third parties. In filling up a proposal form, care should be taken in answering the questions as to age, state of health, and other matters, because if this is not done correctly the policy will be void. It is not "ise to allow the agent to fill up the form. Many eases have occurred in which agents, with an ege to commission, have filled in untrue answers, and in such cases, where this insured has signed without reading the paper carefully, it has heen decided that the agent in filling up the form does so as the insured's agent; with the result that the policy is void.

When an accident brings on a disease causing incapacity the insured is entitled to compensation under an accident policy, lecause there is one chain of events leading from the accident to the disahlement.
Everyday Accidents. The majority of the accidents that nccur in the home are preventable. Firesshould never be lighted with paraftin or other inflammahle liquid, owing to the risk of serious injury or even death. Gas has its dangers also if jets are not kept clean and in good working order. A blow-out in the gay oven may set u flimsy apron alight, or a lighted match in searching for an eacape of gas will cause an explosion and considerable damage and injury.
Everywhere in the home where there is gas, attention should be paid to loose taps that may get turned on by accident. It is also better to leave the gas turned on at the meter all night rather than risk the asphyxiation of someone whose bedroom light has been in use when the meter tap was turned off.
To use the proper utensils for the small details of cooking is a sensible way of avoiding accidents. Severe cuts, for instance, often occur through the careless use of a sharj,
knife for chopping suet, etc. Splitting kindling wood with a large knife or a heary axe is not worth the danger it involves when a proper wood chopper costs only a trifling sum Awkwardly placed pans on the atove are easily upset, with consequent scalding accidents. Similarly the spout of a boiling kettle should be turned sideways instead of towards the front of the stove.

Floor coveringa are л cause of accident when insufficiently tacked down, or when slippery with too high a polish. A loose stair rail or a mat in an awkward place may cause a broken neck. Stairs should be lighted at all times.
The use of a step-ladcler for putting up draperies, pictures, etc., is safer than the nakeshift method of using a chair perched on the top of a table. It should be ascertained that the ladder itself is quite firm before it is mounted.

Low window-sills are a serious danger Persons who walk in their slcep have heen known to step right out of a low window and fall several storeys. Children playing near such a window are only too likely to venture too far over the sill.

Lastly, there is always the danger of live. In addition to gas and paraftin the following should be guarded against : failure to damp coal or wood fires when leaving a room; taking candles to look into a cupiboard in which clothes are hanging; amoking cigarettes in loed; placing a candle too near bed draperies; and carelessly dropping glowing cigarette ends on a carpet or in a wastepaper basket.
ACCORDION. Suited to the needs of those who wish to play only a simple melody, the accordion or melodeon is so constructed as to furnish an elementary accompaniment of chords. Its drawback is that it etands in one key (C) slone, and that as modulation is impossible, except by iniplication. the choice of music is restricted. It consists of a small pair of bellows, worked by the left hand, which also controls certain valves, viz. the wind valve (thumb), the accompaniment valve (index finger), and the hase valve (little finger).

At the other end of the hellows is a key. board having a varying number of keys which are played by the fingers of the right hand. On being depressed these keys adnit wind to the reeds, which produce one sound when the hellows are pressed in and another when they arc drawn out. The compass varies accurding to the size of the instrument, that of the accordion with 12 keys being
the notes required. If there is a long series of push-in notes, they may be fully inflated. The music is written on the treble staff.

After use an accordion ahould be wiped and placed where it will be kept free from dust and damp.

ACCORDION PLEATING. In concertina form instead of flat, this pleating is chiefly suitable for dancing akirts and frillings. It should be put in by machinery, is it requires heavy jressure. Re.plenting is done by cleaning firms at moderate cost.

## ACCOUNTS: How to Keep Them.

 The simplest way of keeping accounts is in n cash book ruled with three columns for the $£$ s d. On one side, the left, or debit, is entered all that is received, and on the other, the right, or credit. all that is paid out. The amounts in each can he added up every week or month as desired. and the balance shown compared with that which actually exista in cash. The itcms on the right-hand side can be examined and put into classes, thus showing olearly what has heen spent in a par. ticular oirection. In keeping a banking account one method is to enter all re ceipts and all payments, whether made in cash or by chergue. in the one accomit. The halance will be that of the two combined the cash in hand and the cash at the bank. Another method is to kicep two accounts. one for cash and the other for items that pass through the banking account. The cash accomit ann then he cherked hy the amount of cash in hand and the other by the pass book provided by the bankHouschold accounts can be kept in an account book with the pages prepared and ruled. for n quarter or a year, as shown in the form ahove.

Daily amounts expended should be entered in the places intended for them and amounts receicerl in the spaces below. At the end of
payment column at the bottom of the page and the amount of cash in hand ascertained and enterad.

Tho last column on the right-hand side of the sample is provided to check exper diture more carefully. In it are entered weekly the ainounta spent up to date on each housekeeping item, and also the total obtained by adding the totals for the waek in question to those on the previour page of the account hook. Thus at the end of any atated period the hol sewife can tell whether her housekeeping is coutin! more than it ought to do or whether any particular item is exceeding the allotted araount.

ACCOUNT STATED. When tuo people have accounts, one against the other, and they agrec the account at so much, it is called an account atated. The account may be relipened on ahowing fraud or mistake, but the innport ance of an account stated is that it gires rise to a new cause of action, and the statute of limitations runs from the date when the account was atated
hoderemeping account fon the Weak Ekding Saturday (dalk) Particulars Sali. Mon. Tue. Wetl. Thu. Fri. Sat. the week to date

ACCUMULATOR. Electric accumu lators are employed for providing eectric light and to a lewa extent for traction. as in electric carriages and motor launches The necumulator is an indispensable adjuict of the small, arlf-contained electric-lizhting jlant. On motor-cycles accumulatols are used for lighting; and on cars for lighting and for the electric atarter, horn, and other devices. As a source uf low tension and, to a less ixtent, of high tension current, the accumulator is used in a great number of wireless 8 eta.

Whatever the compass, all have one fenture in nommon : there is a diatonic succession of notes in the middle, with gaps at each end. The accordion with 21 keya has them disposed in two rows, one in $G$ and the other in $C$, a simple modulation being thus possible

In auch types of accordion every C., $\mathbf{F}$, and $G$ is a pressed-in note, all the rest being drawn out: They form the tonic or key-note chord, while the others mostly belong to the dominant chord (the fifth degree of the scale). It is possible not only to play with the fingers $n$ melody with or without a simple harmonisation, but by means of the accompaniment valve to add therefo the following chords:

and by the bass valve these notes:

For playing, the intrument rests on the performer's knee. The bellows must first be inllated by means of the wind valre, to what extent depending on

each week the accounts are marle up by adding the amounts in each daily column and the amounts in each line, after which the totals of the six daily columns and the totala of the various headings ahould he added up. If no mistake has been made these two totals will agree. The daily total is tranaferred to the

Accordion. The 21-note instrument, taken apart. A, bellows. B, melody kegboard. C, valves for accombaniment. etc.

An electric accum ilator, known also as a accondary battery and as a storage battery, differs from a primary electric cell in that the accumulator deas not generate encrgy, but is charged by sending an electric curment thmugh the cell from an outside source.

The lead-acid type of accumulator it common use consiats of a rectangular conta ner of glass, celluloid, etc., in which are a num ber of grid-like lead plater, grouped into pasiti*e and negative clements. The plates are imiaersed in an electrolyte consisting of sulphuric acid in distilled water. The interstices of the grids are filled with a preparation of lead, and the plates are kept from touching by spaners of aome non-conducting material. The pisitive and negative plates alternate, all the positive being connected together and all the negative grids being similarly coupled

When a auitable electric current asont through such a cell, hydrogen passes fiom the anode or positive plate, which is said thus to hecome peroxidised, to the other pla e-the cathode or negative-where it combines with
somo of the oxygen of that plate, which thus hecrames reduced. This chemical change is the measure of energy put into the cell and atored. The plates will remain in this charged condition for some time, though they will gradually run down if left alone: but if the terminals of the cell be connected outside, chemical action reatarty in the opposite direction, the hydragen removed from the onc plate returns, and an electric current passes through the connexion in the opposite direction to that in which the current entered the cell. The cell is thins dischargerl. J.hese operations of charging and discharging may be repeated indelinitely. It is while discharging that the electricity which has heen put into the accumulator (stored) is utilised.
While essentially simple, accumulators require enreful attention. The inost serious trouhle arises from sulphating. The sulphate is a is hite scale which forms on the plates and rendars them useleas. Sulphating may arisc from over-discharging, running down the hattery below the limit voltage; by leaving the hattery discharged for a time, or from too atroug a solution. If not ton bad the scale may be acraped off the plates, and by alow and careful charging pmper conditions may be rentored. If hadly sealed the plates may hecome huckled or the preparations disintegrated. necessitnting renewal of the pintes Any acid which may be apilled from tho vents should be wiped of carefully, and the termi nalṣ ahould de coated with petroleum jelly to prevent corrosion.
Now accumulatore are generally sent out dry, i.e. without the eleclrolyte. The maker's instructions should be followed carefully as to the rate of charging, apecific gravity of the electrolyte, etc.

If it is necessary to prepare acial of the reguired strength, the strong acid should be slinoly added to the distilled water, stirring it in a little at a time. Never, in any circum. slances, add uxiter to the acid.
Ancumulators are made up of 2 -volt. units, usually sepsrate, although two or more cells may be housed in a single outer container. The output, expressed in amperes, is govcrned by the size of the cells.

The electrolyte in the cell should cover the platus. Any loas cauned by evapioration must De made good by adding distilled (not tap) water until the electrolyte is at least half an inch ahove the top of the plater. The heat time to do this is just before oharging, as the charging procers facilitatea the mixing of the water and acid. Vent holea should always be clear so as to allow gas to eacape.

The aperifie gravity of the cells can be tested with a hydrometer. A handy type of apparains comprises'an outer tube into which a small quantity of the liquid may be withdrawn by compressing a rubber bulbat the topoif the tube. Inside the tube is the hydro. meter proper, which lloats in the liquid. After teating, the electrolyteis returned to the accumulator. The table above gives average readings for an accumulator in different
states of charge or discharge The hydrometer should be used in conjunction with a voltmeter.

Condition of Cell.
Fully charged
Half discharged
Sp. Gravity
Fully disclinged
1.285

The voltage of n cell should not be allowed to fall helow l-85. On charging, the voltage rises to about $2 \cdot 2$. It is useful to rememher. in connecting cells together, that joining them in series adds voltage, and that connecting them in parallel ndda amperage.

ACETIC ACID. The acid principle of vinegar is acetic acid, of which vinegar contains six to twelve per cent. The kinds and strengthe of acetic acid are:

Pyroligneous Acid. A crudo torm sold ns Essence of Smoke to flavour bacon and dried tish

Glacial Acetic Acid. So called because in cold weather it solidifies and hecomes like ice. It consists of pure acetic acid hurns the skin if applied frcely, and liay a pungent smell. When perfunied it forms aromatic vinegar. used to wet the sponge with which vinaigrettc hottles are filled. The formula is as follows :

Invender oil
Clove oil
Lemon ail
Bergamot oil
Cinmamon oll
Neroliall
40 dopy

Glacial acetic act 40 dmps 40 drops 201 drops
10 drops varts, applied once a day with a small camel. hair hrush. 'The skin mund the wart is ameared with vascline to prevent. hurning the sound skin.

Ordinary Acetic Acid. This contams a thind of its weight of acctic ncid and is userl as a pickling vinegar where the colour of ordinary vinegar is an objection. One part of acetic acid mixed with four parts of water forms white vinegar. which is suitable for pickling vegetahles.

To make spicel vinegnr, hoil for 10 min . the following bruised spices in a gallon of white vinegar:

## ACETYLENE GAS FOR LIGHTING

## Its Use as an Indoor and Outdoor Illuminant

For other Forms of Lighting sce Air Gas: Gas: Elactric Lighting, etc.

Acetylene is a colourless gas, and when pure should he filled and then the doors of the has a rather agrecable odour, but it usually generators talien off, the water cock. $h$ opened, contains impurities which give it a distinctive disagreen ble smell. The gas will explode with great violence when mixed with oxygen or even air in any proportion from 3 jo. to 83 p.c It is not poisonous in small quantities. and burns with a white llame.

Acetylenc gas produced from calcium carhide is largely used for lighting farman and other detached residences which are remote from public sources of supply of gas or electricity : and for lanijs of motor vehicles, etc.
In Fig. 1 is seen a diagrammatic view of a small acetylene-prowlucing plant of the autnmatic, water-fed type, suitahle for private houses. A is the gas-holder tank, of iron, partly filled with water, and into the lower portion of which two gas generators are fixed side by side: 13 gives a sectional view of one of these generators. It is a atrong cast-iron cylindrical vessel, solid at the back end and closed at the front by a removable door. C is an imn tray which slips into the generator body and ia divided into four compartments which are partly filled with carbide.

A pije, a, connects the generator with the automatic control cock, D. which is in turn connected with the water tank, $E$. $F$ is the gas bell which rises as the gas accumulates in it, the movement being controlled by the brackets, $b, b^{\prime}$, which alide up and down the guide colunins. One of these brackets is extended at $c$ to embrace the twisted bar, L, which is attached at the lower end to the control cock, D , and turns at the top in the bracket, $d$.

A pipe, $e$, is attached at the bottom end to the generator, and has the upper portion hent round so that the free end dips under the water in the gas-holder tank. Thus, while gas can escape freely from the open end, water cannot get back through it into the generator. $f$ is the gas outlet pije to the purifier, $G$; $g$ is the gas delivery pipe; $J$ is a drain trap to catch particles of water that may he carried over from the holder ; $K$ is the main gas oock.

When starting to work the apparatus the gas bell is in its lowest position, and every. thing empty. The first thing to do is to close all cocks and fill the gas-holder tank with water, which is poured over the edge into the space hetween the tank and the bell. As the water enters the bell will rise. The water tank
and careful observation made to see that no water drops or llows into the generator budies. The cock, $h$, is now to be closed: the generator budies must be thoroughly dried, after which the trays may receive their charges of carbide and be replaced.

The water trap, $J$, should be nearly filled with water, and the drain cock opened. The purifier door may be taken off, and the maill gns cock, $K$, ojened. The bell will then descend and drive out the air. The purifier may then he closed upind the main gas cock closed, when everything will be ready for gaa making.

At this stage the water control, I), is open. and water is only prevented from flowing into thic generator by the cock, $h$. heing elosed.

Acetglene. Fig. 1. Diagram illustrating tha working parts ot a gas plant

To start, therefore, all that is necessary is th open this cock, $h$; water will then drip into the generator, and, coming in contact with the carbide in the first compartment. will immediately produce gas. The bell rised as the pressure develops, but before it reaches its limit it turns the twisted bar, $L$, and thus closes the water control cock, D, whereupon water will cease to flow into the generator, althoug'.
cock, $h$, remains open, and the production of gas should then stop.

When gas is drawn off, the hell will fall, twist back the bar, $L$, and reopen the control cock. When No. 1 generator is finished, water automatically flows over into No. 2: either generator being recharged with carbide while the apparatus is at work. The residuc left in the generators after all the gas has been taken off is simply slaked lime, and may be used on gardens or fields If it smells it ahould be dumped in water. The purificr will require to be recharged from time to time, according to the rate at which gas is made. Special preparations can be bought ready for use.
The gas-producing apparatus cunnot be placed in the house to be lighted, and must not be put in a basement or cellar. It must have its own independent house or shed outside the building to be lighted. The gas should be supplied to the house at a pressure of from $2 f$ to $2 \frac{\mathrm{in} \text {. of water, though when }}{}$ the apparatus is first tested it should be tewted to 10 in . Simple gauges for showing the preasure can be bought.

The gas fittings for acetylene may he the same is used for ordinary coal gas, only they may be smaller. Iron or "compo" pipes may be used and brass fittings.

No pure copper must be used, as the ace!ylene atlacks it, and makes a high explosive at the same time.
Burners for acetylene gas are illustrated in Fig. 2. They utilise the Bunsen principle, the aim being to get as much air as possible to the pas at the point of issue from the burner: $a, a$, arc air passages, and $b$ the gas outlet. When burning properly, acetylene light is exceodingly white and brilliant; colours and shades appear the same as by daylight: it is valuable in photography, being rioh in actinio rays
Acetylene Lamps, Acetylene is used a good deal for the hearlights of motor-cyoles and some motor vehicles A typioal form of acetylene lamp, as used for this purpose, is illustrated. This type hasa separate gencrator, but in the smaller lamps the apparatus is selfoontained, the burnerbcing mounted on the front of the generator. In use, water is allowed to drip from the bottom of the feed-tube into the perforated distributor; it first dmps down to the bottom of the container, spreads out there and nttacks the carbide, whereupon gas is given off and parses at once to the burner. The pressure developed by the pas itself helps to check the supply of water and the production of gas, but mechanical means of regulating are usually provided. In the lamp illustrated the How of water is regulated by turning a disk on the water reservoir : a full light or a low one may thus be secured. The supply of carbide will last three or four burning hours, when the onntainer must be taken out and cleaned and thoroughly dried before recharging with new oarbide.
Owing to the explosive mature of acetylene, it is unwise to open an acetylene lainp while having a lighted cigarette or pipe in one's mouth. No lamp ahould be allowed to burn out : the light should be blown out while still good or, in detached lainps, the feeding.tabe momentarily pinched, so putting out the light. The golden rule for uaners of acetylene
lamps is "Keep them clean" Ninety per cent. of the troubles of acetylenc lighting is caused by failure to observe this rule. The carbide container should he clcancd out after any long night ride, the perforations in the watertube clcared, and fresh water always placed in the water container. Lamp-burners may be kept clear by dipping in liquor potassae and washing afterwards with petrul. The small holes in the hurners are best cleared by wire prickers. It is always alvisable, however, to carry a sparo burner: The containers should never be more than three-quarters filled at the most, and preferably only twothirds with carbide, as the latter expands on contact with water

Portable table lainps on a similar prinoiple to that of the motor-car lamp are available: they give a powerful light, do not require inore attention than an oil lamp, and arc not really more dangerous. In snother self-contained type there is a rising aml falling bell to the generator, and the wupply of gas is automatically regulated by the hell carrying up the carbide container out of the water as the hell becomes full. As gas is used up, the hell and carbide container fall agail.

ACHILLEA. Both for borders and the rockery the achillea or inilfoil (q.v.) is useful. Millefolium, ptarmica and tournefortii aro three good speciea for borders. The most popular is the double Pearl, producing white Howers in suminer and nuch esteemed for cutting. For rockeries the beat are the white-Howering olavennas and tomentosa. The achilleas can be raised from seed, and thrive in plain anil. Pron. Ak-i-lee'-a.

ACID. Acids are of two classes, organic and inorganic or mineral acids. Instances of organic acids are acetic, carbolic, citric, gallio, Inctic, salicylic, tannic, and tartaric ; and of mineral acids, boracic (or boric), hydrochloric, sulphuric, and sulphurous. See Acetic Acid: Boracic Acid; Fertiliser: Prussic Acid. etc.

ACDD DROPS. Boil $1 \frac{1}{2} \mathrm{lb}$. loaf sugar, $\underline{1}$ pint water and $\frac{1}{2}$ tcaspoonful of cream of tartar together until mixture turns a pale yellow, when add cssence of lemon to taste and turn out on to oilcd slab. Sprinkle preparation with one dessertspoonful tartaric acid, work thoroughly in, and when sufliciently oool to touch form into thin rolls. Cut off small pieces with rcissory and roll to shape by hand. Sift with sugar and dry before placing in tin

ACIDITY. Term for excess of acid, usually organic acid, in the stomach, in certain kinds of dyspepsia (q.v.). Where this exists, with occasional risinge of sour, bitter material in the back of the throat, the following mixture, often gives rolief :

```
Blanuth oxycarbonate
Sodlum blearbonite
Mucl!age of tragacanth
I drams
Peppermint watcr enough to nuke 1 ounce
```

Take two tablespoonfuls half an hour to one hour after a meal. See Diet; Indigestion

Acetglene Lamp. Type with separate generator, as

ACID STAINS : Their Removal. Stains, as from sulphuric or hydrochloric acid, can usually be removed by washing the stainel part with a solution of ammonia A strong solution may remove many old acid atains as well, though not generally effective, as the material and dye are oxidised, especially h.. nitric acid. See Ammonib: Strin.
ACNE. This is a chronic skin discase oharacterised by pimples, blotchee black. heads, and a greasy skin, on the chin, foreliead, shoulders and back. In another form of it. acne rosacen, a prominent symptorn is a chronically inflamed, reddened nose. Sto Blackheal: Nose: Pimple.

ACONITE. There are numerous species of aconite, which belongs to the buttercup family. They are all poisnnous. the roots bearing some

Aconite. Left, flower and seed pods at yellow wolls-
bane. Right, typical aconlte root
resentblance to horseradish. The conlmon monkshood is Aconitum Napellus, a British native which favours shade near water. Hesides the blues, there are several varieties bear ing pale vellow flowers, like lyouctonum, which is the wolfabane, anthors and pyrenaicuu. all summer bloomers. The winter aconitw (Eranthis) does well in shade, and is often grown uncler trees, its clear yellow cups on thein green Toby frills appearing in January.

Aconite root has been mistaken for horse radish, with futal consequences.
Horseradiah is a pale vellowish colour outside, whitish inside : aconite root is a dark brown colour outside. whitish inside. Horseradish is oylindrical in shape, aconite conical.

In medicine aconite is a powerful poison. sometimes prescrihed to slow the action of the heart. The symptoms of poisoning are severe vomiting, an icy wat skin, completc prostration, accompanied by a very slow, often irregular pulse. See Monkshood: Poisoning.

ACRE. A land neasure containing 4,840 sq yards, divided into four roods oach of 1,210 sq yarcls. In addition to this imperial acre, acres of other sizes are occasionally used in various parts of the United Kingdom, among such being the Scot tish and Westmorland acres.

ADAM STYLE: In Furniture. The brothers Rohert and James Adam wenc architects, famous as designers of buildings in the Adelplii and other house: in London and the country built during the lattar half of the 18th century. They designed fumiture and decorations to harnoonise with these.

Their atyle was based upon the lighter details of the olassic orders (Doric, Ionic, Corinthian, etc.). Swags, festoons of fruits and llowers, flutes, paterac (mund and oval ominments), festouns of drapery, mythical figures, husks, the vase and urn. key borders, and rams' heads, honeysuckle and acanthus, dentil and egg-and-tongue are the prominent

Adam Style. 18th century steel grate in Adam style which has influenced modern designs Thetoria and Albert Museum
features found in all Idam work. Much of the furniture was painted, though made of mahogany, and Wedgwood plaques were often inserted as panels. Many of the original Adam drawings are in the Soanc Museum, Lincoln's Inn Fields (London), and specimens of the furniture at South Kensington. lig. 1 shows $\begin{array}{ccc}t h e & u \\ n \\ \text { notit Fig } 2\end{array}$ notif, Fig. 2 the honeyment, buth frequent in Adam recoration. Figz. 3, 4, 5 and 6 bhow the character. istic table legs, round. tapered or ${ }^{8}$ quare, eqrived and fluted. Tho photograph of the grate abuve has un almost familiar prosent day look uwing to the catent to which Adam designs have in Huenoed modern decomation in this direction. From about $17 \overline{7} 5$ Robert Adam did much to decelop painted and inlaid satinwood furniture, which then became the foshion. He adso designed some pieces in lacqucr. The typical Adam ceiling has complicated mouldings of festoons, ovals and medallions.
K . and J . Adam were really the last deaigners to create a characteristic British style which has lived. See Anaglypta; Antique l'urniture : Chair: Chimney lyece, etc.

ADDER BITES : How to Treat. The hites of the rariety of adrler found in Great Britain are rarely fatal except in children and debilitated persons. There may be a burning pain at the site of the puncture, but the accident may not be noticed, and the first warning inay be the onset of the general symptoms, which are prostration, with perhaps vomiting and diarrhoea, the skin being covered with a clammy sweat : and the person may poasibly become unconacious. The doctor should be sent for and told the nature of the accident at the time of summoning. so that be may bring with bim such remedies as he may require.
A ligature (q.v.) should be applied round the limb above the wound to prevent the joiscn entering the system, or any more of it
if general symptoms have actually manifested the mselves
The bite should be thoroughly sucked, and no fear need be entertained of evil consequences, as there is no danger in sucking if there are no broken surfaces on the lips or mouth. The month should be rinsed out with water or spirits, if any are available. Any bleeding should be encouraged.
Meanwhile the patient is kept warm, and the limbs may be chafed for this purpose. Stimulants should be given, spirits, sal volatile in teaspoonful doses in water, or hot tea. It is necessary to keep the patient cheerful. The wound will subsequently nced to be kept covered with an antiseptic dressing.

## ADDER'S TONGUE.

This dwarf-growing fern is grown at its best in the partially shaded section of the rock parden, and likes a moist, loamy soil. It may be planted or transplanted at any time during the spring or summer months, and may be propagated by putting sporeladen fronds in a cold frame towards the end of summer. It was once argely used in window fern boxes.

## Adenoids: Cure and After Treatment

How these Troublesome Growths may be Detected and their Consequences Prevented
See further under Breuthing; Nose; Throat; Tonsils, etc.
An overgrowth of lymphoid tissue called an become deformed, flattened from before adenoid is often to be found in children at the backward, or from side to side, with a proback of the nose on the vault of the nasopharynx. This lymphoid tissue is similar to that of which the tonsils are largely composed and is present in every body. It is the overgrowth of this tissue in the shape of small bosses or finger-like processes which constitutes adenoids. These processes may be roft and friable, or may be tough and firmly attached. Adenoids are usually associated with enlarged tonsils.

From their position they more or less block up the air passage between the nose and thront, making it difficult or impossible to breathe through the nosc. They may obstruct the opening of the Eustachian tubes, which lead

Clair back, ornamented with Adam natterns on splat and frame
blocking up of the mostrils causa breathing of the mostrils canser difficulty in breathing, suckling may be seriously interfered with, and the nutrition of the child suffer in consequence. When the child is somewhat older say, perhaps 3 or 4, it may suffer from a constant " wot nose," and the discharge may contain pus or be tinged with blood; the mouth is always open, and it will be found that the child always breathes through the mouth.
The cavity of the nose is so constructed that it warms, moistens and cleanses the air, but when the air passes through a large cavity like the mouth, which is always swarming with microbes, it is neither cleansed nor warmed. The result is that the child with adenoids is liable to suffer from catarrh of the throat and air tubes, and an irritating cough is frequently present. The voice tends to become thick and nasal in quality, and snoring at night is usual. Deafness is very common, and infection may extend into the car.

If the condition is not relieved, the face assumes a characteristic appearance, with a compressed nose and prominent upper teeth, like a rabbit. Owing to the difficulty in taking sufficient air into the lungs the chest may
minent breastbone-the so-called pigeon breast. The liability of such a person to contract tubcrculosis of the lungs is notorious. Sleep is apt to be disturbed, and while awake the child may be peevish and irritable. The expression is often dull and stupid, and the child may bo inattentive at achool, so that the mental development is retarded.
Treatment of adenoids is a matter of controversy. If they are small and recent, if they are only swollen becausc of inflammation, it is possible that the procedures which we shall mention in connexion with the tratment necessary after operation may do good. They should not, however, be persisted in too long. But when the adenoids are actual overgrowths, and perhaps tough growths, operation is the only treatment, and it should be performed without delay. It is usually also necessary to remove the whole or part of the tonsils at the same time. The operation is simple.

It must be remembered that failure to carry out the after treatment is responsible for any incompleteness in cure

The child should be supervised in (1) clearing out the nose by blowing it tivice a day; and (2) in performing simple exercises with the mouth shut. This treatment should be commenced a week or ten days after the operation. In clearing the nose the

Adenoids. Section of the mouth and nasal carities showing the common site of the growths
child should stand erect and grasp the nose with the right hand across the bridge, not on the compressible part. It should then take a deep breath through the nose and finally blow down forcibly into a piece of soft paper held in the left hand. This is repeated several times.

In blowing the nose only one nostril at a time should be compressed. Compressing both at once may result in forcing infectious material into the ears.

W'ith regard to the exercises, a simple one is to make the child stand crect and stoop about 10 or 12 times a minute. The mouth must be shut, and the child bieathes out in descending and in when raising the body. The exercises should be performed, if possible, in the open aip, and should be continued for at least lour or tive months. The tendency to sleep, with the mouth open may persist, and it nuay be neccssary to bandage up the lower jaw to prevent this.
After complete recovery from the operation the patient's health should be buift up in every way possible by plenty of outdoor exercise. plain, nourishing foorl, long hours of sleep and freedom from schoo! if necessary. A month at the seuside or in the country will often work wonders in these cases

ADHESSIVE PLASTER. I mixture ol resin, lead plaster, and hard soap, melted together and spread on strips of linen, are the componenta of an adhesive plaster. Inother form, which has a rubber basis. Mead's jlaster, is obtainable in various widtha, and does not require warming before application These plantors are useful for bringing the edger of a wound together, and for strapping un diessings They are sometimes used round luils to protect the surrounding skin from infection A hole is cut in the centre to permit of the discharge escaping.

ADMINISTRATION, LETTERS OF. When a man dies without a will, liefore his money or property can be dealt with someone must takc out letters of ndininistration lingland is divided into districts, and the proper thing to do is to apply at the registry of the distict wherc the deceased resided. The following is a list of the towns where the district registries are situated:

Group 1. Newcustle, Durhaun, Carlisle Group 2. Lecds, Sheffiedd, York Group 3. Manchester. Group 4. Liverpool, Lancaster. Group 5. Chester, with aub-rgistrics at bangar and Shrewsbury. Group 6. Lincoln, Nottingham, Leicester, with a sul.registry at Dorby. Group 7. Peterborough, Norwioh, Ipswich Group 8. Birmingham and Oxford, wit it a suh-registry at Northampton. Group 9 . ('ardiff, with sublergistries at Hereford, Gloncester, and Carinarthen. Group 10. Bristol and Exeter, with a suh-registry at Bodmin. Group 11. Southampton and Lewes, with a sub-regist ry at Salisbury.
In nny other part of the country, or when lie decensed lived abroad, application should le made to the Principal Prolate Registry at Somerset House, Strand, Iondon.

The widow or widower is the firat peraon entitled to take out letters of administration. and then the children. Fail. ing children, a grandchild; fail. ing doroend. ants, a parent, brother, sister, nephew, nicce, grand parent. ADOPTION: The Legal Aspect. Not until 1921 in Eingland and la30 in Scotland was it made legally possible for an adult to adopt a child under 21 so as to exclude the rights of the natural parents
An adoption order must be obtained from the conrt and the case will he heard in camera. The adopting person must not le under 25 nor, except where the purtien are related, less than 21 years older than the child to be adopted. No malc person can adopt a female ohild as sole adopter except in special circumstances The consent of the pirent or guardian of the child must be obtained to any adoption before an order will be made. A husband and wife may adopt jointly or one of them mny adopt alonc. but in that case the consent of the other must lie obtained unless they are living apart. Money may be given for the adoption, but this must be sanctioned by the court.
The adopting parent has the same rights over the adopted child as over his own children as to custody, maintenance, and education. The adopted child does not lose any rights it may have of succceding to property through its natural parents, nor does it acquire any right torncceed to property as the child of its adopting pasent. A special register is kept of anopited children at Sonierset Housc. London. IV.C.

ADULTERATION OF FOOD. The different kinds of adulteration may be classed under the following headings

The mixing of a cheaper subatance with a more expensive one, the misture leing sold under the title of the latter constituent. Exainules of this are glucose and sugar, sold as sugar, or chicory and cotlee as cotfee.

The addition of worthless substances fraudulently to increase the bulk, such as the addition of coarsely ground shells of fruit stones to pepper and spices, dilution of milk with water.
The addition of preservatives to delay putrefaction and conceal the use of stale food. This, however, is allowed by law in particular cases, and under ccrtain conditions.

The addition of artificial colouring matters, allowed in some cases.

Anyone who suspects that food or drink supplied has been adulterated should interview the medical officer of health of the diatrict. Any private purchaser may submit a sample to the public analyst, who must analyse it and report on payment of 10 s . ( Cl .

Any medical officer, sanjtary inspector, inspector of markets, inspector of weights and measures, or police constable acting on the instruction of the local authority can compel any retail trader to sell him n sample of food exposed for nale. Samples inay also be taken in the course of delivery, with the consent or at the request of the purchaser. In the case of milk no consent or request is required. See Food: Preservatives.

ADZE. This is an edged tool having " curved blade set at right angles to the handle, so that the cutting stroke is always towarda the worker It is used principally for rough planing timber. The tool is extremely danger ous for all amateur to use

AERATED WATERS. Certain kinds of mineral waters which have had carbonic acid gas dissolved in them under pressure. Small quantities can be made with the aid of a gasogene or seltzogene, and the steel capsorles sold at chemista' containing carbonic acid gas under pressure. If pure water is used in the ghsogenc the product is simply mineral vater. F'r soda water dissolve 80 grains of sodium bicarbonate to the gallon : for lithin water $\mathbf{8 0}$ grains of lithium carbonnte ; for potash water 32 to 64 grains of potassium bicarbonate; and for seltzer water 80 to $1 \mathbf{1 0}$ grains of' is mixture of chloride, bicarbonate. sulphate and phosphate of sodium, all to the gallon. Lemonade and similar aerated waters merely require the necesanry fla vouring agenta to be added. See Mineral Waters : Suda Water.
AERIAL: How to Erect. In erecting a hroadcast receiving aerial it is necessary to bcar in mind the limitations imposed by the P.M.G. The combined height and leugth must not exceed 100 fcet. Thus an "L" acrial with a 75 feet horizontal span and a downlead of 25 feet would he permissible. An aerial which crossea above or is liable to fall upmor to be blown on to any overhead power wire (including electric lighting and tramway wirea) must be gurded to the reasonable satis. faction of the owner of the power wire concerned. With present -day broadcasiting conditions it is not always necessary to use an aerial of the full length allowed, and greater selectivity mny be obtained in many cases with a shorter one.

The inverted "L " aerial gives good results and is in the main the easiest to erect. It will be assumed that the aerial is to be attacheal at one end to the house, e.g to a chimney stack, and supported at the other by means of a inast.

Aerial. Layout ol a broadcast recelving aerial of the usual inverted $L$ type

A straight, sound, scaffold pole 30 feet loug may be used: it can be painted and the lower end tarred For foundation place it on a square of York stone, let 2 to 3 feet into the ground. 'The side of the hole on which the pull of the acrial will come should he vertical To the pole must he fixed 8 guy wires for holding it in an upright position. This wire should be about 7-32 S.W.G. galvanised steel wire. Cut suitable lengths and seize four of them round the pole about a foot from the top and four more half way up its length Anchor the guy wires by fastening them to stout stakes ariven into the ground A good anchorage may be made of a stout imn bar formed into an eye at the top end. and hent over at an angle at the lower end. This
is embedded in a mass of wet concrete in a hole. Before proceeding to erect a pole, fasten a pulley-block to the top threaded with the halliard or rope for running the aerial up and down. The halliard must be made endless by joining up the ends. Help will be necessary for erection of the pole. Put the foot of the inast into its foundation, and while one person lifts, two others should be pulling on the opposite guy. When the pole begins to go ul, the side guys must be laid hold of to steady the lift, and as the mast assumes the vertioal the person lifting should lay hold of the remaining guys. The mast erect, roughly fix the top outer guys and then shovel carth into the hole to the depth of a foot or so, ramming it in hard. Then the pole can be straightened up by the guys. After this, lasten the inside centre guys, which, having trimmed, slack off and trim the outer guys. The filling-in can then be completed.

The next thing is to erect the house-end fixture. If there is a convenient chimney, a galvanised iron strap may be fixed round it to take the aerial; a pulley-block should be attached to the strap, and the halliard or suspending rope passed through this. Care must be taken that the strap is kept below i third of the total height of the stack, or in stormy weather there is a danger of the stack being pulled over. Do not attempt to hammer or screw a fastening into the bricliwork. The landlord's permission may be needed for any fixture of this kind.

The aerial wire should be of stranded hard drawn copper wire $7-22$ to $\mathbf{7 - 2 5}$ S.W.G. Run it out on the ground, taking care to avoid kinks, loops, etc. Fix a shell insulator to the

Aerial. Left, adjustable ruy strainer attached to
mast end of the wirc, and, judging the amount required for leading in, fix an insulator into the wire at the point where the aerial will leave off, and the leading-in wirc or down-lead commence. Where the aerial lead is to enter the house a proper lead-in tube should be fixed. The lead-in should he kept at least 4 ft . away from walls or trees. Hoist up the acrisl, hint do not ilraw it too taut, as wind and wet may cause too great a strain. Every three months the stay wires must be examined, and, if neces sary, adjusted. Insulators should be cleaned and dried periodically.

Nothing is gained in broadcast reception by using aerials with more than one wire, except, of course, in the cage type, which is useful in confined spaces.

AEROPLANE: Making a Model. The actual making of model aeroplanes is simple The main consideration is lightness, and it is therefore impossible to obtain much con. structional strength. An illustration is given of a popular type of biplane. The fuselage is marle with four longeron spars of bamboo cane, glued and pinned to a light wonden nose or cap A smaller block is glued and pinned to the tail ends. The length of the fuselage is $2 t \mathrm{in}$., its width at centre of planes $\stackrel{1}{4}$ in. and depth 5 in. l'our vertical compression struts and four horizontal struts are glued and lashed in place between the longerons, as shown dotted in Fig. 1. The whole fuselage is then criss crossed with cotton, and ultinately covered with Jap silk
"he nose is drilled to take the airscrew shaft, which should have a sinall ball-bearing between the propeller boss and the nose to take the pull of the six rubher strands that provide motive power. Detailed construction of the nose is shown in Fig. 2. The tail block is drilled out to $5 \cdot 16 \mathrm{in}$. and a plug fitted in to the hole; the wire hook for the tail-end of the rubber is fixed to this plug, and bent over at right-angles at the outer end to prevent it pulling through. The airscrew is 8 in . in diameter with hlades 1 in . wide, and may be carved by hand. The angle of the blades is shown in the end view, Fig. 3. The shaft of the propeller and the hook to hold the rubber should be made from stout piano wire. A cockpit opening is left in the silk covering of the fuselage near the nose end, and the rubber strands can be reinoved or replaced hy unhooking them from the nose and pulling them through the hole in the tail.

The planes and rudder are attached by thin wires and rubber bands encircling the fuselage. The planes measure 26 in . across and 4 in . wide; the tail plane 9 in . by 4 in wide. The planes are made of bamboo cane $\ddagger \mathrm{in}$. wide. The front length should be a little over $1-16 \mathrm{in}$. thick, but the other long pieces, as well as the ribs, need not be more than $1-32$ in. The joints require to be nailed with fine brads as well as glued, and the whole should be covered with proofed model acroplane silk. The framing of the tail planes may be piano wire, hound with flower wire and soldered.
The chassis is made from thin wire; the whels cut from cork, and mounted on a hent axle, lashed to a bainboo crosblar. A rubber shoek-absorber is fitted near the nose.

AFFILIATION ORDER. Any single woman, or married woman living apart from her husband, who has an illegitimate child may obtain an order at the police court against the father for the payment of a suin not exceeding 20s. a week until the child is 13 or in special cases 16, and of a further sum for the expenses of her confinement. Application may be made hefore the child is born and must be made within 12 months after the birth unless it can be proved that the alleged father paid money for the maintenance of the child within 12 monthe of the birth, in which case the application may be made at any time. Where the alleged father went abroad withit 12 months of the birth, the application may be made within 12 months of his return.

The evidence of the mother as to the paternity must be corroborated by some other evidence, such, for exainple, as some statement or the behaviour of the alleged father.

AFRICAN LILY. A native of South Africa, the African Lily, or Agapanthus, has long, sword-shaped leaves and beautiful blue flowers, the latter being borne on a stem about 3 ft . in height. There is a single species, umbellatus, also several varieties, including whites, and a double form. It is usually grown in small tubs or large pots, which may be placed outside in the summer, and is propagated by suckers. A fairly rich compost is necessary, preferably three parts of old turf, one part of decayed cow manure, one of leaf. mould and a fair proportion of sand III. below.
AFTERNOON TEA TABLE. This light tea table is designed on Japanese lines The
framework is of the slightest consistent with strength.

The legs are $\frac{3}{3}$ in quare t!ıroughout their length They are cut with stıb tenons to enter the top, mortised for the rails as they occur, and notch. ed for the shelves. two at the right hand side and one at the left. Thic si\%es are given in Fig. 1. The top rails are tenoncd to the legs, and the two longer ones (C) may he bridle-jointed to the intermediate

Alrican Lily. Blue towers of this large pot plant
uprights (B), which are 7 in. square.
The table top may be in one piece finishing 8 in. thick. It overhangs an inch at each side, and is held by thumb-screwing through the rails and by glue-blocking. The middle uprights project in below the bottom shelf.

Lower rails may be arranged as shown in the perspective sketch, or two cross rails (lig. 1, K ) and one central stretoher rail (L) only may be fixed. The rails, $\frac{3}{}$ in. by $\stackrel{f}{2}$ in. in section, will be tenoned to the legs, the stretcher rail being tenoned to the two cross rails (Fig. 2, P).

The shelves are notched to the legs and uprights laee Fig. 2, 0). Each shelf may be strengthaned by screwing a stecl picture eve

(angle-wise) into the ley mmediately below the shelf. The shell finds an additional bearing on this and may be screwed through the picture eye from below
Oak, walnut, or mahogany may be used for the table. The wood should be thoroughly sound and tree from knots. A cutting list is given; the lengths quoted allow for joints and paring but all thicknessos are intended to be net finished sizes

AGAVE. With its large, succulent, shiny leaves, and big trusses of greenish-yellow funnel-shaned flowers borne on tall spikes, this

plant is fre quently grown in large pots or tubs. It blooms but rarely and grows slowly It needs little attention, and is able to with stand a great amount of drought and hot sun. The best known rperies is Americana, the American aloe, whichattains an imposing size, and is grown ont of dours.
Two varieties often grown are picta and variegata, both with variegated leavea. Other good sorts are filanentosa and Sartori. A suitable compost is composed of three parts loam, one part lenf-mould, and one part decayed hotbed manure, with sand. To propagate the plant, pot up the small suckers which form at the bese, and grow them on. During hot weather the agave needs copious suppliea of water Pron. A-gay'-vi

AGERATUM. While not iastidious in the matter of soil, the ageratum prefers a dry hut gritty soil to a stiff, damp medium if put out in May the plants flower from June till Octuber. The dwarl garden forms of the species Mexicanum may be ured as bedding plants Such sorts as Imperial Dwarf Blue, Countars of Stair, Swanley Blue, and Heavenly Blue, with slate blue Howers from May to September. are commonly grown as annuals. Pron. Ajer-ray-tum.

AGREEMENTS. Before any ugreement will be enforced by English law there must be present what the law calle "consileration," or else the agreement must be made by a deed-ie a document under seal. "Con sideration " in all agreement means that one party to the ngreement is promising to do something in consideration of the other party promising to do or to forbear to do some thing elae.

Agreements are created by an offer made by one party and the acceptance of it by the other. The acceptance must be in exactly the same terms as the offer For example, if a man offers to buy some boots from another and stipulates the exact quantity and quality and price, and alan that delivery must be on "certain day. and the other replies, agreeing to all the terns except the date of delivery. there is no completed agreement, na the offer

Auternoon Tea Tabie. Fig. 1. Sectional pian aron: and end elevations, tor lettering see cutting list. Fir, 2 (bottom, right). Principal joints: M, top, ler
and rail: $N$, section of leg and rails: 0 , notched and rail: $N$, section of ler and rails; 0 . notched
and acceptance differ on this one point What purpurts to be aceeptance is really another offer
Agreements may take any one of three lorms They may be by deed under seal-in which case we have seen they require no con-sideration-in writing, or by word of mouth. A transfer of shares in a company or a lease for more than 3 years (but not a mere "agreement for a lease ") inust be by deed Tlie following agreements must be evidenced by some written document, (I) guarantces; (2) agreements for the sale of land: (3) ayree. ments by executors to be personally liable for the dobts of the estate; (4) agreements in consideration of marriage; (5) agreements which cannot be performed within a year of the date on which they are made; (0) agreements for the sale of gonids, over $£ 10$ in value, unless some of the goods liave been accepted by the bllyer or some money has been paid. Where some performance of these agreements bas taken place. written evidence is not

Aureale rerrier. Prize-winning sdeciman of this wire-bared terrier which is an excellent house dor
necessary. Agrecments with moneylenders not made in $\pi$ special form ane void.
When a man has been induced to enter into some agreement by some fraudulent untruc statement made by the other party to the agreement, he can in some cases have the agreement set aside and in all cases he can sue the fraudulent person for daniages.
If one party to an agreement fails to carry out his promise, the other party can in some caser complel bim to do so. In all cases, however, the innocent party is entitled to sue for damages and to recover all that he has leist through the failure of the other.
The law of agreements in Scotland differs on many points from that of England. In particu!ar, no consideration is required and a large class of agreements have to be proved by written evidence or by the sworn evidence of the person who is sucd. See Hire-pur chase ; Insurance. Landlord ; Lease; Rent : Repairs, eto.
AGRIMONY. Any fertile soil is suitable for this small genus of hardy herbacenus peronnials, growing from " to 3 feet high, with yellow, fragrant flowers It can be planted at any time of the year except the summer, and is propagated by division in spring. Eupatoria, odorata and suavenlens are a few of the best species. The hemp agrimony is Eupatorium cannabi nuin, a good native perennial, growing about a yard high, with purplish flowers Pron $\mathrm{Ag}^{\prime}$ - ri-mo-ni.

Ague. S'ec Malaria.

## AIGRETTE. It is

 now illegal to import the osprey or aigrette formed from the tuft of feathery on the head of the sinaller white heron, as the capture of the bird for the sakc of the plume involves its death during the nesting season Imita tion aigrettea for mil. linery purpuses are composed of various feathers or of wired jewels.
ot the berbaceous plant
AIR-BRICK. These are of tine same superficial size as the edge of an ordinary brick, namely, 9 in by 3 in . Air-bricks are usually of cast-iron, and are plawed in the base of all exterior walls. immediately below the damp course, for the purpuse of ventilating the space between the ground level and the Hooring See Damp Course.

AIR CUSHION. In round, square, and oblong shnpes, the best cushions are made of pure para rubber, but cheapel kinds are of material like that used for mackinturhes. Air is blown into the cushion through a valve. It should not be fully intlated or undue atrain will be put on the rubber.
When not in use, cushions ought to be bung up by a string fastened to the valve and should alwaye contain a little air, folding them induces cracks in the material. In the event of leakage, cushions can be repaired with a thin cycle-tire patch or sheet rubber attached with rubber solution. This substance can be smeared along the joints if not air-tight, taking care that the material is quite clean.

AIREDALE TERRIER. This is a modern breed of wire-haired terrier and makes an excellent house dog. A large, rather gauntlooking dog square built, standing 20 in at the shoulder, its wiry coat is closeffitting, dense, and a bright, deep tan in colour, except that the baok and neek are dark grey and the nose is black. It has a long, straight and that-
opped head with medium $V$-shaped ears and small dark eyes. The tail, always docked for show purposes, is carried nearly erect. See Dog.

AIRER: For Clothes. Several hinds of airers are used. One is a raci suspended from the ceiling and held in position by cords running over pulley wheels; another is a rack attached to the wall having a number of inovable arms (Figs. 1 and 2). Both may be made by any amateur. Ordinary yellow deal may be used, but beech, birch, or oak will makr a stronger job

Airer. Fig. 1. Convenient form attached to wall. with arms that fold down when out of use
For the airer shown in Fig. 2, the back piece is 11 in by $8 \frac{1}{2}$ in by 1 in., with the comers cut off 1 in each way Two grooves. each 1 in wide and $\frac{3}{8}$ in. deep, are cut in the back, the lower one being 5 in up and the space between If in. Two $7 \frac{1}{2}-\mathrm{in}$. lengths of $1-\mathrm{in}$. wood are fitted in the groover, the width being $8 \frac{1}{2}$ in. with the end of each trimmed to a semicircle. Six holes should be bored in the top piece $\downarrow$ in. a way from the edge and equally spaced along the circumference, the boles being just large enough to take a 3 -in. wire nail. The six arnis must be cut to a length of 2 ff . is in. from straight-grained wood, and carefully planed to $1 \frac{1}{1}$ in by $\& \mathrm{in}$, the edges being rounded and smonthed off. A hole, similar to those in the top, should be hored at one end of each arm, l in. away and exactly in the centre. The bottom piece must be supported by a bracket cut to a triangular shape and measuring 5 in . on the two right-angular sides Fit the work together by nailing the bottom piece from the back of the groove and then nail on the bracket. Next nail on the top piece, and finally nail the arms in position.

Many housewives prefer a ceiling airer: (Fig. 3) which can be drawn up out of the way when not in use, and at the same time has the benefit of the hotter air which always rises It may be made about 3 ft wide by between 5 ft . to 10 ft . long, and is raised or lowered hy
means of pulleys and rope. A serviceable size is 6 ft by 3 ft The end rails should finish $\frac{7}{6} \mathrm{in}$. thick, and may be about 3 or 4 in wide The lianging rails, of which five are shown, but which inay be increased to seven or eight, can be of stout bamboo or $1 \frac{1}{2}$ in. hy 3 in . laths is preferred The latter should be mortised right through the end rails and double wedged The canes. if used, should lie plugged with wood well glued in for several inches at each end. Corresponding holes, equally spaced, will previously have been hored in the end rails to receive them.

A hole in each glued joint, bored and screw. entered from the underside up through the cane and plug into the end rail, will stiffen the frame generally. About 12 yards of stout cord can be allowed, two lengths of which will be cut off for the slings. These can be attached to the end rails by means o! stout galvanised eyes, or the end rails can be holed for the cord to pass through and be linotted

Two single and one donble pulley will be required They should be entered into the joists for a firm fixing. The ends of the remain-

Airer. Fig. 2. Sunple form with gix movable arms. Fig. 3. Kitchen airer with five hanging rails, flteu with cords and pulloys for the purpose of raising it to the ceiling
ing length ol cord can next be passed over the double pulley by way of the single pulleys and knotted securcly to the slings. The oleat hook is screwed to any a vailable woodwork in the roon Sec Clothes Horse Laundry

# AIr Gas for Country Houses <br> <br> Safe Use of Petrol Mixtures for Lighting and Heating 

 <br> <br> Safe Use of Petrol Mixtures for Lighting and Heating}

For other methods sec Acetylene : Electric Lighting; Gas, erc.

Air or petrol ges plants arc cxtensively employed for the lighting (and cooking and heating) of privatc houses in the country, where no public supply of gas or electricity is available. Petrol is highly volatile at ordinary tomperatures, and it is thus possible to vaporise it by mechanical means without the aid of heat.
There are two classes ut apparatus use. Both use incandescent mantles, as the Hame in each case is non-luminous. Lir gas containing from 1.25 to 20 per cent. of petrol hurns safely with proper arrangements; but if the proportion of petrol be anything between 2 per cent. and 5 per cent. the mixture is explosive. Hence in one of the two systems gas containing just under 2 per cent. is used, and in the other gas with over 5 per cent. Both are equally safe, while each clains to have its own

special adviuntages.
The cssentia! features of a repreventative type of apparatus are illustrated in Fig. 1. $A$ is a fixed circular casing of iron supported, together with the gearing and other parts, on a suitable wooden or iron stand. The casing is divided by the diaphragm, $\mathbf{C}$, into two compart ments, $D$ and $E$, the former being the mixing or carburetting chamber, and the latter the gas chainber. $F$ is a drum rotated by the shaft, $a$, and gear, $b$. This drum is in effect a series of circular hollow coils, usually four. Each makes several tums spirally round the drum; a portion of the coils is shown exposed at $d$. A cross-section of this coil drum is shown in Fig. 2 . The outer ends of the coils $1,2,3$. t. open into the carburetting chamber, D, Fig. 1: the other end of each turns down into the small chamber, $e$, formed by onlarging the end of the axle of the drum.

The casing is filled with petrol up to alout the level shown, and
the outer end of each coil dips in succession into the petrol as the drum turns round, the rotation heing in the direction shown by the large arrows in Fig 2. Each coil, as it passes through the petrol, picks up a certain amount of the spirit; this spirit is carried round inside the coil and, as it goes, drives the air before it through the coil, hecoming intimately mixed with it in the process, 1 ill both issuc from the chamber. $e$. Any petrol not taken up by the air drops into the bottom of the rasing E , and finds its way back into the carburetting chamber through a small communicating passage, $\int$. The air gas passes by the opening, $g$, into a small receiver; whence it is drawn as required.

Air is admitted into the carburetting chamber through the opening, $h$, fitted with a valve which, though permitting air to enter, allows nothing to escape. Petrol is put into the apparatus through the opening, $j$. Very little power is needed to drive the machinery, and in small plants it is supplied by a heavy weight and system of pulleys, as shown at G. The frame carrying the upper set of pulleys is attached to a beam in the ceiling. The weight is shown in dotted lines in its lowest position. It is wound up by means of the handle, $k$, the wire cord being at the same time wrapped round tho drum, $l$.

When gas is being taiken from the machine, the weight, m, falls gradually and turns the gearing. As soon as the gas oeases to be taken, the pressure which develops in the casing, A, stops the action of the weight, whereupon gas ceases to be made. The only labour needed is that for winding up the weight once a day, and putting in the supply of petrol

Air gas has many recommendations. Though as a light it has not the briliance of acetylene, it is adequate for ordinary purposes. It can be used for heating and cooking, though it may become expensive when used for thesc purposes. There is little risk involved in its use, provided only that proper burners are: employed and arrangements made to prevent back-Hash through the pipes. Low percentage burners must be gauze packed, and in any case, for either system, a safety chainber.
should te paced on the gas main between the gas-making apparatus and the hurners. One point to be noted is to have the pipes large cnough and the connexions easy; the free passage of the gas must not be impleded by sharp corners
warm water before drying. Alternatively wash with borax and water, half an ounce of the former to a pint of the latter. Dry with a

Trigger
Piston
Cam holding Piston
Pistor ardinary type of air weapon

AIR GUN : How to Look After. The principles on which the various types of air gun work are more or less identical. An air chamber in the form of a cylinder having inside an accurately-fitting piston driven by a powerful spring is attached to the stock. A lever, usually connected to both stock and harrel, which are hinged together, compresses the spring when the harrel is pulled down; the jimton is held in position by the trigger, and when the bullet or pellet is inserted, and the barrel replaced and locked by the catch, the gun is ready for use. On the relcase of the trigger the pellet receives the full force of the compressed air formed by the sudden release of the spring-driven piston

The only part of an air gun likely to get out of order with ordinary usc is the spring. To elfect repairs, and also to clean the internial mechanisin, the metal cover must be unscrewed together with any parts attached thereto If the spring is weak or broken, a new one must be fitted. The piston should he taken out, the new spring compressed in a vice, tied up with twine, and fitterl in position. The trigger catch or attached rocking cam should he examined for signs of wear, and, if necessary, new ones fitterl. The parts should he replaced, and, when secure, the string attached to the apring may be burnt with a red-lot wire and the bits pulled out with a wire hook.

AIR LOCK. In a hot water system an air lock is generally caused by faulty pipe arrangeinents permitting a gap to form in the colunn of water. The How of hot water is thereby impeded by the imprisoned air. The remedy is to provide a release value which can be opened to release the air. It should remain open until the water flows freely. See Central Heating.

AR-PROOF PAPER. A dozen or so sheets of paper may be laid on a table and ironed rapidly with a very hot iron, against which is held a piece of wax. The melted wax is absorbed by the paper through a number of the sheets. Another method is to dissolve one pound of white soap in one pint of water, and in another pint $2 \frac{1}{2} \mathrm{oz}$. of glue and $\frac{3}{4} \mathrm{oz}$. of gum arabic. Mix the two solutions and warm together, then soak the paper before drying. Air-proof paper is used for jam-pot covers.

AITCEBBONE. The thick top piece of the leg of beef next to the rump is economical on account of the small proportion of bone compared to the thickness of meat. It is a suitable cut for salting and boiling. See Beef.

AKEBIA. Quinata is the species mostly grown of this pretty rambling plant with its Japanesc name and its violet or purple, frag. rant, drooping flowers, which are procluced in the axils of the leaves in late spring or early summer. It is best to grow it on a wall in cold districts It likes a fertile and friable soil, preferably one which contains loam and peat. Pron. A-kee ${ }^{\prime}$-bi-a.

ALABASTER. A translucent form of gypsum which is largely used for ornamental purposes. Strong soap-and-water is best for cleaning alabaster. Rinse afterwards in clean
piece of soft silk
in inelted white heeswax
The commonest way of mending broken alabaster ornaments is to use plaster of Paris, but this should on!y be done where the joints are not easily seen. It can be applied cold. A good formula is equal parts of yellow resin, plaster of Paris, and heeswax, this cement heing applied hot.

ALARM. Fire, burglar, and call alarms are the three kinds in general use. The two former are descrilsed under their respective titles.

Call alarms are chiefly used to rouse one from slecp in the early morning. The alarm clock is dealt with separately in the next article, but any person can set up for liinself a simple and effec tive call alatin. The necessary materials are: a plain clock, an electric
bell, a snaall elec-
 Alabaster may be polished

by rubbing with pumicestone and then with a paste consisting of whitening. soap and milk, finally linishing withadry flanncl. Another method is to polislı with a eloth dipped | ax |
| :--- | bell, a small electric hattery (one

or two Leclanché cells will do), and sufficient insulated

## copper wire.

The diagram shows the arrangement: the bell, $A$, is near the bed head ; the battery, B , in any convenient place ; the wire lead, $\mathrm{C}_{1}$ is fixed to the metal frame of the clock, twisted round any accessible part with bare wire against the metal, and goes to the bell. Another lead, $D$, goes from the bell to the battery. from which a third, E, goes back to the clock. Here it is fixed near the end to the woolen part of the clock, leaving a short free piece.

The tip of this piece is exposed and bent into a small hook. If the bell is to go off at 5 o'clock, say, this bare tip is set so that when the hourhand of the clock gets to that time it will touch the tip, and thus complete the circuit, whereupon the bell will ring and keep on ringing until the hand of the clock is released. See Burglar Alarm; Fire Alarm.

ALARM CLOCK. The movement of an ordinary lever drum alarm clock is illustrated.

Alarm Clock. Works of an alarm clock removed
from the case to show details of action. See from the case to show details of action. See text

The motive power consists in a spring connected to the great wheel, $a$, which engages with its 48 cogs an 8 -point pinion on the spindle of the centre wheel, which has also 48 teeth This centre wheel makes a complete revolution once an hour, the minute hand being attached to the spindle, $b$. The centre wheel engages with a 0 -point pinion on a 45 toothed train wheel, which in its turn engages with a 6 -point pinion on the apindle which holos a second train wheel.

The toothed escapement wheel is driven by the second train wheel acting on a connecting pinion. The escape palleta strike against the tectlo of the escapement wheel, and the speed of the lever holding the pallets is regulated by the balance-wheel acting on the pronged end
The hour hand is attached to a loosc sleeve, $c$, which lits oll the spindle of the centre wheel; it has a pinion underneath which is fixed to the centre-wheel spindle, and this pinion drives a train wheel, d, to which is fixed a pinion engaging the wheel, $e$, on the loose hour sleeve.

The alarm action is driven by a spring attached to the wheel $A$, which drives through a pinion the escapement wheel $B$, the teeth of which engage a projection $C$ and vibrate the atriking hammer. The screw D turns the alarm hand $E$ to the desired hour on the alarm dial A slotted sleeve $F$ is attached to the toothed wheel $G$, which revolves at the same speed as the clock hour hand.

On the stationary spindle of the alarm hand is a projection H parallel with the alarm hand. At the hour at which the alarm is set the slot in the sleeve allows the toothed wheel G to slip forward, propelled by the steel catch spring $J$. In moving forward $J$ releases the wire arm K attached to the alarm hammer spindle, and allows the alnmm hammer to work until the spring is fully unwound. See Clock.

ALBUMEN. The chief source of albumen is eggs. It is contained in both white and yolk, but the latter has in addition a proportion of fat. Albumen is imported, and also prepared in this country in a dried condition known as desiccated egge. Only the best qualities are adapted for use in conking.

Preparations of liquid egg are also imported. This form of albumen is sometimes employed in cake-making and pastry. Another form, obtained from milk, is used as a fond for infants. See Diet ; Egg.

## ALCOHOL AND ALCOHOLISM. AI-

 cohol for household purposes is generally used in the form of rectified spirit, which contains about 9 per cent. of pure alcohol by volume and 10 per cent. of water. In beverages. the highest proportion of alcohol occurs in liqueurs and spirits, the lowest in beers and light wines. Brandy and whisky contain from 40 to 50 per cent. of alcohol by volume; liqueurs from 40 to 52 per cent. ; port wine from 20 to 30 per cent. ; sherry 16 to 22 per cent.; ohampagne 9 to 14 per cent.; hock, hurgundy and claret 8 to 12 per cent.; beers from 2 to 9 per cent.; stout from 2 to 5 per cent. ; and cider usually less than 4 per cent.While it may be said that alcohol is never essential or beneficial to a healthy person, on the other hand there is no evidence that. in strict inoderation, it is harmful. The effect of small doses on the stomach is to cause the blood-vessels to dilate, and stimulate the secretion of gastric juice. Hence, in some forms of dyspepsia a moderatc amount of alcohol promotes the digestive processes. Nevertheless, it is better to cure dysjeptic conditions by appropriate treatment. Large doses of alcojool, taken habitually. cause chronic gastritis and permanens digestive disorder.

The effect of alcohol on the hcart is to cause it to heat more powerfully and more rapidly, but this stimulating effect soon passes off, and the heart is left in a more exhausted state than before. Hence the practice of giving alcohol
for fainting or conditions of collapse is not to be recommended. (See First Aid.) It has been found that alcohol is of no value in assisting Aretic explorers to resist the cxtreme cold.

The evil effects of excessive addiction to atcohol may be manifested as acute alcoholism or ordinary drunkenness, and chronic alcoholism. When a large quantity has bcen taken, the best simple treatment is to empty the stomach by administering an emetic such as a tablespoonful of mustard in a glass of warm water. A doctor may think it necessary to pass a stomach tube and wash out the stomach.
Many preparations have been advertised as cures for alcoholism, but no drug is known which will abate the craving, except at the cost of producing other habits and symptoms equally scrious. Real cure can only be obtained by completc abandonment of alcoho!. The practice of surreptitiously adding so-called "cures" to an inobriate's food is useless.

Alcohol is not required in convalescence from illness. Most of the medicated wines contain port or sherry, with meat or malt extract, pepsin, iron, or ot her food or medicinal substance. Alcohol is best avoided hy nursing mothers, and should never be given to children.

ALCOVE. This is a recess in a room or in a garden wall. An alcove was a common feature of bedrooms in older housce, and the fashion has been renewed by some modern architects. The head of the bed with the bedside-table and a chair may be placed in the alcove, the advantage of this arrangement being that there is shelter for the head of the sleeper from any draught, so that the windows can be kept wide open.
In a dining-room which is also used as a sitting-room, the alcove can accommodate the dining-table: or it may serve in a general living-room as a quiet corner where the children can do their lessons or the elders their writing. A shallow alcove may be fittexd with a built-in settee and cupboards as in the illustration given.

ALE. The terin ale is now conlined to lighter coloured beer, the black leers being calleal porter or stout, according to their specific gravity One recipe of many for nulled ale is to add to a pint of good ale two or threc yolks of eggs, two tablespoonfuls of loaf sugar, a pinch of ginger, and the same of nutmeg. Make the ale hot, but do not let it boil : then take it from the fire and stir in the eggs, beaten with the sugar and spice. Pour it from one ressel to another five or six times until it froths, and drink hot.

Ale cin be brewed at home, but it must not be made without a licence, the penalty for brewing without such a licence being $£ 500$. The occupier of a house not exceeding f8 annual value may, under certain conditions brew without clarge, but he must first obtain the necessary licence from the local exciso authorities. See Beer; Ginger Ale, ctc.

AEEXANDDRA SOUP. Take a cupful of lentils and two heaped tablespoonfuls of barley and soak them together for at least 12 hours. Next day chop up an onion and fry it in half an ounce of margarine, add the lentils and barley with three breakfastcupfuls of water, and cook until the lentils are tender. Add a couple of fresh tomatoes when the soup is nearls ready. Rub all through a sieve and heat before serving. See Lentil Soup.

ALIMONY. The term alimony is used in law to denote a sum of money agreed, or oriered, to be paid by a husband to a wife at a time when the marriage is still in existence. Thus alimony is payable either (1) while proceedings are pending for divorce, nullity or judicial separation (alimony 'pendente lite'); or (2) after the making of a decree for judicial separation, whether the petition has hepn presented by the husband or by the wifo
(permanent n!imony). When a clecree has been made in a suit for divorce or nullity, and the marriage relationship is thus ended, any money ordered to be paid by the husband is called. not 'alimony,' but 'maintenance.' Alimony pendente lite will usually a mount to such a sum as will make the wife's total incoine (including any private income she may have) equal to about one fifth of the combined incomes of husband and wife. In permanent alimuny the proportion is usually one third. See Maintenance ; Separation Order.

ALKALIES. The group of chemicals known as alkalics have a strong cleaning action and an alkaline reaction. The four chief alkalies are :
(1).Ammonia, which has the advantage of being in both liquid and solid forms, and which as a liquid leaves no residue behind.

Alcove in a aodern dining-sooin fitirel with a buill-in Easton \& Roberison. F.R.I.B.A.
(2) Freshly slaked lime, a useful scouring agent and water softener. It is best mixed with twice its bulk of dried oarbonate of soda for use as a water softener.
(3) Potashes and pearlashes are obtained by burning wood. They are in the form of coarse, white powder, and are used for scouring saucepans, and cleaning sinks and watercloset pans. For the two last-named purposes, the potashes or pearlashes are dissolved in hot water in the proportion of a tablespoonful to a pint. A stronger form of potash is known as caustic potash. It burns the skin unless it is washed off quickly.
(4) Soda. This is the common name for a crystallised carbonate of soda, also known as washing soda. It is the most used alkali for softening water employed for cleaning purposes. Caustic roda is a st ronger form of soda.

Alkalics shouid not be used for cleaning alaminium ware, as they have a corroding effect on the metal. See Immonia; Lime; Soda.

ALL FOURS : An old Card Game. This card game for two or four players is also called seven up.

Two-handed All Fours. Players cut for deal, and the dealer then gives six cards, three at a time, to his opponent and himself, and turns up the thirteenth card for trumps. If the turn-up is a knave, the dealer scores a point. The elder hand then plays a card, or says, "I beg," according to whether ho is satisfied with his hand or not. If he says, "I beg," the dealer must either allow him to score a point or deal three more cards to his opponent and himself, turning up the seventh
card for fresh trumps 11 trumps remain unchanged threc more cards must be dealt each player, and the seventh card turned up until there is a cliange Any new knave turned up gives the dealer a point.

The clder hand, when he decides to play, leads any card he chooses, and the dealer may take it with a higher card of the same suit or with a trump, the right to play the latter not being affected by his holding cards of the suit led But if, having a card of the suit led, he neither trumps nor follows suit, he is penalised for a revoke

The following are the methods of scoring and the names of the scores High: the highest trump played, scoring one to the original holder. Low: the lowest trump played, scoring one to the original holder Jack: knave of trumps, scoring one to the dealer if turned up, or one to the winner of the trick to which it falls. Game : one point scored by the player who finally holds the greatest numbel among the cards won by him, that number being reckoned as follows: For each ten, 10 ; for each nce, 4 ; for cach king, 3 ; for each queen, 2 ; for each knave, 1.
The order of counting the sooring is High, Low, Jack, Game, except where Jack is the turn-up. The object of the game is to capture the Jack and those cards whioh count in Game. In the case of equal scotes in Game, the elder hand scores a point. If only one trump is ouri, the player holding it counts it High and Lov: If no player has an ace, ten, or court card. the elder hand counts a point for Game.

If a player revokes, he cannot win the game on that hand, nor Jack and Game, his opponent adding two to his score when Jack is out and one if Jack is not out. The player first scoring seven points wins the game, though sometimes nine or eleven points are played for.
Four-handed All Fours The rules are similar to two-handed. but the players cut for partners, and each player plays in rotation, the dealer and elder hand alonc looking at their cards in the first instance, elder hand having tho option of begging. The other two players must not look at their cards until the dealer has decided whether he will give onc or deal three fresh cards.

ALLOWANCE. This term is used for a payment which is voluntary and is not necessarily given in return for servioes rendered. It is thus entirely distinct from a salary or wage, which is a logal obligation. The sum of money given by a hushand to his wife or by a father to his daughter is known as an allowance, the amount varying in accordance with the income and the expenses of the person who makes it. A tenth of a man's income would be a good allowance for a wife, while in most cases much less is given for her personal use.

It is desirable from overy point of view for a wife to have a definite sum as an allowance which should be paid to her weekly or monthly according as the husband receives his salary, and from this she should meet.certain defined expenditure. A wife's allowance should be sufficient to provide her with clothes and pocket-money, but she is not expected to pa! from it the expenses of her holidays or her doctor's bills. Another form of allowance is the separation allowance (q.v.).

A voluntary allowance is not subject to income tax.

ALLSPICE. Sometimes known as Jamaica pepper, this pea-like berry, when dried and crushed, provides a spice which seems to combine the flavours of cinnamou, cloves, and nutmeg.

Its cominon uses are in making gingerbread and pickles, and in curing hams, and it is one of the component parts of burry. powder. It is also used for these purposes and for adding to spiced wine as a tincture, made by letting tiro tablespoonfuls of
powdered allspice soak in a pint of brandy for a fortnight, shaking occasionally to extract the flavour. It should be stiained and bottled at the end of that time.

ALMOND. The Prunus Amygdalus of botanists is cultivated almost exclusively for ornament in British gardens, where its delicate pale pink blossomsopen before its lenves in March and even in February. The swect almond is rather earlier in bloom than the common, and has rosy Howers. The bitter almond, amara, has paler Howers. The dwarf, nana or Besseriana, only grows about a yard high, and has rose-pink flowers There are also white varieties.

The almonds may bo planted as standards between November and February inclusive. They are not at all particular as to soil, but they like a drained site, and should be well staked. Little pruning is required the yolks of two eggs, the white of the head of a young tree contains straggly orange blower water and a fery drops of branohes it may bo regulated.
In Cookery. The Jordan almond from Malaga is the best variety of sweet almond. As a food almonds are highly nutritious, and bulk largely in a vegetarian dietary. They contain iittle starch, and for that reason are invaluable in the dieting of persons suffering from diabetes. (hrushed almonds yield a flour for the bread and biscuits recommended to diabetic patients. Powdered almonds are used for marzipan and macaroons. Essence of almond is a favourite Havouring for cakes and puddings.

To blanch almonds, soak them in boiling water for fire or six ininutes until the skin can easily be removed by pressing each nut between the thumb and finger. After peeling, rinse the almonds in cold water, then drain dry or rub them in a clean cloth. See Bitter Almond.

ALMOND CAKE. The ingredients are 6 oz. margarine or butter, two thin slices of citron peel, 6 oz. castor sugar, 1 teaspoonful bakingpowder. 10 oz . best white Hour, threo large eygs, $\frac{1}{2}$ gill milk (if required), and 1 teaspoonful almond flavouring. Grease a round cake-tin and line with greased paper. Sieve the flour and baking-powder together. Beat each egg separately into the creamed sugar and butter and beat well for a few minutes. Lightly fold the flour into this mixture, which should be soft enough just to drop from a spoon, but not to run off. Add a little milk if too stiff, and last the flavouring.

Put the mixture into the cake-tin already prepared. Bake in a moderately hot oven for three-quarters to one hour. Decorate the top of the cake with the slices of citron peel when about half cooked. When ready the cake should be placed on a sieve to cool.

ALMOND CHEESE CAKES. Take 2 oz. ground almonds, 2 oz. castor sugar, $\frac{1}{2}$ oz. cornflour, $\frac{3}{4} \mathrm{oz}$. butter, 1 egg , and some raspberry jam. Add the well-bcaten eggs gradually and smoothly to the cornflour, following with the sugar, almonds, and butter (melted). Line some patty-pans with scraps of short paste, and spread a little jam in the bottom of each, then pour in sufficient of the mixture to reach within $\frac{1}{l}$ in. of the top of the paste. The cakes should be baked for 20 minutes in a moderate oven. They are suitable either for tea or as a dinner sweet.

ALMOND FINGERS. These are made with $\& \mathrm{lb}$. flour, $\& \mathrm{lb}$ ground almonds, $\& \mathrm{lb}$ butter, 2 oz almonds (peeled and chopped) 2 oz sugar, 1 egg, and a little raspberry jam Rub the butter into the flour (margarine may be used instead of butter), add one teaspoonfuil of sugar with the yolk of the egg and inix all to a stiff dough. Roll this into a strip 3 in . wide, place on a greased tin and spread the jam on the strip Mix together the white of the egg, the ground almonds, and the rest of the sugar, and work to a paste, which should be spread on the top of the jam together with the chopped almonds. Bake for 30 minutes in a moderate oven and cut into fingers.

ALMOND PASTE. Use $\frac{1}{2}$ Ib ground almonds (in the proportion of one bitter almond to four sweet), the yolks of two eggs, the white of
b. castor sugar, 1 teaspoonful of essence of almonds. Put the almonds, sugar, and yolks of eggs into a pan and stir them over gentile heat until reduced to a paste ; add the orange flower water and the beaten white of egg. This will cover a cake of about 3 lb .

ALMOND PUDDING. A good recipe consists of 2 oz . sugar, 2 oz . ground almonds, 2 oz. hutter or margarine, 2 tea cups of breadcrumbs, 1 egg, 2 oz . chopped peel, and a gill of milk. Beat butter and sugar to a cream, add the ground almonds, breadcrumbs, and warmed milk, and stir well. Add the peel and the egg well beaten. Pour into a greased pie-dish, and bake for 10 or 15 minutes till firm. Serve with custard sauce flavoured with almond essence. This is ample for four persons.

ALMOND ROCK. This needs a-teacuplul of best golden syrup, I teacupful of water, 3 teaspoonfuls of vinegar, $\mathbf{1} \mathrm{lb}$. Demerara sugar, 4 lb . butter, and a few drops of almond essence. Boil all together for about 15 minutes. Put a little into cold water, and if crisp it is ready. Add one or two tablespoonfuls of blancher almonds and pour all into a luttered tin.
ALMOND TOFFEE. This is made from $\frac{1}{2} \mathrm{lb}$. almonds, $1 \frac{1}{2} \mathrm{lb}$. loaf sugar, $\neq$ pint water, a little almond essence, and a small pinch of cream of tartar. After blanching the almonds, halve them and dry in a warm oven. Let the sugar dissolve in the water, put in the cream of tartar, and boil until the syrup becomes a deep a mber colour. Do not add the almonds until the stew-pan hus been taken off the fire ; then boil the mixture up again and pour it on to a buttered tin.

ALOE. The true medicinal aloes are evergreen. greenhouse plants, ranging from 1 ft . to 30 ft . in height. They thrive best in large tubs, in a mixture of loam, sand and lime, and are increased by seeds sown in pans of sandy soil, and kept at a temperature of at least $65^{\circ} \mathrm{F}$. The American aloc is the agave (q.v.).

ALPACA. This fine material with a natural lustre is used principally for black linings, aprons, servants' dresses, and men's office coats. It is woven from the hair or wool of the alpaca, which is a South American animal of the camel family. The natural colours are brown, grey, and black. Alpaca cloth is liable to be confused with mohair, whioh it somewhat resembles. Alpaca is washable in any flaked
soap and warin water. If dried without wring. ing, it will be orisp and glossy. See Mohair.

ALPINE PLANTS. The name is applied indiscriminately to plants which are natives of the Alps, Apennines, and other mountainous districts of Europe, and in Britain figuro chiefly in the rock garden. Alpine plants do not need anything special in tho way of rockwork or stonework to protect them. They will do perfectly well on gritty ground in our cool climate if they are not overrun by coarser plants. Alpine plantsare generally low-growing herbs of perennial habit, and thrive in drained soil in which the roots can be kept cool. A garden devoted to these plants is soinetimes called an alpine garden. See Rock Garden.

ALSATIAN, or Shepherd Dog. Introduced into Great Britain in 1918, this breed has achieved remarkable popularity. During the last year or two muoh has been madr. of the fact that a few ferocious Alsatians have been banned in the courts, but the breed, like many others, has its bad-tempered representatives. Most Alsatians are goudtempered and obedient.
The Alsatian lias been produced by the union of two or three strains of shepherd doge, and though molf-like in appearance, the cross with the wolf is fairly remote. In colour these doge may be black, brown, fawn, black and tan, iron grey, cinder groy and sable. White specimens are not favoured. The gait should be a wolf-like lope.

Dogs should stand about twenty-four inches at the shoulder, and bitches a couple of inches less. The ears should be stiffly erect, and broad at the base. Faulty ear carriage (a soft car or ears) is common. The head ought to be clean in its outline, long and strong in the inuzzle, and broad in the skull, with dark almond-shaped cyes. A deep chest, straight big-boned limbs, with well-placed. hocks and strong feet are points of importance. The tail should be carricd down-never curled over the back. Obedience classes for these dogs are a feature at all the leading shows.

Alsatian Wolfhound. Champion of the breed originally bred by the shepherds of Alsace

ALTERNATING CURRENT. This is an electric current which continually changes its direction round a circuit, as distinct from direct current, which flows always in one direction. Both systems are used in electric lighting. For certain purposes, e.g. the charging of accumulators, alternating current cannot be directly employed. The alternating current in such $a$ case must be transformed by a rectifier (q.v.). One complete chango or alternation of current is called a period or cycle. The voltage of the mains, together with the periodicity in cycles, is marked on the supply meter ; the periodicity is shown thus ( $\sim$ ).

The majority of broadcast receivers can be operated entirely from the mains, provided A.C. valves are employed, and sets which utilise ordinary valves can obtain their high tension supply from this source.

See Broadcast Receiving Scts: Electric Lighting; Eliminator; Valves.

ALUM: Its M? any Uses. The kinds sold as in Fig 3, the metal of the pan being en are potash and ammonia alum. Both have the same properties and are used for like purposes. Alum is sold as crystals and as a powder: the latter is the usual kind
Alum is much employed as a mordant in dyeing and as a fire-proofing material. It acts na a water purifier when a small proportion of a solution of alum is added to a large bulk of water The reason for its action is that a gelatinous precipitate is formed when alum solution is much diluted, and as this precipitate settles to the bottom of the vessel it takes down with it any organic impurities in the water. The amount added is not sufficient to give an unpleasant taste to the water.
As $n$ medicine alum is not often given internally As a lotion to check excessive areating of the hands and feet, a tablespoonful of alum should be dissolved in a pint of water As a gargle. mouth-wash, or spray for swollen tonsils, the strength used is ten grains in one ounce of water, sweetencd with honey. Care should he taken to rinse the mouth afterwards, ns alum has a very injurious effect on the teeth
ALUMINIUM. Conking utensils of aluminium become beated through inore quickly and unifurmly than those made of other metals. and this means economy of fuel and generally better cooking. With its lightness and freedom from corrosion, it can be recommended for the kitchen. It re quires less polishing. and does not readily tarnish Gritty polishes should be avoided Lecause ita anrface easily shows scratches A good comporition is-stcaric acid 1 part, fuller's earth 1 part, rottenstone 6 parts
Sodn darkena aluminium and cats it away For this reasnn alu minjum cooking utensils should not be cleanal in sodawater or have soda put in them when in use. Aluminium can be furned white again by nitric acid

Alyssum. Flower clusters of this spring rock plant followed by careful washing. The acid attacks the exterior and leavea fresb metal exposed.

Pure aluminium easily hends, and is mostly alloyed with amall proportions of other metal, usually zinc or enpper For culinary utensils, and articlea which have to be bent and pressed considerably in manufacture, it is almost pure For mout ither purpmeses there is nearly 10 per cent. of other matal. For motor vehicles its lightness hus caused it to be extensively used.

Repairing Aluminium Pots and Pans To a large extent articles made of aluminium have no joints. They are cast in solid metal or pressed from a single piece of sheet. Hanilles of saucepans and similar articles are generally riveted on. as seen in Fig. 1 The hody of the sancepan is a single piece of aluminium drawn to shape in a die, and the bandle is of malle. able iron. Rivets sometimes become loose and the handle of the utensil no longer holds tightly. The remedy is to tighten the rivet by bammering one end while the other heara on solid metal. If rivets come out and are lost the best method of mending is to use small bolts.
Fig. 2 shows a stove bolt. This is the most suitable kind and is easier to insert than a rivet After it is screwed up the projecting end should be nipped off or filed till it is nearly flush with the nut The end can be bammered as well to prevent any risk of the nut working back. If n rivet hole bas become too large a washer can be used between the bolt head and the sheet metal. Sometimes damage to the rivet holes in the pan may be made good by covering them with another piece of metal,
losed hetwcen.
A hole lower down in n saucepan is not easy

Fig. 3

Aaminiam. Fig. 1. Saucepan with iron bsadle attached by rivets Fig. 2. Stove bolt. Pig. 3. Methird of attaching handle by atove bolt
to deal with. The quickest and perhaps most satisfactory way is to use one of the potmenders which are obtainable at most ironmongers. Aluminium is a difficalt metal to solder. Fluxes are considered useleas, and the general practice is to tin the surface as quirkly as possible after it has been cleaned. Solder specially made for aluminium is employed The efficiency of the joint depends on the adbesion bet ween the tinning coat and the aluminium The parta can then be united. As heat is conducted rapidly the metal near the joints should be heated almont to the melting point of the solder. The parts should be kept pressed closely together till the solder is set.

ALYSSUM. The various species of Alyssum or Madwort are dis tinguished by hardiness, freedum of bloom, hright ness ol colour, and ease of cultivation. Of those which are grown as unnuals, the white swect Alyssum (maritimum) is 10.12 inches high, but a more useful variety is the low-growing white compactum or Little Dorr.t, 4 inches high. which blooms throughout the summer. A Lilac Queen, 4 inches high, has

Key to the illastration below. 1. Glue Pot. 2. Stove. 3. Bracket. 4. Brace. 5. Sawing dog. 6. Mallet. 7. Hand Saw. 8. Auger. 日. Tool Rack. 10. Bevel 8naare. 11. Marking Gange. 12. Wing Compasses 13. Amateur Carpentry. Equipment of an amateur's workshop; a key to the tools and accessories is piven above
successfully tackled by the home carpenter with a modestly equipired workshop

A simple and inexpensive kit of tools may include a jack and a smoot hing plane, half-rip handsaw, tenon saw, 4 to 6 firmer chisels from $f$ to 1 in or $\frac{1}{8}$ to $I f$ in., ratehct brace and 6 assorted bits, claw hammer, pair of pincers, axe, medium grade India oilstone A work bench is required, and a suitable sizc would be 4 ft .6 in . to 5 ft . long, 2 ft . 6 in . high and 16 in wide on top

A workshop of some kind is desirable. Wherever the work has to be carried on, be sure that it is well lighted. Get a corner of the room near the window or the best lighted attic, and, if possible, a window that faces north. Probably, however, the ultimate choice will fall on a shed in the garden, and this can be arranged to give the maximum of efficiency. The following notes are hased on this assumption, but those who have to be content with a space in the house should endeavour to adnpt the suggestions as far as possible to their personal needs.

A minimum size for the workshop or shed would be 10 ft . long and 8 ft . wide, with an eaves height of 7 ft . A building with a span roof is preferable to a lean-to, as the roof space is valuable as a storage loft for drying off timber However, details are given of both types of building in the article Workshop A portable building may be purchased in sections from a reputable firm This would be delivered in sections ready to .crect. A wooden floor may be used, or one of concrete may be constructed on the site chosen

The work-bench must be, above all else, strong and rigid. It can be built into the walls The carpenter's bench shown in the illustration has the advantage of portability, and can also be purchased ready for use. The vice, made of hard wood, can be used, or an allmetal one ohtained which has only to be bolted firmly to the bench. While attaching the vice, fixup a benoh stop. This is used to keep a piece of wood in place while it is being planed
The illustration in page 13 shows the equip ment and arrangement of the workshop. The tools, representing a fairly complete range, are identified in the key. In addition to the carpentry implements a tradle lathe with hand turning tools is depicted. See Bench; Cabinet Making: Tools; Wood; Workshop.

AMBER. Ornaments of amber are supposed to bring good luck, and even to bestow on the wearer the gift of eloquence The usual form of a mber necklace is the yellow opaque varicty moulded into beads; but there is also a clear amber both in yellow and reddish brown. Sicilian amber is red with green or blue lights in it. Amber is seldom worn otherwise than as a nerk ornament and usually in the form of beads
To join amber, cover the parts with linseed oil, warm carefully over a flame until the oiled surface feels sticky, and then press firmly together until oold. Caustic soda may be used in place of linsecd oil. A cement for amber may be made by dissolving sufficient gum copal in ether to form a syrupy Huid. Warm the braken portions, apply the cement and bind the two pieces together until the ceinent has set.
Amber Jelly. See Jelly.

## AMBER PUDDING.

A light steamed pudding is made with these ingre. dients: 2 oz flour, 6 oz. breadcrumbs, $\ddagger \mathrm{lb}$. suet (chopped), 2 oz. sugar 1 teaspoonful baking.

American Blight. 1. Wlaged temale. 2. Wing less female and young. 3. Twig of an apple tree
powder, 2 tablespoonfuls golden syrup and 2 egge. Add a little grated lemon rind for lla vouring Mix the auct with the breaderumbs, flour sugar and baking-powder. Warm the syrup and add it, then the well-beaten eggs. Milk may be added if tor dry. Grate in the lemon rind and stir. Place the mixture in a greased bowl and cover tightly with greased white paper. Stean two hours, the water bo:ling quickly all the time. The pudding may be served with a sauce, and is sufficient for six persons

AMBOYNA. This scarce, fragrant wood comes from Amboyna and other Molucca flarils and New Guinea, is hard and durable and is chielly used as vencer for fumiture, taking n good polish It is chestnut brown or reddizh orange in colour with mottled and curled figure

AMBRINE. The name is given to a waxy preparation used in the treatment of burns, frostbitc, chilblains, ulcers, etc. It does not adhere to the wound, and this is a great comfort in the subsequent dressings. It is used in a liquid state, and the melting is done in a water bath: that is to say, the wax in small pieces is put into a receptacle, e.g. a tin or enamel cup, and this is placed in a larger vessel containing a little water, which is kept at boil. ing point for ten minutes. As soon as the water begins to boil the heat is withdrawn a little to prevent spurts of water from entering the inner vessel.

Although ambrine can he applied without discomfort at a temperature of $140^{\circ}-150^{\circ} \mathrm{F}$., there will be burning if there is any admixture of water. The water bath is removed from the heat for a minute or two before applying to allow the ambrine to cool down a little, and it should le used somewhat cooler for varicose ulcers than is comfortable in other conditions The application is made with a sterilised soft camel's-lanir brush, and the ambrine is not brushed but dabbed on Meanwhile a thin layer of absorbent cotton wool has leeen pre pared, and this is applied above the ambrine and overlapping it all round. A layer or two of gauze and a bandlage complete the operation.

For the first few days the dressing should not be left on longer than 24 hours, but as the discharge becomes less an interval of 48 hours will be possible. Raw surfaces should be washed with boiled water, and thoroughly dried with absorbent cotton wool before putting on the war. It is important that strong antiseptic lotions should not be used. See Bandage; Bum; Chilblain
Ambulance. See First Aid; Stretcher.
AMERICAN BLIGHT. Woolly aphis is anotlier name for Imerican blight, which has the appearance of small tufts of cotton wool on the trees. The insect protects itself with the Hufty white copering ; when the latter is removed the pest is revealed as a small plump aphis-like hody. It is a common apple pest sucking the sap and so causing swellings or wounds which become the brceding places of other insect peats and fungus. In its earlier stages the blight can be got rid of by using a brush dipped in methy. lated spirit or paraffin oil, but in the case of larger cultures vigorous spraying or syringing will be required.

In winter an effective wash may be made up of soft soap, $\frac{1}{2} \mathrm{lb}$.; paraffin (or solar distillate), 5 pints; caustic soda ( 98 p.c. purity), 2 to $2 \frac{1}{2} \mathrm{lb}$; water, $9 \frac{1}{2}$ gallons. In summer use the following. Dissolve 20 oz . of soft soap in a bout $\frac{t}{2}$ gallon of hot water. Make up to 10 galions, and then add 1 lb . of

Wohurn Tobacco Extract This should be applied with the aid of a small atomiser to each tuft of aphis.

AMERICAN CLOTH. Consisting of canvas cloth treated with oil and varniah, American cloth is easily washed and kept

American Cloth. used for curtains in a modern house It is obtainable in many attractive colours
clean, and is useful for the surface of desks, wash-standa, kitchen tables, etc. It can be had in different qualities and colours, or in the plain white used for kitchen tables and shelves. The writing-table cloth usually has a mottled surface, whioh is less likely to show scratches than the smonth varicty, and has not the shininess associated with the cheaper kinds. In the kitchen it is handy to have side tables and shelves covered in white American cloth, as they are easily cleansed by a simple application of a damp duster.

American cloth is decorative for curtains in houses of modern style. In bright green, yellow, or scariet, hordered either with black American cloth, or with braid or tinsel galon, they are suitable for living-room or staircase windows. In check patterns they may be used in kitchens or bathrooms. American cloth is also used for pelinets only, in the same colour as the plain repp or satin employed for the curtains, the edges bound in gold or silver American cloth. This scheme looks nell carried out in black. See Curtains.

AMERICAN COWSLIP. The dodecatheon or American cowslip thrives in rich soil in cool places. Seeda are sown in a frame in spring. The Meadin variety is suitable for border or rockery, leing a hardy perennial 15 inches high, with drooping rellexed lilac llowers. Other varieties are Clevelandii, giganteum, album, and frigidum.
AMIDOL: In Photography. The average strength of this developer is $1 \frac{1}{2}$ grains to eaclo oz. of water. It requires to be used with sodiun sulphite, which prevents oxida. tion and discoloration of the developer, as follows: Amidol 50 grains, sodium sulphite 1 oz., potass. bromide 10 grains, water to make 20 oz . Dissolve the sodium sulphite in the water, then add the amidol, and shake until it is dissolved.

As the liquid developer does not keep very well, a dry form has been devised which can be obtained from dealers in photographic supplics See Developer; Photography.

AMMETER. This is an instrument for indicating the number of amperes of electricity Howing through a oircuit in which it is piaced, as distinguished from a voltmeter (q.v.), which indicates the E.M.F. (electromotive force) of the current.

There are scveral kinds of ammbter in use, but they nearly all take a round form with a graduated dial, over which an index travels when the instrument is in use. When used in conjunction with a voltmeter it provides a commercial unit by which electricity in this country is bought and sold. Thus one amperc supplied at a pressure of one volt equals one watt, and if supplied continuously for one hour constitutes a watt-hour ; 1,000 watt-hours make one kilowatt, which is the Board of Trade unit.

Motor-car and motor-cycle owners who use electric lighting battery sets usually have an ammeter included. The movements of the needle show whether tho battery is still discharging, and at what rate, and also may point out faults in the electric light system. See High Tension : Meter : Milliammeter.

AMMONIA: Its Household Use. Liquid ammonia is really a solution of ammonia gas in water. The strength usually sold is ten per cent., but a stronger kind is used by chemists. Liquid ammonia is poisonous. It is pungent to the nose and makes the eyes water when sniffed, and may injure permanently the sense of smell.

Ammonir is a strong alkali, and on this account is used as a cleansing agent. Added to the water in which articles are washed, it softens it in place of soda, and in cleaning windows, where soda is inadmissible, a little liquid ammonia added to the washing water is effective. Sponged on woollen cloth the colour is revived and grease spots are removed. It also revives the colour of carpets, and is excellent for cleaning tarnished silver. Ammonia often restores the colour to delicate fabrics like silks, especially where acid fruit stains have been the cause of discoloration. Brushes and combs are thoroughly cleansed from greasc by a tablespoonful of ammonia being added to the warm water in which they are to be washed. A few drops of liquid ammonia rubbed on the under side of diamonds will clean them and restore their brillianoy.

Cloudy ammonia is made by mixing common yellow soap, 8 grains; lavender water, 20 drops ; solution of ammonia, 1 pint. Cloudy ammonia is added to the bath as a refreshing and detergent agent.
Sal volatile, a solid form, is ammonia catbonate, and when dissolved in water in the proportion of one ounce to a pint, it can be employed for the same purposes as liquid ammonia. Sal volatile is, however, chicfly used as a baking powder-one teaspoonful to a pound of flour.
Sulphate of ammonia is the white powder used as a fertiliser. It is generally mixed with other fertilisers in the proportion of sulphate of ammonia, 12 parts; superphosphate, 50 parts; sulphate of potash, 20 parts. It is often employed for stimulating the growth of grass on lawns.

Ammonia has stimulating properties which make it a valuablo medioinal agent. Spirit of sal volatile, the form in which it is adminis. tered, contains both liquid ammonia and ammonia carbonate, with flavouring agents (lemon and nutmeg). It is a domestic remedy for nervous headache and faintness. The dose is a teaspoonful in a wineglassful of water. It must not be taken alone, as it causes a burning sensation in the throat.

Mindererus spirit is a solution of amınonia peetate. It is one of the oldest remedies for ieverish conditions and promotes sweating. The dose is from one to two teaspoonfuls. In larger doses it is given in alcoholism.

Poisoning. Strong solution of ammonia is sometimes taken in mistake for spirit of sal volatile, with serious effects. Ammonia is a corrosive poison, injuring the surface of the mouth, throat and stomach, in addition to which the vapour inhaled causes inflammation of the lungs. The treatment, which can be commenced while the doctor is being fetched, is to administer weak acids to neutralise the alkaline ammonia.

These are vinegar diluted with water, lemon juice and water, and tartario acid or citric acid dissolved in water, in the proportion of a teaspoonful of the acid to a breakfastcupful of water Then the patient should be given demulcent drinks such as milk. olive oil, white of egg.

AMMONIATED QUININE. Name of a popular remedy for inlluenza and cold in the head. The dose is half to one teaspoonful of the tinoture in a wineglassful of water or milk. When mixed with water an opaque white liquid is produced, but if aerated water is used no whiteness results. A solid form of smmoniated quinine is made as capsules.

AMMONITE. As it contains $\pi$ high proportion of nitrogen, ammonite, whioh is obtained from offal, is a valuable chemical manure. Ammonite is good for potatoes, cabbages, onions, leeks, and celery.

AMPERE. In electricity the name given to the unit of current or rate of llow of electricity. An ampere-hour is a current of one ampere flowing for one hour. See Acoumu. Intor; Ammeter.

AMPLIFIER. The amplifying portion of a wireless receiver may comprise two parts, viz., high-frequency and low-frequency. The high-frequency amplifier magnifies the oscillations received on the aerial, and so enables the listener to tune in distant stations which would otherwise be inaudible. The low-frequency amplifier or note magnifier then increases the volume to the degree necessary to operate a loud-speaker.

The modern long-range set utilises screened high-frequency stages, ench having a valve, tuning condenser, and tuning coil. Two tuned stages can be handled successfully, and if they are properly designed will give enormous amplification. Receivers with more than two high-frequency amplifying valves are outside the scope of the hume constructor.

On the low-frequency side, transformercoupling is the most popular. A well-designed transformer, if used with a suitable valve, will give excellent reproduction.

The maximum number of luw-frequenoy stages for an ordinary broadcast recciver may be taken as two. If still greater amplification is attempted, trouble is liable to occur owing to valve over-loading, and distortion. Even with a two-stage amplifier the transformers should have low ratios-certainly not above 4:1. See High Frequency ; Low Frequency ; Oscillation; Resistance Coupling; Selectivity : Sensitivity: Transformer-coupling.

ANAEMIA. This is the name given to $\Omega$ diminution of the whole blood or of some of its main constituents.
In two forms, chlorosis and pernicious anaemia, the cause is obscure, and these are known as primary anaemias. When, however, a definite cause is ascertainable, we speak of a secondary a naemia. Chlorosis. This form of primary anaemia is most frequently found in young women or in

Anagispta. Festoon in anaglypta used as a frieze
girls just approaching adult life. It is due to some abnormality in the formation of the blood, the chief deficiency being in the haemoglobin, or colouring matier in the red blood-cells.
Not infrequently the sufferer is plump, or even fat. In typical cases the face has a yellowy-greenish tinge, which gives the disease its common name of green sickness. The disease, which is now comparatively uncornmon, is one requiring medical attention.

Pernicious Anaemla. Whereas chlorosis is practically confined to girls and young women, pernicious anaemia is more frequent in men, and is commonest at about middle ago. It is a very severe blood disease in which there is an active degeneration of the blood-cells themselves. Its predisposing cause is absorption of poison from a septio mouth or the stomnch and intestines. It is considered that there is another poison of obscure nature and origin which breaks down the red blood-cells. In a scrious disease like this, the patient must be under medical care as soon as possible.
Secondary Anaemias. A quite mild type of anaemia, or "poorness of blood," is onte of the commonest conditions to be met with a mong sedentary workers, particularly women and girls. The chief outward sign is an unnatural pallor. The lips, instead of being bright scarlet, are dull.

Before any cure of the anaemia can be expected, the cause must first be sought out and removed. If this is possible the anaemia will pass off by itself under the influences of plenty of fresh air and rest, an iron tonic, suitable food and general attention to the ordinary laws of health. If necessary, the mouth should be cleaned up.

Anaemia in Children. This is a much more coinmon complaint than most mothers realize. Lack of fresh air and sunshine, too little outdoor exercise, and rapid growth in the child are among common causes. The diet on which literally millions of children are brought up in this country-bread and butter, cakes, sweet foods, potatoes, and other starchy vegetables, with tea several times a day-is in itself enough to induce anaemia of more or less severity. Bad teeth and the resulting constant pouring out into the mouth of " matter" or pus (which is swallowed and so tends to interfere with the digestion) are other not uncommon causes of anaemia in clildhood.

While an iron tonic is an important part of any treatment, it is equally essential to find out and remove the cause of the deficiency in the blood. Sometimes a tendency to rickets or chronic constipation may be the source of the anaemia. In many slight cases more play outdoors, less study or other brain activity indoors, more sloep, and simpler and more nourishing dietary, with some chemical food, may effect a cure. See Baby; Child; Diet.

ANAGALLIS. The best-known species of this free-Howering annual is linifolia, which grows to a height of about a foot, and is often represented by its $\nabla$ ariety Breweri. Sow seed in March in heat, or without heat in April, prick off, and pot the seedlings. A suitable compost has three parts loam, one of lesfmould, and a sprinkling of sand. See Pimpernel. Fron. An-er-gal'-is

ANAGLYPTȦ. A form of wiall and ceiling decoration which is termed anaglypta consists of a good quality pulp board pressed during the process

ARCHITECTURE: THE MEDIUM-SIZE HOUSE WHEN FINISHED
 together with the contract and sprequitred for the construction of the house.
of manufacture to form raised or embossed patterns. It is obtainable from the same sources as wallpaper. It is applicd to the wall

Anchusa. Bardy plant resembling the forget-me-not attractive in a sunny border
and fixed by a good adhesive paste, or Hour paste with a mixture of gluc. After fixing, it needs finishing with distemper in the case of a ceiling or cornice, or with paint or enamel it used as a dado (q.v.).
ANCHOVY. The anchovy is a small fish of the herring species, chiefly used in a preserved form to make savourics and sauces The foundation of these sances is anchory essence, which is made in this way: Talie 1 lb of preserved anchovies, 1 pint of cold water $\&$ pint of good vinegar, 1 saltspoonful of macc. and 1 saltspoonful of cayenne.
The anchovies must be reduced to a paste by pounding them in $n$ bowl with a wooden spoon, and afterwards passing through a sieve The parts which will not go through the sieve are then simmered with the inace, cayenne, and water. Sillmer half an hour, strain, then mix with the pounded anchovy already in the bowl Place the mixture back in the simmering pan, bring to the boiling point, add the vinegar and gently simmer for ten minutes more. When quite cold bottle for use. Anchovy sauce is made by adding one teaspoonful of anchovy essence to an ordinary white sauce or to $\frac{1}{2}$ pint of melted butter. See White Sauce

## ANCHOVY BUTTER.

Having soaked the preserved anchovies in warm water dry and re move skin and bones To six add 4 oz butter and pound in a nortar. Rub through sieve and then pat the anchovy butter into shape. This is a savoury forsand wiches or toast.

ANCHOVY EGGS. To make this cold savoury take as many hard-boiled eggs as are required, usually one for each person. Having shelled them, split them lengthways, and take out the pieces of yolk, which should be pounded in a busin with a small piece of butter, a inblespoonful of anchovy paste some pepper, salt and a sprinkling of cayenne Fill the eggs with the stuffing, and serve them garnished with parsley, cress, etc. The eggs may be made to resemble baskets by forning handles of parsley stalks

ANCHOVY TOAST. Wash and hone six anchovies and chop them roughly. Heat one ounce of butter in a small enamelled pan, and fry in it a small onion, chopped linely When the onion is lightly browned, add the anchovies, half a teaspoonful of chopped parsley, and the yolk of an egg. Season with cayenne. Stir this mixture till it thickens, then pour it on buttered toast and serve il very hot

ANCHUSA. This is the name of a sturdy family of biennial plants somewhat resem bling forget me nots, to which order they lelong, but attaining a height of over 2 ft . They Hower throughout the summer in sunny borders and need no special cultivation. Anchusas are raised from seed sown under glass in spring, and the seedlings are planted out in the usual way; or by root cuttings after flowering. Pron. An-kew'-7.n.

ANCIENT LIGHTS. Any person who has a window 20 yenrs old and upwards acquires the right that no one shall block out the light from it in such a way as seriously to diminish the amount of light that penetrates into the room. This means for practical purposes : to enlarge the window does not enlarge the right of light.
If anyone is starting to build so as apparently to interfere with an ancient light, the owner should write at once and say in effect: "You have started building, and seem as though you were going to block up my win dow. I give you notice this is an ancient light, and await yout assurance that you will not interfere with it." Failing such an assurance, $n$ solicitor should be instructed to apply for an injunction. It must not be imagined that an ancient light gives the right to n continued uninterrupted view. The only right is to a fair quantity of light.

ANCONA. This fowl, of Italian origin, was introduced into England in the early fifties. It is of active habit, and better suited to an unlimited range than to confinement. A prolifio layer of large white eggs, as a table bird it has few qualifications. There is a sub-variety, with a rose-comb instead of a single comb. See Egg; Fowl; Poultry

ANDALUSIAN. This is one of the best egg-producing fowls. A native of Andalusia, in Spain, it compares favourably with other Mediterranean types, producing a large white egg. It is also a good table fowl, its flesh being of delicate flavour. Although thriving in confinement, it is better adapted to a wide range. See Egg; Fowl; Poultry.

ANDIRONS. More generally known as fire-dogs, andirons were formerly used in open hearths for burning wood, each consisting of a stout horizontal har of iron raised on iron supports a few inches from the ground. The front support was extended in an upright form and finished with a knoh
shield, or other architectural device
The andirons were placed one each side the hearth, and the logs laid across the bars

The modern adaptation of the andiron is to be seen in the fire-dogs, whioh are now used to support the fire irons. See Fire Irons

ANDROMEDA. The most popular specien of Andromeda is known to botanists na Pieris Horihunda it is an American evergreen, with leathery leaves and denscrac emes of white flowers. appearing in Ipril. The height is commonly 3 to 4 feet. Anothor beautiful species is Japonica, with tufts ol creamy bells in abull dance. There is $\pi$ variety called variegata (or ele gantissimn).
indromedo

Andromeda Japonica. Creamy flowers of the evergreen shrub The only true distinct specics of Andromed with pink drooping Howers in late spring, and evergreen leaves, a native of our peat bogs It requires a moist site and a peaty compost Propagation is by seeds sown under glass when ripe, also by layers in autumn. The layers root very slowly. Andromedas thrive best in a position where they are not exposed to liot sun Pron. An drommy-da.

ANDROSACE. Some of the gems of the rook garden are found in the genus of Alpines known as Androsace or rock jasmine. They are distinguished for the most part by dense habit, great profusion of bloom, and beautiful colours. Among the best varieties are the pink sarmentosa, Chumbyi with rose flowers, pink-Howered carnea, lanuginosa, and the scented blush pink villosa. They need well drained gritty soil. 1’ron. An-dros'er-si.

ANEMONE. There are numerous species of the anemonc or windflower. Two of these are British: Pulsatilla or the violet Pasque Hower, and Nemorosa, which is the wond anemone. Coronaria, with its popprylike flowers, white, purple, or acarlet, is an old garden favourite from six to nine inches high; there arc also double-flowered sorts. The Alpine blanda flowers from Jan. to April. The Snowdrop anemone or sylvestris is about 18 inches high and hlooms in May. Fulgens and hortensis have scarlet or purple flowers.

The flower gardener should procure a selected strain of mixed varieties. This will give him a beautiful range of colours and forms, including both singles and doubles. The seed is best sown in pans or boxes in a frame in spring. If spring bloom is wanted, tubers ought to he planted in autumn; a succession can be obtained by planting more tubers in spring. Japanese anemones may be

Andirons. Modern adaptation of the old log fre-dogs. now used to support fire-irons

Waring \& Gillow, t.is.
plantod any time between autumn and spring. and they thrive in most garden soila on a shady or sunny border.
The Japanese anemone is among the most beautiful of late-llowering hardy perennials, the white varieties in par. ticular. Apen nina is sky blue, with tuberour roots. The Hepatica type, hoth single and double forms, is bliee. Pron. A nem'o.ni.

Aneroid See Barometer.

ANGELICA. Made from the stalks of the angelica plant, candied angelica is a beautiful shade of green, and is much used as a decoration for cakes, puddings, trifles, etc. Being pliable it can also he used to give the effect of a handle to a sponge cake basket filled with whipped cream and preserved cherries. See Crystallised Fruit.

ANGELS-ON-HORSEBACK. For this savoury dish take a thin slice of bacon for each oyster used, and an equal number of rounds of toast or fricd bread. Season each slice of bacon by dipping it in a mixture of chopped parsley, chopled onion, and cayenne pepper. lay an oyster on each slice, sprinkling a little lemon-juice over it. Wrap the bacon tightly round the oyster, fixing it with a small skewer made of the woorlen part of a large match. Fry till the bacon is quite crisp, then serve on the rounds of toat.

Angels-on-Rorseback. Savoury dish composed of oysters and bacon

ANGLE-IRON. An inon bar bent to form a right angle longitudinally is called angle-iron, and the shape greatly incresses the strength and rigidity of the bar Angle-iron mary be had from bar-iron denlers or retail from a blacksmith in sizes $1 \mathrm{in}, 1 \frac{1}{3} \mathrm{in}$., $1 \frac{1}{2} \mathrm{in}$., 2 in., and

## 3 in ., and is sold by weight. <br> ANGLE TEMPLATE.

An angle template is used for marking and testing angles on metal, wood, and other nuterials. The most commonly used angles are $45^{\circ}, 30^{\circ}$ and necessary templates are other angle. For use in made for any peture framing a when setting out the angles for hexaconal shapes and other types of framos.

Angle templates are commonly used in building for roof work and other mirpuses, and in such cases thoy arn made to a large size and framed up with strip inaterial. See Roof.

ANGORA RABBIT. One of the most attractive of rabbits, the Angora is conspicuous by its long coat of fine silky wool. either white, groy, fawn, bluc, or black in colour. The does are good mothers and. being very tractiable, are among the most popular rabbits kept as domestic pets When full grown and in good condition the Angora weighs about 7 lb . See Rabbit.

ANILINE DYES: For Domestic Use. Various dye soaps are made with which the dyeing procese is accomplished in one operation.

A bnse of equal parts of powdered soap and hisulphate of soda is cmployed, and to this is added the nniline dye required Generally the proper shadc is obtained by combining two or more dyes. In another variety the soap is mixed with boric acid instead of bisulphate of soda, and aniline dye added in the proportion of 1 lb . to each cwt. of soap) hase.
Aniline dye stains are often difficult to re move Aniline typewriting ink is removed by applying tartaric acid or lemon juice,

Anemone: three varieties.
1.

1. Double-flowered Wind wood anemone. 3. Violet Pasque flower or Pulgatilla
followed by plain water. Soap should not be used, as it tends to fix the ink on the skin. Other inks made with aniline dyes, if spilt on carpets, tablecloths, or other fahrics, may be removed with methylated spirits. Dyeing : Stain.

ANILINE INK. The great variety of aniline colours makes theso suitable for the manufacture of coloured inks. A simple solution of the dye in water is generally required, and although some recipes order the addition of gum-arabic, this is not generally necessary. For red ink, the best colours to use are eosine, erythrosine, phloxine and ponceau scarlet. For blue ink, soluble blue or indigo carmine. For violet ink, acid violet ; and for green ink, malachite green. The proportion of ench dye required is one dram to six or eight ounces of water. The ink used for copying-graphs consists of methyl violet 1 oz., dissolved in alcohol 1 oz ., water $\$$ oz Typewriter ribbons are coloured with an ink of similar composition

These inks may be used for homn dyeing. Red ink sufficiently difuted tints silk under-

Angle-Iron in section and perspective clothing $n$ delicate pink. It is as well to wear rubber gloves when using inks for dyeing. or to remove the articles from the dyeing water with two sticks and rinse well before touching. ANIMALS: The Legal Aspect. Sometimes a neighbour objects to noises made by animals such as cocks and dogs. Anyone is nt liberty to keep on his own premises any animal he chooses so long as it is not a nuisance to his neigh bour. A nuisance is some. thing which interferes with the neighbour's reasonable enjoyment of his own property.

What is reasonable depends on time and place in a great measure. A man living in the country must expect his neighbour to keep fowls, but a man in the centre of London is ontitled to object if his sleep is disturbed by the crowing of cocks in his neighbour's garden. An action for an injunction is the legal remedy for such nuisances. One must not keep animala on one's premises so as to be injurious to health.
Anyone who keeps a dog which he knows to be accustomed to bite human beings is liathle if his pet bites anybody. As to a dog worrying sheep or baiting cattle, horses, or pigs, tho
dog.owner is liable whether he knew or did not know that the heast was femcious.
Cruelty to animals in eaptivity or domestic mimals is an offence. It is cruelty to cause or permit unnecessary suffering, or cruelly to heat, abuse, infuriate or terrify the animal. In the casc of a wild animal, imprisonment for three months, with or without hard lahour, or $n$ finc of f 5 or less; and of a tame animal. three inonths or a fine up to $£ 25$ is the pennlty See Cat; Dog; Rabbit, etc.
ANISEED. As a cough remedy anisecd is much used on account of its sonthing effect, generally in the form of a balsam, which is made ns follows

| Liguorice juice |
| :--- | :--- | :--- | :--- | :--- | ---: |$\quad .. \quad . \quad . \quad . \quad$ I ounce

Firat boil the liquorice juice and gum-arabic (both broken up into small pieces) in half a pint of water, then auld the treacle. Allow it to cool, and add the other ingredients, adding sufficient water to make two pints The dose is one or two teaspoonfuls three times a day.

Anisced syrup, given to children for wind, is made by udding one drop of oil of anisced to two ounces of syrup. The close is a teaspoon $\mathbf{f u l}$.
Aniseed cordial, used by adults as an stomach cordial, is made on similar lines, hut is stronger in anisced, and contains a fair proportion of alcohol. It is taken noat or mixed with hot water.

ANKLE. The ankle is a hinge joint, the two main ligaments binding the bones together being the internal and external lateral liga. ments. These are torn in injurics to the ankle, which stretch them, and especially in those which displace the bones to any extent.

For treatment, a sprain requires the application of cold cloths and elevation of the joint on a pillow. In fracture or dislocation the foot is placed as far as possible in corroct position by pulling it downwards, and well-padded splints are fixed on the outer and inner sides of tho leg, roaching from above the knee to below the ankle. The two legs are then tied together and placed on a pillow. A bed-cradle may be used to take the weight of the bedclothes off the toes of the injured limb This will suffice till the doctor arrives.

The proper reduction of a fracture-disloca tion of the antile requires special manipulative skill and in first aid only gentle handling is permissible.
In sprains, as soon as the acute symptoms have moderated, perhaps after three or four days, the parts whould be masanged, and as the swelling subsides gentle movements are performed. In cases of slighter sprains, after two days the patient may be able to get about a littlc. This after-treatment is very necessary, otherwise a troublesome stiffness of the jointa may persist.
Care of the Ankles. Choice of footwenr is important to ankle slimners. Heels of more than 1 to $1 \underline{d} \mathrm{in}$. in height should not be worn for walking. High hoels, by forcing the foot into an unnatural position, strain and cramp the flexibility of the ankle joint. Weak ankles arc subject to swelling, and to remedy this condition remove shoes and stockings on returning home, apply a cold compress to the joint and then, lying down, raise tho foot on a cushion. Afterwards lightly massage the ankle and apply methylated spirit. Heels of shoes should be repaired at the first sign of crookedness Boots should not be wom habitunlly, except by inodical advice, as they provide too much artificial support
Anaemia may be responsible for swelled ankles ; or, in children, they may accompany a tendency to Hat feet, and are a sign of general
debility Sunshune fresh air and a bone-and-muscle-building diet are of importance. Paddling in the sea during the summer holidays is beneficial. as salt water has tonic properties

Skipping and dancing barefooted or in tlat. heeled shoes strengthen the ankles, and the following simple exercise imparts flexibility :

Stand with feet clnse wgether, toes as well as heels touching knees braced back and the balance on the balls of the feet. Raise the body on to the toes and hold the position for is moment, then fower the heels. Repeat short series of the exercise several times during the day when convenient to discard heeled shofa See Beauty Collure; Dislocation; First Aid : Flat Foot: Foor. : Fracture : Sprain.

## Annealing, Sec Temporing.

ANNUALS: In the Flower Bed. Including what are known as half-hardy anuuals which require more care and attention, the range of annusls is a wide one, with a great variety of beautifil colours. Few plants provide a moro charming pink groundwork for a bod of white tulips than campion or soapwort. Virginian stock, with its slim stems and abundance of mauvy pink and white ilowers, is just as useful, and blooms in spring if sown in August or September: 80 also do Californian poppies. Sume special favourites are cultivated in the samc way, although they are not true annuals, as, for example, pansies, lobelias. petunias, verbenas, Indian pinks, and the antirrhinum or snapdragon.

While chrysanthemums and other halfhardy annuals are raised in-seod-boxes, it is rare for the hardy kinds to he sown ander glass and transplanted. Mignonette and Everlasting Howers do not transplant weil. A dozen seeds of each may be sown in $5-\mathrm{in}$. pots, and the resulting seedlings thinned down to three and five respectively. In muny cases garcleners grow most of their annuals in groups, prorhaps along the front of mixed borders.
Ageratum, alyssum, campion, violet cress, soapwort, end Virginian stuck should be frm 2-3 in. apart. For lupins, double poppies, suntlowers, and tobacco plants the distance is from 18 to 24 in The following ase set at 4 to 5 in. apart : Arctotis, Californian bluebell candytuft. convolvulus minor, oornHower, gilia. Indian pink, limnanthes, lobelia, mignonette, phlox (annual), sweot pea, horned roppy, and Venus's luoking-glass.

A distance of 9 to 12 in . apart is requirod for the following: China aster, chrysanthemum (annual), clarkia, coreopsis, godetia, larkspur, love-in-a-mist. Inve-lies-bleeding, marigold, dwarf nasturtium. evening primrose, petunia, poppy, Prince's feather, salpiglossis, scabious, sweet sultan. verbena. and the zinnia. A temarkable annual recently introduced is the orange-coloured venidium fastuosum; seed is sown under glass in March. Sec Border: Flower Garden.

ANNUITY. An annuity in tho ordinary sense is a yearly income paid to a person for his or her life. It can be purchased, by those who wish to provide for their old age or for the old age of those dependent upon them, from uny insurance office or from the state through the Post Office : the price varies nccording to the age and sex of the person for whose benefit it is bought. The older the person the cheaper the annuity. Annuities for womon cost more than those for men of similar ages.

In addition to annuities of this kind, which are the usual type, there are perpetual annuities, i.e. a charge upon an estate which is paid to a person and his heirs for ever. Terminable unnuities are annuities issued by the Government in order to pay off the national debt.
An annuity can be bought by a single payment or on the instalment plan. The table in the next column shows the amounts payable to secure a Post Office annuity of $£ 1$.

| Aye laxd birlhday |  | Mate |  |  |  | Hemale |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | ¢ | R. | U. |  | $\dot{1}$ |  | d. |
| 10 |  | 18 | 6 | 0 |  | 19 | 10 | 8 |
| 15 |  | 18 | 14 | 1 |  | 19 | 0 | 5 |
| 20 |  | 18 | 1 | 7 |  | 18 | 9 | 5 |
| 25 |  | 17 | 8 | 8 |  | 17 | 18 | 7 |
| 30 |  | 10 | 14 | 11 |  | 17 | 7 | 10 |
| 35 |  | 15 | 18 | 8 |  | 16 | 15 | 6 |
| 40 |  | 15 | 1 | 0 |  | 18 | 0 | 5 |
| 45 |  | 14 | 1 | 1 |  | 15 | 2 | 2 |
| 50 |  | 12 | 17 | 0 |  | 14 | 0 | 0 |
| 55 |  | 11 | 12 | 0 |  | 12 | 16 | 1 |
| 60 |  | 10 | 4 | 8 |  | 11 | 8 | 7 |
| 65 |  | 8 | 16 | 6 |  | 9 | 19 | 0 |
| 70 |  | 7 | 8 | 7 |  | 8 | 8 | 5 |
| 75 |  | 0 | 2 | 1 |  | 6 | 18 | 4 |
| 80 |  | 4 | 17 | 11 |  | 5 | 10 | 3 |

From the figures the amount necessary to secure an annuity of $£ 100$ or any other income can easily be ascertained The state pays on death a sum which is equal to one-fourth part of the annuity

The nmount obarged for an annuity by the asurance offices varies. For instance, a man of 60 can purchase with $£ 100$ an annuity of £8 18s. 9d from one office, while another will give him as much as $\mathrm{f} 9 \mathrm{0s}$. Od a year. The variations are due partly to the class of business dnne by the various offices and partly to some slight differences in benefits. For in. stance, some insurance offices pay the whole or part of the stamp duty which is charged on annuities. Those wishing to purchase an annuity should remember that the main oliject is to ohtain a seoure income, and therefore only deal with the state or with an office whose reputation is sound See Insurance

Antaraclte stove. Fig. 2. Independent boiler installed by the side of a range
smuth id Woduleod, Led.
ANODE. In an electric battery the anode is the positive plate of a cell, by which the current enters the electrolyte or solution The anode of a wireless receiving valve, sometimes terined the "plate," is a metal cylinder surrqunding the grid and filament. Besides heating the valve filament, it is also necessary to apply a certain voltage to the anode before the valve will function. This voltage is derived from the high-tension battery or eliminator and may be between ( 60 and 150 volts (or even more), according to the particular work the valve is called upon to perform.

Suitable anode voltages for a broadcast receiver are as follows: Screened. grid valves, $120-150$ volts;
detector, 60-80 volts; low frequency valves. 120-15) volts.
The a node pin of a ralve is the one farthest away from the other three, and is usually indicated by a vertical ridge on the moulded base. The anode connexion on the screenedgrid valve is the terminal on the top of the vulb. See Cathode Eliminator; Resistance Coupling; Valve.
ANT : How to Destroy the Pest. These little insecte often prove very troublesome in the garden by their attacks on ripe fruit. They will swarm upon ripe straw berries, and an apple or plum whose skin has beer. pierced by a bird's beak will be hollowed out by them. If the direction of the stream ol ants is followed, they can be tracked to their nest, and this should be forked up and dusted liberally with sir-slaked lime. As many of the inmates will be in the ohrysalis stage and protected by tough cocoons-the so-called "ants'-eggs" -the operation must be repeated several times at two-day intervals. Kerosenc oil, diluted with six or seven tines its bulk of water, and carbolic acid in water ted times its bulk, are equally eflechive.

Wherc ants have invaded the house thc problem is more difficult. The principal offender is a

Anthracite Stove. Fig. 1. Cooising range in section, arrows indicating path of hot pases. malling ane of any strongis liable to make the fiod uneutable. So fas us possible all crevices should be sealed witb putty or cement, and a watch kept for the new entry these insects are certain to attempt.

It is, of course, very dangerous to lay poison anywhere in the neighbourhood of food. A simple syrup suffioiently viscid to clog the anta' limbs will serve as a trap. from whioh the insects can be plunged into boiling water. The syrup may alan be marde to kill by adding a few drops of formalin.

Ant bites are treated by the applicntion of ammonis (q.v.), sal volatile, rolution of permanganate of potash. or a strong solution of common salt. See Insect.
ANTHRACITE STOVE.
This stove, designed to burn anthracite on the closed fire

Anthracite Stove. Fig. u. Patern of stove osed for heating a sitting-room or hall
 principle, maintains a continuous fire day and night on an economical consumption of fuel. Its use obviates the dradgery of daily re-laying and lighting. The total absence of smoke and soot makes for health and comfort, and the attention and labour involved arr reduced to a minimum.

Fig. 1, showing an ar. thracite cooking range in section, is self-explanatory The path of the hot gases, as indicated by the arrows, is so' arranged that there is a maximum heating effect obtainel. Some of the ranges are provided with pressure boilers for the clomestic hot water supply.

Fig. 2 shows an independent anthracite boiler installed alongside a cooking range, an arrangement adopted whero a plentiful and continuous supply of hot water is needed.

An anthracite stove for use in sitting-rooms is shown in Fig. 3. In another type there is a small filling donr above the fire door, into which the end of a tapered coal hod may be inserted, so that the fire door need not be opened. These stoves will burn coke nuts satisfactorily. In another kind, in which there is an open fire, very small anthracite ("peas ") is the fuel.

ANTIDOTE. Substanco which neutralises or counteracts the effecte of poisons. A list of the appropriato antidotes is given under the heading poisoning.

## Antique Furniture in the home

## Notes for the Amateur on Its Collection and Care

## Detsils of Sryles and Pieces are glven under Chair; Chippendale: Hepplewhite, etc.

English furriture is divided into the four chairmaker in St. Martin's Lane about 1754. periods of oak, walnut, mahogany, and satinwood, many examples of which can be seen in the Victoria and Albert Muscum, South Ken. sington. In the reign of Elizabeth, ornamental carving was emplnyed for four-post bedsteads and tables. A reaction set in, mainly under the influence of Inigo Jones, when upholstered furniture came into fashion.

Hampton Court Palace has good examples of the furniture of the later Stuart period. This was the time of the gate-legged table, also of the "drawinge" table, one with $\Omega$ contrivance by which the two ends were drawn out for the purpuses of expansion. Chairs bad orrved hacks and sents with panels of canework which were often covered with loose cushions of zelvet; bedsteads had rich hangings of silk and velvet, and a good deal of luxurious furniture, carved, gilt and upholstercd, was imported imm Venice and the Netherlands, while lacquer from the East came into fashion.

With the accession of William III, walnut began to replace oak. Dutch furniture was brought over to England, and lacquered cabinets from China and Japan. Marqueterie, which may be defined as an inlay of coloured woods, came into vogue as a decorative treatsnent for surfaces of furniture, such as doors of cabinets, the drawer fronts of chests of Jrawers, clock cascs, and the tops, sides, and Ironts of the smaller picces. The curved or cabriole leg was introduced from Holland for ohairs and tables; ebony and silver, with ivory and mother of pearl, werc also uscd in inlay. Chairs and window seats were covered with beautiful needlework

Queen Anne and Chippendale Styles
Grandfather clocks, their cases inlaid with marqueterie flowers and birds, and also with a more delicate pattern of stained holly-tree wood, termed "scaweed marqueterie," on a groundwork of walnut, are of Queen Anne's time. Card tables with cabriole legs, sometimes carved with a nulled edge and a shell ornament on the knees of the legs, belong to this time, as do handsome cabinets, presses, and chests of drawers decorated with marqueterie or with different veneers of walnut arranged in geometrical designs. A peculiar and very beantiful feature of some of the Queen Anne walnut furniture is the veneer known as " oyster shell," which has a natural marking of the wood resembling the shell of the oyster; it was obstained from boughs of old and matured trees.

The name which stands out most prominently as a maker of mahogany furniture from the middle of the 18th century is that of Thomas Chippendale, but the first designer to use inahogany was William Kent, whosc best work was done between about 1735 and 1740 . Thomas Chippendale was established as a

ANTI-FREEZEF:. To prevent water freezing in radiators of motor-cars, houschold radiators, and in the generators of acctylene gas, certain substances are added, and from their action in lowering the freezing-point, these are known as anti-freczers. The substances employed ars zlycerine and liquid glucose, the proportion required of either being 32 oz to each gallon of water. See Radiator

ANTIMONY. Apart from its value in the making of type metal, one of the ohief uses of antimony is in the preparation of the Britannin metal and pewter (q.v.) employed for making teapots, coffee-pots, spoons, and other domestic artioles. It is also used for trinket boxes, dressing-table trays, and ornaments. It does not tarnish and oan bo kept clean by simply washing with soap and water. See Poisoning

His rococo style lasted until nearly the time of his death in 1779 Chippendale should lee taken more or less as a generic term, for it is impossible that a hundredth pait of the old furniture of his time and style could have been produced in his workshop. Gillow made a good deal of the so-called Chippendale furniture, and his book of designs, which were available to every contemporary cabinet maker furnished the patterns adopted by many craftsinen whose naines are now forgotten. Hepple white's designs come a little later than those of Chippendale and are more sovere, generally in good taste, and his work is invariably well constructed. The decoration of chairs and settees by beautifully executed japanning was also a partioular speciality of Hepplewhite's.

## Sheraton and the Adam Brothers

The name of Sheraton looms large in the bistory of furniture, but his work more properly belongs to the age of satinwood. The influence of Rubert and Jamics Adam, par ticularly the former, towards the end of the 18th century must he borne in mind, as the Adam style was a distinct reaction from the rococo ornament of Cluppendale to the more classical lines of design.

Satinwood came into use towards the end of the 18th century, being generally used as a veneer. The lines of satinwood furniture did not differ from those followed by mahogany, but this dainty wood suited smaller articles.
The following table of dates, corresponding with the various periods of British furniture making, will serve as an aid to the identifioation of the different styles
Elizabeth, 1558 to 1003
James 1, 1603 to 102i

Chippendale ${ }^{\circ}$ work about 1754
Hepplewhle's work, adain Bros.' work, about 1780 sheraton's work, abont 1781
There are at least two courses open to one who has decided to collect old decorative woodwork for pleasure or profit. The first is to employ an expert whose daily experiences render him difficult to trap. The other and more fascinating course is that of collecting personally. It is, however, better, until experience in the little ways of the sale room has been gained, to enlist a dealer of repute and pay him 5 p.c. for purchasing. It is a good plan to examine thoroughly old pieces on sade in the auction inarts-to watch their sales before attempting to buy personally.

Obviously there are several degrees of faking or imitating The piece in its entirety may be an absolutely modern copy of an old specimen; it may be a copy made so many years ago that it has acquired a certain amount of patina and wear and tear; or it may be, in part, genuinely of the period.

The steady appreciation in value of old decorative furniture offers irresistible temptations to the maker of pseudo antique wood work. It is an important weapon in his armoury to increase the value of plain but genuine old piecca by ornamenting their surfaces with the detail of the period. Formerly the process revealcd itself by incongruity or over-elaboration of detail, but the carver of today often produces work instinct with the spirit of the past. Jacohean, Queen Anne and Chippendale furniture all lend themselves to carring. Genuinely old pieces have their carving skilfully restored by lowering the ground.

The modern cheap copyist of Chippendale usually stints himself in the thickness of his wood, and is therefore unable to obtain the relicf and depth of the original in his carving. No such complaint of undue reticence in his use of fret-cut veneers glued together can, however, be made. He regards these as the hallinark of Chippendale, and applies them to plain friezes, chair legs, and other vacant spaces (leaving their cdges unfinished) with a prodigality undreamed of hy the master whose fret-cut work was finished by the carver

## Detecting the Conyist

Inlaying and veneering arc necessarily confined to "Queen Anne" pieces or to the periods identificd with the brothers Adam, Hepplewhite and Sheraton. However skilful the modern inlayer and polisher may be, the soft mellow tone effected by time cannot be attained, whilst the veneer used is scldom so rich yet subdued in tone-or so fine in figureas the old mahogany or walnut.

Over-elaboration is the pitfall of the imitator of these periods; he endeavours to atone for his inability to obtain the finely Ggured vencers of the originals by lavish use of vases, paterac, shells, lines, or other details of the typical style.
The black-stained, cheap, antique oak, ornately carved, deccives few nowadays. The colour of genuine old Stuart furniture is almost invariably warm, and differs radically from the dead toncs of the black imitations Its fine patina is better imitated by brown fuming.

Antiques are specially liable to the insidious attacks of the wood worm (q.v.).

ANTIRRHINUM. Snapdragon or antirrhinum is a true old English plant. It was originally a wall plant. Madern cultivation has raised its height from six or nine inches to two feet or so, diversified and multiplied its colourings and incrensed the size of the individual flowers.

While, strictly speaking, a perennial, the snapdragon is often at dits best if treated as an annual or biennial : the planta can be raised (1) from sced, sown in August wherc they are to flower, under the proteotion of a south wall, and thinned out in the following spring ; (2) sown in open secd-beds in exposed positions in June, and planted out during the early months of the next year; or (3) nown in a heated greenhouse in February, the seedlings being planted and out of doors in May. The snapdragon can also be propagated by cuttings.

Among the tall sorts, growing from 3 to 4 feet in height according to the nature of the soil in which they are planted, the following are noteworthy

White King (pure whito), Yellow KIng (atrong. arowing deep yclow). Crimson King (deep velvety crimson), Coftare Maid (plak nnd white), Monlight (apricot yellow fuahed with red), Vermillin Brilliant (orange scarlet). Pink Beauty' (rose plnk), Yenas (delicite pink), Nigrescens (dnrk crimeon).

The following are twelve fine intermediate 1 arieties ( 18 to 24 in. high)
White Heauty (pure white), Yellow Queen (large vellow flowers), Ainher Queen (canary yellow,
ilanhed plnk), Bonfre (orange buff, Carmine Quren (rose carmine), Coccinca (orange acarlet), Cottare Mnid (pink nid white), Fascination (pink), Flery iselt (omnge red with white tubc), Nelrome (dect rose pink), Noblle (white and crimson) The Fawl (terrn-cotion and pink).
Moat seedsinen have their own named varic ties. The tom thumbs (about 12 in . high) are generally grown under colours. Most of thesc choice varieties must be treated as annuals or biennials except in the favoured districts of the south and west of England, where they often establish themselves permanently.
Bedding antirrhinums are largely planted instead of the tom thumb varieties: they grow from 10 or 12 inches high and make a brilliant show, as most of thic flowering shouts are of uniform height.

Anturhinum. Intermediate variely of this oldfashioned E'ngisn garden flower
n. 1. Malbu

If sown in summer and planted in well. drained soil in sheltered places in September antirrhinums will stand most winters and flower a month earlier the following year than spring. sown plants. They are then biennials. When treated as annuala they are generally sown in February in boxes in a greenhouse where there is a gentle heat, or in a heated frame; germination is then rapid.

The most difficult stage in culture is before the seedlings obtain their second leaves. Thon they are liable to damp off or to be scorched out of existence by strong sunshine unless carefully looked after. When the plants are big enough to handle ensily they must be transplanted 2 to $2 \frac{1}{2} \mathrm{in}$. apart, into other boxes or frames where they will grow till planting-out time, being gradually hardened in view of this.

Planting or transplanting in the open leeds or borders should tako place in April or early May. If in lines, the intermediates ought to do well at 12 in . apart, the talls at 15 in ., while the tom thumbs reguire $? \mathrm{in}$. After the first t wo have grown to a height of $f$ or 9 in. each plant must be staked, ll-in. atakes for intermediates and $18-\mathrm{in}$, stakes for talls. Pron. An-ti-ri'-num.

ANTISEPTIC. The chief use of an antiseptic is to prevent the growth of organisms which cause putrefaction. Disinfectants (q.v.) have a different purpose. They are used to bill the microbes whinh ('ause communicable
diseases like diphtheria or enteric fever Some aubstances are both antiseptic and disinfectant, but a solution of sufficient strength to suffice for the former use would not serve for the Intter. A deodorant ( $q / v$ ) removes disagreeable odours due to decomposition, but it may do this without making things safer, e.g. in the case of can-de-Cologne, camphor, or tobacco smoke Some of the commonest antireptics are
Perchlorlde of mercury (eorrosive sublimate), Biniodlde of mereny. Solutions in water of strength 1 to 1,000 or 2,000 .
Carbolic Acid-1n water, 1 to 20,40 , or 60 . In milxing the water should be hot.
Tlincture of lodine. Cian be pulnted on or used as a
loilon, $n$ teasponiful to the pint of loilon, a teaspomifnl to the pint of warmi water. in water to produce a solution of a port wine thit. yolution of Potassium Pernanganate $\mathbf{B . P}$.-A table spoonful in a pint of water.
Mydrugen Peruxlde Solution.-Diluted with five parts of water, this makea a gord mouth minh, and ls used In pyorrhoes.
Compound Filyecrin of Thymol. B.P.C.-This makea it useful mouth wash.
Borncle Acld.-A raturated solution (obtsined by muling an execes of the powider In warm water and pouring off the clear solution). Thls can be uaed ns a lotion, gargle, or inouth wash. For an eve wash dilute the above with Ave parts of warm water. Cresol Snap Solution or Lysol.-A teaspmonful in a pint of wirm water.
Perchloride and biniodide of mercury are very poisonous, and if sold dry, to make the solutions, should be in the form of coloured tablets, which will tint the water and prevent their being drunk in mistake for water. Tablets of perchloricle of mercury are sold, which are blue, and biniodide of mercury red. Antiseptics are useful internally, e.g. for fermentation in the stomach, diarrhoen, enteric fever, dysentery, etc., but should only be employed in this way under the direct supervision or instructions of a doctor. See Sanitation.

ANTLER MOTH. This is a greyish-brown moth, with an expanse of wing varying from $1 \frac{1}{2}$ in. to $1 \frac{1}{2} \mathrm{in}$., the female exceeding the male in size The caterpillar feeds below the surface of the ground on the roots of grasses. In this why it frequently becomes a scourge, rendering acres of grassland, as well as smaller lawns, useless. Although it occurs throughout the British Islands, its devastating work is largely confined to the northern districts. The only remedy for its attacks is the enocuragement of ronks, lapwings, and other insectivorous birds that have a lill fitted for digging up the eaterpillars. The caterpillars' activities extend from March to lune, and the moths fly by night in Auguat and September.
ANTOFRET. Antofret is a form of woodwork decoration by which it is possible to create raised and sunk pancls and other features without emploving more than a single thickness of wood for the whole. The cutting of the wood is executed with a hand fretsaw or a treadle fret machine.
The basic principle is that all the pattern lines arc cut to a slight bevel. Fig. 1 shows a section of a piece of thin wond; the bevel cut of the freteaw is indicated by the thin lines at B. If the interior panel $\mathbf{C}$ is cut out all round at the bevel shown, it will be found to fit loosely in its surrounding wood by virtue of the loss of the thin line of sawdust which has been out from the path of the sall ; thercfore.

Similarly, if the bevel is in the opposite direction, as at Fig. 3, the central part C is depressed and produces $\Omega$ sunk panel, lrig. 4. This principle inay be applied to any sliape either of a raised sunk panel or af n formal Horal decoration

In practice the work itself is placed on the slant and the fretsaw is kept in a vertical position throughout the cutting. For this reason Antofret is best done on a machine with an adjustahle culting-table which can be tilted to any angle as well as used for horizontal work. Fig. 5 shows one of these adjustable tables in use. $A$ is the talile, $B$ the wood, and $C$ the saw blade fixed in a hand frame in the position of cutting. The card tray in Fig. 6 gives a good idea of the solid effect which can be obtained from one piece of wond. The rim is made by pressing up the various steps of wood, and the sharp corners shaped down by filing and sandpapering. In the diagram of a section through the tray, the various steps are marked oft, $A, \mathrm{~B}, \mathrm{C}$, etc. An emblellished diamond in the centre, also shown, is an additional improvement.

After the Antofret panels have all been cut each must be secured with glue. The parts should be pressed out to their final position and the glue applied on the reverse side to the face in the right angle made by the raised rings, etc.

Antofret is frequently used in comlination with ordinary fretwork. There exists a large number of specially printed designs which may be obtnined from Hobbies, Ltd., Derchan. Norfolk. Sce Fretwork; Woodearving.

## ANTO-TURNING.

This is a simple method of producing square turned columns, finials, or other similar woodwork decorations. A column such as that shown at Fig. 2, or any other pattern desined, can be produced with an ordinary fretsaw. The wood required for this work may be of ally suitable size, but it must be of square section and all surfaces should be planed up smooth.

First draw the design carefully upon a piece of good quality paper and then transfer the design to tiro surfaces of the wood as shown at Fig. 1. The tracing can be donc by means of carbon paper and a stylus or a liard pencil. It is important to see that the fenturess of the pattern come level with each other upon the two surfaces.

When the pattern has been placed on the wood, the latter is laid upon the fret-cutting table and the finc fretsaw blade enters the
word at the linc $A$ shown on the end of the wood. Thence it cuts alony the pattern line until it reaches the dotted line 1): the fret saw should nut be permitted to enierge from the wool at the other end. but should be unthreaded and witlidrawn ly re. leasing its clamp. After refixing, cut the line (: on the oppositeside, again cutting down the entire pattern line until it reaches the dotted line D, when again the blade is released and with. drawn from the cut.
The wood is then turned over so that the pattern on the side shown at $E$ will be uppermost and the previous process is repeated. When the four cuts have thus been made down to the dotted line D , the surrounding waste wood is severed from the finished column by cutting through the line $\mathbf{D}$ squarely with a tenon saw. In the case of terminals, the point or terminal end should come at the commencement of the cut. Anto-turncry is useful for the decoration of mantels, timepieces, cabinets, brackets, etc.

ANTWERP PIGEON. breeds. which are subdivided

Antwerp Pigeon, a broed which

APARTMENTSS. Considerations of letting and obligations of landlady and tenant in both apartments and lodgings are similar in nature. Information on these points will be found under Lodging sce also Boarding Housc.

APERISNT. Under this name, and also under that of laxative, are grouped the milder purgatives, such as cascara, castor oil, sulphur, etc. Their effeot is to produce one or more soft motions. Doses of common 1reparations of aperients in general use are :

Jry extract of cascara sagradn, 2 to y grains in tablets.
Wquid extract of cascara ragrada, ito 1 drum
Castor oll, 1 to 8 teaspoonfuls.
('astor oil mixture, 2 to 4 tablespoonfuls.
Flowers of sulpliur, 20 to 60 grains.
Confection of sulphur, 1 to 2 teaspoonfuls.
Milk of sulphur, 20 to 60 grains.
8ulphur lozenge, 1 to 2 at bed-time.
Compound Ilquorice powder, 1 to iz teaspoonfule.
Syrup of flgs, one teaspoonitul for chlldren.
Lquid paraffin, 1 teaspoonful to 1 tablespoonful
30 er of 30 to 00 araln 1
30 grains, repeated doses; 30 to 00 grains as single dose.
Inquor of magnesium cltrate, is to 10 ounces.
Tame ol, 1 to 2 tablespoonfuls.
SeeConstipation; FpsonıSalts; Magnesia; etc

APEIS. This is the scientific name for the family of insect pests which inclucles the blue
fly ( $q$ v.) and the green Hy ( $q . v$.). The plural is aphides. See Ancrican Blight; Apple : Plum. ptc.

## Apiary. See Beehive

APOPLSEY. This is luss of consciourness due to sudden interruption of the normal hlood circulation through the brain. The commonest cause is the bursting of a brain vessel, the walla of which have beconio degenerated and brittle. Conditions conducing to this disease of the blood vessels are continuous hard drinking syphilis, kidney diseasc, prolonged severe physical exertion, and lead poisoning. The condition is not often seen before middle life and is more common among men than women.

How so to regulate one's life as to minimise the danger of apoplexy is one of the problems of this strenuous age. The disease is without doubt commonest in people who constantly work at high pressure, who regularly eat more than is good for them (particularly meats and rich, highly-seasoned foods), who take alcohol regularly in any quantity, and who are careless about their health generally. There arc certain warnings, such as dizziness on getting up from the lying down position, constant headache, numbness, or a slight lıns of strength of an arm or leg.
When an attack of apoplexy occurs, the patient suddenly loses consciousneso and collapses into complets helplessness. His face may be pale, but is usually Hushed, and the licad and eyes may be turned to one side, commonly the damager side of the brain. The breath ing is laboured and noisy.
Whenever there is the least doubt, a case of complete collapse should lin treated as if it were apuplexy till its true nature be determined. Unconscious. ness usually passes off in a few hours, perhaps three or our.
Treatment during an ttack begins with laying the patient on his back. Loosen everything about the

and if there is a slight swelling of the lining at the entrance, or if the appendix is kinked, secretions may be imprisoned and decompose Foreign bodies such as grape seeds and fruit pips are not found so frequently as was at one time supposed, but what is found quite frequently is a little piece of hardencd facces, probably resulting from chronic constipation, and this mass may ceven have ulcerated ita way into or through the wall of the appendix.
The symptoms of the disease in the first instance are pain around the navel (sec diagram), nausea and sickness, a rise in temperature, perhaps between $101^{\circ}$ and $102^{\circ}$, a quickened pulse, and constipation. After some hours there is tenderness at a point to the right of and below the navel, and the muscles of the abdominal wall become firm and resist any attempt to press in with the fingers. To ease the pain the patient often liss with the right leg bent up

The patient must be in the care of the surgeon at the earliest possible moment. Many cases have gol beller withoul operalion, l, ul " deplorable number of people lose their lices because operation has been delayed till too latc.
For relief of pain till the ductor comes a hotwater bottle may be laid by the side of the patient, or an ice-bag may be applied to the part, and as this should not press on the belly, it is suspended from a bed-cradle, placed undet the bed-clothes, so that the hag touches but no more.

APPETISER. Besides grape-fruit, hors d'oeuvres served at the beginning of a dinner are appetisers. They usually contain vinegar, something extremely savoury, like anchovy or sardine, and an active condiment, such as Chili pepper. Cocktails are used as appetisers, and often contain orange bitters to give them pungency. See Appetite; Bitters; Cocktail.

APPETIME. When the system requires nourishment there arises auto matically the natural craving for food which we call appetite. It is this and throat, raise the head a little.

Be sure to prevent anyone from moving him until the doctor comes. Many a life has been loat from a poplexy through over-zealous helpers carrying the rictim upstairs, lifting him into bed, undressing him, etc.
Beyond placing an ice-bag on tho head, there is absolutely nothing to be done until the physician's arrival.
APOTYECARIES' WEIGRT. This weight is chiefly used in the sale of drugs. It is as follows.

| 20 Grains |  | ( Scruple (b) |
| :---: | :---: | :---: |
| 3 Scruplex | 1 | Dram or draclın (ì) |
| 8 Drania | 1 | Ounce (3) |
| 12 Ounces |  | Pound (llo.) |

The pound in this weight is somewhat lighter than the lb . avoirdupois, containing 5,760 grains against 7,000 . The apothecaries' ounce, on the other hand, contains $\mathbf{4 8 0}$ grains against $437 \cdot 5$.

APPENDICITIS. This is an inflammatory diseaso of the vermiform appendix, a small blind tube of gut 3 or 4 in . long leading off from the junction of the large and small intestines. It may occur at any age, but is commoner in young. people, and especially males.

The appendix contains a large anount of adenoid tissue like the tonsil, and is sometimes
the laste of food which start the flow of the gastric juices. The appetite may be affected psychically and an ill-cooked and badly-served meal may do much to reduce it, as may any depressing emotion. To a certain extent appetite is a measure of the quantity and a guide to the nature of the food one should take; what we fancy is likely to be good for us. But there are exceptions to this, as a poor appetite may not represent the needs of the body, but may be due to faulty hygiene, such as sedentary habits, too little exercise. or the abuse of tohacco, tea, alcohol or other Iruge.

Where a poor appetite is part of a disease its treatment is inclucled in that of the particular disease. In cases where the habits are at fault the obvious thing to do is to correct such a habit. However, something may be done to improve the appetite by the use of " bitters," such as calumba, gentian, quassia, cascarilla, or a little orange peel. The following is an excellent example of an appetiser :

Take half a small wineglassful ten ininutes beforc dinner. See Diet; Digestion: Invalid Cookery.

## APPLES: HOW TO GROW AND USE THEM

Eractical Hints Concerning All Varieties of the Tree and its Fruit
Numerous separate entries give recipes for dishes in which apples are used. For insect pests and diseases that attack the apple see Apple Mlldew; Apple Sawily, cte.

There nre nearly 2,000 varieties of cessert and cooking apples, yet new ones are still sought for and produced 1 list of tho best sorts for doinestic use is given below

## Deseert Appli:

BEAUTI OF BATH. Bright red, nedlum size, witl/ white sponta, irulting early. It is crisp and sweet.
Blenheim Obanae. Good alike for deasert and baking, lut not boiling.
Cox's Oranar. Pmbably the best deasert apple
Jamps Gulive. Gond late autumn varicty witli large handsotne frult of eond Havour.
LaxTON's SUPRRH. The best of the new descert applen, of firat rate flavour, crops well, nt its best imm Chrlstmias to March
May Qoesn. A valuable inte apple, in seanon from January to A pril, very fortile and well tlavoured. Orleans IRfinktis. One of the very best winter dessert apples, of med'umsize, well coloured and firat rato lla vour.
Worchater Pealinais. Liarly autuind apple. Fine colour, inedlum size, and cond flavour. An excellent cropper.

## listolltw Applis

Brambey's Sepdiino. Iate apple, and an caellent keeper. Umeful where the soll is very heavs of damp, it has a red cheek and a tait finrou
Cfllini. Valuable early apple for small gardens. cspecially in or near towns. For those who like a pice of acid In the flavour, it is a good dessert apple. Grenadisk. One of the best enrly cooking apples, ycllow in colour and finc in flavour. Being ery prollfic, it is of great use in sinall gardens
Early Victoria. A remarkably prolific codlin sultable for uac in July-August.
LANR's Phinor Alifert. Large, striped frult
which "linnger and kerpe for half the vear. Jitie which "linnger and kerpm" for half the vear. Iike

Apple. Left, well-trained Dutch Mignon, Illostrating toe requlaity of the branches, leaving the centre

Apple: methoas of traning the tree. Left, King of the Pipping apple in full fruit. This is a cordon
tree which has been trained bortzontally and supported on props. Right, bush apple tree
icees actually break into leaf. Wide but not very deep holes should be made.

Nost of the manure should be put abovn the roots. The soil should be trodden firmly around and among the roots Stakes for standard trees should be driven down before the trees are planted. It is a good plan to inulch trees with manure after planting

Apple. Espalier trained tree. the best method with apples of prolifio habit, prodacing the maximom amonnt of trait in the minimam space

Some apples are self-sterile and if planted alone will not bear satisfactory orops. A mixed plantation of varieties alone is profitable: it is advisable to plant cooking and deseert apple near each other so that the flowers may le cross-fertilised.
Apples are best turned into good fmiting trees by shortening the heads for three successise years in decrensing degrees of severity, and subsequently summer pruning the side shoots If the tree grows very strongly root pruning may be desirable in winter. Whether for bush or standard the maiden is shortened to about half a vard The two-year-old tree is pruned back to about one-third, the threeyear old to about half.
Most varieties reach the maximum of health, streagth and fruitfulness with ten or a dozen strong branches a foot or half a yard apart near the base, all growing upwards and outwards, so that there is no intercrossing and with the head of the trce oup-shaped.
Grafting and Budding. Excellent methods of propagating apples are described by the Ministry of Agriculture in Leaflet 162, from which much of the following is taken.

Apples are grown in many forms, the most popular being standards-that is, trees with clenn ( $\mathbf{6}-\mathrm{ft}$. stems; half-standards. or trees with clean 3 or 4 -ft. stems; bushes, that is open-headed trees on short stems; cordons, ot trees restricted to one stem, whether perpencicular or horizontai : and espaliers, or trees trained on walls, fenoes, or wites. These and many other forms are developed from a young tree obtained from a bud or graft, and salled in its first year of growth a maiden.
The best stocks are the broad-leaved Paradise for divarf bushes, and the Cml) for the more vigorous and standard treve
Scions for budding or grafting should le cut from prolific and healthy trees. For budding, firm wood of the current year's growth should be cut just prior to use, and kept fresh by standing in a pail containing a little water. For g'afting, well-ripened yearling wood should be cut in the winter prior to pruning, and ufter Inbelling with the variety, bedded in a shady position. In this way the buds will remain dormant until after the stocks have commenced growth.
Bud the stocks in July or Aug., and graft any which have failed to take in the following spring. All stocks, and particularly those which are dwarfing, slould be grafted or
budded an close to the ground level as possible. There is then no difficulty in planting the young trees so that the union between the graft and stock if below ground level

The requisites for bud ding are a budding knile with bone handle: a pail in which to keep the scions raffia for binding For graft ing they are pruning knife hone or wood carving chisel to open the alits, raffia for binding, and wax or graft ing olay For top-graft ing a à $w$ is also required. Grifting wax can be bought ready prepared

The season for grafting is during April and May, when the atocks have just commenced growth, but while the scions are atill dormant Nuccess in gralting can only be accomplished by making clean level cuts so that the exposed surfaces of the graft and stock correspond in size and fit together tightly at least on one side

Apple : method ot prunung. Left, pyramid apple tree beiore praning Right. the same tree alter it bas been properly pruned

For the second method (b), when the stock is larger than the grait (Fig. 2), the graft is prepared in the same way as in (a), except that the tongue is made at the top instead of across the middle of the oblique cut surface.

Apple. Left a badly balanced young bush apple tiee wnich uas been wrongly pruned n earlier stages of growth. Right. the game tree alter correot pruning

The stock after trim ining, is cut almost square across: to 3 in. a bove ground level By an upward atroke of the knife expuse a olean surface on the longest side ol the stuck slightly wider than that cut on the graft At the top ol this surface make a tongue to receive the graft Apply
Tongue Grafting. Chere are two methods: the graft to the atock so that the tongues (a) When the stuck and acion are of the same size (Fig 1) First remove all the side shonts from the base of the stock. Then cut it off 2 in. or 3 in lrom ground level by an upward oblique stroke $1 \frac{1}{2}$ to 2 in long (Fig. 1 A) Across the middle of this cut surlace, and by means of a downward atroke of the knife, a thin tongue should be carefully raised pointing upwards (Fig. $1 \mathrm{~A}^{\prime}$ ).
Next cut a graft containing three or four well-developed wood buds from a piece of the wood selected for the scions. The uppermost out should be made slightly obliquely across the word just above the top bud The lower cut ahould be alout g in. below the lowest bud of the graft, which is known as the stock bud (Fiy 1 B) With a downward stroke of the knife make an oblique out $1 \frac{1}{2}$ in to 2 in. long actoss the graft on the oppositc side to the stuck bud, su that the exposed surface corresponds in size to that of the stock (Fig. 1 B.) Finally, by an upivard cut across the middle of the cut surface raise a thin tongue pointing downivards (Fig $1 \mathbf{C}^{\prime}$ ).

The graft is then applied to the atock and the two tongues fitted together tightly, so that the rinds of each coincide as far as possible (Fig. 1 D) The manner in which the tongues should lit into each other is well shown in Fig 2. Now bind the graft and stock tightly together with raffia, leaving the stock bud free (Fig. 1 E with arrow), and cover all the out surfaces with grafting wax (Fig. 1 F) or clay (pug) to prevent drying.
fit tugether closely and the rinds coincide (Fig. 2). Complete the operation as before by
binding tightly with raffia and covering all the cut aurfaces with wax or clay.
As soon as the gralts begin to grow it is a good plan to tie the main shoots to aticks to prevent the wind breaking them and to secure straight main stems. The raffia ties must be cut as soon as growth commences. otherwise the ties will cut into the wood When the main shoots are 18 in to 2 ft . long all the lateral growths from the grafta should be stopped. The suckers sent up from the stock should also be removed two or three times during the summer.

Shield Grafting or Budding. The seasun lor budding is from the end of June to the beginning of Sept. Stout well-ripened buds from the current year's growth should be used and all fruit buds or young unripened buds should be discarded. The method usually adopted is known ns "shield" or " $T$ " budding.

The bud is removed from the selected wood growth together with a semicircular shield of wood and rind, about if. in length (Fig. 4A) To remove this shield, the cut should commence about $\frac{1}{2}$ in below the bud and tinish about $f$ in above it. The blade of the leal is then re moved, leaving the leafsalk $A^{\prime}$, intact for preas ing the bud under the rind of the atock and preserving it from damage. Next, the portion of wood cut away with the shield is removed from the rind with the point of the knife (Fig. 4 C ), but leaving the hud on the shield unilamaged. Care must be taken to leave in tact the small protuberance at the base ol the bud, inside the rind (Fig \& $3^{\prime}$ )

To prepare the stock, remove all suckers and side growths within 6 in of the tround Next make a " $T$ " shinped cut in the rind as close to the ground level as possible ( Fig 5) The down stroke of the " $T$ " should be about 1 in. long and the cross-cut about $\frac{1}{\frac{1}{2}}$ in The liark on both sides of the downward cut is then raised slightly with the back of the budding knife. The bud shield is slipped beneath the lips of the downward out on the stock (Fig. 6) until the tap of the shield is below the crosscut of the "T" (Fig. 7) Tie with raffia over all the cuts, but take oare that the bud is left uncovered (Fig 8).

Later in the autumn, as soon ay the buds have taken, the ties of raffia should be cut th allow the stock to swell normally Fig. 9 shows the budded stock after the raffia has been iemoved. Suckers or ahonts arising fimm the

Apple: tongue gralting. Fig. 1. Metaod waea stock and scion are of equal size. A, stock cut to receive gratt: $A^{\prime}$. Fig. 3. Union of equal-sized stock and gratt after one year's rrowto
$B_{1 \prime}$ permisition of the Ministry of Agriculture and Fisheries
stock must be removed two or three times during the suinmer

Top Grafting. Rind or Crown Grafting is the method recoummended for top grafting. The trees whioh aro selected for this purpose should have their main branches sawn

Apple. Fir. 4. Pieparation of the bad sbield by removing core of hard wood. See tex! off during the winter and the faggot wood removed. Fig. 10 shows the tree out back in this wny. At grafting timethat is, whon the rind peels quitcessily from the woodthe branches are sawn square across (Fig. 11) where they are stout ennugh to support the large branches which will grow from rigorous grafts. The snwn surface at the end of each branch is then pared anooth with the pruning knife to facilitate healing (Fig. 12 A). Afterwards a longitudinal cut 2 in to 3 in . in length is made in the bark. and the rind at the top of this out is then raised slightly on either side (Fig. $12 \mathrm{~A}^{\mathrm{A}}$ ).
A graft (Fig. 12 B), containing 3 or 4 buds, similar to that used for tongue grafting but with no tongue, is cut and slipped beneath the raised lips of the rind on the stock It is then pressed downwards until the long out surface is level with the top of the branoh

Large quantities of apples may he laid in in the ove heaps, not more than 2 ft . decp, on 6 in . of are tender clean, dry whent atraw laid on the lloor, To stew apples, wipe eight large apples and and covered with a gond thicliness of straw ; but this is not the best method for small quantities. Apples may also be stored in boxes barrels, or baakets placed one upon the other in the store, so as to allow air to circulate. Special trays may be used which rest one upon another and economise space (see Fruit Tray).

The ripening of apples is usually well marked, the green part becoming distinctly yellow. As a rule. the later an apple ripens the longer it will kcep in good condition. Early apples should keep about a fortnight after ripening, Worcester Pearinnin a month, James Grieve six weeks, Cox's Orange and King Pippins two months.

Apple. Fir. 12. Rind or crown rialting. A, branch of stock prepared to receive rrait: $A^{A}$ pared surlace at top of branch ; A. longitudinal bnd. D, completion: grafts bound to the stock and cut suriaces' waxed Bu perniston of the Mtnistry of Ayriculture and Fuheriet

How to Cook. From the health point of quarter them. Stew gently with 1 teacupful view, for most children and adults apples are of sugar, strips of lemon-peel, and pher pint excellent, but in some cases only agrce with water, and serve with custard sauce or cream the digestion when cooked. For very young ohildren raw apples should be grated into a dish just before a nesal and made into sand. wiches with bread and hutter, or eaten with a spuon.

Apples are particularly good for cassernle

Apple : processes in budding. Fig. 5. T-shaped cot on the stock ready for the bud. Fir. 6. Bud abield slipped beneath lips of the downoward cut. Fig. 2. Bod shield pressed completely beneath rind of stock. Fir. 8. Budshield bound to the stock with raffia. Fir. 8. Bad onited to the stock alter removal of raffa $D_{1 /}$ permilaision of the Ninistriy of Auriculture und Fisheries
(Fig. 12 C ). The graft is then bound tightly to the stock with raffia, but the stock bud ( $C^{\prime}$ ) is left uncovered. The top tie shnuld be as tight es prosaible to effect a perfect union at this point and so prevent the graft from breaking when it commences to bear fruit. The operation is completed by covering the cut surfaces around the graft with wax or "pug" (Fig. 12 D) Onc graft is sufficient for branches under 2 in . in dinmeter Above this size two or even three grafts should be used Fig. 11 shows the tree depicted in Fig. 10 with the top grafting completed.

Picking and Storing. The right time to piok apples is when the fruit parts readily from the spur on being lifted gently, but certain varietics part more easily than others. Early varieties are often intentionally picked a little earlier than late varieties, which should hang until some of the fruit has dropped naturally. If picked ton soon fruit will shrivel. Fruit should be picked carefully and placed gently in the picking apron, or into a basket lined with soft material. The fruit should be handled as little as porsible.
For fruit to keep well the store must be (1) Slightly moist (2) Well ventilated: extra ventilation is required for apples during the first three weeks or so, while they are sweating. (3) Cool and of even temperature ; warmth causes shrivelling, and frost generally causes decay. (4) Dark or only dimly lit; daylight spoils the quality.
cookery : in this way the whole fruit is pre served, and can be served more cfiectively than when stewed to a pulp. Baked apples make a wholesome dish when peeled, the cores removed, and the centres filled with sugar and one clove in each. Having put them in a casserole, add a little water with some grated lemon-rind Cover the dish and hake

Apple. Fig. 10. Tree to be top arafted, having been cut back in the winter and with the lagrot-wood removed. Fig. 11. The same tree after top grafting, showing length at which top branches of stock are left By permission of the Ministry of Agricullure and Fisheries
leaves. The wind-borne spores alight on the later a pupa), which has eaten awny the hase fruit, germinnte, and penctrate the skin, of the flower- The blossoms attacked invaribeneath which they form a mass of fungus tissue. In time the skin of the fruit is broken, and dark-coloured spores escape.

Affecter wood is readily distinguished by its blistered appearance. It should be cut out when pruning the trees in winter. Badly diseased wood should be cut out as far as possihle without injuring the trecs, and this should be completed by the middle of March 'To prevent the new wood being affected, it is necessary to spray during spring and summer.
There are two mixtures which may le used, Bordeaux Mixture (q.v.) and Lime-sulphur (q.v.). Bordeaux Mixture is the most effective, though in the case of a few varieties of apples it is apt to cause scorching. These varicties include Beauty of Rath, Cox's Orange Pippin, I)uchess's Favourite, Gladatone, Janics Grieve, I ady Sudelcy. On all of these a lime-sulphur apray only should be used.
In bad cases of apple scab several applications arc necessary, the first immediately hefore flowering, the second is soon as the petals fall, and a third ahout three weeks later. On pears the lirst spraying should be given directly the fruit is set, and a second spraying three wecks or a month aftenvards.
APPLE APHIS. Blue bug blight, otherwise apple nphis. is a pest of apple trees. A description of the symptoms and treatment is given in the Ministry of Agriculture Leaflet 330. The damage is mainly to the foliage and young wood, though the fruit may be stunted.

The blue bug or rosy apple aphis causes the leaves to curl up, and beneath this shelter the lice reproduce, poisoning the foliage by their secretions. They swarm on the leafstalks, shoots, and fruitlets. and by their punctures deform them. The leaves may fall and only a fow stunted and galled apples remain. The green apple aphis feeds upon the young top growths. The oak apple aphis does little harm ad a rule, except when it invades the blossom trusses.
Apple aphides can he controlled by spraying. Limowash should be sprayed early in the season when the eggs are about to hatch. The nurmal time to apply this wash is when the leaf-huds are swelling and ahout to hurst. The whole tree must be corered, and especially the twigs and smaller branches. A contact insecticide, such as nicotine ( $q$.v.) and soap. or pyridene (q.v.) and soap, may he used during the period between the opening of the leaf-buds and the bursting of the hloom. A contact insecticide such as prarafin emulsion is used from the middle to the end of Octoher, when the leaves are falling. The aphides are then laying the winter egga, and can ho killed by a thorough application of aphis wash.
APPLE BATTER PUDDING. Put $\frac{2}{2} / \mathrm{h}$. flour into a hasin, making a well in the centre, and adding two unbeaten eggs, together with a pinch of salt. Work in ! pint of milk until the batter is smooth, then heat it well. and add a further $\frac{1}{\underline{p}}$ pint of milk. l'artly stew 2 lb. of sliced apples with lemon and sugar, put these into a greased pie-dish and cover them with the batter, baking the puilding in a moderate oven for one hour. This is suftcient for $\mathbf{f}$ or 8 persons. See Bntter.

APPLE BLOSSOM WEEVIL. A smnll black beetle harely a third of an inch long, known as the apple blossom reevil, feeds on the leaves of the apple tree in summer. During the spring the female weevil piences the buds of the fruit spurs and lays one egg in each bud. The Ministry of Agriculture Leaflet $1 \bar{J}$ describes its effect on the apple tree.
Certain of the hlossoms fail to expand, the petals having died and become brown in colour without falling off. Such blussoms are known as " anpped hlossom," and underneath the brown petals is a small yellowish grub (or

## ably die and fall off

Weevils hibernate on the trecs, and a winter wash or later a limewash, will leatroy many

Apple Blossom Weevis in various stares of lifie. 1. Larva. 2. bud containing weevil. In 1. 2 and 3 the insect is much enlarged before they lay their eggs. A large sheet is spread under the tree, and the beetles which fall down are tipped into a pail containing a little paraflin.

APPLE BLOSSOM WILT. This diкевя attacks the hossoms and shoots of an apple tree and spreads rapidly throughout an orchard unless suitable precautions are taken The Ministry of Agriculture Iesflet 312 describes its symptoms and treatment.

The first symptom is "blossom-wilt." After the Howers begin to open, the leaves on some of the spurs legin to wilt and hecome brown and withered. The llowers of such trusses will be found to have wilted and to be biown and dead. In moist weather the fungus develops externally on the llowers and flowerstalks in the form of small, rounded, grev. pustules similar to those found on the spurs On the wood the fungus may attack and kill the spurs, grow along the spur into the shoot and form a spur canker, and occasionally. extend considerably in the hranch.

Promising results have been obtained by a winter wash containing $l$ lh. caustic soda and I lb. soft soap in 10 gallons of water, applied immediately previous to the swelling of the buds. Tar-oil winter washes have a clcansing effect on the bark simnilar to caustic soda and are more potent against pests.

The most successful line of treatment is the cutting out and hurning of all infected spurs and cankers. Wherever possible, the cutting out should be done during the summer, when the brown withered leaves of infected spurs contrast with the living ones, and constitute a sure guide to places where the knife is required. Cutting out cant take place any time in winter, but it should he finished before the buds open. Another point to note is that it is necessary to cut back to the sound wood.

APPLE CANKER. A minute fungus is the cause of this destructive disease of apple trees. The Ministry of Agriculture Leatlet 51 details its appearance and treatinent.

In a diseased tree, the early stagen will he seen as small depressed areas, which gradually break away from the surrounding parts of the shoot and are some what darker in hue. Such areas, which often begin around a dead twig, are caused by the fungus. The damnged area increases in si\%e and gradurlly assumes the form of an open wound surrounded in later atages by rugged hark. A marlied feature is the presence of inore or less regular concentric rings around the wound.

The fruiting bodies of the fungus are minute and occur eapecially in autumn and
spring. Those formed in spring and early summer consist of round tough hodies, deep crimson in colour and ahout the size of a poppy seed. In late summer and autumn the fungis develops another form of fruit, which shows as minute white spots on the rough bark around the wound.

Old and badly-diseased trees should he cut down and bumed. From others the cankered whoots and badly-cankered boughs should be cut out. During winter-pruning all infected shoots should be removed. In the case of large houghs the canker-patch may be cut out with a sharp knife or chisel. All cut surfaces should be covered hy a protective substance, such as coal-tar, Stockholm tar, paint, painters' knotting. styptic. or grafting wax. Earth should not be rubbed over the surface.

APPLE CAPSID. The most harmful species of this encmy of apples and currants is the green apple cajpid, almost always found on willows and sallows, and widely distrib. uted throughont England and Wales. Capsid bugs feed on the sap, sucking it up through proboscis: to reach the sap they drill small holes, which form the centres of more or less cxtensive in-

Apple Capsid. Burs whica teed the sap
Marnified three times juries. Apples attacked are usually deformed the skin shows rough russeted patches with scattered pits and pimples. Many fruits fall off before they reach maturity, while a large percentage of the remainder are badly scarred.
In Leaflet 319 the Ministry of Agriculture describes the insect and also recommends certain measures for getting rid of it. The hest time to spray is during the week or ten days preceding the bursting of the hlossom. A wntch should be liepit for the first signs of

Apple Capsid. Four stares in the destruction of an pple by the most barmful of the apple pest Hy vermission of the Ministry of Auriculture.
spotting of the leaves; then after an interval of ten lays, to allow the majority of the bugs to hatch, the spray should be applied very thoroughly. The hest insecticide is nicotine, combined with soap or paraffin emulsion. The following formula has proved satisfactory
Nicotine (98-99 p.c.)
Soft soap
Water
3 oz.
.. ... .. 40 gal!

AP-diE CHARLOTTE. Line a greased ne-dish or pudding basin with slices of bread and butter, leaving no crevices. Fill the dish with stewed and sweetened apples and add a clove, if this flavour is liked. Coven the top of the dish closely with slices of hread
and butter and bake in a moderate oven until the bread is crisp and brown. If the pudding is made in a basin it should be tumed on to $n$ dish to serve. If made in a pie-dish, a meringue of stiffly beaten white of egg poured over the top for the last five minutes of cooking is an improvement.

APPLE CHEESE. All that is required for apple cheese is 2 lb . apples, 1 lb . loai sugar, and the rind and juice of 1 lemon. Peel, core and cut the apples into pieces. Cook them gently with the sugar, grated lemon-rind and femon-juice until soft. Turn them into a basin and beat them with a fork until they are thick and smooth. Dip a mould into cold water and pour in the apple. Turn it out when cold, and serve it with cream or custard.

APPLE CHUTNEY. A good recipe is composed of 4 lb . sour apples, $\frac{1}{2} \mathrm{lb}$. Vemerara nugar, $\frac{1}{2} \mathrm{lb}$ onions, $\frac{1}{2} \mathrm{oz}$. dry chillies, $\frac{1}{2} \mathrm{lb}$. soedless raisins, 1 oz. salt, 2 oz .ground ginger, 1 oz. mustard seed, 1 quait vinegar, $\frac{1}{2}$ oz garlic (if liked). Peel, core and slice the apples, and simmer with the sugar and vinegar in a pan. Peel and mince onions, garlic and chillies Wash mustard seed and dry in oven Chop raisins Pound them in a mortar with the onions, etc., and the ginger. When the apples are soft ald the other ingredients and mix well together. Botille and cover as for pickles. The chutney improves by storing for two or three months previous to being used.

APPLE CORER. A
simple corer is made from a length of steel tule with half the upper portion cut away, and fitted in a handle. The tubing is ground and sharpened on the inside, and when the cutting edge becones blunt it can be sharpened with a small round oilstone, or, failing that, a strip of fine emery cloth may he wrapped round a penoil and rubled along the edge, On no account should the steel be sharpened on the outside.

APPLE DAINTY. This is made with 6 medium cooking apples, 2 tablespoonfuls brown sugar, 2 tablespoonfuls desiccated coconut, 2 oz . sponge-cake crumbs and a piece of butter the size of a walnut. Peel, core, and cut the apples into slices. Put them into a saucepan with sugar and a tcacupful of water, and stew until soft. Turn them into a pie-dish, sprinkle over them a layer of desiccated coconut, then a layer of cake-crumbs, and another layer of coconut. Place small pieces of butter on the top, and put the dish iuto a hot oven until it is a nice golden brown. It should be served with custard or cream. This will be enough for five persons.

APPLE DUMPLING. 'The ingredients required are $\frac{1}{2} \mathrm{lb}$. of Hour, $\frac{1}{\frac{1}{2}}$ teasponnful of baking powder, $\ddagger \mathbf{l b}$. of margarine, (i apples, is teaspoonfuls of sugar, and 6 cloves

Peel the apples and take out the cores with an apple corer. To make the short crust, sift the flour and baking powder into a basin, and rub in the margarine until it is as fine as breadcrumbs. If self-raising flour is used the baking powder must be onitted. Add a pinch of salt and mix with a tcacupful of water. Use a knife for this purpose, and when a ball of dough or paste is formed take this up in the hand, and use it like a sponge until all the flour is worked into a stiff paste. Mix more water as required in lightly without kneading it. Turn on to a floured board and divide into six pieces.

Roll each piece into a round shape, and place an apple on each. P'ut a clove and a teaspoonful of sugar into the centre hole of each apple. Damp the edges of the pastry, and draw it up round the apple to the top; squeeze the erges together and make it look as round as prossible. Press it well, and turn it down on to the sealed end. Brush it over with white of egg or milk, and hake in a hot oven alout 311 minutes.

Try with a skewer near the bottom to see when the apple is done The pastry should be a light brown in colour. Sprinkle with sugar, and serve hot or cold. This is sufficient for six persons.
APPLE FRITTERS. These reguire $\frac{1}{2} \mathrm{ll}$. of Hour, 1 lb of apples, 2 eggs, $\{$ pint of milk, and deep fat for frying. Put the flour into a basin and make a well in the centre. Break the eggs into a basin, and drop each into the flour unbeaten. Add half the milk gradually. stirring all the time. and letting the flour fall in from the sides of the basin to prevent lumps. Do not add all the milk at once, or the batter will be too thin Work it until it is smooth, like a thick custard, and beat it well for 10 ininutes. Stir in the remainder of the milk and stand on one side for an hour for the batter to thicken. A coating batter should be thick enough to cover the back of a wooden spoen as it runs off. If it is too thin, arld moro flour; if too thick, gently stir in more milk.
Peel the apples and take out the cores with an apple corer. Cut them into rings about $t$ in. in thickness. Put into a deep-fat frying. pan enough dripping, lard, or salad oil to fill half the pan. Heat this until it begins to send up a faint blue sinoke, dip the apple rings into the batter, and then take out and drop them into the hot fat-about four pieces at a time. Fry them a golden brown, turning them in the fat; then drain them on kitcben paper.

Bring the fat to smoking heat again and continue until sufficient apple-rings have been fried. Sprinkle with oastor sugar and serve very hot. The fat can be used again and again for frying. This makes a dish for six persons. See Illus. below.
APPLE GINGER. Take $\ddagger \mathrm{lb}$. of whole ginger, 3 lb . of sugar, 4 ll . of apples, $1 \frac{1}{2}$ pints of water, and the juice of 3 lemons. Boil gently together the sugar, ginger (bruised and tied in muslin), water, and lemon-juice. Boil for 15 minutes and add the apples, pared, cored and cut into quarters. Simmer gently for three-quarters of an hour, taking care not to break tho apples; let them remain until they are clear. Better still. if a hay-box is in use, after boiling the apples in the syrup for five minutes. put them into the haybox for one hour and a half. The ginger must be kept in a covered jar in a dry |llace, and will keep good for some time.

APPLE JAM. Goor! flavoured cooking apples should be sclected, and there should be enough to weigh 6 lb . after being peeled and corcd. Peel thom thinly, out into quarters, and, after vemoving the cores, slice them and put into a pan with a pint and a half of water. Pcel 2 lemons thinly, and tie the rind in a piece of muslin with 6 cloves, and add to the apples. Cook until the apples are a soft pulp, remove the clove-bar, and pass the apple purée through a sieve.

Put this pulp back into the pan, add $4 \frac{1}{2} \mathrm{lb}$. of lump sugar, boil for 1 hour, slim and stir frequently. Be careful to put it into clenn, dry
jars when it is cool. A few drops of cochineal improve the colour of this jam, and should be added when the jam is boiling. Tie the jars down closely: and keep them in a very dre. place. See Jam.
APPLE JELLY. An important requisite is to have a proper jelly bag ready for use.

The apples arc cut up in the rough, but should not be peeled or cored, though any bad parts should be carefully removed. Rinso the fruit and put it in a stew pan, covering with cold water. Add some strips of lemon peel and bring to the hoil It should be boilcd quickly until tender.

Next pour the pulp into the jelly bag and let it drain slowly. On no account squeeze the bag, or the jelly will be cloudy, and no boiling afterwards will clear it. Measure the liquid thus obtained, return it to the preserving pan, and bring it to the boil. Add the sugar, allowing 1 lb . of lump sugar to each pint of juice. Remove tho scum as it rises, and boil fast for 30 minutes. Drop a little on to a cold plate; if when cold this is formed into jelly it is ready for puttine into jars. When the jelly is set, the jars should be covered with air-proof papers and stored in a dry place. See Jelly Bag

APPLE MILDEW. In Leaflet 204 the Ministry of Agriculturo deals with this fungus pest of apples, which appears as a white mealy powder both on flower and leaf As new out. breaks commence each year from infected buds these should, as far as possible, be removed. When pruning, all shoots which were mildewed during the past summer, and are recognizable in winter by the whitencss of the young wood, should be cut away.

As the buds expand in the spring the treas should again be gone over and all affected shoots cut off and removed for burning. Should there be risk of infection to sound trees, spray them with lime sulphur shortly after the blossoms set and again later if necessary ( 1 gallon lime sulphur to 30 gallons water. except for the delicate varieties, Cox's Orange Pippin, James Grieve, Newton Wonder and Wellington, for which 1 in 60 must be used).

Apple Fritters. 1. Slicing the apples after ther have been cored. 2. Dropping
the batter-coated rings into fat. 3. The fritters as thes should be served

Apple Pudding. 1. Linlng the bagin wlth a suet crust ; it should be pressed well down. 2. Firing on the top crnst to the edges of the lining pastry
and then a flomed pudding cloth, and hoil $2 \downarrow$ hours For stenming, have sufficient boiling water to comc three parts of the way up the hasin. and add more hoiling water as it hoils away. Boiled puddings must be immersed in boiling water, and be kept covered and boiling fast all the time.

To serve, loosen the edges from the
APPLE PIE. The ingredients arc I lh. sides of the basin with a knife, put a flat diah on flour, 3 oz lard, 3 oz . margarine, $1 \frac{1}{2}$ tenspoonfuls the top of the pudding, gently and carefully baking powder, 3 lb п пpples, $\mathrm{f}_{\mathrm{oz}} \mathbf{o z}$. sugar, 1 oz. lemon rind and 3 cloves. First peel, core, and slice the apples. Put half of them into a piedish, in the middle of which is an in verted eggcup, add the sugar and ila vouring, and on this lay the remainder of the apple slices. Let no sugar be on top of the fruit next the pastry, as this makes it heavy. Pour in $1 \&$ teacupfuls of water.
To make the short crust that is usually employed to cover the apples, sift tho flour with the haking powder into a hasin, add a good pinch of salt, and then rub in the mar garine and lard: $;$ oz inargarine alone can be used. It sliould be well rubled in with the fingers till the whole Hour is mixed with it and looks like fine bipadcrumbs. Then pour in enough water to inake it a dry paste. The water should not be added all at once, hut gradually, though not too slowly. Mix it in with a knife, not a spoon. Turn the paste on to a well-foured hoard, and roll it out with short forward rolls, lifting the pin up between each roll

The crust should be alonit a quarter of an inch thick. Cut a strip from the pastry. Moisten the rim of the pie-dish, and put on it the strip, cut side outward. Damp this, and oover with the pastry, pressing the edges together. Cut off the rough elges, and mark the edge with the hack of a knife or fork dipped in flour. Bake in a hot oven for 36 min
The pastry ahould he a liglit brown and the apples soft. If the pastry browns ton quickly remove the top browning shelf of the gas stove, or put on to a lower shelf in the oven and cover with a greased paper. Sprinkle the pie with castor sugar, and serve hot or cold If the apples are not good cookers, they should be stewed before lheing put in the pie-dish, and allowed to get cold hefore adding the crust.
APPLE PUDDING. In the first recipe given, which contains suet, the folbowing ingredients aro required: $\frac{1}{2} \mathrm{ib}$. flour, $\frac{1}{1} \mathrm{~h}$. suet, $1 \nmid \mathrm{lb}$. apples, 3 oz . ]emerara sugar, 3 cloves, together with soine grated lemon rind.
Peel, core, and slice the apples. Chop the suet finely and inix with the flour, add a pinch of ralt. and mix to n stiff paste with water Cut off one-third of the pastry for the top of the pudding. Flour the board and rolling-pin, roll out the larger piece of crust to a round shape ahout one and n half times the size of the top of the hasin. Grease the basin and line with the pastiy, working the creaser evenly into the sides and pressing well up to the top of the hasin. Put in half of the sliced applea, sugar, and flavouring, and fill up with the remainder of the apples, and add a teacupful of water to make a syrup.

Roll out the amall piece of pastry to the size of the top of the hasin, moisten the edges, and fix on to the pastry lining the basin, not round the outside rim of the hasin. Cover with a greased paper, tie it onl, and steam for $3 \frac{1}{2}$ hours. If hoiling, cover with a greased paper,
the top of the pudding, gently and carefully
turn the pudding lasin over, shalic it, and the pudding should leave the hinsin quite clear. Prick with the knife to allow the syrup to run round the dish, and serve at once

A recipe in which no suet is used call be made thus: Mix four teacupfuls of flour with an cqual quantity of hreaderumbs, two teaspoonfuls of haking powder, and a good pinch of salt. Rub in 6 oz . of margarine, and then add enough cold water to make a stiff dough. Knead on Houred hoard, and roll the pastry into a round. Line a greased howl with it, and put in alices of apple covered with sugar. Cover it with pastry and then with greased paper. Steam for two to three hours

APPLE ROLY POLY. Prepare the pastry as for apple pudding. Roll it out into a strip 8 or 10 in. wide and fy in thick. Spread over it apple jam, or minced raw apples and sugar, leaving 1 in . at the sides untouched by the fruit. Moisten the edges. roll it ip, and put it into a greased 3 -lb. atone jam jar Cover with a greased paper, tie down, and atcam for 3 hours. If it is to be boiled, tie it in a floured pudding cloth, immerse it in boiling water, and boil for 2 hours. This is enough for six persons.

APPLF, SAUCE. Peel, core and slice 5 large apples Place them in a saucepan with half a teacupful of water. Simmer and stir over a slow fise until pulped. Turn them into a basin, licat well with a fork, add 1 teaspoonful of sugar, half a teaspmonful of made mustard, a pinch of salt. and a small piece of butter. Squeeze in sume lemon juice, a nd serve in a sauce tureen. This sance is eaten hot with roast goose, ruast duck, and roast pork.

APPLE SAWFLY. 'L'he injury caused ly the apple sawfly resembles that of the codlin moth. the attackel fiuit weldom growing to any size and generally falling off in July. 'The pest is dealt with in LeaHet ?(05 of the Mlinistry of Agriculture

Apple Sawfy. 1. Adult fiy. 2. Larva of the pest. Both are shown considerably enlarged
The measures which have been found of service are as follows, hut they are suited to amall garclens rather than to fruit-growing on commercinl scale. All attacked fruits should be pioked off the tree and destroyed hefore the larvae have left them. The pupae in the soil may be destroyed by carbon bisulphide injections or by the use of some other powerful soil fumigant. By thoroughly working the soil under attacked trees some of the pupae may be exposed to the attacks of birds, while others
may be prevented from emerging. A dressing of kainit is said to the beneficial.

APPLE SNOWBALLS. Peel four apples and remove the cores with an apple corer. Place them on a baking-dish, and put half a teaspoonful of sugar and a clove into the centre of each. Put a little water into the bottom of the baking-diah, and hake in a moderate oven $\underline{2}$ to 30 min . until tender Beat the whites of three eggs stiffly, and whip into them 1/ deasertsproonfuls of castor sugar. Remove the apples on 10 a shallow dish, and cover each with the white of egg mixture. Place in a warm oven for 15 min , to set the meringue Garnish with angelica or glace cherries and serve cold. The snowballs can tho made to look more attrac tive if surrounderl with chopped jelly.

Apple Snowballs. Attractive way of serving baked apples, the snow being white of err and sugar

APPLE SUCKER. The apple suoker is a recen, filmy tly ahout one-twelfth of an inch long. It is scen flitting about in autumn, and does double injury, as its larvac fced on the buds in spring. How to deal with, this pest by spraving limewnsh and contact insecticide is set out in Leaflet 16 issued hy the Ministry of . Igriculture. The formula for limewash is 10 to 15 lb . of best quicklime in lumps to 10 gallons of water. The trees are sprayed aboul the tine when the buds legin to awell Shortly before the blossoms open a contact insecticide of nicotine and soap should be applied. The following formula has proved satisfactory. Nicotine (98-99 per cent ), ${ }_{3} 0 \%$; soft soap, $\frac{1}{2}-1 \mathrm{lb}$. ; water 10 gallons.

APPLE TART. Pastry as for apple dumplings or apple pie is made. Line a shallow tart-dish with pasiry and spread over witlu stewed aples. Cut atrips of pastry and lay them in cross-bars over the tart. Bake in a goml oven for 90 min .

Another apple tart is made by lining a greased pastry ring with pulf pastry. lake in loot oven, scoop out the soft centre and fill with stewed and sieved apples. Whip the whites of - eggs to a stiff froth, and fold in lightly 1 tablesponnful of castor sugar. P'ut on the top of the apple to cover, and return to the nien for is to 10 min . to bake the meringuc a light brown. Decorate with a few glacé cherrics and serve cold.
APPLE TURNOVER. Make the pastry for apple pie. Cut it into rounds, and put in each a tablespronful of chopped apple with a aprinkling of sugar. Moisten the eriges and double the pastry over. Bake it in hot oven for 20 min.

APPLE WATER. Take 4 large cooking apples, - quasta of cold water, the juice of a lemon, a stijp of lemon peel. and enough sugaı to swecten. Cut the apples into rough pieces and hoil thein until soft with the lemon peel, water and augar. Strain off, add the lemon juice, and serve cold. This is a good drink in hot weather.

APPLIQUE NEEDLEWORK. This French word is used for a form of docorative trimming in which one kind of material is "applied" upon another to form a pattern.

Thus lace is often appliqued on washing satins and crôpes for blouses or underwear, and scraps of coloured silks, satins, velvets, linens or cretonnes can be utilised for making gay patterns on oushions, hags, curtains and table sets Motifs, ready made for appliqué can be purchased in lace and in such diverse materials as tinselled braid and brushed wool (the Intter in white 'animal' shapes for applying to nursery coverlets), but more originality can be displayed by cutting out designs suitable to the work in hand
Iace, for instance, particularly lends itself to gond elfects when a needlerun kind is chosen with a large flower design, which can be cut out and sewn or embroidered on to the garment, smaller pieces of the lace design being used to fill out the pattern as required. Special lace motifs can be made for liouschold linens, but a brighter note in decorntion is the coloured border to white linen, wide enough to take motifs designed rach from a different fruit, apple, pear, cherries, grapes, etc. These can either be drawn on the coloured linen selected or transfers can be obtained Flower designs can be applied in the same way if preferred. Luncheon sets and afternoon ten cloths are most successful with this appliqué, the colours of which should harmonise with the china and table decoration in use.

A simple form of appliqué is shown in the hag illustrated in Fig. 5 Such designs can be used for cushions, blotters, sachets, etc. Button hole stitch, Fige. 1 and 4, and satin stitch. Fig. 3, are the two simple stitches employed for appuqué, and the design should lirst be nently tacked on to the article in the correct position Where possible edges should be turned in, especially for linens which will have to be frequently laundered. Details too small for appliqué, such as stalks of Howers or tendrils of vines, can le embroidered, using stem stitch, Fig. 2.
The simpler the design the more effective the work. Conventional or geometrical pat-

Appliqued yeedlework: Stitches used in the work. 1 and 4, buttonhole; 2, stem stitch: 3, satin stitch. 5. Bag trimmed with a prigue work 8. Cushion decorated with geometrical patterns appliguéd with buttonhole stitch in coarse silk
terns are particularly good for colour notes on cushions or curtains. The stitch employed for the appliqué of the angular design in coloured satins on the cushion illustrated in Fig. $f$ is buttonhole stitch in conrse gilk. See Embroidery

APRICOT. A heary clay soil suits many fine plums, but the apricot requires a fertile, mellow and frinhle loam, with sand or chalk not far from the surface. If the soil is stiff it can be lightened and sweetened by breaking up, and adding lime rubbish and gritty matter. Do not overlo the use of yard manure, which is rich in nitrogen
The following is a good annual dressing: if no yard manure is used, an addition of one part of sulphate of ammonin may be ninde. 4 parts, by weight, superphosphates of lime; 3 parts sulphate of linie; 2 parts sulphate of potash : $\frac{1}{2}$ part sulphate of iron. The mixture is spread round the trces at the rate of $\$ \mathrm{lb}$. per square yard. Mulching with yard manure might he practined in early antumm. Every third year a dressing of ground lime or slatied lime at the rate of 1 th per sq. yd might be given.

Both for size and flavour of fruit no variety of apricot equals Moor Park, but there are other good kinds, as the following list shows:

Brfada.-Very old variety, fruit amall, but of gool Havour, ripe in August on a wall, hut somewhat later in the open. Ahout the best varicty for growing as a standard

Hemskirk. - Large fruit, ripe ahout midAugust, rusembles Moor Park, and must have a wall.

Iarge Ealley.-Large fruit, ripe early in August.
Moor Park.-Largo fruit, very rich in flavour. Ripe at the end of August. Liable to loss of branches by gumining.
lowell's Late-large frnit, paler than Moor Park, ripe in Sejtember

The apricut is 1 rained with main fruiting branches spacel a forst or more apart over the face of the wall, diagonally, in the familiar fan shape. It is hest to renciv the fruiting wood every few years by taking up shouts from word-buds at the hase, and turning them into Sruitors by summer pruning. Apricots are generally propagated by budding them in early aummer on Nussel or Nit. Julien Plum stocks, the former being used for Moor Park and other choice varietics, while the latter is employed for standards.

APRICOT BATTER. Take one small tin of apricots, a pinch of salt, 3 oz . of castor sugar, 13) of flour, 2 volks and 2 whites of eggs, $\frac{1}{2}$ pint of milk and water, 2 o\%. of dripping, and one gill of apricot syrup. Mis the Hour and salt together, and put through a wire sieve. Then nake a well in the centre of the flour and place in the yolks of the egge, gradually mixing the llour into them. Grad. unlly add the milk and water, and as it is added more llour must be mixed in. An even consistency
aliout the thickness of custard must be main tained all the time the hatter is being mixed When well mixed, beat it until the surface is covered with bubbles

Strain the syrup from the apricots and lightly stir one gill of this into the batter, and put aside for an hour. (Sut the apricots into quarters: use only about half of them, as too many would make the batter heavy. When ready to cook the hatter add the sugar and apricots and lightly fold in the whiaked whites of egg. Melt the dripping in a piedish, and when hot pour the hatter into it. Bake in n moderately hot uven for about forty-five minutes. Place carefully on to a hot dish, cut into six, and serve at once. This is sulficient for six persons.

APRICOT CREAM. Sieve enough tinned ol stewed apricots to maki $\frac{1}{2}$ pint. Dissolve without hoiling 1 oz . of gelatine in 1 gill of water, or in syrup from the apricots. Mix with 3 oz of castor rugar and the strained juice of half a lemon, and whip $\frac{1}{2}$ a pint of cicam until it will nearly, but not quite, hang on the whisk Having st rained the gelal ine into the fruit, mix and lightlyst in in the whippel cream. Pour the mixture into a mould that has lieen rinsed with cold water and ienve it till it is set. Dip the mould into warm water and turn the whole on to n dish. This is sulticient for 4 or 5 jersons

APRICOT EGGS. A simple sweet for children's parties is made from apricots without any cooking Cut some plain cakc into large rounds In the centre of each place the half of an a pricot to look like the yolk of an egg Surround the yolk with a thick layer of whipped cream Hattened till pericetly smionth The repult will resemble poached eggs on tonst

APRICOT GATEAU. Take one small tin of apricots in syrup, 2 eggs, 1 pint milk, \& small spongo cakers, and l dersertaponful oi

Apricot $\mathrm{O}_{\mathrm{a}}$ teau. Sweet made with sponge cakes. apricots and egr custard
sugar, with $a$ little vanilla llavouring and cochincul. Grease a border mould with margarine or butter. Heat the milk in a saucepan with the sugar and add it to the heaten eggr, crumble the sponge cakes and mix with the eggs and milk, and tinally add vanillat for flavouring, together with a few drops ol cochineal, sufficient to make the custarl lorok deep yellow in colour.

This mixture should be poured into the mould and covered with a greased paper, tho mouid being then put into a saucepan of boiling water, on an inverted saucer, the water reaching only half-way up the side of the mould. It should not boil, but simmer, other wise the custard will curdle. Steam until it sets, which will be in from 30 to 40 minutes. When cooked, turn it carefully on to a dish, and leave until cold. The apricots should be arranged round the top of the gatcau, the out side being placed downwards, and the
apricot syrup poured all round. The custard may be baked instead of stramed. This is sufficient for 4 or 5 persons.

APRICOT JAM. The ingredients arc 2 lb dried apricots, 6 pints cold water, 6 lh . lump sugar, and 2 oz almonds. Thoroughly wash the apricots in two or three warm waters and cut into quarters. Place in a basin, cover with the water and soak for 72 hours. Put the wholc into a preserving pan with the sugar, and boil the jam for about one hour. Blanch the almonds and split them in half. Add them to the jain about ten minutes before it has linished cooking.

To make jant of apricot pulp, which can be bought ready for this purpose in large tins, take 6 lb . of fruit and 4 to 6 lb . of sugar, 6 lb . if the jam is to be kept Boil all together until a little sets when put on a cold plate. Mix in 2 oz. of blanclied almonds when it is done
APRICOT JELLY. Add the grated rind and strained juice of a lemon to $1 \frac{1}{2}$ pints of apricot pulp, or 1 large tin of ajpricots pulperd and put through a fine sieve. Shell and slined four sweet almonds and add them. Dissolve $\frac{3}{3}$ or of gelatine in a gill of water, taking care that it does not boil, and strain it into the fruit, etc. Mix all thoroughly in a basin, and occasionally stir until it begins to set, then pour into a wet mould Serve with whipped cream.
APRICOT MACAROON. Take a small tin of apricots, half a dozen macaroon biscuits, a quarter of a teaspoonful of castor sugar, a little vanilla llavouring, and one gill cream. Place the biscuits in a dish, soak then with the apricot syrup and then place an apricot on each macaroon. Add to the crean the vanilla and sugar, and then whiski it lightly until it thickens, taking care not to overwhisk it, or it will curdle; it should he poured mound each macaroon and on the top of each apricot, placing a crystallised violet and angelica strip, for purposes of decoration

## APRICOT PUDDING

Sicve together 4 oz . of flour and half a teaspoonful of carlomate of soda. Beat 4 oz . ench of hutter and Demerara sugar till the whole is as soft as whipied cream. Beat 2 eggs till frothr, then work them gradually into the creamed mixture. Sit in ? tablesproonfuls of apricot jam and 2 tablespoonfuls of mill. Mix well and quickly, turn into a thickly greased mould or pud. ding hasin: twist a piect of greased paper over the top and stearn for 2 hours. This will be found suflicient for 6 persons.
APRICOT SAUCE. 'This userul sweet sauce can lx made "ith jam or sieved pulp, l'ut 1 large tallesponful of the jam on pulp into a saucepan with $\frac{1}{2}$ pint of water, and then heat until it boils. Mir 1 tablespoonful of cornflour smoothly with 2 tablesperonfuls of cold water. Stir this into the boiling jam or pulp, and stir and boil gently for 5 minutes. .idd 1 tablespoonful of cooking sherry or lemon juice and then at rain. Sufficient for 4 persons.

APRICOT TART. An open upricot tart, served either with custard or cream, may be miade by lining a greased dish with whort crust pistry, and covering this with apricots and a little of the syrup; one tin of 13 oz . will be ample for a large tart. Sprinkle the whole with castor sugar and bake in a fairly quick oven till the pastry is a light

## Aquariums for the home

How to Construct and Stock Them
Related articles under Fern; Gold Fish; Plumbing; Slate, ecc.
The shape of an aquarium is very important The surface of water exposed to the air should be as great as possible, so as to allow the maximum absorption of oxygen in proportion to its bulk but it should be decp enough to allow the necessary water plants to grow properly.

Aquariums range from the simple, flat earthenware pan to expensive combinations of plate-glass, slate, and fountains. The type best suited for the fish and the plants is that which most resembles a pond, light only entering from above. The drawback is the difficulty of walching the movements and habits of the fish.

The commonest aquarium is of the type shown in Fig. 1. A disadvantage is its transparency, which causes discomfort to the fish, and the rapid growth of plants, but this can be partly overcome by placing the aquarium away from the light. In buying an aquarium of this kind, the broadest and shallowest should he chosen

An casily made tank is shown in Fig. 2. This is constructed of glass, wood, and slate : the ends and hottonn are of wood, the former being lined with window-glass, the latter with slate; and the sides are formed of plate glass An aguarium which is formed of slate and plate-glass is shown in Fig. 3.
procured of any slate merchant. The bottom, 30 in . long and 16 in . wide, and the ends, each 16 in. by 13 in ., will make an aquarium of good dimensions. At 1 in from the ex. tremity of each end, that is, across the broad part, cut a groove $\frac{1}{2} \mathrm{in}$. dee ${ }^{1}$ and 11 in . broad. The groove is cut in the fol lowing manner: First mark with an awl the exact place and dimensions of the groove, then get two straight-edged pieces of wood some inches longer than the breadtlı of the end;
 Simple glage. Fig. 1. place them cach side of
the line which is to be cut, and mail them to the bench-they should be just wide enoughi apart to admit a tenon-sill -and with the saw cut the line to the required depth, it in
Without some such preparation as this it is difficult to cut the sides of the grooves with the necessary accuracy. When both lines have lween sawn in this way take an old chisel and a mallet and cut out the slate which lies between them. Before chisel. er, take the precaution to put two or three folds of carpet between the slate and the bench to prevent all danger of a crack. These grooves are to. receive the ends of the bottom. As a rule, the slate can be split cleanly oul by st riking the chisel against the eilge and not on the top.

Now along hoth sides of the bottom and of cach end, cut, at a distance of 3 in . from the edge, grooves in. deep and ${ }_{i}^{3} \mathrm{in}$. broad. These grooves are In receive the plate.glass sides, \} in. thick. After this bore four holes, $\frac{\mathrm{in} \text {. in diameter, right }}{}$ through each end. Two of these are to $\mathrm{le} \cdot 1 \frac{1}{2} \mathrm{in}$. from the edge and 1 in. below the groove which is to receive the end of the bottom, and two 1 in. from the top and just within the grooves cut for the glass (Fig. 4)

The holes are for the liolts, which inin across from end to end to hold the aquarium together Bore them with an ordinary hrace und a bit used for metal The holts should preferably be made of lrass. Before puiting the aquarium together, place a little cement in all the grooves. Then raise the bottom on blockis of wood to such a height that it will be level with the grooves out to receive it in the two elfds When this has bcen done, put the ends, plate-glass, and bolts into position, and screw them all together, turning the nuts of the bolts with the linger and thumb only. Before the
nuts are quite screwed home, press the glass employed for making the back, but if it ahould gently downward, so that it is forced firmly not be convenient to use only one pane for into its place. Carefully finish filling up the this purpose, the necessary woodwork for

Agarinm Pig. 2. Tank in plass, wood and slate. fig. 3. Slate and plateof slate tank more than one may be tastefully covered inside with cork, with here and there a fern which may be planted in a receptacle made as follows:
Get a mall round tin canister with a few holes punched in the bottom, and sew round it two pieces of sufficiently ourved cork, using thin copper wire for this purpose.

Ferns in suitable backets may be hung from the roof of the frame. No fern should be liung in anch a way that the drip from it would fall inside the aquarium.
Fig. 6 represents a section of the grooves with coment, and the aquarium will fernery and nquarium combination: A, be completed Paint any iron bolta with Brunswich hlack.
The following are cements suitable for an aquarium :

1. Red and white lead mixed together into a stiff maste. The bed for this cenient ought to be painted inth cold size,
2. One plat each of plaster of Paris, Iltharge, and fine white eand, and one-third pint of finclypowdered resin. The mixtire should he kept in well-stoppered bottles, and, whicn wanted, the necessary quiantity

## 3. The hest Portland cenient

4. Four narts pitch and one part gutta-perchia applied when warm. These should be melted together in an lron lade over a gne-fome or lamp. This cenient is espiceially uscful for $n$ wooden aquarlum

An arrangement of an aquarium and fernery combined is shown in Fig. 5. This combination is fixed outside a window. The tank should be of slate and plate-glass, similar to that depicted in Fig. 3, and the stand should be so arranged that there will be a place for ferns heyond the aquarium. The framework to support and protect the aquarium and fernery may be as high as the window, hut its breadth may somewhat exceed that of the window. If the tank is made of slate, according to Fig. 3, only a piece of plate-glass will be seen as its front, no top har being necessary. The whole combination may be supported by a strong wooden stand outside the window (Fig. 6), or, if the room to which it is affixed is an upper one, iron brackets let into the wall must be used.

The frume. back, and sides should be glazed with tinterl cathedral glass. One large sheet is

Aquarinm. Fig. 5. Comblned aquarinm and lernery ared ontside a window. Fig. 日. Sectional view ; see tert for explanation ol lettering

They can be raised from seed sown in late spring, the seedlings being transplanted in autumn. The double Arabis albida produces large spilics of pure white double Howers Lucidn varicgata has light green leaves edged with vellow. Arabis Billardicrii bears pink blomms. Pron. Arrer-bis.

Arabls. Profusely flowering clump of this lowgrowing fock plant

ARBOR VITAE. There are two kinds of Arbor Vitne-the Eastern or Chinese, Thuya oricntalis, and the Western or Amcrican, Thuya occidentalis. They belong to the conifers, and are well adapted for small gardens, whore they may be used in shrubberies, on lawns, and even as hedges.
The Ameri can Arbor Vitae has many varic. ties, includ. ing Ellwan. geriana. The most popular of the other forms is dol. abrata, with drooping branclies, and leaves silvery beneath. There is a dwarf form. nana Gigantea is of pyra
 midal habit.

All these thrire in any good soil that is fairly substantial and moist. Light, thin, dry soils do not anit them. Ilanting should be done in April or Septemher and October. Pron $\mathrm{Ar}^{\prime}$-bor-vi'-tec.

ARBUTUS. The principal variety ol arbutus is the Unedo or common strawberry tree, which has many lance-shnped, brightgreen leaves, and drooping clusters of white Howers hone in September, and followed hy strawberry-like fruits. There are several varieties, such as coccinea rubra and crooniei.

Arbutas. Leavea a nd truit of the common strawherry tree

Andracine has smooth, oblong lenves and greenish white flowers. produced in spring. Most var. ieties attaina heightol 6-10 fect.

They thrive best in a sandy loam or peat, and are suitable for the shrubbery. Propagation is by seeds for species, and by layers or grafts for varieties. Planting may be done in Fel, Pron.Ar-bew'-tus.

## Arches as a Feature of the Garden <br> Decorative Firtures in Rustic and Plain Wood

## Further informatlon is given under Pergola; Rustic Work: Summer House, etc.

Arches for use in gardens are descrihed as be oak, beech, American whitewood, or red rustic when they are made of poles and deal Oak will be finished by varnishing; the branches in a natural state, with or without the hark. They are easily made if suitable material is available. Larch poles, about 3 in . in diameter, are best for uprights and framing; the smaller branches of oak, about 2 in. or so in diameter, provide good material for filling in spaces. The joints should bo as simple as possible, and strongly nailed with stont wire nails. An effective design is given with the necessary joints in detail.
Timber with the bark on gives the ideal rustic appearance, but it is more difficult to make and dues not last as long as timber whioh has had the bark removed. It is advisable in the latter case to varnish the wood in order to nreserve it. That portion of the arch which is placed in the ground should be coated with orsoaked in creosote, or given two or more coats of tar

Rustic Arches. An arch made from larch is shown in lig. 1 The end elevation will be as Fig. : and the side eleva ion ns Fig. 3. To build this arch, the four posts are first planted in the ground and cut off to the required level. The two horizontals are then fixed to the ton of the posts, allowing them to overhang he latter some six inches. The four rafters conic next. Nail them together where they cross at the top ends, and then lay in the top horizontal, and nail each of the rafters to this. The various other horizontal and diagonal picces can next bc fitted and fixed by side nailing.

Another style of arch is shown in Fig. 4, the difierent arrangement of the top of which gives it a more important appearance, especially when covered with climbing roses or creepers. Such an arch as this should le braced at the corners as shown.

There are certain rules of construction whioh should be carried out. The best way to fit a horizontal piece to an upright one is shown in Figs. 5 and 6 , outting a piece out of the underside of the former so that it will fit on to the fat top of the latter ; this will give tirmness and strength, while no depression will be formed in which water can lie. In all cuses where a horizontal piece comes to on upright, the former should be notched to fit on to the latter; but do not make the angle of the notch loo acute, or there will be a risk of splitting the wood in forcing it in. This will also apply to the fitting of the diagonal picces

In fixing the rafters, do not out the horizontal piece to make a flat bed for them, but out away the underside of the rafter slightly, which will answer the purpose better; it is quite as easily done, and makes not the slightest lodging-place for water. The proper method is shown in Fig. 7.
The mitre joint shown in Fig. 8 is a very good one, provided that the timber is nearly all of one size, and that the joint is always on the underside as shown. It has, however, the drawback of weakening the horizontal piece.

Timber and Trellis Arch. A garden arch of stronger build is shown in Fig. 9. It is designed for the best timber. The wood may
other woods will he well painted, a fresh coat being given each year The height must be in proportion to the width, and the width is usually determined by the path which the aroh spans.

Here we assume $a$ width of $: 3 \mathrm{ft}$. $\mathbb{i}$ in. over the posts. The height from the ground to top of the crossbar $(\mathrm{B})$ is 6 ft .6 in ., the total height to apex of arch being 7 ft . If the arch is wider, a little more may bc allowed in height, to give a pleasing proportion. The depth of arch over the posts is shown as 1 ft 9 in . In speating of height, it is, of course, the height above the ground that is referred to. For an arch of this size, the posts have to enter the ground from 18 in to 24 in

Fig 5

Arch. Fir. 1. Simple rustic arcb made of larch wood. Figs. 2 and 3. End and side elevations of the mple arch. Fir. 4. Side view or a larger rustio aroh

From Fig. 9 and the section shown at Fig. 13 it will be seen that reliated posts are used. The upright laths ( E ) are nailed to the top and bottum rails (C), the short horizontal laths (F) lying against the upight ones and resting in the rebate By this method the laths are not nailed over the post, and a better appearance is secured.

The posts (A) arc of $2 \frac{1}{3}$ in. by 2 in material, and a length of from 8 ft . to S ft .6 in . should be allowed. Framing timber $2 \frac{1}{2}$ in by 2 in . may be purchased with a rebate as indicated at Fig. 13 The posts are mortised for the rails (C) to enter, and should have a tenon cut to go right through the top crossbar (B). The lower ends must be well tarred for entering the ground.

The top crossburs ( B ) are 4 in . wide by $1 \frac{1}{2} \mathrm{in}$ thick, lengths of 3 ft . 2 in . being required. The ends should be ohamfered off as indicated, and the bars are mortised for the post tenons, which should pass right through and he wedged. They should also be mortised on the underside for short tenons on the shaped hraces (D).

The aection at Fig. 13 shows a rail (C) 2 in. by $1 \frac{1}{2}$. which will be tenoned (and pinned) to the post so that it is Hush at the outside. The upright laths (Fig. I3) are nailed to the rails from inside.

The rails (C) may be made 2 in . thick, so that they are flush wivh the nosts on both sides. In this case they must be mortised for the upright lathe to enter. The shaped bracce (D) may te straight if preferred, but the shaped ones shown are an improvenient. The shape may be taken from a width of about $4 \frac{1}{2}$ in The thickness may be the same as the posts ( 2 in) or may be reduced to $1 \frac{1}{2}$ in. It is well to provide $n$ short tenon for entering the top crossbar ( $B$ ), and the hraces may be dowelled or simply nailed to the posts.

The laths $E, F$ and $H$ are $1 \neq \mathrm{in}$. wide and may he $f$ in. or $i \mathrm{in}$. thick For the sake of appearance as well as for durability $\frac{g}{\text { g in laths }}$ are recommended. For an arch of this size, three upright laths may be fixed at each side. The horizontal ones may br spaced so as to give square openings, in which case twelve a side will be necessary, but probably the 6 in by 3 in. openings indicated in the illustration will be preferred. For the top of the arch, allow six laths on either side. In regard to the top cross-pieces, the apex of the arch is shown as a very wide angle, this being appropriate to the type of design illustrated
The wood for the top cross-pieces (G) may br $1 \frac{1}{2} \mathrm{in}$. square or 2 in . by $1 \frac{1}{2} \mathrm{in}$. (set 2 in. deep by $1 \frac{1}{2}$ in. wide), and to allow for the overhang and the halved centre joint, lengthe of 2 ft 6 in . should be proviled. The outer ends are chamfered, and the pieces should be cut as ahown to fit close down on the top bars (B). At the centre the pieces are lap-jointed (a Fig. 12) and pinned, care being taken to get all three pairs exactly alike These top pieces are nailed to the crossbars and the laths nailed on above.

All'joints should be painted before putting together, and every care taken otherwise to protect the arch from damage cause by rain. It will be found easier to fit up the tivo sides complete and fix these in the ground before putting on the top. The earth must be rammed down around the tarred post ends so as to a vaid the risk of any sinking. A plumb line can be used to keep the posta vertical

|  | $\left\lvert\, \begin{aligned} & \text { Long } \\ & \text { ri. } \mathrm{In} . \end{aligned}\right.$ | Wide In | $\begin{aligned} & \text { Thick } \\ & \text { in. } \end{aligned}$ |

# Architecture : The Medium-Size House 

## Professional Advice on Choice of Site and Construction of Attractive and Economic Dwellings

The information here is supplied by two well-known experts of wide expericnce in domestic architecture and relates to the scalc plans and sketches in our colour plates, pages 16 itand 17 . For fuller details see numcraus separate entries throughout the Encyclopedia, e.g. Attic: Bungalow; Cesspool: Concrete : House; Roof; Septic Tank; Water Supply; ete.

Before selecting a site, the client will do well to consult his architect as to cost and condi tions of purchase, aspect, houndaries, easements, road charge liability, artificial lighting water supply, drainage, suhsoil, etc. The following points might be borne in mind:-
A good and uninterrupted view will provicle an amount of restfulness and satisfaction which cannot be over-estimated.
The entrance roadway is best on the nortl/ side of the site. The liest rooms can then be placed to the south and therelyy enjoy the advantage of a sunny aspect and the best available distant view
I site having a steep slope or gradient is costly to deal with, because the foundations will require to be much deeper than normal if sulisequent subsidence is to le guarded against. Avoirl a site containing live springs.
Chalk or stone subsoils are the best, but stone rubble, firm gravel and the like are quite good, and less costly to build "pon Rock is the best, but the most expensive to excavate. All the Iatter subsoils will yield good material ht little cost for concrete. patha, etc. Sandy sulisoils, unless free from running water and of very stiff formation, should be avoided.

Clay subsuil is generally considered to be damp, and not good for those suffering from rheumatism, asthina and similar complaints This is, however, frequently exuggerated. If building on clay the foundations should be not less than 3 ft below the surface of the ground to avoid unequal settlement of the suhsoil during very hot weather.

Tipped or made soil should not lue built upon unless it has been standing in its present position for at least 15 years. In any case, it is advisable that the house foundations should rest upon the natural subsoil. This involves additional excavation.

## How the Plans are Worked Out

The site settled, the client conveys to his architect in general terms the accommorlation desired and the a mount of money to be spent. The architect proceeds to scheme his plans in a manner calculated to give the best aitangement of the rooms in relation to each other. He will ulso give consideration to the aspect of the site, and any natural features it may possess. such as distant or near view points of interest, trees, etc. In the planning of the house he will, in addition, have clearly in mind the lay-out of the garden, so as to provirle an appropriate setting for the house.

The two sets of plans in pages 16 and 17 which illustrate this article are typical of the form in which the architect conveys to the buikier what is desired, and upon which, in conjunction with the written specitication, the builder bases his estimate. The first set deals with a medium sized house having four hedrooms, and the second set with a cottage dwelling of the better type, in which the general principles laid down in the first part of the article are worked out in detail.

The ground lloor plan of the medium priced house has first to be considered.

The architect first roughly slietches to scale (generally $\frac{1}{8} \mathrm{in}$. to 1 ft .) the entrince hall and main rooms with their fireplaces, doors, windows, etc., and then fits into their appropriate places the stairs and the various smaller apartments. In the same manner the rooms on the upper floor are dealt with.

These rough aketch plans in turn are auperseded by p!ans worked out to scale in the more
exact and careful manner shown in the illustrations. Here the front entrance porch is recessed to give shelter to visitors when waiting at the front door. The hall is so arranged that easy access is gained to the stairs, living-room, dining-room, and kitchen without an unduly long corridor A small cuphoard for hata and coats is providerl under the stails. If space and cost permit, n basin and w.c. in addition will be of great convenience.

The living-room, mensuring 18 ft . by 12 ft ., is planned with an outlook to the road on the nurth, a laiger window to trap the sun on the S.W side, and a pair of glazed doors to the S.E. giving access to the jergola and garden. The fireplace is shown in recess with a beam over the recess-denoted hy dotted linesthe ceiling of which is lower by 12 in than that of the room. The tire is of the open-hearth type with glazed tiles around the fireplace and hearth, at the side of which a small window has been placed as a peep into the garden. A picture-rail lixed to the wall, low skirting and the sparing use of enriched plaster on the ceiling, a point for electic light (or gas) in the centre of the ceiling or wall bracket, and a plug point or two for a standarll lamp or vacuund cleaner should be provided. The use of pale cream paint for the woodworl, cream distemper for the walls, and hrolien white distemper for the ceiling will produce a satisfying architectural expression.

## The Dining Room and Kitchen

The dining-room, measuring 16 ft by 14 ft ., is entered olf the hall near to the kitchen in order to reduce this distance to a minimum. The fireplace has heen arranged to back against the living-room fireplace, which makes for economy in cost of erection and gives additional heat. Owing to the more nccasional use of this room a gas or electric fire might be substituted for a coal fire. On each side of the fineplace cuphoards are placed for china and glass. On the opposite wall an arched recess is provided for the sideboard. A large window gives an outlook over the garden to the S.E., and in addition small windows are placed in the east and west walls to trap the eaily and late sun. A picture-rail and low skirting, and the use of enriched plaster on the ceiling, an electric or gas litting in the centre of the ceiling, together with paint and distemper as described for the living-room-of perhaps a darker shade appropriate to the use of the room-will make this a comfortable and pleasing room. I plug point for vacuum cleaner is desirable.
The litchen, measuring 12 ft . by 10 ft ., gains access of the enl of the hall, and is lighted on the south side. This room, in conjunction with the scullery, should he very carefully planned with the object of reducing labour as far as possible. The fireplace is situated on the wall at the side of the window (opening to its full height) which will ensure its good lighting.
$t$ cupboard for the storage of oddments and a separate store for dry goods are provided near the dresser.

The dresser is placed on the wall in close touch with the scullery, in which position it will be found to anve a great many ateps. It should be enclosed at the top where the china is kept. The lower portion can be arranged either with drawers or cupboards or left open with what is linown as a potboard. If the
potboard is not litted to the dresser, shelves must be provided for this purpose in a convenient position. The architect, by giving careful consideration to this fitting, will save a great deal of work and labour, and produce an article of great convenience. A good modern type of cabinet might to advantage take the place of the dresser at about $£ 7$ to $£ 12$ extra cost. Rails will also be provided for the dish-covers, etc.

The lloor might be made of tiles for cleantiness, or of wood blocks or ordinary boardswhichever is preferred-for comfort The walls might be linerd with tiles, or if this method is too expensive, painted or distempered. A drying line fixed to-ceiling, raised and lowered with cords attached to pulleys, will be found useful in wet weather

The larder (facing north) is entered ofl the scullerv. Iinple shelf room should he piovided, including, if possible, at least one slate shelf. A ventilating brick should be fixed in the external wall near the lloor and another near the ceiling. 'The window should have perforated wire lixed to a light frame, and le hinged on the inside to keep out the flies. The walls should be tiled or distempered, and the lloor cither tiled or cement finished. If space can be provided for a refrigerator so nuch the better.

## The Scullery and its Fittings

The scullery should be in the closest tonch with the kitclien, and in size about 70 to 80 square ft. It is lighted on the north side by a window about $3 \mathrm{ft}: 3 \mathrm{in}$. uff the floor. The sink should be placed near the window, and lic of glazed stoneware about 8 in . deep, 16 in . wide, and 24 in. to 27 in . long, with a grooved, hardwood draining board at each side if possible. A deal plate-rack will be fixed in a convenient position on the wall over the draining board, and glazed tiles should be fixed to the wall around sink and draining hoards.

The copper, if of the coal-consuming type, should he fixed near a fireplace for the easy connexion of the Hue. If a gas coppior is installed. a flue is not so essential. In the illustration the gas copper is shown under the draining hoard, which is made hinged to lift up for economy of space. The lloor should he of tiles or cement, and, if cost will permit. the walls also should be tiled. As an alter nalive, plaster and painting, or oven distempering diroct to the bricks, is often resorted to. The woodwork for the whole of the kitchen quarters will be painted or stained

Servanta' w.c., coals, and tradea entrance complete the ground tloor. The two former apartments are conveniently planned near the scullery door, and entered off the back entrance luhby, the floors in all cases being of cement, and the walls distempered.
The ground Hoor is 8 ft . 6 in high, and the staircase has 15 steps to the first lloor lancling.

## Arransing the Upper Floor

Coming to the first floor, the stairs are of deal about $: 3$ it. 3 in wide, the treads being 9.2 in or 10 in . wirle. with a "rise" of about of in. If un additional step can he introduced, the rise will be reduced to 7 in
The bedionms are entered of the landing, and are approximately alike in all particulars except size. Care must he exercised in their planning to permit of the convenient placing of the bed, dressing-table, wardrobe, etc Cupboards convenient in size, arrangement. and position should be provided Where practicable, a tireplace should be provided. hut the type of fire to be fixed is not of such importance as in the sitting-rooms.

The Hoors generally will be hoarded. and the walls and ceilings plastered and dis. tempered pale tints. A picture-rail will be provided in each room about 7 ft . off the lloor. and one window at least in each room should
open to its full height. IW here a bedroom is not provided with a fireplace, a ventilating brick should be placed in an external wall.
The bathroom should be placed as nearly as possible over the kitchen, thereby ensuring a ready supply of hot water and economy of service from the range. This room will be fittod with a porcelain enamelled bath fitted with taps of at least $\frac{3}{3}$-in. bore. The lavatory basin will he enamelled fireclay fixed on chromium brackets with chromium taps of easy cleaning pattern, and a towel-rail with hot-water circulation will be provided if cost permits. The walls should preferably be tiled or painted and the foor of deal or an impervious composition material. A ventilating brick should be fixed near the ceiling in an external wall. The w.c. should be separate from the bathronm and fitted with a washdown glazed stoneware pedestal w.c. with enamelled oistern as silent as practicable. A ventilating brick should be fixed in the external wall in addition to the window.
The elevations represent externally the tour sides of the house as they will appear to the spectator looking directly at it when completed. It is in the elevations that the external architectural expression of the house wilf be imparted by the architect, who will so arrange and treat the doors, windows, chim-ney-stacks and roof lines that not only will they be well suited to their various practical uses, but they will be of good proportion and have a proper relation to each other
The section is a form of elovation of the inside of the building. It is assumed to cut through the building in a vertical plane. It shows the depth of foundation, heights of the various rooms, together with certain features of construction and interior design

The perspective sketch shows a general view of the house. The general lines of the garden are here shown, since the setting of the house will have an important bearing upon its effect

## Predaring the Specification

Before reliable competitive estimates can be obtained, the architect must prepare a specification setting out in detailed form cverything needed for the erection and completion of the house

Good stone is the best material for external walls, and sound, well-burnt bricks are next in value. If exposed to weather, bricks known as facing bricks only should be used, but fre quently cheaper bricks are available locally at a much less cost and are therefore resorted to. In such cases the external surfaces are generally covered with cement roughcast in various forms to withstand the weather Where facing bricks are used for external walls it is usual to build them in two thick nesses with a cavity hetween. These are generally known as "hollow" walls

The ground floors may he of ordinary deal Hoor boards, pine blocks, concrete with cement mortar finish or some form of impervious composition material. Ordinary deal floor bonrds on joists are, as a rule, cheaper than any other form, and are less tiring to walk upon Pine blocks laid on cement concrete might be used to advantage on the hall, and are sometines used in the kitchen. Cement concrete lloors finished with cenment mortar are suitable for the floors of scullery, larder, etc. Skirtings might be of the saine material

Air bricks for ventilation should be inserted in all external walls under wood floors. A damp-proof course of asphalt or slates in cement is essential through the full thicknesy of the outer walls about 6 in above the ground.

Ordinary plastering remains the best material for finishing the internal surfaces of walls and ceilings

Deal is the timber most generally used for windows, duors, skirtings, stairs, picture rails, etc. It should be of good quality and
free from sap and loose or décayed knots. Similar timber is most generally used for floor joists, rafters, plates, lintels, ctc., and should be selected with equal care

Deal casements with sash bars cost sornc what less than iron casements. Leaded lights and glazing coat more than sash bars and glazing. Douhle-hung sashes are better for ventilation and are more weather-proof than casements. They are, however, less picturesque and more costly.
Tiles are generally preferred to slates for roofs. They need a stcejer roof and are therefore rather more costly than the commonest Welsh slates ; they look much warmer, however, and time improves their appearance Thick Westmorland or Cornish slates are very bcautiful in appearance, and vary consider ably in shade. Their cost, however, is much in excess of ordinary tiles. Hand-made sandfaced tiles are the best. Machine-made and pressed tiles are not so durable, nor aro they so beautiful. Asbestos alates are cheaper than any other form, but less beantiful Previous to fixing tiles to the roof cover the slope 3 with boarding and felt ; where both make the cost too high the boarding should be retained.

## Internal and External Decorations

With regard to the decorations, where plaster is used in new work, coloured wall. papers should be avoided for a year or two, until the surfaces are thoroughly dry Distemper is the best finish for all new plaster work, and the many shades in which it is now procurable make good decorations easy

Exposed joinery work is usually either painted or stained. The former is generally preferred for lasting effect, but it is more costly. New work if painted should have at least four coats, and all knots in the wood should be treated with a solution known ns knotting, or in due time they will deface the painted work. Enamel is more lasting than oil paint, ns a last coat or two coats
The house illustrated should under ordinary conditions of labour and materials, and providing the site is within fairly ensy reach of a railway station, say, within two miles, be built for about $£ 1,600$ to $£ 1,800$, which allows for good, sound, well-designed and executed work throughout. The cost can be reduced by the employment of inferior materials, but econo mically this is unsound because of the increased cost of subsequent upkeep. Approximatc estimates for a house are generally prepared by means of measuring up its cubical contents This is done as follows: Take the superficial area of the plans measuring to the outside face of the walls, then multiply the result by the height of the building measured from the top of the concrete foundations to half way up the
roof The price per foot cube will depend upon the quality of the materials specified, perhaps Is. 6d to 1s. 9d per cubic ft.

If it is found that the house is likely to cost more than was anticipated, a mere reduction of the size of the rooms will not produce a proportionally lower figure. The whole of the cssentials and more costly work such as stairs. doors, windows, lire-places, bath, and all the other fittings remain in the house precisely as before It will be more reliable, therefore, if the amount of the cubical contents reduced be priced at about one-half the figure taken as the original besis. If it is desired to add to the size of the rooms. the cost then would be increased by the additional cubical contents priced at about one-half the figure taken originally
What a Buildins Contract should Contain
To get the actual cost, the specification should be carefully compiled and invitations extended to several reliable builders to give competitive tenders. Estimates having been received and the builder decided upon, a contract is entered into between the olient and builder. This contract stipulates for the completion of tho house within a prescribed time, in accordance with the drawings and specification, and to the complete satisfaction of the architect. The work is thereupon commenced. During the process of building, the architect issues to the builder certificates for payments on account, in accordance with the contract, which certificates are honoured by his client when received from the builder. The architect, together with his client, selects the fittings required
A well-drawn contract should contain it clause that the builder shall not be entitled th be paid for any extras unless these have been ordered in writing by the architect or by the owner. A careful architect, if he is advising a client on this matter, will always make a stipulation with the builder that the extrey ordered shall be supplied at an inclusive or contract price. If he does not, the builder is entitled to charge a "reasonable" price; and the builder's idea of what is "reasunable" may differ very widely from the idea of the building owner. Out of the neglect to observe this simple precaution of stipulating for a fixed price for extras when they are ordered arise much litigation and consequent cost.
Upon completion of the house the architect certifies to the builder for the balance of the ainount of the contract not previously paid to him, less a bout 5 per cent. of the contract price, which amount is retained on behalf of the client for a period-usually about six monthsduring which time the builder is responsible for all defects arising in his work, and must rectify such defects to the architect's satisfaction beforre the balance is certified as due.

## Architecture: The Small House

## Detailed Description of the Coloured Plans in page 17

The plans and perspective sketch given in the colour plate, page 17, illustrato a small cottage dwelling designed for a family that do not require acconmonlation for a maid. It may be taken as a typical dwellin' for any self-contained family.
The design heing governed by strict ecunumy without undue cramping, every foot of space is thrown into the rooms, instead of being wasted on passages and staircasc. The inain considerations were that both living-room and parlour should look on to the high road, and that the living-room and scullery should also get the morning sun. The bathroom is placed downstairs, and the bath can be filled directly from the copper adjacent, and hot water obtained without the expense of any circulating system
The larder, facing north, opens from the scullery, near the sink and back door, whilat outside, under cover, are the closet and coal
house. The staircase rises between two walls, both for economy and to obviate dirt-collecting balusters, etc Upstairs there are three bedrooms, each with large hanging closet, and on the miniature landing, below the window, is it long cupboard with shelves The walls are 11 in hollow-that is, two $\frac{1}{2}$-brick walls with a cavity betwcen, and whitewashed outside

The problems which meet the designer hero are different from those in a larger building, but certainly no less difficult. He is in most cases bound by the strict limits of economy, and in planning must always bear in mind the need for economy of housework. At the same time many good examples, both new and old, show that charm is the result of care and sliil rather than money.

Is regards the site, this will probably be a compromise between one's own desires and what actually can be obtained. The presence
or otherwise of such services as water, gay electric light, and drainage will greatly affect the price of the land, and, inversely, of the building. The question of sewage disposal will depend upon the nature and extent of the land, prohably by a cesspool or septic system.
Considerinı internal ac commodation and the disposition of rooms. the question of the preparation of food and the elimination of useless walking to and fro will be the main factors. The arrangement shown here-that of a amall parlour, separate from the other rooms, with one large living-roon with range and dresser-is probably the most generally suitable. The adjacent scullery in this case becomes the working centre of the house, and it may be used for cooking if required A small gas. coolier may he provided if gas is available. Sink, Inrder, hot water, fuel, and copper are all concentrated here. If the hath is placed downstairs it must be in a separate room instead of in the scullery, otherwise all the ordinary work of the house must he interrupted every time a hath is taken.

The position of the larder is of importance It should be near the hack door, readily accessible to sink and range, and away from the heat of any flue. A north aspect is best.
The position of hath, sink, w.c.'s, etc., will mean a simple drainage scheme or the contrary. If these, in planning, can he arranged along one side or round one angle of the house, much piping will be saved. If the outside w.c. and fuel store can be approached under cover, especially the latter, it will be appreciated in had weather
In designing hedrooms, not only the position of beds should he considered in relation to doors and windows while in the plan stage but also the possibility of getting a dressing table in a good light before a wrindow.
Much room is often wasted by placing a housn in the middle of the frontage. If it is on a high road, and the light and other services run along this, it nust not be forgotten that the farther it is placed back, to avoid dust and noise, the greater the cost of connexions Externally, the charm of the amall building will be found to consist in simplicity and good proportion: to attempt absolute balance is usually unhappy in result

Brick still remains the most generally satisfactory material for walling. If cost precludes good surface bricks, or the building is in a distriot, such as miany parts of the Midlands, devoid of good brick earth, a good effect may be obtained by slightly raking out the jointe and covering with two coats of limewhite and Russian tallow, or one of the many substitutes now on the market. If the situation is at all exposed, it is advisable to build the walls hollow, that is, two $4 \frac{1}{2}$ in. brick walls with an air space between, bonded together by galvanised ties.

Roofs may be of tiles, slates, straw, or reed thatch. This last makes an excellent and warm roof with a life of 70 years or more. Straw thatch is cheaper and looks neater at first, but has a shorter life and is liable to fire.
As to windows, whether these are of stecl or wood, the main consideration is their proportion and placing. In considering the interior, light and simplicity should be aimed at. Plastering, for instance, if done with a wooden toat and left with a granular face, presents a
delightful suplace without the addition of paper or distemper of any kind In all simple huilding, and especially in the cottage, the three essentials are yond materials, good plan. and good proportion. The first two will give a sound and cconomical building, while the third will add an unconscious charm th the hoine.

ARCHITRAVE. The moulding employed for fixing around doorways, windows, etc., is known to the buikders as the architrave It is made in a variety of patterns, and in sizes 2 in . by $3 \mathrm{in}, 2 \frac{1}{2} \mathrm{in}$. by $\frac{\mathrm{in} ., 3 \mathrm{in} .}{}$ by $1 \mathrm{in} ., 3 \frac{1}{2} \mathrm{in}$. by 1 in . See ()oor.

AREA. Thic area of : house is the suntien space before the basement found in the older class of town houses. The basement is approached from the area, to which a llight of steps leads from the street. It is important to see that the arca steps are in good repair, while a watch should be kept upon the fittings of the gate that guards it See ljasement

ARECA NUT. This is the seed of the betel tree and resembles the nutineg, but is harder and red in colour. The powdered nut is used as a remedy for tapeworms in dogs, the correct amount being estimated as two grains for every pound of the dog's weight. It is not advisalile to give the powder to puppies under six months. Areca nut powder loses its strength on keeping The grantity to be administered to the dog is hest mised into a paste with a little butter. The remedy is not safe for cats. Pron. A-ree'ker or Arry-ker.
ARM : Fractures and Care. Extending from the shoulder to the hand, the arm is described as the upper arm abuve the ellow and the forearm below. The former has one honc, the humerus, and the latter two, the radius and the ulna
Fracture in any of these situations will be marked by pain, perhaps a sense of snapping,
detormity, and loss of power in the limb First-aid treatment consists in pulling on the lower fragment of the bone and the application of padded splints These are upplied on the outer and inner sides of the upper arin for fracture of the humerus and when one or both hones of the forcarm is broken, this is hent. to a right angle at the elbow. in a position midway betwren pronation and supination (that is, with the thumb Iooking upwards), and the splints are applied on the front and back of the limb, reaching from the elbow to beyond the wrist In fractures of the upper arm a lesser arm-sling is used, that is to say, the weight is taken on the wrist only. but for fractures below the elbow a greater arm-sling is put on, thus supporting the whole forearm

## Beauty Cultare for the Arms

For improving the colour, texture and shape a simple night treatment is as follows

Rest one hand, palm downwards, on the edge of the bath and with a loolali or mubber friction glove on the other hand, st roke firmly in one sweep from fingers to shoulder, returning down the arm with a light touch. Repeat the movement several times, apply to under side of arm and then treat the other in the same way. Sponge with warni water and while wet spread over the skin enough toilet almond meal, first nixed to a stilf paste with extract of witch hazel, to cover hands and arins. Leave on till quite dry, then brush off and gently massage the arms with this creain

Coconut oil, castor oil, swect almond oil, cach 2 oz .: hydrous lanolin and white vaseline, each 3 oz Melt together the coconut oil, lanolin, and white vaseline in a jar placed in hot water, stir in the enstor and almond oils, perfume, and allow the mixture to cool.

Should the arms be sore from exposure the cram only can be used without friction or massage for a few nights, smearing on thickly and leaving to soak in, covered liy a pair of old long white gloves, with finger-tops cut off. Ugly elhows can be iniproved by massaging with the palm of the hand each time an emollient is used for arms or face.

A safety razor for the armpit is more sensible than the use of depilatories (hair removers), which sometimes cause irritation See Bandage; Beauty Culture; Dislocation; First Aid; Sprain: Strain

## ARmCHAIRS: HOW TO CHOOSE \& HOW TO MAKE

## Antiques for the Connoisseur and New Chairs for Home and Garden

The first English armchairs were of solid wood and hox-seated. Often the backs were adjustable as tables and the wood oak. Many Tudor chairs were carved, had leather seats and low backs, legs and stretchers turned. Jacobean chairs were inostly high straight. backed, with scrolled carv. ing extending on the arms well beyond the suppiorts Late Stuart ahairs were luxuriously upholstered. and walnut was used in. stead of oak, as the former wood can be more finely carved. Cane

## Armchair by Repplewhite in walout, with shaped back and Prince

 of Wales's feathers splat Fictoria \& Alvert Museumpanelled backs ivere introduced witlin the framework of carved wood. Upholstery was kept within the hack framework, but often carried over the sides and finished with fringe or a hraid. Arms were not padded.

With the Queen Anne period came the fully upholstered winged armchair, needlcworked or tapestry-covered, with cabriole legs and delicate stictchers, loth turned and carved. In the great designer Chippendale's work a French influence is apparent, which continued throughout the Georgian periods of Hepplewhite, Sheraton and Adam, introducing inore refinement, well balanced frames and beautiful decoration and upholstery

Modern chairmakers either hase their work on these classical designs or break away completely with the lounge and divan types fully upholstered, springs being used in seats and hacks and also sometimes in arms

For garden, bungalow and bedroom armchairs, fine examples in canework are also made, while designs are also carried out with metal framework and proofed fabric upholstery.

Many inodern armchairs are upholstered all over. Some have mercly an upholstered seat, or seat and back, or perhaps havc padded arms as well. Others are hare wood. The chen pest variety are of wicker. Another kind.
costing a little more, is of cane wound over mortised in $d$ in. down from the leg tops sо a slender wood framework. After these come as to leave a space of $\frac{1}{2}$ in. each side of the rail the comparatively heavy and substantially built chairs of the cabinetmaker
The wood used may be oak, mahogany, birch, walnut, or beech. In a cheap class of chair, dcal may be employed for parts that aro covered by upholstery. A covering of moroccu leather is the most expensive, but it is durable and retains its colour, while roan leather is inferior Mnet of the imitation leathers are very good they consist of linen or duck coated with a composition. Other coverings are velvet, tapestry, cretonne, and linen. Tapestries may be wool, silk, or mercerised.
Best quality curled horsehair is used for the more expensive chairs, being more springy than any other kind of stuffing. Vegetable fibre resembles hair, and is often empluyed in combination with it Flok on coverings vary in quality. Springs are used in the seat of an armchair, sometimes in the back, and occasionally for the arms, other parts being padded only.

Adjustable Armchairs. The armehair shown in Fig. 1 has a movable scat and back, with separate cushions, and can be made by the amateur woodworker. The four legs should be prepared to $2 \mathrm{in} . \times 2 \mathrm{in}$., cut off to 2 ft . $\frac{1}{\mathrm{i}} \mathrm{in}$., with the lower ends trimmed off to $1 \nmid \mathrm{in}$. square. The rails are 1 ft .11 in . long, with tenons cut off $\ddagger \mathrm{in}$. on one side only and left $1 \frac{1}{2} \mathrm{in}$. long.

Fig. 2 shows details of construction. The top rail is 2 in . wide and 1 in . thick, and

Armchair. Modern easp chair upholstered in
Cordon a Rusoen, Lid.: Dhoto W' Denmis Mose
with it. Flock of various kinds and qualities is the tenon is Hlush with used, alone or with wood fibre or wood wool, mortise in the arin-pieces should be set bhe or a dried seaweed called Alva. Canvas in. to bring the back rail flush with the ends. sill tateta

Apmehair. Carved walnut ohair said to have belonged to Rell Gwyane. Charles II period in. to bring the back rail flush with the ends. Two rails, each $2 \mathrm{in}. \times 1 \mathrm{in}$. and 2 ft . long, should be tenoned into the scat rails and run from front to back 1 in . away from the legs. These lengths provide runners for the seat frame, the tenons being $1 \frac{\mathrm{in} .}{} \times \mathrm{i} \mathrm{in}$. The two sicle frames should now be glued up with very hot and thin glue.
The seat frame is composed of two sides, $1 \mathrm{ft} .10 \mathrm{in} . \times 2 \frac{1}{2} \mathrm{in} . \times$ 1 in., two ends, 1 ft . 8 in. $\times 2$ in $\times 1$ in., and four rails, 1 ft . $8 \mathrm{in} . \times 1 \frac{1}{2} \mathrm{in} . \times 1 \mathrm{in}$. The ends should be tenoned into the sides and the rails into the ends, all tenons being ${ }^{3}$ in. thick, and full width, with the ex. ception of the front and back, which should be $1 \frac{1}{b} \mathrm{in}$. wide. For a distance of 9 in . the front of the scat frame should be cut back $\frac{1}{1}$ in., to allow of it sliding between the front legs The back is composed of two sides, 2 ft .6 in . $\times 2$ in. $\times 1$ in., and six rails each $1 \mathrm{ft} .6 \mathrm{in} . X$ $1 \frac{1}{2}$ in. $\times 1$ in. with the exception of the top and botton rails, which are 2 in . wide. The seat and back frames should be hinged and fit easily in position.

In some adjustable chaira the hinged back frame rests against a hardwood or metal rod which lies in slots cut in the arms, as shown in Fig. 3. The back.
ward slope can be varied by changing the rod from one pair of slots to an. other. The cross rail which ties the arms to. gether forms
 a secondary support for the back frame, should the rod become dislodged.

The arms for a chair of this kind are shown in plan in the illustration, which also clearly indicates the shape and arrangement of the slots. Four slots are cut in each arm, 1 in. widc at the top and 8 in high by in deep, cut on the slope in the manner shown. The slots are I in. a part.

The cushions are both 1 ft .8 in . wide and 3 in . thick, one being 2 ft .3 in . and the other 1 ft .10 in . long. Two bags should be made of hessian to these dimensions, and filled with either horsehair, fibre or flock, and sewn at intervals of 4 in . all over to keep the filling in position.

The covers should be made separately and fitted on, but they may bo buttoned, especially if made of imitation leather or tapestry. A better decorative effect is given if cither brown velvetecn or hair seating is usod for the cushions, without buttoning. and the edges piped. Closely woven tweeds in tones of beige, piped with imitation brown leather, or heavy corded fabrics in geometrical patterns are suitable to the lines of this framework The seat and back may be upholstered direct, and in this case the inner rails of both frames should be omitted, and webbing used instead.

Garden Armchair. Fig. 4 shows a comfortable garden armchair. It should, if possible, be carried out in oak, but any of the harder whitewoods may be sub. stituted. The chair is as suitable for indoor use as for the garden, and, fitted with loose cushions, it will make a comfortable seat for the sitting.room or library. A feature of the design is that the legs are not square posts, but are of $2 \mathrm{in} . \times 1 \neq \mathrm{in}$. section.
The construction is simple and straightforward, and is shown in detail in Fig. 5 . The legs may be tenoned right

Fig. 2
Armchair. Fig. 1. Adjustable armchair with movablo soat and back Fig. \&. Working drawinga giving measurements and dotails of joints employed

The seat rails and back rails arc tenoned in the usual way, while the strut rail, the side slata, and the back slats are rebated in. The seat lathe are nailed on, and the side slats may be nailed or screwed to the side seat rails. The arm is tenoned to the back leg, and is secured to the front leg by means of a stubtenon.

The wood required is shown in inches in the above list. The lengths quoted allow for joints and paring, but all the thicknessey given are strictly net.
ARMORIAL BEARINGS. An Englishman may legnlly assume any armorial hearings he pleases. Thus a chimney sweep from Whitechapel can, if he pleases, assume the arms of the Stanleys, tho Grosvenors, or the Howards If, however, he has them painted on his carriage, he pays two guineas a year tax, and if he displays them in any other position, e.g. on his notepaper, he must pay onc guinea a year. If a man is left an eatate on condition that he assumes the name and arms of Blank, his best plan is to apply for a royal grant of the name and arms, whioh will probably be issued, but he will pay fivo. He may get the same royal licence on a voluntary application for $£ 10$. If he covets armorial bearings, and applies for the water garden and is a good plant to the crown or the College of Heralds for garden, but the water should a grant of a coat of arms, it will also cost him $£ 10$ The penalty for displaying arms on a carriage or elsewhere without paying the tax is a fine of $£ 20$.
ARNEBIA. The best known species of arnebia is echioides, a hardy perennial from Armenia. It is about 12 in . high, and produces yellow Howers in May. Each blossom has five dark spots, fabled to be the marks of the fingers of Mahomet, bence its popular name of the Prophet Hower. It is a ouriosity for the rock garden (q.v.) Pron. Ar-nco'-bi-a.
ARNICA. The flowers and root of Arnica montana are employed in making preparations for bruises and sprains. Arnica flowers are to he preferred to th:e root for the purpose.
Tincture of arnica is made by soaking an ounce of arnica flowers in half a pint of weak alcohol or brandy for ten days, then pouring off the liquid. Squeeze the Howers in muslin, so ns not to waste any of the tincture.
To make a lotion for sprains and bruises mix two tablespoonfuls of this tincture with enough water to make one pint of lotion.
Arnica opodeldoc is a bandy form for rubbing purposes. It is made by mixing
Soup

Tincture of arnica
Strong alcoliol
10 oz
Carefully heat together until dissolved. It seta to a jelly when cold. To ure it rub a small quantity in until the paste disappears.
Aralica should not be used on braken skin, as a disagreeable rash may be produced
ARRAS. Named after the French town, the original Arras was handworked tapestry
 of the room, leaving Corntlour.

ARROWROOT.
A pure starch powder, obtsined from the maranta plant, grown in the Weat Indies and Bermuda. English arrowroot is prepared from potatoes. It is $\boldsymbol{\pi}$ valuable invalid food, being easily digested in cases of gastrio irritation. 'lo prepare, blend a dessert. spoonful of the powder with two tablespoonfuls of milk or water, and pour over it half a pint of hoiling milk or water. Stir briskly, then add a teaspoonful of sugar. If ordered, a teaspoonful of hung before the wall hrandy or cream can also be added See

ARROWROOT BISCUITS. Sieve $\frac{1}{\mathrm{lb}}$. of arrowroot together with $\downarrow \mathrm{lb}$. of flour and a dcsecrtspoonful of sugar into a basin and rub into them $\ddagger \mathrm{lb}$. of butter until the misture is free from lumps. The whole should then be formed into a stiff paste with the nid of a beaten egg, and, if necessary, a little milk. Knend the paste well, and when smooth roll out very thinly on a floured board. Cut into shapas and bake until golden brown in colour.

ARROWROOT PUDDING. Mix two dessertspoonfuls of arrowroot with a little cold milk, hoiling what remains from a pint of milk, and pouring it over the mixture. If the latter does not thicken immediately the arrowroot is not aufficiently cooked, and the whole necds to be hoiled up in the pan. After adding a dessertspoonful of sugar, leave the mixture to cool ; then add the yolks of two eggs and lastly beat
 age whites of froth, folding them lightiy into the mix. ture. Turn the pudding into a thickly buttered dish, and bake it in a fairly loot oven for a little more than half an hour.
ARSENIC. In medicine, arsenio is hest known in the form of the oxide or white arsenic : it is used in anaemia, and also as a general tonic. A favourite preparation is Fowler's Solution or Liquor Arsenicalis Arsenic is very useful in the debility which results from malaria. It is found in rat poisons and in weed-killer.
Arsenic Poisoning. In cases where an overdose of arsenic has resulted in acute arsenical poisoning the chief symptoms are vomiting, continuous diarrhoea, abdominal pain, and great weakness. Give the patient emetica of warm mustard and water (a tablespoonful of mustard to half a pint of water). The antidotes for arsenic are dialysed iron, tablespoonful doses in water every tén minutes, or magnesia given freely in water. Iater give the whites of two eggs beaten up in a glass of equal parts of milk and water. The patient should be kept warm in blankets,
with a hot water-bottle at the feet. Nothing but milk should be allowed for the first week after recovery

The earliest symptoms in chronic poisoning may be cold, running eycs, sneezing and cough; or there may be loss of appetite, nausea, romiting and diarrhoea. Itching of the eyes is a usual sign when a person is taking arsenic that the dose should be reduced More serious effects are observed-inflammation of nerves leading to weakness and unstendiness of the gait, arop-foot and drop. wrist, and increased sensitiveness of the skin.

The only treatment of any avail is to remove the patient from all possible contact with arsenic, and to build up his general health by some tonic, such as Euston's syrup, $\frac{1}{2}$ to 1 teaspoonful in a little water three times a day after meals, while nature expels the absorbed arsenic from the syatem. If the digestion has been greatly upset a very light diet, consisting chiefly of milk, milk puddings, custards, etc., is necessary Where there is the slightest suspicion of ohronic poisoning the advice of a physician must be songht. See Antidote; Poisoning.
ARSENICAI SOAP. This is a paste employed by taxidermists for preserving the skins of hirds and animals that are stuffed and mounted. Its use depends upon the fact that arsenic is a very powerful antiseptic and preservative, but its poisonous qualities render it necessary to use it with great care The paste or soap is made as follows:

It should be mixed in a inortar.
The charcoal gives the paste a grey colour that prevents it being inistaken for $a$ harmless preparation. The soap is used by spreading it on the inner side of the bird or animal skin it on the imner
See Taxidermy

ARSON. This word is used in Finglish law for the wilful burning of a house helonging to someone else, or of a place of worship, public building, or building owned by a public company. Arson in a felony. See Fire ; Insurance

ARTHRITIS. Term used by medical men for inflarnmation of a joint or joints. See Inflammation; Joints: Rheumatoid Arthritis.

ARTICHOKE : To Grow and Cook. Plants belonging to threc different genera are grown under the name of artichoke in Great Britain, namely, the true or Glove Artiohoke, Cynara scolymus; the Jerusalem or tuberous Artichoke, Helianthus tuberosus; and the Chinese Artichoke, Stachys tuberifera.

Jerusalem Artichoke. The plant is a hardy perennial, growing from 8 to 12 ft . high

Large patch of jerasalem artichokes, growing to well over 6 ft. high, showing their close resemblance in foliage and growth to giant sunfowers
in a season, the stiff green stem, without side branches, bearing roundish rough leares on short stalks The rootstock is tuberous. In the common species, the tubers are pink, very numerous, and varinble alike in size and shape. Each plant will produce from half a peck to a bushel of tuhers per annum. The white-tuber variety is superior in llavour to the other kinds.

Planting should be done in early spring and the sets covered 4 in deep. They may be planted about 18 in apart, rather more in rich soil A light hoeing up of the soil over the tubers once or twice during the summer is bencficial. In September the plants ceasc extension and the leaves lose colour and droop The stems inay be cut down in October. From that time the tubers may be taken up at intervals for use as required The plant enjoys a liberal dressing of decayed manure In fertile soil the smallest of setw or secdtubers will produce a strong plant and a heavy crop.

Globe Artichoke. This is a perennial and the young flower-head forms, with the fleshy receptacle, a close ball, globular in shape ; it is this which is the edible part. Scedsmen usually list at leart two varieties-the Green Glolve and the Purple Globe : the seed may be sown out of duors in spring in a drill and covered with an inch or so of soil. The scedlings should be thinned and planted out about 4 ft . apart when strong.

Thuse who have established plants can get strong plants from suckers In each case

Artichoke. Tubera of derualem or white artichokes ready for cooking
Photo from Sulton if Sons
three or four shoots should be left on the old plant. Those removed should be set 3 ft . apart, with 4 ft . between the rows, and bedded firmly in with moist soil.

The stage for gathering the globe is when the scales begin to spread and before the flowers have tinie to open: a portion of stens should be taken with each. When all have been gathered the stems may he cut hard back, together with the decayed leaves, and the soil round the plants mulched with fine ashes, seawecd, or stable litter In colld districts the soil ought to be ridged up over the stools and litter thrown on. In spring a dressing of manure may be given. After the fourth year the plants, having hecome exhausted, should be replaced by fresh stock.
The Chinese artichoke is an edible. rooted species of Stachys, growing alout a foot high The tuber ranges from 1 in . to about 3 in. in lenght and may aver. age an inch thick at the centre. The fiavour rescmbles that of the Jerusalem articholie.

Medium sized tubers are selected in spring and planted 3 in . deep and a toot apart in rows 18 in . asunder. Any well-drained soil will do, but it should be friable. Fresh manure is not desirable. In autumn the tuhers should be lifted and stored in dry sand.
How to Cook When Jerusalem artichokes arc peeled place them immediately in a bowl of water to which a little vinegar has heen

Artichoke. Basket of young fower-heads of the globe artichoke
Plioto from Sutton t Sons
added or they are apt to become discoloured. Have ready a pan of boiling salted water, add a little vinegar, put in the artichokes and boil gently for about twenty minutes. They break casily, hence the water must not bil too fast. When the artichokes are tender, drain thent, place in a vegelable dish and send to table well covered with white sauce
Jerusalen artichokes may be mashed if preferred. When builed, rub them through a fine siere, Havour with butter, pepper and salt, add a little cream and heat up in the oven.

To make artichokes and checse, boil six artichokes till tender, then mash then with a fork, and add pepper, salt, lemon juice, and some cayenne pepper. Place a layer of this in a small pie-dish, then a little grated cheese, and then a little more of the artichoke mixture. Scatter hreadcrumbs and cheese over it, bakc for 10 min . in a quiok oven and serve very hot. This is sufficient for four persons.
Globe artichokes are served as a separate course, usually after meat, with either a sauce made of equal parts of oiled butter and lemon juice or sauce Hollandaise (q.v.) Only the lower portions of the leaves and centre of globe artichokes are edible.

Before boiling take off coarse outer leaves and cut away the stalk. Wash thoroughly to remove any grit or insects. Place the arti chokes in boiling salted water, head downwards, and boil quickly without putting on the lid of the pan for about half an hour Drain in a colander and arrange in a diah, tops uppermost. The sauce is sent to table in " sauce-boat and not poured over the vegetable as with Jerusalem artichokes.
ARTICHOKE SOUP. Also known as Palestine soup, this requires 2 lb . artichokes, 1 small turnip, 1 onion, $\frac{1}{2}$ pint milk, 2 pints white stock ( 2 h pints milk if a meatless soup is preferred), 1 small head of ce!cry, t oz Hour, 1 oz margarine. Pare and wash the vegetables, cut up and boil gently in the atock till tender. Melt the margarine in a separate anucepan, stir in the flour and add milk, stirring till the thickening is smooth. Rub the vegetables through a sieve, return to the stock, add it to the thickening, seasun to taste and hoil up Serve very hot with dice of fried brearl Sufficient for five persons.

Artifcial Fertilisers. This term is used for manures manufactured by the aid of chernicals. See Fertiliser

## Artificial Flowers: How Amateurs Can Make Them

Using Materials of Many Kinds for Dress and the Decoration of the Home

Related information will be found under the particular materials used, e.f. Paper;
Raffia; Shells; Silk, ete.
Made of shells, fish scales, glass, knitting the tup of the petal and blend with a little yains, rnfia, ecraps of sill;, cotton, velvet or mauve from the base, where afterwards a small folt, of crépe puper and of lentlier, artificial llowers of all kinda can lie selected for dress, lancywork, table and Christmas decoration.
Nhells and glase lend themselves to original and striking designs for conventional vase sprays and for Horal treas of the weeping willow type on solid glass blocks and fanny stands. Glass flowers are brittle for personal wear, though ured in small posies, and shell flowers are rather stiff Fish scales are light and adaptable for this purpose For shell and glass flowers. leaves of the same material have a

better elfect than the ordinary artilicial fuliage hud all the petals would be pierced on the thin which is often used Mother of pearl shells, top edge A specinl calyx is obtninable for a which do not require tinting, are sold from ls. rose and double-ended yellow stamens a dozen (prices vary according to required size), miscellaneous shells from is a pound, and fish scales ahout ls an ounce. French enamel varnishes are suitable for colouring all shella and ecales, and cost 9d a bottle. These can be intermixed to obtain other shades and removed or lightened in colour by use of methylated spirit. Leaves and petals are supplicd in crystal or in coloured glass for a few shillings a hundred Where a pearly sheen is liked on glass Howers, a mother of peail solution is obtainable, to coat the petals.

Besides these materials, flower centres, varieties of stamens and folinge, stems, wire, brown or green gutta percha, various liinds of calyx and tuols for piercing shells can be obtained or ordered at art shops and art depart. ments in stores Small camel-hair brushes: are best for tinting: clean them with methy. Iated spirit after using the enamel varnish

## Anemones Made From Shells

Anemones are effectively made in shells and are easier to taclile than roses, water lilies, canellias or apple hlossom, though all these flowers are suitable for this work. Select fivo shells the required size of anemone petals. pierce, from inside, the thickest part of the shell where the linge is, with two holes, a quarter of an inch apart, thread with wire, working from inside shell. Wire the five thus, and then colour For a red anemone, a brushful of crimson enamel varnish would start from
dab of black should be used, as seen in the natural flower. The painted shells will dry in about five minutes. Both sides nust be coloured and various tints will be suggested by the real Howers for sufficient blooms to make an effective vaseful. Have at hand a littla cotton wool and dab off colour if wrongly a pplied.

Talie an anemone centre, Rurround witl stamens (ready made), wired together and spaced evenly round the centre, and then wire to a piece of galvanised wire for the stem Next wire the colnured petals to this stem by the wires already fixed to them Green sealing wax may be used to hide the mass of wires bencath tho petala After a short piece of rubber tubing has been pushed up over the wire stem a special readymade anemone stem is used to whioh short leaves, as found on the real flower, are attached This should be gummed on to complete thic flower.
By piercing the shells at the thin top cdge incurving petals are obtained. Thus, when making a rose or a water lily, the central petal shells are pierced at the thin edge and the outer or open petala are pierced, as in the anemone described, at the hinge side For a

Natural twigs are often used for almond or apple hlossom, gutta percha strips in a matching colour concealing the wiring of the bloom

to the twig. For large leaves, flat sun shells are obtainable from 3 to 4 in in diameter, and can be cut with special cutters to the desired shape and coloured after piercing.

With large shell Howers, rattling of petals caused by too loose wiring must be carefully avoided. Glass flowers are made in the same manner as shell, hut gold, silver or silk-covered wire is used For heavy flowers or tree elfects the stem wires must be extra stout.

Fish scales are good for making small Howers when an enamelled effect is liked for millinery purposes One side of the scale has a satin finish and should be used for the unper sidos of petals. These can be curled round on a knitting needle if desired, cut to shape with scissors and holes pierced for wiring with a stout needle

## Fish Scales Used for Violets

To make violets, select five fish scales, four about the size of a sixpence and one of a three-penny-piece: cut five lengths of wire, 7 in long, wire up the scales, and then colour both sides with violet enamel varnish. Talie a violet centre and arrange the coloured petals, two at the top, one at cach side and the small one at the bottom, overlapping. Twist the wires of the petals together firmly to make the stem foundation. Bind a narrow strip of green gutta percha round this and finish. Ordinary artificial violet leaves may be used, or leaves cut out of green suede, to complete a bunch of a dozen violets tied up with raffia

Wool or ohenille flowers for attaching to knitted work or for posies are usually very simple, effect being obtained by the use of bright colours. A wool needle may be threaded with the yam, a loose knot marle and loops worked with this, overlapping each other all round About $n$ dozen loops of wool should suffice. The centro is formed either with a bought flower centre with a wired stem, or by attaching the flower to the article to be trinmmed with French knots of wool in a contrasting shade Leaves are easily erocheted to

Artifcial Flowers. Left. glass camellias with glass leaves. Right, conventional flowers, buds and leaves made in glass and stack in sand. Above is a flower greatly enlarged to show the details of construction
shape and wired if necessary, or cut-out lelt leaves may be used for a posy.

Raffia llowers usually start with a eanvas foundation, from which the loops of raffia may he worked Daisy-like Howers (Fig. 1) can be

Artifcial Flowers. Narclasi made from shells, the leaves being of cardboard covered with green raffa
The rose is also in shell
made on a circle of canvas rather larger than a penny with an inner circle marked the size of a farthing. To start, thread a raffia necdle with the selected colour and darn into the canvas to a void a knot (Fig. 2); from the centre circle edge make a loop 1 in . in length, taking the needle back close to the starting point (Fig. 3). Pass the needle under the centre circle, bringing it out opposite loop iust made. Take needle back again, leaving a similar loop making it as olose as possible to the first one, and continue all round till the circle of petals is complete.
The centre may be of looped yellow wool or small wooden beads sewn on the canvas. The back is finished off by cutting away the canvas near to where the petals start and covering with green raffia in loops until the remaining canvas is hidden Through the hack, wire is passed to form the stalk about 8 in . long Use double wire and wind round with brown raflia. To keep the raffia in place, pass it through the Hower, when it may be bound with a little brown cotton. Wire in an occasional loop of green raffia on the way duwn the stalk, as shown in Fig. 3

## Flowers of Ribbon, Silk and Paper

Narrow ribhon flowers can be made in the same way. Circles of felt, skiver or suède, with slit edges, in diminishing sizes, form conventional asters with brad llower centres and wired atalks covered with gutta percha or raflia Noie ambitious leather flowers require a know ledge of tooling and use of leather implements (see I eather Work).

Simple shapes for cutting out Howers in silk, cotton or crếpe paper are shown in Fig. 4. Ready-made stems, centres, stamens and leaves can be used if an attempt at natural flowere is desined. After cutting out, if the petals are to be coloured, it is a good plan to pin material to white blotting paper, wet slightly with clean water on a sinall sponge, and tint with water colour to which add a little gum. Aniline dyes are quite useful for this purpose.

In using crêpe paper for decorative flowers suitable for Christmas, cut the paper with the grain, use as little adhesive as possible, and allow pasted petals, etc., to dry before using then. Fold the paper into several thick. neasers so that several petals or leaves may be
cut ont at onc time, draw or trace design oll top fold and use a sharp pair of cissors.

To make a daffodil or a bell flower, turn down the end of a wire and cover with the paper to make a small head on to which to fix six stamens, each made from a square inch of paper, twisted tightly between the fingers to form a thread. Cut the bell or cup three inches square and join with paste. Turn the top edge slightly over, stretching the paper a little. Put over the centre of the llower and bind with fine wire. For the daffodil cut six petals and also bind these with a sheath of brown crèpe, pointed at one end, at the hase. The bell Hower is finished underneath by a calyx cut from a circle of green paper into points. Stalks are bound with crêpe.
Many variations on these schemes will soon suggest themselves. Glass beads may be used for hlossoms with shell or glass leaves, and effective llowers can be made of American cloth with wool or bead centres.

## ARTIFICIAL LIMBS: Their Care.

 The sockets of artificial limbs (those portions which enclose the stumps or remains of the lost limbs) are made of wood, composition such as celluloid and certalmid, etc., or of metal such as alu. minium alloy. They should fit the stump accurately.For the sake of cleanliness the socket should be sponged out with warm water and then carefully dried with a cloth, at the end of each day's wear. In the case of a wooden socket, if the varnish has been rubbed off, it should be renewed; if the surface of the wood is rough or uneven it must be smoothed down with fine glasspaper before the varnish is applied.
Mctal jointa, except those which have leather bushes, should be kept lubricated with oil. If from wear they become too louse so ns to rattle, or allow improper movement, they will nead repair or renewal by the limb maker. The joints which are usually bushed leaving his hands flat against the patient's with leather are the knee and the ankle. The side. The tirst part of the movement should Ieather which is used for this purpose is occupy the time necessary to count slowly thoroughly impregnated with grease, and needs $1,2,3$, and the second, 1, 2. Care nust he no additional luhricant. When a hushed exercised that the handa are actually on the joint becomes too loose it must be Tehushed by the maker.
In some of the older pattern legs the anklejoint is of wood of the mortise and tenon type, connected by means of a leather-bushed bolt. When these joints become worn so as to allow of undesirable side play, they must be rebushed and packed. These joints are usually controlled by tendons and steel spiral apprings.
In the standard types of limbs generally supplied by the Ministry of Pensions, the ankle

Artifcial Flowers. Fig. 1. Daisy made in raffla. Fig. 2. How to start making the flower. Fig. 3. How the petals are formed. Fig. 4. Simple stapes for cutting out fowers in silk, cotton or crêne paper
joint is fitted with ruhber bulfers, which are compressed by tightening two nuts in tha sole of the foot. If adjustment of these nuts fails to make the ankle movement satisfactory, it is probable that new rubber buffers are required. The foot is easily detached when the nuts and locking plate have been removed Certain limbs are fitted with rubber feet. All others have a separate toe-piece, hinged on its lower edge and having ateel or rubber compression springs whioh maintain extension

As a rule, wearers of artificial limbs should not attempt to take them to pieces themselves, as apecial tools are needed and special experience to reassemble the parts. Oil gradually disintegrates rubber, and carc must be talien to prevent ite coming in contact with the buffers

ARTIFICIAL RESPIRATION. 'I'his is a method of reatoring breathing in cases of drowning, gas-poisoning, etc., by alternately expanding and contracting the patient's chest, so that air is draun into and expelled from the lungs. The method usually enployed is Prof. Schiffer's. The subject should lee placed face downward on the ground, with the arms stretched out in front, and the face turned to one side. The operator kneels astride or sometimes beside the prone body, facing the head, his knees being ahout the level of the unconscious man's hips. He then places his hands, one on each side of the patient, over the lowest ribs, with the thumbs parallel and nearly touohing. Leaning forward and downward, he presses the base of the ribs upwards and inwards

In this movement tho arms should be kept quite straight. The result is that the air is expelled, and any water in the lung tubes is pushed out through the nose and mouth. At the end of the movement the rescuer swings back into

Artifcial Respiration. In Schaler's
method the ribs are alternately commethod the ribs are alternately compressed (2) from behind and released pressed (2) from behind and released
(1), this last causing chest expansion

 ribs, 凤a seen in the illustrations, and not down on thic loins.

The whole double movement, consisting of the pressure forward and the withdrawal of pressure, should take alnout five seconds. and should be continued rhythmically until the patient shows signs of recovering consciousness.

When the patient legins to breathe by himself, artificial respiration may be discontinued and the operator should now turn

his whole attention to stimulating the circulation by various means

As soon as possible, in a drowning case, the patient's wet garments should be removed and lie should be wrapped in warm llannel blankets, and carefully protected hot-wate bottles or bricks warmed in the fire should be placed in the armpits and against the soles of the feet. The arms and legs should bus vigorously rubbed, always in the direction towards the body, to force the stagnant blood back to the heart.

After the patient is sufficiently recovered to swallow, a little hot water may be given, or small amounts of heart stimulants, such as a teaspoonful of brandy in warm water ot a small cupful of hot, strong cotfee or tea, or a teaspoonful of ammatic spirits of ammonia in a small wincglass of water.

ARTIFICIAL SILK. Artificial silks are made by different processes, and there are various qualities. They are made by forming artificially a gelatinous material, hardened in contact with air or in passing through a trough of hardening lluid. This jelly-like compound is obtained by dissolving raw colton or wood pulp For artificial silk it is made into fine threads by being forced through minute holes, and endless lengths of filament are thus secured. Usually about a dozen of these are twisted lightly together to compose $\Omega$ single thread for machinc-knitting or weaving. In the ordinary thick 2-ply cord used for knitting there are generally about 24 of such threads and nearly 300 origınal filaments.

Short-fibred artificial silk can be spun like wool or cotton, and certain mixed artificial silk and wool kuitting varns are mado by hending the two materialis together, when the bright silk speckles the yarn.
A good point in artificial silk for lurnishing fabrics is its brightness of surface, and this varies with the amount of twisting received in making the ultimate filaments into yarn. 'light twists wear better than slack ones, but they make the thread wiry and less liexible. To reduce the brilliance and obtain a crêpe-de-Chine lustre, several fancy-twisted knitting cords are made.
Reckoned per 4 oz. hank, artificial silk is cheaper than real silk, but it is not actually so much cheaper to use because it is heavier than natural silk, of which fewer hanks are required to knit the article. Artificial silk should not be knitted or crocheted too tightly or with ton fine a necdle.

Artificial silk can be distinguished from natural by touching an end of thread with a match fame. The artificial will burn frcely with a white flame, leaving little ash behind. Natural silk is nenrly non-inflaminable. The Hame does not run and the ash forms itself into a knob and at the same time a slightly unpleasant smell is emitted

Care must be exercised in washing. Tepid water should be used and a pure soap. On no account should the article be mangled. After rinsing, the excess of water may be gently squeezed out inside a towel.

Artilicial sills made by different processes behave differently in the dye bath, and an experiment should first be made by dyeing a sample of the material.
ARTIFICLAL SKIN. Collodion, or a preparation like it, is used to paint over fresh, clean cuts or hacks to protect them from irritation or infection. These preparations should not be used where the wound is dirty or discharging, as harm is done if the discharges are jent up See Collodion.

## ARTIFICIAL TEETH: Their Care.

 Kinowledge with regard to the care of sets of artificial tecth or dentures is necessary on account of the different nature of the material coinposing the teeth, and the base or plateto which they are attached. The artificial tceth or porcelain part should not be rubbed by anything in the nature of a tooth powder, ntherwise the translucency and polish of the enamel may be lost or injurd. When the surfaces of the tecth beconie discoloured, they should be well rubhed with the forefinger covered with white muslin moistened with soap and water.

The plate to which the teeth are attached may best be cleaned with $\pi$ amall tooth. biush and whiting, special attention being given to hollows and crevices. Time and trouble are avoided by placing the denture at night in water to which a few drops of antiseptic have bcen added. By moining matter which is apt to adhere tenaciously to artificial platea is casily removed.

The difficulty of koeping gold plates and clasps bright is greatly overcome by putting them into a chlorinated antiseptic. Special care is necessary in the cleansing of bands or clasps and the parts in direct contact with the natural teeth.
Artificial teeth should almost invariably be taken out of the mouth overnight. ParticuInrly is this necessary when anme natural tenth are still present. In addition to the cleaning of the denture in the morning, it should be rinsed after every meal. Artificial teeth are fragile and easily broken.

Arum Lily which has produced a considerable number of blooms although grown in a small pot
ARUM LILY. In spite of its naıne this beautiful plant, with its rich, green leaves and pure white llower spathe, does not belong to the genus Arum, but to Richardia, and as Richardia Africana it is also known as the Lily of the Nile. It is grown in a fertile compost of loam and a third of decayed manure (preferably cow manure) with sand. Splendid plants can be grown in $6-i n$. pots with abundant watering and liberal feeding with liquid manure.

In summer the plants are put out into the open garden in well-inanured soil, and given occasional soakings of water in dry weather. They are potted up in September, and kept in a cool greenhouse in winter. Little Gem is a favourite variety, of which Godfrey's arum lily is a special form. There are also two yellow- Howered species, Elliottiant and Pentlandii which are best grown in pots through out the year Pron. Air'-um.
ASBESTOS. Being a fibrous material which is non-combustible, asbestos has nany uses for fire protective purposes. It has a low thermal conductivity, and is thus an excellent heat insulating material. As an electric insulating material it has been extensively used in electric heating devices of
various typen It is made up in a number of different forms, such as cord, felt, mill-board, and in sheets suitable for building nurposes. Asbestos mill-board can be purchased in sheets from about $\begin{aligned} & \text { fin. thickness upwards. }\end{aligned}$ The thinner boards can readily be cut to slape with strung scissors or a sharp linife, and used, for example, on cooking stoves to protect the utensils. When such boards are covered with linen or some similar material they make excellent table miats. Asbestos can alsa be used to make joints in hot waterpipes, or on exhaust pipes of gas engines. Asbestos cord bound around the handlea of pots and pans or on the knob of an oven door prevents burnt or blistered fingers
Moulded asbestos is used in the form of briquettes, balls, etc., for gas heating stoves, the most efficient types being those with ample air spaces, as they radiate the heat better than the more solid patterns

For building purposes asliestos is genera'ly combincd with other matcrials, such as magnesin or Portland cement, and is treated in various ways to render it waterproof For amatcur usc sheets of such a material are very effective. There are scveral proprietary brands which can be obtained from most builders' merchants in convenient sizes It has to be cut to the desired shape and nailed in place. The joints between the shects are cuvered with strips of wood nailed to the "studding" or framework. The niaterial can also be obtained in the form of tiles.

ASH. Tough, flexible, and able to resist shock without breaking, ash is a wond that is extensively used in many trades. It is light brown or nearly white in colour, with rather coarse grain, and the several varieties show certain differences in colour and apparance. Fqr the handles of garden implements, hommers, hatchets, and other tools, ash is peculiarly well suited. It is used also for barrows, sticks and umbrellas, tennis rackets, lincliey sticks, oars, and in gymnasia. It is also employed for furniture, and a thin veneer of ash does well on other wood Sce Wood.

Ashbin. See Dustbin.
ASHES. The ashes from household grates may be utilised for various purposes. The first care is to see that all fucl and kitchen waste is so completely burnt that the ashes are thoroughly dry and powdery. Ashes should be well sifted and the coarser pieces burnt. The cinders are useful for the garden path or the hen-run. The fine, dry powdered ashes that pass through the sieve can be niade up into a paste with water and used for cleaning the outsides of eaucepans Sec Dustbin: Refuse.

Ash Tray made of thin metal sheat. A, Anished tray. B, punching the pattern. C. bending the edges
ASH TRAY. A simple form of tray is illustrated, which may he made without any of the special tools of the metal or repousse.
worker. A piece of thin brass or copper sheet of No. 18 standard wire gauge, measuring 5 in square, is required, both sides being birst cleaned with fine emery cloth and oil, nnd the design drawn on with a lead pencil. The pencil lines inay be lined in with a sharp metal point.
The plate must be secured to a picce of wood with strong tacks driven in close to the edge, and the background of the pattern covered with indentations made with the point of a large wire nail. The plate should next he removed from the wood and the edges lightly tapped over with a hamnier. holding the metal on the edge of a narrow strip of wood and at an angle of $45^{\circ}$. The surface of the metal sloould be rubbed over with dry pumice powler, applied with a hard nailbrush and, after being warmed, coated with colourless lacquer.

## ASPARAGUS : Culture and Cookery.

 Asparagus is propagated almost cxclusively from. seed. The kitchen garden species is officinalis, belonging to the order Liliaceac, a native of Great Britain Favourite sorts are Connover's Colossal, Rattersea and Reading Giant or Large Reading (Perfection is the modern type of this variety). The Giant French or Early Giant Argenteuil is grown by 1 hose who appreciate the large French type.No crop of any importance can be obtained until the plants are three years old. The seed may be sown in spring, in finc, friable, well-prepared soil, and covered an inch or so deep. If more than one drill is sown, it is wise to allow a space of 18 in apart. The seedlings may be thinned gradually to 6 in apart and alternate seedlings transplanted in the following spring, leaving the others a foot apart. They may remain for a year in order to make strong routstocks.

Asparagus is fond of salt at all stages, and sprinklings may be laid along the mus of secdlings during their lirst and second years When the grow'th of scedlings decays at the end of the seasun, it should be cut away, and a dressing of manure spread over them.
Soil Preparation. The plant likes abundance of moisture while in full growth in summer, but is not suited by stagnant soil during the dormant period of winter. It does not dislilie heavy soils, and will thrive on clay, provided the soil is well drained and is made friable. The soil should be laid up roughly in autumn or winter in order to let the frost get well into it. Any disintegrating material available may then be added. After lying for a few weeks exposed to frost, the soil may again be dug over, preferably with the fork. On a substantinl loamy or clayey soil asparagus will thrive for many years with nothing more than an annual top dressing of salt and wood ashes, hut in light land a heavy preliminary dressing of manure is desirable.

The laying out of the beds should be completed sufficient ly early in the spring to permit of planting before gronth is much adianced. It is not advisable to plant inore than four rows at the most, and three, or even two, suffice. The rows may be 2 ft . apart, with a foot and a half of space at each side.

Planting and Cutting. The correct time to ing is a deep pan in which the hund c can be plant asparagus is late in March or in April. In the first summer kesp down weods In

Asparagus : methods of planting and forcing. 1. Sail preparation and plantıng. 4. Where to cut stems. 3. Method of nanting with crowns on ridges of soil. 4othed of manure, with irame ventilated at A. 8. Forcing in a frame between annk pathways Glled with nugnura. B. 日. Messurements of bed for planting in the open
autumn the decaying tops can be cut away and the beds furnished with a suitable winter dreasing.
In the absence of seaweed, a dressing of salt may be given to the bed in spring, a ruarter ol a pound pice square yard being a suitable quantity; or the following dressing of chemical manure may be given :

Superphosphare of lime
Sulphate of ammonial
Sulphate of ammonia after the middle of April, according beds at or and district. With a strong leed any shoots of about the thickness of the little finger may he severed or broken off just helow the surface The first weakly shoots of young beds sliould be left intact. The crop is improved if soakings of water containing $\frac{1}{2} \mathrm{oz}$. of nitrate of soda per gallon can be given during May and June.

Cutting should cease at thic end of June, in order to allow the plants to make their annual grouth, which will extend with great rapidity in July and August. Afterwards with the routine advised alove a bed ought to pield heavy crops annually for a quarter of a century.

Forcing Methods. Only strong roots, three years old or inore, are suitable for forcing. These may be taken up in November and onwards thmughout the winter until the season of outdoor cutting a pproaches Inalarge places there are frequently houses or pits with bottom heat which can be utilised, the roots being paclied in hoses. Cucumber or melon frames may be used, the bottom hent being provided by a bed of manure and leaves. In this case, when the heat of the manure has begun to decline, a layer of three or four inches of soil may be placed on as a base for the roots, which may then be set close together and covered with the same depth of soil. A steady temperature of ahout $55^{\circ}$ to $(3)^{n}$ Fahr. is desirable. Produce may be oxpected to be ready for cutting in five to six weeks from the commencement of forcing. Tepid water may be given through a rose can if necessary to prevent the soil from becoming dry, and air should be admitted in favourable weather. The frame light should be covered in hard weather. The roots are of no further use after forcing.
How to Cook. Asparagus as a rule is served as a separate dish. If fresh when bought, the tips stand up firmly. The utensil used in cook-
placed straight, only the tips being above thic water. Should this not be at hand, put the bundle of asparagns flat in a large pana and, when done, lift out very carefully, so as not in break the puints Sauces in use are equal parts of oiled butter and lemon uice $\mathrm{Ho}^{\mathbf{\prime}}$ landaise, or, when cold, vinaigrotto.
To boil asparagus, cut the stems than even ength to fit the pan Scrape the stalks clean from the tips dounwards, taking care not to break off the heads Tie in bundles of about eighteen, rud place in cold salted water until needed. To cook them, put into boiling salted water and simmer until the heads are tender. Twenty minutes is long enough if the shoots are young Take out carefully and drain, then place in a dish upon a slice of dry toast, which will absorb remaining moisture The water in which asparagus has been boiled makes a good stock for soup. Drop a little butter over the tips of the asparagus lefore sending it to table. Serve the sauce in a sauce-ront.
ASPARAGUS AND CHEESE. Place $n$ layer of boiled tops of naparngus in a pie-dish, and over it grate Parmesan cheese Add a few pieces of butter and pepper and salt to taste: then add a second layer of asparagus with more chcese, etc., till the digh is full. Heat in the oven for 10 minutes.

ASPARAGUS BEETLE. A small bectle with black head dull red fore-body, and the wing-covers over the hind-body glossy black rith an outer edge of brown connected with four yellow spots. The greygreen grubs are a jest on asparagus. The surest way to be rid of them is by handpicking and destroying the sectles as soon as they cinerge In the gruh stage they may be treated in like manner. Where this is not practicable, when the foliage is wet with dew dust it with finely powiered charcoal, soot or lime, which
will adhere to the larvac
Rreatly magnifled

## and destroy them.

They may be syringed with a solution pre pared as follows: lloil 2 oz . of soft soap in a quart of water, stir in whilst hot 2 quarts of parafin oil, and dilute for use with 4 or 5 gallons of water.

ASPARAGUS FERN. The orange or black berries of the asparagus fern are pretty, hut it is the decorative lightness of the folinge which is most admired. Among several orna mental forms Sprengheri is a gond indoor plant, enduring the dry air as few others will.

Asparagns Fern. Foliage and flowers of a plant much used for table decoration Courlesy of Country Life. Lid

Retrofractus is a similar variety. Smilax (Asparagus medeoloides) is useful for table decoration. Plumosus and nanus are used with llowers for buttonholes. A compost of loam and leaf-mould in equal parts, with a sprinkling of sand, suits the plant best.

ASPARAGUS FLY. This is a small ty whose two wings are banded with brown. The lody is dark brown and its hinder division crossed by four lighter lines. The flies may bo scen from April to July, depositing eggs about the scales and leaves of asparagus. From the e'ggs, a fortnight later, emerge leglcss ycllow maggots with dark heads. These bore downwards into the shoots and stems, causing them o turn yellow and rot
The flies may be caught early in the mom ing, settled on the plants : or traps may be set for them overnight by thrusting in the ground sticks whose exposcd parts are smeared with bird-lime or other sticky substance, by which thic insects will be held. Egg-laying is discouraged by dusting the young shoots with charcoal in fine powder. The grubs can only be destroyed by cutting out all yellow or brown shoots and burning them

ASPARAGUS SOUP. Seasonable from March to July, for this soup buy the cheap bunches of slender green asparagus. Cut off the tips and boil gently for 10 minutes, then take out and set aside to garnish the soup when done Now take the stalks of the asparagus, cut into pieces, and place in the boiling salted water, together with 1 pound of well-washed spinach. When tender, rub this through a sieve, and also set aside for a few minutes. In the saucepan melt $1 \frac{1}{2} \mathrm{oz}$. of butter, and gradually rub into it 1 tablespoonful of Hour. When smooth, add to this mixture I pint of milk, hent, and put in the purée made of asparagus stalks and spinach, with enough boiling water to make the soup rich and creamy. Add pepper and snlt to taste. Take off and garnish with the asparagus tijs aiready boiled. Cream may be added. This is sufficient for four persons

ASPHALTE. Strictly speaking, usphalte is pure bitumen, or natural pitch. Rock asphaite is a limestonc naturally impregnated with asphalte. It is applied in its natural form, after suitable treatment, for the construction of road surfaces and other purposes. The term is frequently applied to natural and artificial compositions of a bituminous character.

Aspinode!. Flower spikes of the giant variety
Courlesu of Countril Lije. Lid.

The most prac. tical way to use asphalte for domestic purposes is to buy it in one of its many specially prepared forms. Bitumen or nsphaltic dampproof courses can be laid by obtain. ing the material in the form of $a$ sheet or roll, and setting it in position between the briok courses, or wherever needed. To render a flat roof watertight there are numorous asphaltic compositions on the market that givegood results. See Paths; Paving.
ASPERODEL. The sacred lily of Greek mythology is in gardening phraseology the Asphodelus, a hardy herbaceous perennial of Southern Europe, with white or vellow Howers. The species ramosus attains a height of 4 ft . in good soil; it has long, sword-shaped leaver and
benrs white flowers in late spring and summer It does well in a shady place. Albus, closely related, is a smaller plant; acaulis, 18 in ., bears pink blossoms, and comosus, 2 ft., white.

Closely related to the Asphodel is Aspho deline, the principal distinction lying in the upright stems. The species lutea produces a tall stem, sometimes 3 ft . high, clothed with dark green furrowed leaves, and studded with large yellow fragrant flowers in early summer It is a hardy perennial, well worthy of a place in the herbaceous border There is a double form Pron. Ass'-fo-del.

ASPHYXIA. The condition in which aeration of the blood has ceased or almost ceased owing to interference with respiration is termed aspliyxia. It may occur in the course of disease or it may be accidental. Thus it occurs in (1) Drowning, when water takes the place of air in the lurige. (2) Blocking of the air passages, as in strangling, hanging, or choking, where a piece of ment or other foreign body gets into the windpipe, or where a large mass sticks at the back of the mouth or in the gullet. Or the blocking may be duc to swel. ling produced by stings or by swallowing boiling water or corrosive poisons. Choking may also occur in diphtheria. (3) Compression of the chest, as when a person is buricd hy falling earth, etc (4) Inhalation of coal gas, chlorine, sulphurous acid, and other poisonuus grses. (5) Disease of the respiratory centre in the brain or paralysis of the nerves or muscles of respirntion, as by certain poisons.
 Aspidistra: dividing and re-potting. 1. Plant that needs re-potting, 2. Single
leaf division. 3. Six-leat division, the best way. 4. Roof. showing the leal buds The treatment is to remove the cause, loosen tight clothing about the chest, draw forward the tongue and see that the mouth and throat are clear, and if breathing has stopped begin artificial respiration. Reniember that nore than one cause niay be present. The cause will be dealt with as follows :
Strangling: loosen, or, if necessary, cut whatever is constricting the neck. Hanging : cut down. Chol:ing: prize open the jaws, if necernaty, with the handle of a spoon covered with a bandkerchief, and endeavour to hook forward the obstruction, or, especially in children, invert the body and slap the back. Cumpremsion of the shest: uncover properly if from falling earth, or secure space when the cause is compreasion in $a$ crowd. See Artificial Respiration; Suffocation.

ASPIC. This savoury jelly is made from meat stock and gelatine or from calves' feet, eet, do corporal hurt to mother" It is thus more and Havoured with herbs and sherry. Cutlets, than a threat, although it is still an assault if

Aspic. Savoury dish of hard-boiled eggs served in aspic jelly Courtesu of Waril, Loel: \& Co., Lid.
eggs, prawns and other foods are embedded in the aspio jelly, to form dainty entrees or supper dishes A recipe for aspic jelly is as follows:
Put $\frac{1}{2}$ pint of water and $2 \frac{1}{2} \mathrm{oz}$. French gelatine into a clcan snucepan, together with $\frac{1}{1}$ pint of sherry, the same quantity of chili, tarragon, and malt vinegar mixed, a bunch of mixed herbs, the juice of two lemons and the rind of one, a good sprinkling of salt, ten white peppercorns, the whisked whites of two eggs and their shells crushed, an onion, a carrot, and a turnip, and a stick of celery. Whisk all these together till they boil, and, after boiling up well, strain them through a cloth until clear. Serve in small moulds containing the prav ns or other food required.
ASPIDISTRA. Gicen and variegated are the two forms of the aspidistra. They benefit by having the leaves sponged frequently with soapy water
The variegated is the more delicate, and njtt to revert to the type. The green leaves should be
cut away as they come, and the plant kejt a way from draughts and fire heat. Compost, three parts loann, two parts leaf-mould, and one part sand. Propagation is by root division and suckers in spring. Pron. Aspy-dis'-trer.

ASPIRIN. Acetyl-salicylic acict, a drug used to relieve pain, reducc fever, and combat rheumatism, is equally known under its trade name of aspirin. It gives relief in most cases, but in some people it produces gastric acidity. In feverish conditions it induces perspiration, and exposure must then be a voided. Combined with quinine it is uscful at the beginning of malaria and influenza, and 5 grains of each might be given for the latter. The same close would help neuralgia.

Asplenium. See Spleenwort.
ASSAULT. In English law an assault is "an attempt or offer with force or violence to other with a stick or other weapon misses his aim. Battery is an aggravated form of assault in which actual injury has been done. The maximum punishment for a comimon assault is 12 months' im. prisonment with or with. out hard labour. If bodily harm has been doné, three yenrs' imprisonment may be given. See Separ. ation Order; Summons.

ASSESSMENT. The term assessment is upplicd to the annual value of land or income in order to ascertain the sum which a man should pay in rates or taxes. Houses and other property are asisessed at a figure, known as the rateable valuc, and on this the rates are calculated. The valuation in made by the assessment committee in each area.

Assessments are revised from time to time. A man who considers his property is assessed at too high a figure should apply to the clerk of the local assessment committec See Income T'ax; Rates.

ASSETS. In the case of a deceased person the assets are estimated by a valuation

Stocks and shares are reckoned at the price they stood at on the market on the day of the denth of the deceased. Shares in a company not quoted on any Stock Exchange should be valued by the directors or the secretary. If the deceased had a busincss, an estimate is made of the machinery, stock-in-trade, ctc., and something added for goodwill-from three months' to two years' profits according to the kind of business. But the test is, what price would be paid by a person who wanted to bisy a business of that kind. Sce Executor; Will

ASTER. This name is usually, but incorrectly, given to the popular summer Howering annual the China Aster The real aster is the perennial Michaelmas Daisy (q.v.)

ASTHMA: Self Help for the Pationt. The chief symptoms of asthina, which is a disease of the chest, are attacks of great difficulty in breathing. They often come on suddenly, and inay be followed by equally sudden relief. The discase is due to a sparmorlic contraction of the smaller branches of the windpipe Some shock to the nervous system is probably the primary cause.
The circumstances which bring about this nervous activity are numerous. The inhala. tion of such substances as pollen, horse dandruff, ent or dog hair, the ingestion of some foods, e.g. white of egg, or infection with pusproducing microbes, appear to be responsible in many cases. At other times there is irritation from some condition inside the nose. The discase is often an inberitance from parents who have themselves suffered from it. It affects mainly males, and frequently begins in childhood.

During the attack the patient should be allowed to place himself by an open window and to get into any position which appears to him to minimise his difficulties in breathing. When it can be taken, a mustard emetic (a tablespoonful of mustard in a glass of warm water), by making the patient voinit, sometimes relieves the spasm and terminates the seizure. I cup of strong coffee is useful.
Medicated papers and powders are sold by chemists to be burnt during asthmatic attacks, the resulting fumes having a sedative effect on the excited nerve-endings in the lung. A simple but useful fumigant of this kind can be prepared at home by soaking thick blotting paper in a atrong solution of nitrate of potash, and then drying. Bend the dried paper into a cone and set light to one corner, letting the patient inhale the fumes
It is not desirable, however; that the patient should rest content with a fumigant, a spray or anything else which relieves his paroxysms. The causes underlying these must be investigated, and he can help his physician by carefully observing and making notes of the circumstances which precede the attacks, e.g. the food he eats, or contacts with nnimals or plants. The pollen variety is likely to be seasonal. His adviser can help him to fix responsibility on anything suspect by testing solutions of it on scarifications on the skin If there is a reaction there, he will know what to a void, or his resistance to such a substance can be raised. Or it may lie
found that a vaccinc does good, or the cor rection of some intra-nasal condition

The medicinal remedies most in use are arsenic and the iodides. The patient should live a well-ordered life, with sufficient exercise and plenty of fresh air. His meals, of moderate size, should consist of good, plain food, and the evening meal should be small. He should avail himself of the bracing qualities of baths as cold as he can bear them, followed by a brisk rub down. It is worth repeating that if a man, early in his disease, explores every a venue for escape, there is hope for him but there is little if he accejts a destiny of invalidism in a drug-impregnated atmosphere
In children treatment should be under medical supervision.

## ASTIGMATISM

due to the bulging the eye (the cornea) not being equalls curved in all direc tions, produces astig matism. Rajs of light striking on the deformed cornea are not accurately eflected on the inner, sensitive part of the eye (the retina), with the result that the vision is inaccurate. It should be conect. ed by spectacles. See

Abnormality of vision transparent portion of

to six, or later, and tho guests. remain for the whole afternoon : othervise people come and go as they please, and move alrout the room to talk to their friends, or go to have tea, when this is served during the party in another room. Only at a small paity can the hostess talk to all her guests or introduce them generally. It is unnecessary to take leave of the hostess, unless she is standing near the door, or it is the gucst's first visit, when it would he more formal to do so Guests make their way to the hall, and servants call up cars or taxis, if required. Gratuities arc never offered to servants.
For the formal at Home party invitations are sent out a week or two weeks in advance, and acceptances are expected in writing. The card of invitation hears the printed name of the hostess, with At Home underneath then the date of the party beneath that. The address should be in the right-hand hotton corner, and in the left "Bridge," "Musio," or whatever form of entertainment is to be provided, and the time. The guest's name is written in ink on the top left-hand corner Sec Dinner Party: Etiquatte ; Recep. tion; Wedding.

ATMOSPHERICS. Atmosphericy, sometimes referred to as "Strays" or "Xs," are electromagnetic disturbances in the atmosphere. They can be readily recognized in the form of crackling noises. which occur on any wave-length to which the receiver may be tuned In the summer, when local lightning is prevalent, each Hash will produce a loud crackle in the loud speaker or telephones. Lightning is not an essential feature, and various "frying" and "hissing" sounds can also be caused by electrical discharges in the atmosphere in hoth summer and winter.

Although a great deal has been done to reduce the interference in commercial receiving stations, there is no simple method which can be applied to a broadcast receiver.

Generally speaking, it is only in the tropics or during the reception of long-distancesignals that atmospherics can causc scrious interference.

Atmuspherics often resemble the noises produced by a faulty battery, defective windings, or bad connexions. If thecrackling is due to atmospherics it should cease at once upon disconnecting the aerial and earth leads from the set.

## Atomiser. See Spray

ATROPINE. Atropine or atropia is the active principle of the belladionna plant or deadly nightshade. It is much used in eye diseases, as it dilates the pupil widely.
loth atropine and various preparations of belladonna are dangerous druge, and should never be used except on a physician's directions The practice of using drops of a solution of atropine in the eyes to make them lustrous is most dangerous. See Belladonna.

ATTACHE CASE: Its Renovation. 'The best attaché cases are madc of cowhide. but cases of similar appearance are made with a cardboard foundation covered with thin leather and lined either with leather or cloth. The solid leather caso will stand much wear and tear, but the leather-covered varieties are liable to break away at the corners and get out of shape. Cheaper kinds are made of compressed filure

The leather covering is kept in good condition ly rubbing over occasionally with brown boot polish; fibre covers should be trented with furniture polish. When the sewing at the corner of leather cascs gives way or shows signs of wear, a thin leather corner piece may be sewn on; further strengt h may be given inside by fitting a tin or thin brass corner plate, which is attached by means of bifurcated rivets. To clean an old leather attaché case, use a weak solution of oxalic acid, applied with n rag; polish when dry with a good brown boot polish.

ATTACHMENT. A person can be attached-that is, arrested-hy any judge of a court of record if he is guilty of conteinpt of court. Attachment of debte is the process by which ono person can obtain moncy which is owing to anolher who in turn owes money to him. For instance, A owes IS $£ 100$, which B cannot ohtain $B$, however, knows that $C$ owes A $£ 200$, so he can obtain an order of the court by which ho attaches $£ 100$ of this debt : i.c. $C$, instend of paying $£ 100$ to $A$. pays it to B. The order by which this is done is called a garnishec.
ATTESTATION. This word is used by Inwyers for the act of testifying or witnessing to anything, either by signature or on onth. fll wills inust be attested by two witnesses, who niust be present at the same time, and muat aign their names on the document in the presence of the testator and of each other. See Will

ATTIC. If left in an unfinialied state by the builder, the attic is not of much use until the walls and ceilings have been plastered

Attic. Scheme for the ariangement of on altic as a comfortable bedroom O.r Tomes and תar.lens. and papered; but this is ensily done. It the and swing mirror makes an elfective dressing. saine time it sloould be ascertained that the roof and window are watertight. The fircplace usually possesses a chimney that smokes in n high wind, so lighting and heating should be carried out, if possible, by gas or electricity.

An attic window sometimes lends itself to picturesque treatment with $\Omega$ window-seat. For an attic bedroom quaint chintz or cretonne may be used for the curtains, windowseat, chair cushions, and bed drapery. If children are to play in the roon a large talile should be provided, covered with brightly coloured American cloth, the same fabric being used for the curtains, as it can. le easily and frequently washed with a damp cloth and soap.

Any odd pieces of furniture may furnish an attic, and if they are shabby they may be scraped and enamelled in some suitable shade. The floor should be stsined or painted if good. or, if not, covered with parquet linoleum nad a rug or two. As draughts enter below attic doors, felt wenther stripping is of ten necessary, or a piece of boarding arranged to keep away the draught. The addition of a screen adds to the cosiness of the place.

It is not difficult to convert an attic into a sitting-room. As its window vill doubtless be small, the walls should be made light in colour ; cream or light grey distemper gives a satisfactory elfect, or primrose yellow, or pale green plastic paint for a bad wall surface. A thick coat of the paint is laid on and finely stippled.

A cheap seat ean be mado from a wood frame on short legs, adorned with cretonie hangings and provided with a cretonno. covered cushion. Easy clinirs which are no longer required for rooms downatairs can le given a new lease of life by means of loose covers of cretonne to match.

Wood aholving, enamelled or atained, will conveniently fill the odd corners. A bureau or tallboy alfords a good deal of storage space. and furnished in this way an attic sitting-room, with shaded candle lights, has at night tîne a fascinating appearance. whilo by day there is often a fine view from its window. The hurean ahould be placed beside this to enable the writer to see well.

Should the roon be disfigured by means of a chinney passing through it, the latter can te encased by boukshelves stained to match tho reat of tho woodwork. Treaterl in this way it will be hidden from view.
Many people who convert their attics into sitting-rooms have the walls panelled in such a way that one of the hig panels can be lifted out at a moment's notice. When this is done a large cupboard rumning the entirc length of the room is disclused, and t!!is contains trunks and a collection of other miscellaneous articles usually stored awhy in $\Omega$ loft. If an attic is converted into a bedroon, the furniture should be of the cottage type. A ward. robe is not reconmmended on account of the space it ocenpies, and because a curtaincll recess call bo fitted up with hooks and atretchers to do equally well.

In the case of a girl's bedroon, a long nirror can he fastened ngainat the wall. A pedestal desk with a glass top table, while for a "ash-stand $n$ small table with $n$ coloured rush mat hehind it will serve. A bedstend withont a foot rail gives an appearance of roominess.
A small bedside table, $n$ bookshelf made from a long narmw box and stained to mateh the rest of the furniture, together with an casy chair, brightly col. oured runs and a harmonising cre tonne will farnish a pretty room.

The storage space provided ty an nttic or loft is often wasted because therc is no ready access to it. Many attics are enterol only by a rect angular trap door, and steps or Iadders have to be carried up every time there is any reason to go into the attic. The illustration shows a type of disappearing stairway which can rcadily be brought into use when re. quired This is made in a vide range of standard sizes, and is sent out ready to be

Attic. How it may be transformed into an attractive sitting-zoom
leaf-mould and decayed manure with sand and giving plenty of water. There are white varieties, but the lest cookers are the Early Purple, Long l'urple and Nes Sork Purple.
Baked Auber gines. To pre pare these wipe and put in a casserole with a very littlc water at the bottom Cover them and bake in a moderate oven until tender They can be served in the casserole. In eating cut then
 open and mash them with it iittle butter, pepper, and salt

Fried Aubergines. Take two aubergines, one egg, and a little Hour, salt, pepper and bread crumbs. Kemorc the peel and cut the aubergines into slices. Soak these in strong brine for ahout ? hours, as the plant seems more bitter whel fried. Drain lliem in a cloth, dip in llour previously mixed with salt and pepper, hrush over with leaten egg, and coat with breadcrumbs Fry in hot fat, drain on soft paper, and serve hot A frying batter may be used instead of egg and crimblis. Pron O-ber-zheen

AUBRIETIA. Coming intu bloom before spring is far advanced, the purple rock cres or Aubrietia is generally at its best in April

Aubrietia. Clump of this gaick-spreading. brightly coloured plant which thrives in rock Rardens Photo from Sution \& Sons. Lid
or May, but loses brilliance in summer, and after being cut back moon liegins to grow ngain. On the rockery these plants form cascades of colour, while in beds they are a ground work for tulips. They are propagated by sced sown in spring. preferably under glass. The scedlings should he pricked out in a spare bed for the summer, and planted where they are to Hower in autumn.

Only one sjecies is in general cultivation. This is deltoidea, with purple flowers. Modern varieties of it includo Bougainvillea, Firc King, Royal Purple, Dr. Mlıles, Lavender, 11. Marshall, Leitchtlinii, J. S. Baker, Pritchard's Al, Violacea, Mocrheimi, Lloyd Edwards, Excelsa, and Violet Queen. Pron. O-bree'-sha.

## Auction Bridge. See I3ridge.

AUCTIONS AND AUCTIONEERS In most cases people prefer to do their oum bidding at auction sales, but a broker may be employed at a small commission to bid uil to a ccrtain figure for any articles desired, and his services are useful in a crowded sale-room. He is also useful in arranging for the removal of purchases the day after the sale-a matter of
oxpense whicl inust not be overlooked in determining limits of prices to be bid

There are special sales in various places, and on the premises of certain celebrated firms where the word antique in the catalogue is a genuine guarantec ; but in the mixed sale of furniture and effects antique is used indiscriminately to describe anything not in the style of the last thirty years.

For the casual buyer, cash payments are the rule-n deposit being paid to the clerk for each article as it is knocked down, and the remainder before the goods are removed. After one or two visits resulting in business a client's cheque will be accepted at the conclusion of the sale for the amount owing.
For the vendor also there is opportunity in the auction sale. Instead of bargaining with a private huyer, the haggling is done by the bidders, and there is the possibility of price being obtained in excess of expectation. In selling a housefil of furniture and effects, it is well to consider the question of a sale on the premises, placing the business in the hands of a good firm of local auctioneers The usual commission charged on each articie is $\mathbf{1 0}$ p.c. of the su:n realized.
A reserve price should be put on valuable pieces. The vendor is then responsible to the auctioneer for a commission on the highest figure bid, should it fall short of the reserve and result in no salc-but such commission is usually only $2 \frac{1}{2}$ p.c., with a minimum of 2s. 6.l.
Good furniture and cffects which have in trinsio or fashionable value are best sent to sale-roons which attract a large numher of well-todo buyers, where sales are held once or twice a week regularly, and goods rc ceived to be catalogned four or five days before the sale Sotheby's is a recognized mart for vare books, and Christie's for valuable china. Advice and valuation can be obtained from an expert for a small chaige

## Legal Aspects. Frons

 a legal point of view the auction is an offer of property to the highest bidder. It follows (1) that the owner of the property cannot bid himself, so as to run up the price. If he does so, the buyer can cancel the salc, return the property and demand his money brek: (2) that unless it is duly adverlised, or stated by the anctioneer, there can be no reserve price The only exception to (1) is that in the case of a sale of landed property the owner may eniploy onc person to bid for him The sale is complete on the fall of the haminer.Although a sale of goods, etc., may le advertised without rescrve for a certain day, the owner is not obliged to put them up on that day or at all. He may sell by private treaty beforeliand, or withdraw the property from the auction. This will not deprive the auctioneer of his right to be paid. The auctioneer need not accept a bid; but once he has accepted it he is hound to knock the property down to that
bidder unless there is a higher bid. If two versons simultaneously bid the same amount, the auctioneer can accept which of the hids he pleases. An auction
eer is not entitled to sell except for cash. Those who bid at an auction should read the conditions of sals carefully. Anyone entering into : 'linock-out.' i.c. an agreement among dealers not to bid against one another, is liable to a line of $£ 100$ or 6 months imprisoninent or both.

AUGER. This tool is used for bor ing holes to agreates depth than is practicable with brace and bit, especially in hard wood. It con. sists of a steel shank terminating in a twisted cutting-bit, tho wooden handle passing through the cye of the shank. Augers may be olstained in sizes from

Auger. Correct manner of in. up toldin. In using this tonl it is essential to keep the shank in a truc vertical position while cutting, watch ing it from two different angles. See Boring

AU GRATIN. A dish served au gratin is onc covered with sauce and grated checse or breadcrumbs, and brought to the tablo in the dish in which it is cooked. Fish and vegetables are frequently prepared in this way. Sec Caulillower: Egg; Macaroni; Sole, etc

## Notes for the Month

[^0]AURICULA Hardy and half hardy per ennial, easily raized from seed. The indoor or show varieties are always grown under

Auricula. Fine specimen of the plant allied to the primpose Hepinald T. 3ulbu
has the effect of lusintaining the recpuired temperature without the aid of much fire heat. Watering should be done in the morning so that the at mosphere may be dry by evening. See Gardening: September: October: November.
AV!:ARY. As generally understood this is an outdoor cage for captive birds, sufficiently large to permit the birds inside to fly. One portion should have close walls and roof, and be fitted with nesting boxes and natural branches for perching, the remaining portion (say three-fourths) being left open save for wire-netting of small mesh. This portion should be furnished with growing shrubs in tubs, drinking water, bath, etc.

For the construction of an aviary, the chief materials required are 2 in . deal quartering, feather boards and wire-netting. If possible, it should be built against a wall, and should face S. or S.W. Supposing the length decided upon to be 12 ft .. the height 8 ft . and the depth from back to front 6 ft., the quartering for the framework would be three lengths of 12 ft ., three of 9 ft ., five of 8 ft .4 in ., and nine of 6 ft ; the 8 ft .4 in . to have their lower ends tarred for 6 in ., of which 4 in . will be inserted in the ground.

The 9 ft . uprights having been fastened to the wall at equal distances apart, a 12 ft .

Aviary for hards birds, built against a garden wall. It is constructed with a boarded shelter to protect the inmates from the weather
horizontal is attached to their tops, a simple joint being made by cutting half through the wood, so that they interluck. The remaining two 12 ft . lengths and the five 8 ft 4 in . lengths are joined up in similar fashion to make the fraine of the front, which is then connected with the back by means of the $\mathbf{6} \mathrm{ft}$. lengths, as shown in the diagram. The side, front and roof of the eastern fourth are boarded in and tarred on the outside, roofing felt being added here.

The remainder of the structure is then covered with wirenetting. A small door should be contrived, hinged on an upright and opening inwards to a sort of wire "lock" to prevent birds escaping as anyone enters the aviary. In sclecting tenants, the sced-eating woodland and hedgerow birds will be found the most suitable. The tits, which are mainly insect eaters, may be included, and meaty boncs, suet, and coconut substituted for insect food. Sec Bird Cage ; Canary.

AVOIRDUPツIS WEIGHT. By far the most used of English weights is avoirdupois, food and materials being msually sold by it. It is as follows

```
16 Drams - }1\mathrm{ Ounce (oz.)
10 Ounces = 1 Pound (lb
If Pounds = 1 Stone
112 l'ounds = 1 Hundredweight (cwt.)
20 Hundredwelglits =1 Ton
```

In the case of certain articles the stone is less than 14 lb .

AWL. A fine-pointed tool, the awl is used by bootmakers, saddlers, cobblers, and all leather workers for making holes to receive the thread when handstitching is being clone. Its blade is not edged but pointed. See Boot, Repairing; Bradawl.

AWNING. The fittings of window aivn ings must be strong and well made, so that they may be drawn in and out with eass Where a large French window opens on to a garden a wide awning, the full width of the winduw, fitted in the same way as the ordinary awning used for shop winclows, adds to the amenities of a small house in summer.

Awnings for the garden range from the giant sun umbrella and the simplest auming spread over four uprights to what becomes virtually a summer-house. The favourite material for making these is striped cloth in red and white or green and white.

Awnings should not be exposed to dew and rain without being properly dried. Before they are put away for the winter they should a!ways be well laundered so as to keep) the material in sound condition. See 'Tent: Waterproofing.

AXE. Thistool for cutting wood and felling timber consists of a weighty head with sharp cutting edge, the helve or handle being of varying length nccording to the work required. It is employed with a wicle swinging stroke, at the beginning of which the right hand is just under the head, the left at the other end of the helve. During the swing the right hand slips down the handle, until, as the axe is brought down, both hands are together. For lopping light hranches a blow is given on the uniter-side of the branch.
For felling trunks the axe is wiclded first in a downward sloping direction, then in an upward direction, to take out a $V$-shaped chip:

Axe. How to bold to obtain the correct swing in felling a treo
the $V$ is then gradually increased to the centre of the trunk. A notch is then commenced on the other side, and continued to meet the first $V$ in the oentre, when the tree falle away from the cutter.
If the edge of an axe is rubbed occasionally with a carborundum, the tool will require less frequent grinding. The werge that securas the head is made of some hard wood. If a new werlge is needed, cut one longer than the depth of the cut in the handle and sufficiently wide. Hammer it in as far as it will go, and then saw it off level with the axe head See Chopper; Hatchet.

Axle. See Front Axle; Live Axle; Motor Car
AXMINSTER CARPET, A tufted, machine-made fabric, the pattern being formed by tufts of woollen yarn, cut off and inserted in the body of the carpet. It is made in different qualities and in two kinds, seamless squares and in breadths. See Carpet.
AZALEA. These flowering shrubs, now classified as rhododendron by the botanist, consist of scveral species and numerous varieties of three types:-the Indian azalea (thododendron indicum), the Ghent, and the mollis azaleas. The Indian azalea, largely imported from Holland, is grown chiefly under glass for spring blooming. The Ghent and mollis azaleas are used similarly and also as bardy summer flowering shrubs; the flowers are brilliantly coloured-orange, apricot, salmon, rose, etc. They thrive best in snil mixed with pent or leaf mould. The correct potting compost for Indian azaleas is peat and loam with sand added frcely.

When the plants are potted, room should be left for adequate watering, as many failures occur because of dryness at the root. Periodical syringing of the foliage hefore the plants come into lioom is also beneficial, and as the

Azalea. Laxuriant bloom of a potted plant Courteay of Sution i Sons
buds swell, an occasional top-dressing of manure should tie given. After Howering, the plants should be stood out of doors for the summer on a bed of ashes. Repot immediately after the Howers have faded.

T'o propagate azaleas, cuttings arc taken when the plants are making new growth. Young but sturdy shoots should be chosen, and they will root better if they are pulled off the stem, so that they retnin a heel of the old wood

Good varieties of A\%alea Indica: Dentsche Perle (white), Fielde:'s White (white, large flowers), Alice (deep rose, double), Bernard André (violet purple, double), Souvenir de Prince Albert (rosy salmon with white edge), Criterion (salmon pink), John Gould Veitch (lilac rose), Madame van Houtte (carnine and rose, flaked), and Verraeneana alba (white).

## Baby: The First Year of Life

## Practical Advice for the Young Mother

For infane care from the second year onwards sec Child; other information is given under Baby Chair; Cot; Pernmbulator; cte.

Mother ignorance is responsible for a tail: sickness is not so much a digestive disorder as proportion of the children we lose lefore a symptom caused by chemical changes in their first birthday. Unhealthy motherhood the borly at this time; it usually passes off accounts for many of these deaths, so that the first duty of every expectant mother is to care for her own health. The ante-natul period of life is also very important to the healt! of the haby. That is why ante-natal clinics have been organized so that mothers may attend during pregnancy to receive medical advice.
The expectant mother should always see a loctor three or four times before the baby is born, and before the first baby's birth this is especially necessary, as certain simple measurements have to be made in order to know that the poung mother is capable of bearing a fulltime child of average size.

The term " hygiene of pregnancy " includes proper diet and exercise for mothers during the months before the baby is born, and the provision of fresh air, rest and healthy sleep The expectant mother ought not to over-feed. Indiscretions in diet cause the dyspopsia with heart-hum which inakes so many mothers miserable at this time. Light, nourishing food, with Hesh meat served only once a day, must be the rule.
Eggs, cheese dishes, and fish can take the place of most at two of the three substantial meals, and, in addition to these, a cup of tea with biscuits or bread-and-butter at $4.30 \mathrm{p} . \mathrm{m}$. If an evening meal is not served later than 7 p.m., a glass of milk at bed-time is permissible. During the last month some doctors advise that no flesh meat should be taken at all

The breasts require a little special attention, in order to prevent cracked nipples, which interfere with natural fceding. The nipples should be washed daily with warm water, carefully dried, and a little vaneline or lanoline applied. If the nipples are small, gentle massage will improve them for nursing purposes. Clothing should be light and loose, without any constriction of the body, and supported from the shoulders. Special maternity corsets or helt may be worn if desired. Garters must be discarded and suspenders used instead. High-hceled shoes should be avoided; they are apt to cause loss of balance when walking during pregnancy.

## Expectant Mother Must Take Exercise

Regular exercise and a certain amount of work is far better for the health than the sort of sofa existence some women think justifiable at this time The expectant mother can do light housework, even light gardening. She can carry on her business or profession for several months at least, providing her mork is not physically or mentally exhausting. A hrief rest of 20 minutes after luncheon and also before the evening meal is excellent. Every effort should be miadc to obtain restful sleep by regular bedtime, a well-aired room, a comfortable bed and a tranquil mind. It is usually necessary to cultivate a restful outlook, and not to be emotional or to exnggerate trifling grievances.

Indigestion and constipation are perhaps the commonest ailments at this time. The only medicine which ahould be taken without a doctor's prescription is a tumbler of hot water, with a pinch of bicarbonate of soda added, $\frac{1}{2}$ to $\frac{1}{2}$ of an hour hefore meals.

For constipation take stewed fruit at meal times, regular exercise, and a tablespoonful of liquid paraffin or olive oil once or turice daily. If these simple measures are not successful consult a doctor without delay. Morning

Varicose veins are often quite painful in pregnancy. When they appear it is necessary to wear a crêpe velpean handage, and this must be apred round the instep first (not the ankle, or the feet may swell) and then upwarda to the knec. When resting, keep the feet up on a couch or stool, and do not stand more than is strictly necessary. The teeth should be watched at this time, and any necessary stopping attended to Decayed teeth should be removed before baby is born, as bad teeth, by infecting the milk, will jeopardise its health and development

## Feedink the New-Born Baby

The average normal child weighs from it to 8 lh at birth. He is well nourished and fairly contented with life, and usually shows signs of a healthy nppetite after the first fcw days. He does not require much in the way of food at this time; nevertheless one of the commonest mistakes is lack of patience because the breast inilk does not seem to satisfy the baby, and artificial feeding is resorted to to help the breasts. Nothin, should be given at this stage except a little sweetened water after the breast feed For one thing, the infant's stomach measures only 1 oz. in capacity, about the size of an egg-cup. Further, if the baby is not kept hungry he has not the same incentive to suck strenuously, and so the mills is apt to go.

During the first two days he sloould be fed every six hours; on the third day at four hourly intervals, and after that, either every three hours or every four hours. No night feeds are given to the modern haby from birth, unless in the case of a premature or very weakly child.
When the milk is insufficient, the haby should not lo weaned, but the natural food is supplemented by giving a half-feed, immedi. ately after the breast, of diluted cow's milk or one of the artificial foods Give alternate breasts each feed, so that each breast has six hours' rest by day.

When baby cannot be breast fed through abscesses of the breast or other serious canse. then the child must be brought up on the bottle. His chances of health and even of survival are diminished by bottle fceding. It is the duty of every woman to nurse her own child unless advised not to do so by the physician for serious health reasons Breast milk is freo from germs; it is most easily digested, and it is of the right temperature.

To improve the quality or quantity of the mother's milk, attend to her diet, for she may require extra eggs, milk or meat. See that she has more rest-two hours' rest in bed every afternoon may make all the difference-and teach her to douche and massage the brensts. This is done as follows :

Get a basin of hot water and a basin of cold water and put a piece of Turkish towelling in each. Bathe the breasts alternately with hot and cold water for 10 minutes once or. better still, twice daily. Dry and massage for 10 minutes. With proper care, 90 per cent. of women can nurse their babies

When bottle feeding has to be resorted to good clean cow's milk must be tried, as, like human milk, cow's milk contains vitamins. certain chemical substances only found in live food (milk, fresh meat, fruit juice, oils
etc.) and deatroyed by the preparation o artificial haby foods On the other hand, it is sometimes impossible to procure good clean milk. or to keep it frec from germs, and when artificial foods arc used the vitamins can be given in the form of orange, grape or apple juice, a teaspoonful to a tablespoonful. according to age once daily between two fecds.

Cow's milk should be pasteurised for the baby's use, that is, raised to a temperature of ahout $155^{\circ} \mathrm{F}$. This is done by placing the milk in a clean jug and the jug in a saucepan of cold water, which is hrought to boiling point and bniled for 20 minutes. The milk does not bnil and so the vitamins are preserved, yet thie germs are destroyed.

## How Milk is "Humanised'

The milk has now to be humanised, i.e. made as much like breast milk as possible. Milk is a perfect or complete food, because it contains proteid, fat, sugar. mineral salts, and water in the right proportion; hut in cow's milk there is about twice as much proteid (casein) as in human milk, so that for a new. born haby the milk has to he diluted by an equal quantity of sterile-boiled-water. Some doctors dilute to the extent of one part milk and two parts water.

Now we have too little sugar and fat, so we add half a teaspoonful of sugar of mills and half a teaspoonful of cream.

This table may be taken as a guide to the quantities of diluted cow's milk, although it must be modified as required

Artificial fonds are prepared according to directions They are either dried milks, when the usual mixture is 1 teaspoonful of the food to 1 oz . of water, or condensed milks, sweetened and unsweetened.

The most careful attention should he given to the bottles. They should he of the boat. shape variety, as illustrated, with teat at one end and $r$ ithber valve at the other. They should be washed in cold water and then in lot water after use, and placed in a clean enamel bowl full of cold water. Once daily, prefer ably in the morning, the bottles should
 Baby. HyRienic, boat-ghaped feedink bottle with rubber be boiled, a special saucepan being kept for this purpose. Place the bottles in cold water, boil for five minutes and conl before the bottles are removed.

The valves and teata should only he placerl in the water after it has boiled and left there for tiwo ininutes, as they perish easily. The milli-jug should be scalded with hoiling water, and the food is made up in bulk mornings and afternoons (diluted, and sugar and cream added), so that it is ready to pour into the hottles as required
Clothing, Bathing and Teething. Whilst the diet is the most important factor during the first year, attention must also be given to daily regimen and to clothing. After the cord is healed, at ahout five or six days, a knitted woollen binder may be substituted for the flannel binder. The clothing should consist of a soft wonllen vest, a flannel. a soft napkin, a woollen pilch, a dress and woollen shoes, with a little knitted matinée jacket in cold weather. The long clothes
slould reach only a few inches below the fect Nothing longer than 30 inches, which should be the lengil of the nightgowns Babies need their own pocket handlierchiefs, particularly soft and small ones

The baliy should he bathed in the morning and sponged at bedtime. A long and narrowshaped fattern, which stands equally well on

Baby. Folding bath oi rubber on a light wooden trame
wash tul does equally well not shillings. and saves many shillings. A face cloth and a huttock cloth, a piece of pure eoap, and a soft Turkish towe and one of old diaper for the face lowel complete the requisites for the hath. together with a pure powder for use after drying. At first the teniperature of the bath should he blood heat, $98^{\circ}$ to $100^{\circ} \mathrm{F}$., and the water is gradu. ally made less warmuntil it is about $80^{\circ}$ F., at six months or so. The bath water should be tested by a thermometer. Thorough remorni of soap and careful drying, especially of all crevices, are necessary to prevent scalding and eczema. After drying, dust the skin with a powiler consisting of equal parts of starch, zinc oxide. and boracic powders. After the bath the baby has a feed and is put to sleep. He should sleep in his own cot from the beginning, as it is both unsafe nnd unhygienic to s!eep with mother or nursc. He should lie on a firm hair mattress, and bed and bed-clothing should be thoroughly aired daily in a current of fresh air. It need not be emphasisad that a child must live and aleep in freah air every day of his life. The night air is just as healthy as the dav-time air, and the only time that indows should he closed is in very foggy weather.

A baby should be weighsd twice a week, as regular gain of weight is the best indication of progress. A few days' sickness or unsuitable food will immediately affect the weight. Ho should gain 5 oz . a week in the first month, perhaps 6 oz. a week the second month, and at three months his weight should be between 12 and 13 lb . At six months he should have doubled his weight at birth, and a fair average is 15 to 16 lb , his weekly gain at this time being about $40 \%$. At one year old he should weigh 2! lb., if he has progressed normally

Teething and weaning ale the two milestones during the first year He hegins to cut his teeth in the sixth month. although the teeth have, of course, heen in the gums since
birth. their formation beginning ahout the 16th weel: of pregnancy. The cutting of the teeth is a physiological process and ought not to be attended by any adverse signs or symptoms. There is an increased flow of saliva (dribbling) and some heat and tenderness in the guns, but he should not otherwiso he sick or sorry. Attend to his diet : give him, perhaps, rather less food than usual, with occasional sips of water, and see that the howels are acting well, and he should have no trouble with teething. The comforter or dummy teat does not find its way into any projerly conducted nursery.

## How the Teeth Appear

The first teeth are the lower cent ral incisors, or the biting teeth, which should appear a hout six months, the upper central incisors in the ninth month, and the lateral incisors a month later, i.e. at nine months, which is the time to begin weaning haby. At the end of the first year the first molars are cut; the remaining teeth helong to the second stage of child life.

When he cuts his teeth it is a sign that some change of diet from milk shoulil gradually be made. It may begin on the morning of his ninth month with a little dish of well conked arrowroot or ground rice and milk or
 egg custard, or suff. yolk of egg. He is promoted to onc: meal a day, and in a week he may have two mealsaday substituted for breast or bottle

By the time he is 10 months old he should be entirely weaned, and put on a three menls a day regimen. Suitabla foods, from nine to 12 months, are cow's milk, lightly-cooked eggs, gravy and breadcrumbs or potatoes or cauli Hower, bacon fat, crusta. vegetables and gravy soups, well-hoiled porridgo, rusks, milk puddings, cag custard, junket and cream. Break. fast, dinner, and tea-suppier should comprise his meal-times, and every effort should be made to maintain the morning and afternoon sleep and undisturhed nights for both mother and child.

Naplins are essential for a hahy's comfort. Less than two dozen will mean that they will

Baby. Hamper basket in wicker with tray in which to keep the toilet requisites trensure Cot Co., Lidd.
never be properly washod, liniled and aired, and three dozen is the number recommended. The most useful size is 22 in. square after the hems thave lieen turned. Suitable material is butter muslin, made of four thicknesses stitched together; or old soft sheeting torn into squares and nently hemmed.

Never allow a haby's legs to be cramped and deformed by the bulk of the napkins he wears. The better way is to use one at a time folded in a triangle, and over that a second square of Hannel called pilch. Some woolly jackets and a warm shawl complete the necessitics of the infant's wardrobe.

A small down pillow is required, and is not so expensive if the down is bought by weight and enclosed in a strong ease of calico or jaconet; also a piece of mackintosh to cover the hair mattress. It is economical and healthy to have another mattress on top filled with chaff, an old piece of blanket to cover that, and two new blankets, also an ciderdown. In choosing the hlankets remember that they may the required for a larger crib later, and also they must serve their turn in the perambulator.

It is handy to have a special hasket to hold his immediate requirements, and there are varieties to suit nost purses. In the basket the expectant mother should place in rendiness the following articles

One slanl; one nightgown; one long flannel one vest or wonlly sliirt; onc llannel tinder $z$ yd long and about 5 ill . wide ; $\frac{1}{\frac{1}{2}}$ dozen napking: one Hanmel pileh; one soft towel; one old slinivl or hlanket; IInen thread: one bov or string of safety pins: one tin of starcli. \%ine, and boracic powderone cake of super-fatted sonp one small tube of vasellice; a case containing necdies and white cot ton, for atitching the first. binders; thimble and aliarp, square-pointed ecisanis; a packet of white absorbent wool; a small linttle of puie olive oil: a soit linirbrush; a soft rubber lot-water bottle to ke the ent warm in readincas to receive the baliy.
Elaborate roles of any kind are not to be encouraged, but pretticr day gowns are easily managed by the addition of a little fine lace or, embroidery. Ba bies are rarely dressed in long rohes nowadays. Decp embroidery Houncing makes a dainty gown for any baby. There is a machine-made Shetland wool which is ideal for making a haby's layette. It is light in weight, easy to wash and wears well. A soft silk bonnet is less heating than one made of wool, and will licep the baby's ears in good position when he is sleeping out in his pram. The following list sumnarises a baby's accessories :
Thice day gowns (5\} yds of nuineook) ; three niphitgonvis ( 6 yils. of llanncl); three day flamnels (t vda.); three night Hannels (4 yds.) ; four soft Turkish towels: two innnnel pilches or spuares (is yds) ; two shawla (1 large, I gmall); \& yol. flannel, 27 in . wide. for linders; two knitted wool jackets; four long aleeve vests or shirts; onc flannel apron ( $2 f$ ! vas.) ; one macklntosh apron (if required by mother).

There are various types of fitted baskcts. A hamper basket is made of strong wicker or cane with side handles, the lid fastening with a rod which runs through cane loops and can be padlocked if necessary. It frequently lias fitted castors, which run easily over the floor. On removing the tray there is a deep recess for the baby's clothes. It can be linerl and trimmed to suit the colour scheme chosen for the cot curtains and any other decorations in the night nursery.

The tray has a pincushion attached, and two pockets for brush and comb and powderbox. Clean clothes can be kept in the lower plart of the hasket; those actually in use remain on the tray when discarded night or morning. This form of hasket is dustproof when closed and handy for travelling.

A table basket, trimmed and fitted, is easily carried from place to place and will rest on
any table. It is leas expensive and also makes a uscful work-basket. One of this typo has been successfully made out of a white chip basket, without a handle, used for

Baby Chair. Adjustable chair with play table attached. It can be raised to a higb position
picking fruit in the strawherry fields. The basket is wide and shallow and can he covered daintily with a length of white muslin.
BABY CHAIR. For sitting at table, a Jaby chnir needs to be high, but it should preferably lie low for play.

Baby chaire are often litted with a bar or board in front of the arms, and this must be easily removable. A footboard is generally provided, and in some chairs this is adjustable for height. In the folding chair illustrated the logs are hinged so that the lower part can be turned up the reverse way, the tray at the base serving as $\pi$ table as shown. It is provided with wheels, which allow it to be pushed ahout when in its low position.

Parts of chairs likely

to need repairing are, first, the rails or horizontal rocls which unite the legs. Often these rre plain parallel rods of small diameter, andif broken a new one must be put in, for a strong repair of the old one is difficult If it is turned to an ornamental pattern not ensily matched, a repair inny be attempted by glaing the broken place, and perhaps screwing astrip of metal heneath to assist in holding the parts together.

Often a rail becomes boose without breaking, and when this happens other rails soon go the same way and legs become rickety. The ends of rails are glued into hored holes, as in Fig. 1. If they come out it is generally sufficient to glue them in again, but the parts inust fit properly, and must be forced right home into their original positions. If the gluing does not seem satisfactory, a finc wire nail with small head can be inserted, as in Fig. 2, either crosswise or endivis. The latter is shown dotted. In some cases screws may be better than nails.

Next in importance to leg and rail joints are brealinges like that in Fig. :3, where a portion is split offi allat picce of board. Here also it is stronger to repair with nails, rather than trust to ghue, as is shown in the dotted lines on the diagram.

EABY WALKER. This well-known devics is easily made at home. Fig 1 is $\pi$ sketch showing how the child supports itself whilst learning to walk, the easy running castors fixed at the hottom allowing the frame to be rearlily pushed across the floor. The simplest way to nake the top and bottom rings at home is to cut roughly with a bow-saw a number of pieces of wood to the required
segments, and glue them up as shown at Fig. 2. The scgments should he cut out of $\frac{1}{2}$ in. wool, and a few screws may be put through the timber so ns to hold them tomether and assist the allhesion of the glue. The rings may then be worked up. Another method is to build an octagon, Fig. $: 3$. hy the use of lialving jointa
Fig. 4 shows a method of using square frames A frame lo in. aquore is made by halving joints. as shown in the inset diagram; simila!ly a 24 in . square is made for the bnttom. Thes frames are carefully bored at the correct angle. so as to receive four broom-handles, as shown. At each end of the circular uprights a saw-kerf is cut, nnd after gluing the ends and inserting them through the frames a small wedge is glued and knocked into the saw-kerf to secure them. After putting the work together round off all sharp edges. See Nursery.

BACHELOR FLAT. Bachicior flats in Westminster or other nxpenaive residential districte in London undertake to provide full service, including that of a valet, while meals are charged at fixed prices and, if a restaurant is attached to, the block, served there or brought to the flats. Accommodation includes a bathroom and either one room with sometimes an alcove for the bed curtained off, or a bedroom and sitting-ronm.

Many bachelor men and women aremanable to afford suites of this kin:l, but must simplify domestic arrangements so that they occupy the minimum of attention. In some cases wherc houses have been converted into single llats, with use of hathroom on each floor, cleaning service is provided but no cooking. In others no such arrangentent can be mado on the premises, and a charwoman may bo employed to clean, and, where there is a kitchenette, sometimes returns in the evening to prepare dinner.
Where only one room without service can be afforded, simple labour-saving devices should be installed where possible, and the idea of a bedroom should be renote cluring the day time. Comfort is essential to the worker. hut all unnecessary ornaments and draperies should be discarded. Colour schemes create beauty with simplicity of detail and thus reduce the cleaning problem.

Parquet floors with rugs or small carpet squares are idenl, but, failing thesc. unless the boards are good. linoleum, which can be easily

Baty Walker. Fir. 1 $\begin{array}{ll}\text { Circular } \\ \text { castors. } & \begin{array}{l}\text { irame } \\ \text { Figs. }\end{array} \\ \text { 2-4, }\end{array}$ Working diakrams.
polished, is more satisfactory than mere staining. A vacuum cleaner is a practical help, but a carpet sweeper will serve. A corner cupboard fitted as wardrobe utilises space, the bureau or chest-of-drawers on legs and the long mirror can all fit into a sittingroom schemc. A divan lounge with separatc maitress, ind under the padded spiral spring ${ }_{3}$
a box for linen, is a suitable berl. The eiderdown rolls up into a case and forms a bolster cushion by day, and a fitted loose cover concenls all bedclothes. Sinall dressing tables can be obtained, which open out to diaclose the toilet articles, but when shut look like an ordinary table. Unless accommodation provides a kitchenette or cupboard large enough to contain sink and small gas cooker and fitted with shelves for crockery and cooking utensils, the most convenient combination cooking and heating arrangement is a gas fire with a concealed boiling ring on top and a flap that lets down for grilling and reveals a small oven, logether with a separate gas ring alongside for a kettle.

A gate-legged folding table for meals, and shelves fitter below window seats, for which cushions can be made to measure, are space savers. While it may be possible to make arrangements with the caretaker to receive parcels, it is desirable to provide a store cupboard so that catering emergencies can be met. The tenant may have little time available when shops are open to do marketing. See Bed-Sitting-room.

## BACHELOR'S BUTTON.

 The name is locally applied to two distinct varieties of Howers. One is a form of the species of buttercup known as Ranunculus acris. which produces yellow Howers. It thrives in ordinary border gammon-buard is marked with a series of soil. The other is a variety of Ranuncu- 12 points at each end The points are lus aconitifolius which bears double white alternately coloured black and red, and each Howers: this plant, which is known also as player has six points on each side of his board Fair Maids of France, likes moist soil and To begin play the boand is placed between Hourishes by the waterside.BACKACHE. This

Bachelor's Button, the garden Ranunculus Sutton \& Sonx

Bachelor Flat. Cupboard in sittingroom fitted with tap, sink and hooks for cooking atensils

BACK FIRE. The expression is loosely applied to two entirely distinct troubles with petrol motors. One is the explosion of an unburnt charge of gas in the silencer, generally caused by improper adjustment of the car buretter, or partial failure of the ignition system. The other trouble is premature ignition usually when starting ihe engine. It may be due to imperfect valve setting or faulty carburation, but it is more frequently caused by too greatly advanced ignition. This causes the explosion of the gas in the engine before the piston has passed the top of its stroke ; hence it is driven violently downwards, and the engine then revolves backwards for a few turns.

The remedies are to retard the ignition. test the valve timing, correct if necessary. and overhaul and adjust the carburetter.

A praclical safeguard in starting up any petrol engine is to grasp the starting handle. belween the fingers and palm only-keep the thumb out of the way-as illustrated.

See Carburetter: Motor Car: Motor Cycle.

BACKGAMMON Backgammon, or tric-trac, is a game for two persons. It requires a special board and 30) draughtsmen, 15 white and 15 black or red. The board usually consists of two inged together. The backmay be part of a general condition, may be duc to a local cause, or may have its origin in one of the internal organs. Influenza and smallpox frequently commence with a severe backache, and it is found in anaemia, hysteria, and neurasthenia. Examples of the local cause are backache from lumbago, stiffncss from overexercise, chill or weakness. Bright's disease, gall-stones, and various feminine ailments are instances of pain referred from an internal organ. Pain between tho shoulder-blades occurs in Hatulence, and pain at the botton of the spinc is common in piles

Where the pain is due to muscular stiffness or lumbago, the surest relief is given by rest in bed with warmth applied to the back either by hot-water bags or a inustand plaster, and later the rubbing in of a soap liniment or other embrocation.

Some peaple find comfort in a menthol or a belladonna plaster. Internally 10 grains of aspirin will be useful. In backache due to other causes the application of a hot bag may give easc. See Bright's Discase: Lambago.

Back Axle. See Live Axle.

Backrammon-board with letters indicating the compartments and their respective points, and
the players, so that the points lie in the same direction as the players' face. One compart. ment of the bacligammon-bmard is known as the outer table, and the other as the inner or home table. These tables are not fixed by name, but depend upon the position of the men when the game starts. The figure shows the arrangement of the men at commencement of play, the right-hand compartment $\mathbf{B}$ B' in the figure being the inner or home table, and the left-hand $A A^{\prime}$ the outer table. $A^{\prime} B^{\prime}$ are the outer and inner tablos of one player, A B of the other player.

The hinged division $\mathrm{C}^{\prime} \mathrm{C}^{\prime}$ is known as the bar. The points in the inner table are known by special names. The points D D'are called the ace points, $E E^{\prime}$ the two or dence points, F F ${ }^{\prime}$ the three or trois points, $\mathrm{G} \mathrm{G}^{\prime}$ the four or quatre points, $\mathrm{H}^{\prime}$ ' the five or cinque points, and $\mathrm{J}^{\prime} \mathrm{J}^{\prime}$ the six points In the outer table the order of the points is reversed, $\mathrm{K} \mathrm{K}^{\prime}$ being the
acc (or more often the har) points, $L L$ the deuce points, $M$ M the trois points, $N$ N the quatre points, 00 the cinque points, and P P the six points.

With each backgammon-hoard two diceboxes and a pair of dice for each player should be provided After the men have been arranged as in the figure, the right of tirst move is settled by the throw of the dice, the higher throw giving that player the choice of play. The first player then throws two dice, and the two un mbers he throws decide his move. The object of his game is to get all his men into his own inner table, and to play them out ngain before his opponent is able to succeed in attaining a similar object.

Suppose the
 player throws trois deuce. This entitles him to move one man threc points onward and another two points, or to move one man five points. Double the usual number of moves is allowed when doublets are thrown. If two fours are thrown, for example, 16 moves are allowel instead of eight, which would have followed a throw of cinque trois, for example, or six rleuce.
The actual ability to move certain pieces depends upon the position of the opponent's pieces. A piece can only be moved to a vacant point, to a point occupied by thic player's own pieces, or to a point occupied by one only of his opponent's pieces. When a player has two pieces on a point he lias made that point, and the preventa such pieces being captured, and impedes his opponent's progress, which is one of the important ubjects of the game.

A single piece on a point is known as a blot. If such a piece is legitimately in the way of a player's move after a throw, it is removed and placed on the bar, and has to begin its move over again from his opponent's inner tuble. A further restriction on the moving of such a piece is that it cannot begin its journey again until its player actually throws a number corresponding with a vacant point or blot on the table. Until such a throw is made, too, none of his other pieces may be moved. When all the points of the home table are completely occupied by two or more pieces, that man's play is suspended until one or mone points of the home toble are available for play Of course, it many occur that a player is unable to play the full amount of his throw because of points being occupied, and in that case he loses that part of his throw. When he can play, however, he must do so.
A player, having succeeded in getting all his pieces into his home table, begins to remove them from the board, or bear them of. At this stage of the game each throw of the dice enables a player cither to advance his pieces accoorling to his throw, or remove one from

Backrammon. How a player bering to bear of his men alter retting them into his home tabla Courteny of Selfridue \& Co., Ltd.
the board He can only remove one, however, if his throw specifically allows it.

Suppose, as in Fig. 2, the player has three pieces on six point, none on cinque, four on quatre, four on trois, none on dence and four on ace point. Then, if he throws six trois, for example, for the six ho may either remove a piece from the six point or advance a man from the quatie point to the cinque point. And so in tho case of trois, he may remove a piece or advance it to the quatre point. But if he throws cinque trois he must play forward because he has no piece on cinque If he throws such numbers as are not occupied by pieces, then he is entitled to bear off a piece from the highest occupied point. The direction of movement of play of each player is from the nce point in his opponent's home table towards the ace in his own.

The game is won by the player who first succeeds in removing all his picces from the board. The value of game to the winner depends on the stage which has been reached by the loscr. The game of the winner is called a hit if his opponent has managed to get all his own oieces into his home table and has begun to bear off. Whien the winner has borne off all his pieces before his opponent has started to do so the game is called gammon, and if he succeeds in bearing off all his pieces while his opponent has still one or more pieces on the bar or in the winner's home table the game is called backgamnon For a gammon and hackigammon, double, treble, or other incrensed stakes are puid.

## Throws for Bexinning a Game

Wlien a fresh game is played tho winner of a hit starts, but he throw's a die against his opponent for the right to start if he wins gammon or backganmon. The movements of the pieces at the heginning of a pame are to a large extent standardised. The movements for every kind of throw are here quoted from Hoyle's Games Moderniscll
tors. (The hest possible throw at starting.) Play two men on the bar point, and two on the elique.
Droce: Ade. For a hit, plav the dence from the five men in your advernarys oirter able, nd the nce play the ace from the alx to the ace point ln your plan tuble

Dreces For a hit, play two from thic six to the quatre pkint in your own table and the other two iroun the ace to the trois point in your opponent's iuner table For a ganimon, play the second palr inem thic five men in lisis outcr tuble.
Tross Ace. Make your cingue point
Trois Drouce The appinved play is to carry two men from the five in sour advenary's outer table to the quatre and cincfue points in your own
outer tuble. This, of courac makea tivo blots To avoid this, Rotne, for a hit, play one man from the sume point to the delice point in the above-nientioned table, but holder play is better.
Double Trois. There are three ways of playing thla throw. Some players make the bar point Thie toore usuul play in, for al bit, to play two to the cinglle point in the plajer's own, and the other Two to the quatre point in the ndversary's table For "ummmon, play the last two from the vix to the trois polut in your own table.
QOATRE AOE. Play the quatre from the five men In your opponent's outer tulile, and the nee froun 1.1 is nce point.

Qdatre Dedof. Make your quatre point
QUatre Trois. Play two men from the five in your adversary's outer table.
Dotule Qdatre Play fiwo uen from the aec to the cinque point in thie adversirys linner tiible, und tivo from the five in hils outer tuble. For a gunmon, play two men only, fron the point lust inentloned to the cingue point in your own tuble
CinQte ACE. Play the cincuiue from the floc wen in your adversars' ${ }^{\prime}$ outer tahle and the nce frou the nec point In his inner inble. For "qummon, play the nec from the sls to thic cinque point !n your owil table
Cinque Deioce, Play both men from the five in your allversary's outer table

Cinqur Trois Make your tmols point
Cinque: Quatrr Move one man from your adversary's ace point to the trois point in his outer tible.

Dodrle: Cinqur. Catry two men frin the flve point.
Six Aof. Mukc your bar molnt.

Six Deros Move a man from the five in your ndversary's outer table to the cinque point in your own tnble
Six Trois, Gin Quatre, Six Cinqup Carry one mun from your adversary's ncc point as far ns the thmow will permit.
Sines. Place tiro men on your adverampys bar point, and two on your own
Of the above throws (at the outset of the game), double aces are reckoned the best and double sixes next best Double trois comes third, followed by trois ace and six ace.
Modern Developments. A variation called chouette has heen introduced in order to fit the game for more than two persons Any number may play up to five or six. The player who throws the highest die is said to sit "in the box" or play la chouette. The others combine against him and the one who throws the second highest die acts as their lealer, or as the active oppronent. He consults with the other players a hout playing, douhling
and accepting or rejecting doubles but in case of a difference of opinion lias the deciding voice If the man "in the hox" wins the game he continues therein and the other players move up one, the one who threw the third highest die lesoming the active opponent If he loses he becomes the junior of the opponents and the one who beats him takes his place "in the box." When he wins he collects the stakes from each of the other players and when he loses he pays to each
The popularity of the game has also been increased by the system of cloubling. An automatic double occurs when two players throw the same number; in this case they throw again and the stakes are doubled A player may also declare his intention of doubling before ho throws the dice. His opponent or opponents may accept or decline the louble: if the latter the game stops

## BaCON: THE CUTS AND THEIR COOKING

How to Choose and Prepare it for the Table

## Separate Kecipes follow, and related information will be found under Ham; Pig, etc

The thesh of the pig when cured, salted, or of hacon. Turn frequently and cook gently so otherwise treated comes from all parts of the that the lean is tender, but never let the fat world. Wiltshire bacon, sold under that name, is from Wiltshire, but Wiltshire Cut on a label may refer merely to curing after the method of that district. There are four principal cuts -back, gammon, collar, and Bath chaps, or cheeks The back is divided into best cut or loin, best streaky and Hlank. The best cut is favoured for brealiast rashers, though streaky parts are excellent. The Hank is good for baking and boiling.

The gammon is divided into threo cuts: "pper, middle, and bone end or hock. The upper part makes a substantial joint for boiling, the middle is excellent for thick rashers to fry ur grill. These are suitablefor lunch. The hock is useful for boiling, and with ycllow split peas the stock makes good pea soup.
Boiled Bacen. Bath chaps aro generally bought ready boiled and served cold. Prime or small back, gammon, corner and collar are all good boiliing cuts for serving hot with chicken, turkey, etc., or as a cold breakfast dish.

Put the bacon after washing it into $\Omega$ 'saucepun of cold water to cover it. Bring gradually to boiling point. skin well and simmer until it is very thoroughly cooked. For one pound allow an hour, and an extra half hour for each pound after that weight. When cooked, peel off the skin, which should come away quite easily, and dust thickly with browned crumbs. The liquor in which the bacon was cooked must be thoroughly skimmed when cold and the fat put into a basin. Then pour boiling water over it, and let it stand. The cake of fat that rises to the top can be used for making pastry.
Fried Bacon. In a clean, heated frying-pan lay slices

Bacon. Side marked off to show the Thick A. Fore hock. 1 . Collar. E . Thin streaky. F. Long loin. G. Flank. H. Glmmon hock. J. Corner gammon
become so hot that a smoke rises from it, or its value as bacon dripping is lost. When cooked, the fat should be tinged with brown and slightly crisp, but not chippy.

Toasted rashers are cooked either on a fork over a baking-tin in a Dutch oven before the fire, or can be grilled on a tin under a gas toaster. In cach case tho slices must be turned. Thin, trimmed rashers can be rolled to garnish chicken, veal, etc. Thread them on a skewer, running it through each and pushing them closely together to keep them rolled Lay the skewer on a tin in the oven till the bacon is delicately crisped and browned. then draw out the skewer.

For baked bucon, take a piece of flank or any streatiy cut and score the rind across with a sharp knife. Make the oven very hot and put the bacon in a baking-tin When the rind has become crisp reduce the oven heat and cook gently to avoid excessive shrinking, allowing 20 min . to the lb . It should be served cold for breakfast

Bacon Dishes. Eronch beans first boiled till tender, then fried in bacon fat with two sliced peeled tomatoes and served with rashers, are a change for breakfust. Bacout with cabbage is a favourite Welsh dish, being savoury for lunch or supper, as well as nutritious. Trim, wash carefully, and boil quickly about 21 b . of spring cabbage. Then drain off the water, pressing the greens well and chop. Trim and cut $\frac{1}{2} \mathrm{lb}$. of bacon into largish cubes, and fry till orisp and lightly browned. Keep the bacon hot, and into the fat from it stir the cabbage, and a sensoning of salt and pepper. Add the bacon, mix and heat well, and pile on a hot dish. Garnish with fried bread. Shake over two tablespoonfuls of grated cheese. Heat in a quick oven till cheese is
browned and serve. This quantity will be found sufficient for about four persons

Bacon with macaroni is a useful dish for brealifast or supper Break $6 \mathbf{o z}$ of macaroni into short lengths, ahout an inch long. Put into a saucepan with plenty of boiling water, salted, and boil until quite tender. Meantime tim and cut the bacon into cubes. Fry till lightly browned, and add the strained macaroni, one large peeled, sliced tomato and a careful seasoning Heat all these very thoroughly, serve them piled in a hot dish, with crisp lingers of toast. This is sufficient for about four or five persons

A good supper dish can be made from bacon and checse Toast on one side only as many slices of bread as there are persons to be served. Butter the side that has not been toasted and cover thickly with shredded checse, pepper, salt, and a little marle mustard. Lay on top of this two rashers of bacon and place in a moderate oven to cook slowly.

Bacon Curlng, This is only undertaken safely in the cold months of the year from November to March. The first point in home curing must be to obtain a stone cold side of best fed pork

Salt, sugar, and saltpetre are the usual ingredients employed in the cure, the lirst two being antiscptic, and the third bringing out the line, rich, colour of gond bacon. The sides can be cured cither by the dry-snlt process or the picklc proccss. The former commonces with a vigorous rubbing of salt, repeated several days in succession, and then the side is left with a thin covering of salt, followed by a light sprinkling of saltpetre and granulated sugar. In 10 days from the last rubbing in, the salt, etc., may lie remored and the side hung up in a cold, dry place. For protection from dust and other contam ination it slould he enveloped in a thin butter muslin covering
Tu ensure adequate curing, the thicker parts, such as the gammon and the fore end, should be injected with brine by an ordinary pickle pump. A gond pickle for this purpose is comprosed of 1 lb . of saltpetre. 1 lb . of

Demerara sugar, 11 ll of salt, and 4 gallons of water. This same pickle is suflicient for curing by the wet process. which is done by immersing the side, or parts, in the pickle and keeping it for 10 days $_{\text {c }}$ covered with the brine The result of this cure, either by the dry or the wet process, is known as green bacon. For added Havour the bacon can be smoked by being anspended in n square stone cubicle, with an opening at the top to lot out the smoke, the floor heing covered with peat and set alight, and the bacon kept thicrein from 36 to 40 hours.

BACON CUTTER. A bncon cutter suited to domestic needs consists essentially of a strong base, gonerally of cast-iron, heavily enamelled. Mounted upon an upright is a circular steel knife or cutter rotatable by a crank handle and gearing.

A tray or carriage provided with a safety guard is pushed along on guides on the hase, and carries the bacon or other food to be cut into slices, means being provided to adjust their thickness In operation the crank is turned with the right hand. the left holds the bacon on the carriage, which is pushed past the revolving linife, a nd a slice is cut off, the process being repeated as often os required. T'he same machine may alen be used to cut bread

## Bacteria. See Microbes.

BADGER BRUSH. For shaving, tooth and painter's brushes badger hair is used on nccount of its softness. It is grey on the end with a black portion under, the lower portion being of a creamy sliade. Being an expensive article, it is widely imitated, e.g. by dyeing hog and similar bristles. The real hair is fine, silky to the touch, straight and springy. A badger-hair shaving brush will wear right down to the stump and still remain soft and springy.

Painter's brushes must be cleaned directly after use. They should be washed in warm water with a little washing soda and rinsed in clean water. If used with vamish or varnish paint, this shonld be dissolved with turpentine before washing. See Brush; Shaving.

Bacon: principal cnts. 1. Gammon. 2. Gammon Rock. 3. Fore end. 4. Thick streaky. 5. Fore. bock. 6. Flank. 7. Thin streaky. 8. Corner gammon. 8. Long loin. 10. Back and ribs

BADMINTON : How to Play it. Nlthough played as an indoor anme, hadminton can be played on lawns which are neither large enough nor good cnough for lawn tonnis and it can be enjoyed by people of all nges.

The strokes are not unlike those in lawn tennis, but a shuttle takes the place of the ball. The shuttle is in play from the time that it is hit by the racket until it touclies the ground or the person or dress of any player, or until a fault or let occurs, this period being known as a rally. There is no first bound as in lawn tennis and the service may not be overhand. The shuttle, at the instant of being struck, must not be higher than the server's waist. Most players hold the shuttle loosely close to the cork part, and the object is to hit the shuttle in such a way as to make it diflicult for an opponent to return it.

## Scoring at Badminton

The scoring is adapted from that used in rackets. In the doubles, when one pair of players opposes another pair, and in the nien's singles, when there is one player on each side, the game usually consists of 15 aces. When the score happens to reach 13 all, the side "hich has first arrived at 13 has the option of setting the game to 5 . In other words, the side mny. and generally does, elect that the game shall continue until onc side or the other has won five adrlitional aces.
In the same way, when the score is 14 all. the side which has reached 14 first has the option of setting the game to three. In cither case, when the game is set, the score is called love-all, and the side which first scores $\bar{j}$ in the first instance or 3 in the second, wins the game. Generally in ladies' singles the gainc consists of 11 aces. Here agnin the game may be sct at 9 all to 5 , and at 10 all to 3 . Thie match is decided by the best of three games, which is the rubber.
In badminton, as in rackets, a side (or in singles a player) is either in or out. The scoring can only be done by the in side; the business of the out side is to put the other side out. In the doubles the side ( $A$ and $B$ ) which begins the game has only one liand in its first innings. Thus when A is put out, B does not serve, and the service gocs to the other side ( $C$ and D). But after 1) is put out the turn of the other pair comes, and so on to the end. The service is delivered alternately from cach half court into the half court diagonally opposite. After the service the players can take inp positions where they please till the rally is ended.

The diagrams show that the court for singles is as long as that for doubles, but not quite as wide. For convenience both courts are generally marked out in one, the dotted lines in the diagram of the doubles showing where the singles court comes.

## Bags and How to Make Their

## Some Atiractive New Ideas tor the Needlewoman

For details of Mcthnds employed sce Applique: Beadwork; Embroidery; Tapestry and for Bags in other Materials see Leather: Raffia, ere.

A shopping bag is shown in Fig. I. It may II there is no liandle to the frame, to make be of American cloth, hessian, or striped can- one cut a strip off the width of the material vas. It should be lined through with cretonne $1 \frac{1}{2} \mathrm{in}$. wide, fold double, and stitch along for or similar fabric to give extra strength, and requires $\frac{1}{2}$ yard of 24 -in. wide material, with the same quantity of another fabric for lining. Take the material for the outside, and out a 3 -in. wide strip from one of the cut edges, not the selvedges ; then cut this strip in half, to obtain two strips 3 in . wide and 12 in . long.

Bag. Fig. 1. Simple shopping bag. Fig. 2. How it
Cut a $V$-shaped piece out from onc end of each of the two strips, as in left-hand side of Fig. 2. Fold each strip lengthwise down the centre, and sew the edges of the $V$-shaped opening together. Now fold the larger piece of material to bring the selvedges together, as in Fig. 2, with right side inside. Join the long edges of the folded strips to the side edges of the larger piecc (Fig. 2) so that the narrow strips are sandwiched between the two layers; then turn the bag right side out.
Dlake up the lining in the same way, and slip it inside the bag with seam turnings

lacing, turn top edges in to meet, and oversew along with embroidery silk, a fine coloured twine, wool or raffia, finishing the remaining edges with decorative oversewing to match. Next cut small holes within the top edges to take handlea, and oversew or buttonhole the edges round for strength: then add handles of cord, or strips of material doubled and stitched along. Hand embroidery or appliqué work can be added as a decoration.

Frame-mounted Bags. Handbags of silk and other materials, mounted into a frame of ivory, tortoiseshell, or an imitation of either, or of metal, with chain handle, or one made of the material can be easily worked at home, frames being purchased. These are made with sows of tiny holes through which the bag is sewn on. The bags are lined and may be supplied with pockets to contain powder pulf or mirror, while the top of the lining is finished off with a narrow ruching, galon, or silk lloral trimming.

Details for making such a bag are shown in Figs. 3-5. The mount or frame illustrated measures about $6 \frac{1}{2} \mathrm{in}$. in width ; $\frac{1}{2}$ yd. of 18 in . wide silk for the outside of the bag is required, and also $\frac{1}{2} \mathrm{yd}$ of 18 in . wide silk for the lining.
strength.
Begin by taking the silk for the outside of cutting off the two top sets of corners to form a circle. Now turn in the edge of the silk circle to the wrong side and run in a gathering thread, leaving long ends of cotton. Open out the frame or mount to its full extent, so that it will lic flat on the table as in a circle, and measure all round the inside edge of the frame where the tiny holes are. Then draw up the gathering thread along the silk edges to make them the same size as the mount. New the bag into the mount, working from the inside, according to the pattern sketched in Fig. 3.
Pass the needle through the edge of the hag and through one of the holes to the outside; then carry the needle below the frame edge, and push it through the silk to the inside again, then pasaing on to the next hole. Take the silk for the lining, and from it cut a strip mensuring about 17 in . long (an inch less than the length of the bag ailk) and ahout $8 \frac{1}{2} \mathrm{in}$. wide; that is, 2 in . more than the width of the frame. Fold this strip in halves with the right side inside and curve off the top corners slightly. Then seam up the sides as far as the commencement of the curves.

A pocket for holding a small mirror and comb, and made of a square of material, hemmed at the top and having an elastic runthrough hem, can he stitched to one side of the lining before it is seamed up, as suggested in Fig. 4.

Turn in the curved topedges of the lining and gather up lightly, then slip then inside the bag, and hem them to the top of the latter. Furlly, add a strip of Horal trimming, or ruching wit the edges. Ruching is made by cutting on the ress a long strip of the lining silk, about $1 \frac{1}{2} \mathrm{in}$. wide, folding it over with the wrong side outside and running it along as though for an ordinary rouleau. Turn inside out with the aid of a small safety pin, and with sewing silk to match, run it in a zig-zag line from side to side, as shown in Fig. 5. When th's gathering thread is drawn up, a pretty $t$. mming is the result. This can be sewn to thie bag along the gathering thread, which should now run in a straight line down the middle

Bag. Fig. 6. Brocade bar mounted upon a silver frame and baving a bandle of covered cord

Flat shaped bags on stit, one-piece torloise shell or wooden mounts show off embroidery or make up well in heavier materials such as tapestry, tweed or moiré To make such a bag in brown moire silk, with shell mount and lining of moiré to tone, cut two pieces of moiré, one for cover and one for lining, 9 in . wide and 14 in. long: fold in half, making depth of bag 7 in . Join up the side seams and slip tlie lining into the bag, oversewing together at top; attach a small square tab on one side, made of double moiré. Turn in corners, fit into frame and finish off lining with a narrow gold galon.

An effective way of using strips of embroi dery with a right-angled silver frame and cord-padded handle is shown in Fig 6.

Bag. Fig. 7. Silk bag gathered on to a yoke plece the top of which is sewn to a gilt frame
A variation of the framed bag has a yoke piece as in Fig. 7. A paper pattern can be out to desired size from the diagram (Fig. 8). It requires a gilt frame, $\ddagger$ yd. black silk, nnd the same amount of lining sill, and may be embroidered on one side. Cut a strip of onvering and lining silk, each 23 in . long and 2 in. wide. The yoke part must be stretched Hat. Join the two main parts of bag to edge of $23-\mathrm{in}$. strip, letting in piping cord
covered with black silk (the lining requires no piping) Turn up the scal loped edge of yoke pieces and sew over a strip of cord. Fix lining to yoke and invisibly sew to gathered lower part. Sew top edge to frame and cover stitcheswith narrow bead trim. ming.

Bag. Fi: 8. Diagram with details for making the
Pochettes. Two pieces of material, for lining and for cover, gach mensuring 18 in by 9 in . and folded in thres: re needed for a simple pochetto bag. If to be embroidered, trace the pattern on the first 6 in. of cover and press before making up.

Interline with buckram to stiffen before folding the bag into three and oversewing the two sides. Such pochettes are uscful for evening bags, but not for hard wear. They may be fastened by press studs concealed under the Hap or by a jewelled button and tinsel cord.

For a more practical pochette side gussets are requircd. Fig. 9 could be carried out in heavy corded silk and lined and trimmed with the same in contrasting shade. The trimming has been edged with tinsel thread (six rows) and couched on to the flap. Cut cover and lining, as shown in Fig. 10, to measure 9 in . by 20 in ., also a piece of buckram $t$ in. smaller all round; draw and cut a paper pattern of the trimming, three times size of diagram, lay
on material and out out (soe diagram). Having marked position, tack neatly and sew the trimming to lasg, preasing afterwards with a slightly warmed iron on the wrong side of material. Tack cover to buckram, turning

Bag. Fig. y. Pochette in heavy corded slyx with as appliqué trimmlnz ontlined with tinsel thread
edges $0^{\text {i }}$ inaterial over the buckram so that the trimming comes on edge of bag. Then slipstitch lining to cover. Cut the gusacts in covering and lining ailks, turn in the edges and st itch together. Fold the bag and neatly sow in gussets. Such a shape lends itself to n variety of trimmings; a central appliqué ornament may be used, a mono. gram, or the whole thap may be gaily embroidered: or it may be cut out incan
 envelope shape and made of brocade.

BAGATELLE : How to Play. The baya telle board or table is usually from $\mathbf{0}$ to 10 ft . long, and from $1 \frac{1}{2}$ to 3 ft . wide. It is made to fold up, can be placed on a table for play, is of wood covered with green oloth, and the sides are cushioned with rubber. When open the top is in the form of a semicircle, and let into the surface are nine rounded holes or cups, each the size of the nine halls used.

Thesc holes are numbered

1 to 9 . Some tahles have pockets in addition to holes, hut with these the game is more akin to billiards.

The players, using a cue on the model of an ordinary cue, play from the end of the table op posite to the holes. Each player in turn takes eight balls, 4 white and 4 red, while a ninth, a black one, is placed on a spot in front of the holes. His object is to drive the bylls one by one into the holes, but before scoring he must hit the black ball.
The scores count according to the holes into which the balls are sent, save that the black ball counts double. A player will aim at driving all the balls into holes, reserving the black ball for the one marked 9 . The game is usually for an agreed
Bagatelle Board number of points, and
most boards have holes and pegs at the sides by which the marks can be reconded If the game is played by more than two persons, side will be chosen and members of each will play alternately

A number of other gnmes can be played on the bagatelle table. One is the cannon game, n which only three halls ame used, as at hilliards, by two players. 'Two of them are placed in position, the black on the spot and the white bet ween holes 1 and 9 . The striker plays with the third hall, and to score must cannon before driving a ball into $n$ hole. If he drives one without cannoning the score counts to his adversary. Two is scored for a cannon, while points go to the other side if the balls are mised. As in billiards, he con linnes to play until he fails to score. For this game there is a special table without holes
BAKED JAM PUDDING. Take 1 breakfastcupfuls breadorumbs and pour over half a pint hot milk to which has been added $1 \frac{1}{2}$ on. margarine or butter. Sweeten with 2 tablespoonfuls sugar, Havour with a few drops vanilla essence, and add the beaten yook of an egg, and hake in a moderate oven. Then add the white beaten up with sugar and spread on the top over a thick layer of jam The pudding must then be put back in the oven for the white of egg to brown Serve sprinkled with tine sugar

BAKELITE. This is a synthetic resin formed from phenol and formaldehyde. It is infusible, resists acids and solvents, and has great strength as a dielectric. For use ly manufacturers it is supplied in a form allowing of fusion, but after heating to a certain temperature the material solidifies, hardens, and thereafter resists fusion.

Bakelite is readily moulded into intricate forms, and is extensively employed for switches, plugs and other electrical apparatus, as well as for houschold utensils, being practically unbreakable.
BAKEWELL PUDDING. For serving either hot or cold, this is a convenient sweet To make it, line a pie-dish with ordinary short crust. On top of the crust sprend a layer of jam, and fill in remainder of dish with the following mixture. Cream togethar 2 oz each butter and castor sugar, and add to this a beaten-uplegg and 2 oz . ground almonds, with a little alinond essence. Beat well and put in the pie-dish on top of the jam. Then bake the pudding in a quick oven until thoroughly browned. Sufficient for 6 or 7 persons

BAKING AND ITS UTENSILS. While a roast of ment is cooking in its later stages, baked puddings, scones, buns and short-crust pastrv needing the same heat may share the

uven; but puff pastry, which requires a very hot and dry oven, would be apoiled if cooked in the same oven as meat. Bread requires to bake in a moderate oven. Joints of meat should first be placed in a very hot oven to seal up the surface and
prevent tou nuch of the juice cacaping. When the meat is well browned the heat can be mod erated. Nilk puddinga without eggs should at first be placed in a hot oven to bring near boiling point, then allowed to cook slowly. Eggs may be stirred in at this atage. Custard pudding, or any pudding containing eggs, requires a morlerate oven.

To bake a cake well is one of the most diffioult hranches of the cook's art. To ascertain the heat of the oven, sprinkle a little flour on a baking-tin and place in the oven. If the heut is just right for the cake the flour should be of n good yellow colour in about one minute. The oven should be kept at this moderate heat throughout.

Opening and shutting the oven door should bo avoided as much as possible, as draughts cause a sudden drop in temperature which often spoils cakes and pastry.

Special thermometers for baking are now made, and if used the following temperatures (Fahrenheit) should be recorded

## Meat Ples <br> Cakica ind pastry <br> Bread and puaf jostry <br> $300-(11)$ 290

All kinds of pastry require to be baked in a very hot oven at first, to expand the air enclosed in the pinatry, so that it raisea and lightens the flour If the temperature of the oven is not sufficiently high to set the pastry quickly the air or gas will escape, and the pastry sink again and hecome heavy A sharp hent is also nceded to swell quickly and burat the starch-grains in the flour, and thereby ensble them at once to absorb the fat used as it melts. Unless this happens the warin butter or lard merely oozes out on to the haking tin, and the pastry becomes hard and chippy. It must always be remembered that the richer the pastry the hotter must he the oven. When the pastry is set, the heat must be slackened to prevent it burning.

Heat the oven whilat preparing the dish for which the pastry is to he used. If a coal range is used, make sure that the flues at the back of the stove and mund and under the oven are clean and free from soot, otherwise a proper hent will never he attained

An oven with a gond bottom heat is desirable for pastry baking, and the top shelf is always the hotteat. This shelf throws down the heat on to the fond and thus browns it. Should the pastry secm likely to be too dark before everything is cooked through, this shelf can be pulled right out from the oven. Another plan is to lay a sheet of stout paper over the pnstry.

When putting pestry into or on to tins it is unnecessary to grease them, as there will be sufficient in the pastry itaelf to prevent it sticking, and to add more only wastes fat and increases the risk of hurning. After the pastiy is completely baked, let it cool down in a warm place, and not in a draught. It is a mistake to burry it away into a cold larder, as hy an doing the steam in it condenses and the pastry loses its crispness and becomes tough.

Baking Pan for meat with cover containlng basting colander. A bove, lett, double baking pan with rrid, basting well, rravg colander and lower pan for water Courteay of Selfriflge if Co.. Lid.

Baking Utensils. Double baking pans are best for oven roasting. They can be obtained in oblong or square shapes and in all sizes

BALL BEARINGS. These comprise all types of bearings where the working parts aro separated by means of metal balls, relatively small in diameter. The chief advant ages from the use ages from the use falls, and water is admitted As it rises in the of ball bearings are tank the ball floats on the water, and gradually tho easy running lifts the lever Finally, when the desired height qualities due to re- of water is attained, the lever has lifted suff. duced friction be ciently to close the water inlet by forcing the tween the bearing surfaces, simplicity of adjustment, and long life, if properly cared for
Thero are two great classes of ball bearings: (1)the cup and cone type, as
Ball Bearinga. Hub of a bioyele partly out away to show oup and cone bearinz

extensively used on bicycles: and (2) radial bearings, used on amall electric motors, and for bearings in motor-cars and uther purposes. Ball thrust bearings are adapted to take an endways thrust An example is the bearing in a oycle stcering-head

A typical cup and cone bearing, us usod on a cycle hub, is shown in the illustration. The cones are mounted on a spindle, one is firmly fixed thereto, the other works on a sorew thread, and provides tho means o: adjustment.

The balls run botwec: the cup and cone, and sufficient of them arr used $\omega$ form a complete circle. To adjust any bearing ol this type, slacken the lock. ing nut and rotate the movable cono until every trace of slackness or shake has been eliminated The looking uut is then tightened up hard.
To clean a ball bearing, take out the cones and spindle, placing a clean piece of paper or a large tray on the ground to catch the balls as they fall out. Then wash the balls, cups and cones in paraffin, and clean the hub or part from which the bearing has been removed Assuming there is no wear or clamage, the bearing may then be reassembled First fill one cup with vaseline or thick grease and place it on the bench with the cup horizontal Insert tho balls one by one into the cup (the vaseline will prevent them falling out), then insert the spindle and fixed cone. Hold the spindle in place and invert the bearing, thus allowing the spindle to rest upon the bench Support the bearing with blocky of wood if necessary. Insert the balls in the other cup as before. Finally, screw the adjusting cone on to the spindle and adjust as already described. See Bicycle ; Motor Cycle.

BALL COCK : In House Cisterns. The principal purpose of a ball cock is to regu late the flow of water into a tank or cistern,

Ball Cook. How the flostung ball controls inlet of water. Inset, valve part of high-pressure type
its action depending on the buoyancy of the ball, which is hollow and made of copper. It is attached at one end of a lever arm, the other end of whioh is pivoted to the valve
body or tank. Near this end of the lever

Ball Vapye, Beotion of the zimple type the ball must bo clean, must seat on a knife edge, or very narrow scating, and must be prevented from lifting too high off its seating. The diagram makes the construction of such a valve quite. clear.

BALM. The plants of the genus Melissa, a hardy herbaceous perennial with aromatic stems and leaves, are classitied as balm. They flower in the summer months, al which period thestems should be cut off and stored for winter use Balmi leaves make a good pot-herb and were formerly used exten sively. The plants may be increased by division of the roots in autumn, or by seed sown in March. Any ordinary garden soil suits them, but they prefera sunny border

BALM OF GILEAD. This is the popular name of Cedronella triphylla, a sage-like plant from the Canary 1sles: it bears purple Howers but is valucd chiehy for the sake of its fragrant leavos. It is handy only in mild districts. Propagation is by cuttings under glass in spring. When nosegays were fashionable, they nvariably contained $a$ few fragrant sprigs of Balm of Gilcad.

BALSAM. This is a half-hardy annual belonging to the genus Impatiens, the main types heing camellin-llowered and rose-

Howered The balsam ia linble to damage in bad weather and is more use ful for the greenhouso thnnfor flower beds. When balsam is grown in greenhouse or conservatory, it should be watered freely when well rooted and must be potted in rich soil.

It is raised fromed sown under glass in Feb.
ruary or March, and potted in a compost of three parts loam, one part manure, and a little sand. The wild yellow balsam has apotted llowers, and there is a dwarl type with large tlowers The double white camelliafowered balsam rivals the begonia in beauty.

The common Impatieus glandulifern has white and pink Howers, and in a shrubbery is often a nuisance because of its enormous faculty of rejproduction Pron. Ball'sum.

BALSAM. There are four varieties of balsam which are useful in coughs and bonchitis, namely, balsam of Peru and tolu, Lenzoin, and styrax or storax All are resinous bodies with an admixture of benzoic or cinnamic acids. Benzoin and balsam of Peru form a mild antiseptic for cuts and ulcers. Storax and balsam of Peru are used for removal of lice. The compound tincture of benzoin generally known as Friar's balsam is valuable in arresting bleeding when applied to fresh wounds on a piece of lint. If half a teaspoonful be added to a jug of steaming water and the vapour inhaled, much benefit may be derived by persons suffering from nasal catarrh and other similar affections of the respiratory passages. See Cold : Friar's Balsam.

BALUSTER. The term is given to the supports of handrails, harricades, etc., which may be turned, shaped, or aquare, the latter being sometimes fixed at an angle. Balusters are lest fixed by nailing only, where they are fitted to n sloping surface, as a stair string and handrail, but where fixed to level surfaces, morlise slots should be made to receive them See Railing: Staircase.

BAMBOO. The genus of grasses known as bamboos belong to three groups, Arundinaria, Plyllostachys and Bambusa. They are graceful evergreens which flourish best in moist soil and a sheltered position. They are most attractive from midsummer to early spring ; between February and July the leaves become shabby.

They do well by the side of a stream or pond : if the soil in which they are planted is not naturally moist they must be watered very freely in dry weather. The best time to plant or transplant bamboos is in April or September. Bamboos which flower usually perish a short time afterwards; they can be increased by sowing seeds under glass and subsequently planting the seedlings out of doors. The way to prune bamboos is, in April, to cut out some of the old shabby stems right to the base. Some of the best hardy bamboos for British gardens are

Arundinaria anceps, 8-10 feet, A. nitida, 8-10 feet, A Simioni, 12-15 feet; Phyllostachys fastuosa, $15-20$ feet, and $P$ nigra. 8 feet Attractive low-growing kinds are Bambusn tessellata 3 feet, with very large leaves; pygmaea, 15 inches, and Veitchit, 15 inches The two last named are improved by being out down almost to the ground each year,

Bamboo Work. Bamboo differs from wood, but is easy to deal with when its peculiarities are known. It is obtainable in lengths of pole or rod, is straight and parallel except for its nodes, and is light and comparatively strong, with a hard, glossy skin Dianeters stocked by English dealers are from about $\frac{1}{2}$ in to 2 in . The small diameters easily bend when heated, and remain bent when cold, but old bamiboo docs not bend so easily as does new.

Hot water ann be used for heating, hut more frequently it is done with a smokeless flame, as in Fig. 1. The flame can be allowed to touch the surface, but either bamboo or flame should be kept moving slowly As the diameter increases it becomes more difficult to bend, and then only slight curvatures are attempted In bending there is necessarily some amount of fattening or loss of cylindrical shape at the bends. The outer curve is longer than the inner, and in large diameters and sharp curves this must be assisted by making a number of shallow saw-cuts across the inner part. In bending, these close tightly and hardly show

As bamboo is hollow, it is nearly always plugged with soft wond at places where joints have to be niade A rasp of half-round section is used for preparing the interior. Figs 2, 3. 4, 5 show joints at right angles. Plugs are shown in both parts, but this is not always practicable. Glue and fine nails are used for holding the joints Glue does not hold well on the natural enamel of bamboo, and therefore it should be ras ped or glass-papered before glueing.

A diagonal joint may be made as in Fig 6, the end being gouged or rasped to fit the curve. Fig. 7 shows a piece of dowel put transversely through one piece to fit into the ends of pieces which cross the first. The ends are plugged in the ordinary way, and then a hole to fit the dowel is bored in the centre of each of the plugs, The dowel is smaller in diameter than an ordinary plug.

Many articles of furniture can be made of bamboo, either entirely or in conjunction with wood. Bamboo is often used for fancy tables, chairs, seats, bedsteads, washstands, bookcases, and cabinets. Also for music racks, curtain poles, overmantels, hall stands, and frames for screens. Unless holes are bored for nails there is risk of splitting. A bradawl may be used, but it is better to bore with a brace and bit or a drill. Bad jointa

Bamboo. Well-grown ghrub of Arundinaria metake. a fine foliage shrab for a large rarden
can be filled with a paste of sawdust and melted glue. Bamboo will not take stain, but may be vamished or enamelled.

Bamboo. Fig. 1. Showing how it may be bent. Figs. 2-7 Methods of making diflerent joints. on to bamboo curtain doles. Fig. 10 . Joining bamboo by \& wooden plag

For bamboo pole, a useful size is about If in. diameter. This is cut up for simple articles of furniture, and is used simply as a pole for numerous purposes, one of the commonest heir.g curtain poles. Fior this purpose it is supported horizontally on brackets, and the curtains are attached by means of riugs which can be alid along the pole. It is fitted with ornamental ends of wood or metal, which are large enough in diameter to prevent the rings from coming off The ends are generally put on in a way which permits of rumoval if it is desired to take the rings off

Two methods are shown in Figs. 8 and 9. In the latter the pole is plugged, and the knob fitted with a double-ended screw, so that the knob can be screwed on Poles may be joined end to end to obtain the required length They are united by inserting a wooden plug, as in Fig. 10. The ends of the bamboo should be cut to give sufficient length when the plug is driven in until it reaches the solid part at the node, as shown dotted.

BANANA. A nice sandwich cake can be made with 6 bananas, 3 eggs, $6 \mathbf{o z}$. flour, $\frac{1}{} \mathrm{lb}$. lump sugar, and lb icing sugar. Boil the sugar in pint water until it is clear ; then add the eggs and beat them for 20 min . Stir in the flour thoroughly and bake the mixture in two well-buttered tins for hour. Three bananas should then be reduced to a pulp and spread on the cakes, which can be laid one on the other to make the sandwich. If preferred, another thin layer of cake, made in a smaller tin, may be placed on top to give a decorative effect.

The icing is made from 2 bananas, skinned and reduced to a pulp, and $\frac{1}{2} \mathrm{lb}$. iring sugar. Mix these well together with a knife, and spread the mixture on the cake. Cut another
banana intu rounds, place theer on top of the icing. and put a small silver ball, obtainable from any confectioner, in the centre of each round.

As a sweet bananas can be prepared with coffee or ohocolate icing. Peel the necessary number, dip each into raspberry jam, and cover with almond paste; then coat either with coffee or chocolate icing.

BANANA CRARIOTTE. Line the bottom of a plain charlotte tin with a layer of sweet jelly and decorate with strips of angelica and glace cherries. Trim the required number of finger biscuits and line sides of mould so that they fit closely. Beat up 3 fresh eggs and stir into them a pint of boiling milk sweetened with 2 oz . castor sugar. Put this in the pan and stir over the fire with a wooden spoon; when the consistency of cream add the pulp of 4 ripe bananas.
Stir in $\frac{t}{2}$ oz dissolved gelatine, add $\frac{1}{2}$ tea. speonful vanilla, and lastly $\frac{1}{2}$ pint whipped cream. Just before the cream begins to set pour it into the prepared mould and place it on some ice to set firmly. The shape should be unmoulded carefully on to a cold dish and then served.

## Banana Chartroase, a rioh paris aweot

BANANA CRARTREUSE. Line a Huted jelly mould, having a pipe in the centre, with a layer of wine jelly, and decorate the bottom with halves of glacé cherries and slices of bananas. Cover with a layer of jelly and when set, or nearly so, put in another layer of banana slices and continue until the mould is filled. To set well place the mould in a pan and surround with crushed ice When firm dip the mould in tepid water for a few seconds, and turn out the shape on to a cold dish. Fill the centre with stiffly whipped cream, slightly sweetened, or some ranilla custard.

BANANA-ECLAIR. Put $\frac{1}{2}$ pint of water and 2 oz of butter in a saucepan. Boil and, having removed to a slow fire, add 6 oz . Hour and stir well with a wooden spoon for 10 min . When cold, add 4 egge, one by one. Next pass the mixture from a large pastry bag through a large piping tube on to a but. tered dish, making each piece about the size of a walnut and about an inch apart. These should be baked in a moderate oven for half an hour and then taken out to cool. To pre. pare the cream take 2 eggs, 1 oz . flour, 1 oz. sugar, $\frac{1}{2}$ pint milk, and 6 ripe bananas, Which should be passed through a sieve. Boil the milk, add the flour and sugar, and beat all up well with the eggs. Cook a little without boiling, add the banana purce, and

Banana Rolairs, a delicacy for afternoon tea
mix thoroughly. When oold, cut off the tops of the pastries and stuff each with the cream, afterwards replacing the tops and sprinkling them with sugar.

BANANA GATEAU. Make some short pastry with 8 oz self-raising flour short pastry with 8 oz. self-raising flour, fold and apply as shown in the illustration.

Banans Gatean, decorated with whipped craam
line a deep sandwich tin with it. At the bottom and sides put grease-proof paper and fill up with rice to keep the shape. Bake in a fairly brisk oven. When done remove the paper and the rice, cut 3 bananas into rounds and cover the bottom of the pastry case with them. Take $\&$ pint lemon or orange jelly when on the point of setting. and oover the bananas gently with it. Leave in a cool place until quite set, and then serve. If desired, it can be decorated with whipped creaı.
BANANA PRINCOSS PUDDING. Peel and mash 6 bananas, afterwards placing them in a greased pie-dish. Add a layer of apricot jam, and let it get warmed through in a moderate oven. Whip the whites of 2 eggs with castor sugar until they are quite stiff, cover the pudding with it, return to the oven and bake until a golden brown. This will take about 5 min . It may be served hot or oold.
BANANA TRIFLE. Take 8 sponge cakes, a pint of custard, some jam, 3 bananas, and 1 oz . of blanched almonds. Cut the ment, and to arreat haemorrhage. Various forms are employed, e.g. the triangular, the roller, the T-shaped, the many tailed. Of A triangular bandage is made by taking a piece of calico, 38 in . square, and cutting it diagonally across. The parts of the bandage are named, thus the longest border is known as the base or lower border and the others are the side borders. The angle opposite the base is the point and the others are the ends. The bandage may be used as the whole cloth, the broad fold and the narrow fold. If
the point is brought down to the middle of the base and the bandage again folded we get the broad fold; folded once again it is the narrow fold. In fastening the bandage the two ends are tied in a reef knot. The diagrams in the next column show the difference between a reef knot and a granny.
The various methods of fixing a triangular bandage or dressing are as follows:
(1) Grester arm sling. This takes the weight of the whole forearm. Use the whole cloth and place one end over the sound shoulder, the point being towards the injured limb. Carry the limb across the cloth and carry the other end over the shoulder on the injured side. Knot off behind the neck; take the point, carry it forward in front of the elbow and fasten with a safety-pin.
(2) Lesser arm sling. This takes the weight at the wrist. Use the broad or the narrow
sponge cakes in half and place a fow in the bottom of a large crystal dish. Spread them thiokly with strawberry jam, and add a layer of sliced bananas. Repeat the process until the dish is full. Make a good custard flavoured with vanilla essence, and pour over the trifle while hot. Leave it to soak well, garnish the top with blanched almonds and a few straw. berries out of the jam. The top may be decorated with whipped and sweetened cream and orystallised cherries, violets, and angelica.

BANBURY CAKE. These are scraps of pastry with a mincemeat of fruit in the centre. To make this mincemeat, cream 2 oz . butter and add to it $\& \mathrm{lb}$. ohopped orange and lemon peel, $\frac{1}{2} \mathrm{lb}$. currants, $\frac{1}{\frac{1}{2}}$ teaspoonful ground cinnamon, and the same of ground allspice

Banana Princess rucung with angeica and oberrias
Lay a little of this mincemeat between two oval pieces of puff pastry, pinch the edges. brush over with egg, and sift powdered sugar over the top of the cake. Bake in a quick oven till the pastry is browned lightly and has risen well. Sprinkle again with sugar and serve hot. This quantity is sufficient for 10 or 12 oakes.

## Bandages for WOUNDS and Dressings

## Simple Instructions and Diagrams for the Home Nurse

## For the Application of Principles given here see Arm; Bleeding; First Ald ; Practure; Leg, etc.

Bandages are used to fix on drassings and either sling by placing a folded bandage or a splints, to give support or to restrain move- piece of cotton-wool beneath it. these the triangular is the easiest to apply and and bring back; then knot over the dressing. is usually chosen in rendering first-aid. (4) For the thigh and leg use a broad fold
the centre over the dressing oross the place
(3) To fix a dressing on the neck, the forcarm, and arm. Take the narrow fold, place and bring back ; then knot over the dressing.
(4) For the thigh and leg use a broad fold
and tie as above. (5) For the elbow. Take a broad fold and place the centre over the point of the elbow. Cross in front and carry round the forearm, overlapping the lower edge of the bandage already applied. Cross again in front and carry back round the arm, knotting over the upper border.
(6) For the knee. Take a broad fold and apply the centre over the knee-cap, then proceed as above, making the knot, however, below the knee-cap.
(7) For the shoulder. Take the whole cloth and lay it on the shoulder with the point upwards. The lower border is placed opposite the middle of the upper arm. Cross the ends on the inside of the limb and bring back and tie off. Fix a lesser arm sling to carry the injured limb. Take the point first beneath, then down over the sling and pin off.

Bandage. Above, reet
knot, the beat to make.
Below, granny knot, which is uneate
(8) For the hand. Take the whole cloth and lay the hand on it palm down, with the fingers towards the point. Carry this back to the wrist and cross the ends over it. Cross

Bandage. Left, greater arm sling : the whole cloth is first placed with one end over the sound shoulder and the point towards and beneath the injured limb. Right, bandage for shoulder combined with lesser arm sling

Bandage. Three stages in the spiras application of a roller bandage to Three stares in the spirai appication of a roller
the leg; top, right, shows a reverse being made
free hand is placed in front of the turn which is heing made, the roll is twisted made, the round towards made. the operator, and the turn is completed with the reverse side of the bandage in contact with
the skin. When the bandthe skin. When the bandit is again reversed, and this is continued till it lies cvenly without reversing. The first met hod is the simple spiral, and the second the reversed spiral.

When a joint is reached a turn is taken round the joint, at the knee, for example, across the knee-cap. The next turn overlapping this turn goes below and the next ovcrlaps above, and so on, till the joint is covered in. This is the figure of cight bandage, one lonp of the eight being above the joint and the other below. When the bandage is completed it should be fixed with a safety pin.

Certain rules must he carefully observed: Do not apply a damp bandage, as it will shriuk on drying and be too tight. Apply the turns with uniform pressure and parallel to each other Do not reverse over a sharp, bony edgc. While again in front and tie off on the back. Pull bandaging, the nails should be left frec, the point up and carry down over the linot nind pin off on the back of the hand.
(9) For the foot. Place the sole on the cloth, toes towards the point, and proceed as above.
(10) For a wound on the top of the scalp. Take the whole cloth and make a hem on the lower border of about an inch. Place the centre of this border on the forehead over the nose, the point being thrown back over the head. Carry the ends round and oross lielow the prominence at the back of the head Then bring these ends forward and tie then securely in front, drawing the point well down under the bandage nt the back of the head, carry forward and pin into position.
(11) For a wound of the chest, in front. Take the whole cloth and lay the point over the shoulder on the wounded side. Carry the ends round to the back and tie, leaving one end long; then tie this end and point together.
(12) For the eye. Take a narrow fold and place the centre over the eye. Carry one end obliquely across the brow and the other over the ear. Cross below the prominence at the back of the head, bring forward and tie over the dressing.
The roller bandage may be from one to six inches wide and for fixing dressings should consist of cotton or linen ; for binding or splints calico is better; a Hannel bandage is very comforting for painful joints. To give support to the legs in cases of varicose veins a woven crêpe or elastic bandage is used.
In bandaging a limb always begin on the aside and unroll the bandage outwards, but do not uncover more than three or four inches at n time. First take a few turns round the limb to fix it, and then proceed upwards obliquely, cach turn covering two-thirds of the width of the preceding turn. (See diagram abovc.)
It will be found before one has gone very far that the bandage will not lie evenly, and then it is necessary to reverse The thumb of the
because pressure on them will show whether or not the bandage is interfering with the circulation. In removing a bnndage do not roll it up in the process, but before re-applying it. If no bandage roller is available it is possible to roll the bandage quite tightly betwcen the fingers, purchase being obtained by tating it over the back of a chair.

Finger Bandage. To cover a finger, using an inch-wide bandage, take a couple of turns around the wrist, not covering the free end of the bandage, but leav. ing this loose for tying later. Carry the roll from the inside of the hand over the backs of the wrist outwards. After it is firm at the wrist, bring it down across the back of the finger to be bandaged and then make a series af apir then make a series of spiral in fagure of 8 loops and spirally overlapping the other, downwards to the tip of the finger, and back again to the root of the finger, thence crossing over the base of the finger and over the back of the hand to circle the wrist in the opposite direction to the point where the end can be easily tied into a knot with the free end of the bandage.

## Foot and Leg Band-

 age. Laying the free end on the back of the foot, the roll is carried around the outer surface of the foot across the sole, up over the inner border of the foot across the instep, round the back of the ankle, and again over the instep. This figure of eight is repeated, each layer of bandage overlapping the one below by half its width, until the ankle

Bandage. Dse of a double roller 'capelline 'bandage lor a bead injury
one roll is brought round the head and the otner across tne top
scalp is covered, each horizontal layer serving as a fixation point for the overlapping vertical handages. When enough backward and for-
ward turms have been taken to cover the dome ward turns have been taken to cover the dome
of the head thoroughly, a few extra horizontal turns may be taken in order to keep the headdress firmly in place.

Thumb Bandage. Regin by fixing the bandage with a couple of turns around the wrist, carrying the bandage from the thumb side over the wrist, and leaving a free end of live or six inches After the second turn, bring the bandage down as far as it is necessary to bandlage, and make a loop around the thumb here by carrying the roll around the thumb from without inwards, crossing over the back of the thumb and the back of the hand from thumb side to little finger side as the hand is held palm downwards. The roll is again carried round the wrist, and a second loop is made around the thumb as before, this loop overlapping the former and not extending so far down as the first. The loops are continued until the thumb is covered with the bandage from the end joint well up to the wrist, when the bandage is finished off by tying with the free end around the wrist.
Band - pass Filter. A circuit used in wireless to assist sharp tuning by allowing a hand of frequencies to pass. See Selectivity.

BAND-SAW. The woorl-worker's bandsaw is a comparatively large and heavy machine saw used for cutting flat material into curved shapes. It is used extensively in the cabinet-making and joinery trades. The blade is made of thin steel varying in length from 12 to 24 ft . and in width from $t \mathrm{in}$. to $1 \frac{1}{2} \mathrm{in}$. The saw is joined by brazing the ends and forms a continuous band. See Saw.

Bangle. A thin bracelet made of metal, цlass, ivory, or jade. See Bracelet.

Banister. See Baluster; Railing; Staircase.
BANJO : How to Play. The banjo consists in the main of two portions, the body and the neck. The body is about 12 in . in diameter, and is made of vellum or parchment tightly stretched over a hoop, some 9 in. in diameter, the object being to reinforce the otherwise feeble resonance of the strings. The neck, about 20 to 24 in . in length, is flat on top, and is called the finger-board; the underpart is munded and highly polished. On the finger-board are fixed transversely the frets, which indicate the different sounds to be produced, and in a good instrument are 22 in number: Beyond the neck comes the head, which is slightly bent back from the fingerboard, and in it are placed the tuning pegs, one for each string, of which there are usually five, for the most part of thin wire, although gut and silk are also used.

Music for the banjo is always written on the treble stave, and always an octave higher than it sounds, with a view to avoiding leger lines below the stave as much as possible. The five strings are tuned thus:

The banjo should be held so that the neck rests between the thumb and first finger of the left hand, which must be able to move rapidly to any desired position. The fingers must be curverl and held over the strings. The right hand is held over the bridge, while the arm keeps tho instrument firmly in position against the body of the performer. The tip of the little finger rests on the vellum. Of the other fingers the bulk of the work is done by the thumb, which plucks the 5th, 4th, and 3rd strings ; and by the first and second fingers, which pluck the 2nd and lst strings. The
third finger is used but seldom, and then draw cheques on one's banking account. mostly in playing chords This can best be done by opening the account The frets are arranged at such distances as in the joint names with power for either or to produce a chromatic scale, the left hand the survivor to sign. In the case of the death

Banjo. Diagram of banjo flager-board and the corresponding notes of one of the parties this is of great value as the account is carried on without $a$ break in th. name of the survivor.
legally the rela. tionship between a banker and his customer is that of debtor and creditor. The former must pay any of the latter's money on demand. The law also provides that a banker must not disclose to anyone the state of a customer's account without justifiable cause. Sec Cheque: Pass Book.

## BANERUPTCY.

 Any man may be made a bankrupt, but a married woman cannot, unless she carries on a business moving along the finger-board into different or trade. When a husband has lent money positions so as to obtain the higher notes to his wife for the purpose of her trade or The diagram shows an octave upon each open business, and she is made a bankrupt, he string: 0 stands for an open string, the other figures indicating the finger to be used in playing the chromatic scale. It will be seen that in many cases the same sound can be produced in different ways, as for example, the note D on the fourth line, which is open on the first string, is played with the third fret on the second, with the seventh fret on the third, and with the fourteenth fret on the fourth string.BANKING. Banking accounts are either current or deposit. The latter is only for the investment of money, but a current account is useful even to persons of small means. It enables them to deal easily with cheques, dividend warrants, coupons, and the like. It is a convenience to pay by cheque, which minimises the risk of loss by reducing the amount of ready money a person must have in his house or on his person. Unlike a Treasury note or a coin, a cheque, if lost or stolen, can be stopped and probably traced.

The customers of a bank elljoy other advantages. These include the privilege of depositing deeds and other securitios and vahables in the custody of the bank, usually without charge, and that of obtaining drafts on foreign and other banks in case of travel abroad, while the bank will purchase and sell stocks and shares for them. It is useful also for certain purposes to be able to give a banker's reference.

A banking account may be opened by apply. ing to the manager at any convenient branch on production of a reference or introduction. The bank supplies a pass book for recording the customer's receipts and payments. The counterfoils and the book should be compared periodically with the pass book, which is made up by the bank every day and balanced every half-year.

The charges made by the bank vary as between London and the country, and, to some extent, with the nature of the account. Small accounts in London pay from $£ 1 \mathrm{ls}$. to £2 2s. a year ; in the country 2 s . 6d. is charged on every $£ 100$ turnover. If, however, a certain minimum balance, say $£ 50$, is kept in the bank, usually nothing is charged.

As a matter of convenience, it is sometimes desirable to allow a wife or other person to
cannot claim for his money until all other creditors have been paid in full. The same holds good when a wife has lent money to her husband for the purpose of his trade or business. The whole of a bankrupt's. own property belongs to the creditors except the tools of his trade, necessary apparel and bedding of himself, wife and children to the value of $£ 20$.
When a man has made a marriage settlement before his marriage, it holds good against his creditors.

If a man settles money or property on wife or children after marriage, and becomes bankrupt within two years, the transaction is void and the creditors take everything. If more than two but less than 10 years elapse. the creditors still take the money, etc., unless it can be shown that the bankrupt at the time of the settlement was able to pay all his debts without the money or property settlod.
BANNOCK. To make this milk scone, sift together 2 breakfastcupfuls flour, a teaspoo: iful baking powder and a teaspoonful salt, and rub in a piece of butter the size of a walnut. Mix quickly to a stiff dough with milk, form into a round or rounds and prick over with a fork Bake in a loot oven on a greased baking tin. Sugar, egg, or currants could be added.

BANNS: Marriage by. In England the most usual way of getting married is by banns. The minister is entitled to have seven days' notice in writing before publishing the banns. The banns must be published on three Sundays.

Residence in a parish since yesterday is sufficient to entitle a person to give notice for the publication of banns. If such notice accepted, then fifteen days' residence from the first to the last publication of the hanns will entitlo the parties to be married.

When the parties dwell in different parishes, the banns must be published in each parish. If the marriage is not solemnised within three months, the banns must be republished. Where either of the persons to be married is under 21, his or her parent or guardian may forbid the banns and make the publication void.
The publication of banns abroad is not confined to the announcement of the intending marriage given from the pulpit of the parish
churches of the contracting parties: in France, and stenoplyylla, twu vigorous evergreens, for example, the banns must be published at the town hall, not only of the contracting party, but also of that of the parent or guardian whos: consent is requisite for the lawful celebration of the marriage. See Marriage; Wedding.

BANTAM. Although regarded in many households as a pet for the children and nothing more, the hantam may be made a

source 0 prolit. Being
the smallest of all poultry, it eats less and takes up less rooms but it lays as well as most other fowls. Its egg, aver aging $1 \frac{1}{2} \quad \mathrm{oz}$ in weight, has a delicate ischness.
DARB Noted among pigeon fanciers for the antiquity of its line age, the barb has long been held in high estcen on the Continent and in the U.S.A. It was at one time largely lired in Eingland See Pigeon.

BARBED WIRE. Ordinary wire is made into barbed wire by having little cross pieces with roughly pointed ends woven into the strands. Practical applications of this material include the fencing in of small enclosures, the wire being supported on posts in the ordinary way. As a deterrent to trespassers, a few strands can be run along the top of a wall, and suppurted on small wood or nictal blocks Barbed wire, mounted upon a suitable wooden framework, makes an inexpensive but cffective harrow for use on a lawn or in the garden.

BARBERRY or Berberis. These are hardy slirubs, comprising both evergreen and deciduous sprecies. When given plenty of room they develop into fine specimens, clothed in hlomm from top to bottom. They thrive in any fairly good, friable ground.

The harberry may be raised by seed sown either in autumn or spring, or suckers springing up from the rootstocks niay be removed and planted. Cuttings of the ripened wood may be inserted in sandy soil in a frame in autumn.

Among the species and varieties of berberis are many of the hest hardy ornamental shruhis. They are valued for their flowers or fruits; the leaves of a few, notalily Berberis Thunbergii, become brilliantly coloured before they fall. The barberries are easily managed and thrive in well-cultivated onlinary soil.

The mahonia (Berleris aquifolium, 3-5 ft.). bears yellow flowers in spring and purple fruits in autumn; it will thrive under large trees and is a good covert shrub. Darwinii.

Barberry. Frait sprays of a variety of the shrub
and stenophylla, twu vigorous evergreens,
8 ft. or more, bear orange yellow and yellow fowers respectively in spıring; buxifolia, 8 ft. hears yellow fragrant blonms in April

In recent years many new barberries, valued for their brillinntly-coloured fruita, have been introduced from China, including Wilsonae, aggregata, polyantha and dictiophylla. Many seedlings which have been raised from them also bear profuse crops of brightly coloured fruíts. These new barberries are of low or medium height and are invaluable for the front of shrubberies.

The common barberry (Berlieris vulgaris) is a large leaf-losing hush or small tree which bears bunches of scarlet fruits in autumn. Berberis wallichiana has large evergreen leaves and lears primirose yellow Howers in spring: candidula is a low-growing evergreen, with purplish fruits, suitable for the molk garden.

## Barbola. See Gessn Work

BARGEBOARD 13argeboards, sometimes
called vergeboards, are employed to give a better finish to the ends of gabled roofs, and may consiat of a plain hoard only, or may be shaped to more or less claborate and orina-

Bargeboard. 1. Simple type, sbown in section at 2. 3. Finial apex, to which barkeboards are tenoned. 4. Tenons. 5-9. Patterns used in domestic architecture. 10. Section of 8 , showing doable ornamentation produced by mounting one board on anothe:
mental patterns. Any ornamentation of barge boards should be bold in style ; fine ornament is out of place, besides leeing non-effective.

BARK. The exterior covering of trees has many uses. The hark of onk trees is employed for tanning leather, a tan solution being made by boiling oak hark, broken into pieces, in rainwater for three or four hours. Bark can be removed from a tieetrunk by cutting round the tree with a sharp knife or saw. A second cut is made below the first, and the two cuts joined by a vertical cut. The bark can then be peeled off ; it should be laid out flat on the ground with the rough surface upwards and left to dry. To make it dry out Hat, lay the bark on a board, and weight it down with bricks or ot her handy objects.
Coloured barlis ate employed effectively as coverings for the walls and roofs of summer. houses and similar outdoor structures. Decorative effects are also to be got by covering flower pots with bark, and securing it with a few hoops of withy or thin cane. This can be wired to the bark before the pot is inserted, with thin galvanized-iron wire. A paper template should be cut to fit the pot, and used as a guide when cutting out the bark. The variety of bark known in the trade as virgin cork has a rough surface not unlike rock, and is used to some extent in building up internal ferneries and such-like greenhouse fitments It is preferable to wire this material to the wooden frameworl:. See Summer Housf.

BARK BEETLE The fruit tree inost often damaged by this insect is the plum, but the lieetles are also found on apple, pear cheriy, apricot, peach, and guince. In the case of an infested plum-tree it will usually be noticed that some of the twigs or smaller branches are dead, and that numerous holes have heen bored through the bark, which peels off casily, disclosing little tunnels between the bark and the wood of the tree The trouble may extend Plum Bark beeule, much entarged to the larger branches and even to the trunk itself, and the entire tree niay thus he killed
The adult beetles are brownish-black insects about onc-sixteenth of an inch in length During warm weather in spring the beetles leave their burrows, Hying awry in search of fresh trees to attack On discovering a suitable trec the female selects a twig or branch and bores a hole vertically through the bark It then turns and bites out a tunnel or brood chamber $\frac{1-\frac{1}{2}}{}$ in in length along the branch hetween bark and wood, laving eggs as it goes This information is given by the Ninistry of dgriculture (Leallet No. 49). Sce Plum
The measures to be adopted are preventive rather than remedial. Trees in an unhealthy state are preferred by the beetles, and a bad attack by aphides or brown rot on plums, for example, may cause an increased infestation by bark beetles. Wien the tree attaclied lias died and the wood has dried up the beetles are compelled to desert it and scek other quarters. Therefore all dying and badly damaged trees or branclies should be cut down and promptly burned. The beetles will come out freely for some time from trunks and hranches left lying about.

BARLEY. Pearl barlcy is the grain ceprived of husk and pellicle and rounded and polished by grinding. Pot or Scotch barley is more nutritious than pearl harley, being deprived of the outer husk only, and roughly ground.

Barley is valuable for thickening soups and broths, for making puddings, and for the preparation of barley-water. It contains no gluten, and therefore is not suitable for breadmaking, except with a slight admixture of wheaten clour. It unites well with the oily matter extracted from ment in boiling. If soaked overnight in sufficient cold water to cover, it needs less time to cook.
For a nutritious barley stew, lake $1 \frac{1}{2} \mathrm{lb}$ of boneless shin of beef or ox cheek. Wash and wipe this, then cut into large pieces and place it, in layers, in n saucepan, casserole ol stewing jar, with two large sliced onions, some carrots, and 1 gill of soaked Scotch barley. Un the top of the last lager arrange 1 lb . of washed, preeled, and thickly sliced potatoes Season two quarts of cold water and pour this over the mixture until the saucepan is three parts fill. Then cover and stew slowly on the fire or in the oven until tender. Small suet dumplings and well-cooked cabbage should be served with this dish. Mutton may take the place of beef, but the gravy will then be less rich

BARLEY BREAK. This open air game is usually played by six persons, three malea and thiree females, but it can be played by more. Three hases are marked out and each one is allotted to one of the piairs. The middle base, called prison, or hell in former days, and sometimes the barley field, is invaded by the pairs on either side, and the middle pair, with arms linked, attempt to catch them while they are on the middle base They can be eaught singly or together, and each pair can only retreat into their own base. When both nembers of a pair are caught. they replace the others in the centre base.

BARLEY CRE $\Lambda M$ SOUP.
butter in a 1 oz . flour; then add a pint white atock and stir it with a clean wooden spoon until boiling Put into the mixture $1 \mathbf{~ o z}$ washed pear barley, simmer till the latter is anft, which will take about $1 \frac{1}{2}$ hours, and rub all through a hair sieve Rinse out the pan, pour back the sieved soup, and simmer for 5 minutes

Allow the mixture to cool for a few min., and then strain into it the beaten yolks of 2 eggs and 2 gills milk or cream. Add seasoning and reheat the soup; it must not boil or the eggs will curdle. Serve in a hot tureen with fried croutons if no white stock is available use a mixture of half milk and half water, to which a small piece of onion has been added. Margarine may take the place of butter. Sufficient for about four persons.

BARLEY MEAL. A mixture of llour and barley meal is sometimes used for scones or home-made bread. Mix well 4 oz each of Hour and barley meal, $\frac{1}{2}$ teaspoonful each of salt and carhonate of anda, and 1 teaspoonful of cream of tartar. Rub in lightly and finely 2 oz of butter, and mix with about 1 gill of milk to as soft a dough as possible without making it actually sticky.

Having kneaded it lightly on a floured board, form into a thick mund and cut across into four or eight pieces, taking care not to cut right through to the board. Place the round on a Houred tin, brush over with milk to gloss. and bake in a quick oven for from 15 to 20 minutes. The scones should be broken (not cut) apart, and served hot, split and buttered They can be baked on a hot, greased girdle if preferred. Sufficient for eight scones.

For barley meal cheese mix two heaped tablesponfuls of barley meal with a little cold milk until amooth. Boil the rest of a pint of milk and atir in the barley meal. Cook for ten minutes, then add two tahlespoonfuls grated chcere with some made nustard, and salt and pepper to season. Put the mixture into a pie-dish and bown in the oven.

BARLEY PUDDING. Specially suitable for the nursery or for convalescents. To make mix if tablespoonfuls of ground barley to a smooth, thin paste with a little cold milk, and heat 1 pint of milk to boiling point: then atir in the mixed barley and cook gently for five minutes, continuing to atir frequently Allow the mixture to cool for two or three minutes, then stir in a well-beaten egg. Sweeten to taste, pour into a well-buttered pie dish, grate a dust of nutmeg over the top, and bake in a moderately hot oven for about 20 minutes

BARLEY SUGAR. Put 1 l lb . of loaf augar into an enamelled saucepan, add pint of water and half the beaten white of an egg. Mix well together and then bring to the boil and skim carefully When scum ccases to rise the sugar is clarified, but it is as well to strain through muslin Put back in the pan and boil to the crack, i.c. so that a little dropped into cold water becomes hard and brittle. Remove from the fire, add a teaspoonful of lemon-juice, and after letting it stand for a minute pour out on a greased dish. Before it sets hard, out into strips and twist.

BARLEY WATER. Wash 2 tablespoonfuls of pearl barley in cold water, put it into a saucepan with 2 pints of cold water, bring to the boil and boil gently till the liquid is reduced to 1 pint. Strain, and sweeten or salt according to taste. One cupful of this, added to one cupful of milk, hot or cold, makea a pleasant invalid drink, and for infanta the barley water is used in the same proportion as water in their milk allowance.

For large quantities of barley water as a wholesome drink make as above, adding to every pint, while hot, the juice of half a lemon and one tablespoonful of sugar. Barley water
should be frcslily made each day and kept in a cool place.

To make Imperial Drink add 1 teaspoonful of cream of tartar to 1 pint harley water while hot. This is used in febrile conditions and to stimulate the action of the kidneys.

## Barm. See Ycast.

BAROMETER. Mercury barometers for measuring weight or pressure of the atmosphere are not to be confused with the a neroid instrument, which arrives at the same reault by totally different means. A barometer such as the Fitzroy consists of a largebore glass tube about 3 ft long, filled with mereury, and inverted into a vessel also containing mercury. This allows the mercury to deacend a few inches, thus causing a vacuum at the top.
The surface of the mercury in the container s subject to atmospheric pressure. Hence, as the air pressure increases, the column of mercury is forced up the tube. Conversely, as the air pressure diminishes, the mercury column falls proportionally to the atmospheric pressure at the time. The average height of the top of the mercury column from the surface of the mercury in the vessel at the bottom is ahout 30 in , By arranging the tube so that the top of the mercury is risible it is possible to add a scale and take readings direct.
In general principle this system is used in the Fitzroy, Piesmic, Cistern, and Fortin barometers: the last mentioned is largely employed for observatory purposes. In other types a small float on the surface of the mercury is nttached to a cord passed over a drum on an axle provided with a pointer. from which readings are taken on a suitably graduated scale.
Important points to remember with any mercurial barometer are to keep it always perpendicular and to hang it in a position where the temperature is equable, otherwise it will act as a thermometer

Aneroid Barometer. The aneroid differs froun the mercurial harometer in having no long glass column to get broken, nor any quick. silver to get lost. Also, it works anywhere and in any position. On the other hand, it depends on metal springs, and is, therefore, aflected by changes of temperature, so that it requires to be checked from time to time by comparian with a good mercurinl instrument in the neighbourhood or on about the same height above the level of the sea.

In the illustration, which is a section, $a$ is a thin metal box with the top and bottom corrugated to ninke them more springy. This box is purtly exhausted of air, so that the cffect of the atmospheric pressure is to force the top and bottom inwards. A strong curved spring, $b$, is attached to the top of the box at one end nnd at the other to a fixed stand, $c$, and connected by the lever, $d$, to a bell-crank, $e$. The other end of this crank has another lever, $f$, attached; it joins a fine chain, $g$. which is wound round the spindle. $h$, of the pointer, $k$ A hair-spring, $l$, controls the move ment of the spindle and lieeps the chain taut.

The dotted lines show the move. ment in an exag. gerated form. In the dotted line

Barrel. Leaky barral mended by tightening staves with wire
ring and tar
trcatment
pressure falls the reverse action takes place, and the chain, $g$, pulls the pointer back.

BARONESS PUDDING. Take equal quantities of Hour, suet and raisins ; \& Ih. of cach makes a good-sized pudding for four or five persons. Add a pinch of salt and make into a stiff dough with milk. Steam in a greased bowl covered with greasad paper for three hours Serve with jam or sugar.

BARON OF BEEF. A joint consisting of two sirloins left uncut at the backbone is called a baron of beef. This cut is now seldom used See Beef ; Sirloin

BARREL. This is a cylindrioal wooden vessel made of curved staves bound tuygether with hoops and used for holding beer, tar, and other liquids. A barrel is also a measure of capacity, varying according to the liquid measured. A barrel of bear contains 36 imperial gallons, a barrel of onts equals 14 stone, and a barrel of tar equala 26itgalions.

When they are no longer required for trade purposen, barrels can be utilised in various ways in or around the house. A port wine pipe set up on lega or on a amall platforin serves as a rainwater. butt. It should be coated inside with tar, which is then act on tire and hurned out. A second coating of tar is given, and after the exterior has been painted the harrel is roady for use.
The char.
preserves the wood from rotting A draw-off tap near the bottom and overflow pips at the top and a lid to exclude dust and dirt are desirable additions.

When barrels have been left lying about for some time the staves generally lecome slack; they can be tightened by driving the hoops further down the barrel, or by wiring thent tightly. The wiring is done by twisting several turns of it in. diam. (16 gauge) galvanised wire round the barrel and tightening it up with a tourniquet. Secure the wire with clout nails, or by cutting a shallow groove for it to lie in, to prevent it shifting from its place.
To clean old barrels, wash and serub them with caustic soda solution, or use one of the paint removers.
Tapplng a Barrel. Barrels may be tapped by first metting the cask in such position that nothing will be lost

meter. Aneroid barometer shown in section. Explanatory details are given in the text during the process. Tlien remove the plug in the hole intended to scoeive the barrel tap. Wrap a piece of paper around the stem of the tap and drive it home tightly with a mallet. Set the cask in position with the tap to the bottom, drive position the atmospheric pressure is high, and the air release peg into the barrel, or preferthe hox is compressed in consequence : lever ably withdraw it if possible. The contents d has been drawn down, tae bell-crant: can then be drawn off by turning on the tap. pulled over, and the hair-apring has wound BARREL: In Gas Fitting. The trade the pointer round several degrees on the namc of barrel is given to wrought iron tubing dial in a clockwise direction When the used for gas and hot water pipes and similar
the air release peg int
purposes. Such tubes are made in three thicknesses or weights, according to the size of bore, and are butt-welded. The lightest and commonest class is used for gas fitting. Hot water pipe is stronger and of superior quality, and is usually tested to withstand a pressure of 300 lb . per square inch. Steam barrel is superior to water barrel, and with. stands 500 lb . per square inch.

There are many uses for such tube apart from their specific duties. Numerous fittings, such as angles, tees, and junctions, are svailable, and by their use a large number of articles can be produced by the home worker. Gas and steam barrel is measured by the bore or diameter of the hole. Thus $\frac{1}{l} \mathrm{in}$. gas pipe has $\ddagger \mathrm{in}$. diameter hole, and actually measures approximately A in. diameter on the outside. Gas barrel is connected by means of a screw thread cut on the exterior of the tube, two straight lengths being connected by a screwed socket or sleevc, screwed over the outside of the barrel. See Gas Pipe : Pipe; Tubing.

BARRENWORT. This is a hardy herbaceous perennial, equally attractive in leaf and bloom. The foliage, somewhat like that of a begonia, in autumn colours well ; it gets dingy later, but should be left on through the winter to protect the buds

Barrenwort, a hardy porennial somewhat like a begonia
lt is a spring. flowering plant, bearing yellow, white, blue, or violet flowers. The height of the different species varies from 6-18 in.
The barren. worts grow best in shade, especially in cool, peaty soil, or in a mixture of peat and loam. They are very useful for shady rockeries, and will thrive undertrees. Propagation is by division in spring, or by portions of the rhizomes, which will form plants if put into gentle heat in spring.
BARROW. A barrow is an article used for conveying goods. The commonest form of it is that more usually known as a wheelbarrow, but there are also hand-barrows without wheels, See Wheelbarrow.
BARTONIA. Growing about 15 in . high, the bartonia is a hardy annual with deeply cut, toothed, greyish leaves and large bright yellow flowers showing a mass of prominent stamens resembling those of the wild dog-rose in shape. It thrives in ordinary soil, the seed being sown in September for spring flowering, or in spring for blooming in late summer. Pron. Bar-tony-er.
BASEMENT. A basement is the lowest floor of a building when it is situated below the ground level and when access to it is attained by stepe outside or inside the building. The term half-bsement is used when the ceilings on such a floor are above ground level.

There are various sanitary, hygienic, and other objeotions to basements, and modern houses are built without them. In large buildings, where mechanical ventilation can be installed, there is less objection to them.
The decoration of basement living rooms and flata requires careful consideration of wall treatments, artificial lighting and window curtains. Semi-gloesy paints are helpful in pale, warm colours, avoiding dead white even for ceilings as uncomfortably harsh. Patterned papers should alao generally be avoided, but a distinctive note can be given to plain wall surfaces by the use of colour for woodwork; thus a
pale buff plastio paint may have coral enamel, a primrose yellow distemper, amber painted

Basement. Part of an ingenious and decorative converdion of a basoment into a fiat
advantage in dark rooms and give an effect of space. Wall lighting, which can be both bril. liant and yet diffused, is the best substitute for daylight. Where possible reflectors may be placed outside windows. In the case of bay windows the inner sides of the bay may be panelled with looking glass.

Window curtains may be of light, bright surfaced materials. Pelmets, if used, must be designed not to obscure light. Curtain rods should extend on either side beyond the window frames, so that curtains may be well drawn back. To hide out basement views somewhat, straight French net inner curtains with a light all-over pattern may be used completely to cuver the windows. See Area : Cellar; Flat : Mirror; Window.

BASIC SLAG. This is a valuable chemical manure, its worth depending on the percentage of phosphate of lime which it contains. As influencing the availability of the phosphate, the fineness of grinding is extremely important. Basio slag is slow in action and must be applied in autumn. It is beneficial in fruit, flower and kitchen gardens. See Manure.

BASII. Two species of this potherb are generally known, sweet and bush basil. They are nearly allied to the mint (Mentha) family
and their scientific name is Ocymum. The sweet basil grows about 12 in . high, and is densely covered with small oval leaves. The little white flowers appear in early summer and are borne in long clusters. The bush basil grows about half the size, forming a roundish bush. Both plants are highly aromatic. They are annuals and are easily grown from seed in spring. They like a light, sandy, friable soil.

The tips of the leaves are used to impart their distinctive clove flavour to soups and salads, and are also used for seasoning. By cutting down one or two plants as soon as they come into bloom, and drying the leaves slowly in the shade, the leaves can be used in the winter. A form of bush basil is sometimes grown as a pot-
plant for a green. house or window. It bears shining green leaves, and pale pink Howers. Pron. Baz'-il.
Basil. See Leather : Sheep. skin.
BASIN. Cook. ing basins a re made in enamelled ware and aluminium as well as earthen. ware. The former have advantagea, being light, unbreakable and easily cleaned.
Good quality enamel-ware is essential, as in-
 ferior enamel is liable to contain arsenic, and always chips easily, fragments of the coating getting mixed with the food.

To minimise the danger of chipping delicate chins, glass, etc., when washing it, papiermâché basins might be used with advantage. Clean them with a soft rag dipped in paraffin if marked and stained, and rinse well in hot water and dry. Mixing basins should be 11 or 12 in across. These are useful sizes.

Pudding basins differ from the ordinary bowl, on account of the deep rolled rim in. tended to prevent the string used for tying on the pudding cloths from slipping upwards. These basins can be obtained in sizes from 3 to 12 in. scross. Pudding basins with special covers obviate the need of pudding cloths. Spouted or lip.basins are handy, as milk, stock, etc., can be easily poured from them. See Aluminium : Crockery ; Enamel.

## BASKET MAKING AND REPAIRING

## How to Practise Simple Weaving with Osiers

Other Varieties of Basket Work are described under Linen Basket; Rafria, etc.

Basket making may be carried out with the aid of a few simple tools, and although elaborate baskets require skill in manipulation simple work may be produced after learning a few of the methods of weaving the rods. Most baskets are made with osiers worked up with the bark intact ; others are made with rods from which the bark has been removed, and either left white or stained to a buff colour.

All osiers must be thoroughly soaked in water before use, in order to render them sufficiently pliable for bending. Round baskets may be made with no other tools than a knife and bodkin, but for square-sided work a screw-block is required to hold the stakes whilst weaving. A simple round basket embodies the principal methods of weaving, termed strokes. Such an example is shown, which can be used for marketing purposes.

Short lengths of osier may be used ; either the sizes known as luke and small in brown osier or tack and long small in white and buff will be suitable.

The bottom should be commenced by preparing six 12 in . lengths cut from the thick ends. For the first stage these lengths must be tied together in two sets of three as shown in the illustration, but as there should be an uneven number of spokes, a whole rod should be used to provide the extra spoke, and also the material for binding the lengths together. The long rod will rest with its thick or butt end alongside one of the sets, and the remainder must be carried over and under the crussed lengths until it has been twice round.

The next stage commences the separation of the spokes, and the weaving of the rod is continued. first under and over each length until it is used up. Care must be taken to
bend the spokes evenly and to work the weaving length as olosely to the centre as possible. Having once singled out the spokes the suc ceeding work is quite strnightforward, and only needs care in kecping the weaving rods close up as each round is finished. New rods are started two apokes back and left projecting about 1 in . beyond the top of a apoke, or the end may be pushed down alongside one of the spokes and then bent out. When a dia meter of 9 in. is reacher the end of the weaver should becut off and pushed down alongside the nearest spoke, and the projecting ends of the spokes cut off close to the weaving.
The natural tendency in weaving will be to form a hollow tray, and this is just the formation required. The sides should now be formed by inserting the stakes, which are long lengths sharpiened at the butt end, and pushed in alongside the spokes. It is atill necessary to have an ordd number of rods, so. as there are 13 spokes, 25 straight rods should be trimued at the ends with a wlicing cut aalled a slype. Each rod should be pushed down by the side of a spoke, a hole being prepared if necessary with the bodkin, and the single rod placed at the point where two spokes are closest together. The bottom must be placed flat on a table with the crown uppermost, and each spoke turned upright. If the osiers have been properly soaked, and the point of the knife is dug slightly in to the angle of the bend this can be done readily enough The tops should be gathered together and placed in a hoop, as shown.

The next stage is known as the upsett, three rods being worked round the stakes to atifien them. Sharpen three rods and push the first alongside the single stake and the next two following. The three are now worked together, each one being carried in front of two spokes and behind the third, taking them in order, and continuing until they are used up. This should be done as tightly and closely as possible, working down on the corner in order to give a firn foundation to the succeeding wark.

## Three Methods of Weaving

The quickest way of filling up the sides, known is slewing, consisth of three or more rods worked in and out all the way up, new lengths being taken on required, and each length started with the top or thin end. The used end is left projecting on the inside and cut off later when the work is dry. The slewing should be continued to a height of 5 in ., and the rods worked out to leare the top level: if necessary short lengths of oxier can be worked in in order to obtain the required level

A band termed a wale has to be worked round the sides. Pick out four thin rods of medium length and, commencing with the tops, place them behind four stakes in order. and then carry them alternately in front of three and behind one, until the round has been completed and the commenoing ends coyered. The result of the work will be seen in the stiff. ening of the weaving. A single rod weaver should be worked, adding others to bring the sides up to the height of 8 in . This method of weaving is termed randing. The top should be left level, and if the weaving has been carefully done all the upright stakes will be equally spaced all round.

The sides are now ready for the border which may be quite simple or full. The simple horder is formed by bending each stake down in turn, and carrying the bent top in front of

Basket. Simple round basket, useful for marketing, and three lengths of osier
the first on the right, behind the next, and left outside the third, the ends being trinimed ff a little bevond the stake they rest against.
For the full border, commence by laying down four spokes, the first behind the second, and left in front of the third ; the second is taken behind the third and left behind the tages in weaviak it trom short

fourth, the third behind the fourth, and left behind the fifth. The fourth stake is taken behind the fifth together with the end of the first one laid down, the fifth stake is worked together with the second laid down and so on until the complete round has been worked, the last four stakes being worked together with their corresponding ends underneath the bends of the first four. The projecting ends which are now on the outside of the border are trimmed off quite cluse to the border, when the work is dry. The handle is formed from a atout length of rod, and bound in position with lengths of osier. A rod is cut to a length of 30 in ., with both ends sharpenerl. One end is driven down through the border to a depth of 6 in . alongside of the stakes. The rest of the rod is carefully bent, and the other end driven through the border alongside n stake on the opiosite side. The plain bow may be covered with a double spiral formed by driving the sharpened end of the rod each side of the handle. The rods should be wrapped mund and the ends worked across and through under the border on the opposite side in each сляе.

The basket should be finished by cutting off all the pro-
same method may be followed in recovering a large bow handle when the covering is broken.
The bottom rim of both square and round baskets can he strengthened by driving in, alongside the upright stakes, a number of single stakes, endeavouring to get them as far through the weaving as possible. The upright ends are treated much in the same way as a border, each rod being carried down behind the next, in front of the one following, and left either behind the next or in front of the next but one. When the ends are cut off, the new rim will form a solid foundation to the old work

BASKET BALL. Game played, especially by girls, on a stretch of ground between goals, which consist of a net shaped like a basket. It thus rescmililes net ball (q.v.).

BASKET PLANTS. The culture of plants in baskets is a great convenience to the amateur who possesses only a small greenhouse or conservatory. The baskets are usually made of galvanised wire, wood, or terracotta.

The number of kinds of planta available for basket culture is very great. The following may be named as suitable. Achinenes, asparagus fern, begonia, certain of the campanulas, buttercup oxalis, clianthus or glory pea, Cornish moneywort, fuchsia, ivy-leaved geranium, ivy-leaved groundsel, ivy-leaved toadliax, Cape cowslip, lobelia, mother of thousands, nasturtium, petunia, and thun. bergia.

Wire baskets are beat for ferns, and should be lined with moss. In hot weather the baskets should be dipped in soft water twice a day. Two parts fibrous loann, one part rough peat, one part leaf-mould, and sand make a suit..ble compost. The plants should be put into the

Basket plants and methods of arranging them. 1. Basket placed on fower-not tor convenience In planting. 2. Section of portion of basket: A. moss lining: B, rough soil for base planting. 3. Side plants in finer soil, leavinz space, A. for centre plant. 4. Section of basket witb plants in position. 5. Corract method jecting ends left inside, but as the rods alirink when dry, suffi- baskets in spring. A well-grown plant-one, cient should be left to prevent the end slipping past the stake on which it rests.
Basket Repairing. The handles of clothes baskets are formed with two thoroughly soaked rods which are driven through the border alongside suitable stakes. The ends should be driven down as far as possible. Bend the rod on the left and pass the top under the border fyom the outside alonggide the rod on the right and pull it right through to form a bow: Now twist the seoond rod on itself and carry it in the form of a spiral three times round the bow, carry it under and through the border and return to the commencing side and repeat. The end of the first rod can be treated in the same way, and this is continued until the bow is filled up. The
say, turned out of a 5 in. pot-should be put in the centre, leaving the crown just above the top. An old plant should be divided into a dozen or more young plants, and these should be planted mound the edge of the basket, as shown at 3 in the diagrain above. Several kinds mas be arranged in one basket, the small being ineerted in the sides, the fronds pointing downwards. A large kind should occupy the centre. See. Flower Basket.

BASQUE. That part of a bodice to which the waist is sometimes fitted, extending downwards from the waistline. A basque may be cut on circular linc3, or it may consist of two straight pieces, one attached to the fmnt and one to the back of the bodice, with openings at the side seams. See Blouse.

BAS RELIEF. The decoration of a head and hody are concerned the basset is modern house often includes some form of bas-reliof in the frieze or cciling of a room. The most common material is annglypta, or one of the other variants of fibrous plaster. Modern fibrous plaster, which, with gypsum as a basis, sets into a hard coment, is quite durable enough for ordinary purposes.

The depth of the relicf should depend upon the size and height of the room. In sinall rooms the reliof should rarely execed $\frac{1}{2} \mathrm{in}$. to 1 in . in depth See Anaglypta; Moulding

BASS : Cooking the Fish. To bake. Wish and clean one or two medium-sized lish. placing a little butter or dripping inside each, and seasoning to taste. Lay on a greased haking-tin, smear with more fat, and bake in a slow oven for a little less than half an hour, basting occasionally. Cut some potatoes into neat pioces, and when partly boiled put them into the baking-tin with the fish. and cook for 10 min . or so. When donc, arrange the fish on a hot dish with the potatores placed mund and garnish with fincly chopped pasley. If liked mustard sauce may be served separately.
Bass niay also be stuffed. Trko a fish weighing about 4 lb , wash and olean. and season it inside with salt, pepper and lemon juice Then stulf with oyster forcement, sew the fish up, and lay it on a grcased baking-tin, squcezing sorne more lemon juice over it, and placing a few thin slices of fat hacon on the top. Bake in a hot oven, basting occasionally with the fat. When cooked, place the fish on a hot dish and draw out the trussing tliread. Sprinkle with paraley and cut lemon, serving with it tomato or any other suitable sauce separately. It is sufficient for seven or eight persons.
BASS: A Useful Wood. Bnss or basswood comes from the lime, lut more usually from the tulip, tree of N . Anserica. Alternative names are American whitewood, American poplar, tulip wood, Bassoon. A. Rees. and canary wood. It is a B. Crook. C. Wing. soft wood, usually light D. Double Joint. yellowish-green in colour, is $\begin{gathered}\text { E. Lonf Joint } \\ \text { oltainable in largesizes, and }\end{gathered}$ obtainable in large sizes, and
is often used instead of pine for furniture, pancle, boxes, pianos, toys, and carving l3ass is as straight in grain and as free from knots as pine, and slightly harder. It talion stain and polish well, the usual stains heing obony or walnut. See Wood.

BASSET HOUND. Originally a sporting dog, the basset hound is now liept more as a companion than for hunting harea. So far as

Basset Bound. Once a sporting dor. Specimen of the smooth-coated variety
licad and hody are concerned the basset is
a full-sized hound, but it stands only 9 in. to 12 in . at the shoulder. The logs are so short that the deep cheat alnost brushes the masaive fore-paws. The ears are very long.

The dog weighs from $\mathrm{in}^{1} \mathrm{lb}$. up to 45 lb . the bitch rather less There are two types of basset-the rough, with a harsh, profuse coat variable in colour, with a dense under cont; and the smooth, with a short, fine, and glossy coat of black, white, and tan colour. It is good-tempercd and affectionate. See Distemper: Dog.

BASSOON. An instrument of extensive complass, the bassoon possesses a beautiful tone, and is so useful in an orchestra that compctent players are always in request. To fit the separate parts together, the reed is put into the narrow end of the crook, the broader end of which is inserted in the wing. The wing and the hass-joint are then plated side by side in the holes at the top of the double-joint, and finally the bell is put on. The instrument is held transversely across the person, sloping from the left shoulder to the right thigh. A strap round the nock takes the weight of the instrument, which lies in the hollow of the hands, the left being the higher of the two. The reed is taken into the mouth, but it must not come into contact with the teeth. The beginner will be wise to get at the outset a few lessons from an experienced person regarding the embouchure, the fingering, and other elementary points.

A good instrument ought to last for many years, but this is conditional on scrupulous cleanliness. After use the interior (particularly of the wing) should have a soft rag passed through it. All tone holes should be kept free from dirt, again with a suft rag. Keep the joints clean, greasing them if necessary to prevent moisture working in and thus causing splitting. The orook should be oceasionally washed in hot water. Should the how hole become clogged, free it by using carefully a soft brush or a fine needle. Reeds also should be gently wiped and put in some

Before fixing a bath in a house it is necessary to know exactly the lacation of the water supply, rain-water pipes, and gullics or drains required to take away the wastc. If the rooun is in a basement, a waste-water gully inust be available; if it is on the ground flonr, then it is necessary to ascertain the difference in level between the floor of proprosed bathroom and the level of the gmund outside, and of the gully to be used for the bath waste. The waste pipe must have a continuous fall from the bath outlet to the gully, and this must not be less than 3 in . in 10 ft ., and preferably more.

On upper floors it is oustomary to pass the waste into a rain-water head, or to fit a separate down pipe of cast-iron of at least 2 in . diameter, and having a head on the top and a shoe or bent nozale at the bottom, in both cases delivering the waste water into an open-trapped gully. The local building by-laws may require certain arrangements of the pipes, particulars of which can be obtaincd from the district surveyor, but generally all require the overflow and waste pipes to discharge through the heads and into gullies in the open air and be easily visible.

In the great majority of houses the batli, is made of cast-iron; the best kinds are covered with a vitreous enarnel, giving the porcelain appearance so much lilict, and a surface which will resist acids, cuabling it to be casily cleaned and liept in sound con-
warm place to dry after use. The instrument should be kept in a dry but not over-warm place, protected from dust.
BAST. This is the fistous matorial used for tying up bunches of cut flowers, and also for keeping in hand wayward branches of straggling perennial plants. The fihre, which is very tough, is the dried and dissacted stem of the hardy perennial Scirpus, allied to the bulrush and rush grass. See Raflia.

BASTING: A Cookery Term. A long basting spoon is used so that tho oven door noed not be opened wide enough to lot in cold iiir. The juices out of the mest, etc., collceting in the haking-tin are alluwed to drip from the
 spoon over the article that is cooking. This nrevents burning and improves the riavour.

Basting ladles, being round, are convenient for dipping into baking-tins made with a well in one Basting stitch showing how the needle should be inserted slantwise cornor. in able dripping is Nee Baking. Roasting
BASTING: In Dressmaking. Tacking employed to hold two thicknesses of material together before joining the seams. Begin with a knotted threarl, the knot being on tho top of the work so that the basting threads can afterwards be easily pulled out. Always bring the needle out $\frac{1}{-\frac{1}{2}} \mathrm{in}$. licyond where it is inserted, and make each stitch even. Finish off with two stitches on top of each other and leave an ond of thrend to avoid pulling the whole of the basting out by accident. Sep Dresemaking.

## The Bath: HOW to Fit and Connect It

## Installation Methods in Houses both Old and New

## For Fittings and Arrangements see Bathroom; other associated articles are Boiler; Enamelling: Geyserz; Plumbing; Water Supply, etc.

dition. The bath should be fixed in such a "ay that every part, underneath, at the sides or ends, cun be easily got at and olcaned.
Practionlly only two shajes of hath need be considered; these are known as the taper bath and the parallel, according to whether they narrow towards one end or not. Where safficient roon and adequate hot-water supply allows of the parallel bath, it is of great alvantage, giving the highest comfort in use and a decidedly better appearanco. The lest size for a bath is 5 ft . i in . long, and the roll ellge should be not less than 3 in.
The position of a bath in a room is of great importance. It should be quite clear of the walls at the sides and ends, so that there is no difficulty in being a ble to clean and dust all round it. It should also be raised from the Hoor with wooden supports, if the legs are not long enough, to pernit of swecping under it.

If a geyser is litted a good ventilation pije must be attached to carry the products of combustion to the outer air. A baffler should be fitted into the ventilation pipe to prevent a back drauglit into the room. All vent pipes, elbows, and the baffler must sucket inwards, that is, towards the geyser.

All geysers, of whatcier type and howerer hented, are unsafe unlcss provided with a ventilation pipe.
As to hot-water supply, haths hold from 31) to (6) gallons of water, and from 8 to 10 цallons
of very hot water are needed for a hot bath. If an efficient system is already installed, this can be tapped to supply the bath, other-

packed up to the necessary height with pieces of wood, wedge shaped, hut these so placed as not to be scell from the front The waste-pipe, which must be of lead hecause of its sinooth hore, and of not less than $1 \frac{1}{}$ in diameter inside, is to lso attached to the trap of the waste by means of a union which will allow for rapid disconnexion in case of need, and should be carried out to its destination quite independently of and not in any way connected with the overflow pipe. The union will be attached to the waste-pipe by means of what is known as a plumber's wiped joint.
The overflow, which is found a few nches below the top of the bath and helow the level of the supply taps, has a union connexion to which must be soldered by a wiped ioint the ahort outlet pipe carried obliquely through the wall with an open end in the same manner as the waste-pipe. Unions aie provided to the bath valves, and thesc make the connecting preces to the service pipes easy to fit, as well as simple for purposes of disconmexion. The main hot-water service pipes of the house heing in iron, must be connected to the bath tap by means of a union on the pipe to a piece of lead pipe soldered on to tlie bathtap. These joints must all be wiped on. The above methods only apply to the fixing of a single bath, and not

Bath. Fig. 1. Diagram showing connexions between bath waste and rain-water pipe and gullg. Fig.
wise a geyser is t/io easiest and probably nost efficient to install, requiring only the one cold-water supply pipe, with a branch to the bath. (See Hot-Water Supply.)
Essential connexion for the waste and over. !low pipes from a bath are shown in Fig. 1. When the bath is on the first (or "higher") floor, as at $A$, connect waste and overllow pipes to a rain-water head, $D$. If the down pipe, $N$, is continuous, remove onc section, cut off a piece about 12 in . long, and fit a rain-water head. The pipe, $P$, is 2 in . cast iron, has a head on the wall where the waste pipe emerges, and a shoe over the rain-water head, $D$. If the pipe has to go

Bath. Fig. 3. Method of carrying overflow and waste pipes through house wall to rain-water head
pipe could be taken as at $\mathbf{F}, \mathbf{G}$. With a bath on the ground floor as at $H$, connect by a similar pipe and deliver lyy a trough. Fig. 2, or directly over the gully by means of a slioe. To get the pipes through the wall, chip out the brickwork with a cold chisel (q.v.) or a jumper; it is preferable to chip out a header, or linick that goes through the wall from out. side to inside (Fig. 3). Fill the gap around the pipes with strong cement and bits of brick.
The bath must be placed with the foot as near as possible to the wall or place wherc the waste-pipe may be carried out Test the level of the bath when now in the final place desired, making sure that the natural flow of water will be to the waste. Should a test prove that the water does not run entirely away, then the bath should be
to a place where mose than one bath is fixed or connceted by pipes. for in any such casc proper ventilation must be provided for trap and waste-pipe

BATH BUN. Take I lts. llour, 2 oz mar garine or hutter, $\frac{1}{2}$ oz. compressed yeast, $\frac{1}{2}$ pint inilk and water, 1 oz . sugar. I egg, pinch mixed spice, $L$ oz. currants, $10 \%$ sul. tanas and a !ittle candied peel. Mix the ycast and sugar in a warm basin until it liguefies, then add the tepid milk and water and the egg well beaten up.
Put the Hour into a warm basin and, making a hollow in the centre, pour in the yeast mixture and mix in well. Cover with a eloth and set to rise in a warm place for one hour. Melt the fat and beat this and the fruit in well, again setting the mixture in a warm place for an hour heforc shaping into buns and placing on a greased haking sheet leave thein for 20 minutes, then bake in a hot oven for 10 to 15 ininutes. Just before taking the buns out brush them over with a glaze made of sugar and water, and garnish with pieces of candicd sugar
BATH CHAIR. Unless the working parts, of a bath chair, particularly the wheels. tires, and axles, are kept in good order, a great deal of effort will he wasted in overcoming unnecessary friction. Constructional details vary soniewhat acecording to the practice of in. dividual maliers, but the wheel hinb, axle. and spring arc the points that need attention in most bath chairs. Supposing the chair to have been out of use for some time, the following points should be specially noted.

The chair or loody if of wicker-work should be well brushed and cleaned The cushions or aquabs must be cleaned, and re-covered if need be, or loose covers of chintz or other material can be made without much trouble. A coach-built body, upholstered in leather or leather-cloth, can be cleaned up with a mixture of becswax, turpentine, and paraflin, or prepared wax can be used for the purpose. The coach body should be properly washed allowed to dry thoroughly, and polished.

The chair should now be supported on boxes or otherwise and the wheels removed With the hack wheels this is done by unscrewing
the dust-cap, removing the split-pin, nut, and washer, and withdrawing the wheel. On some machines a hall-bearing hub is used similar

Bath Chair. Diagram illustrating correct method ol making a joint in a wired-on solid tire
to that on a bicycle, and can be treated as such Most bath chair wheels are fitted with solid wired on tires generally circular in cross section. If those on the wheels are badly worn they may be replaced by new tires. (See diagram; also tho article on Perambulator.)
Clean the bearings and hubs with paraflin, and thoroughly lubricate with cycle lubricating oil. Replace the whecls. The front wheel generally rides on a spindle between the jaus of the front fork; it is removed by unscrewing the nuts and springing the forks open to allow the wheel to drop out. The stcering head and arm should be looked to, cleaned and lubricated. The springs must now be cleaned and lubricated. II only one leaf is used for the springs it will only neceasitate cleaning and oiling the supports, but if two or more leaves are used the best thing to do is to lift up the body; this will separate the spring leaves, when oil can le squirt ed betwcen them with the nid of a small oilcan with long spout, all surplus oil being wiped off. See Tire.

BATH CHAP. When hought uncooked a cured or pickled pig's cheek requires soaking for several hours hefore putting into a saucepan with warm water to cover, and hrought to the boil, afterwards being allowed to simmer slowly until tender. To dish, remove the skin and cover the ineat with browned breadcrumbs. See Bacon.

BATHING. Open-air bathing combines the tonic effects of immicrsion of the body in cold water with vigorous exercise of many muscles. In those who are unaccustomed to it over-fatigue and excessive chilling of the hody may easily be induced, perhaps to be followed by fainting, which is the most serious danger in this sport. When a person is seized with a cramp it is possible to turn on tho back: and lloat, but the swimmer who faints will sink

It is not advisable to bathe after a lull meal nor when one is fosting. The hest time is about an hour after breakfast, and if bathing is indulged in before breakfast a little food should be taken first. It is not good, of course, to go into the water chilled, but this can be obviated by a little sharpexercise just before the plunge.

The first swim of the season should he a short one. On coming out of the water there should be no dawdling in dressing, and a sheltered spot should be chosen for the purpose. A short run will help to remove the atiffness, and if ne:cesary profluce a glow. Those who remain chilled and blue in spite of this should discontinue bathing.

BATHING DRESS. The regulation bath. ing dress or swimming suit is worn by both men and women. Other styles, governed by fashion for women only, can be made from paper patterns to be obstained through any fashion journal, while regulation swimming suits can be purchased cheaply.

BATHING SHOES. Shoes in which to walk over the shingle to the water's edge can be made at home. Buy a pair of thin cork soles
of the samo size as the shoes generally worn and also a pair of straw soles one size larger. Cut tiwo pieces of canvas or proofed inaterial for the top of the shoe and two pieces of jap silk in the shape of a flat iron, and measuring
 sides of one piece of material and one piece of jap sils together, and sew along the straight edges. Turn the right side out, place over the toe-part of the smaller sole, turn the edges over to the under side, and sew firmly. forming the toe of the shoe. Now place this sole on one of the straw soles, and with crochet cotton sew the two firmily together, using a buttonhole stitch. Ribbon sandal straps of required length can be sewn on.

Bathing Tent. How to make a tent consisting of a wooden tramework to be covered with canvas

EATHING TENT. The framing shown above for a bathing tent is designed to stand considerable wear and yet be quite portable. Front and side elevations and plan are given in the diagrams. The main uprights are $1 \frac{1}{2}$ in square. The bottom framework is composed of two 4 ft .3 in . lengths of $2-\mathrm{in}$. by $1 \frac{1}{2}-\mathrm{in}$. materinl, into which two 3 ft .9 in. lengths of $1 \frac{1}{2}$-in. material arc tenoned.
The uprights are halved into the 2 -in. pieces, and the floor boards are nailed or screwed on to fillets nailed on the inside as shown at $A$. The top frame is screwed to the uprights, as at B, projecting pieces of iron wire or stout wire nails being driven in to provide a means of fixing the top. The struts are all of 18 in . by $1 \frac{1}{8} \mathrm{in}$. wood, to which lengths of thin iron bar are attached with screws, the tops being shown at $C$ and the bottoms at $D$.
Ordinary bolts and nuts should be used to attach the struts to the uprights and the botton frame The seat is placed on a bracket, halved at the corners and attaohed to the uprights, and the top is composed of two lengths of iron bar riveted togethor in the centre, and fitting on the top of the uprights through holes in the ends.

One length of canvas is attached to the sides and a separate piece cut out and shaped to go over the top. Tapes are the best means of securing the canvas to the framing, and also to close the opening. Give the whole of the woodwork and iron eeveral coats of oil paint.

## The Bathroom and its Fittings

Hints and Suggestions for the Modern Home

## The Technical Aspects of the Subiect are deale with under Bath: Boiler; Geyser, ete ; the Health

 Aspects in the article immediately followingColour is attractive in hathrooms. Even if white baths and fittings are retained, though these are to be had in almost every shade. bright colour is chosen for decorative schemes Floorings in mosaic, marbled rubber corktiling and linoleums; curtain materials of oiled or ruhberised silk, terry towelling and American cloths, tilings for dado and wall, panels of vitrolite, slate, or nicolite for sides of bath, etc., and of glass for ceiling, bath mats and towela-all can he carried out in harmonious colours. When it is a case of doing up a bathroom in a rented dwelling, hrightly painted woodwork and stean resisting enamel will remove a dingy appearance, and with simple accessories not involving much expense.
A bathroom entirely of glass, as illustrated, is highly decorative in hlack and a colour. Another scheme can he carried out in polished and enamelled slate for walls, and for the sides of a huilt-in hath, with capping and skirting in a contrasting colour. Slate can also be ohtained in panels with a marbled effect and used for dado and hath, with a rubber flooring to tone. To modernise a bathroom in an old house niuch can be done with attention to details such as electric fitting, new curtains and colour. A simple acheme, with white porcelain bath, white tiled dado, a colour-contrast in painted walls and ceiling and red cork-tiling for floor, is shown in the right-hand photograph below.

Besides the hath, an important requisite is a pedestal lavatory basin of glazed porcelain, with hot and cold water taps. The one illustrated has an easy-to-clean mirror abore, without frame but with bevelled edges. The curtains are of rubberised silk. Taps, like other fittings, should be nickel-plated. They require no polishing, only wiping with a clean cloth. If there is no hot-water supply laid on to the basin, it is possible to obtain a hath geyser which has taps on either side, and if the Cavatory basin is placed beyond the head of the bath the same geyser may serve both.
Above the lavatory basin may be one or two glass shelves, resting on nickel-plated fittings to hold various requisites Towelrails should he nicket-plated for choice. It is necessary to provide pegs on the door to hang dressing gowns, ete

The bath itself should be provided either with hanging baskets, or a rack, nickel plated, for holding sponge and soap, A crossway seat is liseful for persons who are old or weak

Bathronms arc difficult to keep neat unless overy member of the household using the room puts his or her belongings away tidily. As the hasin or the bath must be flushed out after oach use, it is well to provide, hanging in a convenient place, a suitable swab iVhere

Bathroom made entirely of glass. The use of black and one colour gives a beautiful effect Pholo from Jas. Clarl: \& Son. Led
the hathroom fittings are as described, the daily cleaning is reduced to a mininum, as nothing but a swab for the bath and another for the floor, and a dry cloth and a soft cloth for wiping the nickel fittings, is required. Where there are wooden fittings and an enamelled bath the process is more tiresome. as scrubhing and a weekly cleaning with some dry soap are necessary, and the wood must be kept polished. If unsuitable to be left constantly open, the bathroom window should be fitted with a ventilating pane

Bathroom. Left, modern design with marble bath, paper imitating green marble and sycamore tabla with glass top. Right, scheme with white porcelain bath, white tiled dado and coloured walla and floor H.ght, currte.sy of Country Life

BATHS : Hygienic and Medical. For a warm bath the temperatune of the water should be between $98^{\circ} \mathrm{F}$. (about body temperature) and about $103^{\circ} \mathrm{F}$. A hot bath should be two or three degrees higher. Such a bath induces increased perspiration and opens the pores of the skin. It is, therefore, usually best taken at night to avoid exposure, hut if this is unavoidable it should he followed immediately by a cold sponge and then a brisk rub down with a rough towel. If a hot bath is prolonged beyond ten minutes it is apt to be depressing

A warm bath at about $100^{\circ} \mathrm{F}$. is very useful in the case of shock following large hurns about the body, and especinlly in children it is a form of first-aid which can be quickly employed. This should be done also in the case of convulsions of children, and in the collapse following infantile cholera or any severe diarrhoea
The temperature of the tepid bath is a bout $90^{\circ} \mathrm{F}$. The cold bath varies from anything just above freezing point to ordinary tap temperature A cold bath should never be taken when the body is chilled

Peopl with vigorous circulations find that a cold bath taken immediately after jumping out of led in the morning gives a feeling of exhilaration and health After a momentary chilling a feeling of warmth comes over the body.

## When Cold Baths are Inadvisable

Some people do not have this reaction but remain bluc and cold after their dip, and should discontinue it. They may find that they are able to stand $\Omega$ cold sponging especially if they stand in warm water, or they may have to content themselves with cold sponging of the neck and shoulders The henefit of the cold bath is due to the sloock of the cold water on the skin, and if the water is cold enough to produce this, say $40^{\circ}$ below body temperature, there is no necessity to overdo it in the winter time.
Spartan temerity may be another name for foolhardiness. The cold bath should never last longer than two minutes, and as it is not sufficient to kecp the body healthily clean, a warm bath with plenty of soaping should be taken in addition at least once n week

Mustard baths, made by adding a tablespoonful of inustard to a footbath of very hot water, are sometimes used to check oncoming colds. The patient soaks the feet in the water for five minutes, while the rest of the body is enveloped in blankets

As $a$ rule, infants should have a bath night and morning, and older children a thorough bath once a day.

A thermometer should always be used in prepuring an infunt's bath, to avoid the risk of the infant being scalded by someone forgetting to add cold water.
The hath water should be brought to the re quired temperature, about $100^{\circ}$, by pouring cold water into the bath and then adding boiling water mintil the thermometer shows that.

BATH SALTS. A small varicty of crvatal suited for bath salts may he made by crushing equal parts of ordinary washing soda and borax and sifting until the crystals of one size are separated. These are then perfuned by spraying over them a solution of ionone (artificial violet) $\frac{1}{2}$ dram, in spirit 1 oz ., this being sufficient for 2 lb . of crystals.

Another simple prescription for bath salts is:

Oil of rose geranium
Oil of lavenider
Spirit of wine
Carbonate of soda crustal
Mix oils and spirit
Cover the bottom of a wide-mouthed twopound glass bottle with a two-inch layer of the soda crystals. Over this sprinkle a dozen or so drops of the mixed oils and spirit. Shake
well and stand by for a day in a cool corner Next day add another two inches of the sodn crystals and another dozen or so drops of the oil and shake well again Repeat this until the bottle is almost full, and then pour on the remainder of the mixture of oils Keep tightly corlied for two months before use
A tablespoonful may be added to a full bath or a teaspoonful to a hand basin
'lo colour the salts, a little cochineal may lic added or washing blue ; or, for a purple shade, a mixture of the first two. Just a drop of each should be dissolved in glycerine, or it will not colour the crystals evenly. Put a layer of these in $\pi$ jar, and a few drops of the colouring. shake well, add perfumc, transfer to anothe, receptacle and prepare the next layer.
Bath Sheet. See Towel.
BATIK. The process of colouring fabrics known as batik is carried on principally in Java, where it is used to make native dresses, and is to be recognized by the "crackle." a network of finc lines

Batik. Wooden bowl decorated with a barbaric design before being plunged into the dye bath
Although, in common with other applied arts, subject to fashion in its use, batik is suitable for the decoration of curtains, some ornamental objects, and of silk scarves, dressing-gowns and house coats Before commencing it would he well to study the examples of Javanese batik that are to be found in museums It can be applicd to all rabrics, silk being the ensiest, and it can also be employed for decorating wood and paper. The wooden bowl illustrated was decorated beforc plunging it into the dye bath.
To malie a batik, first draw a design on thin paper and measure to see that the size is correct. Then make a pounce of it either by pricking with n tine needle or using a little tracing wheel. The rough side of the pounce must be placed uppermost on the material and carefully rubbed over with an old piece of sandpaper in order to remove unevenness.
Having fixed the design on the material, which has either been stretched in a frame, laid on oiled manilla pajer or a sheet of glass, go over the surface with a pouncing pad dipped in pounce pouder. If this is not avail. able, make a wad of rag or cottonwool and use powdered charcoal.

Put a piecc of special wax into a small pan and allow
it to get hot, but not boiling, over a spirit lamp. Dip a round brush with long liair into the wax, and procecd to fill in the design If the wax is at the right tem. perature it will penetrate the material. The moment it clogs put the brush into the hot wax and heat thoroughly. The size of the brush varies according to that of the design, but No. 12 is a useful size, with a flat brush about $1 \frac{1}{2}$ in. wide for borders.

## Tools for Applying the Wax

The t.jantin or Javanese batiking spoon rescmbles a metal teaspoon with the edges turned up and a tiny spout at one end, through which the hot wax flows. A similar tool, called a pipette, is ohtainable When using this the work should be laid flat on a table. The point of the spout must not touch the material, as this closes the hole and stops the flow of the wax Do not hold it over a llame : fill by plunging into the hot wax, wipe with a rag, and work as quickly as possible. When cool hold it in the hot wax in the pan until the wax is melted ngain There is also a batik pencil which resembles $n$ stylo pen Small aticks of wax are inserted in a tube, and the pen is held over a flaine until the wax is melted, when it llows through the point It is useful for drawing on wood

To ensure a clean outline, outline the edges of large designs with a fine brush or the pipette, and then lill in with a large brush Before dyeing look nt buth sides of the material, and if the wax has not penetrated apply again on the wrong side.
The dye bath is prepared by mixing concen trated colour into water, either tepid or cold, until the desired shade is obtained. Take a small piece of material, wet, and dip into the dye bath. Leave it a few moments, and then squeeze and hold up to the light to get an idea of the colour when dry. If incorrect, allow morc water or more dye as may be necessary. India-rubber gloves should be worn when dyeing, to prevent staining the hands.

Household dyes can be employed, but those specially prepared are ensier to manipulate. One of the hall-marks of hand-made batik is the crackle, a network of line lines. This is produced by crushing the waxed inaterial between the hands before the final dipping. Good effects are obtained without using crackle.

If only one dye bath is used the material can be rinsed, hung up to dry. and then

Batik. Cornes of a silk scarl decorated in vivid Spanish coloura
ironed between sheets of newspaper to remove or electrodes. The action depends on the the wax. To have more than two colours, decomposition of the electrolyte and the effect portions of the design must be re-waxed. of the liquid on the clectrodes When a cell is If part has been wnsed, and
that material dyed grey, wax in some of the grey and dyo scarlet, then wax in some of the scarlet and dye black. In this way a multi-coloured design will be olitained It is best for the beginner to use the lightest colour first, and to nooid too much crackle, as, owing to the uneven waxing of the design, a certain amount of colour will be sure to gn through where the wax is thin and shade the work.

Another method is to colour the design in with a brush, then cuver with wax and dse the background some dark colour. The effect is quite pleasing, but it is a travesty of the real Javanesc batik. One of the charms of this is that a design can never be repeated

Batiste. A fino cambric, very sofl, for bandkerchicif, underwear, and summer dresses.

BATTEN. In the timber yard batten is the term used for unplaned wood of the following scantlings: 1 in. by in., 2 in. by $f$ in., 3 in. by $f$ in The $l \mathrm{in}$. by $f$ in. hatten is chiefly used for tiling, but the 2 in. by in. has a muititude of uses It is employed for tiling, joist plates, partition basen, framing for attachment of patent wall linings, for sholl supports, light cupboard franicwork, for making mouldings, architraves, and picture rails, and for forming brackets

BATTER. There are various recıpes for making batter. It can be made as follows : Take 4 oz . flour, $\frac{1}{2}$ pint milk, 1 egg and a saltspoonful of salt. If the llour is at all lumpy, pass through a wire sicve, or let it fall through the fingers into a good-sized basin. Having mixed in the salt, make a hole in the centre of the flour, beat the egg till frothy and add to it half the milk. Pour in alout four tablespoonfuls of this mixture, and with n wooden spoon atir in a little of the Hour, drawing it into the centre pool from tho sides. W'ien this centre pool is a bout as thick as rich crearn. add more milk and egg, and work in more flour, always keeping a pool of smoothly mixed batter in the centre. (io on adding the mixed egg and milk until all is used, by which time all the flour should have been drawn in

Next beat the batter well with a spoon, until the top of the mixture is well bubbled. Stir in the remaining milk, and put the batter aside to stand, thus softening the starch grains in the four by sonking. No more beating must lie dune after the last half of the milk has been stirred in Stand the batter for half an hour, after which it is ready for use. See Ipple Fritters; Pancake. Toad-in-the-Hole; Yorl:shire Pudding.

BATTER PUDDING. A richer batter is made from $\frac{1}{2} \mathrm{lb}$. of flour, 3 eggs, one pint of milk, and a good pinch of salt. Mix as in preceding recipe ; then place in a well-greased basin just large enough to hold it, tie a scalded Houred cloth over the top, and plunge the pudding in a saucepan of boiling water. It should be boiled quickly for alout lif hours, and served with meat gravy or fruit syrup. This pudding may also be steamed or baked.

BATTERY. Electric primary bntteries are pieces of apparatus for tranaforming ohemical energy into electric energy. The forms most usually found in the home are dry hatteries, such as are used in pocket flash-lamps, and Leclanché batteries for bell work. A battery consists of two or more primary cells connected according to the voltage or pressure required.

A primary cell consists of a liquid known as the electrolyte and two metals called elements

Cardboard Case
Diagrams showing the arrangement of thrae dry cells in ae case, as used in a pocket flash-lamp battery at work the electrolyte attacks one of the electrodes very vigorously. This is termed the positivc element or anode, the other element being known as the negative or cathode.
The flow of current in the connecting wires outside the cell will be from the negntive element to the positive, hence the negative element becomes the starting point of the current to the circuit. This is ca!led the positive pole or terininal and is painted red or distinguishod by the + sign. The other eloment becomes the negative pole, is painted black, and distinguished by the - sign. It is these poles that are referred to in all wiring diagrams, and not the elements of the battery themselves.
A dry cell consists of a zino pot, open at the top, which constitutes one element, and a carbon rod or plate surrounded by tho
 Leclanehe porous pot
together in series to form a battery for an electric bell circuit
electrolyte in parte form. The paste comprises sal-ammoniac, peroxide of manganese, powdered carbon, ohloride of zinc, glycerine, and water.

The ordinary dry cell has a voltage of almout $1 \frac{1}{2}$ volts. By connecting several cells in series (i.e. the carlion of one to the rine of the next), the voltage of each is added together, hence three cells in series yield $4 \frac{1}{2}$ volts. The quantity of electric current available depends on the size of the cell, and is called the amperage. The quantity cannot be increascd by series connexions, but only by parallel connexions, that is, by joining zinc to zinc, and carhon to carbon. It is imperative to remember this basic principle when doaling with any form of primary battery.

Of wet batteries the Leclancho is the most extensively used for electric bell work. It consists of a glass jar, usually square. The positive element is a round zino rod, the negative element a plate of carbon

Tho latter is contained in an inner pot made of porous earthonware, the carbon plate being packed in tightly with hack oxide of manganese and powdered carbon. The electrolyte is a solution of sal-ammoniac in water, about 2 oz of the former to 1 pint of water. The solution should about two-thirds fill the jar when the porous pot and zinc rod are in place
It is of importance to clean the zinc rods occasionally by washing them in strong soda wator, also to renew tho electrolyte if the hattery becomes feeble. See that the electrolyte does not crecp over the outer odge of the glass jar. If it does, wipo the jar clean and give it n coat of grease around the rim, where it is painted black. Sec also that the termina nuts are clan and free from deposit. See Accumulator: Beils, Flectric:

## tor; High Tension

BATTLEDORE. Similarly shaped to the tennis racquet but smaller, the frame of this bat is of wood with parchment stretohed across, or of gut or st ring fastoned tightly to the frame. From the gamo of hattledore and shuttlecock Badminton has evolved. See Badminton. Racquet; \&huttlecock
BAULK. The term baull: or balk is applied to a large solid piece of timber such us is used for piers or wharves or occasionally for the supports of houses erected on an insccure natural foundation. See Wnod.
BAY. The hay or sweet bay (Laurus nobilis). is an evergreen trce with ammatio leaves. It is frequently known as Poet's Lsurol. It is not perfectly hardy, and ought to have a sheltered place. Sandy loam, well drained, suits it admirably. Propagation is by cuttings in early summer. The cuttings are hest inserted in a frame or under a hand-light, and kept shaded for a week or two. Thero is a variety callod sassafras, the leaves of which in the United States arc used for flavouring swectmeats.

Bay Leaves. These are the aromatio leaves of the sweet bay. An ordinary faggot or bouquet garni for Havouring soup is generally comp-sed of paraley, bay and thyme. Bay leaf should not lie more than one-tenth of the whole.
BAYONET JOINT. Originally devised for rapidly fixing the bayonet to the rifle, the hayonet joint is now in morc extensive use for purposes requiring a securo but readily dernountable joint. Essentials of such a joint or catch are the L-shaped alot and a peg to engage it. An exnmple is the joint on the standard hayonet cap electric lamps. In this type a compression spring is incorporated to form a secure lock. See Joint.
BAY RUM. Originally imported from the West Indies, liay rum owes its distinctive odour to oil of bay, obtained from the leaves of Myrcia acris, the leaves of which are distilled with white rum. It is made as follows: Jamaica rum 8 oz ., spirit of wine 32 oz , distilled water 24 oz ., oil of bny $\frac{1}{2}$ oz. Shake together and after seven days filter through blotting paper

BAY WINDOW : Its Fittings. The decorative possibilities of a room arc often improved by this form of recessed window. The bay space may be used for a writing-table or dressingchest and furnished with a window seat.
The window requires a comice to hide the rod oul which the curtains are hung. The rod itself should be curved so as to allow of the curtains being completely drawn. If the ourtains are of silk or any thin material a second rod with a frilled valance may replace the cornice. If the curtains are of velvet or any heavy material the comice should be fitted with a Hat shaped pelniet. This may be cut in curves or in angular deaign and may be embroideredior edged with trimming to make a good upper part to the window scheine.

Still another method is to provide the windows with casement curtains and to put the rod for the heavier full-length curtains straight across the insidc line of the recess formed by the window, so that when they are drawn the recess is whut off
Window Seat with Locker. We give here a suggestion for fitting up the interior of a bay window about 4 ft . in width. The details shown will apply equally to any recess up to 0 ft . wide. A seat with return ends is shown, together with a locter in centre, the front of which is made to fall. Auserican whiteworl or pine, if available, will answer all requirements. A part plan of the seat is given, showing the intersection of the return end, and also part plan of under-framing.

A start may be made by cutting the battens or rails A which will fix the height of the seat. It must be decided at this point whether the seat will be cushioned or not, making allowance for the thickness of cushion (if any). Roughly speaking (within limits), the shallower the geat the higher it may be. In the present instance the seat is 12 in. decp only, and may, therefore, be made 1 ft . 6 in . high and even 1 ft .8 in . without disconfort. The rail A might be of 3 in . hy 1 in . material to be nailed to the uprights of the lay. In positions where these uprights do not show, the rails nay be screwed to an existing wainscot, or suitable lengtis of 2 in . bu 2 in . material may

Buy Window. Interesting treatment involving the use of casement curtains and the same material for pelmet, outer curtains and the seat cushion

Bay window fitted with a wooden seat having a locker in the centre. Working diagrams are given atove and explained in the text
be erected to and if the front edge is shaped back to not afford a bear less than 9 in . the effect will be improved. In ing at the dealing with the scat the returns can be put limits of the together as shown, and tongued. The front seat. In edges and outer corners will be best rounded additional off, and in fitting it should be notched to interbearing is ob- sect with posts and any other projections, tained upon so that it fits close up to the recess walls when the locker being nailed down. Where there is available sides 13 , which space, a sloping back about 1 ft .6 in . high or can be lin.less so is comfortable and also looks well. Sec thanthe Curtain; Pelmet. finished depth of seat.

In erceting these sides, lengthsof 2 in. by 2 in . wood arefirst nailed to the Hoor at (i, and thesides nailed to thesc. At the
top, two lengths of 2 in . by l in. are shown, cut in thash to the top edges of both sides IB and rails A and nailed, which should afford a firm atruot ure for further procedure. The pieces $C$ are cut back sufficiently to take the piece E, which butts between the locker sides, to which it is nailed, in addition to being fixed to blocks behind, which are nailed to the floor. When this piece is in position it will form a rail for hanging the locker fall to, both being I in. thick. The fall should thus close ensily flush between the locker sides and hed on to the rail D, which serves as a stop to prevent it pushing in. This fall is macle of boards tongued toget her and glied up, the panel effect being formed by lengths of mould or $\frac{i n}{}$. bead, glued and panel-pinned on.

For the sake of linish, a length of thin material ( $\frac{1}{f}$ in. or $y_{g}$ in.) is nailed in front of E , to linislı $\frac{1}{8} \mathrm{in}$. from outer edge of each end, and have its cilges rounded off at top and ends. The front supports or cheeks, F, oan also be fixed ly blocks to the Hoor, as indicated by dotted line, cut to set back so as to be practicully out of sight, and the further fixing can be by means of dowelling, or slot-screwing to uprights. Width can be 1 in . less than seat,

## BEADS AND THEIR

## How to Carry out Designs on Canvas, in Crochet and Knitting, and on the Loom

Other suggestions for the use of Beads are given under Embroidery; Lampshade; Tassel, ete.

Bead work mav loe divided into five classes: ncedle and thread bead work (on ceanras or on the thread only); crochet bead work; knitted lread work; loom bend work. and novelts bead work. The fashions come and go, buit by one of these methods bead-hags, bead-cmbroideries, necklets, hracelets, Howers, etc., can be inade.
I special loom bead can le bought for the finest work in this class. There are wooden millinery beads, Venctian necklet and Hower beads, rondles, a Hat glass disc for threading between beads to lengthen a necklet, applic, ueis, tubes for dress-trimming, large glass beads and long bugles, dianante, imitation cord, jade, ctc.; beads of papier mêché, of corl;, of leather and of metal. Nost of the small glass or crystal beads, and also tiny metal beads are sold in hanks.

Most of the metal beads have fairly large holes and can easily be threaded with a No. ? or 10 lsead needle. These needles run in sizes from 8 to 16 , and have elongated eyes which allow the passing of a thicker thread, although the actual needle is finer than the fincst darning needle. For necklet threading, special cards of silk in white and colours are sold with a threading wirc artaching to one end. The sizes range from 4 to 8 , the lower number being the finest.

Little cards of necklet wire in gold and silver colours, medium size only, are sold for threading heavy beads.

In Fig. 1 a design for working on canvas is shown. Ilesigns can be bought ready stamped on canvas. but an ordinary transfer can be used, with two-thread canvas that is. two threads going both ways of the canvas and prolucing a square mesh. When buying the beads, get $a$ size that will just cover the mesh, so that the canvas will not show afterwards. The beads should not be too large or the work will not set flat.
This work is done in rows from left to right. Join the thread on the wrong side, then bring up the needle at the left-hand lower corner of the mesh. Thread a bead and pass the needle down through the upper right-hand comer and up again through the mesh right unclerneath, making a stitch like the first half of a cross stitch with a bead resting on it. The work can be done in coloured sections, if desired. (See lig. 2, with the needle in position.) When the end of the row is reached, pass the necile and thread through the meshes just under the beads to get back to the left-haid side. The alternative is to fasten off at the end of each row, as you must begin the following one at the left-hand side. The patterin must be followed in each row Follow the

Bead. Fig. 1. Design for a bag on cauvas worked in beads. Fig. 2. Portion al canvas anlarged in order to Design lor a bar on cauvas worked in beads. Fig. 2. Portion of canvas anlarge
show how the pattern is followed. The work is done in rows from left to right
colours and the outline for the shape of the bag, as marked on the canvas.

Bags, purses, etc., can be worked in crochet bead work, in short rows. If a square or oblong bag is required, it is best to work in rounds like a stocking, beginning on a ring of ohain accord. ing to the width of bag required, and working from the inside so that the beads are always on the outside. In Fig. 3 the sides of the bag are worked in circles. and these are joined by a long crochet strip eight beads wide, sewn to the circles as far as the hinge of the metal top to which the purse will afterwards be sewn. The straight strip of crochet head work will give more capacity to the bag. Fig. 4 shows the work in progress.

## Bas in Crochet Bead Work

To work them, first procure a metal top so as to know what size to work to. Unwind the thread, passing it on an empty reel, and as you unuind, slip the thumb and forefinger of the right hand along the thread to feel for knots. If you leave a knot that is too large to take the beads you will find that they will not push down in the course of working, and all the labour of threading will be wasted. Sylko No. 8 can be used with a No. 10 bead needle, a No 3 steel crochet hook and No. 7 beads. If No. 9 beads are used fewer increasings must be done to keep the work thit. A whole bunch of beads can be passed on, and when all the beads are worked up the thread can be broken, another ball threaded, and the two thrends joined by a knot at the back of the work close up to the last bead. For the purse illustrated 25 amber and 25 brown beads were threaded alternately, and produced a maze design when worked up, no fewer than 3,100 beads being used in the whote design.
Make 4 chains and join into a ring by slip. stitching to the first stitch. lst round: * I double cruchet into the ring, push up a bead close against this stitch, and repeat from * 5 times. 2nd round : 2 double crochet in each stitch all round, always pushing up a bead after each stitch and taking up the back loop of the double crochet. The beads will apprear on the side of the work that is away. Now sew a piece of white cotton in the first stitch of the round to know when you come to it, as it is important to keep the rounds uniform Do three more rounds like the second onc 6 th round : * 1 double crochet in first stitch, 2 double orochet in next stitch, and repeat frum * all round. In the case of bigger beads increase in every 5th stitch 7th round: 1 double crochet in each stitch.
Now repeat the last two rounds until the circle is big enough to fit the top. The work inust be quite flat ; if loosely worked the circle may Hute a little. This is remedied by working un extra plain round or two without any
 of of bag and lining togetler, then sew oll the metal niount with st rong linen thread thus: Join the thread on the wrong side, push up through the first hole from wrong to

Bead. Fig. 3. Bag with beads crocheted on in circles Fig. 4 (above, left). The work in progress
right side, thread $a$ bead on the ncedle, then push the needle back through the same hole then repeat this in each hole around mount When the end of the clasp is reached draw up the sides of the bag a little to close them and fasten off securely
Fig. 5 shows head work on plain knitting 'Ihread the beads on the silk, then decide whether a plain bag or one that will be gathered on the mount is required, so that enough stitches are allowed when casting on.
For a striped bag, cast on any number of stitches divisible by 6 and 3 over for edge stitches, which are knitted plain Knit two rows plain without beads. 3rd row: Slip 1 . knit I , put the needle in the next stitch in position for plain knitting, then push up a bead against the last stitch and finish knitting the next stitch; repeat from * to the end. and knit plain the laat stitch without a bead. Now knit the next row without beads. If threaded correctly, you should now have 3 beadn of the same colour to begin each row so keeping the stripes intact. If knitting a pattern the beads should be carefully threaded in the right order before beginning to work Any cross-stitch pattern can be copied in cruchot. knitting, or loom bead woik.

Loom Bead Work. The loon is a simple wooden device marle in three sizes. The medium loom, $11 \frac{1}{2}$ by $7 \frac{1}{2} \mathrm{in}$., is used chiefly for necklets, purses, and bags. On this size a bag 7 in. wide oan be made (Fig. 6), but it is best to work wide designs in strips taking 20

Fig. 5. Beadwork applied in stripes to plain 4 nitting tor a bag
to 40 beads according to size and join the strips together afterwards by threading in and out of the bead on the edge of the strips. Extra long bead needles are sold for wide designs. Any cross atitch or tupestry design can be followed and there is no preliminary threading of the beads, as they are taken up each row according to pattern.

Ordinary strong linen thread or silk twist can be used. First prepare the warp threads. allowing some inches over the length of the intended article. Cut the threads in separate lengths, allowing one more thread than there are beads for ordinary Hat weaving, as in the case of a bag. The loom is always placed with the spool end farthest away from the worker, Fig. 6.

## How to Set the Warp

To set the warp, tie all the threads together on one end, and recure on one of the nails on the spool at the top of the loom. Then place the threads in rotation on the notches of the first bridge, and oarry this thread down to the corresponding notch on the lower bridge. When all the warp threads arc set, draw them down firmly, pass the ends through one of the holes at end of loom and push in the little peg to lieep these threads quite taut; then wind the remaining length of thread round the end of the loom and pegs.

Take the weaving thread, which can be the saine kind as the "arp thread, thread it intu the needle, and tie at the top of the first left. hand warp thread. Thread the full number of heads for the first ruw, pass the needle from left to right under the warp threads, and push the bead up in prosition between each warp. Where there are too many beads to keep on the needle let them slip down the thread, push them in position and hold under the warp threads with the forefinger of the left hand,

Fig. 7. The beads should be pushed well up the two sashes as in Fig. 2. Fig. 3 shows the vated for many yeara, but in dry soils sume between the threads so that the latter do not section of a bead used to break up the surface come up over the necdle when passing back. of flat panels, etc.. while the centre bead, Fig. 4,

Take the neerlle in the right hand, and pass it back from right to loft through all the beads, taking care that the

is a dado or chair rail bead. Fig. 5 is the common half-round beading. Beads are often used to break the joints between various parts of work, such as on the edge of matcherl boarding, the panels of some kinds of doors, a round door frames, to fix the glass in bookcases, shop fittings. etc.
BEAD PLANT. This popular plant has graceful feather-shaped leaves, and the flowers of different varieties are blue. white, or pink in colour. Usual green. house soil suits them, and they require to be kept moist and warm They are propagated by means of cuttings taken in spring.

BEAKER. These are either vessels used for mensuring liquids or large drink-
wet decayed material should bo put in a trench about the width of a spade blade and ahout 18 in deep. Over the manure replace several inches of earth, which should be well broken up with the ralie. Upon the surface spread wood ash liberally, or a lesser quantity of sulphate of potash, and place the beans upon the compost

Broad Beans. These may be sown 4 in deep and about 9 in apart, the first sowing being made in November, except in very cold districts and exposed positions. Seville longpods or the early mazagan may be sown in November.
The second sowing may be made in February, the third three weeks latcr, and the last in the fourth week of April. One pint of beans is sufficient to sow a row about 70 ft . long As soon as the plants are 2 in . high powder the ground on both sides of the row with soot or wood ashes, hoe thoroughly, and draw a little soil up to the beans. Beans should be hoed once in ten days, and slightly earthed up after hoeing. If the weather is very dry, water heavily once, and mulch with any available litter, covering it well with dry earth. Before the blossom sets, nip out the top blooms to check the brecding of black aphides, and burn them at once.

Scarlet Runners. Theso may be sown as directed fur broad heans They must not be sow $n$ in the south until late in April. and in the north in May. It is well to make a sccond कowing about the first wee! in June. In light

Fig. 8. Draw the thread up firmly. The ing cups. The former, made of passing of the thread under and over the work glass, are used by chemists and makes a sclvedge on both edges When marlied with the various quantithe loom is full wind the work round the ties. The latter are of interest spool away from you, but leave a little of the as antiques, and valued by colwork to project over the top bridge. as the lectors. See Glass.
threads can now only be pressed down the notches of the lower bridge. If they were passed down the upper bridge a gap would result in the work. Secure the ends firmly round the pegs again before beginning to weave. At the left-hand side of the spool there are three holes, into one of which a toose nail is passed to keep the spool in position when working, and so keep the warp threads taut ; they nust not be allowed to slacken in the working.

Embroidery is often enriched by head outlining, as also are tapestry and paisley designs. Novelty beadwork includes necklaces, flowers, and various methods of decoration in vogue utilising beads, such as fringes and tassels for fancy work and dress.

BEADING. This is used for making fancy senms to connect two edges of material, and is an imitation of hemstitching. Beading can be bought by the yard under tho name of vcining. See Henstitch
BEADING. Although often used to of birds and insects. Ground that strictly speaking, a half-round moulding

These can be seen in almost any housc. quantity of decayed vegetable matter or farmThus the staff bead which holds the bottom yard manure, placed well below the surface sash of the window in position is shaped as in Fig. 1, and the parting bead which divides

BEAM. In any building a heam is a piece of timber fixed and supported at each end, and itself supporting more or less weight. It follows, therefore. that the beam as a rule is placed edgeways, or, in other words, the depth when in position is greater than the width. Beams are called by particular names, according to the purposes which they serve. That which supports the joists of a floor is it girder or binder, over a window opening it is a lintel, when supporting the middle parts of long rafters it is a purl.

BEANS : How to Grow. Bean plants may produce very poor crops in dry seasons unless measures are adopted for resisting drought, blight. and the attacks Fig. 1, and the parting bead which divides manure in a garden that has been well culti-
lacks lime naturally must be improved by
timing, and shallow soils require a generous

string. 6. Strings stretehed between horizontal wires
soil, sow in a trench and leave the earth slightly banked up on hoth sides. Hoc frequently along the rows and anoong the plants, and diess occasionally with soot or wood ash. In prolonged dry weather it will be necessary to drench the bean row with water once a week, and the leaves may be sprayed with a syringe two or threa times a week Growth should he checked when the runners are about 7 ft . high, by nipping off the top shoot. A mulch of manure or litter should be applied in a drought after a heavy soaking of water. When flowers appear weak, liquid manure may be given once in 10 days. Always stir the soil with the hoe after watering, unless the rows are mulched when the heans are young.

Dwarf or French beans should be sown late in April, and about once a fortnight till the end of June. Sow in thenches and treat as for runner beans.

Beans as Food. A combination of beans. potatoes and butter with a green vegetable
will supply all the elements necessary for a In the thrust bearing the load or pressure complete meal containing everything which health demands.

Haricot and brown or dried beans make a nourishing soup. French beans, runner beans, and broad beans are excellent as vegetables and in salads, while all the varieties of dried bean make savoury supper dishes in combination with tomato sauce, onion, cherse and other flavourings Beans tinned with pork and tomnto sauce are usoful for an emergency supper dish

Dried beans, though not so palatable as fresh ones, make a nourishing dish when properly cooked. Soak the heans for 12 hours in cold water. After this rinse well in several waters and leave for two days in a basin set in a damp, cool place, where the air can circulate íreely. Then put this basin in a larger one with a little water in it and cover the whole with a damp cloth. Within 12 hours it will he noticed that the beans are, beginning to sprout, and they are then ready for cooking. Usually dried beans require boiling for about 45 min , though young haricot beans will cook in less than 30 . Beans, like all other pulse foods, have in them a valuable form of anti-scurvy vitamins, and these are apparently non-existent until the beans germinate

BEAN CAPER. Bean capers are the flower-buds of a small tree of the genus Zygophyllum, sometimes used as substitutes for the true caper. Gather the buds on a dry day, lay them on a paper out in the sun for a few hours, and turn into wide-mouthed bottles or jars. Boil one pint good vinegar with $\frac{1}{2}$ oz salt and 6 peppercorns, for five minutes When the liquid is cold, strain this vinegar on to the capers and cork down tightly. They can be used in about a week's time, but will be better if they are kept for threc months or a little more. Sce Caper.

BEAN CUTTER. A handy machine which performs the cutting of French heans and scarlet runners with rapidity, thus saving time and labour. Most of theso machines also slice other vegetables, oranges for marmalade, etc.: a sprecial grooved attarhment being supplied for the cutting of beans. The machine should be kept clean and dry, and receive an occasional drop of lubricating oil

BEAN WEEVIL. The name is applied to several species of small bectles which attack beans and peas, but it belongs properly to Sitones lineatus. The wing cases of this tiny grey-brown weevil are streaked with white lines and the head drawn out into a broad snout. The female deposits her eggs in the nowly formed pod, and the young larvae feed in the seeds.

Similar destruction is wrought by two species of Bruchus (B. rufimanus and B. pisi), the first frequently found in the grub stage when green peas are being shelled. The young plants may be protected by sprinkling them with soot or fine road dust. Bean seeds should be examined before aowing, and any that have been attacked by the pest should be picked out and destroyed.

BEAR BERRY. 'This is the popular name applied to trailing heath-like plants belonging to the genus Arctostaphylos. They are useful for the moist side of the rock garden, and the best sort, A Uvaursi, hay pink llowers in early summer and red berries in the autumn The bear berry needs only the culture given to ordinary rock plants. See Ruck Garden.

## Beard Tongue. See Pentatemon.

BEARING. A bearing is any support for a rotatable shaft or aimilar driving part of a machine. In its simpleat form it is a plain hole in the part that forms the support for a cylindrical shaft. In the journal bearing the load acts at right angles to the axis of the shaft, and includes such examples as the bearings of a mangle and the axle of a railway carriage.

The two great enemies of a bearing are the ingress of grit and dirt and the absence of a suitable lubricant. Small or delicate instruments such as typewriters and sewingmachines should have their bearings cleaned with a small brush dipped in paraffin, and then be well oiled with light-grado oil. Heavier machines such as washing machines, mangles, chaff cutters, lathes and small machinery generally need a heavier-bodied oil, known as light machine oil.

The oil must be present between the two working surfaces, and any excess outside the bearing should be wipcd off, as an oily exterior only attracts and retains dust. Adjustments are made in many different ways; the point to bear in mind is that the bearing should allow of iree and casy morement of the shaft, but should prevent any shake or alack ness See Ball Bearings; Big End; Front Axle ; Live Axle, etc

BEATRICE STOVE. The name is applied to a particular variety of oil-heating stove burning paraffin oil. The heating elementa are the wick and the tall, oval-shaped chiminey or body, the vessel to be heated being placed upon the platform at the top of the stove The oil is contained in a cast-iron vessel forming the base of the stove. These stoves are malle with one or more burners Success with these atoves demands scrupulous cleanli. ness, attention to the wick and the use of a gord oil. See Lamp. improper diet and laziness are benuty's enemies. A short walk can generally be managed daily, and five minutes devoted to the following simple exercises will improve the circulation and the digestive organs and strengthen the body.
(1) Stand with feet slightly upart, head thrown back, and bring both hands so that the backs come under the chin, fingers pointing forward, el bows cluse to ribs. Send hands up and out in front, as in the breast-stroke in swimming, then separate them gradually, aweeping them back and down as far as they will go. Then draw elbows up to the sides again. With these arm movements noes a trunk and leg part. Crouch low and bring the hands under the chin as described. While rising to an upright position, finishing on the tips of the toes, send the hands out in front as described. Then beginning to crouch again, send the hands back and dow'n, bringing them once more under the chin when quite crouched Repeat six times. This exercise keejos the body supple and expands the chest.
(2) A trunk twisting exercise for strengthen ing ahdominal muscles and reducing the wrist

Beants Culture. Fir. 1. Correct nosition balt-way through exercise 5 as described in the text

BEAUMONTAGE: Hard Stopping. 'This is used in the home for filling amall holes, repairing damaged veneer, and similar purposes on all kinds of furniture

It is made by dissolving a lump of resin, about the size of a large walnut, in a gill of common orange shellac, and adding a piece of heeswar about half the size of a walnute This must be melted in an iron pot or tin can, either in the oven or on the top of a stove; only gentle heat is needed, and the mixture inust not be allowed to boil. Before heating, a suitable colouring pigment must be addel (about a teaspoonful) in powder form By suitable blending alnost any colour can be made to match the work to be repaired. The mixture is made into sticks by pouring some of it on to a wooden board, laying it in a line, and rolling with another boarl. The boards should be warned, as the stopping harlens rapidly.
To use the material, it is melted into the hole or over the damaged places by means of a rod of hot iron. Do not have the iron too hot, or the wood will be scorched and blis tered. Press the mixture well down into the hole, and leave a little of it above and around the damaged part. When dry and hard the surplus is removed with a chisel. knife, and fine or old sandpaper

BEAUMONTIQUE. In certain classes of cabinet and joinery work an adhesive known rs beaumontique is employed It is composed of equal parts of litharge, white lead and whit. ing, worked into a stiff paste with boiled oil.

## Beauty and Beauty Culture

## General Rules and Modern Methods for the Improvement of Personal Health and Appearance

Information on Special Aspects will he found under Ankle; Complexion; Diet; Figure; Hand, ete.

Want of daylight, freah air, and exercise, atand with feet apart and arms atretched
over head. Bend forward to touch right foot, keeping knees straight, then describe a cirolo with arms and rotate body to left, letting the trunk twist from the waiat and bending well back as arms come up and go down again to the right foot. Repeat the movement several times and then reverse direction, bending to left foot and circling towards the right.
(3) To flatten any tendency to bulge above the waist line-inhale deeply through the nostrils, and raise knee level with oheat; exhale slowly through open mouth, holding in the abdomen and put foot down, trannferring weight on to it. Repeat movement with other knee and foot and alternate up and down room, keeping hands on hips.
(4) A bicycling movement to flatten abdome: ahould be taken easily at first: lie on back with both knees drawn up towards chest. Raise right foot, but keep knees close together, and pedal with the feet.
(5) To combine stretching with strength ening the whole spine, lie on back, with arms at sides Slowly raise arms, while inhaling deeply, and extend beyond head till fingers touch Hoor. Stretch the whole body and begin to exhale slowly as arms return to sides. Begin another inhalation as body rises to sitting posture, taking care to let head follow shoulders and not come up first with a jerk. Then in slow continuous movement touch the thes with both hands. Do not bend knees. Exhale while returning to first pusition, relax whole body and repeat exercise.

At first it may be necesary to do the sitting up part of the exercise with feet hooked under a steady piece of furniture. Fig. 1 shows the correct posture assumed in this excrcise.
The benefit to be derived from outdoor sports hesides muscular development is the natural promotion of perspiration, thus eliminating poison from the system. In order to obtain full advantage from such activity of the pores, on returning home rub the body briakly with a fleah glove and take a tepid bath.

Carc of toeth cannot be too much insistel on. the physical exercises in the morning, as the In themselves they are an important point of beauty or the reversc, and proper mastication is essential to good digestion. Regular visits to the dentist and brushing the teeth night and morning should not be neglected.

Diet is the next factor to be considered. Tou great restriction in the case of normally healthy people is not to be encouraged. Plenty of green vegotables, fresh salads and sound ripe fruit supply the important natural asits, which keep thic blood healthy, and therefore help to secure a good complexion.

An excess of foods containing starch, sugar or fats should be avoided when there is $n$ tendency to put on flesh. For older people the mistakc of drastic measures for reduction is that after youth the skin loses elasticity and when the fleal, under it is reduced the stretched skin bags and wrinkles Soragginess, which comes from malnutrition caused by indigestion, together with the flaccid sagging of the muscles caused by lack of healthful exercise, is equally to be guarded against.

## Iniurious Eifects of Stimulants

Alcohol has a coarsening effect on the toxture of the slin. Also, coffee, tea. or cocos must not be indulged in to excess; the first two stimulants often causing indigeation, with flushing or sallowness as a result, and the latter overhenting and liver clogging. Roughness, blotchiness and redness of the skin are usually caused by acidity. In addition to the elimination of poisonous acid by perspiration and avoiding sugary and starchy foods and acid fruits such as currants, strawberries, plums, etc., the habit of frequently sipping a glass of water beforc mealy and at night should be cultivated-an internal bath, cleansing the system of many inpurities. Constipation should never be allowed, but drugs should only be taken on the advice of a doctor, as promiscuous dosing may have harmful results.

Eating between meals is a mistake. The digestive organs require a reat Constant chewing of sweets spoils the shape of the mouth, and over amoking is detrimental to clear cyes There are other bad habits to be avoided or corrected. In walking, too short or too long a step is tiring and throws out the balance of the body. A stride should suit the length of leg; there should be a free swing from the hips without wobbling, and steadiness of the sitoulders. When standing in incorrect att $i$ tude is to thrust one hip outwurds and distribute th ${ }^{3}$ weight of the body unevenly (Fig. 4). A bud habit in sitting is to Hop downso that the end of the spine, instead of supporting the tody correctly, is ourved under (Fig. 2). As this, if continued for any length of time at a sedentary occupation, causes a strain on the internal organs, backache, a stoop and restrioted brenthing, it is most important to practise sitting upright, the base of the spine touching the back of a chair and the head in line with the body (Fig. 3). When resting it is better to lie down Hat than to loll in an easy chair. Sorcwing up the eyes is sometimes imitative, and should bo checked; where caused by eyestrain, glasses should be worn.

## Proper Care of the Hair and Skin

Hair should be combed out at night, but vigorous brushing has a more beneticial effect when the body is not tired. If the hair begins to come out a good tonic should be used Dandruff must be prevented ; it is impossible to have beautiful hair unless the scalp is kept clean. Most hair, if properly hrushed, has sufficient gloss without recourse to brilliantinc.

Cosmetics have a place in beauty culture, their use being to preserve, whiten, smooth and brace the skin. To keep the contour of the face and the elasticity of the skin a sinnple form of massage may be gone through daily, after
muscles relax during sleep and want keying up Having apread a little skin lood or cold orean over the face, place the fingers of both hands on the cheekbones, the thumbs meeting undor the chin, and with firm pressure pass then upwards to the fingers on each side, repeating the movement for a bout two minutes Next place the tips of the fingers on the points of the jaw and work them firmly upwards pas the corners of the mouth to the base of the nose
Repeat this movement for about a minute. Then tap in a small quantity of creain round the eyes, using the third finger of each hand very lightly and working from the inner corner of the eye outwards for a minute, and for another ininute, having closed the eycs, very gently pass a finger along each eyelid, con tinuing the movement outwards to the edge of the hair. The whole process takes five minutes. After the massage the face should be bathed in cold water to which a littlo eau-de-Cologne has been added.
Allowing live minutes for the extra hinr hrushing, five minuter for the physical exercises, and five minutes for the facial massage, it will be seen that beauty culture only demands one quarter of an hour ench moning. Soaking daily in a hot bath enervates instead of braoing the muscles. A quick warm bath, using a long.handled bath brush and followed by a cold sponge, keeps the skin in gond oondition. On alternate nights cold cream and an astringent complexion milk, such as a cucumber and benzoin preparation, should be applied. The first should be lightly rubbed and tapped in with the third finger, thus a voiding the danger of stretching the skin, and any superfiuous cream wiped off; the

alse, be one for the individual, emphasisin! good points and glossing over bad, not a meaningless routine of cosmetics Artificial colour may be unnecessary, because by following hygienic ruies, sallowness and the whiteness of anaemin will be corrected. The clear, healthy fallor that is natural to some complexions is a beauty and should not be rouged. When colour is used the shade must be chosen to suit the skin, the smallest quantity applied lightly to the upper chcek bancs with absorbent wool if a powder, or with the tip of the finger if crean or liquid, and the face powdered afterwards. With regard to the lips, lipatick should tono with rouge or harmonise with natural colour. Castor oil used every night, applied by a camelhair brush, has a darkening and at rengthening effect on lashes and cyebrows. Should tunch. ing up be desired use mascara unobtrusively.

Siensitive akius may develop a rash from washing in unaccustomed hard wator away from home, and a oleansing cream may then be used instead of soap and water.

It is most impurtant to select the right orenm, sonp, and powder for the individual skin; once these have been discovered they should be adhered to. Cheap powders olog the pores and produce blackheads-a silk. sifted pure ricc powder delicately tinted to tone with the natural skin is the safest and most becoming.

Sound sleep in a well-ventilated room is important. It is in fact one of the best leauty specialists in the world. When late hours have to be kept at night, if possilile make up arrears of sleep in the afternoon

BEAUTY OF BATH. This is a smal!. flat, red and juioy apple, of prolifio habit, and flourishing at its best from July to September. It is recommended for culture in small gardens. being useful alike for dessert and oulinary purposes See Apple.

BEAVER. A line greyish-brown fur used for winter coats and expensivo fur trimmings, Though light in weight beaver has great durability and a beautiful quality which easily distinguishes it from its imitations.
A silk beaver for hats has been largely nusted by velour. See Fur; Velnur
BEAVER BOARD. A Canadian product named beaver board is used for the covering of internal partitions and similar purposes It is composed of wood fibre worked by a patented process, and resulting in a five-ply board approximately $\frac{i n}{}$. thiok It is clean
and pleasant tu handle, is made in a range $o$ convenient sizes, and obtainable from any good builders' merchants. Sec Partition.

Bed Bug. This is a variety of the insec known as the bug (q.v.).

BED CRADLE. A cuge minde ul mefa hoops and long wouden or metal struts is used under the name of $n$ bed cradle in cases of illness to raise the bedclothes off the patient This is necessarv in fractures of the lower limbs, ns the weight of the bedclothes may displace the foot. The apparatus can be used to give a liot nir or vapour bath or to suspend an icebag for the relief of pain in oppendicitis In case of an emergency, a three-legged stool a strong cardbuard box with ends cut arch. shajed, or a child's hoop cut in tivo pieces, crossed and screwed together, inake excellent cradles.

BEDDING. 'L'uo much importance oannut be attached to proper bedding, when it is remernbered how vital sound sleep) is to health and the amount of time spent in bed. The best kind of foundation is a good spring mattress. This may be either of the bon spring variety or the ondinary spring with $a$ stuffel overlay, or the wire spring mattress.

When an overlay mattress is used on box or spring it should be sent to be cleaned and remade periodically. Unless this is done every few years it is impossible for a stuffed mattress tu be hygienic or comfortable, as the stufting becomes mntted and cunsequently lumpy. A good mattress will last for many years with occasional re-covering if cleaned and restuffed.
The wire spring type of inattress consists of a series of springs sewn into pockets and placed inside a cover. Over the springs a padding of hair or felt is laid, obviating the necessity of an overlay and keeping the full resilience of the springs The mattress is then upholstered. There is no expense of uplieep with such a mattress, as it is fitted with vents for airing the bedding is automatically kept fresh and does not nbsurb or retain any perspiration from the body. Lsose washing covers for top mattresses and box springs are desirnble and wave the mattresses.

The pores of the slin are most active during sleep, and for this reason the thonough airing of bedding and bedcluthes is essential, and the temptation to make the beds immediately their occupants rise in the morning should be registed. The mattress itself shonld be turned every other day from end to end, and on alternate days frome $\begin{aligned} & \text { ide to side. so that each }\end{aligned}$ jpit in lurn bears the extia weight. It onghi to be taken into tho garden and expused $t$. sun and air at regular intervals. Ill blankets must be regnlarly sliaken and, if possibie, pul out at intervals in the sun. See Bedstend Bhanket ; Bulster; Bux Mattrow : Eiderilown Mattress; Pilluw.
BEDDING: In the Garden. The llower gardener always arranges for his principal lloral features to be diaplayed in the position where he can best enjoy them. The suburban or villa a:mateur cannot generally have his best Horal effects beside the approach to his front drior or under his front windurs, but the country gardener can make such a provision.

In laying out tedes the curverl plan is preferred by many, especially where there is a lawn with a curved line. Rectangular beds econonlisg working, and are more easily kept $t \mathrm{rim}$. The aize of the beds ought to bear some relation to the width of the walk and the area of the lawn, where there is one. Small heds are tmublesome if there are many of them, but very large beda have practical drawbacks too Fixtracere has to be taken in the planting, for every cultural process among the inner planta encans getting on to the beil

Neither bedding plants nor herbaccous perennials can give an unboken display of bloom throughout the year, but it is possible to have culour by the utiliastion of shrubs, eapecially those which are fairly sminll and compact, such as miczercon and other daphnes, azalens, heathes, and kahmias.
Sume evergreens are slow in growth and thrive in ordinary soil, notably some barberries, laurustinus, veronicas, box, selected cypresses and tree ivies. These would be long before they outgrew the arcommodntion of small heds. There nre small, neat evergreens in abundance which keep the beds green till spring brings in the Howers. Some of the bost spring subjects arc primroses, poly. anthuses, auriculas, wallfowers, forget-me nots, aubrietias, arabises, dnisics, yellow peremial alyssmm, and Brompton stuchs.

Beautiful beds can be provided at no greal cost. It is possible to buy most of the plants named in autumn, but it is far chenper and more satisfactory to raise them at home. By parchasing seed quite early une may get the very fincst strains for a small outlay. See Nlower Garden : Primose: Tulip; Wallfower, etc.
Bedding Out. While bedding simply means a rearrangement, hedding out impliez the transference of plants of a half-hardy nature from the shelter of the grecnhouse to the open bed in late spring or early summer.
BEDFORD CORD. The feature common to all fabrics known by this name is a raised tubular cord or rib running lengthwiso. Woollen Bedford cords are one of the best instcrials for riding breeches. The material is intended for breeches, and made in thousering width ( 27 in .). It looks a little clumsy in coats, but officers' complete uniforms have boen made from it. Cloths similar in weight and appearance are incule also in cotton and are cheaper: they are not su warm, aw more easily soiled and less suitahle for wet weather.
A ligiter make of ootton Bedford is used for summer dresses and is sometimes called piqué, although in true piqués the tubular ribs run

crussivise, nut lengthwisof the piece. The better qualities make excellent coats and skirts, white or in light colours. They wash and wear well, and are especially suitable for sporta wear. See Piqué.
BEDLINGTON TERRIER. An intelli. gent guarlian or the house: entirely depiondable with children, this dog stand in the front rank нy $\boldsymbol{a}$ destimyer of rats and othei vermin. But although affectionate where his owner's family is concerned, he in suspicious of strangers and jealous of his own kind. The Berllington has a
under-blanliet is used it should be large enough to tuek well in ull round so that it may be kept smouth and not cause bed sores. The lower shect is then put on in the ordinary way, and on top of it a draw sheet may be placed: 'This is an old sheet, folde.! to a suflicient width to reach from the sholidiler blades of the patient duwn to his linces, and laid across the bed. It is tucked in at cach side.
hard though rather woully coat of dark hlue, tan liver, or sandy. The head is narrow, with n long, tapering, sharp muzzle. The

Eedingtos Terrier. A goos house doz and ratte:
long, sharply pointed inil, which used often to be docked, is only slightly curved. The nnimal stands about 15 in high, and weighs ahout 24 lb . See Dug.
BED-MAKING. The bed should be stripped overy morning, the mittress thricd and the hedclothes left to air. The underblanket is then laid amoothly on the mattress The bottom slieet must he thoroughly tueked in all wund, so that there is no possibility of rucking (1p). Top sheet and blankets are then put on olle by one, and tucked in at the boltom. The top shect is turned down over the hlankets, the pillows put in place and the whole covered by the bedspread. The bedspuead is removed at night and the down quilt put in place.

Bed-Making for Invalids. A feather Led should never be used in cases of illness. A goul hair mattress is best, but a straw one dues very well, particularly in infectious enses, hecause the stutfing can be burned. Where the illness is likely to be prolonged it is best to dispense with the under-hlanket and to replace it by a mackintosh wheet. If the

Bed-Making. Cbanging an Invalid's sheet. Above, changing sheet from above downwards. Below, changing sheet from side to side
teginning with the greater part on one side and only a small turning on the other. It is shifted along a little every day until the hulk of the tucking in is done on the opposite side from which it started. In cases where the under blanket is rotained, a muckintosh shoet, mav be placed under the draw sheet.

The upper clothes should be warm but light. and no heavy, airproof counterpane should be used. A ventilated down quilt is the best means of obtaining extra warmth, as its weight is insignificant In some illnesses, e.g. acute rhemmatism or nephritis, the patient is nursed betwcen blanketa, and no slieets are used.

When the hed has to be made it can be done quite simply without disturbing the patient. First loosen all the bedclothes. Then let two people stand one on each side of the hed and take hold of the under hlankict or mackintosh sheet, pulling against cach other until all wrinkles are smonthed out. The same is done with the under sheet. Raise the patient slightly under the shoulders and shacke up the pillows. Then liy him down and make all tidy.
Shects can be changed as follows: When a clean top shect is required, have it aired, warmed and ready. Remove the top blanket from the bed and lay it over the clean shect. Then take sheet and blanket together and lay them on the bed, while n second jerson stands at the opposite side ready to assist. Ioosen the soiled sheet and the remaining blankets on both sides. The second person then seizes these and draws them quickly away, while the first holds the clean sheet and blanket in position. The clean shect is then tucked in

## Methods of Chankink the Under Sheet

There are two inethods of changing the under sheet, according to the nature of the patient's illness. The more usual is to change it from side to side. 'I'wo people should assist, one on each side of the bed. First the hod. clothes are looscned and the clean sheet, rolled lengthwise, is brought to the berlside. The soiled sheet is then rolled up until it reaches the patient, who should be lying on his right side, and the clean sheet is rolled along behind it. Thus the two shects will he resting against the patient's back in two long rolls down the middle of the bed. The patient is then rolled gently back on to his other side, and the second person draws the swiled slicet from under him, following it by the clean slieet. Once it is clear of the pratient it can be straightened out and tucked in. A draw sheet is changed in the same way.
If the patient has to le lifted, as in most surgical cases, the change is effected from top to bottom of the bed instead of from side to side, and the shect rolled widthwise instend of lengthwise. In this case the sheets will be rolled down until they are under his shoulders. The second person then raises him under the shoulders sufficiently for the sheets to lre passed on as lar as his hips. 'These are then raised, and the sheets can be drawn down bencath his legs and the change completed.
It is even more important in winter than in summer to are that a patient's lied shects are thoroughly aired and warm. When the invalid is not too ill to leave his bed during a change of linen, the best method is to fold back the upper sheets and blankets, and to iron the lower sheet backwards and forwards several times with a hot iron. When, as in cases of severe rheumatism, etc., it is nccessary to make a hot pack, the bed is prepared by putting a inackintosh covered with a hot blanket on it. A large sheet is rolled up lengthways and wiung out in boiling water, a large towel being used as a wringer. The patient is turned on one side, the shect, half umrolled, is placed alongside, and then he is rolled in the sheet. The blanket underncath is then tufned over to cover the jalient in the shect.

While anuther mackintosh and several more hlankets are placed over him See Bedspread Blanket - Nursing : Sheet

BED-PAN. The lreal-palu is a utensil which should bo in every liome. In many cascs of even slight illness patients suffer harm from chills, strain of the heart, cte., by getting out of lred. liefore use, the bed-pan should ha warmed and the margin coverell with finnnel After use it should be emptiell and clansed as soon as possible. It is wise always to keep some disinfectnat in it, such as Lysol or a carbulic solution.
BED-REST. A comlortable led-rest is a necessity in many cases of illncss. A chair placed upside down and covered with a large pillow can he used as a temporary substitute. hut where the patient has to face a long convalescence, us after a broken leg, it is usually worth while to buy a proper bed-rest. It is essential to have one in some types of chronio heart disease, where the patient cannot breathe comlort ahly if lying down.

Making a Bed-Rest. The ligure shows a simply made folding led-rest. The framework, 1 , is 27 in . hy 21 in and nade of woud $1 \frac{1}{i n}$ in $\mathfrak{i} \mathrm{in}$. for the uprights, and $1 f \mathrm{in}$ by in. for the raila, which are tenoned or dovelled into the sides 'The hack is welibed

 joined by a stretcher rail $1 \neq$ in by $\}$ in. B and $C$ are hinged to $A$ by iron bolts 2$\}$ in by $t$ in. A washer should be placed between the two pieces of work. Pine, beech or American whitewood are suitable for maling this atticle.

# THE BEDROOM: DESIGN AND DECORATION 

# Ideas that Produce Harmony and Hygiene in the Sleeping Room 

For the Furniture of the Bedraant sce Bedding; Bedstead; Dressing Table; Wardrabe, etc.;
also Bed-making; Bed-Sitting Room; Colour Scheme, cte

Fxciting designs and colours ane out ol place in a sleeping room, where the effect should be restlul; also, it is advisalle to dispense with heavy hangings and furniture not easily moved and cleaned.
In a small house, whicre the bedrooms open off one landing or corriclor, a pleasant schome allows of individuality in the separate cooms, hut is harmonious when the doors are open. Thus the pattern of a cretonne in one room repeats the colour-note of paint and carpet in another, and so on. Building a colour sclicme up to the alrcady chosen design of "all-paper or faloric for hangings is often a good way to start new decorations.
The aspuect of each room has also to be considered. In enst room which will get the moning sunshine may to in cooler colours, and the same applies to a south room, hut in a north room it is necessary to have walls which will suggest sunshine and reflect all the light there is Fur a room facing north, or where, as in the case of many town houses, the sunlight is intercepted by other buildings,

Hedroom. Small room in Georgian style with sprigred chintz canopy bed
hiere is nothing lietter for the walls than the colour-range from crenm to orange with clear vellows and discreet use of pinks; for a sunny south room, cool hlues and greys, and in a west room manves may be selected; but in the case of bedrooms, individual taste should make itself felt and the room be characteristio of its occupant.

If wall-paper is used it should be of smooth surface so that dust can he removed. For the tloor, parquet is alvays desirable, but ordinary boards can lie made dustproof before staining: by lilling up the cracks. Linoleum is a clean lloor covering, and easily swept and polished. Nothing more is required for the lloor in a small room cxcept mats which can be laken up and slanken. It is never advisable to have a carpet right inp to the akirting.
The most important piece of furniture is the bed, and the beat should be bought witli the means at dispesal. Bedspreads nnd day cushions can add to the colour of the room, in harmony with the curtains. In many houses hanging cupboncds and euploarde with shelves are built into the "alls, or built in Hush with the ivall, so that they form n kind of panelling.
The pedestal basin with hot and cold water is fitted into some houses, but the ordinary wash. stand is disappear. ing as a piecc of furniture. I well. fitted bathroom and a hall clonk $=00 \mathrm{~m}$ do away with the necessity of wash-hand stands in smaller houses
For the larger bedruom a wardrobe which has a hanging cupboard on the one side. sletives
on the other. and in the centre drawers and a chesta are available the hangings and bedoupboard may be chosen where there are no spread are of printed linens whioh reproduce bujit-in fixtures. If apace is limited a chest the designs of the period. If the cost of a good
 modern copy of the Jacobean bed is too great, have a divan bed with legs and a head-board which suits the style of room. If the centrul piece of the room is a good eighteenth century chest or tall. boy, a simple drop table with a reproduction of an eight. eenth century mirror will serve as a dreas-ing-table. and the window hanginga may be in daniask. For a room with
uf drawers may te selected which inill also serve as a dress. ing-table. A long mirrur placed panel like hetween two urindows, or elsewhere in a good light, is a distinct addition to the roons, as it catches and diffuser the light. It is of utmost importance to avoid overcrowd ing, butan armchair, small writing-table, a hedside table, and a couch are desirable additions, so that the occupant will be able to read, write, rest, study, or sew without disturbing or being disturbed by the rest of the household. In a sinall room, by the elimination of the washhand-stand, of
 the wardrobe in favour of the hanging cup- jainted furniture, hangings should emphasise board, and of the dressing-tablo in fivour of colour and type of painted decoration. Placing the bureau, there is usually apnce for a table furniture must dopend upon the shape of the and an easy cheir, thus giving additional room. Fresh air is indispensable. The window usefulness to the room as well as conifort.

Well placed lighting is important for the mirnor. Candle-lamps fixed to the dressingtable itself are convenient. A good readinglamp is essential : either of the hook on to the end of the bed type, a pendant, or a standard. Ingenuity is shown in adapting the rest of the furniture to antiques. Where Jucobenn
can then be gone over with the swecper and the surround with the soft polishing mop. If the room has only small mats thesc can be romoved daily and slaken. The room must ther, be thoroughly dusted. Once a week it should the turned out. A vacuum cleaner is holpful for carpet and hangings. All wond work has to be dusted, partioular attention heing paid to the tops of furniture, ourtainpoles, blinds, pictures, etc., which are out of reach in the daily dusting. Marble und tiles are washed, mirrors and furniture polished, and small rugs beaten.
The Invalid's Bedroom. The icleal prosition for the bed is between door and window; fail. ing that, it should be placed between dour and fireplace. A single bed is more convenient, and for any long illness a nccessity, as a double bed adds to the fatigue and diffioulty of lifting the patient, changing of sheets, etc. An iron bedstead about 3 ft . wide and not too low is hest. It should be devoid of valances or curtaing, and stand away from the wall ac that the air can get to it from all sides.
All furniture, except essentials, should be removed. The best covering for the flow is cork carpet or linoleum, because it can be wiped over eqvery day with a oloth wrung out in diainfectant. Even hare hoards are preferablo to $a$ fixed carpet, and the necossary warmth and quiet can be prooured by placing mats on the floor.

The top of the window should never be shut. and it ahould be possible to have the bottom open, too, for long periods at a time. If this places the patient in a draught a screen can be put mound the bed. For purposes of ventilation a fire should be kopt in night and day, unless the weather is exceptionally hot; not only does it ensure the ohimney being clear, but it makes the temperature of the mon casier to regulate. This should be from $60^{\circ}$ to $65^{\circ}$ Fahr, and kept even.

Heavy window curtains are unhygionic, but gaily patteried washable ones help to make the room bright and cheerful. Too many pictures, or two elaborate a wallpaper, are trying to the eva, and inclined to worry a patient. Plenty of Howers (not too heavily. scented) should be kept in the room and should be removed at night.
There should be a confortable chair or couch which the patient can occupy while his hed is being made, or when he begins to sit up.

BED-SITTING ROOM. One of the ohief considerations is space. Aocommodation must be found for clothes without introducing ordinary hedroom furniture. An antique style dressing chest or a flat-topped bureau are useful pieces with long wall mirror conveniently placed. Two large cupboards are shown in the illustrations, which provide in the une hanging room for olothes and space for

Bed-Sitting Boom. Left, general view of the room which forms a complete fat. Tbe cupboard on the left bolds all domestic necessitics, the one opposite all wearing apparel. The small gas cooker has a convenjent shelf beneath. Right, the other side of the room, showing the divan
bed linen, and in the other a sink for washing up and places for cooking utensils, otc.

A divan bed may be covered in cretonne or silk, the cover lined to give weight. The pillows have covers to match or contrast. A day-bed with narrow head and font-pieces and two bolater cushions at either ond during the day may be aubatituted for the divan. Another type of bed is the settee bed, which has railings on one side and at the head and foot, and wired springs with an upholstered mattress. The cover should be removable so that it can be washed.

There are hanging cupboards described as hall cupboards, which do not look out of place in a sitting room. The best type of table is the gate-legged variety of the drop-table, the lenves of which let down when not required. A gas fire is desirable, and also a amall cooking stove, as shown in the illustration, but if there is a coal fire it is useful to have a gas ring in arldition. See Bachelor Flat.

BED SORE. The cause of bed sores is the weight of the hody constantly filling on bony points not well protected by fat. The chief sites are the heels, ankles, elbows and the lower part of the back. Beginning with slight red. ness, the affected area soon turns a dusky purple, and the soft tissues slough out or the skin ulcerates, leaving an angry sore.

The nurse should be vigilant in her efforts to provent a sore forming. The shect must be kept smooth and dry, any soiling being quickly attended to. Every day the skin of the back and other susceptible parts, having been washed with soap and water and thoroughly dried, should be sponged with methylated spirit and dusted when dry with taloum powder. If possible the patient should at least occasionally change his position. The mattress should not be a feather one, and if necessary a water-bed should be procured: Goorl results have been obtained by dryrubbing the back with sonp till the surface is quite smooth. If the akin becomes reddened it should he painted with flexible collodion. If the condition progresses and a slough is scparating, fomentations may be npplicd in order to assist this.

These fomentations are nande by wringing out clean napkins in a very hot saturated solution of borscic acid and should be just large enough to cuver the affected area. They should he applied every two hours, being covered with oiled silk and a bandage to prevent too rapid cooling. When the slough has separated, wash the ulcer frequently with an antiseptic lotion and apply an ointment. Either of the following would serve: resin ointment and balsam of Peru, an ounce of eich, or camphor gr. x., zinc ointment to an ounce.

## BEDSPREAD. The bedspread should bo in

 relation to curtains and carpet. While them is nothing daintier than the linen embroidered bedspread enriched with fine needlework of all kinds or by coloured border and large central appliqué deaign, linen bedspreads are not always favoured hecause of the cost of laundering or suitable for the style of the room.For period roons a selection should be made from printed linens, silks or satins which are in the designs nearest to the period. Chinese lacquer demands the beautifully designed ailky of China, and if these are unobtainable the decorator may fall back on black or gold satin if matohing the curtains, and trimmed with Chinese embroideries.

For ordinary purposes artificial taffeta the colour of the walls may be selected with a bold embroidered design introducing colours of curtains, etc. ; or a patterned soít cretonne or print may be edged with casement cloth of the prevailing colour, or printed cotton bedapreads may be bought to tone with the mom See Appliqué Needlework; Embroidery ; Linen.

# Bedsteads: Antique and Modern Types 

Their Choice, Construction and Repair
For the arrangement of the Bedstead see Bedronm; other associated heatings are Bedding; Bed. Making:
Divan; Mattress; Shernion, etc.
The chenpest iron or brass bedsteads have of ailk or damask aro chosen, and for the the bars of head and foot placed transversely, painted four-poster there is the blocked print. but better types have the bars of the head and All thesc heds arc chosen for their decorative foot in a vertical position. They may be quality, and nust be justified by choice of obtained enamelled in black, in white, and in a variety of colours, or the brass may be lacquered. The best brass bedsteads have the minimum of decuration, and the uprights are square and not round in section. In cleaning thesc, only a soft polishing rag is necessary. Polishes of any kind should be used sparingly.

A wooden bedstead, with upright bars at head and foot, is the commonest type of bed chosen to go with plain or fumed onk furniture. The pattern can also be obtained in mahogany and in painted wood. If the bed is to stand by the wall it should alwaya be provided with anstors.

The cheaper kind of beds in the two foregoing types are of combination design, i.e. the wirespring is fixed to the frame of the bed itself, screws allowing the wire to be drawn taut. It is better to choose a bedstead with iron frame complete, but without tho wire. The wire or boxspring can be bought and superimposed.

For lasting value there is nothing better than the wooden bed with solid headboard and footboard made of mahogany or walnut. Where a fincly mark. ed piece of wood is used, it is in itself sufficiently decora.

Bedstead of English oak, dated 1593, with finely carved pillarg detached from the framework of the bed Vicloria and Albert Museum accessories. The Chinese four- poster, the most ornate of all, is made to accompany Chinese lacquered furniture in black, green or red.

The best model for a child's bedstead is one with half sides, which prevents all danger of falling out. These can be had in light and fumed oak, or in painted wond to auit the rest of the nursery fittings. In choosing a child's bed it is important to see that all the parts are solidly fixed, that the laths are solid, and cannot be displaced by the most energetic child. A folding bedatead for the use of all emergency visitor is a useful addlition to the household in a London flat or a country cottage. One wooden model, folding up on the concertina pattern, occupies a very small space when not in use, and the thin overlay can easily be stored in a cupboard. There are also several varieties of the inili. tary canvas folding. bed. These are provided with n stout canvas overall cover, and form a very useful part of the family holiday luggage.

For use in hot clinatea an iron or brass four-poster is the best type. No wood is used, as wood is accessible to variety of what is known as the French bed.

Period wooden bedateads are copies of old deaigus. A Tudor bed in Ilark oak will have a low footbnard and two low posts at the foot, or no footboard at all ; a Jacobean dark oak bed will have the twisted posts to be found in Jacobean furniture with upright hars at the head and fout; or if the solid head and footboard are chosen it will possibly have aome carving. These Jacobean hedsteads have added strength by a transverse beam placed bclow the footboard. Good beds in inlaid mahogany in the Sheraton style can be hud cither with solid head and font or with a central panel and upright bars.

A cane-panel bedstead looks right with furniture of 18 th and early 19th century design, or with the lighter types of French furniture. The four-poster is an interesting revival, though hardly the most practical. It can be had either with or without the canopy. It is not necessary to retain the hangingm behind the headboard, though this is usual Curtains must be fixed so that there is no great difficulty in taking them down to clean and replace. The hangings are narrow, so that they do not prevent a free passage of air, but are only for decorative purposes. For the older patterns draperies of costly stuffs are in keeping. Models with twisted posts have lacobean printed linen, or genuine embroidered hangings and an embroidered bedspread of the same pattern For others hangings and bed covers
ants and other insects. The high posts have thic transverse rods connecting them fitted with secondary rods for the mosquito curtain, but these are not always used, as niany people prefer the curtain to have no division between the canopy and the sides.

Between a wooden and a metal bedstead there is little to choose in the way of strength

Bedstead. Example in walnat with cane panels, adapted from a seventeenth century model Photo Irom lleal \& Son, LId.
provided both are good models The wooden bedstead has one possiblo point of "ealinesswhere the iron angle-picce which connects the iron bed-rail with the wooden head and footboards is fixed by four screws into the wood After years of hard service it is possible for these screws to become loosc in the wood; it is then necessary to take thic hedstead to pieces, plug the wood, and reset the acrews It is wise to count the cost of the spring and the mattress before choosing the bedstend.

Repairs and Renovations. These are well within the capabilities of most amateurs, provided they excrcise cominon sensc and nay due regard to the nature of the work to be done to the damaged piart, as this determines to some extent the inethod of repair

Four-Poster Bedstead The earliest English spccimens are few in number, those which have come down from Elizabethan times being chietly of Italian or Flemish make. They lost popularity in the 17 th century, and remained out of favour until the time of Hepplewhite and Sheraton, who gave the type a lease of life that lasted well into the 19th century.

Sheraton designed pieces are particularly graceful.

The majority of bedsteads of this type will he found to be more or less worm-eaten, and probably damaged. If the worm is still in the wood, it can be detected by the deposit of fine woud dust on the ground beside the part affected It can be treated by injecting petrol into the worm holes hy means of a very sinall syringe; a hypodermic syringe answers very well. Other effective methods are to steep the parts in turpentine or paraftin. The work is then cleaned and rejolisned, treating the worm holes with beaumontage ( $q$. v.) or other filling.

The joints were frequently held together with a form of coach screw ; this will probably no 'onger hold in the wool, so bore out the hole, plug it with n well-fitting wooden plug, well glued into place, and drill out a suitable size hole for the screw. If the original canvas mattress is badly torn, cither replace it with new or carcfully patch and stitch together all the torn places, and re-work the holes for the lacing, using a buttonhole stitch. Probably only the old framework will be retained and a box-spring mattress fixed to it. All that is needed are some extra battens at the head and foot or elsewhere to support the framework of the box-spring.

Iron Bedstead. The usual failing of iron bedsteads are chipping of the enamel, rusting and tarnishing of the ornamental brass knobs and other parts, and breakage of castors. The paint work is readily dealt with by filling the chipped places with hard stopping, after cleaning the metal, and re-enamelling the whole

Bedstead. Modern design by Joseph Emberton, A.R.I.B.A. Twin bedsteads linked together by one large head board
framework If the brass work is badly tar nished, or covered with a kind of black growth of spots, it is best to remove the partsgenerally by unscrewing them-then boil in strong soda water to remove the reminants of

Bedstead. Fig. 1. Single oak bedstead, the making of which is descrited in the text' below
the old lacquer. Polish with very fine and old emery cloth (that known us blue back is the best), then polish thoroughly with good metal polish, wash in hot water and re-lacquer. A good effect is often obtained by bronzing the brassworl, say, to blue grey, and cnamel. ling the metal worli in a contrasting colour.
Nissing castors are difficult to replace, as they are of ten cast on. One method is to cut off the old castor with a hacksaw, and drill out the end of the tubular leg. Obtain a new castor of similar size to the others on the bedstead a nd mount this on a hardwood, or preferably metal, plug that can be tightly driven into the hole of the log. An alternative is to fix a tube to the castor, either by riveting or brazing (q.v) and then fit the leg into the tube. A length of about $t i \mathrm{in}$. aliove the castor will serve the purpose.

All-brass bedsteady can be dealt with along the same lines, but the re-lacquering job is no easy one for an amateur, as the whole section must be done at one time and must be kept at proper temperature

Wooden Bedstead. With the so-called sanitary iron fittings, wonden bedsteads sometimes give trouble by the failure of the screws holrling the shoe or cast-iron fitment into which the side bars are fitted. The only remedies are to withdraw the old screws, plug the holes, glueing the plugs securely into place and fitting new screws. A drastic and effective remedy is to holt the shoes on with coach bults. The heads will, of course, be visible, but this need be no detriment.
Sometimes it is desirable to alter the colour of a bedateal so as to harmonise better with the scheme of decoration. When the bed is an enamelled one, the treatment is obvious re-enamel it in the desired tint. Many bedsteads are
made of oak, birch, or similar
material and then stained and polished Here the old colour can to a certain extent be removed with methylated spirit or turpentine. Follow this with a careful rubbing down with fine glass paper Re-stain the wood with a good quality water stain of the (lesired colour (olitainable from an oil shop) and then re-polish, or even work up a glass with a goond grade of furniture perlish.
Making an Oak Bedstead. The bedstead shoun in lig. $I$ is intended for a room of moderate dimensions. It is a 3 ft . size, hut the general character may be preserved in a 4 ft . 6 in. size, if a double bed is required, or " pair of 3 ft . bedstcads could be inade to stand side by side as twin beds. Width, as stated, is 3 ft ., but for n child's bedstead it is possible to get an iron fraine with diamond meshwire spring combined $2 \mathrm{ft} .3^{*}$ in wide. This hint might prove of service when space is limited, the accommodation being sufficient for comfortable

Fig. 2. Dovetail iron socket for angle iron sleeping without much sacrifice in appear ance with the low foot end. The height is 2 ft . 3 in, and may be as low as 1 ft . 10 in for any special reason. The length of bed is governed by that of the separate iron angle sides or combined apring, whichever is fittell, the aize

Bedstead. Fir. 3. Foot end. Fig. 4. Patterny Which may be applied to the foot of the bedstead.
usually supplied being $6 \mathbf{f t} .4 \mathrm{in}$. Fig. 2 shows a type of dovetail iron socket used in conjunction with angle imn bearers to connect the head and foot of a wouden bedstend. The height of head end is 4 ft . 3 in ., giving a sufficient display of curtain.
A start may he made with the fout end. The posts, allowing it in on for height of castors, will require two lengths of 2 ft 1 in . by 2 in by 2 in ., finished sizes being a shade under for a stout hed. It is prossible to use wood 2 in . wide on face by $1 \frac{1}{2} \mathrm{in}$. thick, if this happens to he inore accessible. For the former size the posts are square for their full length, but have the corners just nosed off. A $f$ in ovolo is in tended to be worked down the outer angle, and this can be carved effectively with pip-and-bean detail, or this ornamental portion can be ubtained scparately in long strips (about 10 ft .) from the woodivorkers' sundriesman, ready for grooving into the corner of the posts, to be glued and fastened here and there hy needle points. Castors are often omitted in a 3 ft . size, in which case it should be remembered to allow the slight extra length for he posts.
The top rail (A, Jig. 3) is murtised and tenoned into position, but is often dowelled, or might be dovetailed in. It looks well if the top edge is slightly rounded away, D-shape. This rail is shown $2 \frac{1}{2} \mathrm{in}$. wide, and should be at least 11 in. thick. The foot-rail (B, Fig. 3)
enters the pusts with a couple of shouldered tenons, and is $4 \frac{1}{2} \mathrm{in}$. wide.
The inner uprights (C, Fig. 3) take two pieces 12 in . by $\mathrm{t} \frac{1}{2} \mathrm{in}$. by $1 \frac{1}{2} \mathrm{in}$., to include $\frac{1}{\mathrm{~d}} \mathrm{in}$. tongues, entering top and bottom raila and uprights, and all three are grooved to receive the panel. The panel (D, Fig. 3) should be of 8 in. thickness, reduced at edges to enter the $\frac{1}{2} \mathrm{in}$ or in. grooving. A flat section of mould can then he mitred up, to drop in on face and be glued and pinned.
This finishes the construction of tho foot end, but if some relief is required the left-hand device at Fig. 4 might very well be introduced into the centre of panel. It is easily set out and cut fmm a piece of $\frac{1}{8} \mathrm{in}$. thickness for the centre diamond, this being notched for the smaller dimmonds out of $\ddagger$ in materinl to intersect. Size for the device to finish is 8 in . by 4 in ., and in mounting care must be taken to get the extreme pointa level. The casiest way is to pencil in centre lines on the panel, and glue up the pieces over these, the final being by the addition of a few needle points. The right-hand device is an alternative. The centre device is cut from a picce of $\frac{1}{4}$ in. niaterial cleaned up, with n four circle and crossbar opening, and the corner shaped ogec to form a centre panel. This last device would he very suitahle if the bed were made in-darls mahogany.

The head posts (lig. 5) are 2 in . by 2 in ., and are shown with 4 in. by 4 in moulded cappings stub-tenoned on. It will not be necessary to introduce the pip-and-hean mould on the angle of the posts as for the foot. end. The top rail ( E ) is $3 \frac{f}{f} \mathrm{in}$. wide, which will afford an opportunity of applying some relieving device in lieeping with the foot-end. The mid rail ( $F$ ) might he 2 ft . $\mathbf{6}$ in., or a trifle higher: width is allowed 6 in ; thickness of both this and the top rail (E) should be 1 in . The lower stretcher rail (G) can be $2 \frac{1}{2} \mathrm{in}$. by 1 in ., and can be fixed anywhere between $(\mathrm{i}$ in. and 10 in ., from lower end of posts.
The curtain rod (H, Fig. 5) ean he of $\frac{1}{2} \mathrm{in}$. brass tubing, and special fittings are obtainable in brass for a small sum from most furnishing firms.
Details are given in Figs. 6 and 7 of a 4 ft .6 in . bedstead of strnightforward design. The woodwork, as in the bedstend described above, consists only of the head and foot, which are joirred by dovetail sockets and angle iron sides. The posts, which are finished off with a moulded capping, are $2 \frac{1}{8}$ in. by $1 \frac{7}{4} \mathrm{in}$. the rails are 1 in . thick, and the central splat $\frac{t}{i n}$. thick. The upright slats are 1 in . by $\frac{1}{d}$ in. The top edges of the upper rails are finished. with a moulding, as shown. The panel on
width of the end, measured over josts, is 4 ft . 6 in . Tho upper edge of the lower rail for the head end is 1 it 9 in from the floor. that for the foot being 2 in. nearer the ground. These rails are 6 in wide, and the top rails are $2 \frac{1}{2} \mathrm{in}$. wide. The central splat is 8 in wide: the 1 in vertical slats are in pairs, as shown, spaced so ns to lenve intervals of 5 in . Tho dovetail sockets are attached so as to bring the angle-iron sides 1 ft . 3 in. from the floor

This design can be readily adapted lor a single bed. The overall height of the poats for hoth ends might be 3 ft ., and the overall width of the ends from 2 ft .6 in There would be a single pair of upright slats each side of the central splat. If a pair of tivin bedsteads is made, the head ends might be taken a little higher than the foot.

BED TABLE : For Invalids. The bed table shown in Fig. 1 has a double ad. vantage. The legs are hinged so that the article may be converted into an ordinary

Fig 1.
trav. 13y means of a very simple contrivance (Fig. 2) the legs are held down firmly, so that the tray will stand flat on a tahle or sidehoard. When the lega are unfolded for hed. table use the same arrangement provides for them being held rigid. A trny of this kind may he made in almost any wood. American whitewood, or even pine, will serve the purpose. For a stronger article oak may he used, or if a specially nice piece of furniture is wanted, mahogany may be taken.
The size suggested in Fig. 4 is n tray measuring 22 in . by 14 in . This might be Bedstead. Figs. 6 and folded with the spring 7. Simple design in lath holding them lown.
the centre splat is formed with amall moulding, which may he pinned and glued.
The posts for the head are 4 ft .3 in . high over all, including castor and capping. The latter is planted on, and has an ovolo moulding worked on its edges. The height of the foot posts is 3 ft .8 in . over all. The extreme
tionately shorter legs, if only a smatl tray were wanted ; or could be increased to ahout $2 x \mathrm{im}$. by 18 in . for a patient who was likely to do much writing in bed. The legs are shown, $8 \frac{1}{2}$ in. long, which places the table at a convenient height.
Fig 1 shows the bed tahle ready for use. At Fig. 2 is given a view of the underside, one pair of legs being up, while the other two legs are shown Fig. 3 shows the article when used as a tray, while
$t \mathrm{in}$. 3-ply would serve the purpuse for a light tahle. The front of tray may be gently curved inwards as shown.

To the underside of the top at each end are screwed two battens, which may he $12 \frac{1}{2}$. by 1 in by $\frac{1}{2}$. thick. These should he chamfered on the outer edge (Fig. 6) and at the ends, and each is held with four brass screws. A rail is required for the back and sides of tray. The height may be 3 in, with a finishing thickness of $\frac{{ }^{5}}{6}$ in. At the corners the rail may be simply notched, as lig. 5, D, or dovetailed, or mitred and keyed The top edges should he gently rounded, and the front chils of the side rails neatly finished off, as in Figs. I and 3. The raily are serewed with fine screws passed in from below. this being done before the battens are fixed.

The legs are $8 \frac{1}{2} \mathrm{in}$. long and 1 in . square, and are shown tapered on two sides. The leg rails shown in lig. 5 (A and B) are fixed with an angle bridle joint. They are $1 f$ in. wide by I in. thick. The outer side of each has a shallow piece cut away to take the spring lath when
the legs are folded. This is shown in Fig. 2, and also at Fig. 5 C. The part thus cut off will be $2 \hat{y}$ in. Wide and ${ }^{3}$ if in. deep, and must he in the centre of the rail. The cut provides for the spring lath lying llush with the legs when the article is used as an ordinary tray. so that the tray

lies quite flat when the legs are folded down. Each pair of legs is hinged to the underside of the tray as shown in Figs. 6 and 7. The perwpective sketch (Fig. 2) and the plan (Fig. 4) will also assist the worker. Strong back-Hap hinges, $1 \frac{1}{2}$ in. by 1 in., are used. They are so fixed that the lega, when up, will lie against the llat $\frac{1}{2} \mathrm{in}$. edge of the hatten. It is important to note this, as if the lega stood away from the batten, tho hinges would gradually loosen.
The spring lath holds the legs secure both when up and down. It is approximately $17 \frac{1}{2}$ in. long, but allowance should be made for a little adjustment when fitting. In width it miay
 $\ddagger$ in. hare. If the table is made in pine or American whitewood, it will he desirable to use sycamore or ash, or any other wood which vields a good spring, for the lath. If oali or mahogany is in use, the same wood may be taken for the lath.
BED-TICK. For a feather bed and for pillows and bolsters an all-linen tick of a close weave should be chosen, and the sewing must he close and strong; otherwise feathers and down will cacape when the outer covering is removed. For hair and wool mattresses it is safer to choose a stock pattern, as when mattresses are re-made there is usually a cortain amount of shrinkage and new tick may have to be added. See Feather Bed; Mattress; Pillow' Ticking.

## Bees And Bee-Keeping

## How the Amateur Apiarian May Secure Proftable Results

Instructions for making Bechives are given in page 86 See also Bec Pest; Beeswax Honcy, erc.

Bee-keeping is eminently suitable for small. holders, cottagers, and others with a limited area at their disposal. The prospective beekeeper should begin with not more than a couple of stocks, increasing the number as ho acquires experience. The following inatructions on bee-keeping are based on information given in Leallet No. 128 issued by the Ministry of Agriculture

A stock resulting from a cros; between the English, or so-called Black Bee, and the Italian, or Ligurian race, will probably be found the best: but on this point it would be well to take the advice of an exparienced bee-master in one's own neighbourhood. A normal colony of bees consists of the queen a large number of workers, which are rudimentary or undereloped females, and a few male becs or drones. A swarm is a mass of bees, frequently numbering 20,100 , with a queen. The first swarm from a hive is, as a rule, much larger than succeeding ones.

Bees thrive best when protected from frequent variations of hent and cold, and a steady temperature can only be minintained when the walls of the hive do not conduct heat. If they do this in summer the warm sunsline will soon make the interior of the hive excessively hot in the daytime. During the cool summer nights the reverse will be the case. In winter, when the temperature of the air outside is constantly lower than that inside, a steady loss of hent from the bec cluster occurs. This often results in the denth of the bees from exposure and starvation although ample food inay be accessible.

Bee. Fig. 1. Section of double-walled W.B.C. Beehive 1. Bee way. 2. Section. 3. Metal divider hallow frame box. 7. Shallow frame. 8. Air space. 8. End of brood chamber. 10. Bee space between frames and hive side. 11. Brood frame. 12. Lifts. 13. Queen excluder. 14. Metal runner for frames. 15. Outer case. 16. Porch. 17. Alighting board By permission of the Minfstris of Agriculture
A double-walled hive of sound pattern is that called the "W.B.C." Fig. I shows the arrangement of this hive, full instructions for constructing which are given in the artiole Beehive. It consists of a floor boa d having four splayed legs, and a brood chamber containing ten frames with a division board. These frames hang by ears or lugs on a metal runner, so that there is a space of $f$ in. bet ween the end bar of the frame and the side of the
hive. This is $n$ bee space, and therefore left olear. Betweon the hottom bar and the Hoor board $\frac{1}{2}$ in. spacc allows the leees free passage, and they are also able to clean out in comfort the dend and any dirt which accumulates. Their natural instinct teaches the hees to lenve this space open, and they therefore do not build coinb there

To obtain combs of the right thickness for brood rearing, i.e. $\frac{7}{7}$ in., metal ends are fitted on to the lugs of the frnmes; these are $1 \frac{1}{2} \mathrm{in}$. wide, so that when they are in position, and all the frames are pushed together until the metal ends touch each other, there is a space of $1 \frac{1}{2} \mathrm{in}$. from the centre of one comb to the centre of the next, allowing for ? in comb and a $\frac{A_{1}}{}$ in. passage hetween each comb to accominodate the bees when carrying out their work in the summer, and to cluster in during the winter

To compel the bees to build their comlis in the frames they are provided with comb foundation. This is pure becswax, in sheets impressed with the base of the cells. By its use straight combs oan be obtained in any desired position. To make the broorl comb strong, wire is first stretched across the frame; $n$ sheet of worker base foundation cut to fill the frame is then inserted into the saw-cut made in the top of the frame for this purposc and a serrated grooved wheel, called a spur embedder, is then heated in the flame of a spirit lampand run along the wire, thus melting the wax slightly in order that the wire may sink into it. This holds the foundation rigid, and when the comb is built the wire is right in the centre of it, and there is vers little fear cither of the comb dropping out if held in the wrong position, i.e. horizontally instead of vertically, or of the combs breaking down, should the hiven be sent any distance. The combs in these frames are reserved for the rearing of young and the storage of winter food, and should not be touched for surplus honey.

## The Siructure of the Chambers

A second chamber, or super as it is termed, contains ahallon frames, the combs in which are used for the production of extracted or liquid boney. The thind chamber is a section rack containing 21 sections (bottomleas wooden boxes $4 f \mathrm{in}$. square by 2 in . wide) in which comb honey is produced. Each section holds about a pound of honcy. Surrounding these chambers and the brood chamber there is all outer case which also carries the porch over the entrance; the size of the latter is jegistered by sliding doors. There are also lifte which fit on to the top of the outer case, and on one a nother to accommodate the supers during the honev season. A roof completes the structure.

The hive should be stocked as early as possible in the spring. It nay be populated in three ways : by purchasing a colony of bees, a nucleus, or a swarin. The first is the most expen. sive method, as the bees have already built the combs, are rearing broorls and have stored a certain amount of food. A nucleus consists of four combs, and undet favourable conditions may be worked into a full coloniin time to give a limited amount of surplus boney before the end of the season.

Fig 2. A nine-holed bottle feeder

The safest way for a lieginner to start is with n first swarm (not a cast, or afterswarm). The most satiafactory method of purcliasing a swarm is by weight. A swarm weighing 5 lb should be obtained, if possible After-swarma weigh about 2 lh . and have a virgin queen
The swarming season varies somewhat in Britain, according to the weather. There has heen, in a very early senson, a swarm on the 19th of April, the carliest in a 40 years' oxperience in the south of England. As a general rulc, however, the Intter part of May is the busiest portion of the swarming scason, extending as it does through June and into July. Most of the swarms issuing in July are casts or second swarms, and, except in the hands of all expert keeping many colonies, are of little use and should be returned to the parent colony.

When the box or skep containing the purchased swarm arrives, it must be placed in the shade near the hive the becs are to occupy. If the sivarm is in a box, the box shouli be placed upside down and the screws fastening the lid taiken out. The lid should then be wedged open at one end about $\frac{1}{2}$ in to allow the bees to fly. If the bottom is of perforated zinc it should be covered with a sack to exclude the light, otherwise the bees may escape If the swarm arrives in a skep, the cording nnd wrap, should be removed, and the skep placed on a board with a stone under one edge in order to allow of Hight and ventihation

## How to Hive a New Swarm

The hive must be made ready before the arrival of the swarm, and should face south. east. An ideal situation is by the side of but not under a standard fruit tree. The legs of the stand should rest upon bricks to prevent them from rotting. The hive must lee set perfect.ly level from side to side, with a lown. Ward inclination of about $\frac{1}{2} \mathrm{in}$. towards the front In the early evening the roof, lifts, and outer case should be removed. To prevent the bees ascending to the roof a thin quilt of ticking or unbleached calico is placed over the frames. The front of the brood chamber should be raised from the floor board about an inch by means of two wedges. A board the width of the alighting board should then be placed in front of and level with the latter, sloping down to the groind. Both bourds are covered with a cloth hanging over the sides to the ground, to stop the hees from crawling underneath.
The skep or box is gently carried mouth downwards until it is just above the sloping buard. With a smart jerk the bees are thrown out in front of the brood chamber, about 1 ft . awny from the entrunce, when they will at once begin to take possession of their new home. It is their natural inclination to run uphill. As they run in watch should be kept for the queen, to see that she enters safely. When all are in the wedges should be taken away and the front of the brool chamber gently lowered to ita proper position. Any bees in dan ger of crushing should be brushed away with a feather.
The swarn will benefit grently if it is fed for at least a week with warm thin syrup, made by adding threequarters of a pint of water to one pound of white cane sugar, and heating it over the fire until the sugar is dissolved. Add a tea spiconful of Bacterol to each pound of sugar. It is ad ministered by means of the bottlefeeder, Fig $\quad \underset{y}{c}$ Bown sugar must not be used. On the second day
after hiving. the becs are closed by means of the division board on to the number of fraines of foundation which they are able to cover.

Bee Fir. 3. Shallow irame super perforated with slots of a size to erclude the queen. Fig. 4. Bee escape, the $\nabla$-shaped springs only permitting egress Fig. 5. Clearing board fitted with bee escape Fig. 6. Ertractor for withdrawing honey from comb by rotation. Fig. 7 Bee smoker with bellows

If the swarm bas been obtained early in the season building up will proceed fairly rapidly until all the combs are completed, and brood rearing will bo carried out on such a scale that the hive will become overcrowded with bees before the honey flow is over. If this is allowed to continue the bees will swarm.
Swarming can bo prevented to a great extent. Remove the quilts and place a queen excluder in position over the brood frame tops. This is perforated with slots made so accurately to size that the workers can pass through, but not the queen. Thus boney. without intermingling of brood or pollen, is ob. tained in tho super that is now put on. If it is a shallow frame super, the frames should be fitted with sheets of wired drone base foundations.

When the combs in the first super put on are drawn out, and about two-thirds of the whole are filled with honey (i.e when the bees cominence to seal over the honey in the middle of the central combs), the super should be lifted and a second one placed underneath it. When the honey flow commences to decline it is better to allow the bees to complete those supers alrcady in situation than to givo extria ones

## Clearing the Supers

The bees are cleared from the supers by means of an cacapc. Fig. 4, which allows the bees to pass through a hole into a passageway in which there are two springs placed in a V -shaped position. This escape is fitted into n clearing board, Fig. 5, clented so that it entirely covers the top of the brood chamber. The clearing bourd, with the escape in position, is placed in the evening under the super or supers which it is desired to remove. The only means of exit for the bees is from the wide ends of the springs in the eacape, which are so finely adjusted that the bces can push them apurt to pass out at the points, but are unable to return when the aprings are closed.

The honey in the shallow combs nust be extracted as soon as it is removed from the hive, while atill warnı. Tho extractor, Fig. 6, is a tin cylinder with an inside cage revolring on a spindle when the handle is turned. The cage will accommodate cither two combs, one on cither side, or twelvo sections, six on either side.

The first operation in extracting honey is to uncap the combs with a speciad knife or an
ordinary sharp carving knife. A ung the deptli of the length of the knife blade, is filled with hot water and the knife inserted. If a cold knife is used it will spoil the comb, The cappings are removed by cutting "pwards from the bottom of the coinb with a see-saw movemont.
Two combs arc placed in the cage and the cage is turned slowly. When n portion of the honey has been extracted from one side, the combs are roversed, and the other side treatod in a similar manner. Extraction is completed by revolving the crge more rapidly. When the honey in the buttom of the extractor reaches to tho cage, it is drained off and atraincal through muslin into 28 lb . tins or other suitable vessels.

The wet combe are now given back to the hees to clean down. The clearing board is left in position over the colony, and the tin slide over the holc on the front side of the board is withdrawn so that the bees can jase frcely up into and down out of the super. When the empty combs are quite dry, the tin slide is pushed back over the hole, so that the only exit for the bees is through the eacape.

The most profitable system is to work for extracted honey. It takes from 10 to 20 lb . of honcy to mako 1 lb . of beeswax, so that when a section is sold the bee-keeper parts with $\Omega$ valuable asset in the form of wax.

At the close of the honey season the keeper should see that sufficient stores have been left in the body box for consumption by the bees throughout the winter. A knowledge of the amount or weight of atores can be gained by tilting the hive at the front; if it feels like lifting from 15 to 20 lb ., there is a suff. ciency; but if it feels light they must be fer until it does so feel. To feed them, place a piece of perforated zinc, 5 in . square, of a gauge similar to that used in a ment-safe, over the feed hole already made in the quilts. Fill $\quad 3 \mathrm{lb}$. glasa jam jar with syrup made as directed for the swarm, but using only half a pint of water to the pound of augar. Cover the mouth of the jar with two thicknessea of muslin and invert it on the zinc.

As the bees empty the jar, replenish it with syrup until they have had sufficient by weight. There will then be a perfect colony or stock to commence the next season. Should there be any doubt as to the sufficiency of the syrup to last through the winter, a cake of bee candy should be placed over the frames.

The ohief attributes necessary for handling bees succersfully are a knowledge of the habits of the bee, firm but gentle movements, adequate protection of the manipulator and proper subjugation of the bees. The only protection necessary is a veil for the face. This can bo made of black mos. quito netting, with an elastic band top and bottom, fitting tightly round the crown of the bat and under the collar of the coat to prevent

Bee. Shaking a swarm from branch on which the bees have settled
the ingross of the boes. Gloves should not he worn, os they conduce to clumsiness. which will irritate the beos.

Subjugation is carried out by frightening the bees When frightened they gorge them selves with honey, and are not inclined to ating. One of two subjugators can bo useda amoker (Fig 7) or a carbolic cloth. The former consists of a tin cylinder having a conical nozzlo. open at the pointed end This is fastened to a pair of bellows with a connexion between the two at the back. Ordinary thick brown paper, corrugated paper, or fustian is rolled into n cartridge, lightod, and placed in the furnace of the amoker, with lighted ond downwards. When the bellows are workod a volume of smoke is emitted from the nozzle and can be driven in any direction. A carbolic cloth is marle by sprinkling a picco of calion the size of the quilt with a solution of one part Calvert's No. 5 carbolic acid to two parta of water.

When manipulating it is inadvisable to stand in front of the hive. When handling or turning the combs, keep them vertical and not horizontal. Bright, warm woather should be chosen for manipulating hees, as they are then usually in a good temper.

## Economics of Bee-Keepine

The strength of a healtliy colony depends on the vigour and laying power of the queen, who is at her best in her sccond season, and should be replaced in the third by a young onc. The econnmy of $\Omega$ hive depends on : (1) the generation and keeping up of the warinth of the hrood nest (by means of the hent evolved from the bodies of the clustering bees) to such a point as will stimulate the production of eghs and enable young bees to be reared: (2) the nursing of the larvae, and the cleanasing of the cells for the queen to las in; (3) the collection of pollen, water and nectar for food; and (4) the building of storage coinbs and collection of nectar for future supplies of honcy.

The aim of the bec-keejuer is to keep his colo nies at rong. The crowded condition of the hive should be secured at the right time-i.e. at the honey flow. Honey is mado from the nectar of llowers. Spring and early summer are the timev when tho honey crop is gathered. Thore is a period every year, varying in oach district, when the supply of nectar is most a bundant. This time should ho ascertained by the bee-keeper, who will then stimulate his colonics beforehand.

Bees are thirsty insects, and at the end of February a shallow pan half-filled with washer stones should be placed at a distance of four or five yards from the hives. This should be partly filled with water to which table salt has heen added in the proportion of one teaspoon ful to a pint. The tops of the stones should be left dry for the bees to alight on.
BEECH. One of the chief uses of heech wood is for chairs. Most of the bent wood variety are of beech. and so are the windsor and other non-upholstered chairs. The framas of upholstered chairs and couches are often of heech, if they are not of birch; also turned table lega and many other turned articles. Beech may be stained to resentble maliog any or walnut. It is used for tool handlea and for mallets and planes; sometimes for wood-workers benches and dowel rods; alao for brushes, and rollers for wringing machines and mangles. Beech is a heavy wood with straight and close grain, light in colour, sometimes with a reddish tinge See Chair.

## Beef and How To Cook IT

Heipful Intormation atout the Joints and Tested Recipes for their Preparation
For general cooking methods sec Baking: Boiling; Braising; Roasting; also specific cuts as Brisket; Sirloin; Stenk, etc.

Grass-led, short-homed cattle provide the best beef on the English market Cow-beel is not so tender or well-flavoured, but is sold at a lower price Chilled beef is superior to and a little more expensive than the frozen ment imported from abroad It may require to be slowly thawed before being put in the oven, and is wholesome and tender if properly cooked

If raw boef is pale pink or purple the animal has not been in good condition; a clear red indicates health. If the fat is streaky, giving the beef a marbled appearance, the animal has been in prime condition. The fat should be without brown spots or streaks of blood. The flesh should feel firm and elastic. Then is no diangreenble odour from good meat. After keeping it at home for a day or so, washing with diluted vinegar will restore freshness Meat that is in prime condition docs not get watery on standing, nor lose much juice in the process of cooking

The Parts of Beel and Their Use;
The hind parts at a bullock are the most expensive. Sirloins and ribs are used for roasts: the rump gives the best steaks for broiling. The topside of the buttock is useful for ronsting or gives good stewing steake. The silverside or underside is usually salted and boiled, as is also the brisket, which is a cheap joint. The aitchbone (buttock) is cheap and used mostly for boiling Flank of beef pro vides good steaks for pies. The leg and shin are used for soup and also for potted meat. Cow heel makes a jelly as good as calves-foot jelly

Oxtail is stewed or made into soup Tripe is the ruminant stomach of the ox, and is easily digested The heart, liver and kidneys are moderately digestible. The sweetbreads of an ox require long and carcful cooking. The suet around the kidneys is specially good for the finest of cookery uses.

When a joint of meat is kept for a lew days it should be wiped and hung up in a cool, dry place to which llies have no access. The under cut of a sirloin may be takien off and used separately for beef olives or fillets of beef, thus giving an extra hot dish out of the joint

Boiled Beef. Choose a salted round, aitch bone, brisket, or silverside, and tie it into a shape convenient for carving Put it into a pot with just enough water to cover-cold water if the beef is very salt, otherwise warm Bring the water slowly to the boil, and then add two onions, several carrots (cut lengthwise into pieces). some sliced turnips, and soine herbs Let the beel simmer, but not actually boil Make some small suet dumplings and boil with the beof. Allow 25 min . for each lb the joint weighs and 25 min over. Serve the beef on a hot dish, pouring over it a cupful of the water in which it was boiled. Garnish with regetables and dumplings.

These are made with (; oz llour, 2 oz. suet. I small teaspoonful salt, \& teaspoonful bakingpowder, and a little water or milk. Firat the suet is chopped and mixed lightly with the llour, baking-powder, and salt; then all are bound together with the water, lineaded lightly and made up into soft balls of dough, which are cooked during the last 15 min . the meat is boiling. Serve at once, otherwise they turn heavy.

Braised Beef. A round of beef is the most suitable. Flour the meat lightly and brown in a saucepan in hot fat. Add a teacupful of hot stock, salt and pepper, a little mace or nutmeg. any sliced or chopped vegetables, 6 or 8 pepper corns, 2 cloves, and a little parsley. If no !resh celery is available, add a little celery
seed and a teaspoonful of dried herbs in a muslin bag. Cover and cook gently till the meat is tender, laying a piece of greased paper over it to kecp in the steam. A couple of Spanish onions, boiled for a few minutes and then quartered, may be arlded to the braise Place the incat on a liot dish, strain off the liquid, arrange the vegotables in four heaps round the dish. and pour some of the grapy round, serving the rest separately

Roast Beef Ribs of beef are often boned and rolled before roasting. Rounds and aitchbones can only be rossted successfully if very tender. Put in a very hot oven and reduce heat after first 10 minutes. Give 20 minutes to each pound, and 20 minutes over. The roast should be served on $\Omega$ hot dish with pieces of Yorkshire pudding, horse radish sauce, and gravy separately scrved.
Rolled Beed. Procure a large steak cut from the topside of beef, weighing about 2 lb ., and cut about if in. thick Wipe and llatten

> Beel. Quarters marked off to show bow they are cut tor market.

D. Thirk fank. E. Rump. F. Loin. G. Flank. Dotted lines D. Thirk fank. E. Ramp. F. Loin. G. Flank. Dotted lines show B Brigket. C. Middle oiece. D. Clod and Sticking. E. Sbin
slightly by beating with a rolling-pin or a cutlet-bat dipped in cold water. Remove the skin from $\frac{1}{2} \mathrm{lb}$. of raw pork sausages, mix the sausage meat with 2 oz . fresh white crumbs, 2 teasposnfuls chopped parsley, a dust of powdered herbs, a little salt and pepper, and one well-beaten egg. Spread this forcemeat evenly over the beef, but not within $\frac{1}{2}$ in of the edges.
Roll up the beef, bind in shape with tape, put in a baking-tin with 2 oz of beef dripping and a teacupful of water, and bake in a moderately hot oven for about if hours. Baste frequently, and if the dripping smokes, add more water. When cookerl, remove the tape, place the roll on a hot dish, and atmin rouni it about $\frac{1}{2}$ pint of hot tomato snuce If liked, a veal forceneat of crumbs, suet, and herbs can be used instead of the sausage filling.

Stewed Beef. Trim 2 or 3 lb of meat, tie neatly, and lay in an carthenware dish. Then boil If gills of vinegar together with 2 teaspoonfuls mixed of allspice, cloves, nnd mustard seed for 5 min. and pour over the beef. Leave in this marinade for 2 hours, and
lurn uccasionally Cut 4 oz bacon mon large cubes: melt 1 oz of beef dripping in $n$ sauce pan, and fry the cubes lightly When done, lay them on one side and put the beef into the hot fat, letting it brown well.
Lift the beef onit of the pan putting in itg place slices of onion Fry these, and add 4 oz of whole new carrots. Lay the heef on these vegetables, add 1 quart of stock, a small bunch of herbs. and a few spring onions Cover the pan and simmer contents for two or more hours, until the meat becomes tender Meanwhile melt 1 oz of bcel dripping in another pan adding and carefully browning 2 oz . of flour Colour and flavour will Iargely depend upon this Strain and stir in gralually the stock from the bcef, then boil, skim, and season this gravy
Beef à la mode This is a useful casserole dish Take 1 lb . of steak, and place in a pan to brown with a little butter, flour, and some small onions. Add a glass of olaret to a breakfastcupful of stock. Pour over the meat und add carrot, a little mixed herbs, pepper, salt, and the juice of half a lemon. Simmer slowly for two or three hours, adding boiling water if necessary. Scrve the meat in the casserole with the onions and carrots and a little chopped parsley. Cold Beef. Scraps of cold ment may be utilised to make beef cake. It can bo orna. mented by pressing into the thickly greased top and sides of the mould thinly cut rings of boiled macaroni or cooked peas rings of cooked carrot. etc.

Take a plain round mould and thickly grease it inside. Melt 1 oz. of butter or dripping in a saucepan, add 2 teaspoonfuls of choppor onion and fry a light brown Stir in $\$ 1 \mathrm{~b}$ finely minced cooked beef, 2 oz. fresh white crumbs, and 2 teaspoonfuls of chopped paisley Mix these with one whole egg and one cxtra yolk well beaten, and $\frac{1}{2}$ gill of stock. Season and mis carefully.

Press the mixture, : little at a time if the mould is decorated, into the greased mould. 'l'wist a piece of greased paper over the top and steam the cake for $\frac{1}{2}$ an hour, or till lirm in the centre. Remove the paper, slip the shape on to a hot dish, and strain over and round it a well-flavoured hot brown gravy

Beef Polantine. This may be sorved cither for breakfisst or as a supper dish. Cut $\$ \mathrm{lb}$. of cold roast beef into fine slireds. Have ready 1 gill of good brown gravy heated in a stewpan. add the meat to it, and allow to heat gently. Peel and thinly slice one Spanish onion and divide these slices into rings.
Dip each of these in slightly beaten white of egg or milk, then draw them through a little tlour and fry them in smoking hot fat until they are a golden brown tint. Keep these hot, and in the same fat fry three small firm tomatoes cut round in halves. Put the meat and well-seasoned and thickened gravy in the centre of a hot dish, arrange the tomatoes round and heap the fried onions on the top of the meat. This is sufficient for 3 persons.

Pickled Beel. To Irv-pickle remove any bones or unsuitable bits from about 5 or 6 ib
of thin flank or topside Rub well over with common salt and leave for $2 t$ hours Pound together in a mortar 1 it of common salt, $\frac{1}{2} \mathrm{lb}$. of brown sugar, $\frac{1}{2} \mathrm{oz}$. of saltpetre, and $\frac{1}{2}$ teaspoonful of black pepper to a tine powder Rub this mixture thoroughls into the beef, keeping it in an esrthenvare pan Turn and rub every day, or at least 3 times a week. Continue this process for 8 days, or until sufficiently salted.
BEEF GOULASH. A Hungarian stew Cut 1 $\frac{1}{2} \mathrm{lb}$. of boneless beef into 1 in . cubes, also 3 oz . of streaky bacon. Put these into a stewpan or casserole with 2 oz of chopped onion, and one small, fresh red chilli, or 2 dried cayennc pods. Add $\downarrow$ pint of good stock. cover the pan, and simmer contents for one hour. or until the meat is tender.
Mix 2 teaspoonfuls of fine ontmeal with 1 gill of cream, and stir into the stew until it boils. Allow it to cook gently for another 10 min . then season carefully and serve in the casserole or poured out on a hot dish. Small pickled gherkins and wholemeal bread should accompany this dish, which will be sullicient for five to six persons
BEEF JELLY. Prepared by cutting 4 lb . of good gravy beef into sinall pieces, laying them in a jar with a pint of cold water and a little salt. Cover tightly, stand in a pen three parts full of boiling water, and steu gently for cight hours. Then strain through a clean pat, and allow it to become cold; just before assimilate.
hair sieve, and remove every particle of fat the following day. A sheet or two of best leaf gelatine or a little isinglass can be used to stiffen the jelly.
BEEF NOISETTES. Select "good fillet of beef weighing $1 \frac{1}{2} \mathrm{lb}$. Trim off rough pieces and divide fillet into round slices not less than $t$ in thick. Melt $1 \frac{1}{2}$ oz of beef dripping or butter in a frying-pan, lay in the noisettes, and fry them quickly for 8 to 10 min ., taking care they are under rather than over-cooked. Arrange neatly in two rows on a bed of liot mashed potato or apinach. pressing the round pieces of beef down to hold in position. The next process is to strain mund them some hot brown gravy and lay on them a small pat of maitre d'hôtel butter.
To prepare this, work into 1 oz . of butter, I teaspoonful of finely-chopped parsley, 1 teaspoonful of lemon-juice. salt and cayenne to

Beel. Joints cut trom the fore-quarter, as shown marked of in the previous page. 1. Fore-rib. 2. Clod and sticking. 3. Shin. 4. Brisket. 5. Middle piece serving place a small piece of it on cach noisette.
BEEF STEAK PUDDING. Take 2 lb , of ateak, wash quickly, dry and cut into pieces about an inch square. Mix together 3 teaspoonfuls flour and a good seasoning of salt and pepper; dip each piece of steak in this mixture.

From lb . of suet pastry cut off about a third and put it on onc side; this is for the lid. Grease a pudding-basin, line it with the pastry, then pack in the pieces or rolls of steak. When the basin is full, pour in enough water or stock to come half-way up. Wet edges of pastry. put on lid, and press the edges together. Scald a pudding-cloth and tie securely over the pudding, taking care to make a pleat in the middle of the cloth to allow room for the crust to swell.

Put the basin in a pan of fast-boiling water and boil from 2 to 3 hours. Serve in the basin with a clean napkin pinned neatly round it. See Steak.

BEEF TEA. When properly prepared beef tea may provide some of the nutritive materials of beef, hut the common idea of its excellent food value is unfounded. It is always of less value than milk as food. The stimulating effect on the digestion and the bowels of the neat extractives which it contains is often valuable.

Beef tea must not be allowed to boil, or even become so hot that the albumen it contains

Beel Joints cat from the hind-guarter, as shown in the previons page side. 4. Lain. 5. Leq. 6. Topside. 7. Top-rump.

taste. When mixed, shape into a little Hat coagulates, as this renders it less easy to

Wash 1 lb . of lean beef and dry, cut in slices, and scrape these with a sharp knife. As each piece is scraped, lay it at once in a pint of cold water with teaspoonful of salt and let it atand for half an hour. Then put the nicat and water in an earthenware jar, tying a piece of thick paper over the top. Place the jar in a pan of boiling water on the fire and let the water simmer gently for $3 \frac{1}{2}$ hours, stirring occasionally. When cooked, strain out the meat, but do not use too fine a strainer, unless it is imperative that not a particle of solid matter is given. Season carefully with salt. If more convenient, the jar containing the beef tea can be put in a slow oven instead of in a pan of water. Serve with thin dry toast, unless the patient is restricted to a liquid diet
Uncooked beef tea may be ordered in cases of extreme exhaustion. Usually only one or two teaspoonfuls are given at a time, as it is very strong. It should be prepared only in small quantities, as it will not keep.
Wash and wipe 3 oz . of fresh topside of beef, trimming off fat. Scrape the meat finely, and as it is scraped lay in a shallow dish with three large tablespoonfuls of cold water and a saltspoonful of salt. Cover over and let it stand until the meat is almost white and the water deep red. Keep pressing the meat well. It will take an hour or mone to soak sufficiently. When ready, pour through a piece of fine muslin, squeezing out all the juice.
For beef essence cut 2 lb . lean meat into small pieces, sprinkle with one teaspoonful salt, put into a covered dish with one tablespoonful water, and liake in a moderately liot oven for five or six hours. Serve a teaspoonful of the juice at a time, hot or cold

BEEF TEA CUSTARD. A useful invalid dish. To make, beat one whole egg and one extra yolk lightly, but well together, without frothing. Heat $\ddagger$ pint of beef tea, and pour gradually on to the egg and season Strain the custard into well-buttered little moulds, twist a piece of huttered paper over the top of each, and steam slowly until firm. If cooked too fast they will be watery and full of holes. When sufficiently cooked, let them stand for a minute or two and then turn them out carefully.
BEEFWOOD. This wood, which is used by cabinet-makers, comes mainly from the various species of the Australian tree Casuarina. It is also obtained from the bully tree grown in Guiana. See Wood.

# Beehrve: Construction of a Modern Type 

## Comprehensive Instructions for the Craftsman Beekceper

For the Principles and Internal Arrangement of a W.B.C. Hive see the article Bee
Madern bechives are of two main types, the This allows the rool to s!ip over the upper porLangatroth and the IV.B.C. The former is an tion of the outer case, and so dispensea with a Ancrican invention dating from 1852, and an plinth, whilat effectually keeping out the wet. improved form is extensively used in Great The top of the roof is of $\frac{1}{2} \mathrm{in}$. wood, each piece Pritain. The W.B.C. is a hive planned in 1890 being 24 in by 12 in Where the parts meet at ly W. Broughton Carr, solely to inect the needs of Brit ish bee-keepers. Its internal arrangenent is shown in the illustration under liees and liee keeping on p. 82, and we give helow all necessary instructions for making a hive of this type.

The hive is slown in perspective in Fig. 1. The outer enso, including the roof, consists of the centre the ridge piece (of 3 in . by $\frac{7}{6}$ in. material) is cut on the underside to cover the joint as shown, so that no water can pussibly get in. This roof portion should casily fit over the other: let there be no tightness anywhere so long as the bees cannot enter from the outside.
Some amateurs may prefer to use the type of roof shown at Fig. 9. By making the front

three parts, and it is advisable to commence by lirst making the portion slown at lig. 2 .

The construction may be by nailing the case together; if this is done, fine oval brads should be used, and the work should he akew-nailed so as to prevent the joints opening when exposed to the weather. Or, the construction may be by the combing or curner-lock joint (Fig 3), and this would, of course, be glond nad nailed at the joints Thirdly, the worker could adopt the through. dovelailing method illustrated in Fig 4.

The front and back troards of Fig. 2 are 10$\}$ in. long, 8 in inde, and 1 in thich; the sides, 19 in by 8 b in. of in matorial The inside measurement, when fitted together, is it in from frout to rear and 18 in . across the front. A plinth $1 \frac{1}{}$ in wide diops in below the edgo of the cuse so ns to lit around the lloor hoard und carry off the wet. The two slidea, A (Fig 2), which enlarge or ieduce the entrance, are 10 in
 a rebated guide piece (B, Fig. 5), litted helow the porch $A$ is one of the slides.

The porch is $4 \frac{1}{2}$ in. wide, and a weather groove is worked along the edge (Fig. 6) to carry off the drip. This porch is supported at each end by two $\frac{1}{2}$ in brackets. The second portion of the outer casc is a "lift" $6 \frac{1}{2}$ in deep, the wood being the same thickness as the lower portion (Fig. 2). It is advisable to make this in duplicate. A sketch of this lift is given at Fig 7, and the inset, lettered $P$, shows an enlarged end sketch of the plintl. The lift may be removed to reduce the height of the hive for winter, and a second lift may be added in the summer when necessary.

The roof is very simply formed with a view to lightness, and is thoroughly rainproof Fig. 8 will make the main pinints in the construction quite plain. The front and back pieces are $\frac{t}{2}$ in. thick, 203 in. long, $2 \frac{1}{2}$ in deep at the ends, rising to $3 t$ in in the centre or ridge; the sides are of $\frac{7}{6} \mathrm{in}$. wood $20 \frac{1}{8} \mathrm{in}$. long and 2$\}$ in. deep. Along the lower edge of the side pieces a rebnte is cut $\frac{3}{8} \mathrm{in}$. by $\frac{1}{2} \mathrm{in}$. deep

Fig. 3

Beebive. Fig 1. W.B.C. hive which can be made by the amsteur wood worker. Fig. 2. Lower portion. Fiz. 3. Corner-lock joint Fir. 4. Through-dovetailed joint. Fig. 5. Details of slides. Fiz. 6. Weather rroveve in porch. Fig. 7. Dpper portion or lift. Fig. 8.
Wool of caso. Fig. 9. Alternative method of making a rool
and rear of the roof of the shape heie shown, the necessity of working out a V -shaped recess under the ridge piece is removed Suitable ventilation holes should be bored in the front and rear, and a small piece of tine wire gaure should be fitted behind the holcs to keep, out intruders.

The lloor hoard may be made separate from the legs and supported hy a distinct leg frame, or the thoor may be built in combination with the splayed legs (Figs 10 and 11). Beginning
with the fluor board, the boards forming it are $\frac{1}{\text { in thick, tongued and grooved where }}$ joined, and nailed on to the stout battens $2 \frac{1}{2}$ in. deep by $1 \frac{1}{2}$ in thick. Between the points at $A$ it measures 20 in ., nnd the width acmss is 19 in. The sloping alighting board projects $\bar{i}$ in. beyond the point $A$ The form of the entrance, as seen in sketch, explains itself. It is $15 \frac{1}{2} \mathrm{in}$. long hy $\frac{1}{2}$. high. liig 2. of courso, fits on to this flonr portion
The splayed legs ( $\pi$ single line plan diagranı of which is shown at lig 10 ) are likely to cause some little difficulty to the amateur builder; and the following suggentions will considerably help him. Take a joiner's adjusaable bevel and, with a protractor set the blade to 10: degrees, as shown at lig 12; then mark at thic shoulder lines, as shown at Figs. 13 and 14 . Cut the joint as shown, and it will be found that the portion abuve the shoulder line lits closely into the corner of the frame. whilst the shouldered portion gives rigidity to the whole structure The height fom the floor proper to the top of the fionring loards of the hive may be about 12 in.

## Details of Body and Frame

Tho budy box (Fig. 15) is $155^{8}$ in by 14$\}$ in. inside ineasurements. It holds ten standiand frames and a division buard (or dummy). along with tivo strips of thin wood in wide and 16 it in long. The front and back boards are fin thick. 15 g in . long by 8$\} \mathrm{in}$. wide : sido pieces, 17 io in long, 9 in wide and $\frac{8}{6}$ in. thick. Tho strip $0^{\circ}$ wood, I) ( $166_{3}^{3}$ in by 18 in by $t$ in. ), nails on the outside to enclose the frame ends as shown. Prior to nailing oll this strip, a piece of wood $S\left(\begin{array}{l}\text { a inn. by } \\ \text { 各 in } \\ \text { in }\end{array}\right.$ in position level with the top edge of the front and back boards, along which are nailed the tin angle-picces forming the metal runners. whereon the Irames (fitted with W B C ends) work. Fig 16 slinws one end of a standard frame: the purtion above $A$ lies on the recoss formed in the body box
The shallow frame box (Fig 18) is an exact counterpart of the budy box with two excoptions: first, the depth is reduced to 3 in . second, the front and back boards are only $15 \frac{1}{\mathrm{~s}}$ in long. The capracity of this box is ten shallow Irames 5 d in deep with ordinary onds, and two thin slips of wood. or eight similar frames fitted with W.B C ends.
The eke (Fig. 19) may be described as a slice 3 in deep from the lower side of the hody box (Fig 15) and. beyond stating that the four slips of wond shown on the upper edge are for leeping it in position when fised. the sketch explains itaclf Fig 17 is a slietch of the housing joint for constructing the frame, and due allowance must be made in

Beehive. Fir. 10. Ler frame with plan diagram. Fig. 11. Flooring and allighting board nailed 20 frame Fig. 12. Joiner's adjastable bevel, set to $105^{\circ}$ for marking of splayed legs. The eke placed beneath the shallow frame box
the length of the front and rear pieces to fit this housing. The eke may bc used for giving space below the eumbs in winter and, having served this purpose, by reversing and setting it above the frames in early spring it helps in tucking in additional warm wrappings Finally, when set below the aliallow frame box (Fig. 18), it converts the latter into a fullsized brooll chamher for standand framea
Suitable timbers fur the making of the hive are ycllow pine and red deal, or a combination of the two woods. Where required, screws alone are usod, and these are previously dipped in paint, the overlaps and plintlss heing serewed in their positions from the inside of the cascs. Il here the wood overlaps, it should have two conts of white lead and oil previously. The outside of the hive is generally painied middle green, the inside being left unpainted. The illustrations aro laken from The British Beakcepers' Practical Notebook, Madgwick Houston \& Co

BEE PEST : How to Counteract. Also known by the name foul brond, this disease spreads so rapidly that, unloss precautions aro taken, a whole neighbourhnod may become affected, and tho chances of successfil beckeeping therein will he scriously inperilled if not utterly destroyed. Two forms of foul brond have long been recognized as existing in Europe, a viritent or strong-sinelling and an adourless form. A third type, sour brond, has usually been found associated with the strong-smelling type.

When stocks are found to be weak and are working languidly, with little desire to lly and swarining litile, foul brood may be suspected. If it is present, an examination of the combs will show celle containing dying or dead larvae, and others with their covers sunken or perfurated

Chilled bmod must not he mistaken, as it verv frequently is, for foul bruod. The dead larvae of chilised brood turn first grey, and afterwards become nearly black, whoreas in foul brood the larvae turn at first pale yellow and then brown, except in sour brool, when they turn from grey to ycllow.

When the disense is discovered in a wenk colony, the destruction of bees, combs, frames and quilts, together with a thorough disin. fection of the hive, is the best course. 'The spores ano then destroyed and the source of infection removed.
If an affected colony be still strong, the hees may be preserved by making an artificial swarm into a sliep or swarm hox. The hees should be confined in the skep or box. They should be kept confined in a cool place, such as a cellar, for 48 hours without fond, by which time all the honoy they may have taken with them will have been consumed, and the diseased lees will have died. After the outside has been well painted with oil paint the hive will again be ready for use.

At the end of the period of starvation the bees alinuld be lived into a movable comb hive in the same manner as a swarm. They are then fod for at least a week on syrup, to which as much naphthol beta as can be heaped on a threepenny piece has been added to every pound of white cane sugar used; the naphthol heta being dissolved in methylated spirit, sweet spirit of nitre, or whisky, and nilded to the syrup while warm but not hot.

In the case of mild attacks disinfection or fumigatimr may be resortcd to with success, formaldehyde being the chiof agent used.

These remedial measures are described in Leaflet No. 32, issued by the Ministry of Agriculture. Before attempting them it is advisable to consult an expert bee keeper wherever such help is available.

BEER. Beer is a fermented infusion of sugary substances with added bitters. At one time the sugary substance consisted of
sugar-derived from malted barley, and the
bitters tonk the form of hopa, but now sugar from other sources is used, one of these being by the action of sulphuric acid on starch, and calumba chiretta, quarsia, and other sub. stances are used to give the bitter flavour. Notwithatanding thesc changes the beer may be perfectly wholesome, though many beer drinkers prefer to have the old brew when they can get it.

Beer is a lood to a greater extent than other nicoholic liquor, mainly in virtue of the malt or sugar which it contains: but, as a general rule, it is taken as an agrecable form of bitter tonic to stimulate appetite and nid digestion: or it is taken to alake thirst. If taken with a meal it should be in modernte amount, as apart from the nature of a liquid, any large quantity taken during digestion dilutes the gastric juice and delays digestion.

During convalcscence from acute illness, and in many cases of consumption, a glass of beer or stout makes a useful and agreeable tonic. Stont is uften recommended to nursing mothers by their friends as a means of meeting the aulditional strain thrown upon them; but. its n genoral rule it is mucli more antisfactory to lenve alcoholic liquar alone. and rather to supplement the dict with extra milk. Stout and porter arc heers to which colouring minter has been added Formerly this was burnt malt, but now it may be carainel. molasses, or liquorice.

People who drink a lot of beer are apt to become stnut and gout and rheumatism many be other legacics of the liabit A beer-henrt is one which has tiruken down un der excessive strain, largely imposed upon it by the necessity of pumping through the blonil-vessels of the body streains of blond swollen by inordinate beer drinking over a long period. Again. the heavy drinker may produce permanent dilatation of his stomach, and chmonic giatrio catarrh may be a result of intemperate beer drinking.

One has always to be careful about the quality of the becr purveyed. A good beet should be clear, transparent, and reddishbrown in tint. and should not be soured. Beer is sometimes watered, and alum or sugar is added to produce a "head " ; the beer goes bad very readily with an increase in its acid content. Such beer may upset the stomach in any quantity. During hot weather many penple bring on sickncss and diarrhoca by the combination of lager beer and fruit of sone sort. There is always some common walt in heer, but in some samplen this is materially increascd, apparently with the object of creating thirst.
Beer becomics sour on standing in consequence of the growth in it of a minute fungus which converts the alcohol in the beer into acid. This acid is the one which is found in vinegar. If beer becomes dead-that is to say, only slightly sour-it can be restored by aulding a teaspoonful of carbonate of soda to each gallon of beer, mixing well, and allowing to settle. The beer will recover a good deal of its sparkle and llavour by this means, but will have lost sume of its potency.

If inarkedly sour the beer cannot be restorecl, but should be kept to make vinegar This is done by allowing the beer to stand in contact with the air until souring has progressed to the required stage. The liquid that results may be used as vinegar after having been clarified by filtering through several thicknesses of muslin or through cotton-wool. See Ginger Beer; Lager Beer; Spruce Beer.

BEE STING: How to Treat. The constitutional effects of a bee sting may be
severe, and are those of shock coldness of the body, faintness, etc The sting should he searched for and removed. The bost npplication is ammonia, butanlutions of bicarhnnate of soda, common salt, or permanganate of potash may be used. Where the sting is about the oye, mouth, or outer passage of the ear ammonia would not be used. For the shock the patient is kept warm and stimulanta given. If speedy relief is not obtained the doctor should he sent for. See Bite; Sting.
BEESWAX. Wax is not gathered by the worker bee, but is organically produced in her body from honey and pollon, by secretion bencath scalcs. When cleaning hives a box should be kept for the collection of all refuse and burr combs The scrapings from the lloor board during spring cleaning should be saved, for there is generally sufficient wax to make it worth the trouble of extraction Wax can be obtained from old broud combs and the cappings from extracting combs

The following methods for extracting the wax are recommended by the Ministry of Agriculture (Leaflet No. 378) : (1) The solar "ax extractor; (2) steam: (3) builing water: or (4) the heat of the oven.
The solnr wax extractor is really a miniature garden framc, with a double glazed and hinged light Inside, the frame is fitted with a metal tray which slopes down to a tin trough covered with wire gauze. The extractor is placed in a sunny position and the material to he treated is spread thinly over the bottom of the inetal tray The wax inelts and runs into the trough being strained of impuritics by means of the wire gauze covering.
he matcrial to be extracted by methods (2) and (3) must be stored until required in an airtight tin for protection against the ravages of the wax moth In the winter it can be melted over the kitchen fire by means of a Gerater wax extractor, an arrangement similar to a domestic steamer.
To extract wax by means of boiling water the material is tied in a bag made of porous fabric and stond on laths of wood placed acmas the hottom of a copper or saucepan, so that the bag does not tonch the bnttoin The bag whould be weighted with a stonc, and water poured in until it flows above the bag. The water should then be boiled very gently. The melted wax will percolate through the bag and float on the water, and when cold it can be lifted off in a solid cake.
The chief use of beeswax for domestic purpuses is for lloor and furniture polinhes.
A flonr polish is prepared by shredding yollow wax, 14 oz , and placing it overnight in spirit of turpentine, 32 oz . In the morning place the basin containing the above in a vessel of boiling water and stir until clear. Then renove the basin from the hot water and st ir the polish occasionally until it is cold. Many accidents have happened in preparing floor polish through contact of the turpentine vapour with tlame. By the above method no danger of fire need arise
White wax, which is employed for cosmetics. cold cream, and ointments, cunsista of beeswax hleached by exposure to sunlight. The beeswnx is melted and furmed into ribbons by pouring it upon rollera partly immersed in water. See Cold Cream; Cosmetic: Furniture Creain.

BEET. Of the orlinary garden beet. Beta vulgaris, there are several species, but the only two other than tho common kitchen-garden beet which are much cultivated are the spinach beet and the Chilian, the variegated form of which has extremely beautiful foliage and is much grown in Hower
gardens. There are both green-lcaved and red-leaved varieties, and there are whiteskinned as well as red-skinned roots.
Most of the beets are natives of Italy and other countrics of Southern Europe, and aro best if lifted from the ground and stored for winter use, instead of remaining in the soil.
There are two types of culinary root beet-the round and the long. The typical round beet is the turnip-rooted or Egyptian. The skin is dark red and the Hesh crimsun. but not so deep in colour ns some of the long beets It grows quickly, and consequently gardeners have come to use it for their early supplies storing only the long type. The Hinvour is excellent. Somewhat larger than the turnip-rooted, and yielding a heavier crop quite as oon, is the plohe, in which the roots wile quite as wide as the Egyptian, are deeper 'The liavour and colour are good.

Beet is usually offered for sale at shops in a cooked state The resson for this is that the skin of the edible beet is very tender, and easily cut, scratched, or pierced If such an accident happens in its raw state. the beet bleeds or loses its colouring matter, and, at the same time. its appearance and Hatvour. Hence the value of cooking the root as soon as possible after it has been lifterd

As a native of the seashores. heet пppreciates a light, sandy soil, but it is not fastidious, and will succeed in the heaviest clay, provided the soil is made friable. It is raised from sced and thrives in most parts of Great Britain Early sowing is not advisable for the long or parsnip-shaped beeta, because, apart from the risk from frost, there is the danger of the roots becoming large and coarse Nay is generally quite early enough, but in light. dry suils sowing may be practised about midApril The turnip-rooted and globe beets may be sown abnut a month earlier As a further safeguard against coarseness it is usual to sow beet on ground which was manured for a fihrous rooted crop the previous year. It may follow peas, beans and leeks.
The seed should be sown in drilla drawn 15 in . apart and about 2 in deep, rather less than more. It is well to sow a patch as a reserve. transplanting th the rows in showery weather as occasion may require. Then only hoeing and thinning will be needed until the crop is ready. Some like to sow the tumip or globe beet in July after early peas or potatoes, and useful roots are thereby necured. To store, fork beet lightly up in Octoher, taking care not to pierce the taps, draw them out by hand. romove the tops, and lay them head to tail and tail to head in sand, covering with straw, bracken or litter to keep out frost. It is not the case that cutting off the tops necessurily leads to loss of sap and colour. As long as the leaves arc ripe it does not matter whether they are cut off or twisted, if at least an inch of the stem of each leaf is left on the crown.
Spinach and Seakale Beets. Even the smallest of kitchen gardens is the better for a row or two of spinach beet, which grows to a height-not including the flower-stem-of two feet or more in rich soil The root is a parsnipcoloured tap. The seakale beet, which is the same plant as the silver beet, is

Beetle Trap with delicately balanced plates that yield with the weight of the insect and drop it into a central well
even more vigorous than the spinach beet, from which it is distinguished by having bmad, white midribs instead of somewhat narrow green ones. See Beetroot.
BEETCARRION BEETLE CThe beet-le which attacka the beet is Hat-hacked about half an incla in length, and of a blackishbrown colour, the wing-cascs ridged in their length The larva is a shiny black. Ilat oval whose natural food is carrion, but in the absence of this it attacks the leaves of beet
 and mangold. The de scription applies to Silpha opaca, but a near ally, Silpha atrata, of blacker hue. is equally destructive
The white eggs are laid in the ground in spring, and these soon hatching the larvae are ready to attack the tender seed. lings of the beet. When the leaves show signs of being eaten they should be examined carcfully, and the insects picked off and dest royed Stimulating chemical manures should be applied to give the plants a chance by rapid growth of outliving the injury Where manures of animal origin are used these should be well worked into the ground in autumn. so as not to attract the beetle in spring.
BEET FLY. The grubs of Pegomyia betac, n small two-winged Hy, known as the beet or mangold tyy, feed upon the leares of beet and mangold The white eggs are laid in batches on the underside of the leaf, and if these are lonkod for in spring and early summer they may be destroved by the pressure of finger and thumb. If allowed to hatch, the legleas grubs ent the lleshy parts of the leaves, thereby impair ing the liealth of the entire beet plant.

The application of arti ficial manure, by stimulat ing growth, may enable the plant to thrive, in spite of this set-back. If, however, some plants have had their leaves skelotonised, it is better to puli these up and destroy both plant and insecta

BEETLE DESTRUCTION trap consists of $\Omega$ well into A beetle diluted treacle is put, and sloping ends which make the well accessible. Attracted by the odour, the insects fall in and die. Phosphor paste spread on thin bread is a deadly lure. Store-room beetles of different kinds will be found on or in the food they attack.

In the case of furniture the problem is often difficult owing to the large size of the article attacked. If small, it may be suhjected to a high temperature in the oven; but if large, corrosive sublimate dissolved in methylated spirit should be forced into the minute wormholes with a fine syringe If it runs over the surface it will spoil the polish.

Furs or feathery attacked by beetles may be treated by the hot oven process, but great care must he talien that the temperature is not so high as to scorch or singe the articles. Naphthaline in the wardrobe will keepl the beetles away; but it may not kill those that have made their way thercin.

BEETROOT. The root of the beet is rich in sugar. It must be bniled and left to get cold, and is then peeled, sliced, and
 globe or turnip beet
the greengrocer, but if raw, wash before boiling. Do not touch the skin with a sharp instrument or the ront loscs its colour. Boil from one to two hours, according to age and size, adding a tablespoonful of salt. Press the skin with the fingers; if it begins to peel off the beet is rearly Drain well in a colander, and when cool remove the skin.

If to he served hot, peel at once on removing from water, slice and send to table cov. cred with a dressing composed of a teaspoonful each of Hour and mustard, and a piece of butter the size of a walnut, $\Omega$ teaspoonful of salad oil, and one tablespoonful of vinegar This dressing should bo mixed with a little gravy, milk or cream, and hoiled till it liecomes as thick as melted butter or white sance. See Reet.
Beetroot Pickle. Prepare a quart of malt vinegar for the pickle by boiling it with $\frac{1}{\mathrm{oz}}$. each of whole blach peppers and allspice and grated horacradish, anil then let it cool Cook 4 large bectroots, peel and slice them. place in bottles, and pour the vinegar over. It is important to take care that the bottlea ure securely covered.

BEGGAR-MY-NEIGHBOUR. A sinmple card game for two people in which the pack is shuffled, and the dealer deals out the whole pack one at a time to himself and his opponent. The non-dealer has the lead, and he and his opponent turn up cards altemately. When certain cards are turned up by a player his opponent pays him as forfeit a certain number of cards. One card is paid if a jack is turned up. two for a queen, three for a king, and four for an ace. The cards are turned face upalternately by the players until one of the fout forfeit carls appears, when payment begins.
If while turning up cards for paying a player reveals a jack, queen, hing, or ace, he ceases paying, and his opponent in turn begins to pay the number of cards required ay forfeit. When the whole packs of ench player are played, the hands held by each aro played out again, and the game is so continued until the cards are in the hands of one plaver.

BEGONIA : How to Grow. For foliage and bloom, the begonia ranks among the best of greenhouse plants. The summer leafing or tuherous hegonias are excellent for the cool greenhouse, or for bedding out during the warm months; the winter llowering or fibrousrooted sorts are valuahle under glass when the supply of blossom has becoine scarce
The culture of the tuberous sorts is not difficult. An ordinary 15 -inch box is big enough, with an inch of drainage material at the bottom and a layer of moss over it. The compost is one part ieaf-mould, one part loam and one peat with a dash of silver sand. Begonia seed is so tiny that a lot of it mny be lost if any lumps are left on the surface. The box or pan should be immersed as far as the edge in a tub of water in order to soak the soil. Any excess of moisture should be allowed to drain away, and the seed carefully sprinkled on the surface. All that is then necessary is a covering of the finest silver sand. Another method adopted by some growers is to lay on a fow flakes of clean moist moss instead.
Afterwards the box should be placed in $\Omega$ propagator or in an even temperature of $60^{\circ}$, and be covered with a sheet of glass and a piece of hrown paper in December or January. When the tiny seedlings show, they should be carefully shaded. In a month they will be ready for transplanting to other boxes. The seedlings should be kept thereafter in a moist atmosphere at as near $60^{\circ}$ as possible. If they are to be grown in pots the next shift should be into a 3 -inch pot If intended for bedding they can be kept in boxes.

## Growing Bexonias Out-of-Doors

Bedding plants should be carefully hardened. The beginning of May is usually the proper time to put the boxes in a cold frame. Begonias in heds should be well treated. The beds should be dug deeply and well raked over. It is advisable to add spent hotbed manure if available. The plants do best in semi-shade.

Many begonia lovers ignore seed and start with tubers purchased in winter or spring. In starting tubers into growth, lay them on a hed of fibre or in a box of leaf-mould in a moist position in an ordinary greenhouse temperature, where they can get at any rate halflight. All the little fibrous hairs should be carefully rubbed off

The winter flowering hegonias, of which Gloire de Lorratine and its forms are the principal sorts, are invaluable. Gloire de Lorraine is propagated by cuttings. The Howering period extends from October to February, and at its best the plant is a mass of beautiful hloom. After Howering it should be cut back and one or two plants put aside for young stock. New shoots appear after the pruning, and these, which should be removed

Begonis. Waxy white flowers of a single variety of Photo, Sutton \& Sons, Lid.
with a heel of the old wood, form the cuttings There are several winter varieties
The rex begonia is grown for its foliage. Its leaves are large and ear-shaped; they are coloured in a great variety of ways, including remarkable conihinations of silver greys. crimsons, and bronzes Propagation is effected by means of the leaves The best way is to cut half-way through the larger ribs and to pin the leaves down upon the top of a pot or pan containing candy loam and peat, just above the places where the incisions are made. In due course tiny plants will appear at the points of these incisions. Pron. Be-go'-ne-er.

BELCHING. Besides being common in certain types of indigestion. belching occurs in hysteria and ncurasthenia. The gas is not from fermenting food. but consists of air which has been gulped down. All that may be necessary in the way of treatment is to limit the
consumption of sweet or atarchy foods. In liysterical cascs h alf-teaspoonful doses of ammoniatcd tincture of valerian will generally suftice See suffice see Flo

BELGIAN HARE. This is a pupular breed of rabbits. It is long in body, has large black ticking. It attains a large size, can be easily reared, and is marketable at an early

## Bells: Electric \& OTHER HOUSEHOLD TYPES

## A General Guide to their Installation and Repair

Electric Batteries for Bell work are described under Battery and Dry Rattery ; Appliances using Electric Rells under Alarm; Rurglar Alarm; Fire Alarm, eic
Bicycle bells are usually nctuated by a lever $t$ and have a train of wheels and a rotnting hammer that sounds the bell mnny times with once moving the lever, as shown in Fig. 1 Useful types of doorbell are those that have a press knol, outside the door and a clockwork device within the bell itaclf, the whole mounted

Bell. Fir. 1. Bicycle bell, showing rotating hammer

Electric Bells consists of several distinct elements. These may be classed as follows: (a) The souree of the electricity to sound the bells. (b) The bells themselves. (c) The contacts or pushes. (d) Indicators to acquaint the person rung for with the whereabouts of the ringer (e) The connecting link hetween all these elements, viz., the wiring system. So far as the source of power is concerned, this is usually obtained fron a battery of dry cells or Leclanché bat. teries located in some convenient place, such as a dry cellar or the top of a cupboard.
It is a true economy to begin by installing adequate battery power. The average smalif house of eight rooins will need a battery of three or four Leclanché cells. A large ramhling building on three lloors with a subbasement may well need twice this number. Every yard of unnecessary wire in a circuit means so much current wasted, and any bad adjustments or faulty connexions will increase the resistance, and add to the demands upon the battery. The best place for a battery is somewhere near the centre of a systein, as all the leads or connexions are then shorter, and current consumption is less.
For indoor use the wire generally used is No. 18 or 20 copper, india-rubber double cotton covered, and paraffined. It is known as No. 18 (or 20) I.R., D.C.C. This wire is usually tinned, to facilitate soldering and guard against oxidation. When measuring up for wire remember to allow for the corners and for waste. When ordering wire it is usual to purchase it in several different colours to assist in identifying the various leads. Twin wire consists of two separate fully insulated wires, enclosed in an outer covering of cotton. In
this case one of the wires is usually identified by means of a coloured strand Flexible wires are used for hanging pushes.

A method of fixing wires ahove ceilings is shown in Fig. 4, insulated staples being used to fix the wires to the rafters. All joints in wires should be thoroughly well made, as upon the closeness of their metallic contact will depend the excellence or otherwise of the system. Fig. 5 shows two methods. After the wires have been soldered the joint is covered with insulating tape (Fig. 6). This should extend for at lnast one inch each way on to
 the covering itself. Connexions to puslies and bells arc generally mado by means of in binding screw or terminal nut, as in Fig. 6 Thi hest bells are mounterl on an iron frame indenendent of the wooden basc, and provided with a dustproof Bell. Fig. 2. Sectional view of door- cover. The bell actuated by a spring which is type nost frequently used is the trembling or vibrating bell illustrated in Fig. 3. It consists of an electro-magnet, A, fixed to an iron frame, B, provided with a soft iron vibrating armature, $\mathbf{C}$, one end of which is fitted with a hammer. The other end is lixed to the frame by a spring, $D$, an extension of which carries n platinum contact. Fixed to the iron frame but insulated

Bell. Fig. 3. Common type of electric bell. The lettering is expla ned in the text
from it a able platinum-pointed contact scre

When a press button is pushed curnen Hows from the battery, through the wires to one terminal of the bell, thence through the magnet coils, armature, contact screw and post to the other terminal and back to the battery The circuit is thus complete, but as the current fousthrough the marnet coils it energises the core. This attracts the armature, causing it to move and strike a blow on the gong while at the same time the contact spring moves away from the screw and thus breaks the circuit. The current ceases Howing, the spring returns the armature to its atarting point, when the contact screw again Bell. Figs. 4-6. Diagrams makes contact and illustrating details of work closes the circuit in wiring an electric system Owing to this continuous sequence of operations the bell continues to ring while the press is pushed The contact points should be clean, and the screw adjusted so that the armature is free to vibrate The armature should not touch the corc. Usually this is prevented by a projecting stud of non-magnetic material on the corc.

Continuous ringing bella are used in connexion with hurglar and fire alarms Their construction is similar to that of the vibrating bell, but with the addition of a catch on the armature, which engages with a lever to which
 Courtess of General Electric Co.. Lid
is fixed a spring This bell works na follows : First, the current llows ns in the trembling bell, but ar the armaturc moves it releases the lever, which falls against a second contact post. This closes the oircuit through another wire to a third terminal, and thence to the battery. The bell therefore continues to ring until the lever is lifted and the circuit is again broken by resetting the lever.
Relays are necessary on long circuits, and many forms of indicator are improved by their addition. The п pparatus comprises an electromagnet with armature nod contact screws. Its duty is to close a local circuit when actuated by a relatively weaker current Howing through the coils of ite magnet.

Bell pushes, pulls, and switches are made in various patterns and materials. Their purpose is the same. viz., to close

Bell Indicator with pendulum disk oderated
by an electro-magnet

push consist of two metal plates fixed to the base ; one Hat, the other shaped like a pig's until it is again altered, whereas a pull or a push has to be held to keep the circuit closed. With the aid of the forcgoing notes the amateur should have little difliculty in tackling the installation of a new system or the repair or alteration of an existing one. The only real trouble is in knowing where and how to place the connecting wires or runs. For this purjose reference should be made to the different wiring dingrams, Fig. 8 In dealing with an existing system, either for purposes of addition, or to trace a fault, it will be necersary to find out the runs of the different circuits. An ordinary vibrating liell may be em. can be tested by any single circuit impairment of swallowing and speech, thirat, ising it-attaching one end by a temporary wire to a battery and the other end to one terminal of the bell. A separate temporary wire connects the other bnttery terminal to the bell. Hence, the circuit being complete and closed, the bell should ring; if it does not, the fault will be somewhere in the circuit under test.

When dealing with a failure of the systems as a whole, suspect the battery or a biroken wire. If one or more bells ring feebly and
 some riot at all, then the battery is almost oertainly run down. When only one bell faily, and the others are up to standard perforinance, look for trouble on the affected circuit. It will probably be found in the push, the adjustment of the contact screws of the bell or indicator, or a broken wire. The latter is, however, compara. tively rare.

Bell Indicators. In an electric bell system the indicator tells from which room a call has been received and so dispenses

The contacts of a tail and sufficiently springy to lift itself clear of the flat or lower plate. The press button is held up by this spring.y contact An improvement is the morse-key type of push (see Fig. 7) The pear push, mostly emploved in hedrooms, consists of a pear-shaped handle suspended by twin flexible wires from a rosctte on the wall or ceiling.
Switches are sometimes used in bell work to break a circuit or transfer it from one place to another. A wwitch remains open or olosed
with separate bells. Indicator movements resolve themselves into two maill classesthose that drop a shutter or move a disk and have to be reset every time the bell rings and those that swing like a pendulum and do not require resetting.
A form of the pendulum variety is illustrated lelow It consists of an electro-magnet fixed at one end to a metal frnme An arm on the frame lightly supports a pendulum armature trom which is suspended a paper vane or disk. When the current flows through the magnet the armature is attrmeted and set swinging and will continue to awing lor some considerable time
These indicators are generally mounted in a polished hardwood case with a glazed front. through which the paper vanes can be seenThis type of indicator seldom gives trouble ; all that is needed to keep them in perfect order is to see that they are clean and that the wires and connexions are sound
BELLADONNA. Both the leaves and the root of the deadly nightshade, or bella donna, are employed in medicine, the active principle being atropine. The liniment of belladonna often gives good results in neural gia The symptoms of poisoning by belladonna, or deadly nightahade, are dryness of the mouth.

Wiring corelay local Circurt
inpairment of swallowing and speech, thirat, dilatation of the pupils, dry skin, and frequently a scarlet rash, delirium, and unconsciousness. The best antidote is warm strong ten administered immediately. See Atropine Poisoning.

BELLADONNA LILY. The popular name of belladonna lily is given to the Amaryllis. of which A. Belladonna bears rich leep pinli or asamon-coloured flowers. It needs deep rich soil and the shelter of a southern nspect to thrive in countics north of the Thames. The bulbs should be planted in June and the flowers appear, before the folinge, in

Belladonna Lily. Cluster of the large delicately coloured
fowers of the Amaryllis

Angust and September. The greenhouse or half-hardy apecies of the belladonna lily are known as Hippeastrum (q.v).

BELL CRANE. A mechanical device for transmitting motion from one direction to another at an angle to it, uamally a right angle. By suitable proportion of the arms a different stroke or pull is obtainable. The device is in extensive use on machinery, hut derives ita name from its application to domestic bells of the old spring operated type.

Belleek Ware. Basin of genuine tinted porcelain made in the North of Ireland

BELLEEK WARE. While similar lustreware is manufactured in Glasgow, Staffordshire and the United States, the true Irish porcelain from the factory at Belleek on Lough Erne is easily distinguished by its characteristic mark, stencilled or stamped in colour, of the name with a device of a round tower, greyhound, harp and shamrock leaves.

For a quarter of a century after 1857 the factory turned out its hest thin, eggshell type of parian ware, sometimes with an ivory glaze and a mother-of-pearl lustre. See China.

## Bellflower. See Campanula.

BELL GAUGE. Made of nickel-plated ateel, and shaped as shown in the illustration, this is used for measuring knitting needles and crochet hooks. The latter should pass through easily and never be forced. For sizes 1 to 5 use the holes, but for sizes 6 to 24 inclusive use the slits leading into the holes. the holes in these particular sizes being intended to release the pins when gauged. See
Bell Gauge for measuring knitting needles and crochet hooks Crochet: Knitting.
BELL - GLASS. A glass vessel, bell-shaped, with a knob at the top, this is made in various sizes, the mouth fitting into an earthenware saucer. Seeds sown in a pot and stood in the saucer under the glass will rapidly germinate and grow, owing to the close, moist atmosphere. Bell-glasses are also invaluable for foroing cuttings quickly to take root, or for growing seeds that need the protection of glass in their earlier stages. In the largest sizes-those which are used for the French system of intensive horticulture-the native word cloches is now so usually applied that it has become anglicised.

BELL METAL. The metallic alloy used in hell-casting is generally composed of 78 p.c. copper and 22 p.c. tin. The material is expensive, hut by ite use alone can a good tone be obtained. Bell metal is occasionally used for very bigh-class cooking utensils, such as stewpans and kettles.

BELLOWS. In their simplest form bellows are elementary types of air compressor, adapted for blowing fires. The same principle is frequently applicd to the bellows used for blow. ing the organ in a church or hall, to vocalise certain small toys, and to actuate part of the mechanism of a player piano. A concertina is another type of musical instrument embody ing bellows to act as artificial lungs. Many
cameras have bellows to exclude extraneous light rays from the lens and photographic plate (See Camera).

Bellows are designed for single action double action, or treble action, according to the number of stages through which the air is compressed. An example of the first is the domestic fireside bellows. Double-action bellows are largely used for small brazing and blacksmithing jobs: a usual form is operated hy foot power.

BELL'S PALSY. Paralysis of the muscles of the face is known as Bell's palsy and is usually confined to one side of the face. The cause may be exposure to cold, as when a person sits at the open window of a railway carriage, or a blow in the region of the ear. It may also be brought about by diphtheria, meningitis or car-troubles.
When due to cold, a mustard leaf should be applied behind the car and the patient protected from further cold. If there is much pain. 10 grains of aspirin may be given. Medical advice must be taken.
BENARES WARE. The decorated brassware produced by Hindu artisans at Benares includes trays and salvers. plates, tumblers, hookabs, gongs, and various forms of waterbottles and ewers Especially graceful are the melon-shaped lotas, used for religious purposes Cheap Benares ware has been produced for export, with shallow designs

## soft leather See Brass.

## THE BENCH: FOR CARPENTER AND MECHANIC

## Two Examples of a Necessary Feature of the Workshop

## See also Amateur Carpentry and the articles on Chisel. Hammer, Saw and other tools

The combined bench and cupboard shown is made of beech wood or other hard in Fig. 1 is within the capabilities of any material. The top fits into special slots, the anateur. Convenient sizes are 3 ft . long, oross rails being secured by long hardwood 1 ft .9 in . wide on top, and 2 ft 9 in . high. The wedges. Two vices are fitted, one for ordinary legs are 2 ft .7 in . long, made from $2 \mathrm{in} . \times 2 \mathrm{in}$. use at the left hand end of the bench, the deal, the oross-pieces of similar scantling other, or tail vice, works longways of the mortised and tenoned into the legs. The bench and acts as a cramp for wide work. back and ends are enclosed by 昌 in match- Square holes and the pegs provided to fit lining, nailed in place, while the top is made them enable work of widely varying widths from two pieces of 11 ins. $\times 2 \mathrm{in}$. deal glued to be held firmly. A tool-well prevents the and pinned together and screwed in place with tools getting in the way of the work, while a $3 \frac{1}{2} \mathrm{in}$. screws passing through the framework. drawer holds others not needed at the moment. The front is enclosed by two simple doors Convenient sizes for such a bench are : 6 ft . hung on 6 in . cross garnets and provided with a long, 2 ft . wide, 2 ft .6 in . high, legs 4 in . bolt. The floor is of match-lining; and the square, rails 3 in x 2 in ., top 3 in. thick. A

shelves and racks are cut from 6 in. $x$ 各 in. deal.

A fow small drawers at the bottom accommodate screws, nails and other small parts. A back board 4 in . wide and $\frac{5}{8}$ in. thick prevents the tools falling off at the back. A portable bench vice with a olamp fitting is very convenient ; it is fixed up in a few moments, and when not wanted is accommodated within the cupboard. The various toole are supported on racks or shelves or hang from hooks, as may be most convenient.
The regulation joiner's bench, as a general rule,

based on foreign requirements, such as jardinidres and ash-trays. The inside of a piece of lemon rind rubbed hard on the surface and washed off with bot water will clean the article ready for polishing with a soft, dry cloth. Ordinary metal polish should never be applied Good pieces, which should not he lacquered, may be cleaned with a mirture of sweet-oil and rottenstone, free from grit, rubbed in with a flannel, and finished off with
portable carpenter's bench of a useful type is cross braces and stout longitudinal members. shown in the picture of a workshop on page 13. The thick top may be bolted to the cross Such a bench may be purchased ready for use, members, the bolt heads being sunk below the or it is quite easily constructed.

Where a regular workshop is available it is frequently possible to build in a work bench. This is both economical and practical ; stiffness and rigidity are assured, and for metal work it is preferable to the portable benches. One important item is to see that the bench stands fair and square on the floor: it must be accurately levelled, which may be done by means of suitable packing beneath the legs.

The construction of a mechanic's bench is illustrated in Fig. 2. A convenient height is 34 in ., with a width of 30 in . and a length of 6 ft . The top is composed of oak or other hardwood 2 to 3 in. thick at the front, and 1 in . thick at the back.
 attention. The leas must be at least 3 in and in attention. The legs must be at least 3 in.
square and very well framed up with diagonal
end to its plate, and is raised or depressed by

Bench Stop. Loft, wooden stop to insert in mortiso. kight, fing metal atop controlied by screw

BENCE STOP. This is a hardwood or metal stop, fixed or adjustable, against which work is rested on the bench when planing, etc. In its simplest form it may be a wooden strip screwed to the bench top a short distance from one end, close to the front edge of the bench. Another kind of stop, made from a piece of hardwood about 4 in . long by 2 in . square, is mortised through the top of the bench about 2 in from the edge. The stop fits tightly in the mortise, and is knocked upwards or downwards with a mallet to adjust its height above the bench. A face iron may be made by heating and flattening the end of a piece of $2-\mathrm{in}$. iron, and cutting serrations in its edge with a saw file. (See illustration).

Adjustable metal stops ąre made in various patterns, and are easily fitted to the bench top. In one type the stop piece is binged at one turning a large screw-head in the plate. In
another type the stop rises and falls in a socket as the adjusting screw is turned.

## BENT IRON WORK: SOME OF ITS USES

## A Process that Can Be Used to Beautify the Home

## Seefurther the entries on Lacquer; Piercing; Wrought Iron and other related subjects

Bent iron work is used for numerous household articles, including giriles, screens, lamps, hobby by amateurs at home. Only a few stances and the skill consists brackets, photograph and picture frames, and mainly in producing graceful curves, symother purposes. It varies in character from metrical proportions, suitable designs and work done at a forge on red hot metal to that secure unions of parts. The iron can be which is easily done cold by bending with pliers bought in coils, or strips of it can be cut with or with the fingers.

the thickness of ordinary tin plate, and bends nearly as easily as the latter. Widths range from \& in. to $\frac{1}{1} \mathrm{in}$. In most articles there must be something in the form of a frame, or substantial element, to which the comparatively weak and slender ornamental work can be attached. The apparent endless variety is made up of a fow elementary forms ropeated continually. These are shown in Fig. 1. Besides these we get plain circles and ovala.

The strip of metal is cut with shears and then bent with pliers. Round-nose pliers are used for bending small curves, the unbent part being held with Hat-nose pliers or with the fingers. Pliers are used to hold the strip securely and to bend a little at a time. They are moved along as required, and the workman judges by his eye when the curve is correct. Heavy, flat pliers are used afterwards to assist in taking out kinks and improving the curve.

Parts in contact are generally held together by clips (Figs. 2 and 3). These are made from the ordinary strip and pinched tight with pliers. Sometimes joints are riveted and sometimes soldered. Riveting is only practicable when the parts can be laid on an anvil for hammering the riveta. Holes for rivets are generally punched. In thick metalthat is, more than about $\frac{1}{18}$ in.-drilling is the only way. In metal too thin to be countersunk the rivets used must be of the types shown in Fig. 4.

Fig. 5 shows a rivet in place before it has been closed by hammering, the type of rivet shown being the cup-head or snap-head. The tool shown in Fig. 6 is used, in the same way as a punch, for imparting a neat convexity to the tail of the rivet, after the preliminary work has been done with the hammer only. A block with a similar concavity should be placed beneath the head of the rivet to keep it from flattening on the anvil.

Small bolts are occasionally used instead of rivets. For soldering, the surfaces must be cleaned and flux applied. They can then be coated with solder and pinched together with hot tongs, or bound with wire and heated by a Hame, or pinched with pliers while the solder is running. Of all the above methods the clip is the most popular and the quickest.

## Use ol Twisted Strips

Fig. 7 shows how strip can be twisted, either for appearance or to make it equally stiff each way. The ends are held with pliers or, preferably, one end is held in a vice and the other twisted with pliers. Fig. 8 shows chain made from strip iron. Fig. 9 shows examples of sheet metal ornaments. These are often of copper and, strictly, they are classed as repousse rather than bent iron work.

Fig. 10 shows a wall bracket, the frame of which consists of stout iron rod. Fig. 11, made entirely of bent iron, is a stand made to suit a glass or china vase. Fig. 12 shows how the large areas of grilles and screens are filled in by a repetition of some simple pattern. Fig. 13 shows the same method applied to narrow borders.

For the floating flower bowl, shown in Fig. 14, a polished copper or brass bowl can be used, or one of brightly-coloured china. The combination of a tlame-colour bowl with the dull black iron is very effective for table ornament. Make the foundation ring, A (of a size to suit the bowl), from stout iron, to which is attached the ornamental ironwork. The stand is made in two units. as shown in Fig. 15, each composed of three parta ; these, when made up, are riveted to the foundation ring and form the four legs.

Making a Standard Lamp. A design for a Hoor lamp is shown in Fig. 16. First choose the lamp and make the top ring to suit it from by
 meter, and at the lower end fit a gas flange,

Dent Iron. Figu. 14-15. Stand for a copper or cinina bowl screwing it on to the tule. The flange has to be cut away to form three arms (Fig. 17) and to these the bottom legs of 14 by $\frac{3}{18} \mathrm{in}$. iron are riveted or brazed. The long and continuous outer members, $A$, of by sit in. iron, and then the pieces B (Figs. 16 and 18) are bent and riveted in position. The inner ends of the latter are turncd down into the bore of the upright pipe and secured by driving in a ${ }^{\text {In }} \mathrm{i}$ in. Whitworth nut filed to fit as in Fig. 18. This part is completed with a rosette and ball
head scrow. The remainder of the decorative soil Propagation is by seed sown under glass work is carried out in ordinary $\ddagger$ in strip iron, in March or outdoors a few weeks later; also shaped and clipped in place as shown in by division in autumn or apring.

The only other species of note is the wild bergamot, a somewhat taller plant with purplish flowers, also having aromatic leaves
The essential ofil of the same name is ubtained from a variety of orange taking it name from the town of Bergamot Its rind yields a very fragrant oil used in h:gh-class confectionery. ligueurs, and largely in perfumery liergamot is sold as an essence Pron. Ber ger-mot

BEST MAN. A relative or personal friend who accompanics the bridegroom to the churc!. or wherever the ceremony is to take place. Previously he has seen that the neccasary arrangements have been made and received instructions from the hridegroom as to what he wishes him to do. With the bridegroom he stands in position to receive the bride, and remains just behind the pair during the ceremony At the right inoment he hands the ring to the bridegroom and he accompanies the newly married pair to the vestry, where he usually signs the register.

If a reception follows the ceremony, the best man helps to attend to the comfort of the guests. The best man sees to the payment of the officinla who have assisted at the marriage service - the clergyman or regintrar, the organint and others that are necessary, and distributes gratuities See Marriage; Wedding

BEVEL GEAR. 'The use of bevel gears is for transmitting motion from one shaft to another when their centre lines are at an angle to one another. The teeth are cut radially and to an angle or bevel formed on the outer part of the face of the wheel, the angle and shape of the teeth being determined largely by the rela. tive diameters of the pair of wheels. Two equal size bevel gears that are used to transmit motion at ight angles are known as mitre wheels.

Farniliar applications are the gears on egg whisks, hand
bevel wheel and pinion on some makes of drills, butter churns and som
window control gear. See Gcar

BEVELLING. It is chiefly in woodwork that bevelling is found; it menns the production of surfaces which are neither at right angles nor parallel with each other. A box or tray with splayed or sloping sides and ends, or the hody of a barrow, are instances where joints are bevelled to obtain the required shape of the article. In other cases an exterior surface may lie bevelled in relation to other surfaces, e.g. the top edge of a plinth.

In furniture, edges ane frequently chamfered, whioh means planing off the angles so that a narrow Hat at the angle of $45^{\circ}$ is formed.
 the fragrant parden herb Parts meeting with a joint at $45^{\circ}$, such as the corners of picture frames, are a日id to be mitred A sloping joint uniting pieces in the same plane is, a acarfed or spliced joint. lll come under the hearling of hevelling.
As a general rule lines are
marked on the work to show the exact extent of the required bevel, and the cutting tools work to these lines. In other cases appliances are used for guiding the tools In sawing sinall pieces at an angle of $45^{\circ}$ a mitre box or a mitre block may be used to guide the saw. For planing the angles two types of shooting hoards are used These may be for $45^{\circ}$ only or adjustable to any angle. One kind is used for planing long edges (Fig.1), the other for short ends (Fig 2). In both the plane is used
 of making bevelled edges In carpentry
lying on its side. It is alid backwards and forwards with the right hand, while the work is held in position with the left.

A woodworker's bevel is used for marking lines (Fig. 3) and testing (Fig 4). The bevel is adjustable to any angle, and is tightened bo a screwdriver or by a wing-nut. Detinite angles are obtained from a protractor, or by drawing a full-size view of that portion of the work on paper. Fig. 5 shows a type of bevel used chietly by metal-workers. Besides this there are bevels in combination with protractors.
Beveren Rabbit. This rabbit is largely hred for its pelt; there are two varieties, one late blue, the other white. See Fur: Rabbit.
BEZIQUE : For Beginners. Bezique is a game of cards for two, three, or more players, and is played with two or more paclis, one for each player, shuffled together. The pucks do not contain the sixes, fives, fours, threes, or twos The cards, in order of importance, are ace, ten, king, queen, knave, nine, eight, seven. For the sake of simplicity the game for two players will be described.

Two ordinary packs, with the noted eards removed, are thoroughly sliufled together and cut by the two opponents, the player cutting the higher card having the right to deal. The denler deals out the cards, three to his opponent, three to himself, then two to his opponent, two to himself, and finally three to his opponent and three to himself. The 17th card is turncd up for trumps, the remainder of the paok, face downwards, lying between the two players. If the turn-up happens to be a seven the dealer scores 10 points.

The game is $1,000 \mathrm{up}$, and the points scored are for the following combinations held by the players, nnd declared by then, i.e. placed face upwards on the table. The table gives the names of the declarations
Bezique (qucen of apades and knave of Pointe monde or aucen of clube and knnve of heart according to trumpa)
Double hezique (both queens and both knaves).. 500 Sepuence (nce, ten, king, queen, knave of (rumps)
Common marringe (king and queen of any suit
save trumps)
Royal marrlage (king and queen oi trumps)
4 Aces
Queens
Knaves
Seven of Irump (turned up)
Playing seven of trumps
Exchanging seven of trumps for trume car
Ninning of last tric
20

Earl ace und ten in tricks of scoring phayer 10
the play is as follows: Each player looks at his hand, and the dealer leads a carl which

He thinks ne is least likely to want for one of the combinations given in the table. His opponent need not take any trick, though if a ten or an a0e is played he generally tries to do so, s:nce such cards count towards his score at the end of the game. He may also wish to take a trick - because he wishes to deolare one of the com. 'binations enumerated. He need not follow suit, and may take a trick by playing a higher card of the same suit or by trumping.

Whiohever player takes the trick turns over the two cards, and then either declares any combination he may wish to do, or takes another card from the top of the paok His opponent takes the next card, so that each player makes up his cards again to eight. One of the drawn cards may provide a card of a required combination, but a player cannot declare until he has won another trick. He must, too, declare anything before taking another card.

The trump card may be an important one, e.g. the ace or ten, and a player may exchange it with the seven of trumps, if he holds that card, on winning a trick. Playing either seven of trumps in this way, or playing it on a trick, except when playing the last eight cards, entitles the player to acore 10

When to Declare Bezique
fiach declaration, as made, must be laid down face upwards on the table. Bezique is declared by placing the proper queen and knave on the table. The berique queen and knave must be of opposite colour and neither may belong to the trump suit; i.e. bezique must either be queen of spades and knave of diamonds or queen of clubs and knave of hearts. Double bezique may be declared either by placing both queens and both knaves on the table, or by first declaring bezique and then afterwards adding the other two cards. But all four must be on the table at the same time to obtain the double bezique score Should the bezique be declared and the cards afterwards played, the player may afterwards hold the second queen and knave, but he can only declare bezique with them and not double bezique. The same rule applies to all combin. ations, i.e. all the cards of that combination must be on the table at time of declaration.

Sequence consists of ace, ten, king, queen, end knave of trumps. The king and queen may be declared first (but not afterwards) as a royal marriage, and the other three cards added when convenient. In some forms of the game a royal courtship is allowed, scoring 20 points. This consists of the knave and queen of trumps.

## Use of Cards a Second Time

Cards once declared in a combination cannot be used again for a similar combination, a for a royal marriage. Such cards, however. may be used a second time in different combinations, e.g. the ace in sequence may be used to form one of four aces, the queen in bezique may be used with three other queens to give four queens, and so on.

The play goes on as described until the stock between the players is finished, and each player is left with eight cards. Though he may, by his very last cand, complete a combination, he cannot now declare it. The last trick befure the stock is finished counts 10 points to the winner, and in playing the last eight cards players must follow suit, if possible. If not, they are at liberty to trump. When the final card is played each player goes through the tricks he has won and counts the eces end tens he has in them, these being added to his score.

The following are a fow hints on playing. first of all it will be found by a player that he often holds parts of one or more combinations. It will not be always possible to keep all the cards, and one or more cards of a wanted sombination will have to be played on tricks.

In such a case it is better to keep four kings and four queens than four aces. The two former sets can always be used for marriages and so increase the score.

It is not always advisable to declare or play valuable cards as early as possible. To play one of two kings of trumps before any declaration tells your opponent that you have both kings, and he will not trouble about getting sequence.

When the number of cards in the stock is becoming low, it is advisable to take as many tricks as possible and to declare everything at once, and not separately. That is, if you have sequence, declare it as a whole and lose the royal marriage score.

In three-handed bezique, played with three packs of cards, triple bezique may be scored, counting 1,500 points, and the game is often fixed at 2,000 up. With four-handed berique, players may either play for themselves or act as partners, as at whist. In the latter case each player may declare when lie or his partner has won a trick

BIB. A baby's bib oan ue made trom a double equare of bath towelling bound with white tape, cutting a semicircle from the square to fit the baby's neck and attaching tie-on tapes. Bibs are also made of silk over a pad of cotton-wool quilted and lace-edged.
BICARBONATE OF SODA. In con. junction with oream of tartar, bicarbonate of soda is used in making baking-powder. It is also frequently employed in the making of scones, etc., in the proportion of about teaspoonful to a teaspoonful of cream of tartar and 1 lb . of flour. For soda ciake. it is used without the cream of tartar. If too much soda is used in a cake it will flavour it disagreeably and give it a yellow colour.
It is also valuable as a medicine, being given for indigestion in doses of ten to twenty grains, dissolved in water. It is also taken in the form of compressed tablets, known as soda mints, containing ginger and peppermint. Moistened with water and applied to the part, bicarbonate of soda relieves the pain from insect stings. See Baking Powder: Soda Cake.

## The Bicycle and its Mechanism

## Care and Adjustment to Secure Good Ranning Order

## The articles on Balt Bearing; Brake; Chain; Coaster Hub: Three Speed Gear; TIre, and other

Dealing tirst with the frame of the bicycle, the two parts requiring attention are the ball races in the steering head and the cup cones of the bottom bracket. To keep out any wet, the cones A (Fig. 1) are a press fit into their housings. These cones may be driven out from the inside and replaced with new. The cone B at the crown of the front forks is only a light press fit, so can be easily replaced. Ball races must not contain a full ring of balls; there must always be one short. The object is to allow freedom of movement for the balls.

When the head is complete, as shown at Fig. 1, tighten down the lock ring C just sufficient to stop all luoseness, and no more. After seeing that the handle-bars are the right height and square with the front wheel, tighten the nut D .

With the bottom bracket (Fig. 2) the inner cones, $A$, are in most cases in one piece

Bicyole. Figa. 1-6. Diagrams illumpatiox some of the more important parts of the meabenilum
with the spindle, B , that carries the cranks. The outer races, C. are carried in the bottom bracket shell. In assembling, set the balls in the outer races with vaseline, and first screw the ball race on the chain sprocket side into its original position. This assures correct alinement of the chain over the sprockets. Next scrow in the other outer ball race, finally locking by the means provided. When fitting the cranks on to the apindle, take partioular note to fit the head of the cotter pins head to tail, i.e. if the head of the sprocket cotter is on top; the head of the other one must be underneath. If this is not observed the cranks will not be in line. When fitting new pedals it will be found that they are screwed into the crank, a left-hand thread being used for the sprocket-crank and a right-hand thread for the other.
The hubs of the wheels follow two distinct types. In one the adjustment is carried out by the cone, $A$, on the spindle (Fig. 3); in the other the outer race, $B$, is used as the means for adjustment (Fig. 4).
Where adjustment of the wheet bearing: is by the former means (Fig. 3), it is advisa.lle to leave the bearing very slightly slack: the thrust transmitted to the cones by the nuts that hold the wheel in place between the forks will take up the slack that was left.
Should the rims of the wheels be out of truth, remove the tire and tapes that cover the ends of the spokes. Then mount the wheel between the forks, turning the bicycle upside down so that it is supported on the handlebars and the seat, and give it a vigorous spin Now hold a piece of clialk to the edge, allowing it to approach the spinning rim until it just catches the high places. Stop the wheel, and with the nipple-key tighten all the spokes on the opposite side to the chalk marks, and slightly let down all the spoken on the same side as the chalk marks. Then wipe off all marks, and repeat the procoss until the rim runs true. When finished, the tone of all spokes should be nearly the same; but if there is a considerable difference, work at it until a fairly uniform note is achieved. After any adjustmont to the spokes, file down any ends that may be protruding through the nipples.

If the machine is fitted with a free wheel it will probably be one of the two types shown in Figs. 5 and 6. To remove the free wheel from the hab of the wheel, first undo the lock-ring. Since this will have a left-hand thread, it must
be turned in a clockwise direction. Next, by means of the holes that will be found on the face of the free wheel, slack this off with a punch and a light hammer. In this case turn it in an anti-clockwise direction, as it has a righthand thread. In most patterns a repair of the mechanism is impracticable.

Of the saddle there is little to be said, except thet an occasional dressing applied on the under side with a leather preservative will help to keep it in good condition.

When adjusting the chain remember that there is sure to be a tight place during the complete travel of the chain's length round the sprockets ; . therefore, find this tight place and adjust accordingly, not too tight. Also note that the wheel is central between the bottom forks, otherwise the machine will not track properly, neither will the chain be in true alinement Do not forget that, where fitted, the back brake, if of the bottom stay pattern, will also need adjustment.
BICYCKE SEISD: How to Make. A portable shed for two cycles, framed up in sections, is shown in Fig. 1. The front, back, ends, and roof are made up in separate parts, and are fixed together with bolts and nuts.

The framing should not be less than 2 in . square. That in the back (Fig. 2) consists of two end uprighte, $A$, bottom rail, $B$, and top rail, C, which are half-lapped and screwed cogether. There is an inner upright. D, which is notched into the top

grooved and tongued match boards, fixed with the joints running from top to bottom. The boards on the ends should overhang ? in. at the back edge to cover the edge of the boards on the back. The front and back seotions fit between the end sections, to which they are fixed with bolta and nuta.

The roof should be of 1 in . matoh board, with the joints running from back to front, and overhanging 3 in . all round. The boards are held together with battens fixed across the ends on the under side. The roof is screwed on. A pair of doors are made from 1 in matchboard battenel together, as at Fig. 3, and hung with hinges. The left-hand door is lit ted with bolts at the top and bottom, and the righthand one with a lock, while a fillet is fixed on this door, to cover the joint, as at Fig. 5. The bottom of the slied is covered with 1 in . boards, resting on the bottom raik of framing. When complete give three coats of oil paint.

BISNNLAL. Most flower-garden biennials are distinguished by a single main stem, whioh branches freely above the root. True biennials start from seed one year, flower and seed the next, and then die. Most biennials seed freely and germinate surely, because at the season when they are sown, mid-May to mid-June, he ground is warm.
The following are the most useful hardy biennials. Some are not true biennials, but are best treated as such: Brompton stock, Canterbury bell, chimney bell-flower, foxglove, Iceland poppy, Indian pink, sweet rocket, sweet-william, wallHower, forget-me-not and honesty. See Annuals.
Biffins. These dried apples are similar to Normandy pippins (q.v.). See Dried Fruit
BIG BUD. The pest known as big bud is caused by the black currant mite. The plant which suffers most is the black currant.

In the blaok currant the developing buds are attacked and swell until they are almost globular in shape, and are about twioe the size of the normal buds. As a rule the buds dry up and die in early summer. The natural result of this loss of buds is a progressive decrease in the crop, whioh may ultimately ail altogether.
The disease is dealt with in Leatlet No. 1 of the Ministry of Agriculture. Badly affected rail. The ends and back are covered with $\frac{1}{8}$ in. bearings at each end of the connecting-rod,
work is strength ened and kept rigid by the stays, E, whichare fitted and nailed in position. The ends (Fig. 3) each consist of a back uprigbth $F$, front upright, $G$, bottom reil, H , and top rail, J, which are half-lapped and gerewed to gether. The stays, $\mathbf{K}$, are simply fitted and nailed in position.

The front framework consists of two end uprights, $L$, bot tom rail, M , and top rail, N, which are half-lapped and screwed to. gether. The top rail should be 4 in . deep, or it may sag when the roof is fixed. The bottom rail should be framed into the uprights so that the face of uprights projects 1 in . beyond face of

Bicyele Shed. Fis. 1. Simple shed for maling which instruction aro stiver in tho reat. giviag worlding details and dimensions
By arrangement with Evans Bros., L.d.. London bushes should be grubbed up and burnt. In gardens, attacked buds should be destroyed as soon as they can be detected, so as to kill the mites be. fore the period of migration, which is from March to May. The best treatment is to use lime-sulphur on the bushesfrom early March to mid-May. Herc is the mixture:
Slake 1 lb . Ni quicklime; add 1 Ib. or flowers or sulphur and gand stir
Boll the mixture or ten minutes, stiring all the time: allow it to cool and the sediment to sot. le, then pour the lquid into a bottle, and cork it well. For use, mix 1 pint with 12 gall. of water. SeeBlaok Currant.
BIG-FND. The big-end in an internal mbustion engine is the larger of the two
the smull-end or gudgeon-pin bearing being the one on which the piston is mounted. The bigend in its most common form is of the split type, and the bottom half, or cap, is bolted to the upper half, which is machined integral with the connecting-rod, by two or more bolts.

The illustration shows a bearing of common type. $A$ is the connecting-rod with big-end housing drilled and countersunk at $B$ to receive the bolts, C, that hold the cap, D , in pusition, alar, oil ways. These bolts are secured by a castellated nut and a split pin The cap $D$. is drilled cen. trally at the bottom. and fitted with a scoop for picking up oil to lubricate the bearing as it passes over the oil sump located in the crank case.
Between the cap and the upper half of the housing are placed two packing pieces E, known as shimms. 'These are

Big-End bearing ol type ased for intarnal combastion engines formed of a number of very thin sheets of brass, and are provided so that wear in the bearing may be taken up. The housing, F, called the brasses, is in two pieces and of phosphor-bronze, having a shoulder at each end to locate it in the main housing, and is machined rough on the inside and recessed, as shown, to receive the white metal lining. The white metal, G, is cast in, turned nearly the correct diameter, and finally scraped a true fit to the crank pin.

Big-end bearings un motor-cycle engines are solid and not split. as in large engine practice. They are constructed with a phosphor-bronze bush, or with roller or ball bearings, roller bearings being most favoured. The usual construction of a motor-cycle crankshaft allows of the big-end being slipped off the crank-pin on parting the two ty-wheels that go to form the crankshaft.

Repairs to Split Bearing. To get at the big-end on the majority of engines fitted with
 the split type bearing, it is only necessary to remove the oil sump, thereby exposing all the connecting-rod big-ends to view. Dismantle the bearing requiring attention. and withdraw the conneoting-rod with piston down past thecrankshaft. Thiscan bedoneun most modern engines ; otherwise it will be necessary to take off the cylinders and withdraw it from the top.
To take up wear in a split type bearing proceed as follows: Thoroughly cleanse off all oil and dirt. Next remove one thickness only off each of the shimms; then very thinly coat the crankshaft with a mixture of thin oil and blue mineral or red lead. Replace the housing en suite on the crankshaft and bolt up tight, giving each bolt a half-turn alternately to ensure keeping the pressure on each equal. The connecting. rod should now be given one complete turn (not more), then Bis Bud. Its eneot on a caro black carrant
carefully dismount to avoid disturbing the marks that the blue coating has made on the
nigh places on the white netal housing These high places should now be very carefully acraped off with a proper scraper. Having done this, clean and remount the bearing. following exactly the same procedure, and continue until there is practically an even film left all over the faces of the white metal Always bear in mind that any white metal removed from the unmarked surface ineans that an equal amount has to be scraped off the ontire face to correct the error.

On finally cleaning and assembling remember that the connecting-rod must on no account be an easy fit, neither must it be too tight ; it held horizontally with piston and gudgeon-pin in position, it should have a tendency to fall a little way only This test can only be applied when the crankshaft is removed from the engine. See Bcaring : Motor Car Motor cycle : Piston.

BIGNONIA. With brilliant Howers of varying colours the bignonia flourishes in the greenhouse, and is a good climber for roof. pillar, wall or trellis Propagation is effected by cuttings in the autumn, and inserting them in sand under a bell-glass or a frame or in a propagator. Loam and half peat, with sand, form a suitable compost. They are better planted out in pots Magnifica, crimson, and Tweediana, yellow, are suitable for the greenhouse. Capreolata, orange-red, may be grown aqainst $n$ sunny wall out of doors. Pron |lig.no'ne-a.

BILBERRY. Growing wild in woods and moorlands, this fruit is also known as the blaeberry in Scotland and the blueberry in America, and is much used for making jam and tarts by reason of ite distinctive flavour.
Bilberries should be washed and picked over before cooking, and are then steamed in a jar placed in boiling water, allowing about 2 oz sugar and 2 tablespoonfuls water to zach lb. of fruit. With a short crust the berries make a delicious tart. For jam-making the fruit is preserved as in recipes for black currant (q.v.). This is essentially a home-made jam, and is not often to beobtained in the shops, the reason being that the demand far exceeds the supplies available. The bilberry leaves a stain on table linen and light-ooloured garments which is hard to remove unless treated immediately with cold water If the stain has dried, it is best to stretch the material across a basin, pour hot water over the affected parts and afterwards apply fresh lemon juice.
BLLIOUSNESS. Eating ton much rich indigestible food often results in a bilious headache, especially with those who suffer from indigestion. In normal conditions poisonous substances formed during digestion are rendered harmless by the liver before they reach the general blood stream, but in in digestion these substances may overwhelm the protective resources of the liver, and accordingly we have symptoms of poisoning in the shape of malaise, physical and mental, and sometimes pronounced headache, with or without vomiting. The latter is beneficial, as it rids the stomach of much of the disturbing material.
Bismuth salicylate in 10 grain doses three times a day or 10 grains each of bismuth carbonate and sodium bicarbonate will be useful. Two grains of calomel at bedtime and 2 drams of Epsom salts in half a glass of water on an empty stomach in the inorning will assist in clearing the liver and intestines. Very little and simple food should be taken.
A sick headache is a different thing, though people who are subject to it may precipitate an attack through indiscretion in diet, it may follow overwork or worry or other cause. In this form eye trouble is not uncommon. Some people who require glasses have periodical headaches; a visit to an oculist obviates distress and the taking of a lot of medicine.

Bilious attacks in children are, as a rule. simply bnuts of acute dyspepsia due to overeating or the eating of too rich or not quite fresh foods. The only treatment needed is a teaspoonful orso of castor oil and a starvation diet fos twelve hours.
Sometimes what may be considered to be mild bilious attacks. occurring at intervals of $n$ few months, with vomiting and more or less severe abdominal pain lasting for a day or two. ma, be mild, recurrent appendicitis.

The greatest care should be taken here in preacribing purgatives, and if there is the slighteat abdominal lenderness (particularly over the lower right abdominal area), the physician should be sent for.
In some children there is an inherited incapacity of the liver which gives rise to repeated attacks of biliousness on the slightest occasion. These begin about the age of three or four years. A railway journey, a visit to the seaside, fatigue, a fit of anger or grief. paddling, or expusure to cold wind may, for example, be enough to bring on an attack of biliousness with vomiting.
Treatment consists in putting the patient to bed in a quiet, darkened room and giving no food whatever. A glass of hot water or ice sucked at intervals relieves the thirst Hot fomentations or a hot bag will ease the pain. As soon as the vomiting ceases, give the child two to four grains of grey powder, followed by a small dose of Carlsbad salts after six or eight hours. As soon as the aperient has acted, give some light nourish ment, such as milk and sodawater, iced whey and jellies. Next day plain, ordinary diet may usually be resumed. Sodium bicarbonate, in 5 gr . doses, in milk before breakfast might be given to the patient for some days, and doses of Epsom or Carisbad salts every three or four days. See Appendicitis: Diet; Indigestion.
BILL: Tradesman's Account. An account contains a list of the items purchased, with the price opposite each, and the total. This bill should be checked at once. If any mistake is discovered, the liability should be at once repudiated in writing, a copy of the letter being kept. An example of such a letter is the following

## 2 January, 1931.

Dear Sir,-With reference to your account delivered this morning, I want to call your attention to two items, one of Dec. 2 and the other Dec. 15. I ordered the joints on that day myself at your shop, and paid cash across the counter. Please correct mistake in your books.

## Yours truly,

Annie James."
It is important to write at once. If nothing is done till the tradesman renders his statement to account rendered overwhelming evidence will be required in a court of law to prove the money not owing.

Where sums of money are paid at intervals on account, the tradesman can appropriate the payment to any of the items owing. The householder, on the other hand, can also appropriate it to any he likes, and he has the first choice. If neither party appropriates the money to a specific item, the payment is by law considered to be appropriated to the oldest of the itenis. This is important when considering the question of old accounts, which are irrecoverable after six years, unless something is paid on account, or some acknowledgement of indebtedness is made within six years before the action is begun.

It is not the case that if an incorrect bill is sent in by a tradesman, the debtor need not pay it. No one, except a solicitor, is ever bound to send a hill in at all, unless he expressly agreed to do so. If the bill is not correct, send or take the amount really due, and if the tradeaman refuses to accept it, pay it into court with a plea of tender before action when sued. If it is the correct amount he will have to pay ull the legal costs. See Accounts.
BLLLBERGIA. This plant is sometimes grown in greenhouses in England. It possesses thick and fleshy leaves on a short stem, and ${ }^{\prime}$ bears large heads of hlossoms in late autumn and winter.

Equal parts of loam and peat, with a little decayed manure and a sprinkling of sand, suit them. Suckers form at the base of mature plants, and these can be used for purposes of propagation. The best species are B. moreli. hlue and rose ; B. thyrsoidea, scarlet : and B. vittata, green. red, and violet. Pron Bil-berjy-er.
BILLHOOK. In its various forms the billhook is a useful tool for wood-chopping, sharpening the ends of stakes, and cutting down busbes or brushwood. The shorthandled handbills, however, are the most serviceable for chopping firewood.

When cutting
 sooll whill with chopping blade. a blow. The long-handled billhook is used for hedge cutting, or in places otherwise out of reach. A billhook needs a keen, sharp edge. Most workers will find it best io hold the edge of the bill away from the body. The object of the hook part is to facilitate cut. ting growing timber.

BILLIARD BALLS AND CUES. The standard size for billiard batls is between $2\}_{6} \mathrm{in}$. and 2 s \% in., and they must be of equal size and weight. Ivory balls are used in British official championships, both amateur and professional, and are generally employed in first-class play. When bnying a set of ivory balls, a fair price should be paid to get a well-seasoned set made of the right kind of ivory, and they should be bought ${ }_{2}^{1}(\mathrm{in}$. full, thus allowing for adjustment.

A new set of ivory balls ought to be kept in the billiard roon for a week or two to get accustomed to the temperature before they are taken into play, and at first they should be just tapped lightly while playing a series of gentle strokes, a process which hardens the texture of the surface of the balls; it is well worth while to humour a set of new ivory balls for a month in this way before playing an ordinary game with them. Any chalk on the balls should be removed with a cloth.

They should not be handled any more than can be helped, and in particular the ivory ball should not be held in the hand while waiting to play. On a damp day especially the balls are all the better for an occasional rub while play is in progress.

Professionals know that it spoils ivory balls to leave them in the pockets when play is finished, and are careful to place their set in a
proper box lined with soft material. (See Fig. 4). Nor would they leave ivory balls on a window-sill exposed to cold and draughts, or on a mantelpiece when the heat of a fire would ruin thein at once. This explains why a professional will have a good set of ivory balls in use for years.
Composition halls, which are not affected by changes of temperature, are cheaper and more lasting than ivory. They are much in favour where economy is the deciding factor, although they are not ao pleasant to play with and do not throw quite the same angle as ivory. Their absolute truth is a strong point in their favour, their durability is another, and so is the fact that all sets of one make are alike, whernas ivory may differ very considerably. For snooker and other pool games requiring a large number of balls the low cost of composition is an inprortant consideration.

Comprosition balls, however, need much more cleaning, as chalk marks and dirt of all kinds stick to them inore easily. They should be washed in warm water, ruhbed thoroughly clean and dry and then given as inuch polish as they will take from a perfectly dry cloth

## Size and Weisht of Cues

Billiard curs of any weight or size are permitted by the rules of the game. In practice, weights vary from 14 to 18 oz , but size as regards the length of stock cues does not vary so much as it inight. Many faults might be remedied if cues suitable for very short or very tall penple were more readily obtainable. Cues under 15 oz . are seldom used, but the championship has been won by a player using an 18 oz . cue. Generally from 15 to $16 \frac{1}{2} \mathrm{oz}$ will cover every reguirement, and it is preferable to have a cue heavy rather than light. When it comes to judging a billiard cuc, appearances are even more deceptive than usual. No matter how high the polish may be, anything whippy should be rejected at once, and wood twistcd in the grain, especially towards the point of the cue
where it slides over the bridge-hand, is another thing to guard agninst.

When play is over, the cue should he replaced in its casc, as no cue will keep straight if it is left leaning against a wall. If the cue feels sticky as it slides over the bridge-hand, it should be rubhed briskly with a dry cloth or a sheet of paper, but not sandpaper. The use of anndpaper to remove temporary stickiness wears the wood away unevenly in a very short time, and renders the cue useless for real billiards. Sandpaper may be used with advantage on the leather tip of the cue. Constant play makes the tip hand and shiny, and if it is lightly rulbed against the grain of the leather with a piece of coarse glasspaper, or even a wood file, a constant source of miss-cues will be removed.

## How to Tip a Billiard Cue

When tipping a cue, the firat thing necessary is a flat true surface on which to lay the new tip. Useful little machines are sold which do this troublesome job very neatly, hut if it has to be done by hand it must he completed well and truly. Select a tip as nearly as possible a perfect fit, soak the adheaive wafer in hot water, adjust the tip firmly and accurately, and leave it to dry thoroughly. If proper care is taken, especially as regards selecting a tip which fits, there should be small need for trimming and filing. But if this has to be done, never allow the woodwork of the cue itself to be touched by file or aandpaper. The tip must be made to fit the cue, not the cue sandpapered to fit the tip. The tip of a cue should be large rather than small

Besides the ordinary cue, there are the long. rest and the half-butt, which should be kept straight and well tipped. It is hettor to lay them on the lloor under the tahle than to try to prop then up in a rack.

Cement for fastening the tips of billiard cues is mude by soaking 1 oz . of isinglass in 2 oz . of water, and adding 1 oz . of glacial acetic acid, warming together until dissolved.

## The Billiard Room and its Accessories

## General Information on Lighting, Beating and Equipment

The main requisites of the game are considered in the preceding article, Billiard Balls and Cues, and in that on Billiard Table, while the construction of some of the lesser accessories is dealt with here

The ideal billiard room is built on a ground floor with brick or concrcte supports for the lega of the table and should he a substuntial and well-lighted structure. A skylight for play during the day is the only perfect natural light, as a side-light which throws shadows as the balls lie on the table is most disconcerting. Ventilation is also helped by the skylight, parts of which should open to let out amoke and allow fresh air to enter; but an open skylight should always be watcherl in case of rain.

Electric light is the best artificial illuminant, but gas mantles are quite good, though the wasteful naked flame should be avoided Whatever light is used, the shades should be adjusted so that the full glare of the light cannot catch the eye of a player as he shapes at his stroke. A well-arranged room in a private house is illustrated in Fig. 1.

The heating of the room requires careful attention, as hoth balls and tuble are very sensitive to changes of temperature, and the game is not pleasant to the players if the weather is cold and the heating insufficient. Onc of the many systems of heating by pipes or radiators is far hetter than an open fire, which should be avoided on account of the glare, the dust, and the impossihility of maintaining an equable temperature.

The space required for a full-sized table is rather more than 21 ft . by about 16 ft ., which must be clear space after allowance has been made for settees. A little less is possible, but the measurements given sllow a margin of comfort. The flow covering ahould be of woven
material where the fcet of the players tread on it. The marking board (Fig. 2) and cue-racks must be well niade and kept in good order. Nothing is more annoying than a marking board which sticks, or cue-racks fitted with cheap clips which disfigure the cues with handlike marks.

But for every fortunate possessor of an ideal billiard room there are many who cannot
 allowed to sulfer.
get a bsolutely the best of everything. The most usual shortcoming is lack of ground-floor accommodation, which generally means that a

Billiard Raom. Fig. 2. Standard pattern marking board, with scorers sliding on brass strips
top light is impossible. When this is the case the upstairs room selected for the table must. be strong and well built, for a hilliard table is a heavy piece of furniture, and if it begins to settle down unevenly it is at once out of truth and useless

Those who have to fit a table of lcss than standard size into an ordinary house will be well advised to make sure they have room enoughto play properly. A sinall table in a room too small for it is notworth having, and the saine may be said of sinall tables which are set up without due regard to levelling. In in ordinary house, especially if fitted in an upstairs room, these small tables take time to settle down, and often re-

Billiard Room Fig. 3. Cue rack. Fig. 4. Padded box for billiard bal's. Fig. 5 . Sectional view of a cramp for a billiard cue quire read. justing more than once before they can be depended upon. For the rest, everything which applies to the ideal room for a full-sized tuble is applicable to the small table; but when it comes to making the best of what must necessarily fall a good real short of the ideal, the light is the last thing which should be

A badly lighted table, be it large or small, is an ahomination, and there is no reason why the small table should suffer in this respect. Generally a top light is out of the question, so that it is all the nore important to arrange for the best of artiticial light, as all play will be dependent upon it, so far as seeing the balls well is concerned.
There are various styles of cue-racks and stands. The wall rack is simple to construct and quite efficient. It is conveniently made in two lengths, the one fitted with the slotted ledge (Fig. 3, A) above a rail, which is fitted with equally spacerd spring clips and secured to the wall by braseplates and screwing. The rail can be of $\boldsymbol{s}^{3}$ in. thickness and 4 in . or so wide, with the ends and under edges plain or moulded ovolo as preferred. The spring clips are purchasable from a
good-class ironmonger in dozens, and merely require screwing into equally spaced positions. The shaped ledge above is screwed and glued on, and the clips are fixed on the centre line of each recess so that the cue lies evenly within it. Width of this ledge can be about 2 in . and its shaping a repeat such as Fig. 3 C .
The revolving cue-stand is specially suitable for some rooms, but as it is not likely that a player would undertake its construction we do not give details. These stands can often be obtained second-hand at low prices.
The amateur craftsman might, however, exercise his skill in the making of $n$ box to take three balls, as illustrated at Fig. 4. Finished dimensions can be $8 \frac{1}{4} \mathrm{in}$. long, $3 \frac{1}{2} \mathrm{in}$. deep and $2 \frac{3}{i n}$. high. The lower box portion can be $1 \frac{1}{2} \mathrm{in}$. high. and the workmanship is usually of the best. Sides, back. and front are carefully
dovetailed together of $\frac{1}{2} \mathrm{in}$. or $\frac{\mathrm{l}}{\mathrm{h}} \mathrm{in}$. mahoganv. and a $\frac{1}{3}$ in. hottom rehated in. The lid is dovetailed together in similar fashion. and the top rebated in. A separate partitioned hox is inset, made from ${ }^{36}$ in thickness. mitred together, and finished to pmoject with bevelled edge about a full $\frac{1}{4}$ in above the box.

A cue cramp (Fig. 5) is an essential accessory of every hilliard room. In action the cue top is passed through the centre of cramp, and the cemented tip compresed into position by forcing down the stop upon it and securing it in position by pulling down the cramping ring over the cuts in the splaved end. In addition there is a hole to take a small length of file with which any unevenness of tip or adhesive is corrected The file is holed at one end, and a length of brass chain secures it to the stop above

# Billiards: How the Game is Played <br> <br> The Strokes Explained and Mustrated 

 <br> <br> The Strokes Explained and Mustrated}

This work contains also articles on Pool, Pyramids and Snooker Pool

English billiards is played on a table ineasuring 12 ft . by 6 ft . The spot is $12 \frac{3}{4} \mathrm{in}$. from the top cushion, the middle spot is half-way across the table in line with the centres of the middle pockets, and the pyramid spot is equi distant between the iniddle or centre spot and top cushion. The table has six pockets. one at each corner and two in the middle of the longer sides. Those at the spot end are known as the top pockets; those at the balk end as the bottom pockets.
The game is usually played by two or four players. l'oints are scored as follows: two for a cannon, i.e. when the playing ball strikes the other two balls two for going into a pocket after hitting the white; and two for potting the white, i.e. driving it into a pocket.

Billiards. Fig. 1. Fullsized table, showing the lines and spota Three is the score for going in off the red or for potting the red. A miss counts one to the non-striker three if the hall is sent into a pocket or off the table without striking a ball This rules should be consulted for other examples of scoring. Wach player or pair o players has his own ball, these being the two white ones, one being distinguished by a spot. Various ways of deciding who whal start first are in vogue. Beginning the game is known as hreaking the balla
A player can continue playing as long as he scores from every stroke, but ns soon as he misses, his opponent takes his place. The total score made by a player without losing his turn is known as a break. If the cue-ball, when at rest, touches either of the other halls, the balls must be spotted and the striker continues his break. Fouls and their penal ties are matters concerning which the rules should always be consulted.

## Importance of a Correct Stance

A correct stance is of primary importance in billiard playing, but is difficult to define with exactitude, because players of varying height and physique have to play on a table which measures, from the floor to the cushion rail, from 2 ft .9 in . to 2 ft . $10 \frac{1}{2} \mathrm{in}$. The safest guide to a reliable stance is to remember that absolute steadiness is the ideal in view. A cueman when standing as he should to make his stroke is, above all things, firm and steady. Only his cue-arm, lissom and ready to propel his cue should be flexible and ready for the utmost nicety of movement.

As $a$ general rule it will be found that by advancing the left leg and slightly bending the left knee, while the right leg is kept firm and straight, the foundation of a correct stance is assured. The upper part of the body should be bent forwards, the left arm thrown well out and the left hand arched to form a bridge over which the cue slides. The cue butt should he held without force or effort, always learing in mind that the cue is
 to be swung at the hall, not pushed or thrust with a movement having continuous and appreciahle power behind it

To gain impetus for the swing, the cue must be drawn hack-it is sometimes helpful to draw the cue back very slowly indeedbut when the swing forward is marle it should be kept ns llat as is consistent with frecdom, and must be continued until the cue goes clean through the hall in the line of the strake. "Iet the cue do the work," is continually dinned into the cars of pupils by professional teachers of billiards, and is such excellent advice that no progress can be hoped for if it is ignored.

Face the balls when sighting a stroke, and always endeavour to have the cuetip on a line taken from fairly between the eyes when the ball is struck by swinging the cue at it. Never forget the swing-it is all important. In actual hall striking, the first thing to do is to learn to hit the cue-ball truly in its atrikable centre. This is by no incans an easy thing to lo with consistent accuracy, but it must be done, and the best way to master it is by utilising the fami liar one-ball stroke, played by placing the cue-ball on the
 centre-spot of the talk-line and playing it straight over the line of spots.
If struck truly in its centre the ball should rebound straight to its starting point. Mostly, however, it will show a tendency to return to the right, which proves that right-hand side is being imparted unintentionally, a fault which must be rectified. To eliminate any tendency to strike the ball above or below its centre, it is a gooll plan to practise this stroke with the spot-ball, adjusting the spot for each stroke exactly where the cue-tip should
this as merely a preliminary stepto wards higher ilights in the game. Plain ball striking is the backbone of all billiard playing, and no man can make a break of any size unless
impinge on the ball. This one-ball practice is admittedly tiresome, but it ranst be per severed with if real billiards is to be plaved.

The half-ball stroke with the resultant natural angle is the next step, and it is a very big one, towards aptitude at the game. The half-ball stroke is made by directing the centre of the cue-ball towards the extreme edge of the object-ball. It inust be played without the least side on the cue-ball, without strength enough to force the stroke, and with free cueing to impart life and brisk forward rotation to the cue-ball. There are four set positions usually demonstrated as showing the half-ball stroke and the natural angle, but in a strictly scientific sense the angles thus shown differ appreciably. In practical play. however, it is indisputable that the hazards can be scored as described from the following positions

Place the red ball on the centre-spot and the cue-ball $7 \frac{1}{2} \mathrm{in}$. from the centre-spot on the balk line (Fig. 5). Place the red ball on the pyramid spot and the cue-hall rather less than an inch inside either of the spots at the ends of the balk-line (Fig. 6). Place the red hall on the billiard spot and the cue-ball in ine with the shoulder of the middle pocket (lig. 7). Place the red ball on the hilliard spot and the cue-ball in the centre of one of the top pocket openings or on a line a shade nearer the top cushion (Fig. 8). If the halls are placed as directed above, and a half ball stroke played as shown in the dingrams (see p. 99), the losing hazard will always result, and if the strength is correct the red ball will travel as indicated by the dotted line in the diagram and stop in excellent position.

## Hall-Ball Shots the Key Strokes

These four strokes, for open billiards, may be called the key-strokes of the game. Any player who can handle them really well, especially Fig. 5, is well on the way towards cuemanship of no mean order. But unless they are mastered as well as opportunity permits, the making of diflicult strokes at uncertain intervals, or even the making of them fairly frequently, will be of very little use. The plaver who has a sound working knowledge of the half-ball stroke knows what he is doing when he tackles any other st roke on the table. He has a reliable standard of comparison to work by, knowing as he does that a half-ball contact will produce a given result; he can calculate what a contact thicker or finer than half-ball will give him as regards variations from the natural angle.

All this is done, it should he noted, without atriking the cue-ball anywhere except in its centre, and it is altogether wrong to regard

Billiards. Figs. 2 and 3. Two views of a good bridge, Grm, but not rigid, as made by Tom Newman Pliotos. Wriulitson
he has reasonable command of it. It is an left-hand side, the clicek action is at once bination of side and screw are to be avoided if all too common fallacy to imagine that screw apparent With running side the cannon is nnd side arc the things that really matter, scorable, but there is indeed a difference if the stroke is attemp:ed with check side, which illustrates yet another important attribute of side. This is the effect it has after a side-laden ball inipinges on a cushion. At normal pace, if a ball has no side on it, the angles of incidence and retlection are equal when it strikes a cushion and rebounds from it, but running side makes the angle off the cuslion more nbtuse, wider, ns it is called, while check side makes the angle more acute.
Screw may be defined as latent brekward spin. It may bring the cue-ball back as much as 6 ft . or more after full contact with an object ball lying a foot Photo. Wrighteson and that the beautiful simplicity of plain ball or so away. When striking is a mere rudimentary commonulace of no interest.

There are, of course, very many strokes which lie beyond the power of plain ball striking; then, and not till then, does the employment of side, top or screw become neceasary and justifiable. Side is imparted by striking the cue-ball to the right or left of its centre, as the case may be, and is not so much a matter of striking the ball as far aq possible to the right or left, as it is a question of nent and crisp cueing. When putting side on a ball the best results are obtained by keeping the cue-tip on a line struck fairly across the centre of the ball. It is a inistake to put top or hottom on the hall when im. parting side, unless it is done purpozely to combine side with either of these things.

The action of pure side is to take the ball away in the divection of the side imparted, excepting when a ball is moving rather slowly against the nap of the cloth, when the action of side is reversed. Side has a certain amount of effect on the course of a ball before another ball or cushion is struck, but the effect is much more apparent and decided after contact with a ball or cushion, cspecially if force is ueed when a ball is played at and the ball to ball contact is thick. In billiard parlance, mention is often maile of running side, check side, and pucket side. These definitions are apt to confuse the beginner unless clearly explained.

Place the red ball on the billiard spot. the cue-ball on the centre spot of the halk-line and the second-object ball near the left balk pocket (Fig. 9). If a smart half-ball is played on the right of the red with plenty of righthand side on the cue-ball, it will be scen at once how this side helps the run of the ball off the cushions. If the same stroke is tricd with

Billiards : the key strokes Billiards : the key strokes. Fig. 5. Standard half ball shot : cue ball on balk line, object ball on middle spot. Fig. 6. nbuve its centre is concerned, top helps to casily damaged than is commonly supposed impart life to certain strokes. It is, however, Slate, cloth, rubhcr, wood and a little inetal as well to avoid the use of top whenever are the raw materinls which enter into the possible, as it panders to inaccurate cueing.

Top may be used in conjunction with side. so may screw, and only experiment is of much use in demonstrating the multitude of effects thus to be ohtained. But it cannot be ton of ten repeated that plain ball billinrds comes first, and that intricacies such as the com-

Fig. 8

Fig. making of a billiard table. The nature of these suhstances differs widely, and to fashion and adjust them into a perfect and harmonious whole is no mean feat of craftsmanship. The cloth and cushions are the most sensitive parts. Damp and cold will ruin the beat cushions, so will the player who never uses the rest, but
possible. When employing side or screw it is advisa ble, as a general rule, to use as inuch of either as the cue-power of the individual can impart, obtaining any desired result by varying the strength of stroke and the ball-to-ball contact
1.)rag means striking a ball low with the intention of preventing it from running untruly when it is desired to play a long shot at slowish strength. The cueing is more free than is used for the screw stroke pure and simple, and the stroke, although difficult, is worth practising, especially if the table and balls are short of absolute perfection, as drag helps to minimise such defects. Stun is produced by hold. ing the cue heavily when playing rather full on the object ball; the cue-ball is struck rather helow its centre and can be made to stop dead, when the atmke is known as a stab shot, or it can be made to travel slowly to make a cannon or pocket, usually a cannon. The stun atroke is very useful when it is desired to send the first object-ball a long way and barely move the second object-ball, many pretty gathering cannons being made in this way.
Break-building can be summed up as the art of playing one casy stroke in suc! it manner that another easy one is left : in its highest forms, notably in top-of-the table billiards, it depends upon a sense of touch and insight into the possibilities of the game which amount to a gift. In the ordinary way, however, much can be done if thought is taken before a stroke is made, thought directed towards computing where the balls will be when they stop, usually the last thing the novice troubles about !

Ivory balls of standard size and equal weight are presumed to be in use when playing the strokes mentioned in this article. If composition balls are used, it will be found that the positions will be apt to vary alightly.

BILLIARD TABLE : Its Care. Because of its bulk and size, a billiard table is apt to be regarded as a fixture which cannot very well come to any harm if left alone, or as something atrong enough to stand any treatment short of wilful and malicious damage The truth is that such a table requires constant attention to keep it in good playing condition. and, although far fomm fragile, is inuch more
insists on clambering on the table to reach a shot he cannot get at in the ordinary way.

The table should be brushed frequently, always with the nap of the cloth, and the brushing should be so thorough that the fibres of the brush dig well into the nap and fetch out the chalk and dust ; a perfunctory brushing is very little use. If a cloth is brushed in this manner it does not want ironing half so often as is supposed, especially if $\bar{u}$ duster is wrapped round the brush and the table gone over again after the brushing is completed.

When ironing a billiard table the iron should be hot enough to imon linen, but it is too hot if it leaves the least trace of singeing on are old piece of white rag with which the face of the iron should be cleaned before it is allowed to touch the cloth. The iron should be grasped firmly and run quickly up the centre of the table in a straight line with the nap of the cloth, and the operation completed by taking in successive swathes of cloth until the whole is covered, care being taken not to press the iron needlessly against the cushions, e8jecially when ironing near the pocket openings. Above all, do not iron against the nap of the cloth; one such application of a renlly hot iron spoils the cloth entirely.

When a new cloth has been on for a little time it needs stretching and readjustingalways a job for an expert. This operation throws the original balk-line and spots out of

Bllliard Table, Miniature table, the top of which can be replaced by leaves, thus making a diuing table Pholo. Thurston
place, and they have to be changed accordingly. Banging a ball on a spot is bad for both the ball and the cloth, and slould be sternly discouraged
BILL OF SALE. A bill of sale is a document whereby personal goods are tiane ferred or else mortgaged, and is commonly used by people who wish to horrow monev on their furniture. A mortgage bill of rale must be in a particular form and registered.
The creditor can only seize the goods for one (or more) of the following canses: (l.) default in payment of principal or interest : (2) bankruptcy of the debtor; (3) if thic debtor fraudulently removes the goorls; (4) fails to produce his last receipt for rent ; or (5) suffers an execution to be levied on the goods

A mortgage bill of sale cannot be giren for less than f30. It can only be given by the true owner of the chattels

BINDING: How to Apply. Seam edges are sometimes finished with a special tape binding to neaten, and edges of garments are hound with braid, self-material, or a contrasting coloured fabric, as a decorative trimming. In other cases two edgen or ends are bound together to secure them, e.g. the $t$ wo ends of a wire sewn to the outer edge of a lampshade, etc., and set to a certain shape. Here the binding is done by lapping the ends of the wire a few inches, then tivisting a strip, of muslin round and round until both ends are hidden (Fig. 1), fastening off with a few stitches. Another method is to fold a long strip lengthwise, and to slip the wire up into the fold, then to sew along within the edges
To bind seams, place the binding along the raw edge of the seam, so that half its width lies
over the material and half extends beyond the rair edge; then hem or run the lapped edge of the binding down, after whioh turn the

Binding. Diagrams showing how braid of other material should be applied for binding purpnges
remaining or unattached edge over to the other side of the seam turning, and hem down (Fig. 2) so that the turning is sandwiched between. In using braid, sewing-silk of the same colour as the braid should be employed, and the running or hemming stitches should not be made tightly enough to indent the braid If the loraid is to be taken round a corner, it should be set in a mitre (Fig. 3), or if along a curve, the ting cotton thread gencrally woven into each edge of thic braid ahould be pulled up to make the requisite shape.

If a very narrow binding is required, nnother method is followed. The braid is set over the right side of garment, so that none of it extends beyond the edge, but so that the outer edge of braid comes level witl. garment edge, after which it is stitched on within these onter edges (Fig 4). The remaining or unattached edge of braid is then turncd over to the wrong side of garment and hemmed.

If the edge of a dress, elc., is to be bound with strips of self or contrasting coloured matcrial, the strijs inust be cut off on the cross, and joined to the required length. The joins inust come on the straight of the grain, so that the ends of the strips will be necessarily slantwise and the joins corresponding. To do the hinding, follow the second method explained for braid binding, and illustrated in Fig. 4, though in this case, if any curve is to be bound, the strip, being out on the oross, can be st retched to the deaired sliape, and need not be drawn up. In binding, carefully note that no part of the garment edge which comes on the cross is stretched in the process. After binding press well. Sec Bookbinding.
BINDING COURSE. In brickivork this is the name given to a row of bricks set acroas an inner and an outer course to bind them together. See Architecture ; Bond; Brick; Building.
BINDWEED. 'Two plants bear the name of bindweed or bearbind, Calystegia sepium and Convolvulus arvensis, and both are very pretty, hut if once they get out of hand they become weeds of the woist type. The safest means of extirpation is to dig them up by the roots, which usually extend for a considerable distance horizontally undergiound.

BIRCR. The silver birch, Betula alba, so called be cause of its shiny white bark, is a most graceful and ornamental tree that flourishes best in light soil. It is a beautiful lawn tree. Planting may be done from Nov. to March inclusive. The birch is raised from seed which is sown as soon as it is ripe or in spring.

BIRCH: In Furniture Making. The wood of the birch is one of the cheaper hardwoods, used for much the sainc purposes as beech. It is a light brown in colour, closegrained, sometimes with a figure similar to maliogany, and is uften stained to resemble that wood. Birch is easy to work, and has a smooth surface with a rather lustrous appearance. It is used for bedroom furnituro and frames of chairs and couches, turned articles, lirush heads, casks and tubs, handrails, and dowel rod Plywood is often made of layers of biroh, and in this form it is-used for chair seats, vehicle hodies, as well as for panels for various purposes.
Birch dowel rod is sold at most hardware and general stores, and by timber dealers, in lengths of 3 ft . and upwards. Diametera are from ${ }^{3} 0$ in to $\frac{7}{4}$ in., the most useful size being about $\frac{1}{2}$ in. Cabinet-matiers use it for dowelling the frames of chairs and other articles, as an alternative to making mortise and tenon joints. For this purpose it is used in short pieces, thesc usually not exceeding 3 in. or 4 in . long. See Wood

BIRCE TAR. Tarry oil obtained from a birch, the Betula alba, and known as birch tar, is used as an application in skin diseases associated with itching, e.g. chilblains, cczenia, or psoriasis. It should not he used if the skin is acutely inflamed and moist. A useful combination is birch tar, 1 dram; zine oxide. $2 \frac{1}{2}$ drams: vaseline, 5 drams. See Chilblain

BIRD BATE. Onc of these shallow stonc basins may be put in an open space in the garden to provide water for hirds Some

are fashioned like miniature fish-ponds, ahout 2-:3 ft. across and $2-: 3$ in deep, but $n$ more useful kind stands on a pedestal, and the hirds are thus protected from cats. One of these makes an effective centre for a small lawn. It is cheaper and lese difficult to erect than a sundial, as it only needs to be kept full of fresh water. If the basin is a large one, it may have a rnised stone in the centie as an additional perching ground for the bircls.
BIRD CAGE. The designs and types of birdcages are imnumerable, but they all naturally divide themselves into two types, viz all-wire cages, with which must be grouped cnges of light wood framing and open wirework all round, and hox cages.

The danger of the all wire cuge lies chielly in the fact that cold wind or draught can pass through
it. and if this cage is placed in $n$ window it becomes a death-trap for even the most hardy species of birds. This danger ean be eliminated by placing the cage against a wall, and in such a position that no current of air can pass through it from end to end. If it must stand in $\pi$ window, then the only sale procedure is to surround it on three sides with clear glase The screen must be the full height of the cage, and be placed hetween the cage and the window. Thus an all-wire cage can be made n safe habitation for all specics of birds.

The hest cage is of the box type. Every cage, whether its materials be of wood or metal, should be fitted with a inetal draw tray for cleaning convenience, and the fond receptacles ought to be so placed as to be easy of access both to the hirds and their owner.

As to the size of the cage, it must be sufficient to allow the occupant to move about and perch without fraying or otherwise damaging its plumage. It must he large enough for the hird to turn about without bending its tail feathers, and the perches so placed that its head does not rub agninst the top of the cage or its tail come in contact with the floor of the cage. A small active, vivacious bird no larger than a wren often needs a larger cage than one four tinea its size. It is an indisputable fact that to put such a bird in a cage in which it ean

Bird Cage London breeding cage containing a separate compartment and rest for the birds on right Courlesy of J. J. 7 liomas $\mathbb{\&}$ Co., Lid.
merely hop and not mose about freely is to rob it of any chance of a long or happy and contented life. Many species of birds become corpulent and fall into ill-health if they cannot take some wing exercise.

For canary fanciers both type and size of cage are regulated by the governing bodly of each variety. For other apecies the cages are invariably of the box-type, and the novice exhibitor had better leave himself in the handw of the cage-maker.

Of parrot cages there are threc types-round. square, and rectangular. The rectangular is too large for the average romm, and of the two former the square is the better, as a cage of 2 ft . sq. contains more space than one of 2 ft . diameter.

Cages should have a spring and autumn clean, when they need to be scalded with some insecticide solution, dried, distempered inside, and the exterior re-stained. See Aviary; Canary ; Parrot.

BIRD CRERRY. This is a name sometimes given to ornamental flowering cherries. The botanical name of the tree is Prunus padus. A native of Britain as well as of Manchuria, it is a hardy, May-flowering tree, often attaining a height of forty to fift! feet. The flowers take the form of pendulous racemes six inches in length, and are white or pink.

## BIRDLIME.

 Made in Japan from the bark of the holly, birillime is the chief ingredient in fly-papers and fly-strings, and is also used for spreading on boards to traj mice and rats. Artificial birdlime for the same purposer is inade by melt. ing together boilet! linseed oil, 6 oz.; gum thus, 1 oz. ; and castor oil, 2 oz. This is npplied. while still warm, by means of $n$The bird cherry thrives in ordinary loam, 2 in long by $\frac{1}{2} \mathrm{in}$. diameter, having slots 1 in and is best gown as a specimen tree on a lawn, long to receive the sails, and bored 1 in. into or grouped in park or woodland. It is rather the stock. This method of fixing the sails allows too vigorous a subject for the ordinary garden. of their being easily set on the angle to catch stiff brush. See $1 \cdot 1 y$-paper.

BIRD LOUSE. Bird lice are unrelated to the true lice, ind are more of the nature of scavengers, feeding upon scurf, skin secretions, hair and feathers. They are amall, flat, wingless insects of the order Platyptera, and have makean armed with shorp They affect domestic poultry and pigeons chiefly. The egge are attached securely to the hairs or feathers Where they causc annoyance to pets, finely powdered sulphur or insect powder should be blown into the pluminge.

BIRD SCARER. The scarer shown in Fig. 1 is driven by a windmill, which revolves a rod, and causes Lwo metal plates to clap together. The post and arm, Fig. 2, are $1 \frac{1}{2}$ in. square, half. Inpped and screwed together, the post being pointed for fixing in the ground The windmill is attached to a hardwood rod, Fig. 3, which is $13 \frac{1}{2}$ in. long over all by $d$ in. diameter, working through $n$ hole in the post bored in the position ahown at Fig. 2. The stock of the windmill. Fig. 4, is 3 in . in dinmeter by $1 \frac{1}{2} \mathrm{in}$. thick, with a $\frac{1}{2} \mathrm{in}$ hole in the centre to fit the irod.

The six sails, Fig. 5, are 6 in . long by 3 in . wide at the ends, tapering to $\frac{1}{2}$ in., by about $\frac{1}{3}$ in. thick. They are fitted to dowels, Fig. 6 .

Bird Cherry. Sprays of banging blooms of the ornamental flowering cherry the wind from whichever direction it may happen to be blowing.
'Two round fixing blocks, Fig. 7, are required to adjust the rod to its correct working bearing in the poat. The blocks arc $1 \frac{1}{2}$ in. in diameter by 1 in . thick, having $\frac{1}{2}$ in holes in the centre to fit the rod, while a small loole bored from the circumference to the centre admits of $a$ small pin being driven through and into the rod when the blocks are finally adjusted. The metal plates are 4 in. by 2 in. by about $\frac{1}{16}$ in. thick. The plate on the arm is attached with two wire staples, while that on the rod is fixed by making a save cut in the rod and driving two small screws, as illustrated in the diagram, Fig. 8. See Scarecrow.
BIRD SEED. The principal seeds used as food for cage birds are canary, flax. hemp,
millet and raje. The first named is the flattenerl yellow sced of canary grass; flax or linscerl is also compressed, but smaller and hrown in colour, and produced by the common flax Millet is the round, hard seed of Sorghum vulgare, the guinea corn ; hemp, the large. roundish grey seed of Cannabis antiva; and rape is the dark shot-like seed of $\pi$ variety of the turnip. To these miny be added the seed spikes of the plantain obtainable from any plot of waste ground; and for the larger birds tares, Indian corn, and the seeds of sunllower. Seedheads of thistles are appreciated by some finches, who pick the scedsfrom the thistle heads with avidity. See Aviary; Canary; Parint.

BIRDS' EGGS. In making a collection of birds' eggs the first thing to do is to acquire some practice in the handling and preparation of the specimens, in order to avoid spoiling them and thus taking eggs wastefully.

The easiest and simplest way to blow an egg is to make a hole in each end with a pin and then blow out the contents with one's mouth This metlod may be tried on the common egga till one is sure of holding the egg so judiciously as to cscape breatiage. A drill and blowpipe should then be got from a dealer in natural history requisites, and some egga blown by the proper method of making a neat round hole in the centre of one side, and expelling the contents through this alone. In both methorls a pin should be inserted to break up the yolk before the blowing process is begun. If an egg is hard-set, the embryo bird should be snipped to pieces with a pair of fine scissors, and the bits withdrawn with a pair of fine-pointed forceps, but the taking of such eggs should be avoided wherever possible.

When cleared, the eggs should be thoroughly washed out with water injected by means of $a$ fountain-pen filler or similar instrument; carc should he taken to a void wetting the egg more than can be helped After washing out, the hole or holes in the egg should be closed by gunmming a tiny disk of paper over the opening; the egg is now ready for the cabinet, and should on no account be varnished. Neither should the eggs be gummed on a card or strung on strings, as is sometimes done. The eggs of some water-hirds have a chalky coating, and this should not be scraped off

For keeping eggs till one has a cabinet ready, chip lill-hoxes bedded with any soft matcrial
will do; each egg should be marked with a number with a fine pen and marking ink, and the numbers should be entored in a notebook with the name and any other particulars opposite. For exhibition in a proper cabinet, the best bedding is black cotton-wool ; the name labels can be gummed on to the edges of the partitions. Jucks' eggs should the bedded on a little of the down with which the bird lines the nest, since this down differs according to the species of duck, and is a considerable help to identilication.

## Identification of Birds' Egrs

Practice in the blowing of large eggo like these should be obtained with the eggs of ordinary ducks and of fowls. In the case of large eggs it is often only convenient to exhibit one, and indeed to take only one egg from a nest is a good rule in the case of most birds. It is the taking of the whole set, and the accumulation of numerous sets of the same species, regardless of its scarcity, that has brought egg. collecting into disrepute.
In order to be sure of the name of an egg one must not take it till one has seen the birds, or one of the birds, to which the nest belongs. As often as not an egg cannot be identified apart from its producer by a beginner, and even the expert may be unable to distinguish between the eggs of some species. This is most often the case when the birds are nearly related; thus, the eggs of the various tits are often very hard to distinguish.

Sometimes the egge of quite different hirds may be alike, as in the case of the sedge-warbler-and the yellow wagtail. In this case, however, the nest is some help, for that of the sedge-warbler is constiucted in the bushes, while the yellow wagtail's is a rough affair built on the ground among the grass.

## Birds' EgGS: A Cabinet for Collectors

How to Make a Compact Set of Airtight Drawers The woodworking enthusiast who is also a naturalist will readily adapt this design to other collections,
such os Buttertics. Information about similar hobbies will te tound under rlowers; Shells, etc.

The cabinet shown in the diagrams in this and the next page measures 3 ft . $0 \frac{1}{2}$ in. wide ly 1 ft . $6 \frac{1}{2} \mathrm{in}$. deep over the carcass. The total height is 3 ft . 2 in . There are 30 drawers. The cabinet is adaptable, with little alteration, to the needs of the collector of butterflies or other natural history objects.
The cabinet is of solid mahogany through out, with veneered door panels and end panels. For the drawers, which call for most careful and exact workmanship, a perfectly sound and well-seasoned hardwood is cssential. The cabinet has no ornamental features. The top is moulded and the ends (like the doors) are panelled. In Figs. 1 and 2 are shown respectively the front and end elevation; whilst Fig. 3 shows a front view with the doors removed.
The carcass consists of two $Z_{6}$ in. framed ends (for section see Fig. 7, A), to which the carcass top and bottom are dovetailed (Fig. 4). The ends are rebated to take the framed back. The $\frac{z}{z}$ in. central gable is fixed by grooving to the top and bottom. Half-way up are the stiffening shelves (solid shelves, not merely rails), $\frac{8}{8}$. or $\frac{1}{2} \mathrm{in}$. thich, grooved to the middle and end gables. In each case the grooves will be stopped hack a little from the front to mask the joints.
The top is shown in Figs. 5 and 6. It is 19 in . deep, made up of a solid $\frac{1}{2}$ in. top and a moulded and mitred $\frac{\xi}{} \mathrm{in}$. by 2 in . slip below.

The base in dovetailed together, and faced up with $\downarrow$ in. lengths. Stout angle blocks are glued and screwed on to take circular toes $3_{\frac{1}{2}} \mathrm{in}$. in diameter by $\frac{7}{8}$ in. thick, which are screwed on from below. The base mould is shown in Fig. 5.

The doors are framed up of $2 \frac{6}{8} \mathrm{in}$. by $\frac{z}{8} \mathrm{in}$. atiles and rails, sections being shown at Figs. 5

The thrush's nest in very characteristic with its plain hard lining of mud-plaster: but though the bright bluc eggs, with their fow and distinct black spots, s.o very different from those laid by any other bird which nests here, they are not always true to type, and in rare cases may lie marked with brown instend of black, or even be plain blue altogether.
The thrush and robin are the two birds most likely to be found breeding early in the year, but, generally spreaking, it is not of much use to look for eggs till March, and the great months for eggs are April, May, and June. After that, although many birds breed a second or even a thind time in the year, the supply of eggs rapidly falls off.

Before setting out to search for cggs one should find out which birds are protected by law, and the particular regulations applying in the locality.

It is a mistake to think that one will always find the nests in the most out-of-the-way places: birds often nest in a frequented spot, and in a wood, for instance, the nests are more likely to be found along the pathways than right in the depths of the thicket. Birds which build in holes are often careless of observation, and less inclined to secrecy than thoso which build among the boughs. and twigs.

Birds which build high up are also less secretive than those which build low down, and the hardest of all nests to find are those of birds which nest on the ground.

In searching for nests which require climbing to reach them, it is always best for two people to go together. Assistance may be required, and someone will thus be at hand in case of an accident. The eggs of many cliff-building sea birds, indeed, are not to be got by any ordinary amateur, and must be obtained from men who make it their special business to collect then.
tillets are fixed to both faces of the central gable as well as to the ends, and all are stopped back about 14 in . to correspond with the drawer grooves.
The back is framed in the manner indicated nt Fig. \& The necessary brass fittings consist of two pairs of strong brass butts, two flush bolts for left-hand door, lock, and two drop, handles.

The drawers are so constructed as to be virtually airtight. Everything depends first, on accuracy in setting out, and secondly, on exactness in construction. The drawers are 17 in wide, 16 in. from front to back (not including knobs), and 2 in . deep outside. A part side view is given in Fig. 8, sections in Figs. 9 and 10, a part top view in Fig. 11, and details of the disinfectant reservoir in Fig. 12. Tho drawer in reality is a box with a framed lift-up glass top. There is no space between the drawers. There is a scratched bead, which will be seen in the sections. Figs. 8 and 9 . The drawers, by means of their side grooves, run on the iillets already described, and the lift-up glass tops are hilden by the fronts when the drawers are shut. The details and sections here given are drawn half size.
The drawer fronts (Fig. 9) are 17 in. long, 2 in. deep, and $\frac{5}{8}$ in. thick. On the top, at A, a tiny V-groove is run, and at $B$ there is a Hat lead. looth of these features heing simply finishing touches. If Fig. 8 is examined in conjunction with Fig. 9 it will be observed that the lift-up top comes flush with the top of the drawer front.

## How the Cabinet is Kept Airtight

The inside of the front is rebated to receive the top, a rounded fillet, $C$, being carefully worked right along to engage with a corresponding groove, $\mathbf{E}$, run in the top frame. These rounded fillets keep the top practically airtight when on, and must be neatly initred at the corners. About $\frac{1}{i n}$. from the lower end a groove is run to take the $\frac{3}{3}$ in. bottom of drawer. The fronts are dovetailed to the sides as in Fig. 8. The drawer sides are shown here as if $\frac{8}{8}$ in. thick, but in the actual cabinet under consideration they are only 8 in. They are slightly narrower in widtl/ than the fronts, as the top comes right down upon them Fig. 10 shows a scction through the sides. The top edge is finished with a rounded bead gables, so that access to the drawers is easy. The rails are shouldered and tenoned as indicated by dotted lines at Fig. 4. The astragal is shown at $A$ and B, Fig. 5. Note should be taken of the section at $A$, and also of the detail at B, which indicates the stopped bead at the ends. The ends of the cabinet are framed and panelled to appear like the doors. As, however, the inside faces have to lse fitted with narrow fillets on which the drawers run, the panels arc flush with the stiles and rails at the back, as Fig. 7, A

At Fig. 7 is also shown a sketch of the lillets. A reference to Figs. 8 and 10 will show that grooves are run in the drawer sides to engage on the fillets, and as the comfort of using such a cabinet depends largaly on the easy running of the drawers, there must be absolute accuracy in the fixing of these fillets.

Their positions should be accurately marked, and, for preference, shallow grooves should be run in the gables to receive them. In the case of the present cabinet the drawer grooves are ${ }_{10}^{3} \mathrm{in}$. by $\mathrm{i}^{3} \mathrm{in}$., and thus the tillets will project $\mathrm{in}^{3} \mathrm{in}$. by ${ }^{3} \mathrm{i}$ in. to engage with the grooves. If hedded in the gables they may be cut ift in. Wide by $\mathrm{I}^{3}$ in. deep Of course,
 elevations and sectional and other details of construction
exactly similar to that on the front; in this case, however, it is easier to work as there is no rehate.
The groove by means of which the drawer alides is shown at $F$ in the section, Fig. 10. The groove, which may he $\frac{3}{} \mathrm{i} \mathrm{in}$. wide by $\mathrm{i}_{6} \mathrm{in}$. decp, runs to the back of the drawer. hat is
stopped $\frac{8}{8}$ in from the front The greatest care must be taken to sct out these grooves accurately, and to cut thom clean and sharp. The slightest error will cause the drawer to stick, and if force is required to open or close it the gable fillets will soon wear. Like the front, the sides will be grooved in order lo take the drawer botton
Two thumb. slots (shown in Fig. 8) are worked to the top edge of each side, so that pressure with the linger may be exercised on the lift-up lid to remove it. A section is shown. The back is shown in rection in Fig. 9. It also may be ? ${ }^{3}$ in thick, with rounded fillet, C. It is dovetailed to the sides as in. dicated in Fig. 8. The bottom mny be $3^{3}$ in thick, of sound wood. It is slid from the back into the gronves cut in sides and front to receive it. To the back it is firmly bradded to prevent its working loose

In Fig. 3 the two middle drawers are shown slightly deeper than the others. The nctual drawers are no decper, but the front is taken down half an inch to hide the edge of the stiffening shelf, which is set back ahout $\ddagger \mathrm{in}$. from the front edge of the gable-ends and centre parti-
 tion.

All draw. ery, with their lids, should lve numbered, so that each may be kept in its phoper place. Preferably, tohc numbers of
Fig. 12. Details of she disinfectant the draivers sich is placed in the front should be
side of drawer
stamped on drawer front and on the the top edge of drawer fro
under front edge of lid frame.
The lift-up top is a frame which fits closely on the drawer. It is shown (in section) separately in Fig. 9 and in position in Fig. 10. It engages in thirec distinct ways: first, the front edge of frame fits into the rebate cut in the drawer front; secondly, the groove, E, fits on the rounded lillet, $C$; and thirdly, the projecting bead, $D$, fits exactly within the four sides of the drawer
The frame sides are only $\frac{1}{2} \mathrm{in}$. wide by $\frac{3}{3}$ in thick. Thus the wood used inust be in perfect condition. The inner top cdge is slightly chamfered, and the lower edge is run with a U-shaped groove, E, to fit the rounded fillet, C, formed on the draver sides, front and back. A rebate is cut to receive a pane of medium heavy sheet glass, and the frame is mitred at the corners and keyed as shown in the inset sketch at Fig. 11. (The mitre key is also shown in Fig. 8.) The glass, which must fit closely, is held by a fine bead, $D$, which projects as shown to fit inside the drawer. This bead must be securely glued in.
BIRTH. The birth of every child, whether horn alive or still-horn, in ust he registered at the local registry within 42 days in England and 21 days in Scotland. A child must be
registered loy the father (i) the child is legiti mate) or the mother: failing them by the occupier of the house where the child is born, or by any person present at the birth. The father may register an illegitimate child and give it his own name. The cost of a birth certificate is 2 s lid In the case of a foundling information must lie given to the registrar. The name may be altered with. in 12 months (Scotland, 6 monthis) of the registration. birth.

BIRTHDAY. Most people think that a person born onthe 3oth of June, 1900, would come of age on the 30 th of June, 192l. The person in question comes of age on the $29 t h$ of June, 1921 , because that is the day on which he returlly completes 21 years. And as the law takes no notice, as a rule, of fractions of a day, it does not matter at what hour on the 30th of June, 1900, he was born. He is 21 and of full age at the very tirst moment of the 29th of June, 1921.

BIRTHMARK. Angiomata, naevi, or port wine marks are masses of dilated blood-vessels slightly raised on the skin, scalp, lips, etc. Moles may be flat, but are usially somewhat raised above the skin. Common sites are at the side of the nose or on the check on the line between the angle of the mouth and the opening of the ear.
The treatment is best left to $a$ doctor, as some of the conditions require excision, liquid air, or electrolysis, whilc others are treated by radium and carbonic acid snow. It is never safe to irritate moles by the use of caustics or otherwise.
BISCUIT : How to Make at Home. All flat bread that is baked until it is crisp may be called biscuit, but as a rule the word is uscd for the two principal sorts, referred to as soft and hard biscuits. The soft variety is easier to make at home. To ensure crispness the dough should be thin. It is difficult to keep it of equal thickness, so have two strips made of hardwood that does not readily warp-say, mahogan $y$-and when the rolling of the sheet of dough is nearly finished, the two strips of wood are placed one on cach side of the sheet, and near enough toget her 10 support the ends of the rolling-pin. The pieces of wood are made of a thickness the biscuits are intended to bealout $\frac{1}{\frac{1}{8}}$ in. The whole shect is then easily liept of one thickness, and the biscuits are not so readily burned.

Rich biscuits need no rerating ngents; they are made short with butter or other fat, and bound together with eggs. Those with less shortening, and made into dough with milk, have usually chemical aerating agents inixed with the flour, or self-raising flour may be used. Biscuits should be baked on a shelf near the top of the oven, so that they may colour.

A rolling-pin about $1 \frac{2}{2} \mathrm{in}$. in diameter, 16 in. long, and the same thickness throughout, is better than the ordinary kitchen moller with handles. A variety of cutters can be made from oval and oblong inustard and other tins; sll that is necessary is to pierce a hole in the bottoin to let in nir. A soft broad brush
should be kept for washing over with n glaze of egg added to twice its volume of inilk A fork serves for pricking, or a little docker. with the spikes equidistant.

Wholemeal Biscuits. Into lf lb. medium fine wholemeal mix $\frac{1}{f}$ oz. bicarbonatc of sods and $\frac{1}{2}$ oz. cream of tartar. Rub into this 4 oz. good margarine, or half margarine and half butter. The meal is then placed in a basin, and at once mixed into dough with about $\frac{1}{2}$ pint milk, in which 4 oz. sugar has been dissolved. The dough should bo stiff and yet easy to handle. Turn on to $n$ board dusted with meal, and roll out in sheets $f$ in. thick. Usc only a small piece of dough each time The baking-sheets require no grease, nor do the biscuits need pricking They bake in a hot oven in ahou 12 min . and if cooked should feel hard when pressed.
l3y using half the amount of flour, 3 lb . medium oatment, and more milk, oatmeal biscuits could he inade from the asme recipe.
Short Biscuits. Sift $\frac{1}{2} \mathrm{lb}$. flour-all ordinary llour or half ground rice or cornflourand rub into it 4 oz . butter or margarine. Mix in 2 oz. white sugar, turn out the whole on a floured board, and mould to a paste. When well worked together so that it does not crumble roll out thinly and cut into fancy shapes Put a piece of almond, angelica, cherry or candied peel on the top, and bake in a slow oven until lightly brownerl. Do not attempt to remove from tin until cold
BISCUIT WARE. The term denotes pottery which has been fired without or before being glazed. It includes unglazed ston ewarc. black Egyptian, terra-cottr, and Wedgwood jasper. China collectors prize certain fainous and beautiful biscuit groups made at Sóvres, as well as those modelled in the Derby factory, capecially between 1790 and 1810 .

These figures, which have the feel of new clay tohacco-pipes, sometimes with a slight translucent glaze, include groups suggested by Angelica Kauffann's drawings, rustic figures and scenes, Derby medallion portraits of British generals and admirals, besides small mound or oval plaques of Bristol make. After the best period the secret of making biscuit ware was lost, and a long interval intervened before Parian ware took its place.

Pieces ought to be dusted with clean cloths. and washed in clean water, otherwise the unglazed surface may become ameared or discoloured. See China

BISMUTH. The various compounds of bismuth have an antiseptic, astringent, and sedative action. Those most commonly used in medicine are bismuth oxide, bismuth carbonate, bismuth subnitratc, bismuth salicylate. the duse of each being $5-20$ grains; the liquor of bismuth, dose 1 dram; and the compound bismuth lozenges All these are used in irritable and inflamed states of the stomach and howels, and relicue the pain, vomiting, and diarrhoea.

Bismuth carbonate is perhaps the best of the preparations, as it relieves acidity. For indigestion, a useful combination is bismuth carbonate, grains 10 ; magnesium carbonate, grains 20 ; and bicarbonate of sorla, grains 20. 'I'his can be taken in milk or in sods-water, three times a day, half an hour after meals.

BISQUE SOUP. A shredded onion and a piece of cucumber are fried in a tablespoonful of butter and added to a quart of fish stock, the whole being seasoned with salt and pepper and cooked until the vegetables are tender. Then the yolks of two eggs arc heaten into $\$$ pint cream and added. 'The soup should not be allowed to boil, but stirred thoroughly until it thickens, when it is ready to serve Ilavoured with anchovy sauce. See Soup.

BIT : For Driving. A bit is the mouthpiece of $n$ bridle carried by the horse in its mouth so that the driver may cause it to oley his will.

It is usually of metal, and both the cheek atraps and the reins are attached to it. A curb bit has a curb chnin instead of a bar, and zives the driver a atrong leverage by enabling him to compress the horse's mouth. A snaffle hit is joined in the centre, and is usually provided with check pieces so that the reins may not go into the horse's mouth. See Driving: Harness; Reins.
BIT : For Wood and Metal. Small steel cutting tools or bits are used for horing wond or metal; they are rotated by means of the brace or stock, into which their squame tapered ends are fitted Of many patterns designed to suit all kinds of boring work the most useful are the following :
Auger bits, Fig. I, for deep horing, are made with a long shank, a twist, and a head. The latter has two spurs uhich dcfine the size of the hole, two cutters which remove the wood and place it so that the trist draws it up, and a screw which draws the bit into the wood. Sizes range from if to 1 it in .

Bit. Figs. 1-8. Bits of patterns in common use. Figs. 9 and 10 . Expansion bit and extra

Centre bits, Fig. 2, for shallow boring are made with a central prong, a apur, nad a cutter which acts as a lifter or lip to carry off the shaving. They are mado from $\ddagger$ in. to $1 \frac{1}{2} \mathrm{in}$. in diameter.
Countersink bitw are employed for boring conical depressions to allow screw-heads to he turned in flush. 'There are three kinds in ordinary une. The tlat bit, Fig. 3, hnving two inclined erges ground to opposito anglea, is mainly used for iron and for enlarging the holes ill hinges, etc. The rosehead bit, Fig. 4, is for brass, but is useful for hardwood: it has a conical head with edges which may be sharpened on astone. The snail-head, Fig. $\overline{\text { on}}$, for soft woods, is conical, with one side cutter.
Nose hits, Fig. 6, are for end grain ; they are hollow in the shank, with a cent reing projec tion at the point, and range from in. to $\frac{1}{2}$ in. in diameter. Shell hits are similar in shape, hut have a plain rounded end. They are bandy for cruss-grain boring where deep holes are required. Spoon hita, also similar in form, have a pointed end.
Twist or gimlet bits, Fig. 7, are for hardwoods : they have a gimlet point and are out on the curved sides of the shank. They are difficult to sharpen. Sizes range from质 in to in .
Turnscrew or screwdriver bita, Fig. 8, are used in thuse cases where a large number of screws have to be driven

Expansive or expanding bits are intended for horing shallow holes up to ahout 3 in . in diameter. They have a fixed screw-head and an adjustable spur and cutter. In Figs. 9 and 10 are shown Clarke's patent expansion bit and the extra routing cutter for obtaining large diameters.
A type of hit having practically no centre point is Forstner's auger bit, a splendid tool for horing away the groundwork for carved panels, etc Bits should be kept cither in a wooden atand, with the shanks fitting in $a$ tapered hole, or in a canvas or baize roll. Soldering bits are described under the lieading soldering. See Brace; Drill; Soldering.

BITE: Of an Animal, A lite is likely to produce a poisoned wound, or, at any rate, should always be treated as such. Blceding should be encouraged for a short time, imless it is too free, and the wound should be washed out with an antiseptic lotion, such as saturated solution of boracic acid, carbolic acid lotion (1 in ( 0 ), or a solution of permanganate of potash. If the bite is a severe one, ra by a hoise, the treatment will have to include that for shockwarmth and stimulants, hot coffee, spirits in water, or a teuspoonful of sal volatile in water.
In the case of a dog bite a ligature should be fastened on the limh (if the bite occurs on one), and this is done by tying a handkerchief round the limb, passing a piece of stick through it, and twisting the ligature tight. This can be left on for half an hour if necessary. Inmmediately the ligature is applied, or at once in hites on other parts, the wound should be sucked. There is no risk in doing this if the lips and mouth are free from abrasions. The mouth should be rinsed out with water or apirits after the operation is completed. A piece of boracic lint or a clean rag wrung out of horacic or carbolic solution is then applied. The doctor will have been sent for, of course, and may decide on further measures. The anxiety in dog bite is whether or not the animal is suffering from hydro. phobia, though, of course, one may be bitten by other animals or even by human beings suffering from hydrophobin. Therefore the dog should not be destroyed until suflicient observation of its condition can be made.
In Great Britain the only snake whose bite need be considered is the adder or viper, and the bite is rarely dangerous except in the case of children and debilitated persons.

Where insect bites or stings have occurred the sting or atings should be searched for and treatment applied as given under Bee Sting. See Adder Bito: Bee Sting; Frost-bite : Hydrophobia; Sting.

BITTER ALMOND. The skins are rough and indigestible, so they should always be removed by blanching. Bitter almonda contain a substance called amygdalin, one clement of which is prussic acid. Therefore, though useful for pounding with sweet almonds, or as a flavouring, they should be used in moderation. See Almond

## Bitter Apple. See Colocynth.

BITTER PIT. The name is given to a disease of ripening apples, npparently not caused directly by fungus or insects, but physinlogical and due to some weakness in the tree. It is so named from depressions in the skin of the fruit, which correspond with brown spots in the underlying flesh. The tissues of the apple are stored with starch, which during the ripening process is changed into sugar. In fruit suffering from bitter pit it is found that the starch of the brown spots remains unchanged and bitter to the taste, whilst the surrounding white flesh has become sugary. At present no cure is indicated, but the trouble is less likely to occur if the trees are lightly pruned and planted in well cultivated and adequately drained land See Apple.

BITTERS. Various kinds of bitters, including Angostura, Khoosh, orange, and peach, are made by cordial compounders, and taken with sherry, gin, etc., as an appetiser. Bitters can also be made at home. One recipe requires a bottle of orange wine, a quartern of proof apirit, and 2 oz . of bitter orange peel. The latter should be steeped in the spirits for a weck or 10 days, and then run off. The spirits are then mixed with the wine, and the litters are niade.
BLACK : The Dye. There is not one black, but many, and lyers of fabrics are able to offer several shades of black, more or less blue, full or reddish. Comparison of blacks should be made not merely by looking downwards at the samples but by holding the patterns up to the light at eye-level, when the difference of tone is much more apparent. Blacks of the same shade look different when they are dyed upon a shiny or a matt surface.
There should be no difficulty in olstaining permanent blacks. auch as will not turn rusty in wear. On cottons the fastest black is an aniline dye.
Linen dyes back with difficulty, but silks, natural and artificial, are satisfactory. Professional garment dyers have the neans of making a better job than can be turned out at home, but facled blacks can be improved by re-dyeing with home dyes.
BLACK-AND-TAN. This neat-looking, short-coated terrier, also known as the Manohester ierrier, is a good house-dog. Quiet and alert, he is always ready for a romp with the oliildren. He is, moreover, a good ratter.
The head is long and wedgo-shaped, with tapering jaws, small bright eyes and n black nose. Jet-black is the predominant colour, picked out sharply here and there with rich tan. The muzzle, lower jaw and throat, a spot on each cheek and over each eye should le tan; so should the front legs below the knees, but the hind legs should have tan on their inner side only. The same colour marks the under side of the tail, the vent, and there is a touch of it on each side of the chest.

Black-and-tan Torries. Specimen of the mlniature variety of this short-coated breed of dog

The weight varies from 10 lb . to 20 Jb ., but there is also a toy race which does not oxceed 7 lb . Sce Dog; Terrier.

Black Beetle. This is an incorrect nume commonly applied to the cockroach, whioh is not a beetle. See Cockronch.

BLACKBERRY. The cultivated varieties of blackberry are rarely superior to the best of the wild brambles in Havour, but they produce much larger fruit, ripening in September and Octoler. The parsley-leaved blackberry is one of the best for gardena The best of the newer ones are Edward

Langley, Pollards, Best of All, and Himalayan Giant. All Hourish in ordinary soil that has been dug and manured. The latest novelty is a white blackberry which was found growing wild in Bedfordshire and is available for cultivation in garclens.
Blackberries are readily propagated by pegging down the tops of canes, or roots arc thrown out freely, and when they are abundant the tips can be cut away and the parent liberated. They succeed on arches, trellises and frameworks of stout stakes.

The principal difficulty is to get the plants established, and severc pruning is required. It should begin with the planting, and consists in cutting whatever canes the plants may be carrying close to the ground. The canes will bear a large number of strong laterals if they are stopped when they have grown to about half their normal height, say, 3 ft . The laterals may be pinched at the foot. This treatment dwarfs the plants, which may be convenient in some gardens, and as a rule it gives very good crops of fruit. After the first year pruning is done as soon as the fruits are gathered by cutting out the old canes. See Apple; llottling.

## BLACKBERRY AND APPLE JELLY.

 Stalk and examine 4 lb . ripe blackberries and turn them into the preserving pan with $1 \frac{1}{2} \mathrm{l}$. of apples, washed had cut in slices, but not peelei and cored.Then pour into the pan $\&$ pint water and the juice of one lemon. Boil until the apples are soft, then strain off the juice through a jelly bag. Rinse out the pan, mersure the juice back into it , and add 1 lb . white sugar to every pint of juice. 13oil it steadily until it will jelly firmly when tested on a plate. Pour the liquid into dry, warmed jars and tie them down at once. Should the blackberries be poor and what is termed bullety, use double the amount of apples and only $\bar{f} \mathrm{l}$. sugar to each pint of juice. See Apple.

BLACKBERRY AND APPLE PLE. For overy pound of blackberries used to make this covered tart take $\frac{1}{2}$ lh. apples, 3 tablespoonfuls sugar, and a breakfastcupful water. Fill a pie-dish with the fruit and sugar in liayers. taking care that the fruit is on the top. An inverted egg-cup should be stood in the centre. Then pour in the water and cover the dish with a short crust. Bake the pie in a moderate oven for about $\frac{s}{}$ hour. One lb. blackberries will be enough for 4-6 persons.

## BLACKBERRY CREAM. Put 1 lb . of

 blackberries in a saucepan with \& lh. sugar, the thinly peeled rind of a lemon, and 2 or 3 apples peeled and sliced. Stew slowly until the fruit is soft, stirring frequently; then rub the mixture through a hair sieve. Dissolve I oz. gelatine in 2 tablespoonfuls of water, and strain it into the juice. When the latter is lukewarm, stir in $\frac{1}{2}$ pint of whipped cream, and pour it into a wet mould. When the mixture has heen allowed to set in a cool place, it can be served with jelly.BLACEBERRY JAM. Aithough it is often made without apple, even a little of the latter is an improvenient to blackberry jam. Peel, core and slice $1 \frac{1}{2} \mathrm{lb}$. of apples, and put then in the preserving-pan with a gill of water and 4 lb . of white sugar. Stew the apples until soft, stirring frequently with a wooden spoon, and adding more water if necessary.

When soft, add 4 lb . of stalked blackberries, and boil steadily until some of the jams sets when tested. Remove scum during the boiling. Turn out jam when finished into dry, heated jars, and tie them down at once. See Apple; Janı.

BLACK CAP PUDDING. One beaten-up egg to $\frac{1}{l b}$. of tlour and a pinch of salt is the proportion for the batter, half a pint of milk being added to bring it to the right consistency.

The batter is heated and stirred. A mould liaving been thickly grcased, 1 oz. of cleaned currants are sprinkled into it, then the batter is poured in and the mould covered with greased paper and allowed to steam for an hour and a half. See Batter.

BLACKCOCK. This game bird, in season from the middle of August to the end of November, is usually roasted and is excellent

BLACK CURRANT GIN. Made from 1 quart of black currants, $1 \frac{1}{2} \mathrm{lb}$. of Deinerara sugar, and $1 \frac{1}{2}$ quarts of gin All that is necessary is to put these ing!edients into it stone jar and shake them occasionally. This drink improves with keeping.

BLACK CURRANT JAM. I little less than a pound of sugar is sufficient for 1 lb . of black currants: it should be added to the fruit in the preserving.
 llowed the whole some time. T sugar and fruit are brought slowly to the boil, being thoroughly stirred so that they do not stick to the pan. Aliout 35 minutes' boiling should lie sufticient, but the only. safo test is to place a little in a saucer and stand it at an open window to see whether and economical. The female bird is known it will jelly when cold. The covering of the as grey hen. They should bo hung and kept jam should be done whilst it is quite hot for a fow lays after shooting. After plucking See Jam. and cleaning the bird, wipe it inside and out with a damp cloth; washing spoils the flavour: It should be trussed as a chicken. Roast for about an hour in a moderate oven, basting it irequently. Dish on a slice of buttered toast with brearl sauce, gravy and fried breadcrumilos served separately. See Game.

BLACK CURRAN'T. Of all currants the black are the richest in Havour. They have none of the extreme acidity of the red, but have a rich almost vinous taste. The plants thrive best in heavy, retentive soil, and are most healthy and productive when throwing up an abundance of suctiors from the base. Whatever the soil, large pieces of young wood may be selected for cuttings, and planted for most of their depth, 5 to 6 ft . apart, in autumn, with all their buds left on. They should become protitable in their third year and be at their best in the seventh year from the insertion of the cutting.

The rooted cutting is shortened to about 9 in. at the end of the next season's growth in order to increase the number of main branches. No summer pruning is needed, and the winter proning merely consists in cutting out parts of the old branches in order to make room for young ones. The young wood that is produced from the plant in one season bears fruit the next.

Currant Diseases. One of the most serious is that termed nettlehead, or reversion. The bushes may revert bv degrees. The leaves become elongated and narrow, assuming the nettlehead form; there is change in the Howers, and fruit production almost entirely ceases. May and June are the best montlis to detect the diseass, which can only be done by carefully inspecting the bushes.
Methods are recommended for dealing with reversion in Leaflet No. 377 of the Ministry of Agriculture. The plantation should be oxamined systematically, if possible twice a year, at blossoming time and again in May or June. Reverted loushes should be marked, and after the crop has been gathered they should be grubbed up and burnt. Care should be taken to propagate only from sound stock. Since the disease is conveyed by the big bud mite, keeping down this pest will reduce the incidence of the reversion disease. The surest mothod of detecting reversion is to count the reins running from each side of the midrib in the terminal lole of the leaf; if there are fower than five veins, reversion may be suspected. See Big Bud; Bottling; Mag. pie Moth; Red Currant ; White Currant.

BLACK CURRANT JELLY. Simmer the currants in an earthenware jar placed in hoiling water until all juice is extracted and then strain through muslin. With a pound of sugar to each pint, the juicc is boiled until it sets firmly when dropped on a plate. It is then poured into jare and covered at once.

Black Currant Mite. This is the name of the insect which causes the disease known as Big Bud (q.v.).

BLACK CURRANT PUDDING. The ingredients are: $\frac{1}{2} \mathrm{lb}$. of Hour, 5 oz of suet, $1 \frac{1}{\mathrm{lb}} \mathrm{lb}$. of black currants and 2 tablespoonfuls of brown sugar. The suet is chopped and mixed with the Hour, which is then made with water into a soft but not sticky paste. A quarter of the suet crust should be now cut off and put aside for the top of the pudding, the remainder being rolled out about $\pm$ in. thick on a tloured hoard. Line a greased pudding basin with this pastry, then put in the currants, with the sugar and about a gill and a half of water. The small piece of pastry for the top is rolled out and pressed on to the hasin (a little water leing used to make the two edges adhere) and then covered with gicased paper. A floured pudding cloth is tied over top of basin and the pudding boiled in fastboiling water for about $2 \frac{1}{2}$ hours. It should he served with cream. This will be sufficient for 4-ij persons.

BLACK DOLPHIN. Collier, black Hy and hack dolphin are names applied by gardeneıs to the aphis that settles on the terminal shoot of broad beans. Similar in form and halits to the aphis that troubles the rose-grower, the black dolphin is rendered distinct by its sooty hue, delicate pale legs and antennae, and a long tine beak which is thrust into the cuticle of the plant whose juices are sucked through it. It exists through the winter in the egg-stage on some perennial weed such as dock. The eggs hatch in April, and the wingless young colliers settle upon the new vegetation. These are nearly all females, which produce living young, and the multiplication of these pests goes on indelinitely.

Is suon as the pest appears the tops of all affected bean plants should be nipped off, dropped into a tin and emptied on the kitchen fire. Where this course is not possible owing to their having been allowed to spread, the plants should be syringed with an insecticide or with strong soap-suds free from soda, washing oft the soap with clean water within twelve hours. Broad beans which are sown in November suffer much less danage from this pest than spring-sown piants.

BLACK DRAUGHT. This name is given to a strong aperient containing Epsom salts, liquorice, spirit of sal volatile, and senna The usual dose is $1 \frac{1}{2}$ oz. taken early in the morning. The previous evening a blue pill (o grains) is taken, the combination being a common remedy for such ailments as congestion of the liver or biliousness.

BLACK EYE. This is an eflusion of blood under the loose skin over and around the lids It is due to a blow As the tissues beneath the skin in this region are very lax, considerable subcutaneous bleeding takes place, and this accounts for the discoloration, which at first is dark purple and then passes through brown and green to yellow. Apply cold compresses made of folded flannel or lint, sulhcient to cover the area, wrung out of iced water, and applied as continuously as possiblc for a few hours An older remedy is the application of a piece of raw beef

When swelling has subsided the removal of the discoloration can be hastened by conpresses soaked in spirit lotion, metliylated spirit, one teaspounful, water up to two tablespoonfuls, and covered over by gutta-percha tissue, the whole being held in position by a bandage. Several times a day a little vaseline should be smeared over the evelids, which are then gently massaged. See Eyc.

BLACKHEAD: How to Cure. Black. head or comedo is a little white or yellowish elevation of the skin with a black centre and is often associated with common acne, which is a chronic skin disease characterised by pimples, blotches, blackheads, and a greasy skin on the chin, forehead. shoulders, and hack It is commonest in young people at the change from childhood to adult life. The hard pimples with little black dots in their centre are the tiny skin glands which have become choked with secretion which has undergone degeneration Later these little red mounds become pustular and discharge. New crops of pimples and blackhends succeed each other, the affec tion often persisting for years.
The parts affected should be washed thoroughly night and morning with soap and warm water. After this, mop the parts for five minutes with water as hot as can be borne Then press out with the finger-nail, guarded by a thin silk handkerchief, or with a comedoextractor (which any chemist can supply), as many of the blackheats as possible. At bed time apply the following lotion with a little cotton-wool, and allow it to remain on all night

## Precipitated sulphimr

${ }_{2}^{1}+$ part
Rose water
${ }_{2}^{2+1}$ parts
The diet should be of the phanest, with plenty of green vegetables, and fatty foods inust be a voided, as well as pastry and sweets. A tablespoonful of the following inixture may be taken in a little water three times a day, about an hour after meals

Bismuth oxycarbonate
Sodiull bicarbonate
Mucllage of tragacanth
2 drams
Peppermint whter $\quad \therefore \quad \begin{aligned} & 2 \text { drall11s } \\ & 1 \text { ounce }\end{aligned}$
Whine) 0 ounces
Where the pimples tend to become full of matter, $\ddagger$ grain doses of sulphide of calcium taken four times a day often have a drying-up effect on the spots.
For the anaemia and constipation so fre quently noted in acne the following prescription is recommended

Take a tablespoonful of the above prescrip tion in a wineglassful of water, at least half an hour before taking breakfast.

BLACKING. For preserving and polishing Mack leather hoots, various dressings mostly depend upon the use in their manufacture of a form of charcual made from bones, known as
ivory lilack or bone black. The lirst recipe makes a liquid blacking.
Mix 8 oz . of ivorv hlark with 1 oz, of sperm oil 80 that $\pi$ smooth paste resulta, then add 6 oz. treacle Sinired with an equat glamtity ol gordirall 1 negnt weight) sulphuric acid Eflervescence and licat reanlit weight) sulphuric acid Eftervescrnce and licat. result, vinegar, and tottle the blacklag whilst. stial warm.
For use on calf leather boots, the recipe of a polish which is waterproof is:
Carnauba wax, 10 oz.; becawax, 3 oz . stearin, Ioz: flaredded and meltell tore lier in A Am sunce man of turnentine, 45 oz . : witlo wh'ch aniline hlach op oz, and ivory black, ${ }^{2}$ o\%, have licen proviously nixed. The paste should then be made smooth biv nubbing in a mortar.
If the paste is required for brown leathet boots, phosphine and bismarck brown, 2 dr . of each, are added in place of the aniline black and ivory black.

Hont varnish is made as follows, and applied with a small sponge :
Dissolve 20 dr . Wue-black aniline dye and 31 dr bismarek brown aniline dye in $n$ galloll gpirit to form the " mother-liquid dye." Then nilx ${ }^{2}$ pt. of this with 1 gall. apirit, and camphor, 11 oz, Venice turnentine, 16 oz., shellac, 36 oz: Hnally adding 2 nt
lienzine with which has been mixed 3 oz castor oil lienzine with' which has been mixed 3 oz . castor oil ind If oz. linsced oil.

## See lioot.

BLACK JAPAN. A compound of asphalt, boiled oil, and turpentine is used תa a varmish for motals under the nanic of black dapan. l3runswick hack is a similar article: when imparting a dull surface it goes by the name of Berlin black.
BLACK ROT. Nearly all the cultivated plants lelonging to the cabbage family are liable to be attacked by this disease. In l3ritain it is most frequent in kale, cabbage, and caulithower A characteristio feature is the ap pearance of dark or blackened veins in the foliage, which turns pale or yellow, the veins sometimes standing out so clearly as to ap. pear like a black network. When the affected leaves and atalks are cut across, the veins or vascular bundles appear as darli points, and when the stem is thus examined a characteristic black ring of wond is present.

When young plants are thus attacked they may survive for some considerahle time, but remain stunted and unhealthy. In the case of cabbage and canliflower, no hicad is formed, and in turnips and radishes the root fails to develop properly. In severe cases all the leaves may fall off and the plant remain merely as a long stem with a few deformed leaves at the apex ; in other cases a head which is apparently sound is found to be discased inside. Plants are attacked at all ages. Infection usually takes place through the parts above ground and generally by way of the leaves. Slugs and caterpillars are carriers of the disease.

Another source of infection is contaminated seed, which may produce infected seedlings. Contaminated manure or soil in which diseased cabbages have been grown is a source of danger. A small amount of infected soil may ruin the bed, and if there is any doubt such aoil should either be rejected or sterilised. Diseased plants should always be burned. They should never be buried, thrown on the manure heap, or given to pigs, chickens or other animals. Where the disease has existed no cabbages should be grown on the land for five years.

Black Rot. Its effect on a cabbage stalk, bere shown in

Leallet ?()0 issued by tho Ministry of Agriculture deals with this disease, and gives informa tion aliout inethods of disinfecting the soil.

BLACK SCAB. This is the name of two discases, one affecting apples and pears, the other potatoes. The first shows itself in the form of black specks and spots. which spread into large discoloured patches. The fruit, leaves, and twigs may all he alfected In bad cases the fruit cracks. In drier years it is rarely so severe as in wet ones. The best treatment is, in winter, to prume out all diseased and unhealthy-lonking slonts, and to spray with Bordeaux mixture (q.v.) or lime sulphur. just before the Hower-buds opien and again as soon as the petats have fillen.

In potatoes black scab (wart disease) appears to be a disease of the tuber only The first sign is a series of waits in the eyes which develop into black crinkled masses The affected tuber rots, and a clark tluid of offensive odour oozes out. The disease may not affect potatoes in store during the winter, but inay show itself at the eves when the sprouts begin to push Every tuber affected and the huulms should be burnt. No seed from the affected stock should be planted even if part of the crop appears to be clean

It is perfectly easy to prevent potatoes being damaged by this disease by planting on! y varieties which are immune to its attacks e.g. Witch Hill, Arran Comrade, Abundance. Great Scot, Majestic, and The Bishop, See Apple: Pear: Potato.

BLADDER PLUM. The malformation and distortion of the young fruit of the plumtree, known as bladder jlum, is caused by a minutefungus. Ascomyces pruni, which is perennial in the tree affected and in spring sprearls into the fissues of the new shoots. The plums attacked are distinguished by their larger size, pointed ends, hollowness, and the skin having a bloom upon it due to the threads of the fungus bursting through: they soon turn yellow and shrivel. It has been suggessed that the twigs bearing these bladder plums should be cut well back and destroyed; but it is probable that the fungus runs through most of the tree. See Plum

BLANCHING. . Calf's head, calf's fuot, sherp's and lainb's trotters, veal and lamb sweet bread and brains are all blanched before cooking. They are first placed under a tap of running water in order to rid them of blood. and then put in a pan of cold water and brought slowly to the boil. They are allowed to boil for from 15 to 20 min ., with the exception of veal sweetbrend and brains, which should only be allowerl to hoil for 10 min . and lamb's sweetbread, which must not be allowed to boil at all. The water is then drawn off and the meat cooled before cooking.

Celery, artichokes, endives, turnips and small onions which have been kept for some time may be hlanched before cooking. Thes are Acalded, and then cooled by steeping in cold water until just warm. when they should be placerl on a sieve ready for use. See Almond; Calf's Head, etc.

BLANCMANGE. Blend two heaped tablespoonfuls of cornllour with a little cold milk, till it is like sinooth, thick cream. Boil the rest of a pint of milk, with $\Omega$ piece of
lemon rind to flavour, and add about two for blankets for babics' cots, and there are also tablespoonfuls of sugar, stirring-till the sugar camel-hair blankets in colours and satin is quite dissolved. Remore the lemon and bound to be obtained in all sizes. Jacquard pour the hot, sweetened milk over the corn- dyed blankets are not so practical. where flour paste, stirring all the time, as in making colour is liked, as those plainly dyed. starch. Put the mixture back in the pan and boil gently for five minutes, still stirring blankets, thanks to the sulphur fumes with

Blancmange. 8 weot cornfour blancmange favoured with oranges and coloured with cochineal
continuously. Then pour into a wetted nould and allow to stand in a cold place for several hours before turning out.
If a few drops of cochineal are stirred in before taking it off the fire, the blancmange will be pink. A little vanilla essence or almond flavouring may be used instead of the lemon. A large tablespoonful of grated chocolate may be added to the above recipe when blending the corntlour and milk, and the blancmange served with whippod cream.
When in season, stewed raspberries yield sufficient juice to make a delicious blanemange. Cook this as for ordinary blancmange, using the syrup of the raspberries as liquid, and serve with whole raspberries.
A more elaborate blancmange is made by pouring the cornflour mixture over several layers of fruit placed in the bottom of a mould. Glacé cherries, bananas, and tinned pineapple will make a good foundation. When the mould is half full, add another thick layer of mixed fruit and fill to the top with blancmange. The first layer must be nearly cold before the second is added.
BLANBET. Roughly divided into four types, blankets are of (1) a loose cellular weave, (2) Witney, (3) cloth, and (t) Scotch diagonal twill. The first of these are expensive, loosely woven to admit free passage of air, very light, but of the finest wool to ensure warmth: made in colours and satin bound.
The hairy pile of the Witney blanket is scratched or teased out of the body of the article, and the fabric is weakened to that extent. The better qualities are made with long wool, and the loss can be afforded, but the lowest qualities are less satisfactory, because there is too little foundation left, and the pile comes away in wear and washing. Witney blankets are warm when new, but become in effect cloth blankets when their pile has been lost. Cloth blankets are made of shorter wool and their surface is slightly raised, but not by wire brushes, and their wear is dependent upon quality. There are both all-wool and union blankets, and the best qualities of union (i.c. wool and cotton) are to be preferred to the cheapest all-wool varieties. Scotch blankets are made of strong wool, and wear well.

Blankets are sold per pair, of dimensions which should be stated in inches, and calculated to fit respectively single or double beds. It is advisable to see that a good overlap of half a yard per side is left.
In any blankets it is essentially desirable to have a maximum of warmth to a minimun of weight. The fine wools are warm without being heavy, but are much more expensive than the hairy wools. The finest wools are used
mild soap should be A good fiake soap of guarantced suitability in washing woollens may be used and dissolved before use. The quantity should be sufficient to produce a quick lather to be poured in and the blankets left to steep bofore beginning to dolly them or to plunge by hand. Blankets must never be rubbed in washing. When a large part of the dirt has been removed, the blankets should be given a second wash. The water should be wrung out either by hand or by mangle, and the blankets should have two washings in lukewarm water to remove all vestiges of soap.
A yellow tinge may be corrected by adding a little bluc to the washing water. They can lie whitened a little by prolonged exposure to sunlight, which is also the best way to dry them. In washing blankets the aim is not merely to cleanse, but if possible to improve them by turning them out in fresh, light, spongy condition, and the method of drying is all-important. The housewife has to use lines or stretch the blanket on the grass, and in either event it is advisable to turn the article about frequently. A sunny day with good wind should be chosen.
Old blankets are useful for ironing-table pads, or, cut to shape and blanket-stitched, for table underlays to prevent the spoiling of polished table tops by hot dishes. Odd pieces of blanket afford good scouring cloths for washing floors and similar work. See Bedding.
Blanket Cloth. A heavy woollen fabric used chiefly for colourerl and white sports coats.
BLANQUETTE. A form of veal stew, for which the ingredients are 2 lb . breast of veal, 2 onions, 2 cloves, 2 carrots, a bunch of herbs, salt, pepper, 1 oz. Hour, 1 egg, and 1 tablespoonful chopped parsley. The meat must first be freed from skin, fat and gristle and cut into small pieces $t$ in. thick. These are put into a saucepan and as much warm stock or water poured over them as will cover them, generally about a pint, then brought to the boil and skimmed The onions are peeled and a clove put in each; the carrots are scraped and cut up, and the herbs tied up. All are then put into the pan, seasoned, covered, and allowed to simmer gently for one hour.
Take out pieces of meat and strain gravy. Mix flour with a little cold water, stir into gravy and bring to the boil, stirring all the time. Simmer for five minutes, then cool slightly and add the yolk of an egg well beaten. Put pieces of veal into a small pan, strain gravy over and heat tlirough ; on no account let it boil. Pour out on a dish, and garnish with parsley, and the blanquette is ready for the table.
BLAUD'S PILL. A favourite preparation of iron, Blaud's pill is chiefly used in anaemia,
especially in those types where there is a great deficiency of haemoglobin, the red colouring matter in the blood. Each five-grain pill contains one grain of carbonate of iron, the dose being one to three pills. To be of use the pills must be freshly made.
BLAZER. An unlined jacket resembling a cardigan with three pockets, but with collar of the step variety, a blazer may be used lor ordinary sports wear by boys or girls. Blazers for schools, colleges, and universities have their special colours, as also have those of many clubs.

BLEACEING. The articles calling for treatment are mainly white cottons and linens. sometimes woollens and, less frequently, silk. Cottons and linens are best bought lully bleached. Unbleached cottons and linens are dingy in colour, as the raw material carries with it impurities of a waxy or gummy nature. These discolorations disappear gradually in wear and washing and the article assumes a whiter appearance; the whitening process is assisted by drying the washing in the open air, and preferably in a good brceze. Country and sea air are better than town air for the purpose of this natural bleaching.
It is wrong to boil linens in washing soda, although cottons may be treated in that way to whiten. Soda disintegrates the linen fibre and causes it to come away as short Huff. A good mild soap should be used in washing linen and well rinsed out. If linen is ironed with soap still left in it, or if linen after washing is stored above a hot cylinder, a yellow tinge is caused which may call for bleaching. This colour can generally be removed by careful re-washing with repeated rinsings, followed by open-air bleaching. The article should be apread on the grass and periodically moistened. The continual wetting and drying has much to do with the removal of the colour.

## How Cotton Fabrics are Bleached

When cotton is bleached by professional bleachers from its natural colour to a full white it is boiled in clear lime water and washed ; treated with weak acid and washed ; boiled with caustic soda and washed; steeper from 2 to 4 hours in clear solution of chloride of lime ; hoiled for 12 hours and washed; left in weak acid again for 3 or 4 hours and washed ; finally it is rinsed and blued. To attempt the process at home without the necessary plant would lead to damage to the fabric. If chloride of lime, i.e. bleaching powder, is used at all the solution should be made three days in advance and the mixture should be stirred up or shaken in a large jar repeatedly at intervals. Only the clear liquor must be taken and about 1 lb . of the powder should be used to a gallon of water. The cottons should be fully washed and rinsed before they are put to steep in the bleaching fluid. The action of the bleaching powder is hastened if the cottons are previously rinsed in water acidulated very slightly with s:Ilphuric acid. When taken out it is important o rinse them well in water to which washing soda has been added. They must be well rinsed again and then dried.

Bleaching powder should not be used on woollens. It dissolves wool if left for a sufficient time, and in any case makes it harsh. Necessity to bleach woollens chiefly arises when repeated or careless washings have turned what should be white flannel or white knitted goods to a vellow tone. To whiten these a solution of 1 lb . soap and 3 lb . amınonia to 5 gal. water may be used. The action is slow, and the articles may have to be left some days.

A more expensive method of bleaching is applicable to cottons, linens, woollens, and silks. It involves the use of peroxide of hydrogen. A solution should be made in an earthenware vessel of one part of commercial peroxide of hydrogen to ten parts of water
and a fer drops of ammonia, sufficient to water a faint smell This provides an effective
matie the mixture slightly alknline. The bleach which, in addition to its remarkable articles should be put to steep wholly under whitening properties, does not injure the lace water, or stained portions will result The Another simple way of bleaching lace which vessel should be covered against light, which has becone discoloured is to press it gently interferes with the result After half an hour with a warm imn and then set in a clean linen or so, when the articles have been thoroughly bag. The latter is left to soak in olive oil for penetrated, they should be squeezed semi- a whole day and night, and afterwards boiled dry and hung in a draught to dry. The in a lathery mixture of soap and water. When heaching takes place while the articles are the boiling has continued for $\frac{1}{4}$ hour or 20 min ., drying and only if the atmosphere is cool enough. The operation cannot be done if the ail is warmer than $68^{\circ} \mathrm{F}$., and the peroxide must be new. A good white can be obtained with peroxide without danger to delicate goods, but pains must be taken to wash it out afterwards
lace needs to be treated with special care during the bleaching process. For this use a rery weak solution of chloride of lime and
water, just sufficient of the former to give the
tor

Bleeding. 1. Place for compressing common carotid artery. 2. Pressura to arrest bleeding from subclavian artery. 3. Pressure applied to subclavian artery by means of key handle. 4. Compresslng occipital artery behind ear. 5. Facial artery pressed akainst lower border of jaw. 6. Pressure applied to superficial temgoralartery. 7. Forced ferion of elbow joint to arrest bleeding from arm. 8. Preasure on brachial artery. 8. Bleeding from sole arrested by pressure on posterior tibial artery. 10. Comprassing temoral artery
as a bleach for clothes, a tablespoonful of the powder is added to a copperful of clothes

It is useful also for removing mildew stains from linen For bleaching engravings. a tablespoonful of the clear liquid is mixed with a pint of water and the engraving soaked in the liquid. It is necessary afterwards to remove all traces of the bleaching liquid by soaking the engraving in several changes of clean water, as any trace of chlorine left in the prper would in time cause deterioration

BLEACHING SOAP. The chemical generally employod in these is perborate of sodium, a salt which releases oxygen on contact with water. Oxygen plays an important part in open-air bleaching, and when the bleaching sonps are used, the wash-tub does work that is ordinarily done during open-air drying. Bleaching soaps present one neans of increasing the whiteness of articles which cannnt be exposed for long.

BLECHNUM. This is a family of vigorous hardy and greenhouse ferns. B. brasiliensc and B. glandulosum are grown under glass in a compost of peat, loam and sand, and need abundant supplies of water from spring till autumn, but do with less during the cold months Blechnum spicant, the hard fern, grows wild in Britain; it is dwarf and evergreen. There are many varieties of this fern. Pron. Blek'num.

BLEEDING. Haemorrhage, or hleeding, may be exterial, as from a wound, or it may bo internal. It may occur from arteries, veins, or capillaries, the small vessels which unite arteries to veins Bloorl from the arteries is bright red, and comes in spurts, the direction of these heing away from the heart. Blood from the veins is of a dusky red or a purple hue, and flows in a steady stream. Blood from the capillary vessels is redder than venous blood, and it onzes out of the surface of the wound. Of the three forms heeding from an artery is the most serious. Vein blceding can nearly always he stopped by pressure. Bleoding from capillarics is slight.

Hacmorrhage in certain parts of the hody is given specific names. Cerebral haemorrhage (one of the causes of apoplexy) occurs from an artery in the brain; haenoptysis from the lungs; hacmatemesis, the stomach; haema. turia, in the kidneys or urinary passages : epistaxis, from the nose.
In wounds of the hand, arm, foot, log. or other parta, the simplest plan to stop hleeding is to press the fingers on the wound; or, if that is unavailing, then to apply pressure to the main artery. In bleeding of the forcarm, one method of putting pressutio on the hrachial artery is to place a pad in the hollow of the elhow and bend the arm. Bleeding from the leg may be controlled by placing a pad in the hollow of the knee and bending the leg.

In the case of the thigh. the femoral artery is compressed agninst the bone in the middle of the groin. When the bleeding is from tho neck, pressure is applied to the carotid artery, a little helow and on the outer side of Adam's apple. In bleeding from the nose a cold cloth on the naje of the neck and another on the forehead are often effectual.

Another method of stoppling bleeding is by the application of an improvised tourniquet. See Tourniquet.
In capillary hleeding over a large surface one may employ styptics such hs tamnin, perchloride of iron, gallic acid, turpentine, or alum; but very hot and very cold water often prove effectual. In internal bleeding, indicated by excesaive pallor and a thready pulse, send for the doctor and meanwhile keep the patient perfectly still.
BLEEDING HEART. Dicentra or dielytra, popularly termed Bleeding Heart, is a herhaceous perennial, hard! except in the-most
expused situations, and makes a bush nanr!y
3 ft . high. The pink flowers are borne on long arching stems, and are nearly an inch across, heart shaped, and particularly gracefal in effect.

Propagation is by division when dormant It is frequently giown in pots and forced in the greenhouse. It is almost inpossible to give the plants ton much water while they are in full growth. After flowering the plants can be divided, watered for a fow weeks, and then allowed to rest until the autumn.

Bleedlag Heart. Foliage and arching aprays of drooping pint flowers
BLENDING. Indian or Ceylon teas are frequently blended with Chins tea, the strong. coarse flavour of the Indian product being mellowed by the subtler and more delicate flavour of the China tea.

The housewife can make her own blends of tea, coffee, or butter and margarine with perfect success and much saving of monev.
No fixed rules as regarde proportions can be laid down, hut the following would make a goorl blended tea : take 1 lb . coarse Indian tea,
 broken Pekoe. These amounts of the dry teas should be poured on to a paper or tray and then mixed with a spoon, mixing thoroughly but gently.

A good after-dinner coffee would be obtained from equal parts of Mocha and Mysore coffec ; Costa Rica and plantation coffee, in equal proportions, make a good breakfast coffee. Chicory adds body and colour to the infusion. and effects a considerable saving if the Havour is not objected to. A good proportion would be one part of ground chicory to three parts of the ground coffee

Butter and margarine can be hlended in the home, but such a mixture is not so good for children as genuine butter. The mixing may be done on a pastry board, the butter and margarine being worked together with the aid of wooden butter pats, or they may be melted together in a basin and then thoroughly stirred whilst cooling. See Adulteration; Coffee; Tea; Tobacco, etc.

BLENHEIM ORANGE. One of the bestknoun varieties of apple, useful alike for dessert or culinary purposes, is the Blenheim Orange. When grown as a standard tree on the crib stock it takes many years to reach a profitable fruit-bearing atage. The Blenheim Orange has a deep yellow akin, atreaked and tinged with red, is of fine flavour, crisp and juicy, and is in season from November to February It is probably second only in flavour, when fully ripe, to Cox's Orange Pippin. See Apple.
BLIGHT. The term is used loosely to indicate that plants have been attacked by some insect or fungus pest ; but it is now usual to indicate more preciscly the nature of the attack. Among less intelligent persons one may still hear a murky condition of the atmosphere ieferred to as a blight; but it
has no connexion whatever with the troubles nffecting the crops, as the ancients believed See American Blight; Apple; Green Fly, etc
BLIND : Their Training. Each local authority is ohliged by law to provide suitable education for the blind children in its area from the age of five years. The parents should get into touch with that borly in good time, so that the child is able to begin his schooling as snon as the age of five is reached.
The aim of the parents and others associated with the child should be to make him as normal as possible. They should seek to cultivate habits of self. reliance and independence in the child, who must not he waited upon but be taught to dress and feed himself, and to move about freely. Mannerisms such as swaying the body, shaking the fingers. poking the eyes, and twisting the heard must be firmly corrected. Blindness ought never to be discussed in front of him, and tactless visitors should be restrained from talking of him, and sentimentalising over him in his presence.
When a jerson loses his sight in middle life, his friends should seek the rssistance of the county education authority, for it is the duty of that body to see that blind persons receive such occupational training as will fit them to earn their own living. During training a maintenance grant can be obtained. Do what is possible to

## Blinds: Their Fitting and Repair

## How to Fix and Adjust Window Blinds

## Special forms of blinds are described under Sun Blind and Venctian Blind, and various <br> other ways of treating windows under Casement; Curtuin, ctc

Blinds have gone out of fashion owing to the use of practical long and casement curtains; and also of pelmets or valances to finish the window scheme. Owing to these the lace erlging of sitting room or trimmed blinds is no longer required, and in town houses obscures the daylight when the blinds are only partially drawn up to show this decoration at the top of the window. For kitchen and back premises dark green blinds are best as they only require dusting and can be kept clean if aponged or wiped with a dainp clath. Even here oiled silk or American cloth is being used for casement curtains.
The stiff linen blind excludes air as well as light. Another substitute is the latticed out. side shutter, which with the casements thrown open gives a sufficiently darkened room for sleep with a regulated supply of air.
Where holland or linen blinds are washed at home, the best plan is to unstitch the hems before putting them in the water. Then, if the material stretches, it may be cut to fit the roller and sewn up again, with little or no trouble, while, if it shrinks, the roller may be cut to fit the blind.
Fitting and Repair. Apart from Venetinn blinds, almost all blinds in use are mounted ujon rollers, upon which the material forming the blind is wound. The first thing to see sbout is that this moller is horizontal ; if it is not, the blind will not mill up Hat, but will crecp over to one side. A spirit level can be applied to the roller, if in place, as a test, and any necessary adjustiment made accordingly. When putting up a new blind a string can be stretched tightly between two thin nails driven into the framework of the window, the string occupying the place where the roller is to be fitted. This string should be tested with the spirit level and adjusted until it is hori-
banish self-commiseration from the patient. Keep his mind alert and in constant touch with former interests.

If blindness comes on in advanced nge, the same principle of keeping alive in the patient's life as many interests as possible should be followerl. His friends should get in touch with the nearcst Home Teaching Society, which will send a visitor to teach braille. A blind person unable to follow his employment can obtain an old age pension at 50 . See Braille; Pension.

BLIND HOOKEY. A caid game for two or more players, to which the name of blind hookey is given, is beat played by four or five, and they cut for deal, the lowest dealing The cards are shuffled by any or all of the players, and by the dealer, who is the banker, last The banker then presents the cards in turn to cach player to cut a num her of cands from the top of the pack. The cards so cut must not be less than four, and when cut remain face down.

Each player lays a stalic on his cards, and when all stakes liave been made the cards are turned up so that the bottorn card of each pack is shown. If the banker's card is higher than that of any particular pack, he takes all the money on that pack. If lower, he pays over to the player a stake equal to the amount on the pack. If the two carda arc equal in value, the banker takes the inoney staked. The banker keeps the bank, though the players may deal in turn, until there comes a hand when he pays all round. In that case the next player takes the bank. Any player can stake any amount within the agreed limit on any other packet but the banker's, and onlookers may stake on any pracket as well.
zontal. It then acts as the centre line for the roller, and the fittings are screwed in place so that the bearing holes or centres will register with this line. The simplest arrangement of mechanism consists of two metal supports providing bearings for a plain wooden roller, with suitable pins in the ends to act as an axle. At one side of the roller is a $V$-shaped pulley wheel around which passes a stout string or cord, joined at the ends to make it continuous, tension being brought upon this cord by an adjustable whee mounter in a netal framework known as a blind rack. Some of these racks have a ratchet arrangement; others a screwed rod and milled nut for adjustinent. Racks of all patterns are fixed to the window frame by means of screws.

Points to watch are that the blind roller can revolve truly and freely; that the cord is sufficiently thick to grip; the pulley, and that the small wheel on the blind rack rotates easily. The fault with this type of blind is that the cord soon stretches and needs more or less constant attention if the blind is to function properly.

In blinds of the semi-automatic type (Figs, 1 and 2) a ratchet arrangement is provided, so that when a single cord is pulled the blind can be raised or lowered, and stops wherever desired. A lever pawl is so arranged that when the blind cord is pulled, the lever is moved and lifta the pawl clear of the ratchet on the end of the blind roller, the blind being lowered by keeping a slight tension on the cord. On releasing this tension the weight of the lever causes it to fall back and engage the ratchet, thereby holding the blind in place.

The renewal of the blind cord is done by winding the blind up to the top and removing the old cord and threading a new one through the hole in the lever. turning it once or twice
round the spool and then through a hole in way to make sure the blind will hang properly the roller end provided for the purpose is to place the end of it over the roller, letting (Fig. 1). A knot is then tied in the cord, and the blind hang down in its proper place, and this prevents it from pulling out of the hole. Takc care to wind the cord the right way round the spool, noting that the cord winds up or around the spool when the blind descends, or vice versa.

The brackets are gonerally niade to screw on to the front of the window framing. Other patterns are available that can be screwed to the top of the window frame, from which they hang downwards To facilitate the lowering of the blind a lath of wood is generally inserted into a hem in the lower part of the blind, and various tassels and pulls are often fitted to this lath by means of a metal fitting known as a knotholder. To secure the biind cord, a frequent practice is to fix a metal cord-holder to the window frame.
Automatic or spring blinds are made with a hollow roller, into which is fitted a coiled spring. One end has an automatic ratchet action; the spindle is square in shape at one end, and fixes into a square bole in the bracket to prevent this end of the spindle from rotating. The opposite end is a plain peg, and rotatea in the bracket as usual. With these blinds no cords or controls are necessary. The blind is merely pulled down as far as needed. To raise it, the blind is first pulled down slightly to release the automntic eatches, then it is released or moved up quickly, thus allowing the spring to wind up the roller very quickly, centrifugal force sufficing to keep the ratchets out of engagement (Fig. 3).

## Spring Blind and its Fitting

A nother form of spring blind (Fig 4) has a hollow roller, in which a spring is located at one end of the roller, also a ratchet with a spring pressed lever pawl. When the blind is pulled down by a centro cord attached to it, the spring is wound up. The blind is, however. held in place by the lever paivl. When the release cord is pulled, the lever pawt is raised, and the spring winds up the blind; it is checked at any fosition by releasing the cord. This type is good for general domestic use.
To tit spring blinds proceed as before de scribed, but when putting the roller in place finally have the blind lully wound up on the roller and twist the roller a turn or two to bring a little tension on the spring. If such a blind fails to act, examine the automatic ratchets, which are on the square spindle end of the roller. See that they can work quite loosely and freely. If they are choked up with dirt and dust, clear this away. If the blind works but does not go up to the top, the spring is probably slack, and is remedied by lifting the plain end of the roller out of its bracket and winding it up a little tighter.

The blind itself must be correctly fastened to the roller, or it will always give trouble. One
then to secure it with a few tin-tacks to the roller, avoiding all creases Afterwards carefully take down the roller and fold over the end of the blind, thus giving a double thickness of material through which to nail. Some

BLOATER PASTE. For n savoury paste, grilled bloaters have morc flavour than those cooked in water. Cook one dozen large hloaters about 10 min or till the slin and hones come away ensily. When free from these, pound the flesh finely with about half its weight in butter.

Rub with a wooden spoon through a fine wirc sieve : season with cayenne and powdered mace to taste, and press it into small dry pots, lenving a space of $f \mathrm{in}$. on the top of each. To make air-tight, pour in melted mutton fat, and leave till they are aet hard. Mutton fat hicing harder than bref is less likely to crack across or melt.

BLOATER TOAST. Take two grilled hloaters, bone, akin, then chop the llesh into small pieces. Prepare six pieces, of huttered tonst and kecp hot. Melt 1 oz. butter in a sancepan and add to it the fish, a teaspoonful chopped parsley, cayenne pepper and seasoning to taste. Bent up an egg and, when the lish. etc., is hot, pour it in, and stir the whole near, but not over, the fire until it thickens. Pile lise mixture on to the hot buttered toast. If desired a little checse could now he grated over the tish, which should be put for a few minutes in $n$ hot oven. The roes, if any, might be grilled and served as a garnish.

BLOODROUND. Formerly used in the tracking of fugitives, this dog, in apite of his bulk and manifest strength, is gentle and obedient. He is an affectionate companion, and, in aldition, is a trusty custodian of any premises or property.

A solemn-looking dog, standing a little over 2 ft. and weighing about 100 II ., he varies in colour from black-and-tan to red-and-tan or tawny, with perhaps a little white on the broad cheat, the feet and tip of tail. The narrow head is long in proportion to the length of body, with folds of loose skin, especially over the forehead. The eyes are deeply set, and the long, thin cars hang straight down in soft folds The forelegs are straight and largeboned, the feet large and strong. The long, tapering tail is curried high with a moderate curve. See Dog.

Bloodbound. Specimen of the breed of dar once used for tracking fugitives

BLOOD POISONING. Three distinct conditions are comprised under the name of blood poisoning. When the blood nhsorbs only the poison produced by disense germs, the resulting condition is termed sapraenia: if the germs ns well as the poison are circulating in the blood, septicaenin results. In pyaemia the germs are carried by the hlood to various parts of the hody and cause multiple abscesses to break out.

The chief symptoms of mild sapraemin are hendache and fever; in septicaeniia there are shivering, pains in hack and limbs, hot and cold sweats, and high fever. Septicaemia is
usually due to the introduction of pus-producing organisms through a puncture, e.g. a pricked finger.

When shivering and fever follow the slightes! wound, no time should be lost in sending for professional aid, ay both septicaemia and pyaemia may require surgical treatment.
BLOODSTAINS. To remove hloodstains from silk or wool, these should be washed with water and rubbed with soap liniment. For cotton and linen goods use solution of chlorinated lime (bleaching powder), and wash out the solution with clean water. Where the stain is old-standing it is sometimes necessary to employ pepsin

Blossom Wilt. As this pest attacks apples, particularly certain varieties, it is generally known as apple blossom wilt (q. V ).

BLOTCH. This may consist of pimples, discoloured areas of the skin, or small groups of pustules, and may occur in connexion with skin diseases or eruptions. A blotchy face is not uncommon in constipation. A laxative should be taken, as cascara tablets or sulphur at night, or Epsom or Carlsbad salta first thing in the morning. Sugar, sugary foods and pastries should be left out of the diet, though fats need not be reduced. It is probable that in most cases more open-air exercise is needed In washing, too coarse a soap must not be used, and if the water is hard add a little borax.

The following ointment will be found useful:

Oxide of zinc powder
Precipitated sulphur
Salicylic acid
Concentrated cainplior witer

## nolin

## See Blackhead; Pimple.

BLOTTER. To make the simplest kind fold and stitch about six sheets of strong blotting paper, the size of an exercise book or larger, into a cover of stout coloured paper. This may be quickly ornamented by stencilling (q.v.). Alternatively, make a cover of two sheets of cardboard, fastened together by a strip of linen, glued securely down one side of each. To this linen stitch the blotting paper, and the book is ready to slip into a loose cover.

For an embroidered blotter cover, take 3 yard of silk, linen or other plain material, with the same quantity of lining silk, $1 \frac{1}{4}$ yards narrow galon and a piece of cardboard, is by $11 \frac{1}{2}$ in.
Cut an oblong in the covering material and also in the lining measuring 19 by $12 \frac{1}{2}$ in. Fold the material in half, across, and in the middle of one half draw or transfer the pattern selected for embroidery or appliqué work. Decoration must be done before the blotter is made up.

Half an inch has been allowed for turnings and the cover and lining must be seamerl along three sides; the cardhoard is then slipped in, the fourth seam closed and the inside of the blotter is finished off all round with galon. The blotting paper is attached by means of a tinsel cord to which a tassel may be added.

Blotters may be covered with brocade or shof taffeta edged with tinsel gaton and finished with a heavy silk and beaded tassel, arranged to hang over the edge of the writing table.

A leather cover can be made with no other tool than an embroidery needle. An oblong piece of dark sheepskin is needed, large enough for the back and front cover to be in one piece. One inch extra should he left all round for turnings and an inch for the fold at the back. A pattern should then be designed in the centre of the front, and outlined in coloured fine cord stitched down or couched, with sewing silk all round its edges and across it, as desired. The rest of the design can be filled in with coloured beads.
Two pieces of stiff card board are then needed, as mounts for the back and front. Cover them
with soft interlining (domette is the best) and lay in place on the leather. Turn an inch of the leather down over the mount and fasten it securely by means of long stitches from top to bottom and from side to side. Cover these stitches with interlining, and then slipstitch in a silk lining of a colour to match the design. Such a blotter is suitable for dining-room or study. Colours should be in harmony with the decorative scheme of the room.
A hlotting pad is simple to make. Across each corner of a large piece of very stiff cardboard fasten a strip, of American leather or suede, about $2 \frac{1}{2}-3 \mathrm{in}$. wide, glueing the ends round underneath the board. Several thicknesses of blotting paper the same size as the cardmard can then be secured on it, by slipping each corner under one of the triangles so formed. Blotting paper can be obtained in nearly all colours to match covers or corners.

Blotters can also be obtained mide in the form of a semicircle of wood, with a handle fastened into a thin piece of wood which fits, and is screwed down, on to the flat side. The blotting paper is placed on the curved part, the ends being slipped under the handle to keep it secure See Leather Work: Writing Table.

BLOTTING PAPER. Besides its obvious use, blotting paper is effective in removing grease from clothing. Heat an iron, lay a pad of blotting paper over the grease-spot, and pass the iron over it, allowing sufficient time for the heat to penetrate. When the blotting paper is removed it will be found to have absorbed the grease.

A filter for water can be improvised with a piece of clean white blotting paper cut in a circle, according to the size of the vessel into which the water is to be filtered, and foliled into three, to make funnel-shaped, and inserted into the bottle or jug. For pressing and keeping flowers blotting paper is used owing to its absorbent quality.

BLOUSE. What may be termed the two classical styles of blouse are seldom quite out of fashion in some form. The first of these is the tailored shirt hlouse to the waist, and the second the Russian overblouse or tunic, belted, fastening down the side-front and pouched at the back.

Most fashion journals illustrate styles of blouses that arc in vogue, and it is quite easy for the home worker to select a pattern and adapt it to her own requirements.

BLOW-FLY. This is a large, stout bodied, two-winged tly of a steel blue colour, whose presence indonrs is made known usually by a loud buzzing noise.
The blow-Hy or bluebottle lays its 500 to 1,000 white eggs in batches on such joints of meat as it can reach, cooked or raw. These egge hatch in the course of a few hours, and white, legless maggots or gentles issue from them. In spite of the absence of jaws or any cutting apparatus, these apparently helpless creatures are able to break down the firm muscular material of the meat and use it for
 fully rrown fy. Above, highly mar

Blow-fly. Left : top, errs ; bottom, nifled head of a bluebottle, showing its relatively large ejes
their own sustenance. This they nccomplish by pouring out a fluid from the month which rapidly dissolves the firm flesh and reduces it to a condition in which the gentles can absorb it. A few days of continuous feeding bring the maggot to its full size, and it changes into the pupal form within the larval skin, which hardens and turns dark red Ahout a week later the pupa skin aplita to release the perfect hlow-fly.
Blow-Hies are not bred in ordinary dwellings ; they come in from without. Great care should le taken, therefore, to prevent their access to any flesh foods. The larder window must be kept open for ventilation, but it should be covered sccurely by a sheet of wire gauze. Should the female fly have deposited batches of eggs, these should be at once cut out and the joint washed with a solution of boracic acid
Besides the bluehottle described, there is nother blow-fly of similar habits. It lacks the blue hut owing delicate clothed, it chequered with and the fore-
 tint and instead is black, to the disposition of the hairs with which it is appears to be hlack and grey, body appears to e striper.

BLOW LAMP Plumbers, gas litters and elec. triciana use the hlow lamp to cut and make up connexions, painters

to blister old paint so that it may be easily scraped olf. The instrument con sists of $n$ strong body of sheet-stee or brass. A, capable of holding from a quarter of a pint, in the small sizes, to two pints or more in the larger ones, of petrol, para. Blow Lamp in use for removing old paint. Aboved diagram
showing how the appliance acts petrol para flin, or kerosene. The apirit is forced through
a nozzle in a vary line annular jet into a special Bunsen type burner, B, either by means of compressed air or by warming the hody of the lamp. As the spirit passes through the hurner it is more or less completely vaporised hy heat from the walls of the hurner, which hecome very hot, and at the same time draws air in with it The result is a very hot, strong llame. The diagram shows a form for hurning paraffin oil, in which an air pump, $C$, is used. There is a groove, G, running round the base of the burner, in which a little methyla ted spirit is placed and lighted when starting the lamp, to give n pre liminary heating. 1) is the filling cap, E a relief valve to reduce pressure when needed, and l , the handle.

A few strokes of the small air pump, forming part of the lamp develop the necessury pressure to force out the jet of oil, and, once started, the heat of the
burning flame is usually sufficient to keep the lamp going, though a stroke or two of the pump may be given when necded.

BLOW PDPE. The many forms of the blow pipe in use, from the simple bent tube to elaborate appliances, are divisible into two classes: those blown by the mouth, and those operated by mechanical ineans, which inay be merely a special form of bellows. The object in all cases is the same, namely, to supply an cextra amount of oxygen, either as oxygen or as air, to a Hame or jet of burning liquid or gaseous fuel, or a mass of solid fuel, to increase the intensity of its heat.

The simplest form is shown in Fig. 1, and consists of a piece of metal tube bent and tapering to a point; air is blown through this from the wide end by the mouth. Fig. : shows a mouth blow pipe with a connexion at $A$ to a source of gas, and Fig. 3 shows an injector blow pipe to be blown by bellows.

In using the common blow pipe, some skill and practice are needed to maintain a steady stream of air from the month. The hlast is to be kept up by utilising the muscles of the checks, breathing being carried on through the nostrils alone

The introduction of the jet of air from the blow pipe into the body of the flame, as shown in Fig. 4, gives rise to a double combustion. The outside of the large, shaded, hollow cone is burning with the aid of the external air; the inside with the aid of the forced jet of air from the blow pipe. In consequence, the sharded cone part acquires a very high temperature, more than sufficient to soften a bar of iron, or an iron tube to bend it, to solder any common article, or to weld two pieces of iron together. See Bunsen Burner.

BLUE: The Colour. For laundry use, blue consists of indigo, prussian blue, or ultramarine, in solid or liquid form. It is used in the rinsing water for white clothes, to neutralise any yellow tint after washing. It is also, for the same reason, used to rinse white hair. The solid blue sold in various shaper and in small bags consists of a mixture of 10 parts of ultramarine, 10 parts of hicar bonate of soda, 3 parts of liquid glucose. These ingredients are ground together in a mill until a stiff paste results. From this various shaped oubes or cylinders are cut, which are afterwards dried. On account of the presence of bicarbonate of soda the blue is a remedy in cases of wasp sting. For this purpose the blue bag is moistened and dabbed on the stung part.
Liquid blue, which is often preferred to solid blue for laundry purposes, is made by mixing prussian blue, 4 oz , and tartaric acid, $\frac{1}{2} \mathrm{oz}$, with one gallon of hot water, and atirring occasionally with a wooden stirrer for twelve hours. Then strain through a woollen oloth. Another method is to dissolve 1 p.c. of aniline blue in water, the advantage of this variety being the absence of acid. See Colour.

BLUEBELL. The wild hyacinth that flowers in the woods in spring is popularly knowh as the hluebell. It improves with cultivation if grown in cool shady places with a moist soil. The bulbs are best planted deeply ( 6 in deep is not too muoh), and when suited will send up an abundance of deep blue spikes year after year. There are many varieties, some bearing pale blue, some white, flowers. See Harebell; Hyacinth; Scilla.
Bluebottle. See Blow'fly.
Fig. 1

BLUE FLY. This name is given to one of the many aphides pests which infest gardens jects growing under glass. The best treatment is by nicotine fumigation, assisted by sprayings of soft soap and paraffin emulsion. See Rose.

## Blue Gum. See Eucalyptus.

BLUE MOULD. Starting from minute spores, this appears as a smail white speck, which spreads gradually over the surface of
 the food until a large area is covered, the older parts of the growth being blue or greenish-blue in colour. face. Jams, preserves, mould may grow: In the the typical appearance and Havour of the cheese. of blue mould where it is destructive, food should be kept covered and in a dry place, and food tins should have well-fitting lids. Oiled

lor different purposes
paper should be put on jam while still hot from boiling to keep out the air; or a little melted paraffin wax poured on to the surface of the jam as soon as it has set. See Cheese.

## BLUE OINTMENT.

 colour, this ointment is prepared by ruhbing together metallic mercury and benzoated lard. A small proportion of suet is added to stiffen the ointment. It is employed in skin diseases, chronio inflammations, and enlargements of the glands, also for killing parasites. It is better to use it in a diluted form (one part of the strong ointment with two parts of larrl) to a void the risk of sulivation.BLUE PILL. An oldestablished remedy for liver complaints is the blue pill, followed next morning by a black draught (q.v.) or saline. It is a hlue mass, consisting of metallic mercury rubbed for a dong time with confection of roses and powdered liquorice root. The dose is from four to eight grains.
BLUE PRINTT. A kind of photograph of bright blue colour, known as a blue print, is made by printing from a negative on to a special paper which may be bought as ferroprussiate or cyanotype.
To make a print, a sheet is laid with the yellowish coated side in contact with the negative in a printing frame and exposure made to bright daylight until, on opening one half of the frame, it is seen that a when finished; and the shadow parts should square feet.
have a semi-metallic, choked-up appearance.
When it is judged that exposure has been sufficient, the print is simply soaked in clean water, when it quickly becomes of bright blue colour, showing all details. It is washed for a few minutes in water and left to dry by hanging up at a little distance from a fire.

It is really a plant which grows best on a moist surhread, flour, condensed milk, fruit and cheese are a mongst the articles on which the produotion of certain cheeses, such as Gorgonzola, hlue mould helps to produce

To prevent the occurrence

Named from its greyish-blue picture is visible. The picture must diagram. Matchboard and weatherhoard are appear much darker than it is required to be sold by the square, that is, 100 nominal

Blue print paper is very largely uscd for making copies of engineers' plans or drawings, etc. When exposed to light behind an original of this kind it will yield an excellent copy in white lines on a blue ground. See Dark Rooin; Developing.
BLUE STONE. Sulphate of copper crys. tals is so named. It is most popularly known as an application for exuberant granulations, or proud Hesh, and it stimulates the healing of sluggish soncs. The crystals may he rubbed on or used as a solution in water. Copper sulphate is a speedy emetic in narcotio and phosphorus poisoning, in a dose of 5 to 10 grains, but the doctor should administer it. It is recommended for styes as a one p.c. solution, applied every half-hour after the affected eyelashes have leen pulled out.

Chronic poisoning produces a green line along the guins. In poisonous doses it acts as an irritant. After the use of an emetic, white of egg and milk should be given, and followed up by drinks of harley water and thin arrowroot. Fomentations may be applied to the abdomen to relieve pain. See Poisoning.

BOARD : Varieties and Uses. A board as generally understood means a plank or piece of wood relatively long in proportion to its breadth and thickness. In the timber trade a hoard is reckoned as 1 in thick, and most hardwoods, whitewood, walnuts, etc., are sold by hoard measure, at per foot super. If the material measured 2 in . thick, then the price at lid. per foot super would be 1s., because there are two layers, as it were, each worth 6d.

For general indoor use, and many outdoor johs as well, the ordinary wood, known as yellow or red deals, answers very well. Such deal is sold in planks, that is, 11 by 3 in.; deals, that is, 9 by 3 in. ; hattens, that is, 7 by $2 \frac{1}{2} \mathrm{in}$. From pieces of timber of these

Square Edge Board

Sawn Weatherboard

Motched Weatherboard Board. Sections of standard prepared board used in building basic sizes all smaller sizes of timber are cut.
The term prepared boards means that the edges and one flat surface have been machined or planed amooth by machinery A rough hoard is one that has heen left by the saw. Shelving boards are cut 9 in., 10 in., or 11 in wide, and 3 in., 1 in . or $1 \frac{\mathrm{f}}{\mathrm{in} \text {. thick. They }}$ arc planed on face and two edges, and sold by the lineal foot or per foot Matchhoard is made in several thicknesses and widths ; it is planed on one side, and machined on each edge. The sections illustrated are the ones inost generally used. Weatherboarding is inade in two general forms-the ordinary tapered or feather-edge board, and the rebated, which presents a Hat surface on the interior and the familiar appearance on the extetior. A matchedweatherhoard is also made; this is tongued and grooved and staned, as shown in the

For the average indoor use ordinary squareedge planed boards can be purchased from stock at most timber yards in 3 in., 4 in., 5 in., 6 in., 7 in. or 9 in. uilths and $\frac{1}{2}$ in., $\frac{3}{3}$ in., 1 in ., and 1 fin . thick. Flooring is usually stocked in $\frac{3}{} \mathrm{in} ., 1 \mathrm{in}$. and 1 f in . thicknesses, 1 in being that most genelally in request.

Matchbord is made in $\frac{1}{2}$ in in., $\frac{1 n}{}$., and 1 in . thicknesses, and 4$\} \mathrm{in}$.. 5 in . and $i \mathrm{i}$ in widths. The quoted thichnerses of boards are nlways nominal, being derived from the deal or plank from which the material is cut. Thus a $\frac{!}{2}$ in board will only measure a full $a_{\text {a }}$ in. actual thickners. and a loard nominally 6 in wide will only hold up to an actual 5\% or pessibly 5 in if planed on both edzes

When using boards for shelving it is important the see that the thickness is adequate for the space to be spanned by the board. In ganeral a 9 in . by z in. hoard will only span 2 ft. without sagging, under normal loading. See Amateur Carpentry; Floor: Vatchhonrd. etc
BOARDING HOUSE. In towns or at the seaside hoarding houses resemble private hotels, and differ from furnished apartments in the fact that the guests take their meals in the same room and sliare a general sitting. room, in which a piano and comfortable chairs and couches are usually provided. In large cities hoarding houses seldom provide more than two meals a day, breakfast and dinner. except on Sunday when all neals are provided. The terms for room and mouls are inclusive. At seaside hoarding houses lunch and afternoon tea are usually pmoided at an inclusive charge City boarding houses charge much the same all the vear round, hut the boarding. houses at watering places, which have no
winter reason, increase their tariff during the on fiat pieces or chocks secured to the deck with summer reason. This culminates in August, which is, as a rule, the most oxpensive month in which to seek holiday accommodation

A bonrding house keeper, as distinct from a loriging house keeper, has no right to detain a boarder's lugazge for an unpaid bill. (In the other hand, she is uot linhle for thie safety of the hoarder's luggage or belongings, unless she is guilty of negligence. In a case where a servant was takien on who was a convieted thief, the lonarding house keeper was held guilty of neglivence, because she rngaged thie servant without any inquiry, and under such circumstances that she inight have known the sort of servant she was engaging. So that, when the servant stole from the boarders, the hoarding house keeper was held liable. See Holiday; Lorlgings.

BOARD WAGES. A servant who is ell gaged in the usual way, that is, at a wage with the mistress to provide food and drink cannot be compilled to accept board wages hut if the mistress does not provide the food and drink the servant is entitled us provide them herself and can claim the coat from the mistress. In England, if a mistress dismises a scrvant with a month's wasey in !icu of notice, she only pays ordinary and not board wages. In Scotland she must pay month's board wages, to compensate the servant for the board she could have had during the month. See Servant.

## Boat: The Making of a Model

## Fascinating Work for the Amateur

The reader should consult nlso the articles on Aeroplane: Engine and other Madels; also Soldering; Woodworking. A companion article is the one on Yacht
The making of a good working model boat with Indian ink, and coloured with water is a fascinating occupation for the amateur In this article full instructions are given for making (a) a model cross-channel steamer of modern type, and (b) a fast electrically propelled model apeed hoat.
In the construction of the ateamer (Figs I to 5) commence by making the hull from a solid block of sound pine or deal, free from knots. This hlock when finished must measure 24 in . long, 3 in . wide, and 3 in . deep. If a larger hoat is required the drawings can be enlarged in proportion

The hull can be shaped as follows Plane the wood block smonth and Hat on all four sides, and draw a centre line along the top and hottom faces. Square of the three section lines, A, B, C (Fig 2). on all sides of the block. Mark on the upper and lower faces of the hlock the deck !inc, and on the sides of the hlock mark the slieer line or profile. Now saw away the surplus wood nearly to these lines thus producing a boat-shaped block.
To ensure getting the hull the correct shape, cut three cardhoard moulds. shaperd as shown in Figs. 3-5 Apply these from time to time to their corresponding section lines while the work of shaping goes on. This is best done with the aid of chisels and gouges, warking from the middle towards the ends until all three moulds fit properly, their upper edges flush with the upper part of the block. Mark of the sheer-line and cut this to shape. Then hollow out with gouges and chisels the interior of the hull, taking care not to run the toola through to the outside. Cut a deck from a piece of yellow pine ${ }_{32}^{3}$ in. thick, and fix it temporarily with a couple of fine brads.
To complete the hull, cut $n$ recess $\ddagger$ in. wide into the bottom of the hull on the outside and fill it with lead. Then cut a way the middle part of the deck so that the whole of the superatructure can be lifted off to get at the machinery. The superstructure and bridge are made from $\frac{3}{32}$ in. pine or cigar-box woud. The captain's cabin is cut from mahogany, and the windows and doors drawn on it
colour paints. The railinga are made fron model stanchions and lloral linding wire secured with solder.
The funnels are made of tin-plate, the stays being floral hinding wire soldered in place as shoun. The top af the funnel is beaded over. and $a$ wire ring soldered beneath it. The two hatch covers and the skylights are out from mahog. any. A cigar-box oftersuseful material for this kind of work.

The lifehoats are carved from solid yellow pine blocks, fitted with seatr.and nountel

Boat. Fig. 1. Madel cross-channel steamer which can be made by the amateur. Fig. 2. Sheer plan and deck plan. Figa 3-5. Drawinga giving form of hull at the three critical points indicated on plang above
spray hood ends is $5 \frac{1}{2} \mathrm{in}$., tapering off to 4 in at the stern.
The amateur who does not care to tackle the job of making auch a hull can procure one from Whitneys, 129 City Road, London, E.C., who supply the power plant here illustrated and described. The hulls are made 24,30 and 36 inches long, and aso in the metre size. We will assume that the 24 -in hull has been made or purchased. A permanent-magnet motor to suit this size will run from $n$ dry battery (Ever Ready No 12i), or a special low-built light-weight accumulator may be purchased. This, while costing three times as much as the dry battery, has the advantage that it can be re-charged quite cheaply. Fig. 7 shows the motor with propeller shaft, atern tube and three-bladed propeller.

The motor shaft has a projecting pin which engages with the forked end of the propeller shaft and so acta as a driver. The motor frame is already set at an angle, so that when it is screwed down by its lugs to a wouden base made to fit the floor of the hull, the shait will be inclined approximately at the correct angle to line up with the propeller shaft. The stem tube, through which the latter protrudes, must be soldered into a hole carefully made in the hull The propeller shaft is supported further by a simple bracket made from a strip of brass bent up and soldered to the $l$ all The inner end of the stern tube is providsd with a atuffing gland to exolude water. The tube may rest on a block fixed to the wooden base, and may be secured by a brass or rinc strap passing over the tube and acrewed to the base. A clip for the dry battery or accumulator should be fixed at the stern
A wooden dashboard may be litted just under the mouth of the hood, and a simple switch on this will start or stop the machinery. The rudder is made from sheet zinc or brass, and soldered to a brass post. The past passes up through a brass tuhe soldered to the hull and protruding through the deck. The rudder is held in place, when set, by a lock nut Fig. 8 shows a larger motor for a

Boat. Model Electric Speed-hoat. Fig. 6. Bull, which ts made ol zinc. Fig. 7. Accumulator. Fir. 8. Motor with propeller shaft, stern tube and three-bladed propeller. Fig. 9. Larger power plant suitable for 36 ln . hall pricked holes using the pins as the key to the design. the middle of a hem. hardwood. Brush.
is drawn in pencil upon cardboard and pointa are inked and then pricked to show where the gimp must be made. A tracing of this draft is made on parchment, and this is fastened down upon the lace-making pillow Solid-headed pins are then inserted at the

The bobbins from whence the name comes are wood or bone, and carry the thread Two threads are tied together, and they, with their bobbins, hang upon the pin. The lacemaker deftly throws one bobbin over another.

BOCCONIA. The plume foppy or bocconia is a tine herbaceour perennial plant, growing 6 to 8 ft . high, with glaucous leaves and long plumes of buff-coloured Howers. It loves a deep, moist, subatantial soil, and thrives in well-tilled clay. It is effective if a small clump of it is grown in an isolated position as a form of lawn decoration. Propagation is by division in autumn or sprinu under glass, and by pieces ol root laid in shallow boxes of gritty soil in a frame in spring. Pron. Bok-coney-er.
BODKIN. A thick needle with a blunt end and a wide eye for threading elastic or ribbons through slots or lace, etc. A good substitute is an ordinary safety-pin, which also has the advantage of not becoming unthreaded in

BODY BRUSH. In best makes Iristle only is used, the knots are wire-drawn, and the backs screwed on as with good clothes brushes. The handles, which are lengthy for convenience and atraight or bent to suit various tastes, are usually made of beech or similar

Cheap fibre mixing brushes, which are harsh, or pure bristle of white and grey. can be had of any required stiffness. They should not be left lying on their backs in a sodden condition when not in use, hut hung or propped up to drain and dry. Occasional rinsing in hot water to which a little am monia or antiseptio preparation has been added will tend to keep them wholesome. See

BOETTGER WARE. Genuine pieces of the jasper-like stoneware in dark red, which was produced by the inventor of Dresden china early in the 18th century, are rare. They may bear imitations of Chinese marks, or the famous crossed-swords device, or be unmarked. Unglazed red ware of German make has been faked up and passed off as Boettger. The various styles include half-busts or figures with the drapery beautifully polished in a lathe, sprigged teapots, beakers and candelabra, hesides vases with lacquered or enamelled designs. All these form effective ormaments for the living-room, but do not mix well with $30-\mathrm{in}$. hull. Two 4 -volt accumulators in more delicate work, such as Chinese Horal parallel are needed for this set. The motor is mounted parallel with the floor of the hull, and is connected to the inclined propeller shaft by a flexible spring coupling.
Bobbinet. Machine-made plain net made with extra stout cotton and suitable for window curtains See Lace.

BOBBIN LACE. Lace hand-made, not with the needle, nor by knitting nor embroidery, but by twisting and plaiting threads into a pattern, is known as bobbin lace. Other names for the same kinds are pillow ace and bone lace (now obsolete). A design
pieces or old decorated white china.
BOG: In Gardening. An artificial bog is a piece of moist ground, natural or prepared, in which may be grown water-loving plants which do not actually require a pond or stream. These hogs are usually made of concrete or Portland cement basins, about 1 ft . in depth, and filled with peat and loam. The bog is kept wet by means of a drip from natural or artificial sources

Most of the ferns make good bog plants, and other popular specimens are the sundew or drosera, hardy lady's slippers, side-saddle

Howers or sarracenias, butterwort or pinguicula, marah marigolds, and Japanese primroses. See Water Garden.

BOG BEAN. This interesting aquatic plant is sometimes found by the edges of streams and pools It is called Menyanthes

Bog Bean, a plant for the water garden trifoliatn, and is also known as the luck bean. It is herbaceous and Howers in early suinmer, the Howers being bell-shaped, white inside, and strenked with red outside. The llowers are horne on stems which float on the surface of the water.
The bog hean is eusily propagated by taking short lengths of the stems and jegging them down with carnation pegs to the moist ground or bot- tom of the water, until they throw out roots. See Water Garden.
BOG OAK. This is the name given to oak found buried in peat boge which centuries of immersion have turned to a deep black colour. It has applications in cubinet-inaling. In various parts of Ireland where deposits of thag oak are found a considerable industry exiats in carving and fashioning this material into curios for souvenirs
BOIL : How to Treat. A boil is caused by a germ finding its way into the skin either into a hair follicle or elsewhere, there setting up inflammation. A cause may be any temporary falling off in the patient's health, but the general health may be apparently good. Over-eating, especially of rich foods, is a cause of boils. The patient should keep for a few days to a light diet and avoid aicoliol. Boiled Spanish onions are beneficial. The hoil should be sponged several times a day with a solution of one part carbolic acid to 20 parta water. If it is about the nostrils or in the ear, medical treatment is neccasary, and a pliysician should be consulted.

Impaired nutrition through under-feeding may cause boils in young children. The diet should be carefully looked to in such cases Chenical fond will be a good tonic. The skin all round the affected area should be wushed every day with saturated boracic acid solution, and the following ointment is then applied: buracic acid powder, one dram; vaseline, one ounce.

More sunlight and more hours spent out of doors will alao help greatly to build up the general health, and if a change of air is possible it may be, the best thing. See Gumboil.

BOILER: For Hot Water Supply. The development and successful use of any hot water boiler depends upon an appreciation of the fact that water rises when it gets hot. It is easy to see, therefore, that in an enclored boiler the water will tend to. rise as it gets hot. If a regular supply of cold water be introduced through a pipe at the bottom, and another pipe be taken from the top of the builer, the hot water will rise up this pipe, and the heated water can be stored up in a tank at any convenient spot in the house above the level of the boiler. The storage tank is connected by a second pipe to the bottom of the boiler. The pipe that the hot water goes up is known as the How pipe, the other as the return pipe, and both should be $1 f$ in. diameter.
A boiler of this type (Fig. 1) is generally placed at the back of the kitchener, as indicated in Fig. 2. The direct heat of the kitolien fire is about three times the value of
the Hue heat at the sides and back of the ment, provided they are not nearer than 18 in boiler, so that the most efficient boilers are to any woodwork and that any requirements those nearest th the direct heat of the fire.
Many of the troubles of
boilers are caused by the fact that they are neglected on the assumption that as they contain water they are automatically cleaned. The water, however, must be regularly drained off, the stove itself taken apart sufficiently to give access to the boiler, and the manhole or clearing plug located and unscrewed. When the manhole is opened and the water remaining in the system escapes, a can should be placed to catch as much of the water as possible, and

Boller. Fir. 1. Type largely used in kitcheners, and shown in position in Fig. 2 (above) by dotted lines are complied with The boiler should stand on a good solid bed of concrete (q.v.) or other fireproof material. The outlet tlue is generally made of cast or wrought iron in the form of a stove pipe. The water supply and the flow and return pipes should be of iron, except in certain districts where the water is very soft, in which case copper or lead pipes will have to be used.

An anthracite boiler is illustrated on page 20, fixed alongaide a cooking range. Both this boiler and the one shown in Fig. 3 will burn antliracite, broken coke, or coal, and consume all combustible household rubbish The boiler shown in Fig. 4 is intended to supply hot water for the bath. It is generally possible also to heat an old sack or one or two small radiatora with a boiler of two used to this kind, but a different type is required for soak up the re. a proper central heating system. mainder. After In addition to those illustrated the boiler has there are many other excellent makes been emptied. Boilery of this kind are fitted the scale or with a hot plate on which lur is removed by scraping it out with a metal chisel or a piece of hoop iron.

When a boiler is heavily coated with fur the coating acts as a screen or insulator between the water and the heat from the fire It also prevents the water from coming in contact with the metal of the boiler. Contact is necessary to prevent the iron from burning away, and this is most likely to happen where the deposit is thickest and the hent is greatest, just at the crown of the arch forming the Hue beneath the boiler After acrupulously cleaning the boiler, wash it out thoroughly and replace the manhole covers, well bedding them down with red lead, putty, and a piece of stout string coiled around and pressed down into the bed before replacing the cover, which must be serewed up tightly.

Independent Boilers. The home installation of a new hot water system is most conveniently carried out by the amateur if the independent type is chosen. These, being selfcontained, can be placed in any part of the building on the ground floor, or in the hnse-

Boiler. Fig. 3. Independent boiler which produces a constant aupply
of hot water. Fig. 4. Boiler which will supply bot bath water and may also be connected with two amall radiators or a towel rail smith if Wellstood. Lid.; and Nutional lladtator Company. Lid

Boiler. Fig. 6. Sectional dlagram of a dome-top boiler. A, water inlet : B, grate level below which is a water way, C ; $D$, mud bole ; $E$, hot water
outlet : $F$, fire door: $G$ feed door
cookery, a slow process which ensures the retention of the natural juices, is often pre ferred for such fonds.
The second object of boiling is to impart Gavour and nutriment to the liquid, e.g meat and bone soups and broths. To accomplish this result, the materials are placed in cold liquid, and allowed to soak for a time before heat is applied slowly till boiling point is reached. Boiling is continued till the ingredi ents have yielded their nourishment.

Boiling is employed thirdly to give part of the nutriment and llavour th the liquid, and partly to retain it in the meat, etc., e.g stewed chicken, Irish stew. This effect is produced by placing the food in cold water, and quickly heating it to boiling point, keeping it at that temperature for about five minutes and then lowering the heat to simmering point.

Boiling for the entire time of cooking s required for bone and meat soups; all green and most other vegetables; all boiled pud dings, all starchy foods, e.g. Hour in sauces and for rice, macaroni, etc.

It should be noted that once the surface al liquid bubbles briskly, no amount of fuel will make it uny hotter. The on! y result of furious boiling is that fuel and food are wasted.

Water in which meat, vegetables, nce. macaroni, etc, have been boiled should the used for stocks, soups, and sauces See Beel Chicken; Cooskery: Pudding etc

## Bokhara Rug. See Rug

BOLECTION MOULDING. In build ing work bolection moulding finds a place largely in the panels of doors. Such mould ings rise above the face of the framing and are rebated over the edges, forming a narrow projecting ledge between frame and curved part of the mould ing See Moulding.

BOLERO. A very short jacket with open fronts, the lower edge terminating some inches above the waist it periodically returns to every day fashion, and is employed for Spanish or gipsy fancy dress being worn over a white blouse.

BOLSTER. Usually round in shape, it may be stuffed with feathers or with white horsehair. A variety for use with the large, square pillow is the wedge bolster This is about 20 in from hack to front. deep at the back, the height about 5 in . and sloping to the front. weight about 5 in. and is as thin as possible.

Upholstered like a mattress, a bolster should have a permanent under-cover, and a cover which is changed regularly in the same way as a pillow-slip. See Cushion; Pillow

BOLT. For doors, cupboards, and similar purposes, bolts are made in hundreds of different sizes und styles They have one object in common-to secure a movable part to some other part usually immovable Essen tial considerations are security, efficiency, and neat a ppearance.

A few of the more useful types of bolt are illustrated, their principal uses being as follows

Common japanned tower bolts (Fig 3) are made in several sizes, from 4 in . to 12 in long, and are used for outhouse doors and general purposes. They frequently shoot into a plain hole drilled in the doorpost.

Brass barrel bolts (Fig. 4) are made in sizes from 2 in. to 24 in. long for internal work, and are screwed flat on the door. Flush bolts (Fig. 6) are generally made in brass, with a sunk slide, in many sizes and
widths, trom 3 in long by $\frac{1}{d}$ in. witle to $\because 4 \mathrm{in}$. long by 1$\}$ in wide. They are fixell to the enge of a door, and embedded by cutting a recess, and are frequently used on the one side of a double door.
work. high tensile steel

Engineers' bright bolts are machined all over, and hold up very closely to size. Made with bexagonal head from superior grader of mild steel. they would always be used on machinery or any jol, where strength is a consideration

Coach bolts, which are much used for bungalow work and poultry houses, have a rounded head and square portion on the shank immediately beneath the head to prevent the bolt turning round

Eye bolts are so named because the head is formed as an eye or ring. Generally
Bolk. Figa. 1-8. Verious patterns of doorobolts in common asa soe text

Fig. 5

Fig 6

Blind bolts (Fig. 1) are made straight or screwed Whitworth and made in the black necked, and cxtensively used on cabinet work, for doors of small cupboards, etc. They screw flat on to the door, and may shoot into a hole, through a brass plate, or into a socket.

Monkey-tail bolts (Fig. 5) are largely used for warehouse and garage doors. They are
 in length. Padlock bolts (Fig. 2) are sometimes used on the outside of storehouse or shed doors, the bolt being locked to a staple with a padlock. Such bolts are usually gal. vanized to resist rusting.

Bolts seldom give trouble, the only things likely to affect them being the shrinkage or warping of the door, or the wear of the hinges, allowing the door to settle. This generally necessitates the removal of the staple or socket, plugging the old holes, and rescrewing.

Bolts fitted with stamped metal sockets sometimes work stiffly. They are generally corrected by holding a heavy hammer beneath the barrel and striking a few sharp blows with a light hammer on the upper part of the barrel or socket. This stretches the metal somewhat and makes more room for the bolt. The bolt should be shot into the socket while doing this, as it then presses on the tight spot; the jarring due to the hammer blows is transmitted to these tight spots, and they are thus stretched. See Latch; Lock, etc

BOLT AND NUT : Elow to Use. In the general meaning of the word a bolt consists of a circular rod of metal having a solid head formed on one end, and screwed or threaded at the other end to receive the nut. The pieces to be held, or bolted together, are thus clamped between the head of the bolt and the nut.

Bolts are made in a wide variety of forms, sizer, and shapes, adapted to various purposes. The forms of the screw thread and its pitch, or number of turns to the inch of length, vary according to certain standards.

The ordinary black ironmonger's bolt with hexagonal head is used in all houses. The hole for it to pass through must be slightly larger in diameter than the nominal diameter of the bolt, as it is not machined to exact size.

British standard finethreaded bolts, known as B.S.F. bright bolts, are extensively employed on automobile and aircraft

is known purchased as a screw or set screw.

BOMBAY DUCE. A tish obtained in Indian waters, and exported fron Bombay either in a dried and salted condition or in tins. Bombay ducks are usually crisped in a brisk oven for a few minutes, and served with curries. To powder these dried fish, crisp in the oven without burning, pound finely, and put through a strainer. See Curry.
Bonbon. This word is. used for certain large sweetmeats. See Cracker: siveets.

BOND: In Brickwork. Bond is the name given to any arrangement of bricks so that the vertical joints in one row or course do not come exactly over or under a vertical joint in the next course. To ensure a
satisfactory bond, the bricks must be uniturmly arrangerl, have as few hats or partial bricks as possible, and the vertical joints or perpends in every other course must be above cach ot her.

Several kinds of bond are in general use. the principal of these being known as English, Flemish, garden-wall, and herring-bone The ordinary dwelling-house is usually built with English or Flemish bond. The names apply to certain recognized ways of arranging the bricks in the one brick or 9 in . thick wall, and the one and half brick or $13 \frac{1}{\mathrm{~s}} \mathrm{in}$. thick wall See Bricklaying.

BONE. Grouped together as the skeleton, the bones of the human body form the framework upon which all the tissues depend. Bones are composed of chalky substance (carbonate and phosphate of lime) together with fibrous tissue In youth the fibrous tissue preponderates and the bones are elastic to a large extent, whereas in old age mineral salts make up the bulk of the bones. Children's bones, therefore, tend to bend and yield under pressure, whereas the chalky bones of old ago are brittle and break easily.

Inflammation may occur in the periosteum (the tough membrane that covers the bone), the bone, the bone marrow, or in all threc. It may follow an open wound or be due to microbes brought by the blood, nore especially after an injury Hence superficial bones, like the shin or bone in the neigh bourhood of joints, are specially liable. The inflammation may be acute or chronic. If the bone is denuded of periosteum the portion laid bare is likely. to die.

Children who are run down, or who have some source of infection about them, such as a sore throat, are occasionally liable, after a slight injury perhaps, to a virulent and dangerous infection of the bone marrow of a long bone. The child looks very ill, highly fevered, perhaps somewhat delirious, and screams if some part of the bone, say. the lower end of a femur, is touched.

The importance of remembering this condition is that it is sometimes mistaken for acute rheumatism, and valuable time is lost. Dragging at the arms of small children is a cause of inflammation at the growing ends of the bones. The treatment of these conditions is surgical. See Arm; Fracture: Leg, etc.

BONE BLACK. A form of charcoal, prepared by heating bones at a high temperature in iron vessels front which air has been excluded. It is employed for bleaching sugar and also in the manufacture of blacking. The best kind, ivory-black, is made from waste ivory. In this variety the charcoal is in a very fine state of division.

BONE MIEAL. This contains about 45 p.c. of calcium phosphate with about 5 p.c. of nitrogen. It is a useful fertiliser to apply to plants which are coming into full growth in the ordinary heated or intermediary house. It is a valuable atimulant, and is practically inororous.

Bone meal is largely used, on account of the phosphates it contains, to promote growth in young chickens. It is often confused with green cut bone, from which it differs materially, the latter possessing a high nutritive value, and bone meal little, if any. See Chicken : Fertiliser : Poultry.

BONES : Use in Cooling. Clean, fresh bones contain a large amount of gelatinous matter, but this can only be extracted by quick and long boiling. It is quite easy to know when bones have yielded all nutritive and gelatinous elements, as they have then a spongy, perforated appearance and are of no further use.

Bone stock is a foundation for various soups. Poultry and game bones, which nust not be the least high, and ham and bacon bones are especially valuable as flavourers. To make stock, wash 2 lb . of bones, removing the fat and marrow. Saw or chop into ahort
pieces, and put in a saucepan with 2 quarts of cold water and a teaspoonful of salt.

Heat slowly until they boil, and remove any scum. Add 2 oz . each of clenned and scraped carrot and onion cut in quarters. Do not peel the onion, as the skin will add colour and flavour. Boil the whole stendily for 4 hours, strain into a basin and leave until cold. The hard white fat that forms on the top may be saved for dripping, for use with vegetables, etc.

For devilled bones select those with sufficient meat to afford a meal. Sirloin of beef bones or those from a roast saddle, or blade-bone from a shoulder of mutton are best. Mix together 2 teaspoonfuls of French and one of English made mustard, a tenspoonful of chopped chutney, $\frac{1}{2}$ teaspoonful of strained femon juice, with salt and cayenne to taste. Work all these into 1 oz . of butter. Spread and work this mixture well over and into the meat on the bones, and dust with a few browned crumbs. Place on a baking tin in a sharp oven until thoroughly hot, or they may be broiled Serve at once with any of the melted mixture poured over them, and garnish with tufts of prepared and seasoned cress.

Marrow bones contain nutriment and make a savoury or lunch dish. Select large, fresh bones and have them sawn through if more than 3-4 in. long. Cover the end of each bone with a little stiff paste made of flour and water only, to prevent the escape and wasting of the marrow during cooking. Tie each in a cloth and boil from $1 \frac{1}{2}$ to 2 hours. Take out of the pan, remove cloths and paste, pin a clean napkin round each bone or half bone and send to table upright on a hot dish, with dry, orisp toast in a toast-rack. A long marrow spoon is used to extract the marrow.

BONING: Joints and Peultry. Some joints of beef, mutton and veal, e.g. breast of mutton, brisket and aitchbone of beef, and shoulder of veal, and also, on occasions, fowls, ducks and other birds, are boned before they are cooked, to lessen carving difficulty.

If a boning knife is not available, a sharppointed kitchen knife may be used, and should be slipped with a olean cut to the bone. Do not include in the joint any pieces of gristle, etc. that might be left on the bone.

The secret of successful boning is to cut the meat as little as possible. In some cases, e.g. a shoulder of vea!, the hole left by the bone can be filled with forcement. Such meats ay pig's heard and calf's head, and also sometimes breast of mutton, etc., are boiled whole until the bones readily lerve the meat.

Fowls, turkeys and ducks may be boned and their original shapes retained, if so desired. To bone and shape a turkey, take one that is plucked and (Irawn, cut off the neck and loosen the skin from round it, pushing it well back. When the wishbone is exposed, detach it carefully from wings and breast bone. Divide the joints of the wings and clear them. The breastbone has next to be freed; detach the most prominent part carefully.

Roll back the ment over the part unboned, keeping the knife close against the bones. Detach the legs at the joints, and, after a little further work, the entire skeleton will come away. Then wash and dry the turkey. To bone the legs, the knife is worked gently round the bone, the thigh bone being removed whole. Continue until about half the drumstick is exposed, and then saw it off, leaving a little bit of the bone in to help to give the prepared turkey a more natural appearance. The small end bones of the wings are also left. For a galantine the end bones of the wings and legs are removed.

Turn back the meat the right way out. Fill the legs and wings with forcemeat, pressed tightly in until they resume their former shape. The trunk may be stuffed with forcemeat, or filled with a cooked ox-tongue, the bend of it
lying where the prominent part of the breast- Hesh of the wings and legs, and trim off the bone should be. The spaces left are stuffed rough edges of the neck.
with ns much forcemeat as the turkey will hold. Work the turkey with the fingers until it has nearly regained its shape, tie securely in a buttered cloth, and it is ready for boiling.

A fowl boned in a similar way could be stuffed with sausage meat, the spaces being filled with mushroom, bacon, or other stuffing. Ducks are stuffed with sage and onion. To bone a bird that has already been cleaned, slit it down the back, and work round it from there. The back can afterwards be drawn together.

Our illustrations show how a chicken can be boned. In Fig. 1 it is represented as ready dressed, but an untrussed bird is dealt with in precisely the same manner. When trussed, remove the skewers and strings, reserving the liver, gizzard, extreme ends of the wings, and the feet up to the first joint.
To bone the chicken (Fig. 2), it should be held uip on end supported by the left hand

Arrange the flesh evenly over the surface of the chicken. Spread carefully 1 lb . of sausage ment flavoured with $\& \mathrm{lb}$. of chopped mush. rooms, 3 oz . of bacon, cut in fingers, and a hard-boiled egg, sliced. Arrange it as shown (Fig. 5) and roll it up neat'y, but do not sew the edges together. Tie it in a oloth like $a$ roly-poly pudding, and it is ready for cooking.

The finished dish is shown in Fig. 6. Remove the cloth, rinse it out in hot water, and tie the chicken up in it, tightly shaping it. The bird should then be pressed between two dishes and allowed to cool. See Beef; Breast ; Chicken; Fillet: Garnish; Stuffing.

BONNET: Of Motor Car. The bonnet's seating, both on the dash and the radiator, is threaded through noles with a strip of some soft material. Should this be hard, which is more than likely, through the ingress of oil and dirt, replace with new.
A frequent cause of noise is due to the bonnet butting up against the seatings, thus giving the impression that it is too long. This is seldom the case, the fault usually being in the radiator, the holding bolts of whioh have become loose, allowing the radiator to vibrate. These should be tightened.

Where a top centre hinge is employed see that it is firmly secured at each end. Finally, a little very thin oil worked into the hinges will oure a lot of puzzling noises; the same applying to bonnet fsstenings. Sec Motor Car.

Cornmence by turning the skin of the neek back over the brenst and back until the shoulder bones of the wings are laid bare. Divide each joint as in the photograph and scrape the bones of the wings quite olean, removing the wing bones from the carcase.

The flesh of the body must now be removed carefully and cleanly with the boning knife down towards the thighs, and must be scraped off the breast bone without breaking the skin (Fig. 3). Divide the thigh joint as shown, scrape the bones quite clean, breaking them at the joints, and remove them also.

Now proceed. \&s shown in Fig. 4, to remove the Hesh entirely from the carcass. Cut off the "parson's nose," turn inwards the

## Bookbinding for the Amateur

## How to Repair and Rebind One's Books

The article on this subject is one of a group that describes hobbles which can be taken up with advantage hy the amateup. Sec Leather Work

Simple bookbindiny may be done at home with a few tools and applianccs, and the liandy man can iniprovise or make for himself many of those required. The tools needed nre as follows:

| laying | 1 mewing frame and keya |
| :---: | :---: |
| 1 pair backlog hoards | 1 backing hamm |
| 1 pair cutting boards | naring knile |
| 1 pair presalng boards | 1 bone folder |
| 1 pair pressing tlns | 1 knocking down fron |

To these may be added others likely to he in the amateur's tool box, i.e. a small tenon saw, a aquare, and a glue pot. A paste-pot will be needed also. The bookbinder uses a small "tub" for this purpose (Fig. 8), a rectangular wooden hox having fixed across it at one end a wooden strip on which to rub out surplus paste from the brush. Glue and paste brushes should be the proper ones made for the purpose. They can be obtained, together with other requirements of the amateur hookbinder, from the firms which specialise in these goods

Since the cutting of book edges presents some difficulty to the amateur, and is done by machinery in a fraction of the time taken by the old-fashioned method, it is suggested that the local bookbinder be asked to trim the edges of any hooks which require this treatment. If this course is adopted the annateur will not need the tool called a plough, which is used, in conjunction with the laying press (Fig. 8), to cut book edges by hand.

We will commence with a oloth bound book which has come out of its cover, and is otherwise in fairly good order. Dealing first with the cover, remove any loose portions of the end papers and any hard glue adhering to the back. If the cornera have been "teleacoped ' they can be carefully hammered out flat. The back of the case may be repaired with pieces of binding cloth of the same sort and colour as the original. Should the back be damaged beyond repair, a new back may be made from a strip of cloth. The new back must be cut wide enough to allow an overlap on each side, which is glued and pressed between the edge of the old cover and the board.

The edge of the old cover fabric must be rubbed down with a bone folder to make a close joint, and the case can then be put aside in a press, or under a weightcd board, to dry. An old oopying press, often to be picked up cheaply, would be very useful to the worker.

A new case is ensily made, the old one serving as a gauge for size. If the old boarda are

Bookblading. Fir. 8. Laying press, showing ploarb for cutidin book edres; (above), paste tub
usable, the measurements of the case should be observed before stripping, and a piece of binder's cloth cut to the size, allowing an overlap all round for turning in. If new boards are necessary, strawboard of the appropriate thickness should be obtained and carefully cut to size with a sharp knife and a metal straight-edge. A piece of stiff paper is glued to the back, leaving a space between the hoards and paper strip. Fig. 2 will make this clear.
The cloth is glued out and left for a minute, when the left-hand board, $A$, is placed on it, leaving the correct margin for turn-in. The manilla strip, $B$, is then placed on the cloth, and finally the right-hand board, C. The positions might be marked on the cloth by pencil lines before glueing. Turn in the edges, rubbing the cloth down with the folder. It will be noted that the point of the board comes a little within the diagonal edge of the cloth, just leaving a little cloth to form a fold when the edges are turned over the board.

Bookbinding. Fig. 1. New end papers, A and B. Gpped on to the frat section. Fig. 2. Making a new Backing board. Fig. © Cuting board. Fir. $\boldsymbol{\theta}$. Book alter backing Fig. 7 . Bow book ts rounded

The cover is then turned right side up and the whole surface rubbed down well with the folder. If the glue is hot and in proper condition there will be a smooth surface and no bubbles.
The book itself must now be dealt with New end papers will be needed, and perhaps the atrip of mull which held the back to the covers has come away. The mull may be pulled off and replaced by another atrip, but if the sections are loose or some of the stitches are broken, this must be attended to first. The sections of a book are sewn through the fold from the centre, each section being also caught to the next. Ordinary hooks are machine sewn, the better-class work being sewn to tnpes or cords. The methods adopted for hand-sewing books are shown in Figs. at and 10. The latter explains the process of sewing on tapes.

Make new end papers by cutting a sheet of stout white paper twice the size of the book page and folding it in the middle (Fig. 1, A, B). This is pasted at the fold and tipped on to the first section of the book. The end papers for the final section are made and fixed in a similar way. Any torn leaves in the book may be mended with paper resembling that of the original. The old end leaves will furnish paper for patching or mending, and gummed transparent mending paper may be utilised. Loose plates should be tipped with paste and carefully replaced.

Book binding. Fig. 9. Sewing press, slowing the
method of sewing on cords. Path of needie indicsted on cords. Path
by dotted line
After any loose sections have been dealt with, and new end papers attached, the back should be glued up. Place the book in the press between boards, and work thin glue well into the back. When the glue is dry, but not hard, the book may be rounded Fig. 7 shows how this is done. Place the book Hat on the bench, front edge towards you. With the four fingers of the left hand stretched across the side and the thumb pressed into the front edge, pull the thumb and fingers towards each other, at the same time hammering the back of the book towards you. Turn the hook over and repeat the hammering. This will force the sections forward on each side, and the book will now be perfectly flat with a round back, instead of being wedge-shaped with a flat back as when first sewn (Fig. 11). The threade used for sewing do not now fall exactly over one another, and the increased thickness or sewing swell is thus reduced (Fig. 10). (These illustrations show a book which has been sewn on cords. In good class work the ends of the cords are laced through holes in the boards of the cover. The cloth or leather cover is then made on the book itself.)

Place the book between backing boards in the laying press back outwards. The top of the backing boards should be ahout the same diatance away from the back edge of the book as the thickness of the cover boards (Fig. 3). Sorew up tightly and hammer outwards ! rom the centre to form a groove into which the oover boards will fit. Care inust be taken to kecp the round true, as near as possible the third of a circle (Fig. 6).

If the back of the book was in fairly good onder it will not have been neccssary to re-sew
soctions or to round and back the book. Glue and bring the cover over on to the book with up the back and line it with stout paper, the lcft hand, watching meanwhile to see rubbing down the lining after a while with a that the margins are even and equal to those

Bookbinding. Fir. 10. Sewing on tapes ; path of needle shown by dotted line. Fig. 11 . Book sown on cords, showing catch stitch betwoen sections: Loft, after sewing; right. baok ronnded. Fig. 18. Wethod of overcasting singio loaves
folder. When dry, glue up again and place on of the front cover. The book must be placed the back a strip of mull about $1 \frac{1}{2} \mathrm{in}$. wider botween pressing boards and left overnight than the back, leaving unglued the overlapping portion, which is pasted down to the covers when casing in the book. The book is then placed aside to dry.

To insert the book into its cover, the front end paper, together with the overlapping portion of the strip of mull, should be evenly coated with thick paste and the book laid carefully on to the cover, seeing that the "squares" (margins) are equal on head, tail and fore-edge. Next paste the other eug. (back) end leaf, which will now be uppermost, the illustration of a sewing frame (Fig. 9) a and leave it for a minute. Then hold the section is shown boing sewn to cords, a method book with the right hand between its leaves, adopted for better-class work.

## BOOKCASES AND BOOKSHELVES

## Fittings to Make or Buy for House or Flat

Here is shown how accommodation for the books of the household can be provided at small cost. For information on the Carpentry details involved see Cabinet Making; Jolnt: Mortise: Tenon; Wood, etc.

The shape and size of a bookcase nust vary painted to suit the woodwork of the room or according to the space available for its accommodation. Those most usual in houses of moderate dimensions are made to fit the recesses on each side of a fireplace, or to reat against a wall. They should havo the advan. tage of light, without the disadvantages of st rong sunlight or appreciable heat from coal or gas fire or hot-water pipes. The golden rule is to make the bookcase for the books. Any ornament should be of the simplest kind, and the shelves should be movable, so that the books can be placed upon thent according to their size.
Sectional bookcases on the unit system are useful in this respect, and possess the adven. tage of being easily moved and added to. On the other hand, their appearance is not so deonrative for a drawing-room or in associstion with period furniture as shelves well placed in niches or recesses, or bookcases of the Chippendale style (q.v.). Space saving is so necessary in many homes that bookshelves are often added to built-in corner seats, above the padded backs; or low book. cases form separate and yet composite parts of a divan sofa, made in threo seotions, with upholstered centre and the two-shelved book. cases at either end,

Bookcase. Fig. 1 (above). Bookcase
cabinot made to fit in recess. Fig. 2 (risbt). Front elevation, section and pian
made in oak, walnut or mahogany.
The total height of the bookcase shown in Fig. 1 is 4 ft .3 in ., the width 2 ft .10 in ., sud the depth $10 \frac{1}{\mathrm{i}} \mathrm{in}$. The bookcase portion has three spaces, and will hold from fio to 70 volumes of crown 8vo or deiny 8 vo size. Fur living-room bookcase oak will look best, or American whitewood will serve if it is tained to the colour of one of the hardwoods.
The cnds, Fig. 2 (A), niay finish $z$ in. thick. The

- Manc
upper part is cut back with a sinuple shaping, and the lower parts may be shaped as indicated if the cabinet is not to stand in a recess. Both ends aro dovetail-grooved to take the cupboard top and bottons, the gronves being stopped about fin. from the front odge in order that the joint will be hidden. The back edges may bre rohated for the upper and luwer backs

The cupboard bottonı ( $B$ ) and top ( $C$ ). likic the ends, should finish $\frac{7}{} \mathrm{in}$. thick. They are dovetail-housed to the ends, and the front edges will be cut back to correspond with the stopped grooves. At front the edges are Hush with those of the ends. The back (D) is indicated as three-ply, but may be matched or framed according to the use to which the cupboard portion is to be put. The shaped rail (E) below the cupboard bottoni

|  | Long In. | Whide In. | $\begin{gathered} \text { Thick } \\ \text { inl. } \end{gathered}$ |

| $2 \text { shelf brackets ( } R \text { ) }$ | 5 | 2 |  |
| Panel mould (If used-s) | 72 | 1 |  |

stands back about so in. It may be dowelled on, or giued with angle blocks behind.

The upper shelf ( $F$ ) is shaped as shown in the plan, and is plain housed to the ends. If the upper back ( $G$ ) is made in two parts the shelf may be cut $\frac{1}{2} \mathrm{in}$. wider than shown, in order that it may go right to the back. The small brackets ( $R$ ) stand in $\%$ in., and are fixed with small glued blocks.
(In the section the upper back ( $G$ ) is shown in one pieco. If preferred, it may be in two parts, the upper portion being dowelled to the shelf ( $F$ ). If in one piece, or if jointed (the joint ooniing behind the shelf), $\frac{1}{f}$ in. wood may be used. In this case, H is a $\frac{1}{\mathrm{t}} \mathrm{in}$. pilaster, planted ont, and JJ are two moulded slips, $1 \frac{\mathrm{in}}{} \mathrm{i}$ wide by $t \mathrm{in}$. thick, planted on to form a kind of plinth. If it is preferred to have the upper back divided, the wide portion between the shelves might be (a)
 franted up with a long mirror, or (b) framed to form two panels as in. dicated, or (c) it might be a solid board with a small mould ( S ) pinned on to form panels. The ends, which are $5 \frac{1}{2} \mathrm{in}$. wide at the top, are rounded off to tho section shown.
The doors (M) and N) should not be made till the carcase is otherwise com. plete. They are framed up of stiles and rails 2 in . by $\frac{7}{8} \mathrm{in}$. and are shown without a mould. The astragal (0) should be quite plain if the doors are made to the section shown. Insideshelves ( P ) are ${ }_{3}$ in. thick, and may be hung on fillets or on studs.

In the cutting list given un page 119 the lengths and widths allow for joints and paring, but all thicknesses are net. If the upper back $(G)$ is cut in two pieces, the lower one will be 10 in . wide and the upper one $2 \frac{1}{2} \mathrm{in}$.

Making a Set of Bookshelves. A set of book shelves which are suitable lor a narrow recens at the side of a fireplace, or the return corner of a room at the window end, is shown in Fig. 3. The addition of a small cupboard helow adds to its usefulness. Additional wide shelves may replace this, if desirod If other furniture has to be matched, oak or other hardwood may be used, but for ordinary purposes American whitewood will do.

The cutting list is as follows, lengths given allowing for joints, but all thicknesses are net.

Buck (matched) about 15 ft . super.
The sizes given on the scale drawings in Fig. 4 are necessarily suggestive. A carcase width of 2 ft .6 in . is useful for the narrow recess, but this could be slightly increased or reduced to suit requirements.
The uprights (about 6 ft . 2 in . long) are $s$ in. in width. Dut widened by glue-jointing to

the amsteus wood worter ? in. thick, with or without a mould. The shaping, also of canary woorl. if in. thick. inside clupboard shelf, fixed or adjustable, is screwed in position from top of cornice boart will act as a door-stop.

When shelves have to be fitted into a recess, and no screws or nails may be driven into the wall, a good plan is to provide two uprights of Hat board as wide as the shelves, onc for each side, or alternatively two narrow uprights, about 3 in . by 1 in ., for 9 in . wide shelves, for each end. If the shelves are not to be adjustable for distance apart, it only remains to cut grooves in the uprights at the desired levels. An alternative method, avoiding the need of wedging between the wall and the upright, is to cut two or more shelves so that they have projecting ends that pass through slots cut in the uprights for that purpose. These are then secured with wedges driven through alots in the projecting ends of the shelves.

Assemble thc parts as follows: Glue to the grooyes which are cut in the ends, and fix in the three shelves: glue, nail, and screw the cornice board, and allow the glue to harden ; cut the shaped piece, and glue and sorew it to the cornice board. If the screws be put in from the topof the cornice, the method of fixing in the shaping will be concealed from view. Three coats of suitably coloured enamel will make a good finish

Ends, ehelves and cornice board are of canary wood, 7 in. thick; they sliould be kept as thick as pussible but planed out of winding. The

11 in. for the lower part. The added portions are shaped at the top, and at the extrene top of the uprights a little piece is glued on to give a break. The uprights should be dove-tail-housed to the top, shown 9 in . wide.

The cupboard bottom and top and the top shelf should be dovetail-housed to the uprighte,

the hollsing being stopped in each case to mask the joint. The other shelves may be housed, or fitted on fillets or secured in position with bookcase pins. The shaped rails below the bookcase top and the cupboard bottom may be glued on with angle blocks behind. The
dours are framed of material 2 in . wide by

Fig. 5 shows a hanging bookshelf. The shaped part of the ends shown in the elevation is cut out with a bow saw and carefully cleaned up to a smooth finish. The ends are then marked out, and the dovetail grooves cut so as to receive the ends of the shelves, which are cut as at C (Fig. 6).
The front and ends of the cornice board should have their edges moulded, as shown at A or 13. The moulding at $\mathbf{A}$ is worked with a moulding plane, but those who do not possess a suitable tool could easily cut the moulding shown at $B$, which would be alnost as effective. The shape cut at $B$ would be worked as follows: Mark the work as deeply as possible with a cutting gauge, and plane roughly to aliape with a jack plane ; then work away the square or fillet with a tenon saw and chisel, pare up, and glasspaper to a finish. It will greatly facilitate the working of the moulding if the glasspaper is wrapped round a small piece of wood about 21 in . long by 1 in . by 1 in .: there will then be little or no tendency to ruh he flat or chamfered portion of the moulding out of shape.
with 3 screws, 11 in . long by 10 or 8 gauge. The cornice board is fastened to the ends with 4 screws 2 in. by 10 gauge and 4 oval nails. 2 in . long. To fix the bookshelf to the wall, 3 brass ear plates are required; ¿2 ear plates are fastened to the cornice board and I to the centre of the bottom shelf.
Movable Shelves and Portable Shelving. When a large number of books is to be provided for, and perhaps the whole side of a room will be taken up with the shelving, the system described below is suitable. The sides and any intermediate uprights are I\} in. by 8 in . or 9 in . boards, and the shelves are 1 in . thick. Oak is very suitable for the purpose. A pair of uprights are connected by a base at the bottom and a comice at the top, these being of the length selected for the shelves.

Bookaase built ap on the unit system from bozes with and withont doors, made by Venesta, Ltd.

Bookcase. Sef of shelves, so constructed that each shelf can be adjustej to the height of the volumes it is intended to bear Courtesy of Counsril Life, Lid Angle bracketa and screws are used to fasten he pasted inside the cover of a book to mark them to the uprights. Slotted brackets can be its ownership, a book plate may be specially obtained which permit the removal of the base designed and an elaborate production blazoned or cornice by just slacking off the screws, with cont of arms or some fanciful design, or a which need not be entirely unacreverl. Two simple form with the owner's name. The grooves are ploughed in each upright to take earlieat existing examples date from the narrow metal strips (Fig. 7) picrced with rect- early l6th century, and these, as well as angular holes about an inch apart. The atrip fine sjecimens of workmanship of the 17th lies in the groove flush with the face of the wood, and is secured by screws. and 18th centuries, are collected by some peoplc as a hohby.
The shelves are supported on steel studs which fit into the holes in the strip. The strips are sold in lengths of 6 ft., but can be had in special lengthe at a little extra cost. Iron brackets from 2 in . to 6 in. wide are also made for use with the bookcase strip (Fig. 9). In making up shelving on this system it is imperative that the strips on each of the uprights shonld be the same height from the floor line. Intermediatc "prights willb

Book Rest. Fir. 1. Tilted book rest suitable for a stody table or writinn-desk. Fig. 2. Front aspect. Fin. 3. End of book rest inlaid with black and white check pattern the squares indicated represent each hati inch

## BOOK REST : How to Make. A book rest

 or book rack differs essentially froin a bookease or bookshelf in that it is mainly used for holding books which are constantly in use. It is gencrally designed so that the books are tilted at a convenient anglo for quick selection.The book rack shown in Fig. I, which is made with two ends, a back and n botton, could be carried out in oak, in which case the

Book Table in polished oak. It has sheives on every side and is admirable for the lounge. See below
ends may be inlaid with a black and white patten, as shown at Figs. I and 3. If this plan is adopted, the rack should be fumed fairly dark and waxed, and the inlay could be elony and holly. Mahogany and walnut are alan anitable woods.

The ends, which are $\mathrm{f}_{\mathrm{l}}^{2} \mathrm{in}$. wide by ( i in. high, are cut from $\frac{1}{2}$. material with the grain running from top to hottom. The shape may easily he transferred from Fig. 4, if the squares indicated in the illustration represent each it in. The back and bottom alould he 1 ft . $\overline{5}\} \mathrm{in}$. long, the foriner being 6 in . wide, and the latter 4 in ., while a thickneas of $\frac{1}{} \mathrm{in}$. will be found sufficient. The back and hottom are simply housed $f$ in. into the ends in the positions indicated at Fig. 4. The joints are cut to fit fairly tight, and are glued.

BOOK TABLE. This space-saving piece of furniture takes the place of $n$ revolving hookcase. having shelves on every side to accommodate looks and periodicals in use, and is also a convenient occasional table. It has the advantage of being solidly made and perfectly atcady for a reading lamp or tray of glasses, etc. See illustration above.

## Boots: Useful Hints on Choosing

## How to Recognize Good Footwear and to Preserve it in Use

Related articles are those on Boot Polish; Boot Repairing; and Leather. Sec also Brown Boots
When buying a pair of boots, to the casual the vamp or golosh, the perfect insertion and eve the chenper boot, nicely treed up, well stnetched to take out all creases, and then care. fully polished, will not present much difference from one at perhaps double the price ; but close inspection will reveal the greater smoothness or velvety feel of the grain if of a high grade hox-calf, which will lo found to give greater satisfaction in wear, and to retain its appearance longer than the cheaper bont made from a lover quality coarser skin, or perhaps from box-hide, which can usually be recognized by the absence of grain marking, and the harsher surface when the hand is passed over it making it more liable to crack in wear. The higher giade box-calf has distinot grain markings and is beautifully supple.

The tinish of the boot should also he regarded, the neatness of the closing of the uppers, the exact regularity of the atitching to
alinement of the eyelets, and, alove all, the quality of the leather of which the tongue is made and the wry it is attached to the inside of the opening. A cheap bont often reveala itself in the tonguc, being of very poor, rongh stuff carelessly fastened into the inside of the front.

The lining of the linot sliould be examinel. and, whether of linen or leather, this should fit without wrinkles. Then the fingers should be passed down towards the toe. If there is a crease in the toe, where the lining has been hadly lastod, and this is quite a common fault in a cheaj, boot or shoe, it will cause constant trouble in wear from the first day. The lnoseness of the lining will form a hard ridge, which will rub) hlisters across the toes. At the heel, the fit of the stiffener inside shoull be noted. If on passing the fingers downward the
adge of the stifiener is plainly to be felt, then it can usually be anticipated that the friction of the wearer's heel will rub a hole in the back lining very quickly, and a blistered heel will probably result

If all these points are satisfactory and the boot fits closely to the foo: when the wearer stands up and puta his weight upon it, without painful compression of the big.toe joint or cramping of the toes, then, whet her the bonts ara chrap or expensive, it may rafely lie assumed that comfortable wear will result, and as much durability as tho purchaser has a right to expect.

In buying patent leather shocs it is well to choose the best, although even the best patentcolt or patent-calf cannot be relied upon to wear without cracking in spite of many attempts to produce a patent leather that will not crack; but cheap patent, which is often not leather at all, but Amcrican cloth, is certain to become cracked in wear and quickly to lose its smart appearance. It is all the more important, therefore, to see that the finish of the inside of the shoe is all that it ought to tro.

Owing to the hard cnamil surface patent shoes will not stretch in the least degree. They are also nirtight. When the foot becomes warm and siwollen there is no possibility of the shoe stretching, and thus the liot foot, prevented from swalling, becomes cramped and still hotter through lack of ventilation which ordinary leather afords

A glacé kid boot is sometimes made with a patent leather cap, and to preserve the surface of the patent this cap is rendered unbrakable with a toe-puff or case of hard leather, atifiened canvas, or compressed libre inside This looks amart at lirst, but in wear the Hexible glacé has a tendency to crease in the same place every time the foot is bent, exactly where the atiff toe-cap finishea, and very quickly an unsightly crack develops.

## Leather which is Waterprool

In regard to the soles, it is difficult to tell the quality of leather used, as the leather is scraped, and what is called fake applied to it, cither black or brown. This applies to vegetable tanned leather. Chrome tanned sole leather can be diatinguished as it is aluays left in its natural green colour. This leather is absolutely waterproof, and in the best tannages is far more durable in wear than even the best quality oakhark-tanned. While clirome is watertight, it is also airtight, and is not recommended if the wearer has hot feet.

It will be found the truest economy to have two or three pairs of boots in use at the same time. After being worn for a day, the boots should be placed on a pair of trees. If wet, they should not, in any circumstances, be placed "ear a fire, hut should be laid on their sides in a dry place, and not with the sole to the floor, so that the wet sole can dry in the air. When boots have been thoroughly soaked, an cxcellent plan for drying them before putting on the trees is to fill them with sawdust that has been well dried. This absorbs any moisture that may have soaked through ; and if the sawdust is tightly packed, it swells as it absorbs the moisture and keeps the uppers nicely stretched as they dry. When the boots aro dry the sawduat can be shaken out, and after being dried in the oven, this can be kept for further use.

The boota should then be placed on the trees and well polished. The uppers of wax-calf or kip should be treated with dubbin in wet weather, and chrome uppers can be treated with a dresaing of glycerine. This will help to reast the damp, or if it is not applied until after the wet boots have been dricd, will keep them supple. Before being polished, either with wax polish or other suitable blacking, according to the character of the upper leather, the surface grease ahould be carefully wiped off
or a good shine will not be obtained. Wet soles will be lound to dry hard and present a shrivelled appearance. An applicntion of glycerine well rubbed in will not only restore the nature of the leather, but will render the soles more watertight when again worn, and prolong their life.

A hot water pipe has ruined more good boots than the wearers have ever dreamed of, the subsequent rapid deterioration of the boot being attributed to poor quality leather or faulty workmanahip. Leather scorches and perishes if aubjected to heat. The damage is not noticed at the time; but when the boots aro again worn, the perished brittle leather cracks and crumbles away.

## How to Determine the Fit

The fit of the broot is determined across the joint over the crown and the arch of the inatep and the heel. From the joint backward the bont should fit snugly like a well-fitting glove. but there must be plenty of room for the toes, There must be no looseness in the heel, but this will be kept quite snug by the fit of the joint. There can be no greater mistake than to have the thes fitted. The icleal is close heel, well-fitting joint and instep, and leave the toes plenty of room to look after themselves. In walking the weight of the body is put on to the foot, and is transferred to the toes as the heel leaves the ground. If there is no room for the thes to apread naturally under this transference of weight, the result is cramp, discomfort, and pain, with eventual corns and foot trouble generally.
Leather improves with keoping, and it is a good plan to buy boots several months beforo they are uom. They should be atored in a dry cupboard and occasionally cleaned. A little vaseline round the edges of the soles from time to time will add to the durability. A varnish dreasing which produces a shine without rubbing or brushing is injurious to the leather. Polish cannot penetrate when applied over such a varnish, and polish, which helps to preserve the leather, cannot do so unless it penetrates it. When shoes are varnished it makes them impervinus to the perspiration of the foot, which is absorbod into the leather itself and gradually rots it.

Chrome upper boots or shoes (box-calf, willow-calf, dull chrome, glacé kid) should never be cleaned when damp. The best makes of polish only should be used. Vegetable tanned upicra, wax calf, waxed kip or split, such as farm boots, etc., inay be kept soft by rubbing in nightly dubbin, neat'sfoot oil, or tallow.

BOOT BRUSE. Owing to the improvementa effected in leather polishing prepara. tions the old method of boot.cleaning has in inany liomes completely disappeared; but for preparatory cleaning from dust or mud the boot or shoe brush is still a necessity. Pure bristle is the cheapest outlay. If fibre is used in a mixture it will soon break, and horse-hair will not last so long in hard wear. The butt or ront end of the bristle supplies what is needed for the reliable hard bruah, and the bright, needlo-like stiffness of these knots should be looked for. They can alan be obtained with a row of knots set in the end of the atock to brush out the welts. For blacking with oil or water blacking, or applying polish, a softer quality is required.

The polishing brush should be of merlium stiffness wherc

Bootes knitted according to the directions given in this article
blacking is used, and a softer one will give the right finish after applying polish. Ses Blacking : Boot: Boot Rack: Brown Boots; Brush.

BOOT BRUSE BOR. For those who use both black and brown boota the box shown in lig. 1 will prove serviceable. The sizes given are approximate for an average size brush and pad, and the usual small tins of polish.

The partitions provide for brusheg in the centre, and black or brown polish and pard on cither side. The sides can be housed and nailetl and the holes atopped; or, in a rougher faahion, the parts can be nailed toget her.

Boot Brash Box. Fig. 1 (above). Box holding cleaning apparatoi lor both black and brown boots. Pig. 2 (below). Detaila showing how the boz, with ite partitiong, is made

The partitions can be of $t$-in. thickness, baing plain-grooved into position, as indicated at Fig. 2. These parts should be secured in position with just a touch of glue. The gronves ars aquared and the sid?a cut with the tenon saw, the core being removed with a $\downarrow$-in. chisel.

The bottom is best cut $\frac{1}{\frac{1}{2}} \mathrm{in}$. Inngef and wider than the sides of the box, so that the edges, when the bottom is screwed on, can project $t \mathrm{in}$. on all sides, to be nestly rounded off for finish. A brass handle is screwed on for lifting purposes. This side of the bnx can be $t$ in. or $\frac{7}{m}$. in thickness, using a 4 in . handle and $1 f$ in. screwa, entered well home. U-shaped openings in the sideq of partitions fronting the amall wells will facilitate the removal of the paste boxes.
BOOTEES: How to Rnit. In choosing wool for a baby's bontoes be sure it $\mathrm{i}_{4}$ of good quality, well shrunk, and soft in texture. They will often be in the wash, si) cheap wool is a mistake, and they miust not be inade too small, or they will stop, circulation instead of rasist. ing, it. In using wool or ribbon tiea, be sure they are not pulled too tight.

The following pattern is simple in plain knitting, and two needles only are use. 1 till just at the finish. The materials required are 1 oz. of well-shrunk 4 -ply fingering in white, pink, or blue, three knitting-needles, No. II). and 1 yd. of narrow ribboa. The ribbing may becontinued
nenrer the ankle by working an additional 8 rows with 30 rows plain linitting.

Cast on 40 stitches. Rib knit 2, purl 2 for 16 rows : then work 38 mws in plain knitting. For the next row-the 55th-linit 2 . wool forwaril. knit 2 togetherto
makc a row mance a row
of holes, and repert this till the end of the row. Knit 2 rows in plain knitting. Then begin the instep of the foot as follows: Knit 14. then knit backwards and lorwards on the next 12 stitches. for 34 rows Break off the wool (fastening the end firmly) and leave these stitches on a needle or safety-pin.

Begin again with the 14 stitches on the left of the ankle, picking up the 17 stitches along the side of the instep piece just finished, and 6 of the stitches left on the safetypin. Take another needle and knit on the other 6 stitches across the toe, the 17 stitches on the wher side of the instej, and the 14 stitches at the ankle. Knit backwards and forwards, using the three ncedles for 14 rows, without shaping. Then work 6 rows, decreasing once at the beginning and end of each nedde. Cast off.

Sew up the seam neatly, threading the ribbon through the holes at the ankle. See Bahy.

BOOT LACE. East India kip provides the leather for laces used with heavy brots. Mohair laces are usually a mixture of wool and cotton. The leather huckle lace worn with golf and other sporting shucs consists of a thin strap of leather inserted through the eyelets of the shoe, and fastened by means of a nickel. or other metal buckle inatead of being tied.
BOOTPOLISH. Wax polishes arc coloured with aniline dyes, black or brown as required. The surface obtained on the hoot must not be sticky, hence a very hard wax, known as carnaubia wax, is employed.
The wax is boiled with borax or sodla to form an emulsion, and this is mixed with a hot

## Boot Repairing in the Home

## Essential Processes Simply Described

Readers may usefully turn to the preceding article on Boot, in which hints are given on the
selection and carc of footwear. See also Clog
Most hoots and shoes in ordinary wear to hammer, with one head; a couple of shoedny are either welted, where the outer sole is maker's knives, one ground right down to a stitched through the edge to a welt sewn round small triangular hlade, which will be found the the edge of the upper, or machine-sewn, where the outer sole is sewn through to the inside of the boot by stitches going right through the sole substance. The outer soles may also be attached by riveting, hy thin wire screws or, less fiequently nowadays, by wooden pegs. Of these, all may be repaired by riveting on a new sole, although in the case of welted hoots it is preferable that it should be stitched on. With machine-sewn boots, a sewn sole makes a better repair, but it is quite adaptable for riveted repairs, as described in this article, the only method practicable for the average home worker.
The essential tools are a shoemaker's
solution of soap coloured with nigrosin (an
aniline black). Boort dressings in liguid form. used for ladies kid shoes, contain shellac, which has been dissolved in borax or soda solution. If soap is added a dull finish is given in place of the glose of the plain shellac dressing. See Blacking: Boot.
BOOT RACK. A folding rack is shown in Fig 1. It is made with a back and two folding frames, and in the size shown is capable of holding eight pairs of ladies' or six pairs of gentlemen's hoots. If a larger rack is desired the length of the rail inay be extended or height of rack inercased. To make it, 4 ft .6 in . of
 8 ft 1 in . of 3 in . round material nust be arranged for. The 3 in . material is cut into two 2 ft .3 in . lengths. the 11 in . into thrce 2 ft .2 in ., and four 1 ft ., and the $\boldsymbol{z}^{2}$ in. into four 2 ft . $\frac{1}{\mathrm{in}}$. lengths.

Boot Rack. Fig. 1. Dgeful rack made to fold againgt the wall when not in use. Fizs. 2-8. Diagrams showing details of construction By arrangement with Exans Bros., London

For the back take the two 2 ft . 3 in. lengths of 3 in . material for the sides, and the thrce 2 ft .2 in . lengths of $1!\frac{\mathrm{in} \text {. for the rails. }}{2}$ Dovetail the two front rails into the front edges of the sides, and the back rail into the back edges, in the positions at Fig. .2. The ends of the sides are shaped as at Fig. 3, and hanging holes are bored.
The two folding frames are exactly similar. For each take two of the 1 ft . by $1 \frac{1}{2} \mathrm{in}$. pieces for the sides, and two of the round pieces for the rails. The frames are made to the dimensions shown at Fig. 4 by shouldering down the ends of the rails to $\frac{1}{2} \mathrm{in}$. diameter, for a lengtlı of 3 in., and boring holes in the sides into which the shouldered portions of the rails may fit.

The frames are fitted to the hack with rivets or round head screws, as at Figs. 3 and 6. The frames when extended rest on the cilges of the front rails of the back, as at Fig. 3. A coat of stain or varnish will be necessary as a finish.
most handy for cutting off the worn sole of a
welted or sewn hoot; a shocmaker's rasp, rounded on one side and with a Hat file surface on the other; a straight awl, sandpaper (No. 1 $\frac{1}{2}$ ), a glazing iron, the most convenient shape to use being the combination iron. Ilso shoemaker's ink, heelhall, and the indispensable rivet. The rivets will he of the length most suited to the joh in hand, and should he preferahly brass, except in cases where a double row of rivets is fixed to take wear, when iron should be used.

An iron foot or last is necessary. This can either be attached to a shaft in an iron socket fixcd to a bench, or, where repairing is only
an occesional job, an iron foot fixed in a wooden stick or "leg" resting on the lloor may ber used. Several sizes of iron feet will be required for men's, women's, and children's hoots, and these will be interchangcable in the same wonden leg.
leather can ho purchased ready shaped up in soles and top-pieces, or it can be hought by the piece. Siclect a piece with cren, smooth grain and equal substance. The flesh side should not be loose, but should be firm and hard. If a pattern ot the sole to le replaced is taken in paber (Fig. 1), this can casily lre applied to the piece of leather chosen and waste avoided.
The pattern is made by placing a piece of newspaper flat on the sole of one of the bonis with the edge across the waist where the graft is to lic, and passing the tile side of the rasp, downwards round the edge of the sole, leaving the exact shape of the sole filed out In cutting the soles from the picce of leather, take eare to turn the pattern over when cutting the second sole. Temper the leather by atcep. ing it in a pan of cold water for 5 or 10 nim. Then take it out, bending and twisting it in the fingers until the superlluous surface moisture is absorhed and the lenther is mellow.
When the leather is fairly dry but still moist and plastic, place it grain downwards on the lap-iron-an old flat-iron minus the handleheld on the knees, and strike it firmly and evenly with the Hat head of the hainmer, commencing in the middle and working out to the ciges. The strokes should not be tor vigorous or the fibres will be crushed. This hammering makes the leather tougher and closes up the pores, making it more waterproof and more durable in wear.
Now take the hoot to he repaired, and, after damping the bottom and placing on the foot, take off the old sole. The little pointed knife is inserted in the joint at about the spot where the new sole will join the old, and the stitches cut through to the corresponding point on the other sidc. In Fig. 2 a machine-scwn boot is shown, and the same method will apply to ripping a welted boot. If the old hoot has a nailed sole, the toe should be prized up by inserting a screwdriver or blunt old chisel and the toe end of the sole seized in the nippers and levered hack, the middle sole heing held down firmly with the other hand meanwhile. The old sole should be cut off actuss the joint with a slanting cut, leaving a longer length of waistline on the old sole on the inside than on the out (Fig. 3).

## Repairins the Midde Sole

Before procecding further the middle sole should he made good. If the hoot is wom so hadly that pait of the middle sole has heen worn through, a thin patch should be placed over the worn spot with a couple of short rivets tapped in to keep it in place. Boots should never be allowed to wear through the middle sole hefore heing repaired. It may he found that in ripping a riveted sole the middle sole has been pulled away from the inner sole. This should be knocked down and half a do\%en rivets put in These should be just long enough to penetrate the inner sole and hurr over on the iron foot, but not long enough to turn over appreciably. They should be hammered well home.
Having made all secure, take the new sole and, placing it in prosition on the atripped hottom, with the back of the knife mark $n$ line ncross the old waist where the groove or skived hollow for the end of the new sole is to start. (Fig. 4). Skive out on the old waist from this line, tapering towards the joint cut (Fig. 5). Now skive off on the flesh side of the waist end of the new sole, tapering towards the joint, but not too finely or suflicient substance will not be left to hold the waist rivets securely (Fig. 6). Place the new sole in position and, holding firmly, make a row of holes from side

Boot Repairing. Figs. 1-9. Illustrations of the various stages of soleing and heeling a pair of boots. the correct method of dolng which is described in the accompanging article
to get worn through, is a worn-over heel destroys the shape and appearance of the boot, in aldition to putting in undue strain upon the boot upper at the heel But if the second lift is worr, then a cut should be made acruss the heel, so that the worn part can be prized off and a new half-lift nailed on (Fige. 8 and! !).
Trim off and, after taking out any protruding mails or hammering down, rivet on the top piece. To mecure this. 3 in . rivets should he used, and then a double row of shorter rirets to take the tread (Fig. 10).

Sole and heel are now ready to he finished off. The first process, supposing the edges to have been closely trimmed up with the knife, is rasping. This is effecterl with the round side of the rasp, and gives the edge a slightly hollowed shape (Fig. 11), which is accentuated with the round edge of the huffing knife (Fig. 12).

The heads of the rivets on the sole should be rubbed over with the llat side of the rasp. If it is desired to finish the joint in a workmanlike manner, the upstanding edge of the new sole can be skived olf with the knife, the surface at the joint rasped, and then the whole surface of the aole 8an be buffed and linished off with sand paper.

The edges of the sole are now finished off with sandpaper and inked. When this is dry we proceed to the operation of setting the edge or polishing. For this the combination iron will be found most convenient. Fig. 13 shows this tool with its difierent fnces, A, B, C. First the inked edge, having been allowed to dry, is ironed, and then a thin coating of heelball is applied, and the iron, warmed up but not made too hot, distributes the heelliall evenly over the surface. Firn, even pressure with a quick motion will produce a amooth, shiny surface, and then, to finish off, the superfuous heelball is taken off, and a final polish applied with a piece of cloth, which is folded acrors the thumb. Figs. 14 and 15 illuatrate the method of holding the iron, and show the differentedges that are emploved for sole and heel.

BOOT SCRAPER. A bout scraper saves dirt and mud being hrought into the house, and one aimilar to that shown in Fig. 1 can easily be made. The soraper is constructed
to side near the joint, but not ton near. The first rivet is knocked in on the side (Fig. 7), and the row of rivets in now finished across the waist.

After nailing the waist, press the fingers across sole, hammer from waist to toe, and, holding down firmly, drive in a rivet in the centre of the fore part quite near the toe. The new sole should now be lying snug on the middle sole, and the edges of the sole should the pared close, care being taken not to cut the edge of the middle sole.

A line is now drawn about ${ }^{3}$ in. from the outer edge all round the sole. This can be done with the thumhnail, using the first finger as a guide on the edge of the sole. Now with the awl make the holes for the riveta at equal distances all round, not too far apart, taking care to hold the awl perfectly upright.

When some degree of expertness is attained in driving the rivets, the bole-pricking may be dispensed with, the rivet being pressed into the leather (which should be still sufficiently moist and plastic to enable this to be done) with the left hand, as if placing in the hole made by the awl, and then one smart tap should drive it home. After the whole row has been completed, the edge of the sole should be well hammered all round in order to drive the rivets liome

Before finishing the edge, the heel may he taken in hand. The corner of the top piece should be prized up and seized with the nippers, and the top piece pulled off, the boot being held firmly on the foot with the left band. The second lift should never he allowed

Boot Repairing. Figs. 10-15. Concluding stages In soleing and heeling a pair of boots, showing how the heels and soles should be fnished of with a rasp and sandpaper and Anally burnished
with a wooden framework consisting of two sides and a bottom bar, and is fitted with a scraping iron at the top.

Theside lours of the framework are 103in. long by 2 in . wide by 1 in. thick, and slots $\frac{1}{10}$ in. wide are cut $\frac{1}{2}$ in. in from the top ends. The loottom har is 12 in .
long by 2 in wide by 1 in . thick. Notches 1 in wide by $f$ in deepare cut in the upper face of the bottom bar to receive the bottom ends of the side hars.

Boot Scraper. Firs. 1 and 2. Simple
scraper and method of fixing jit
The scraping iron slould be 12 in . long by 2 in. wide by $\mathrm{I}^{3}$ in thick: the top corners are rounded, and ${ }^{3} \sigma$ in. holes are bored wt the ends. The ion fits into the slots at the top onds of the side hars, and is fixed with rus $^{\prime}$ in. rivets, which pass through the hars and iron.

Before fixing, at least three conts of good oil paint should be applicd. A hole must be prepared in the ground to receive the framework, the scraper being fixed at the height suggested in Fig. 2. The earth around the Iramework should le well stamped down.

BOOT TREE. There are various patterns of boot trees, and to use them to the best advantage they should conform as nearly as possible to the shape of the boot worn. It would not do, for instance, to put a round-toed tree into a pointed-toed boot, as it would be alnost certain to stretch the toe out of shape. A boot that is treed-up immediately after wearing and left until again required will retain its original shape. See Boot.

BORACIC ACID. One of the inost useful of the mild antireptics is horacic or loric acid. For soothing irritated or painful cyes, one part of boracic acid to forty parts of water is a widely used lotion. Nixed with equal parts of powderd zinc oxide, it is a good dusting powder. For excessive perspiration of the icet, a powder containing one part of boric acid, two of starch, and tiro of zinc oxide, dusted into the socks, gives excellent results. In saturated sohution boracic acill forms a non-irritating, antiseptic Intion excellent for cleansing sorcs.

BORAGE. The flowers and also the aromatic leaver of lorage are ured for flavouring such bever. ages as claret. culp or negus: the leaves and young tops inny be einployed in salads. The flowers are hlue, the leaves oblong and clothed with white hairs, the stems about 2 ft. high, hollow and rough. The plant is lest grown as an annual, sced being sown out

of doors in spring. A foot apart is a suitable distance for the plants, which like a rather dry and stony soil. See Claret Cup: Negus. Pron. Büridge.
BORAX. The white powder known as lorax occurs naturally in Califormia, and has the chemical name of biborate of soda it is much used as a mild antiseptic and as a water softencr. Dissolved in glycerin (1 oz. of purified borax in (6 oz. of glycerin), it is known as glycerin of horax, and is used for thrush and in other forms of sore noouth. Good results have followed the adininistration of horax in cpilepsy.

As a gargle for sore throat the proportion to use is 1 oz . of borax dissolved in a pint of water. As an eycwash 8 grains of borax in 1 oz . of water is the proper strength to employ. Borax ointment, made by mixing 1 oz . of borax with 8 oz of spermaceti ointment, is an exccllent application for chilblains or cracked nipples. For softening water a teaspoonful of borax is added to a civerful of water. the advantage of borax over soda being that horax docs not affect even the most sensitive skin. Borax is no longer used as a food preservative.
BORDEAUX. The wines of Bordeaux contain the least amount of sugar, alcohol, and acid of any, and are not fortified with any spirit. They arc generally divided into four classes, which differ in toste, colour, bouquet, durability, and price. In the first class are
what are known as the Chatenu wines, such ns Châtcau Lafitc, Château Latour, Clîatcau Margaux, and Château Haut Brion
The second class comprises wines such as Rauzan. Beaunc, Mouton, Leoville, La Rose, Pichon, and Longueville. In the third class are wines such as Château d'lssan Poujets, Cantenac and Giscours, In the fourth clase are the clarets. St. Julien, Pauillac, and St Fstephe. See Claret: Grape; Sauterne, etc

BORDEAUX MIXTURE. The most effectire spray for apples and pears is Bordeaux. mixture, and it can he relied on to prevent scab. The Ministry of Agriculture Leallet No. 131 describes its preparation and use in orchards. The best formula is: copper auphatc. 4 lb . : lest quicklime (in lump formi), $4 \mathrm{II}^{2}$. and water, 50 gal. The copper sulphate should be dissolved in a small wooden vessel at the rate of 1 gal . of water per lb . of sulphate. On no account should iron or tin vessels be employed.
The lime slould be slaked to a tine paste with a little water in another vessel, and water added gradually to make a milk, and finally diluted in a large harrel to the requisite amount ( 46 gal .). The 4 gal . of copper aulphate may now be poured slowly into the diluted milk of lime, and the mixture stirred thoroughly during the process. The two solutions may be kept separately for a long time, but after mixing the solution should be used at all events within $2 \&$ hours. See tpple: Pcar.

## Borders: Their Effective Garden Use <br> Choice and Arrangement of Flowers and Plants

In this work the reader will find entries on the various planis and flowers mentioned in

I garden border is, strictly, an cxpanse of soil devoted to the cultum of flowers, fruit or vegctables, which has the shiclter or protection of a wall or fence along one side. Modern usage, however, gives the name to any cxtended Hower bed, e.g. one by the side of a lawn or in front of a shrubbery.

Borders are described as herbaceous, mixed, spring or autumn fowering, according to the nature of their contents. Thi best are those which rely chietly upon perennial subjects for their seasonal beauty. Beautiful herbaceous borders are practicable in almost every garden, provided the site is open and unshaded, and the soil good and of sufficient depth to permit of $n$ leed of friable mould 18 in . to 2 ft . deep. A short, wide border is better than a long and narrow one, as the narrower the border, the more difficult it is to arrange the plants in bold groups. In very narrow borders plants have to be restricted to the small kinds.
In a 6 ft. horder most of the large kinds would have to be left out or used in units, but with n support at the back for climbers or creepers, satisfactory groups of the smaller plants could be formed.

The great majority of hardy herbaceous plants flourish in ordinary well-cultivated soil. Heavy soil needs rough digging and full explosure to weather some weeks before the time comes for planting, which is best done in early autumn or February-March. Let no effort lo spared to get a dcep bed of friahle soil. Decp and thorough hoeing is essential during the growing season. If the border is being made beside a path, the front area should bo levelled and rolled to $n$ width of not less than 2 ft . and turf laid, a strip of well-kept sward forming an admirahle foil for flowers.
In dealing with a single-faced border, one backing a wall, hedge, etc., the planter will work from back to front: but in dealing with a double-fronted horder, he will work from centre to front on two aspects.

If there is no wall, fence, hedge, ctc., shrulis or small trees should be included to provide a
permanent background. This should not be attempied in a horder less than 12 ft . wide bit, insteal. some of the taller, coarser herhaccous pereınials-golden rods, sunflowers, and inulleins, for example, might be used
Thic following is a short sclection of the principal horder plants

Taidi liants for back areas

| Campunula | Golden rod |
| :--- | :--- |
| (pyramidalis) | Hollyhock |
| Delphinlum | Mollein |
| Rellenlun | Concllower |
| Foxglovo | Suntlower |

| Memum plants for Midmle 1 reas |  |
| :---: | :---: |
| Erigeran | Michaclmas dasy |
| Day lily | (small kinds) |
| Gypsophila | Monkshood |
| (paniculata) | Phlox |

| 1 ily. | Spiraca | Lupin

Dwarf Plants for fuont areas

Campanula
Campion
Carnation
Columbine
Corcopsis
Geum
Inula
Monturetia
It has to the remembered that not only must there be liberal spacing between the various groupa, but also between the components of each group.
Rose pillars may lee introduced with good effect. As a rule the best line for them is just hehind the centre, and they nced not he nearer than 12 ft . apart.
In the double-fronted border, the centre will be occupied by hollyhocks, eremuruses, Iarger Nichaelmas daisies, willow herbs, mulleins, delphiniums, golden rods, and other tall or bulky plants, not forgetting the rose pillars. In the half-centre spaces will go phloxes, monkshoods, heleniums, coneflowers, spiraeas, peonies, etc.; while in the front will come day lilies, Japanesc anemones, antirrhinums, columbines, Canterbury bells, coreopsis, geums, pentstemons, cinquefoils,
achilleas, leopard's banes, cvening primroses, heucheras, pyrethrums, and globe flowers The following is a selection of plants suitable for borders only 4 or 5 ft . wide They may be set singly if the border is a short as vell as a narrow one, or grouped in threes if it is of fair length :

Aclillea
Antirrlinum
(intermedlate)
Aubrietin
Campanul:
(persecifolia)
Carnation
Chiristmas rose
Cinquefoil
Columbine
Corenpsis
Crancs bill
Day lily
Evening primrose
ronm thower
Gailardia Grs. Bradshaw)
Goat's licard
Golden drop
Hencliera (xanguinen)
Incarviltea
lnula (olandilobr)
Iris
Jacob's Indder japances ancimone Jerusalem Crioss
Lenpard's bane
(Doronicum)
I.ungwort

Mcadow rue
Montbretia
Pentatemon
Peony
Peruvian lily
Phlox
Plantain lily
Pyrethrum,
scabrous (Scalinosa Caucusica)
Sea lavender
Scdum (spectabile) Stokesia
Tondtlis
Vemnica (longifolia) Wallthower

It should be an aim with the flower gardencr so to dispose his plants that each area of the horder has bloom throughout the season; and to aid him to accomplish this, the most important plants are given in three groups

Early flowfring Haruy planty

| Columbine | Pcony |
| :--- | :--- |
| Gcum1 | Pink |

Sueeze weed
Suntlower

Border Terrier. Prize-winning specimen of this popular breed of dor

To let plants alone year after year is to invite gradual degeneration, and it is an accepted iden that the most rigorous perennials should be divided every two or three years Some take several years to re-establish them selves after being transplanted. Among them arc peonies, perennial poppics, Christmas roses, lupins and others with long, tap-like roots. When such plants are overcrowded it is quite possible carefully to lift portions of growth without disturbing the main roots
Most hardy plants like sunshine, but a fell will succeed in the shade, and some of these are giren in the table lelow:

Wood hyacinth wood lily W゚oodrulf

Border. Herbaceous border in a large garden at Hindhead. Surrey. The clipped bolly bushes make an effective background for the sequence of flowers, those shown being the blossoming of dune

BORDER TERRIER. This is a very interesting breed of terrier and its degree of popularity has cone into line during this last oight or ten vears According to the Eiarl of Lonsdale these terriers have been kept in the licnnela at Lowther Castle for over a century the Border Terrier should weigh nhout sixteen pounds and its colour is either red wheaten, blue and tan or grizzle but the first named colour is certainly the most popular and it is one thint is \&enerally accepted Tho cont should be harsh in texture and close fitting A compact body and straight limbs, with catlike feet are esaentials, whilst the head should be broad in skull, strong in nuzzle and jaws levol, with V-shaped ears The tail should be oarried gaily but never docked. See Dog.

Borecole. This is the name of the rege table more usually called curly kale (q.v.).

BORING: And Boring Tools. Boing is any process for making a hole in wood, metal, or other material, and, strictly speaking, it is a nuachine process Apart from the recognized drilling operations, the tools mostly used for boring include single hand tools, such as the bradaivl and gimlet, doublehand tools such as the brace and bit, and the regulation wood-boring machine. This last consiats of a wooden or metal base, with an angularly adjustable upright member carrying a spindle, rotatahle lig means of bevel gears nnd two crank han dles. The tool is usuallyan anger bit and fed intothe work by means of a rack and pinion, actuaterl anto. matically or by hand.

Bradawls are used to make holes for nails and screws. The brace and

Boring. Vertical boring machine for large timber
 bit arc ensploved to makie holcs from a small size up in it in. or 2 in . diameter in wool.

Holes are bored in brickwork or stone by menna of a atcel chisel or har shaped with four Hutes, thus forming an X-shaped cutter. Sometimes a jumper or tubular cutter is used. Either is pressed agninst the brickwork, given a hlow with a hammer, rotated a quarter turn, and given another blow, and so on until the tool is driven in to the required depth. Chiun und glass are lored with a special drill stock.

When the lathe is used, if the object to be bored can be mounted on a faceplate or held in a chuck, it is customary to hore the hole with a hand tool, or preferably a tool held in the tool post of the slide rest. If the nature of the jol, prohibits this trentment, it is customary to holt the work to the saddle of the lathe, adjusting it by means of packing hlocks until it is axial with the lathe centre. A roung hole having heen previously cast or drilled through the work, a loring bar is inserted through the hole and mounted het ween centres in the lathe.

A cutter is adjusted to the correct diamoter and secured with a wedge or otherwise to a transverse slot in the horing bar. The latter is set in motion, and the work fed up to the tool, which thus bores the hole. A rough cut is usually taken first, followed by a smooth or finishing cut. Other methods of horing include the use of the oxy-acetylenc blow pipe. See Bit; Blow Pipe; Brace; Bradawl; Drill; Gimlet.

BORZOI. This dog is a Russian wolfiound of great size, graceful form and majestic appearance. He is a first-rate house dig.

Borzol. Champion of the Russian breed of large white wolfhound. It is one of the tallest dogs
perfectly companionable, and of affectionate disposition. The colour is white, variously marked with yellow, fawn, brindle, bluc, or black, or the coat may be without narkings.

The long, slender head is triangular in shape, with dark eyes, and small thin ears set far back. The long cont may be either flat, curly, or wavy, but it must not be at all woolly; on the neek it should form a profuse curly frill. The long tail, carried low, ahould be well feathered. See Dog.

BOSTON : A Good Card Game. For this there are four plavers, the cards rank ns at whist, are cut for deal and choice of sonts The cards are shuffled only once throughout the game, and the player to the right of the dealer cutis. leaving at least five cards in each packet. The player opposite the dealer cuts the pack, and the top card is turned up for trumps. This suit is callerl first preference and the suit of the same colour second preference. The remaining two suits are plain suits

The object of the game is to win a nominated number of tricks. Beginning with the cldest hand, cach player in turn bids that he will win a certain number of tricks, naming his own trimps, or to lose a certain number of tricks without trumps. The player whose hid is accepted plays against the other three

The bids rank as follows: Boston, to win 5 tricks; to win 6 tricks; to win 7 tricks little misery, to lose 12 tricks ufter discarling a caird which is not shown; to win 8 tricks to win 9 trioks; grand misery, to lose every trick; to win 10 tricks; to win 11 tricks little misery with the cards exposed, also called little spread; to win 12 tricks; grand misery or big spread with all the cards exposed; grand slam, to win evory trick.

Players ano provided with white and red counters, the latter heing worth five white. One red is placed by cach player in a pool, and when there are more than 2.5 reds in a pool the surplus is set aside, only 25 being allowed to be seen on each deal. No bid of less than 7 tricks wins a puol unless the adversaries insist on playing the hand out. If a player wins the nominated tricks he is paid by the others and takes the ponl for 7 tricks or over If the loss be donble the pool he pays his opponents. One red counter must be placed in the pool for a misdeal and four for $\boldsymbol{n}$ revoke. Playens are only paid the number of tricks they have originally bid, though they may win more.

A bid must be made with named trumps. The next player may say "I keop," meaning that he bids the same number of tricks in nne of the preference suits A plaver calling higher says "I keep over vour." If all pass,
the deal is void, each player sorts his cards in sequence ind they arc packed and cut for a freshl deal. Whichever player wins the bid oldest hand always leads. When littlo miserie are played, each player diacarda a card which he does not show. Spreads must be laid down beforo any card is led.

The actual paying for winning $n$ bid varies, but is gencrally as follows: 10 for 5 tricks 13 for $6 ; 20$ for $7 ; 25$ for 8 ; 35 for 9 ; 45 for 10; 65 for 11 ; 105 for $12 ; 170$ for 13 ; 20 from each player for little inisery; 40 for big misery ; 80 for little sprend; $\mathbf{1 6 0}$ for big spread, with corresponding penalties for losing
BOTTLE. The average household does not make as much usc of carcfully washed old bottles as it might do. The ordinary graduated medicine bottle, for exsmple, malies an excellent liquid measurer. Most of them are divided off into teaspoonfuls or tablespononfuls. Besides the advantage of quickness in measuring n number of tablesponnfuls of liquid the hottle is more nccurate, as tablespons vary in size considerably.
Bottles are in constant request in photo graphic work. Different slapes or different sized bottles should be used for developing, fixing, and other solutions, so that they can be handled and used in the dark ronm. wiere the light is not alwinys sufficiently clear to read the labels
simple way to remove $a$ cork that has fallen into a bottle is to make a loop of string, or preferably wire, and insert it into the neck of the bottle. whake until the Turn upside down and that the loop of string or wiro catches it, when it can be forcibly withdrawn. For a cork that has broken off in the neck of a buttle insert the blades of two penknives on opposite sides of the cork, and pull the handles slightly towards one another and slowly twist and pull. This will generally remove the cork.
The stoppers of glass bottles are sometimes difficult to remove. One method is as follows Place a little olive oil between the stopper and the mouth of the bottle, stand the latter in a pan of cold water, and hent the water alowly. Tako the bottle out and allow to conl In the cooling process some of the oil will he drawn in between the stopper and the bottle neck and loosen it. Often a tight stopper may he removed by wrapping the neck of the bottle in cloths dipped in hot water. This allows the neok to expand sufficiently to force the stopper out. It is advisable in the case of hottles which are constantly in use to tic the cork or stopper to the neok of the hottle.
Wrarm water and soap first, then a thorough insing with cold writer, will olcan most hottles ; and if they are wanted to dry quickly little methylated spirit should be sluiced
round inside the bottlea and the latter stomi upside town to drain. Small botiles may be cleaned with a solution of egg-shells in time juice. Discolorations can be removed by putting into the bottle a raw potato (cut into pieces) with a teaspoonful of ralt and twice that amount of water. Shake well and when the bottle is clean rinsc with cold wate Alternatively, rinse with strong canstic aoda Salt and vinegar is an old-fashioned way of cleaning bottles which is effective. A bottle which has contained petrol should be washed out with thin, warm milk of lime

Bottles sent by post should be wrapped in corrugated cardhnard, as a protection against brenkage. It is advisable to label all bottles containing liquids, for it is not always possible to tell what a bottle contains by the appear ance or smell of the contents. See Baby Cork; Feeding Bottle: Hot Water Bottle

BOTTLE WAX. Ordinary sealing-wax has $\Omega$ basis of shellac, which readily melts at a Hame, and quickly sets when the heat is with drawn. For hottle was resin is used insteal of ahellac, tho properties of which it resembles A preparation made with resin answers well as a sealing for bottles and parccls, and is cheaper. Bottle wax is used for wine bottless and to keep nirtight jars or bnttles of pickles

Bottle. Simple metbod of extracting a cork which has sallen into a bottle
The following table gives repre sentative recipes :

The gencral process of preparation is to melt the resin and tallow in an iron pan over a gas flame, taking care that the mixture does not catch fire. When this is done rub down separately the colouring matter and other powders ordered with the resin oil or cotton sced oil. This should then be stirred into the melted resin. When the mixing is completed the wax should be poured on to a warm plate which has licen slightly greased, and rolled intn thick sticks by means of a warm roller

## The Bottling of Fruit

## How to Secure Successful Results

## The articles on the various firuits suitable for botling, c.g. Apricot; Loganberry; Plum, etc., may be consulted for further information

Fruit may te preserved for an almost inletinite time if it is properly bottled. This object is attained by placing the fruit to be preserved in a suitable jar and then raising the temperature sufficiently to destroy or render inactive any germs present on the fruit. The jar is then sealed, so as to prevent germs from entering from the outside. This is termed pasteurisation.

Screw-top glass jars are the best, though those supplied with a metal spring are quite satisfactory. Before use the bottles should be carefully tested for possible flaws, as the seat ing for the rubber bands is apt to be imperfect

When small quantities of fruit are to be bottled, a large silucepan or fish kettle for heating water will suffice for a steriliser, provided it is deep enough. For fairly large quantities, a pan holding one or two dozen bottles is necessary. Care in the choice and renewal of ruliber rings is essential.

Fruit for bottling should be of good quality and not over-ripe, or fermentation may take place. It should be graded, wined and prepared, e.g. currants stalked, plums stoned, pea's cored and halved, otc.

Pack it tightly in the bottles without bruising $i t$, and fill them with cold water to
orertlowing Place on the rubber ring, cap, and screw-band or clip; screw up and then release slightly to allow air to cscape during pasteurisation. Clips or springy allow the air to oscape automatically. Place the bottles in the pan in which they are to be pasteurised; the cold water in the pan must just be within an inch of the tops of the bottles. Different fruits require different treatments, but for most the following method will be found satisfactory
With Thermometer.-Bring 10 the required heat slowly nt the rate of npiroximately $2^{\circ}$ Fuhrenhct per minute. A temperature of $155^{\circ}$ to $180^{\circ}$ is cecssary.
Without 'Thermometer.-Bring the water very slowly to simmering. or until the hand cannot le hold on the pan itd When this point is reached ift up a bottle ior exanination If the frult is atill on ns to bing to move ahout when bot 80 twisted it is ready to come out.
Should the water in the pan become too low through boiling, more should be added, but it must be of the same temperature as that in the pan. When ready the bottles should be renoved, the covers at once securely fastened down, and the bottles allowed to cool alowly. Hot bottles must be placed on a cloth wrung out in hot water to prevent cracking. When quite cold, remove the screw or clip and test the efficiency of the scal by lifting the hottle by the cover

## The Dry Method of Bottlins

The dry method of bottling, which is more particularly suited for plums and gooseberries, is very simple. l'ack the fruit tightly in the bottles, and place in a slow oven on a piece of wood, cardboard or asbestos, or the hottles crack at once, until the fruit shrinks slightly; it is then ready to come out. Have hoiling water ready, remove one hottle, fill up with the hoiling water, and fasten securely before taking another bottle from the oven. See that the lids and fittings are warm before heing placed on the bottles.

Though glass jars with a special device for sealing are to be preferred, if they cannot be obtained, ordinary wide-necked bottles or jars may be used, and sealed. The necks of the bottles should not be larger than is necessary for the insertion of the fruit. Sealed hottles should be examined from time to time, in case fermentation or mould growth occurs in any of them. If this bappens the contents should be consumed without delay. Ordinary bottles or jars should not be packed so full of fruit as special bottles, on account of the senling necessary to render them airtight: otherwise pasteurisation should follow the lines of bottling in apecial bottles.

Two layers of parchment paper may be pasted separately one over the other and tied with fine string, provided that the bottles are afterwards kiept in a cool, dry place.
Corlse may be Corlis may be used instead, scalding them well first, and then sealing the tops with bottle-wax. The use of syrup is, not
essential, pure water being equally suitable and rather more transparent. This bottling being done without sugar, when the fruit is nceded for use pour juice into a pan and add sugar to malic a syrup l3ring this to boil, then add fruit and cook over top of stove very slowly for $n$ few minutes only
Ripe tomatoes can lie bottled in this way and are useful for soups, etc. in winter

BOTULISM. The form of food poisoning known as hotulism is due to the presence of a microbe in fruit or vegetahles which have heen canned or hottled; nearly all the outbreaks have occurred where the preserving was done at home. The symptoms are vomiting and diarrhoca, with abdominal pains, cramp, and paralysis or weakness of the legs, and perhaps difficulty in speaking. Deatlo may result.

The danger of poisoning is removed by cooking the food hefore usc ; warming is not suflicient. See Fond Poisoning

BOTTOM HEAT. The term is applied in gardening to the process of raising the temperature of the soil in which plante are being grown in a heated greenliouse. It is usually obtained by running a row of hot water pipes underncath the borders, but occasionally, as with mushroom beds, the desired effect is obtained by the ferment of manure
lBottom heat is chiefly used to hasten the growth of scedlings and cuttings for planting out purposes and for forcing early vegetables.
lbottom heat should be used very sparingly when forcing half-hardy subjects for hedding out, otherwise the young plants will grow up very tall and weedy. Soil temperature can always le taken by means of thermometers manufactured for the purpose. See Gardening ; Greenhouse.

BOUGAINVILLEA. This is a greenhouse climbing plant, a native of $\mathbb{S}$. America. As it loses its leaves in winter, it is valuable because it does not interfere with the admission of sunlight into the house for the benefit of other subjects. Its rose-coloured flowers are borne in bracts from spring till summer. The ordinary potting soil suits it admirably. It thrives in a temperature which may vary from $55^{\circ}$ to $70^{\circ}$, according to the season. The shoots should be hand pruned in spring.

BOUILLON. To make this clear broth, wash and dry 2 4 . lean heef and cut it into sinall pieces. Chop any bones, and soak bones and meat in 2 quarts cold water for half an hour, add a teaspoonful salt and bring the broth slowly to boiling point.

Then skim it and add to it a carrot, an onion, and a turnip, prepared and cut in quarters, a small bunch of herbs, parsley and a bay leaf. 2 cloves, 4 allspice, is peppercorns, and 2 chopped sticks of celery. Simmer (do not actually boil, or it will he cloudy) for 3 hours, removing any scum. Strain through n fine clean cloth into a basin and leave until cold. Remove all grease, re-heat and carefully season before serving in small soup cups, a tiny dust of chopped parsley being added to each cup. Sufficient for about 12 persons.

BOUQUET : Of Flowers. The florist's elaborate houquet is usually presented on ceremonious occasions, at public functions, and also at werldings, though at the latter the sheaf of long-stemmed flowers or the round closely packed quaintness of the Victorian nosegay is often seen.

For the sheaf, long-stalked lilies of any kind, gladioli, tulips, carnations, or a inixture

Bougainvillea. The delicately tinted Bougainviliea. The delicately tinted popular greenhouse climber
such as delphiniuns and pale pink roses can be used. The flowers are arranged in the same way as in a florist's bunch of fine daffodils, but a layer of moss or fern is placed between each graduated row of stalks, and tied in with them, to form a packing which prevents the flowers from shifting, and the whole is completed by ribbons.

The Victorian bouquet is a round massing together of small blossoms, and the inore compact and conventional it is the better. A delightful example is conmosed of pinli moss roses in the centre with circles of forget-me-nots, white pinks, mauve and purple violas, magenta stocks and mignonette. widening out to the desired size. The whole should be encased in the lace paper holder of the period and tied up with harrow ribbons to match the Howers.

The etiquette of bouquets is simple. For the débutante, on presentation, or other lady attending a court, the bouquet is not includer in dress regulations, but may be carried il wished. and is usnally a costly affair, chosen at a court llorist's to match the dress. The wedding bouquets for bride ancl bridesmaids are the gift of the bridegroom. At the beginning of the service the bricle hands her bouquet to the chief bridesmaid to hold It is permisaible for a widow-bride to carry a bouquet of coloured flowers. See Bride; Flowers.

BOUQUET GARNI,
This is more delicate in llavour than the packet of mixed dricil herbs. and is used for sauces and stews. It is made of a few sprigs of parslev, a bay leaf and a sprig of thyme tied up together.

BOUVARDIA. There are pink, scarlet. double pink and double white varieties of Bouvardia, which is a greenhousc slirub bearing fragrant flowers in winter. It is dwarf and bushy, and grows well in a compost of three parts lonin, one part leaf-mould, and some sand. l'ots of 5 in . or fi in . diameter will suit it. The plant should be atood in a shady place in the garden, or in a frame during thin summer, and brought into a wann house in September.

After flowering, the young growths should be cut back to the old wood. New shonots will ripen during the summer. and producc flowers the following winter. Propagation is effected by young shoots inserted in pots in spring.
BOW. The bow is the nacans wherely the strings of $\Omega$ member of the violin family are

Inrade to vibrate. It consists of a shender stick of $s$ narke. woodor 13razilian lance-wood. cut straight. following the grain, subjected to heat and then slightly bent.
Strands of white horsehair are carried ftom the toll of the bow to thenut, the latter
being fitted with a screw; it is tightened for playing, and relaxed after use in order to preserve the resilience of the wood

It is a characternstic of horse-hair to possess certain tooth-like roughnesses, which, aided by resin rubbed on to it, catch the string of the instrument, and cause it to vibrate and thus sound In course of time the hair wears away to smoothess, and the bow must then be res haired. Holding the how in his right hand, with the thumb upon the nut, the player drava it across the atring at a right angle, bet with the stick slightly inclined towards the left hand and ahout midway hetween the bridge and the finger-hoard. The wrist must be kept loose and supple. and the movement of the forearms should be fiee, but without any unnecessiry motion of the elbow. By variation of pressure, and by differences of movement in the bow, the player is able to secure all gradations of tone, as well as any desired species of phrasing

## BOWDEN CONTROL

 The Rowden wire control for cycles and other machines of the same kind consists primarily of two members. The cuble, or inner member, is composed of tine wire strands twisted together. The outer member, or sleeve, is formed of square-section non-rusting wire wound close up like a tension spring, and covered on the outside with a flexible waterproof material, as shown at $A$ (Fig. 1). The working principle of this form of control is as follows: The inner member is fastened at one end to the part to be controlled, and its other end anchored to the control lever ( 13 and F, Fig. 1), which shows the mechanism controlling a carburetter. There are numerous forms of control levers, all of which work on the same principle

Bowden Control. Fig. 1. Separate parts of the mechanism controlling a carburetter (see text). Fir. 2.
Diagrams illugtrating methods of making temporary repairs. Fig. 3. Permanent repair: correct methad
Bowden Control. Fig. 1. Separate parts of the mechanism controlling a carburetter (see text). Fif. 2.
Diagrams illugtrating methods of making temporary repairs. Fig. 3. Permanent repair : correct methad of senuring a Bowden wire into the nipple

Particulars of the brake control mechanism are given in the article on bmkes (q.v.).
An advantago of the Bowrien contml lies in its adaptability for all classes of contro where awkuard turns have to be overcome. To ensure ensy working never assemble tho control without first coating the wire with a mixture of thin oil and fine graphite. The best method to secure the wire to the control is, where possible, bo the use of the nipple supplied by the nakers. If this is not practicable, double the wire over and bind with thin copper wire, not forgetting first to solder the wire where you have to cut it, should it be too long. The control lever must be right home against the outer casing. It should not be forgotten that the lever to be operated is at rest. i.e that the length of naked wire show. ing at the end attached to the lever to be operated must be equal to the distance travelled bi the lever during its full movement ( $F$, Fig. 1).

So that the position of the lever may be set to a given position when at reat, a form of adjustable atop is provided as shown in $\mathbf{C}$ (Fig. 1). By such a stop the position of the outer member nlay be brought closer or withdrawn further from the operated lever, the result of so doing being either to lengthen or shorten the radius of movement. This adjustable stop con-
sists of a sleeve ( $a$ ), cuppicd at the end to receive the outer casing and screwed the whole of its length, so that it may hic positioned where required in the stop (b), and locked by means of the nut (c).
A tension spring is attached to the lever to be operated, so that it is pulled back to it.s original position when the control lever is released, or returned to rest, as the case may be, according to whether it is of the friction
design, B (Fig. 1), that stops where placed, as used for thmttle contmls, etc., or of the free design, D (Fig 1), as used for cycle brakes and exhaust controls. In onc tivic of Bowden control the spring is placed over the cable at the controlled lever end, and the whole enclosed in two tubes, the outer one heing stationary with the outer member, and the inner one travelling with the wire ( E, Fig 1). Fig. 2 shows various methods that may he emploved as temporary only, by which it is possible to get he:ue if a heratage should occur on the road. Fig. 3 shows the correct method of seouring the Bowden wire into the nipple. See Bicycle.

Bowl. Implements used in beating out an ornamental metal bowl. See tex!
BOWL : How to Make. In silver, copper, hinnze, lirass or Benares metal, howls hold plants or Howers. In papier inâché or pottery they are useful for bulhs, cut llowers or fruit, and are charming for this purpose in coloured stone ware. Glass and lustre howls also have a decorative value.
The making and omamenting of a bowl of simple form in one of the ductile metals, such as copper, hrass. or silver, can le accomplished at home with the aid of an anvil-block and a few tools. These comprise a hall pene hammer, a round-faced hardwood mallet (Fig. 1), a few ormamental punches, a pair of tinnian's snips, pliers, and file.
The anvil-block can be marle from an odd length of hardwood about $t \mathrm{in}$. hy 4 in . wide by $\mathrm{i}_{\mathrm{in}}$. deep. Set it with the end grain upwards, aind fasten it to a basehoarrl with a piece of felt on the underside, as in Fig. 2, if the work has to be done on a table. It is preferable to hold the anvil-hlock in a vice. The best material to begin on is sheet copper ahout No. 20 gauge.

Cut a disk of copper of ahout $(6 \mathrm{in}$. diameter and file the edges clean and smooth. Then draw circles from the centre of the disk, spacing the lines $\frac{1}{2}$ in apart. Holding the disk in the left hand, press it flat on to the anvil-block. so that the centre of the disk may he over the hollow in the block, and strike a lilow near the centre with the round-faced mallet. This will cause an indentation or stretching of the copper, and it is lyy a series of light, rapid blows, producing numerous indentations, that the howl is ultimately shaped. If the hammering, commenced in the centre, is carried
steadily round and round the howl, using the lines as a guide, until the rim is reached, then working back to the centre, the metal will speedily assume a howl-like form, as indicated in Fig 3 The next step is to beat out ns mans of the hammer-marlis as possible, obliterating them by light blows, and using a curved faced block or the curved corner of the block shown in Fig 2 .
Repeated hammering hardens the copper, and when this is observed the metal must be annealed, which renders it quite soft. The cdges of the disk may exhibit a tendency to cockle or pucker, but this will be of no great consequence when the design exhibits a scalloped edge, as shown in lig. 4. This is formed by hammering the edge in a hollow-shaped part of the anvil, as in Fig. 5, working scallops on opposite sides of the bowl instend of progressing round the rim. The ornamentation, consisting of a conventional Horal garland, is formed with the aid of a steel punch with a leaf-shaped end, held between tho thumb and forefinger of the left hand, while the bowl is supported between the third and fourth fingers, as in Fig. 6.

A circular block shaped as in Fig. 7, seen in section in 7A, will facilitate the llattening of the base. The use of the hlock is shown in Fig. 8, where the hammer is seen beating the basc to a Hat surface and forming the stilfening rim in the bottom. A tinal touch up with the hammer, giving a light blow or two here and therc, will produce the finished bowl (Fig. !), whioh then only requires scouring with silver arnd and water and a good rubbing with netal polish. Sce Batik; Bent Iron Work; Bull): China; Finger Bowl; Salad Bowl

BOW LEGS. Ricliets in chilliren are usually the cause of handy or bow legs. The legs should be loosely bandaged from the ankle to the crutch with a wide, soft Hannel bandage. Then splints 4 in . wide, carefully padded with cotton-wool, should be bandaged along the outside of the thigh and leg. The splints should extend well up aloove the hip joint, and some 3 or 4 in . beyond the solc of the foot, and should le worn during the day for a inonth or so.

BOWLS : How to Play. The full-sized howling green is 42 yd square with six rinks and a ditch about 6 in. wide all round, hut the game may bc played on a sinaller space and is in vogue oll many private lawns as well as on club greens throughout Great Britain. In the north some of the greensarecrowned

Bow!s. 1. Correct way of holding the bowl or wood 2 and 3 . Two wronk ways of holding sition; they must not exceed $16 \frac{1}{2} \mathrm{in}$. in circumference and $3 \frac{1}{2} \mathrm{lh}$. in weight, and are made with a bias, one side being weighted in such a way that the course of the howl tends to run in a curve The extent of the bias varies, hut, strictly speaking, the bowl should draw at least 6 ft in a distance of 30 yards

Any number of players up to four may oppose each other in a separate game, and on a full-sized green alnost any number in reason can get a game. If thereare only two players, or two on each side, each player uses four howls; in a three-a side game each player has threc bowls, and in a rink, or four-a-side, each has two howls. In all cases the points (or ends) are 21 up.

In an ordinnry game one of the leaders places the mat within a yard or two of the houndary. He then places on the mat one foot, which he ought not to lift. He rolls the jack in any direc tion which scems con venient about the order in which each playere rule and direct the aims of the other bowlers.
is an earthenware ball which should not exceed $2 \frac{1}{2}$ in in diameter nor more than 10 oz . in weight; it serves as the tee and must be at least $2 j$ yd. away from the mat on which the player stands. The bowls are of lignum vitae or other hardwood, or in some cases of compobut the last to howl are the two skips, as the captains are called. If the players are expert nearly all the bowls will be lying close to the jack some time before the turn of the skips cones. Till then they remain behind the jack

When all the shots have been delivered the plavers examine the positions of the bowls nearest to the jack, and 8 times out of 10 there is no difficulty in linding the bowl which is nearest, and wins the end for its side. If there is any doulst, accurate incasure ments are made. When the point has been settled the leader of the side which has won the end takes the mat and rolls the jack to some ot her part of the green. to slope from the centre to the ditch, but in and the game then procceds as lofore the south they are generally level.

All that is reguired for the gane is a jack and a few sets of lowls, together with an india rubber mat alout 22 in . hy 14 in . The jack

Bowls. Correct attitude Immediately after delivery of the ball, one foot being still on the mat Couriesu of Jurrold di Sons. I.td

BOW SAW. A bow or frame saw is used for cutting out various curved sha pes in wool. It consigts of a central bar with two end menibers, the holins of which are Irawn inwards by a cord tensioned by twisting the lever or tourniquet.
The opposite ends have handles movable in the holes drilled to receive them. The saw blade is long and narrow, pierced at eath end to receive a pin. Slots are cut in the metal ends of the handles and the saw is retained in position hy slipping it into the slots and insert ing the pins. The hlade should le tensioned hy twisting the cord. The saw is generally used with a vertical up-and-down movement, the teeth cutting on the down stroke.
Good quality bow saw frames are made in beech or similar hardwond. The length of the blade depends on the size of frame, 12 in . leing suitahle for amateur use. The width of the blade should be governed by the work to he done. For delicate work use the narrowest blade, and with fine teeth; for laige work

Bow Ware. Chimney piece ornamen characteristic of this porcelaid
use a wider blade with coarse teeth Threc different widths of blade will be ample as a selection for amateur work The work should be lield in the vice and hoth hands used on the bow saw, the sawing being done in a horizontal position when possible See Saw.

BOW WARE. A soft parte procelain made at kow and Chelsea in the 18th cen tury Old Bow is generally chalky white and coarse and heavy for its size, although some is of eggshell thinness It has a glassy lead-glaze, which with aqe has lecome iridesecnt and discoloured, often with brown patches anll stains.
The figures, usually de aigned for chimney-pieces, were more highly coloured than Chelsea. and often have square holes at the back for the metal stems of candlcnozzles Bow never imitated Sèvres vases or Dresden groups, but was successful with partridge, hnwtliorn, and dragon services in the Chinese taste, as well as with blue-painted "are, white with modelled reliefs, openwork baskets, sprigged tea. sets and landscape mugs It was mostly unmarked.
The common use of the anchor-and-crescent device in some styles often causcs true llow to be lablelled Chelsea or Worcester: The marks are easily forged, and inexperienced collectors should beware of the Bow imitations with copicd marks cleverly turned out in Paris and else where. See China
Bow Window. So called on account of its shape, this tyje of window is commonly termed a bay window. See Bay Window.
BOX : The Tree. The common apecies is a compact evergreen shrub with a characteristic pungent smell, thriving in most soils. It is a pronounced surface rooter, and is perfectly hardy. It grows up to 10 or 12 ft . in height, lout is of very slow growth.
Box is ensily increased by cuttings in frames in late summer. The lower hranches may be laycred into the soil in autumn, when suckers may also le drawn off and planted. The plant used for edging is a form of common box which is propagated by means of small rooted picces in May. Box is one of the chief suhjects used in tho practice of topiary work, which is the art of clipping trees and shrubs into fantastic forms of bircls, beasta, ships, etc. The timber of the full-grown treo is used for small tu:nery articles such as peg tops. See Wood.
BOX : How to Make. In making the simple hox shown in Fig. I the two end pieces should first be cut. These should preferably

Bow Saw. How the saw should be held with both bands to ensure a steady cot

be thicker than the sides, and in any cass stout enough to give a good hold to the nails. Then cut the two side picces and, standing the ends upright with one side piece spanning them, nail the side to the cnds, as in Fig. 1. Then add the remaining side and the hottom, nailing with thin wire or French nails.

If a stronger box is wanted, or the ends are in several pieces, fit upright battens as in Fig 2. It is customary when making this class of box to clench the nails, that is, drive them through the thinner wood into the hattens and then knock over the projecting ends. A goorl method is to hold a spare hammor ngoinst. the head of the nail while using another to clench the point

A quick and effective way to strengthen an old box is shown in Fig. 3, where comer pieces of square wood are nailed to the inside corners. Incidentally, this enables the lid to be screwed on if desired, as the corner pieces are stout onough to hold a screw. See Kínife Box; Trunk: Windour Box, etc.

BOX CALF. Box calf is largely used in the manufacture of handloggs and of boot and shose uppers, the letter grades being made from first selection calf-skins. For the cheajer clans of upper leathers, hox-calf is imitated under the names of box kip, this being made from the East Indian small cow-hide and finished with a box pattern; or from aplit hislea, in which case the leather is known as hox sides. When chrome tanned calf is dyed brown instead of hlack it is called willow calf, and is fre quently finished with the characteristic pattern of box calf.

All hox calf is tanned by the chrome process, the skin being converted into leather by the action of chrome compounds, so that it is quite distinct from leather tanned with inaterials like oak bark. When first tanned the leather is of a blue colour; during later stages of manufacture it is dyed and tinished. recpiving the characteristic grain of box calf.

Genuine box calf is one of the best of all upper lenthers. It wears sell, gives to the foot, and if properly lasted the shape of the boot does not spread or become unsightly after continued wear. Even under the influence of excessive perspiration a box calf upper is durable. lt should not crack after long wear, and if it does it is a sign of faulty tanning.

As with other types, the life of a box calf upper largely depends upon its preservation. Cleaning and polishing with a good reliable polish is all that is required; but the polish must he of sound quality. See Boot ; Leather.

BOXING GLOVES. In buying these gloves it is necessary to ree that they fit the hands comfortably, for if they are too loose or too tight a great deal of discomfort is certain to follow. Many hoxers pay little attention to their gloves, but they ought to lee kept absolutely clenn, free from grit and grease. When they are new they want no attention except to work the fingers frequently about in them, in order to make them pliable.

If, as may easily happen even in the mildest
form of boxing, sprinkling of hilnod should get upon the gloves, they should bevery carefully cleaned with a little linseed oil, for if the hood is allowed to cake it will make a hard spot which may damage an op ponent's face. On no account should the gloves be damped with water. If they have to be putaway for any length of time they should be thoroughly but
sparingly oiled, for leather always has n tendency to jerish and harden when it is not in use. The gloves should not he placed in a damproom, nor in one which is too liot.

BOX IRON. The old-fashioned kind was litted with a plug, made red-hot in the kitchen firc and then plunged into the metal case. This was superseded by electric or gas irons. with which a continuous hert can be obtained. These are con. venient, but unless a special plug or burner has heen provided, they cannot be used when the fittings are needed for lighting purposes. See Flat Iron; Ironing.
BOX MATTRESS. A variety of the spring mattress, this is one in which the springs are enclosed in n horsehair or rugging stuffed mattress made on a strong wooden frame and fixed to the bedstead. It

Boz Iron. Showing block of metal which is heated in the fre
linen and underclothing. It is useful in the nursery for toys, appropriately loosecovered in coarse linen on to which toy designs are appliqucid. Pine, if availablc, is suitable for use in constructing the box portion, the liead scroll being of birch, beech, American whitewood or other liardrood

If to be linished ns a plain hox without scroll heacl, the construction of the ottoman is of the simplest. I serviccable size will be 3 ft . 6 in . long by Ift. 6 in . vide, and 1 ft .3 in deep. Floor boards 1 in . ilicli and tongued are suitable, and are best dovetailed. A strong box, however, is made without the trouble of dovetailing by nailing or screwinf a 3 in liy 1 in clamp inside each of the longer sides, setting it back to the thickness of the short sides or ends, so that these can be nailed flush into tho rehatc thus lormed, and a hottom nailed up to this Castors should then be fitted, and this will complete the making of the hase portion of the ottoman

The lid may be of plain clamped boards of similar thickness and hinged to position, re membering to malio the clamps sufficiently short to allow the lid to shut easily. The lit can be minde as a tray, and is stayed from opening too far back by means of a couple of wide tapes nailed to the inside of the lid and the box side. The interior of the box can then be lined with sateen or ang other material that is suitable for the purpose
In upholstering the sides and onds, these can be padded to curre nicely with cotton-woil and covercd with cretonne or damask, carrying the material over the edges and into the inside of the box, where the edges are doubled and tacked gives the bed a neat, upholstered effect. but down. Thecovering is edged along the line of an overlay has to he used as well. See tho box bottom outside with variegatod cord Beilding; Divan; Mattress.

BOX OTTOMAN. This piece of fumiture is a combination of the long seat or couch, or gimp. tacked as before
The lid of the box can be casily covered with an evenly diatributed layer of brown wool hetween two layers of wadding, the edges of the canvas being tacked to the box edge, and the final covering stretched tauly over this and tacked with gimp, cord or ball fringe edring.
In conotructing the box for an ottoman such ac that pictured in Figs. I to 4, a length of 5 ft . 105 ft . 6 in . should he allowed, includin. space for a head scroll. The height of the seat framing may finish 1 ft .4 in . to 1 ft .5 in . In this way the rails of lid or seat framing are 3 in. wide, the box sides 12 in vide, and bottom 1 in.. an additional 1 in. or so being allowed for cators. Naterial 1 in. thicli should be used for sides and lid throughout, this latter being preferahly of birch, and the parts dovetailed together, and the bottom sciewed well home with 2 in. screws. In making the lid $n 3 \frac{1}{2} \mathrm{in}$. hy 1 in stretcher is being formed by enclosing the lower part of the article. The scat is made in the form of I hox ottoman may be made from a large box with $\Omega$ hinged lid. The top is upholstered to make a comfortable seat, and the sides are covered in the same material
In addition to its value as a couch or bed, the hox ottoman is serviceable for holding surplus things that crowd a room, hedclothes for an emergency bed, or even some of the houschold

Box Ottoman. Figs. 1-4. Diagrams showing how to inark out and make a box ottoman with a scrolled bead end
cut into and screverl to the bottom part in the centre, as indicated at Fig. 1. Stout brass hutt hinges should he used.

There are various shapes for the seroll portion of the ottoman, such as drum, scroll, holster. roll, pillow. etc For this poition of the work deal is often unantisfactory, on account of its tendency to split when a considerahle number of upholatering tacks are driven in, and it is better to use birch or hecch 1 in. thick. A plain scroll may rise 6 in. to 7 in . only, or with any taller type of shaping. 12 in will he a serviceahle allowance. À choice of shaples is offered at Fig. 2, and these will suggest a variation in the finishing.

The elevation vicwnt Fig $3(\mathrm{~B})$ is of a verage size, and is set out in 2 in . syunres. When cut to shape the two scrolls will be fixed in fosition to the box framing with four hardwood dowels each, the four stufling rails upon which the upholstery is built having previously been fitted between. The numher of these stuffing rails, which can be 2 in. hy $l$ in.,

may vary according to the upholstery deaign to be carried out. A stretcher rail of the same height as the lifting lid is fitted, as Fig. 3 (A). The scroll can be stiffened by means of two pieces of 3 in by 1 in . "ood screwed to the insicle of head prition of box, as at Fig. 4 (C), these heing sufficiently long to project and form stays for screwing to the inside of front and back scrolls. A plan of the underside of hox lid is seen at Fig. $t(B)$. This shows the stretcher rail dovetailerl in.

For comfort it is preforable to linish with a spring seat. For this about 3 dozen strong 4 in . springs will be required, and these should be tiel down to about two-thirds of their height when put in and covered with hesaian. Every attention must be paid to the even spread of the stuffing, arching it well in the centre and diminishing it towards the edges, so that they are regular and devoid of lumpiness. Unless this is done very carefully and methodically, the ottomian will never make a comfortable seat. A covering of calico over the second stuffing, especially where hair is used, is recommended previous to receiving the linal covering. An improved effect is obtainable by buttoning the seat; a plan of this is shown Het Fig. 4 (A). The head stufting would then be buttoned to agree See Divan: Upholstery.
BOX PLEAT. The material is folded alternately towards the loft and right to give
large flat pleats, which muat be all of the same size. If the pleating is to be all round, the material required is twice or three times the

Box Pleat. How the pleat in the material is tacked down ready for pressing : left, front ; right, back
length necderl for a plain skirt, according to depth of pleat desired They retain their shape botter when lecply folded.
fix the folds with pins as they are made, measuring accurately to get each box-pleat exactly the same size. When all the fo!ds are pinnerl in position tack them firmly with a needle and cotton. noticing that the three erlges, pleat and material, are even. Finisl! the pleating at the top by sewing it into a double band of material or binding. Box pleats only set well when firmly pressed.
For louble box-pleating two folls are placed to the left and two to the right to separate each box-pleat. See Pleating.
BOX THORN. Lycium chinense, or the bna thorn or tea tree, is a vigomus leaf-losing

shurb heacing small purple flowers which acc followed by red fruits in autumn. It grows quickly and densely and makes a useful sereen, especially in seaside gardens. It Hourishes in ordinary soil in a sunny position and is increased by seeds sown in spring.
BRACE : For Drilling Holes. The carpentor's brace consists of a cranked metal bar, one end provided with vided with
meanstohold the drilling implement or bit; the other end hasa circular wooden kinnb or heal. In the iniddle of the crank is a wooden handle frec to rotate.
'rouse such a hrace, a bit is inserted in the holder. which is known as a chuck. The left hand grasps the head, the right hand grasps the grip on the crank. The brace is held upright with the point of the bit exactly on
the centie of the spot marked on the wond where the holo has to be drilled (Figs. 1-3).
The left hand is prossed firmly downwards, while the right hand is employed in rotating the braco and bit. The chuck is composed of a hexagonal exterior member that turns on a screw thread cut in the brace, this in turn contracting two or three jaws which grasp the bit or drill. Some chucks are only adapted for grasping brace shank bits, while others will do this and will also grasp ordinary circular slask drills. This kind is to be preferred for all-round use. Better quality braces are made with a ball-bearing head. which is a great advantage. The ratchet brace has a ratchet movement which can be thrown into or out of action by moving a slecve on the orank. This device onables holes to he drilled in awk ward corncra or near to a wall, where it would be impossible to rotate a plain hrace.

Amongst the usos of the brace, apart from drilling holes, is that of driving screws. This is accomplished very quickly by aubstituting n acrewdriver bit. The enlarging of holes in metal or wood is done with a rimer bit The conc-shaped recess to accommodate a screw head is formed by the braco, using a counter sink bit. Rounding the ends of dowel pins is accomplished by using a dowel shaver bit and a dowel rounder bit. Shallow circular receases or sinkinge for a nameplate are formed with a brace and a Forstner auger bit.
The engincer's brace, Fig. 4, is a ratchetdriven tool for drilling holes. It is simple and effective. hut is only employed where a hand drill would not he large or powerful enough, and when the work cannot he conveniently taken to a regular drilling machine.

A rim brace is Inrgely used for removing and replacing the nuts on most types of detachahle wheels on motor cars. They are made in two forms, the plain hrace, and an improved form with ratchec. Separate sockets are obtainable to fit these hraces, and thus various size nuts can be dealt with from in in. to $\frac{7}{W} \mathrm{in}$. across flats. See Bit; Boring; Drill.

BRACELET. In the wide, old-fashioned varieties, which return to favour when hracelets are the vogue, one part likely to go wrong is the joint, through opening the brace let too wide, straining the hinge and ultimately tearing it from its seating; this is prevented by attaching a safety chain just long enough to enable the bracelet to push over the hand.
Sometimes the small pin in the hinge will work looac und drop out. Another can be made by taking an ordinary stout brass pin and, with a pair of pliers, pushing it well into the joint until it is a tight fit, giving it a tap with the pliers to drive it home, Fig. 1. With a small file, nick the pin where it projects, break it off, and finish hy filing it flat, Fig. 2 . Should the clasp become weak, it can be insNhouk the clasp become weak, it can be in

proved by inserting the point of a pocket knife hetween the spring and raising, Fig. 3. Where the front is set with jewels it slould be cxamined periorlically. Should one be loosc.
it is best to let tho jeweller examine it, as a part of the setting may have worn away; but with a fairly new bracelet the edges of the setting miny be rubbed down on the stone with the back edge of a pocliet-knile, or, if claw set, the points pressed on to the stone with the blade.
Pins in the joints of a flexible bracclet sometimes fall out. I new one can be made with a hrass pin, as described in stiff bracelets. Expanders depend on the strength of small coiled springs inscrted in each link for their expansion They ought not to be opened and shut more often than is necessary, or the springs will weaken. If this happens, it is best to return it to the jeweller for respringing. An occasional wash in hot water, with soap and a few drops of olive oil. will keep the springs easy and smooth running.

The gold slave hangle is hollow and is usually sold in 9 ct and 15 ct gold. The calibre is a circle closely set all round with small stones, which are held in position by rubbing over the outside edges of the hoop The greatest care lias to be taken of these, hecause if they are twisted it is almost certain that a stone vill Hy out, or at least be lonsened. If one stone should be lost, the bracelet should be taken to the jeweller and a now stonc inscrted, otherwise they will all work out.

Ivory and tortoiseshell hracelets are inlaid with gold wire or elephant hair. The gold inlay is apringy, and a jar may dislodge it. Should this occur, brush a little Canada halsmm or seccotinc into the groove, press the wire down, and bind tightly with thin string and leave for 24 hours. As heat renders tortoiseshell soft and pliable, it should never be put into hot water. Should thic surface become dull with wear, it can be improved by polishing with jeircller's rouge and a soft rag, ifterivards washing out with lukewarm water and sonp.

BRACING. This term is applied generally to all such work as the strutting of a rafter to prevent ita sagging, the fitting of a diagonal brace to a timber framework, or an angular strut or brace to aupport the back of a chair. The principle is that of stiffening $\pi$ structure by means of $n$ supporting braco generally placed diagonally between the parts to be strengt hened, thus tranamitting the weight froin the overhanging, or weak part, to the wall, foundation, or strong parts.

The principle is shown in the ledged and braced door illustrated. The ledges, A, cannot entirely prevent the planks which form the door from sagging, but the two braces, $B$, act as brackets or supports, and also help to prevent warping. Other examples will be found in the articies on Shed and Workshopl.

BRACKEN. Although quite wild, this common fern (Pteris aquilina) has certain donnestic or semi-domestic usea. The fronds are largely used for hedding cattle. They are also used to a slight extent for thatching houses and stacks. The stem of the bracken contains starch and has been used as a food.

Except in the wild garden hracken is of no horticultural interest, and, unless the wild garden is a large one, should not he introduced, as it spreads with great rapidity when once it has taken root, and it is somewhat difficult to get rid of it successfully.

BRACKET. Is ordinarily understood, bracket is an L-shaped metal support for a shelf, although there are other types, such as the bracket of a lamp, or a gas bracket, or electric fitting.

The iron hracket (Fig. 1) is intended for the repair of chairs or other furniture : these are usually $\geq \mathrm{in}$ or 3 in . long and $\frac{1}{2} \mathrm{in}$. wide. The strong light shelf bracket shown in Fig. 2 is known as the London pattern; it is made from pressed steel, and is finished in hlack japan. Usual stock sizes aro 3 by 4 in . to 12 by 14 in . Inother type similarly made, but with the additional stiffness given ly the curved brace or atrut, is shown in Fig. 3. They are handy for the rapid erection of shelves, a convenient nethod being to screw the brackets to upright battens of wool securely nttached to the wall and reaching to the floor

Shelf brackets intended to support plate glass or narlile shelves ate generally made in cast brass, cither polished and lacquered or nickel plated (Fig. 4). The littlo upturned nib or lip at the outer end cnsures the glass shelf from accidental movement. Such hrackets ane made in many sizes and shapes, also adajted for use on hars and posis for shop-window fittings.

Partition brackets (Fig. 万) are atont iron castings supporting a wooden or other partition, and canoften be tumed to good purpose by the aniateur. Stock sizes range from 12 in . wide by 24 in . ligh to 14 in . Wide by 48 in . long.

Bucket brackets (Fig. (i) are made in strong galvanised iron, and should be securely holted to the wall to sustain the weight of a large tire bucket. Gutter brackets of two types are illustrated in Figs. 7 and 8, one to drive into $a$ wall, and the other to screw on to woodwork. The householder should inspect the gutters and brackets occasionally, to be sure they have not sustained damage. If hroken they should be replaced as soon as possible, as a damp wall is the result of neglected rain water gutters and their supporting brackets. There

Brads of various sizes in common use. Top, floor brad;
centre, carpenter's oval wire brad: bottom, left, shoomaker's brad : ripht, joiner's brad
are numerous types of wooden bracket. Plain or ornamental wall brackots arc everyday requirements in the home: thoy can be quickly made from add materina and coloured or decorated to suit any stylo of furnishing. This kind of bracket is effectively carried nut in fretwork (q.v.).
The strong bracket shown in Fig 9 is useful for supporting heavy weights, and the sizes given may be modified to suit requirenents The parts ns shown in Figs 10-12 consist of a plain top, cut from commercial 11 in. by 1 in dcal, planed up on the face and edges, and finished off with hevelled corners. The hack is of heavier stuff. $1 \frac{1}{4} \mathrm{in}$. thick, and has notches cut out at 3 in . centres from ench end, 2 in deep at the front and $2 \frac{1}{2} \mathrm{in}$. deep at the back, and $\frac{l_{1}}{}$ in. wide.
The brackets are shaped as shown and can be sawn out with a handsaw, planed up on the top and front edges and cleaned up to shape at the back with a chisel. The half dovetail projection must be cut to fit tightly into the notches cut in the hackboard, its purpose heing to prevent the hracket drawing forwards and to relieve the screws of some of the work. To assemble the bracket put the back in the vice. then gluc the edge of the bracket and the notch in the hack, and sorew the bracket firmly in place with $2 \frac{1}{2}$ in. No. 10 countersunk screws inserted through clearing holes drilled in the back. Then glue and screw on the top, using four screws at the back and three into each bracket. Drill holes through the back and screw the whole to wooden plugs cemented into a brick wall, or to the studding on a plaster wall, or employ Rawluge. See Bent Iron.

BRAD. Generally this name refers to an oval section wire nail with a narrow oval head. They are preferahle to the ordinary wire nail for much internal household work. Convenient sizea are $\frac{3}{3}$., 1 in ., $1 \frac{1}{2} \mathrm{in}$., and 2 in .

Tyjucs of nails known as brads are illustrated in their actual size, and their purpose is apparent from their names.
BRADAWL. A small hand tool not unlike a screwdriver in aplearance, the bradawl is used for making holes in wood preparatory to inserting a nail or screw. The secret of success in performing this operation lies in cutting across the fihres. Conmence by pressing the hradawl firmly into the wood, cutting ncross the grain and as deeply ns possible; then twist the bradaul a little, thus enlarging the holc, and again force it down, cutting across the grain, and repeat the operation until tho hole is deep enough. If the hradnal is pushed in with the hade set the way

Bracket. Figs. 9 12. Strong wooden bracket. Ior supporting heavy

of the grain it will act as n wedge and
split the wood. aplit the wood.
Irndawla are made in 12 sizes, from a $^{3} \mathrm{z}$ in wide to in wide. Three sizes will neect most requirements ; and it will be found convenient to buy them ready handled.
BRAD - PUNCH. A small steel punch, known as a brad-punch, is used for driving the head of a nail below the surface. These are made in four sizes, with cupped or hollow ends.
BRAG. In this card game, a variation of policr ( $q . \nabla$. ), there are three special cards, the ace of diamonds, jack of clubs, and nine of diamonds, which may be called any card by the plaver bolding them. Thus, a player niny hold in his hand the ace of diamonds, king of chabs, queen of clubs, jack of clubs and ten of clubs. In that case he can call the ace of diamonds the ace of clubs to make a royal flush The three cards are known as braggera. In brag, however, any natural hand beats any similar hand made with a bragger. Thus a pair of aces beats one ace and n bragger : or three kinga beat a king and two braggers If two hands with braggers in each tie, the cards rank in the order ace of diamonds, jack of clubs, and nine of diamonds.

BRABMA. Massive size and heaviness of feathering arc the chief points in the appearance of the Brahma fowl, which formerly had a reputation for being a good lager and table hird, but is now kept almost exclusively for exhibition purposes. There are two varieties, light and dark See Poultry.

BRADD. Composed of plaited threads, nmong the more familinr types are bootlaces, costume braids, Prussian bindings, cords and gimps used in upholstery, tinsel galons, and fency artificial silk braids.

Cost ume braids, formerly made from worsted or mohair, are now composed of artificial silk. Russian braid, having a groove running down the centre, is easily stitched to ot her material

To hraid is to bind edges of revers, cuffs, etc., or to stitch a fine make of braid over a design already marked on the dress or costume, outlining the design completely and forming an effective trimming. This is usually done by machine, but may also be stitched by hand.

Braid. Method of applying Russian brald to a piece of material marked ont with a pattern

To do the actual braiding, place the braid on the garment-on the ink lines if a tranafer has been ironed off-and sew it down with small running stitches along the groove that runs down the centre, as ahown in the illustration. When the design is complete, the material should be pressed from the wrong side. The end of the braid can be made neat by sewing it to the eye-end of a large darning needle, and pulling the latter through the material to the
wrong side Braids to be used lor trimming purposes can be hought in widths varying fromi $f$ in to 9 in , and even 12 in See Binding.
BRAILLE. The system of embossed realing and writing moat widely used by the blind bears the nanie of its inventor. Brailic has no resemblance to ordinary print. The letters are inade up of a combination of dota, the largest number being six, arranged in three pairs. Space is saved by the use of contractions and ablireviations: but, even so, books in braille arc very hulky Nuch general literature is now in braillo type in Great Britain, in addition to several monthly magazines and two weekly newspapers. There is also a free National Lending Lihrary at $35, \mathrm{Gt}$. Smith St., Westıninster, London, S. W.. from which hooks are postel to all parts of the United Kingdom. Full details of the Rraille system can be obtained by application to the National Institute for the Blind, 294, Great I'ortland Street, London, W. See Blind.

Braille. Alphabet and contractions which ars em-
bossed on paper to enable the blind to read by tonch
BRAIN. The brain is the predominant part of the nervous system, and, like all nerve cent res, which originate nerve force as opposed to nerves, which merely conduct it, its activitics depend upon nerve cells, of which it contains millions. These are spread out in layers on its surface, and to increase the aren the surface is thmown into folds or convolutions The cells vary in size and shape, and have different functions. The brain is the organ of conscionsness and voluntary movements, and definite areas are mapled out for originating move ments of the hand, the arm, the face, etc., and for vision, hearing, smell.
Movements on one aide of the lody originate on the other side of the brain, and in righthanded people the centre for speech is on the left side of the brain. There are other minases of cells at the base of the hrain, and in the bull, or medulla, where the brain becomes continuous with the apinal cord. In the latter are the centres for the functions which carry on the life of the body, heart control, breathing, swallowing, control of the hlood vessels, and so on; hence injuries at the top of the spine are likely to be immediately fatal. The lesser brain, lying behind and hrlow the main mass. is mainly concerned with the maintenance of balance.
Injuries and Diseases. Bran abscess is a serious complaint, requiring immediate surgical treatment. The cause may have been originally a blow on the head or an unclean acalp wound, from which the inflammation bas extended inwards. A common cause is suppuration in the ear. The symptoms are dis. turbances of vision, recurring scvere hendaches. giddinces, and vomiting.
I person who has received a head injury of any severity will suffer froni concussion or stunning, with inore or leas unconsciousness If this deepens and the patient becomes comatose, breathing in a laboured, stertorous fashion, with Happing cheeks, and a slow, full pulse, which becomes feeble and irregular, it is probable that he is suffering from compression. In compression the hody is paralysed, but if the damage alfects one side
of the brain, there may be, to hegin with, loss of movement on the opposite side of the body. For treatment until thic doctor's a rrival, heep the patient lying in a quiet room with his head low Apily cold cloths to the head The condition may last for a long time
Concussion is the name used to describe the conditions resulting from n blow on the skull, with a sudden shaking of the lorain, which may or may not be accompanied by gross damage to the brain. The concussion may result in nothing more than a slight headache, dizziness, and mental "fogginess," lasting for but a moment or two; but in a well-marked, severe case there is loss of consciousness. For treatment pending the artival of the doctor, the patient should be put to bed, and no effort made to arouse him. Hot "nter bottles should bo put to the feet and legs, and cold cloths on the forehead. As a rule, recovery from concussion is complete.

## Cause of Soltening of the Brain

Should an embolus or clot bluck up a brain artery, and so cut off the blood supply, softening of the hrain may take place, the part afiected dies, and becomes liquefierl. Brain tumours may be cancerous, tuherculous, syphilitic, or sarconatous, etc. Disturbances of vision are common, and there is severe headache with vertigo and vomiting. There is likcly to be mental disturbance also. The treatment depends on the diagnosis.

Lethargic encephalitis, nlso known as aleepy sickness, is an inflammation of the grey matter at the base of the brain mainly, and is due to a microbe. The disease gets its name from the fact that most of the patients become drowsy. The eyes usually squint, and various nervous disorilers, one of then resembling St. Vitus' dance, may be left when the drowsinces disappears. The symptoms are sometimes very slight, perhaps a tendency to fall asleep during the day, and some reatlessness at night, with forgctfilness of the little things of evcryday life ; and the real nature of the condition might be overlooked, with detriment to the future health.
BRAIN FAG. Like all other working tissues, that of the brain may be tired by overwork. There is a diffierence in the amount of work which different individuals enn do comfortably, but the natural capacity of any person may be reduced by a poor supply of hlood to the brain or by the blood being of poor quality, as in anaemic states, or being loaded with toxins from the alimentary canal, when the contents of the last named are not moving along sufficiently frst.

A generous supply of blond is not only necessary for the provision of food and oxygen, but to cariy off the waste products formed by the working cells. Organs which are acting receive more blond for the purpose, and after a full meal, when the stomach is getting its supply, the brain gets less, and this accounts for the somnolence and dullness of the mental faculties at such a time.

Brain fag comer quickly in the neurasthenic, and may be due to inherent weakness in the brain tisaue; but a similar condition may be caused by overwork, especially when associated with worry, though worrying may also be a symptom of brain fag. Other symptoms are loss of power of attention, impaired memory, irritability, loss of pleasure in work and recreation, bodily weakness, perhaps digestive tmublo, and a large variety of sy mptoms.
If the condition in well developed the patient must rest. For prevention we should aim at beeping ourselves physically fit by open-air exercise and other menns. The idea that the best rest is a change of occupation is cssentially a sound one, but should not be stressed. A sufficiency of sleep is nll-important.

BRAINS : Recipes for Cooking. Calves' and sheep's brains are used in cookery, being sometimes bought separately, but usually sold with the head

Having blanched the brains by washing in salted water until all discoloration is removed, soak them in cold water, then remove skin, wrap them in a piece of muslin, and put into a saucepan with a little onion, a teasponfful of lemon juice or vinegar, a pinch of salt, a sprinkling of pepper and just enough cold water to cover them. Bring io the boil and then remove the brains and put into cold water until needed One set of calf's or two of sheep's brains will serve 4-5 persons

To fry, slice when hlanched, and coat the slices with warm butter; then dip into wellbeaten egg, cover with hreadcrumbs, and fry. Alternatively, dip the slices into a rich frying hatter (q.v.) and fry till a golden brown. Fried either way, the brains may be served with a hot piquant sauce, or garnished with slices of lemon.

Fried brain cakes or halle are useful for garnishing a calf's or sheep's head. To make them, chop the blanched brains up with the yolk of a hard-hoiled egg, a tablespoonful of white snuce or cream, a little nutmeg, a little grated lemon pecl, a pinch of herbs, and some seasoning. Add enough hreadcrumls to bring it to not too stiff a consistency, and when cool form into little Hat cakes the size of a penny, or into balls. Dip them in llour, then in egg, cover with breadcrumbs and fry a golden ljrown
For brains served on toast chop one set of calf's brains or two of sheep's rather coarsely, removing any stringy pieces. Whisk one egg until it is slightly frothy, add to it two tablespoonfuls of milk, and stir in the chopped hrains, seasoning the mixture carefully. Heat 1 oz butter in a pan, pour in the egg and brain mixture, and stir hriskly with a wooden spoon over $\Omega$ very gentle heat until it becomes thick and creamy. Heap on pieces of hot buttered toast, and sprinkle with chopped parsley.
Scalloped hrains make another appelising dish, prepared by cutting up a set of calf's or two of sheep's brains into amall pieces, and placing them in a little less than $\frac{d}{}$ pint of white sauce to which a tablespononful of cream and a few chopped mushrooms have been added Season the whole, and put the mixture into $\overline{5}$ or ${ }^{6}$ greased scallop shells, sprinkling each with breadcrumbs Place a small lump of butter on top of each, and brown in a quick oven. See Calf's Head; Forcemeat ; Sheep's Head

Brain Sauce, To serve with calf's hend boil and chop a set of calf's hrains, then add them to a thick melted butter or parsley sauce, well scasoned.

BRAISING. The process of braising can be carried out with success in caeserale or sancepan, braising pans being costly utensils Coals on the top are omitted, and the pan placed in the oven, in order that it may be surrounded by a gentle. even temperaturc. Braising, an economical method of cooking. develops a specially rich flavour, owing to the bed of mixed vegetables in the pin on which the food it placed. Mirepoix is the correct terin for this vegetable mixture. Like stewing, this method of cooking is particularly ndapted to meat or birds that, if cooked in other ways, would he tough, dry, and Havourless. No nutriment is lost from it, as the liquid reduces slightly and forms a rich gravy containing the nutrilive and thavouring juices that may have been extracted from the food. In some cases it is advisable, if the food is very delicate, to place n piece of buttered paper between its surface and the lid to prevent scorching and drying. See Beef; Casserole.

## Brakes: On Bicycles and Motor Vehicles

## Their Mecisanism, Fitting and Adjustment

## The arricles Bicyle: Motor Car ; and Motor Cjcie should also be consulred Sec further Con~rar. Hub

The brakes generally used on bicyoles comprise (a) the front wheel rim brake (Fig 2); (b) back wheel brako fitted on the back stays (Fig 1); (c) back wheel brake fitted on the sprocket bracket (Fig. 3) ; (d) coaster hub brake. Rint brakes are operated through a system of rods and levers, or by means of Bowden cahle control. The latter system is shown in Figs. 1 and 2.
A rear brake of the type shown in Fig. 1 consists of an inverted U-shaped piece, A, fixed in position over the tire and held in place nt the top, or fulcrum, by the Bowden wire, 13 , the ends, or legs, being held down out of action by two tension springs, $C$, attacherl to clips, D, that are secured round the forks or back stays of the machine The brake pad bracketa, E, are formed with grooves to receive the pads, $F$, generally made of fibre. The adjustment of the brake pads to the rim of the wheel is secured by the milled nut, G, and locked by the nut H
The action of the bralic is as follows: By means of the Bowden control the U-piece is pulled up, thereby bringing the pads into con-
tart with the rim.
The springs, C, return the brake to rest on releasing the Bowden lover. The distance, or clearance, between the rim and the pads is determined by the cable adjustment, J, provided with the of the usual type of clips, retains the pin, $C$ Bowden control. in a true line with the wheel, and also carries the studs, $D$, that keep the irms $A$ and $B$ up to their work
Vith the back wheel pattern irms $A$ and $B$ up to their work
With the back wheel pattern $\cdots$ the studs, $D$, are dispensed with, becanse the arms, A and
$B$, are kent up to their work hy B, are kept up to their work hy the direction of rotation of the wheel.
Fig. 3 shows a back wheel brakc made for attachment to the sprocket made for attachinent to the sprocket
hracket, with operating control rods. To tit this pattern proceed th follows: Unscrew the nut, $A$, nind remove the rod, $B$, from the draw-bolt, C. Fit clip D on the down tube so as to

Fig. 1
When in action this type of brake takes its support from the down stays. The direction of rotation of the wheel tends to keep the brakc tight When fitted to a front wheel and controlled by cable, the top, or fulcrum, of the ( U is held in position by enclosing the cable in tubes. one sliding over the other, the inner tube, A (Fig. 2), being fixed to the tension rod, 13. and the outer tube, C , secured to the clip, 1). that holds the outer inember of the cable This is necessitated by the action of the wheel, which tends to tear the brake from the forks The ends of the U-piece are fitted with pins which pass through holes in the clips, F , that are scoured on the forlis of the machine. The U-piece, G, acts in this case as the spring to withdraw the brake out of action and works as follows. The legs of the U-piece are sprung outwards, and the pressure is thus transmittex to the pins, $H$, causing them to slide to rest through the holes in the stationary clips, IF. Beyond seeing that the parls are not loose in the brackets, and also that they are not allowed to wear ton low, there is nothing requiring attention.

Brakes of the caliper-action pattern are used where it is desirahle tor have the pads acting on the side of the rim instead of underneath, as in Fig 4. Two arms, $A$ and $B$, are hinged at the top by tho $\mathrm{pin}, \mathrm{C}$, and the brake parls attached to these arms engage the sides of the rim through the medium of the Bowden wire, drawing the extension arms of $A$ and $B$ together A stalionary ${ }^{1}$-piece, which is secured to the forks of the machine by means in lin tio cios,

bring tube, E , in line with the liead Fit fork clips, $F$, on thi forks, but do not tighten. Then fit clip $G$ on down tube, leaving the screws, H and J, lonse Spring thic stirrup, K, over the wheel, and place the pega. $Q$ into the fork clips, F. The next operation is to adjust the screv, J, so as to leave the siving arm, M, a working fit. and tighten lock nut.
Tighten up screw, $H$, and carefully note that stirrup, K, lies parallel with the tubes, R, then tighten up lock nut. Now shorten tho rod, $B_{\text {, if }}$ if necessary, and pass it through drawholt, $\mathbf{C}$, till there is sufficient tension on spring. L. to force back the swing arm, M ; then tighten nut. A Adjust the pad holders, N, up to within $\frac{1}{8}$ in of the rim by means of thic milled nut, $\mathbf{O}$, then lock hexagon nut, 3 ', finally fitting the fork clips, F, in position. The stirrup, $K$ when at rest must not butt up against the fork clips. A stop is provided on the hand lever by which the position of $K$ should be set as shown.

Coaster hub brakes arc sometimes employed in conjunction with a two and threespecd gear. Generally speaking, the conster hub brake is designed on the internal expanding principle, employing either an expranding bronze ring or an expanding slecve, the braking power being applied in each design by back-pedalling.

Motor Cycles and Motor Cars. The various types of brake used on motor vehicles may le olassified under the following heads. Internal expanding, as shown in the diagram, Fig. 5. External contracting band brake, Fig. 7 ; and the front wheel brake, Fig. 8. In Fig. 11 is given a dingram of an interconnected fourbrake s.psten. Its particular feature is that pedal and hand lever actuate all four sets of brake shoes.
In the motor cycle class there arc the band brake, Fig. 9, the belt rim brake, Fig. 10 and alaso various forms of internal expanding brakes, designed in nearly all cases to give inaximum braking power in a forward direction, i.e. the expanding band is operated from one end only, its other end butting against a stop. In most censes this type of brake is fitted either on the gear box or incorporated with the belt pulley.

Figs 5 and 6 show the action of the Perrott-Bendix two-shoe internal expanding hrake. This is adapted to give a complete servo action

both forwards and backwards. Fig. 5 slows the two shoes with their operating mechanism, while Fig. © shows the operating mechanism in several positions. The shoes are connected to one another at their lower end by the short link $e$, and their upper ends are expanded so as to engage the inside of the drum by a floating lever, $f$, carrving two small rollers, $y$, one for each brakic shoe. The lever, $f$, is adjusted angularly by connecting its lower end to a short arm; $h$, fixed to the brake operating spindle. the outer end of which carries the usual operating lever, $k$ :. Each of the brake sloos is free to move within narrow limits determined by holes at their ends through which prass, with a certain amount of freedom, pins $l^{1} l^{2}$ fixed to the back or anchorage plate. A spring, $m$, contracts the brake shoes and keeps their ends in engagement with the rollers, $y$, in the usual manner.
The brake shoes are shown in their disengaged position at A in Fig. 6 , the ends of the slots in the shoes then being forced against the fixed pins $l^{1}$ and $l^{2}$ by the spring, $m$. When the lever, $k$, is rotated to apply the bralies (B, Fig. 6), it imparts an angular movement to the floating lever, $f$, and the shoes are therely forced apart until they engage the inside of the rotating drum. Both shoes are caltied round in an anti-clockwise direction, their rotation being resisted solely by the pin, Il. The motation of the brake drum thus drags round both shocs and increases the force with which they engage.
When the drum is rotating in a clockwise direction, as shown at C in Fig. li. the opernting lever, $k$, is moved as before and turns the Hoating lever $f$. The two shoes are, however, then Iragged round by the drum in a clock. wise direction, their rotation heing prevented by the fixed pin $l^{\prime 2}$, the pin $l^{\prime}$ being then out
obtained from both shocs as before. Friction washiers, $n$, carried on fixed pins prevent play of the brake shoes when they are disengaged.

Fig. 7 is the extermat contracting hand bralie, which usually operates on the same drum used by the internal hrake. The design of this type is very simple, and in its hest form is arranged as shown at A. The fenturc with this design lies with the controlling of both ends of the band: by so doing the braking power is ncarly as effective with either direction of wheel rotation. At B is shown a hrake band controlled at one end only. With this design the grip is very powerful in the anme direction as that takeil by the lever, applying the brake, hecause the brake drum is trying to wrap the band more tightly against itself. But if the action is reversed it will be seen that the direction of the hrake drum through its frictional contact with the band is doing all it can to nullify the power exerted by the lever, whereas in the design $A$, the resistances nre hetter balanced.

## Principle of Front Wheel Brakes

Fig. 8 shows a front wheel brake. The control rods nust be designed so that the brake may be applied irrespective of the posi tion of the whecls: this is carried out by means of a universal joint, D, positioned on the control rind so as to be over the dead centre of thi steering head.
With this class of hrake it is alsolutely imperative for the point of contact of the tire with the ground to coincide with the point touched by the imaginary lines, $\boldsymbol{E}, \boldsymbol{r}^{\prime}$. drawn down through the centre of the steering head and wheel. In the tigure A is a hall joint allowing univeral movement during spring dellection: 13 is a roll which is a sliding fit in $C$, the operating tube; $\mathrm{E}, \mathrm{F}$, lines meeting at the tire contact point with ginund. Firont wheel brakes are without exception of internal expanding design.

Brake: for motor vehicles. Fig. 5. Operating mechanism for Perrot-Bendix two-shoe gervo brake. Fig. 6, A, B, C. D. Mechanism shown in several positiong.
Fig. 7, A, B. External contracting band brakes. Fig. 8. Fiting of a front wneel brake. Fig. 8. Common type of motor cycle band brake. Fig 10 Principle Fig. 7, A, B. External contracting band brakes. Fig. 8. Fitting of a front wneel brake. Fig. 8. Common tyne of motor cycle band brake. Fig. 10. Principle
of a belt-rim brake. Fig. 11. Interconnected four brake system in which pedal and band lever both actuate a cross shaft connected to all four sets of shoas

An interconnected four brake spatem shown diagrammatically in Fig. 11. The brakes on all four wheels are connected to a cross shaft with twu ur three bearings. In the latter case one bearing is a slack fit, and comes into use only if the shaft or one of the other two bearings should fail. Some systems eniploy two cross shnfte, thus increasing the safety margin. To lessen the effort required of the driver in operating the brakes, various types of servo neechanism are employed. In the mechanical tvpe a clutch or brake is dragged round by the tranamission, and thus caused to apply the brakes. In another type the suction of the engine is utilised to create a vacuum in a brake oylinder. In some hrake systems the braking effort is transmitted by hydraulic pressure.

Fig. 9 shows the common type band brake employed on motor cycles, which operates on a drum, $a$, mounted on the hub of the back wheel. The brake band, $c$, is secured hy one end to the bottom, or chain stay, and the other end secured to a lever, $d$, this lever being usually controlled by a pedal, but may, if desired, be operated by the Bowden mechanism. This type is sometimes fitted to the front wheel, or to the gear-hox. In this position the internal expanding is also employed Fig. 10 shows the niethod employed with the belt rim pattern, and needs little description beyond stating that it is usually operated through a pedal. But when fitted to a front wheel it is operated through a lever on the handle-bars. A similar type is minde operating on the under side of rim as marked at $X$.

Unless brakes receive periodical attention, sooner or later they are bound to seize up, the causc of this in nearly every instance being the ingress of water which is liable to get in through lack of oil on the various moving paits. Always keep the binkic parts well lubricated, by frequent use of oil or grease. In conclusion, it should be noted that the proper functioning of brakes depends far more than is realized on the care of the operating rods or cables. Any stiffness of the joints or had adjustment, which would cause unequal braking where a compensating device is not litted, will all help towards causing brake troulile which may have serious consequences.

BRAMIEY'S SEEDLING. This is a very line cooking apple. The fruit is very large, Hat, with a vivid green skin, clianging to red on the sunny side, and the flesh is firm, crisp, acid and juicy. Some people eat this apple raw in order to cleanse the palate, but Bramloy's seedling is essentially the fruit for tart, pie, or dumpling. It is best as a standard on a rather heavy clay soil. The fruit is ready to pick firat of all in November, but with careful storage will keep till May or June. See Apple.
BRAN. The outer husk of the wheat grain, bran can be bought at little cost from any cornchandler. It is used as a feeding stuff for hoises and cattle, is onc of the staple foods for rabbits, and is mixed with the meal in the fowl's warin minsh.
It is often employed for packing, and is especially suitable for glass and china or other fragile material. A bag lightly packed with bran and warined in the oven for a few minutes retains its heat, and is a substitute for a hotwater hottle.
Bright-coloured materials. cretonne, chintz, ahantung. etc., will not fade if washed in a bran hath. To make one, about $\frac{1}{2}$ pint of hran is required for every 2 quarts of water. Sew the bran into a bag of fine muslin, leaving plenty of room for it to swell, and put it, with the water, into an enamel-lined or aluminium saucepan. Bring to the boil. and stew for about is hour. Then pour off the water, fill again with cold, and stew once more for a shorter time.

Is the bran softens the water, soup is un-
mnterial is put into the first bran water. It should not be rubbed, but squeezed lictween the lingers, and put, when clean, into the basin containing the second brew. Rinse it final!y in tepid water. No white ot delicately coloured material should be washed in this waly, as the water is tinted. The brancan afterwards be used instead of tea-leaves for keeping down the dust when the carpet is being swept. See Packing ; Poultry ; Rablit.
BRANDY. This spirit is best drank with plain water rather than with sorla or any sparkling mineral. Hot brandy and water is an excellent "night cap" The linest liqueur brandies are drunk neat at the end of dinner after black coffee, being served in a large glass, convex towards the lip, and not filled to the top. Fifty years old is a sufficient age for a good liqueur brandy.
Medicinally brandy is uned as a restorative in cases of temporary faintness, and a further use for it is found in the later stages of acute febrile disenses when the patient's ןowers are waning, e.g. in jneumonia, enteric fever, influenza, ctc. Then a tablespoonful may be given every hour or two, in milk, and as much as A pint or more may be taken in the 24 hours. As a quick stimulant in an emergency, a teaspoonful of brandly in one or two tablespoonfula of champagne is very elfective. See Alcohol; Cherry Brandy, etc.
BRANDY BUTTERR. This thick sance miny be served with plum pudding. Beat up 4 oz butter to a cream, then add castor sugar until it is stiff and rocky, a few drops of vanilln, and a little tiqueur brandy. Pile up in a glass dish. It is best made a few hours before it is wanted, and left in $n$ very cool place until served.
BRANDY SAUCE. To make a sauce, which is often served with pudding, melt 3 oz . of loaf sugar in alrout $\frac{1}{2}$ pint of water, and hoil until symupy. Add to this about a dessertspoonful of cornflour mixed into a creamy paste with "ater, and atir until it boils. Add about half a wineglassful of brandy before serving.
BRANDY SNAP. To make these biscuits take 6 oz each of Hour, butter, sugar and cane syrup, to which should be added $\ddagger$ oz. ginger and a few drops lemon juice. Melt the butter, syrup and augar together in a pan, and then stir in the sifted flour, the ginger, and the emon. Pour the mixture into small romnds on a greased baking-tin and bake about 10 min . in a moderate oven. Roll them up when just cool enough to handle.
BRAN TUB. A tub full of bran, in which are concealed a selection of amall toys, brightlycoloured bags of sweets, oranges, apples, or any other gifts is an old-fashioned but still popular amusement at children's partics and nt garden fêtes. If the tul) is a deep one, a thick layer of bran is put at the hottom before any toys are introduced, so as to bring them within the reach of small arms. The tub is then filled with alternate layers of bran and toys, bran being on top when it is full. The childien plunge a hand into the tubl and pull out the gift they touch first. See Children's Party.
BRASS. One of the most useful of metals, brass is olstainable in rods, sheet, or tube. It is easily turned, filed, or soldered, takes a high polish, and can be coloured without difficulty.

Brass wire is sold in coils, from very fine to quite stout rods. Round stuff can be bought in drawn rods, with a clean and bright aurface. Cast rods are rough and of little use to the amateur. Strip brass is the most convenient form in which to buy flat material up to $\because$ or 3 in. in width and 1 in. in thickness, lown to ${ }_{1}^{1} 6 \mathrm{in}$. wide by $3^{\frac{1}{2}} \mathrm{in}$. or less in thickness. Tubes are solid drawn and sold according to their outside diameter, and are stronger than the hrazed tube commonly employed for gas-fittings. Brass-cased tube is nade of iron covered on
the outside with a thin layer of brass, and generally used in cheap liedstends and for curtain rods and poles Circular brass blanks from 1 in. to 4 in . diameter and $\frac{1}{8}$ to $\frac{1}{4} \mathrm{in}$. thiok, as well as screwed brass rod, and brass gears of all kinds, aro valuable aids to the home-worker

Brass castings are extensively employed. Soft sheet brass, which can lse readily hammeren, is used for repoussé work, and can be cut with n fret-saw. Many stock patterns of pierced brass are ohtainable. As lirass does not rist, it should be employed for screws and hinges in damp places. Fur electrical work it is extensively used being a good conductor

How to Lacquer Brass. The cleaning of brasy is an everyday task in nost homes, much of which could be asoided by lacquering, especially with such artic!es ns door handles, fenders, and the like. The brass is first thoroughly cleaned and a mixture of paraffin and whiting is applied as a paste. Very dirty brass can he cleaned with a dilute mirture of nitric acid and water or sulphuric acid and water.

IVhen mixing the sulphuric acid it must alwaye be poured slowly into the uater: the ualer must never be poured on to the ncid or an accident may result.
Boiling in strong soda-wator also cleans ordinary brass-work. The work to be lacquered must he polished brightly, frosted or otherwise finished; it is then dipped into a hot bath of dilute soda water, rinsed in cold water and dried off in hot dry sawdust. This is to remove all grease. The work should not be touched with bare hands, but a piece of clean tisaue paper aloould be used.

The next step is to beat the work evenly but slightly, and a film of moisture will form on the brass. Directly this disnppears the lacquer is applied with a clean camel-hair brush in one even cont. The work must not be touched twice with the brush or it will be spuiled. The article is then turned about over the heat from a gas burner until it is dry, and set aside to harden off. Lacquer is ohtainable in crystal or colourless; pale gold, which imparts a slight colour; or deep gold, as usually applied to domestic articles If the crystal lacquer is used it will be absolutely invisible to the eye. Under normal conditions laçuer stands for a yenr or no:c without any other attention than that of an occasional dusting. See Ash Tray; Brazing.

BRASS COLLECTING. Examiples of old brass work, which arc within ordinary reach, belong to the last three centuries. They include caldrons and skillets, snuffers and candlesticks, mortars and door-stojes, trivets and chestnut ronsters, tinder-boxes and ember tongs, andirons and fire brasses, ladles and funiture handles, warming-pans and foot warmers, lantern clocks, trinket boxes, and table hells. Such ohjects enhance, when used with decorative discretion, $t$ he effect of lounges and halls furnished in oak or mahogany, with leather upholatery or deep-linted tapestries, and self-coloured wails.

Much continental hammered brassware. collectively called dinanderic, has for centuries been made round about Dinant in Belgium. It includes coffers, platters, and Dutch tobacco-boxes with liblical scenes based on old wood-cuts. The modern work is often poor in material and exccution, but good examples are to be had.

Oriental brass is best associated with eastern carpets and related colour schemes. The domestic brassware of the Hindu kitchen. whose unurnamented surfaces are burnished daily, generally preaent delightful forms; such are water-bottles or lotns, both large and small, wide-mouthed milk howls and sliallow ricedishes. Images of Buddha or of Indian deitics, if not placed in trivial surroundings, may be
displayed with one or two pieces of solid hammered IBenares ware.
A good deal of modern English hrass, including some which is spun or stamped by inachinery, is in good decorative taste. The production of replicas is a thriving industry, and if they are of honest fabric and sold at their face value only they have ornamental uses. Spurious old brass is hander to detect than any other class of counterfeits.

Medieval hrass is hardly possible to acquire except in the anction-room. It comprises pattens and alms-dishes, pilgrim signs and curfew hoods, astrolabes and sanctuary rings. Of a later age perforated homseamuleta, of which there are more than 1,000 designs, including rayed auns, horned bull's heads, and crescents. are charming in form and decoration. A full ret of thesc harness-trappings consists of a face-brass, $t$ two ear-pieces. six shoulder ornaments, and six or ten metals for the martingale over the chest.
Stuart and Georgian pipe-stoppers, fohseals, and other objects with engraved bases may still le met with in out of the way places. They irequently sinulate or caricature the leatures of famous men of the day. There are also miniature reproductions in brass of period furniture, such as Chippendalc tables, grandfather chairs, and the like. Some collectors specialise in old door-knockers, whose designs may be arranged to illustrate the development of taste. Gorgon-heads and other grotesque forms, derived from ancient sanctuary rings, are favourito designs for miniature linockers

Delightful figures-they are hardly statu-ettes-were produced in the 18th century

Brass Collecting. 1. Horse amulets. 2 and 3. Figures made by brassworkers' apprentices on completing their apprenticeships. A. Alms-digh, with desizn of Adam, Eve and Serpent ; early 18th cent. 5. Cande sanflers, 18th cent.
for the finials of door-stops and fire-dogs. They were often in pairs, such as peacock and pheasant, loy with dog, and girl with rabbit: hesides groups and variouq national and allegorical figures.
Brass should be kept dry by regular leathering. Unpleasing stains may le removed with chalk moistened by apirita of turpentine ; deep-scated tamish will yield to weak oxalic acid applied by a ring. followed by washing, and drying with whiting. Liquid polish serves for large surfaces, such as ivarning-pans. but if used for perforated or hanmered surfaces deposits innst not be left in the crevices See Benares Ware.

BRASS-BACK SAW. Small brars-back hand sawe are used for cutting thin, soft sheet metals and tubes, such as lorass, copper, or pewter. They are inexpensive, and are useful in the home workshop, being preferable to a hacksaw for cutting brass tulings. See Saw'

BRAWN : How to Prepare. 'luke lialf a fresh or salted pig's head, 1 carrot, 1 amall turnip, 12 peppercorns, 4 cloves, 1 blade of mace, 1 sprig cach of thyme, parsley and marjoram, and some salt and pepper. The pig's head should be well washed in tepid water, rinsed, and put into a saucepan with sufficient cold water to cover it. Bring slowly to the hoil and akin carefully; then add the vegetables, which should be cut into small pieces, the herbs and scasming. Simmer the whole slowly until the flosh leaves the lomes easily; then strain the liquid into a basin and put the head on a dish.

The meat has now to be cut from the head into sinall pieces and the tongue into thin slices, removing any skin or gristlc. Return the liquid, skimmed of all fat, to the sancepan with the hones from the head. Boil quickly till reduced to half the quantity, then strain over the meat. Scason igain if necessary with pepper and salt. When slightly cooled pour into wetted moulds and set aside to get cold and firm. Turn out to serve and garnish with parsley. The time requircd for hiniling the head depends upon its size, one weighing 6 ll . taking from two to three hours.

The inside of the moulds may first be decorated with some hard-boiled egg cut into thin dice or small fancy slinpes.

To make spiced brawn, use $1 \frac{1}{2}$ Ih. of lean beefsteak and a small pig's heat which has been in pickle for a week. Placo the meat and the head in $\Omega$ saucepan and cover with cold water. Bring to the looil quickly, skim well and simmer for 3$\}$ or 4 hours. Then strain off the liquor, reinove the bones, and clop the meat finely. Season the brawn with cayenne pepper, salt and a little allspice. Make the meat inoist with a little of the liquor carefully frced from fat, and prese it into a plain round mould with a heavy weight. It can be turned out next day.

For veal brawn take a knuckle or any bony piece of veal and wipe
with a clean cloth, removing any fragments of bone. Put the meat into an enamelled sancepan, cover with cold water, and bring it to boiling point. Skim the liquid well, add an onion stuck with cloves, and a teaspoonful each of salt and pepper. Sinmer very gently till the meat comes off the bones and the gristle is nearly melted. Having taken out and boned the meat, chop it into small pieces, add tivo or three hard-boiled eggs cut into alices, and season the dish lightly with salt, lemon juice, and chopped parsley. Arrange all in a mould. Pour a little atrained stock over it and set it aside to cool.
Calf's head brawn is useful, and if a little care is taken in arranging the pieces of egg in the top of the mould, it can also be made ornamental.

Take about l. It. of hoiled calf's head (q.v.) and 1 lb . of hoiled ham or bacon, and cut both into neat dice. Shell and cut three hard. boiled eggs first into thick slices, and then cut the latter into quarters. Arrange pieces of the egg in any pretty deaign at the bottom of a plain mould or basin, and then lill up lerosely with layers of the head, ham, and any egg that remains. Between each' layer sprinkle in a little seasoning, made hy mixing 1 teaspoonful of grated lemon rind with 2 teaspoonfuls of chopped parsley and salt and рерре:

Heat pint of the liquor in which the head was boiled. This should be a stiff jelly, but if it is not, recluce by boiling without the lid 10 ahnut two-thirds of the original amount. Dissolve in this stook 3 shects of gelatine, but do not let the liquid boil. Then atrain into the mould till the latter is full, and puta plate on the top of the mould with a weight on it. Leave until cold and set. Wipe off any fat that inay be on the top, dip the mould into hot water to loosen the jelly from it and turn the sliape out on to a dish, garmish. ing with lufts of washed cress or lettuce.

## Fish and Vegetable Brawns

For fish hrawn the ingredients are some white fish and the bones of a rabbit or chicken or some veal bones. It needs also a little onion, pepiser and aalt, some chopped paraley and hard hoiled eggs. Cover the looncs weil with water and stew them well and slowly. adding the pepper, salt, and onion liefore straining. Decorate $n$ mould with a little chopped parsley. Fill half full with altomate layers of llakes of cold fish and hard boiled cggs in slices. Then atrain in thic atock gently till the mould is full. When cold turn it out. It should be seried lecorated with parsley.

Egg and vegetable hrawn can be made as follows: lboil 2 eggs hard and alice them. Make sonc clear stock with a few bones, strain it through muslin, and to each pint of stock add $\frac{1}{2}$ oz. gelatine. Arrange in a wetted mould the slices of egg, some slices of tomato and cold potatocs, and reason with pepper and salt. After putting in one laver of these add a little of the stock in which the gelatine has been dissolved. When set add another Inyer of eggs, etc., and continue the process until the mould is full
To make rabhit brawn, thoroughly clean a rabhit, cut it into joints, and let it simmer gently for 2 hours. Then take the ineat from the bones, and cut it into small pieces. Arrango these in a plain, round mould with 2 hard-boiled eggs and $\frac{1}{1}$ lb. cooked ham, cut sanall. Add to 1 pint stock $\frac{1}{2}$ oz. gelatine, and dissolve it very thoroughly. Pour this over the rabbit and turn it out when cold.
BRAZIL NUT. Imported into Great Britain from South America, the Brazil nut is a favourite for dessert. The kernel yields an oil used by artists and watchmakers.

Brazil nut cutleta are made from 4 oz . bieadcrumbs, the white of one egg, 3 oz.
skinned 13razil nuts, \& pint white sauce, 2 teaspoonfuls mixed herbs, and a pinch of powdered mace Put the breaderumbs and nuts through a mincer, add the herbs, and mix all with the white sauce. Beat up the white of the egg to a stiff froth and add it lightly to the mixture. Shape the whole into cutlets and fry in hot fat : then drain and dish on a doily, garnishing with parsley before serving.

BRARING. Brazing is a method of uniting metal parts by means of a film of brass in the form of alloy, known as spelter. Metals that are usually brazed together are steel, wrought iron, brass, and copper. Cast iron is not usually brazed, as better results are obtained by autogenous welding.

The various stages in brazing are as follows. Thoroughly clean the parts to be brazed, apply a suitable flux to the joint, then assemble thic parts, and secure them so that they cannot move relatively during the brazing operation. Next apply the spelter to the joint. Heat the work thoroughly until the spelter runs or melts and unites with the metal parts. Finally clean the job, and remove any scale or surplus spelter.
The tools and materials required are a powerful brazing blow-lamp, or preferably a gas blow pipe supplied with air from a foot bellows, a stout iron pan on legs, and filled with coke or lumps of asbestos, some spelter, borax in powder form, and a few rough pliers or tongs for holding the work while brazing. Sotne soft iron wire and a packet of brazing pins aro needed to secure the parts, unless they are screwed or driven tightly together so that they cannot move while being operated upon.

A simple example is to braze a steel tuke into a steel socket. Clean the joint thoroughly by polishing with emery cloth, or by filing or grinding, and paint it with a solution of powdered borax. Now force the tube into the socket : there is no fear of its being too tight, as the brass will run into the joint although there is apparently no room for it The danger is in having a slack joint. A lirazing peg has next to be inserted. For this purpose drill a hole through the socket and tube, insert the small end of the peg, and drive it in hard with a light hammer.

## Use of the Blow Pipe

Now place the work on the brazing pan and pack asbestos cubes around the back and sides. leaving space for the burner flame. The idea is to retain as much heat around the joint as possible. Light up the blow lamp or gas blow pipe, adjust the flame to burn clean, that is, without yellow streaks or any trace of smoke. Move the lamp about so that the Hame warms up the asbestos and the metal generally. Watch the borax or Hux around the joint, and directly this begins to bubble and turn white, apply the spelter to the joint. Sjelter is obtainable in granular form, like brass filings, and can be mixed with an equal proportion of powlered borax. In this state it is applied to the joint with a metal rod. Heat the end of this rod, dip it in the spelter, and sufficient will adhere. Apply this to joint and as much more as is needed.

If spelter is bought in the form of brass wire it is roughly square in section and sold in rolls. Cut off a few feet and coil up one end. then heat the other and dip it in the powdered borax, a globule of which will adhere. Then heat the work stesdily and thoroughly, at the same time melting off a piece of the spelter wire, or brazing wire, as it is usually called. Push this with the end of the rod into its place, or as near as possible; continue to lieat the work, apply a little more flux from time to time to prevent the surfaces oxidising, and watch for the spelter to melt. When it begins to melt, watch where it runs. It should
disappear into the joint Spelter will follow the heat and the flux, and will not adhere to the metal except where the flux has been applied Brecarcful not to inhale the fumes given off during the brazing process.

To be sure of the job being a sound one, it will have to be turned over. When one side is brazed, kcep the flame on the work so as not to lose the heat, and turn the work over with the tongs. When satisfied with the job, turn off the blow lamp flame, and allow the work to cool off before touching it. When it is black hot, take it from the pan, holding it with tongs, and with a wire brush remove all surplus Hux and scale: being in a plastic state it should brush off easily. When quite cool, the scale has to be cleaned off, by pickling in a weak solution of sulphuric acid and water. The pickle should be made in an earthenware or glass jar and preservod for future use. Leave the work in tho pickle for an hour or so, then wash it in hot water. and filc and polish until the metal is clean and bright. If feasible, run some oil or paint into the interior of the pipe to prevent it from rusting.

The secret of success in brazing is clean work at the start, sufficient heat applied in the right place, and to see the spelter run nicely and freely. On soine work the spelter and borax mixture can be applied direct to the work and then heated, but generally on all steel or iron parts the brazing wire is the best.

13 rass and copper are brazed in the manner already described, but call for more care and skill on the part of the operator. The brass has to be heated to a dull red heat before the spelter will run, and at that heat the brass itself is on the verge of melting. It is best
to use a soft spelter strip or specialiy prepared white spelter, as this melts at a lower tempers. ture than ordinary brazine wire. The same care is needed at all stages of the work. Much small brasswork is, however. joined by a process known as hard soldering or silver soldering. See Brass; Soldering.

BREACR OF PROMISE. An action for breach of promise of marriage can be brought by $n$ man who has been jilted, but almost invariably the plaintiff is a woman. The lady must prove that the defendant promised to marry her. The promise need not be in writing or words lut may be presumed from conduct. The plaintifi's word and oath alone ane not sufficient to establish a case. She must be corroborated; and this corroboration generally takes the form of love-letters ; an engage-ment-ring; evidence that the lady was introduced by defendant to some other person as his fiancée.

It must be proved that defendant had broken his promise. This he may do by breaking it off formally; or by getting engaged to or marrying someone else; or by neglecting to marry the lady within a reasonable time. Fur a promise to marry means to marry within a reasonable time.

The damages reooverable are practically whatever the jury like to award. They generally give the plaintiff anything she is out of pocket for trousseau and the like; something for injured feelings ; and something for what may be called the value of the match. A promise by a minor (under 21) to marry is void; but if he inakes a fresh promise after he is 21 he may be sued if he breaks it. See Engagement : Marriage.

## BREAD AND BREAD MAKING

## Essential Facts for Every Honsewife

This entry is followed by several dealing with various uses of bread, and by other relevant headings, including Bread Basket; Bread Curter, etc. See also Baking; Diet

Tho necessary ingredients for household bread are flour, yeast, sugar, salt, and warm water. For small loaves, rolls, etc., baking powder may take the place of yeast, and butter, milk and eggs may be added. As a rule, 支 oz. yeast, a teaspoonful each of sugar and salt, and rather more than a pint of water are used to 1 lb . flour. The same proportions are employed for brown bread, but wholemeal flour is substituted for ordinary white flour.

The method of preparing household bread is as follows. Mix yeast and sugar well together, add a tablespoonful of tepid water (tepid being $\$$ boiling water and of cold), cover basin with a clean cloth and stand in a warm place until yeast is well risen and frothy. Meanwhile, measure flour into a basin and warm it, either in front of the fire or on the rack above the range. When yeast has frothed, pour it into a well, made in centre of tlour with a warm wonden spoon, and sprinkle a little of the Hour over it and a teaspoonful of salt round edges of Hour. Cover basin with a cloth, put in a warm place and leave until yeast has cracked well through flour. Stir in gradually the tepid water, preferably with a warm palette-knife, and the mixture is a warm palette-kni

Kneading presses the yeast cells between the grains of Hour, and by it the dough is rendered smooth and clastic. A warmed board, lightly sprinkled with Hour, must be used. Turn dough on to this and knead (i.e. rub firmly together and pound) with bith hands. The success of the loaf depends largely upon the kneading, and a light, firm touch with dry, warm hands is essential. When the dough has become smooth and elastic turn it again into a warm basin. cover, and set to rise in a warm place until it has at lcast doubled its size. This takes about 2 hours.

Then turn once more on to board and knead quickly and lightly before forming into loa ves. Thesc may either be stond upon a large, floured baking tin or small floured bread tins may be used. This done, let the dough stand (or prove) in a warm place for 20 min . It should always be remembered that uniform warmth is the secret of yeast bread. If raised in too cool a place a very close consistency will result : if too hot, a solid cake of Hour will tollow, or loaves with large holes in them.

During the time of final proving the oven must be niade very hot. All yeast bread must be baked in a very hot oven at first, to kill the yeast. After the bread has risen still further. and browned, the heat may be gradually reduced. Allow about 1 hour for baking a halfquartern loaf and $t$ to $\frac{1}{\frac{1}{2}}$ hour longer for a quartern loaf. When the loaves sound hollow on being tapped briskly underneath, they are done. They should bo cooled on wire trays and turned upside down.

## How to Make French Bread

French bread is made with Vienna Hour. Nilk is added to the yeast and sugar instead of water: tepid milk and sometimes a little beaten egg is employed to mix the dough. Kneading, rising, proving, etc., must take place as previously explained, and after forming into plaits, rolls, etc., the dough must be brushed with beaten egg and allowed to rise again for ten minutes. A very hot oven is again needol. Small fancy twists and rolls usually take about 15 min . to bake.
Any good pastry flour can be used for fancy bread. Currants, sultanas, or a pinch of mixeil spice or cinnainon mny be added if desired.

Three rolls of a richer variety are illustrated in Fig. 5, two of which are dealt with in the text. To prepare, sieve together in

Bread and Roll Making. 1. Kneadinf the dourh. 2. Pricking dough in baking tio. 3. Glazing rolls. 4 . Placing top on cottare loaf. 5. Milk ralls in lancy shapes

f, is $s$ and $s_{1}$ courlemp of Comulty Live. J.inf.

a warmed hasin $\frac{1}{2} \mathrm{lb}$. flour and $\frac{1}{2}$ teasjoonful small loaves should he brushed with beaten salt, ruhbing into them 1 oz. butter. In ogg. Ten minutes in a hot oven is sufficient nnother warmed basin mix a little less than for small baking-powder dinner rolls or loaves. $\frac{1}{1}$ oz. yeast, with $\frac{3}{3}$ tensponnful castor sugar ; To muke these rolls, sift with $\frac{1}{2}$ |h. fine llom then warm up $\ddagger$ pint or less of milk, adding to it a small, well-benten egg. Pour the latter mixture into the yeast and sugar, mix all well, and then add the whole to the flour and salt. Beat up all these ingredients, and put the covered dough in a warm place to rise for about one hour. When it has risen, divide it into four portions, and from one of thesc make a plait roll. Divide the piece into three equal parts, rolling each until it is about 5 or 6 in long.

Pinch these strips together at one end before plaiting them, and finish the botton in a aimilar manner.

The horseshoc roll is made by forming a portion of dough into a triangle and, taking the longest side, rolling it over to the point. Twist the roll to form a horseshoe, and cut it across the top in several places with a knife. The roll with a plaited effect on top is made by dividing a piece of dough into two unequal portions, and placing the smaller part, plaited in the way already described, on top of the larger piece, shaped to form an oblong. Let the rolls rise in a warm place for $20-25 \mathrm{~min}$. then brush them over with milk, and bake then for about quarter of an hour.

Method of Makins Aerated Bread
Aerated bread is so called because the bread is raised by means of the carbonic acid gas given off from baking-powder when moistened. It is made as follows: Take 1 oz . baking-powier and 3 oz. salt to every 2 lb . flour, incorporating the salt and baking-powder well into the flour hefore maistening. Pour about a pint of water into the centre of the flour and make it quickly into a dough. Divide it into loaves and brush over with milk. Put the loaves into the oven immediately. No time must be lost between the moistening of the flour and getting the loaves into the oven, otherwise part of the aeration will be lost. Bake in a quick oven for about half an hour.

Bread raised with baking-powder is made by simply rubbing fat into the flour and adding salt. haking powder and sugar. The dough is mixed with water or milk (the latter preYerably sour) and when formed into rolls or
$?$ teaspoonful baking-powder, and $\ddagger$ teaspoonful salt into a hasin. Rub in 1 oz butter and mix all into a stiff dough with I gill sour milk or water. Divide it into 6 equal portions and make these up into round rolls. Bake them about 10 min . and serve them hot. These rolls can be made suitable for tea if the butter is increased to 2 oz and a like quantity of castor sugar ndded : also, if an egg is beaten up and odded to the liquid whon mixing up the flour.

## Value of Wholemeal Bread

Wholemenl bread, which includes all the bran, may pmove indigestible for some people, or may even produce irritation of the digeative tract. But those who ain digest it neceive additional nourishment, ineluding a much larger portion of organic phosphates, which are indispensable to the chemistry of the body. Also, in wholemeal bread we retain the vitainins which are so necessary to growlh.
Without a doubt, wholemeal bread is the linead which should the supplied to children. Anong the well-to-lo the deficiency in vitamins and organic phosphates may te made good by other articles in the dict, such as butter, eggs, and fresh vegetables; hut children who are brought up on skim milk. margarine, and white bread are starved of things necessary to their proper growth, and rickets and ill-detined forms of disablement may result.

With regard to the irritating effects of wholemeal bread on the intestinal tract, this may be in many cases the stimulus required to produce a proper innvement of the bowela and prevent or cure constipation. New bread is npt to be indigestible; it is better to use it a day old. The proper toasting of bread makea its digestion easier; but this does not apply to hot buttered tonst, on which the butter has been made less digestible by heat. If buttu is used, it should be put on when the toast has cooled.

In diabetes it is necessary to limit the amount of starch in the patient's diet, and starchless bread is sold for this purpose. It is made from gluten, the sticky substance in dough, brnn, casein, the pinteid in mill. curd.
nuts, and almonds. Some samples are quite frec of atarch, but others contain more or leos of it. Such bread should he bought of as reliable maker to ensure ita being what it is represented to be.
BREAD AND BUTTER PUDDING. ' 'o prepare this, butter a piedish and aprinkle currants or sultanas or spread a little jam or marmalade on sufficient slices of bread and butter to half-fill the pie-dish. Heat 2 eggs to a froth and mix them with a pint of mille and is tablespoonful of white sugar. Pour in this custard and let the bread soak in it for half an hour, or until it is soft. Stand the pie-dish in a deep baking-tin with water round the diah, and bake the pudding slowly till set and browned lightly. The water round the dish together with the slow baking provent the custard froin curdling.

BREAD BASKET. The craftworker call make the raffia bread basket shown in Fig. I with one hundle assorted colours and of natural raflia. It measures 8 in . aeross whon linished and is horcered with blue, orange white, hrown and black raffia.
Thead a raffia needle with a strand of nitural raffia and take six morethreads level nt one end. Bind these together with the tirst, taking eight or nine wraps over from front to back. Now coil into a small ring,个 in. in diametor, to begin spiral for base. going in a left-hand direction. Take a few "raps with needle-strand mund the ring and coil and then make a knot-atiteh, by bringing the needle through from the back betwcen the coil and the ring on the left of the last stitch. Then take it across front of this stitch and pass needle through on the right of this stitch. bring it round to left again, between ring and coil. This part of the process is finished by taking needle round coil.
liake a long stitch, by taking needle thongh centre of ring from the back, then over cuil, as before, and make another linutstitch. Continue the operation in this way until the one row is completed, then thicken foundation coil by adding a few more striunds to make it $\frac{1}{3} \mathrm{in}$. thick.

When the base is 6 in. across, gradually raise the coil to form the fingt row of the side of the basket, and make each succecding row a trifle vider, until the sixth row gives a diameter of 8 in to the bread basket. Carefully watch the shaping and see that the millos me woll balancerl

The horder is now begun with "original weave " instead of knot-stitch. For this take the raffia round the coil and insert the needle under one of the stitches in the previous row, Hus securing the loose coil to the baslict. Point needle in slanting direction to left when inserting, and then procced to make every atitch in patterned border in this manner.

Bread Rasket. Fig. 1. Basket waven in raffa in several bripht colours

The design is shown called raspings, as some bakers sell them when in Fig. ‥ It is built they have rasped over the surface of the loaves. up by use of the Put any crists left from making white crumbs, colours, row by row or any small stale pieces of bread, on a tin in a as shown in the chart, monderately hot oven and bake until they Fig. 3. Taper off the finishing end to $n$ point and bind the last inch of coil to previous coil.

wenving. Fig. 3. Chart showing colour schemes
than 8 in . or less, the design must he adapted to fit before introducing colours. A cardboard circle 8 in . across fitted now and again to the inside, as the basket is worked, helps to lieep the sides to shape.

The aunateur can also nuake the wooden bread basket or bost in Fig. 4, which exhibits Norwegian influence. It is made by cutting the botton, Fig. 5, from $\frac{1}{2}$ in. wood, such as mahogany or oak. and the edges are bevelled as indicated. The two sides, Fig. 6, are cut from similar material not more than $\frac{3}{3}$ in. thick, bent to shape, glued and pinned to the hase, the ends being held tngether temporarily by strings wound round them.

The two handles are sawn to shape from a piece of material 6 in. long, $1 \frac{1}{2} \mathrm{in}$. wide, and 1 in . thick, as in Fig. 8. The V-gmove, Fig. 7, is cut out with $\Omega$ chisel to fit closely on the ends of the side pieces, A, B. The horns are carved, and when completed the handles are glued and pinned in place. A cover piece, $C$, Fig. 7, is cut to shape and glued in position in the apex of the triangular joint at the ends. The construction is clearly indicated in the section, Fig. 9. The work is completed by sand-papering and polishing, or by stencilling in liquid washable colours.

BREADCRUMBS: In Cookery. Finer if rubbed through a wire sieve with Whe hand than if grated, fresh white crumbs are used for puddinges bread sauce, and often for crumbing fried foods, although dried crumbs will ho found best for this purpose.

To prepare the latter put any fresh white crumhs that cannot be used in a baking-tin in a slow oven to dry, but not colour. Turn them over now and then, and when quite dry and crisp re-sieve them, and when cold store in a dry tin with well-fitting lid. These will keep for ycars, as long as they are dry, and are used chiefly for coating foods brushed with beaten egg previous to frying.

Dried browned crumbs are often

Bread Basket. Figs. 4 9. Basket or tray made in wood, in the lorm of a boat, with explanatory diagrams a cut thick or thin as requircd. and past the cutter. These inachines seldom give trouble, and only require keeping perfectly clean and occasional sliarpening.

BREAD FRITTERS. Use either ordinary household bread or French dinner rolls, cut into rounds. Cut $\mathbf{6}$ or 8 neatly shaped pieces of hread or molls $\frac{1}{4} \mathrm{in}$. thick. Heat $\frac{1}{2}$ pint of milk with the thinly pared rind of half a lemon till it is well llavoured. Dissolve in this a tea spoonful of white sugar: take out the lemon

rind, and pour into the milk a well-beaten egg. Pour this mixture on to the bread, and have ready a frying pan containing 2 oz . of butter.

Directly the bread is soft, fry the pieces a golden brown on each side in the hot hutter. Lift out of the pan, drain well, sprinkle with castor sugar and serve quickly with jam sauce (q.v.)

BREAD PAN. An old-fashioned but re liable bread pan is made of earthenware, with an earthenware cover Such pans have the advantage of maintaining a more equable temperature than enamelled iron bread pans. Scrupulous cloanlincss is essential together with periodical removal of breadcrumbs, and the placing of the vessel in a cool, dry place

BREAD POULTICE. Cut uj bread, stale if possible, into small pieces and put into a bowl which has been scalded. Pour boiling water over, cover bowl with a plate and put by the fire for a minute or two it is then beaten up with a fork, excess of water being re moved by wringing the mass rapidly in a towel, and tios poultice is applied between layers of muslin If a piece of jaconet or oiled silk is applied 8 a as to overlap tho Bead Cuter wirb loar whit is placed on the back of the plate or is pushed wil! be retained longer. See Poultice

BREAD PUDDING. To prepare this, soak $\left.\frac{1}{2} \right\rvert\, \mathrm{b}$. stale bread in cold water until soft. Drain and press out water, put in a hasin and mix with 3 oz . butter, niarg., or chopped suet. Add 3 oz . Hour, 3 oz . sugar, $\ddagger \mathrm{lb}$. currants or sultanas and a little chopped peel. Beat an egg, mix with a gill of milk, and stir these in with about $\frac{1}{\$}$ teaspoonful mixed ground spice or nutmeg. This pudding can be either steamed for it hours in a greased hasin covered with buttered paper, and served hot, or baked in a greased pie-dish for about I hour in a moderate oven, and served either hot or cold.
BREAD SAUCE. To make bread sauce, which is served with chicken, etc., boil about $\frac{1}{2}$ pint of milk with a small onion in which a fow cloves have been stuck for flavouring. Add 2 oz. of soft breadcrumbs and cook gently for 15 min . It should be seasoned, a very little powdered nutmeg added if liked, then a piece of butter, and, if desired, a little cream.

BREAKAGE. It is illegal for a mistress to deduct anything from a servant's wages to pay for any crockery that the girl breaks when washing or dusting, unless she has expressly agreed with the girl that she will do so. If a maid breaks anything on purpose, or by gross negligence, the mistress could, no doubt, sue her in the county court for the damage done or dismiss her summarily; but beyond that she cannot go. The law regards accidental breakages as one of th ose incidents of domestic service that may happen without anyone being specially to blam3. See Servant.

BREAKFAST : How to Serve. The British habit of eating a good breakfast encourages the housewife to make the meal as attractive and varied as possible. Many people, men especially, are most conventional in the matter of bacon and eggs; though fried tomatoes, potatocs, parsnips, bananas and mushrooms can all be served in turn with the bacon for a change.

It is convenient to provide a hot dish and a cold one, where there are several in a family.

Fior instance, with hot fish, cold bacon or a decorations of the room, breaklast china and galantine may the on the sideboard: with table linen may introduce more colour and eggs, soused herrings, brawn or sardines. As a loot dish, uncurled whitings cooked in a fireproof dish with butter and parsley are often liked for a change, or dabs fried whole with a grilled tomato placed on top. Dricd haddock is apt to be woolly unless a thick one is chosen, and well basted with milk and a
be mone informal than those in use at other menls. Thus cottage china may be seen with check cloths, or orange ponttery with unbleached linen appliqué with fruit and flowers. As a general rule the patterned service looks best with plain coloured linen edged perhaps with border to tone.

Brealfast.
A wholesome breakfast of fruit, brown bread and butter and coffee, the a
lumpl of butter lsefore serving; kippers are good cooked in a tin in boiling dripping and then toasted for a minute or tipo to crisp them. These dishes, when servell, may be on a henter on the sideboard, or sent to table in attractive oven-ware.
Eggs can be cooked in many ways, but a simple plan is to put some butter into a Hat fireproof dish and, when melted, break the eggs into the dish and replace in the oven for a fow minutes till set, sprinkling with a littio chopped parsley to serve.

## Value ol Cereal Foods

Porridge is a valuable adjunct to the family breakfart. Many children take a dialike to this, and the reasons are usually hecause it is not stirred enough, and is therefore lumpy; because it is not cooked enough, or hecause the salt. which Havours the ontmeal, is forgotten. A change froin porridge is a saucerful of one of the ready-cooked cereal foods which, served with hot or cold milk with stewed fruit or a little crenm, is most nourishing. Fruit should always find a place on the breakiast table. Some people eat only toast and butter with grape-fruit or an orange, while the habit of linishing up breakfast with an apple is an excellent one for children.

Stands must be placed under hot tea or coffee pots if there is no tray or if this is of wood. For coffec a good mixture is equal quantities of Mocha and Plantation, with a very sniall anount of French chicory. if impossible to roast and grind the beans at home, only a small quantity of colfee should be bought at one time. A change for children is a big jug of cocoa made with milk. Should there he any sour milk left over from the day before, it does not take long to make n few soda scones, or ordinary rolls may be popped into the oven for a few moments

A well-laid table is a great appetiser. A cheerful scheme is fruit in some quaint pottery bowl, or one of polished wood, on a coloured damask tablecloth, with jam, etc., in attractive dishes. While preserving harmony with the

What is known as a breakfast service in a shop is a somewhat incomplete affair, unless several silver or other ware articles are to supplement it. It is sold for 6 or 12 persons, and usually only consists of that number of cups, saucers, and plates, a milk jug, a sugar basin, and a teapot. Brenkfast dishes, toast rack, egg cups, larger jplates, coffee pot, hot milk jug, cream jug, slop basin, jam and butter dishes are not included.

For those who prefer everything to match, or who do not wish to have silver articles used daily on account of the cleaning that Hey involve, there are a good many stock patterns. in which it is prasible to buy each piece as required, including the extra articles named, together with poriidge or stewed fruit jlates, and grape-fruit holders. A stock pattern has the further advantage that any lorenkage can he replaced.

In earthenware-or $n$ as it is often called, semi-porcelain-these stock patterns are reproduced in some of the old designs suoh as Chelsea, Worcester, Lowestoft, etc.; they are not expensive, and the jugs and dishcs in plain old-fashioned shapes are attractive,
especially it breakfast cloths and napkins are cross-stitched in colours and designs to correspond with patterns selected
In pottery there is not so much sariety. except in bright colouring, particularly suitahle for country house use. In china there is a wide innge of Hower and conventional patterns. For the nursery amusing rhyme illustrations and animal designs in stock patterns can be ohtained. These suggest delightful inhlecloths to correspund. See lplpliqué; 'Tablecloth.
BREAM. Wrap the cleaned lish in lntered paper, and bakc in the oven for about $\hat{f}$ hour. A more elaborate way is to stuff the lish with forcement made of breadcrumbs, chopped suet. and anchovy paste or chopped oysters, with inace, salt and pepper as seasoning. 13ind the forcemeat together with milk or heatenup egg, and cook the stuffed fish in the oren for about 40 min ., keeping it basted all the time with dripping. Brenin may also be hroiled. In cleaning do not remove the scales
BREAST : In Cookery. This name is given to the joint of mutton, veal, or venison below the shoulder, and including the thin end of the rils. A sinilar piece of beef is called the brisket (q.v.). I brenst of mutton can be stuffed and boiled or roasted, and is bettel honed, or it is difficult to carve
Skin and bone the lireast, taking away some of the fat, then spread it about $\frac{1}{2}$ in. thick with forcement, sage and onion, or some whilici stuffing, taking care that the stuffing does not come too near the edge of the meat. Roll up and tic with tape, then drop into just enough warm water to cover and simmer slowly Skin off any scum, lut keep the lid on the saucepan as much as possible. It should require 15-:0 min hoiling to every lb and 15 min over. It is equally good served with hot enrrots and turnips, or cold with salad.

To roast, hone, stult, and roll in the same way, and put in a good oven. Baste well, and allow $\frac{1}{2} \mathrm{hr}$. to the lb . Serve it with apple sauce. This dish is known as muck duck.

Breast of lamh can be coolsed without honing. Trim and put in $n$ stewpan with enough stock to cover. Add a buach of herbs and an onion stuck with a few cloves, and let the whole simmet gently until the liones can easily be removed. Season the meat, brush over with egg and hreadcrumbs, and hang in a broiler heíore a clear fire, turning it so as to brown both sides. The dish should be servel hot with mint sauce.

To hoil a breast of veal, corer with wnrm "ater, adding paraley and a few peppercorns. Allow 20 min to the lb . and 20 min . over. Serve with onion or parsley sauce and hoiled hacon. It can also lie broiled similarly to breast of lamb, but just before serving sigueezo the juice of a lemon over it.

A breast of venison can be stewerl, roasted, or broiled in a similar manner.

## Breathing and Breathing Exercises

## How to Improve Health and Strength

## This article is one of an important group that den! with the care of the hody. See also Gymnastics ; <br> Plysical Training, etc.

The process of hreathing, or respiration, is being drawn downward into the aldomen one by which carbonic acid is removed from the ribs being elevated, and the breastbone. the hlood, and oxygen is supplied. The esprecially at its lower end, being moved carbonic acid, produced ly combustion in the forward. For free and full inspiration it is tissues, comes from all parts of the body, neocssary that neither the cliest nor the chiefly in the plasma, or blood-fluid. The abdomen shall be constricted by tight clothing oxygen conbines with the haemoglohin in the In ordinary expiration no muscular effort red corpuscles, and is distributed to every is made, the chest and lungs contracting by part. Hence the necessity for maintaining the their own elasticity ; but in forced expiration, blood in a healthy condition, with abundance of red corpuscles. Breathing is controlled by the respiratory centre in the medulla oblongata, or bulb.

Inspiration is accomplished ly increasing the size of the chest cavity, the diaphragm
as in coughing, sneezing, singing, etc., many muscles come into action.
The number of respirations of a healthy aduit is about 14 to 18 per min., one respiration occurring to each 4 or 5 beats of the henrt. During cxercise and in feverish disenses, the
rate of hoth breathing and the heart-beat is increased, and as a rule both go up and down together. In some morbid states the respira. tions are diminished.

The air changed in the lungs of a healthy adult at cach reapiration, which is called tidal air, is aliont $20 \mathrm{cu} . \mathrm{in}$. By a forced inspiration 100 cu. in. morc can le breathed into the lungs. This is called complemental air After
(f) The arms are held at a sllflit angle frmm the sides of hie hody. on inspiration the nims are turne ivall puslicel forward On cypirtlon tic armanal and ribs return to atarting poaition and the alshoniun wall is contracted. See Clicst
BREATHLESSNESS. Short ness of breath on exertion may be due to a large number of causen, e.g. obesity, anaemia, ndenoids, emphysema, organic disense of the heart,

disordered action of the heart, neurasthenin, Bright's discase, the a busc of tobacco, and tight lacing. See Anaemia; Heart; Lung, etc.

BREECHES. Whether designed for walk ing or riding, sports underwear for women, or period costume, the general style of breeches is a loose thigh, a close knee, and a tight fit helow the knee. Thi looseness aliove the knee should be at the sides, and never at the inside of the legs, where the garment should be clean fitting.

Walking breeches are fastened below the knees hy either buttons or laces, the latter being arranged to come on the front of the leg, while the former should be just off the shinbone, on the outer side.

Riding hreeches should le vory loose on the outsides of the thighs, the knees should le tight, and helow the knees skin tight. Extra insitle leg length is necded, to provide the necessary "arch" for sitting the horse. The
materials are of heavy weight and firm texture, such as woollen or Bedford cords. Velvet cords are sometimes employed. Knee strappinga may be of the same material as the breeches, hut are moro often of buckskin. Either leggings or top boots are worn

BREEZE BLOCK. Fine cinders, crushed coke, furnace clinkier, and burnt brick are used under the name of breeze in the construction of blockis for house building. When made up in the form of concrete, breeze bloclis arc lire-resisting, light and porous, suited for partitions and other internal walling The surface is rough and takes plaster readily, while rooden sheetings or battens can be nailed directly to the blocks.
As a lloor covoring breeze blocks are laid on a damp-proof course set direct on tho concrete foundation. The hlocks are set in mortar, and if laid to a fair level the floorboards can he nailed directly to them. The clamp-proof course may be any hituminous sliceting. or good rooling felt if set in hot pitch.
Cuko breeze hlocks, which aie often used for cxterior wallings of bungalows and other dwellings, should be built in the form of a hollow wall, with a cavity between the inner and outer skins, cross-bouding being effected rith galvanised iron wall ties, or loy using some of the ready-made hollow bricks.

When a limited number of blocks are wanted they can he made up on the site, by casting in woorden inoulds, which need not be anything more elaborate than shallow boxes of suitable size, generally about 24 in . long. 12 in . wide and 3 in . deep. The concrete is mixed in the proportions of 1 part of Portland cement to 5 parts of coke brecze, these being measured by hulk, as in a pail, and not by weight. Only sufficient water is added to make the mass hold together; complete mixing is essential. The blocks arc set to break joint. See Cement ; Concreto.

BRIBE. It is not an unknown thing for tradesmen to pay what they call commission to domestic servants. If the miatress knows about it, and permits it, well and goorl. But if she does not, the law regards cvery such payment as a bribe paid to the scrvant.
The servant may le summarily dismissed and is legally liable to disgorge everything received. An action will lie against the tradesman for damages.

Further, a criminal prosecution will lie against the tradesman and the acroant. It makes no difference at all that the tradesinan has only charged ordinary market priccs.

## BRICKS AND BRICKLAYING

## Materials and Processes Described and Hustrated

## Related articles include Architecture; Building; Garage; Greenhouse; Mortar, etc. Ses also Drawing

Bricks are the stiple material uscd in Great and 3 in . thick; they weigh on the average Britcin for walls and general house building about 7 lb . each when dry. A brick will purposes. Good bricks are durable, but require careful selection for outside surfaces, hoth in regard to weather-resisting properties and artistic olfect. They have a longer life and lower cost of mainteriance than most other building matcrials; their fire-resisting qualities are good, and insurance rates for brick buildings are generally less than those for other forms of construction. timher especially. Brick build. ings arc casier to raise money upon, and they sell morc readily.

Brickwork generally is measured by the rad of 272 ft . super, reduced to $1 \frac{1}{2}$ bricks in thickness. Sixtcen bricks will make a wall one brick thick and 3 ft . long of 4 counses, or 1 ft . in height. A 9 in . wall would take just twice that number. When laid Ilat, 32 bricks will be needed to cover 1 sq . wil. ; that is, an area of 9 sq . ft. ; but, if laid .on edge, 48 bricks would be required.

For ordinary purposes, bricks can be reckoned ns measuring 9 in . long, $4 f \mathrm{in}$. wide,
frequently absorb 7 to 8 oz. of water. For outside facings a good rule is to reject any brick that alosorbs more water than 15 per cent. of its dry weight.

The kind of brick in most general use is known ns the Fletton. It is hard and square but not of good colour, and is reputed not to last long in damp and exposed places. It is so lacking in porosity that plaster will not alhere to it, but has to hang on to the mortar joints in the brickwork. Flettons are a raw red in colour, and are extenaively employed in building walls which are faced with bricks of other kinils.

The Ioondon stock brick hasquite a different character. It is aoft, sandy, and porous, and able to hold plaster. Fromis hugienic point of view it is better suited to house building than the Fletton, because it will breathe, or allow air to pass through the walls.

The red, sand-faced, hand made facing-brick is the most highly esteemed wherever it is
abtainable. It is made chiefly in the southern foundation to rest and eastern counties. In the north, west, and upon. After marking Midland the pressed red briek of even shape out the ground, a and amooth surface is used for facing. Staffordshire blue bricks are in demand for foundation work, or any purpose where the mnximum resistance to damp is of importance.

Glazed bricks with a white or coloured surface are made of fircclay and glazed in the same way as pottery. Thoy are used for halls and bathrooms and in courtyards for external facing where light is lacking.

On the top edges of garden walls and parapets or gables of houses coping bricks are usecl. specially shaped to throw off water and protect the brickwork under them. Splay bricks and others with mouldings on one edge or one end are used to form plinths, strings, comices, or window-sills on the external faces of buildings.

Amateur Bricklaying. Although bricklaying is a skilled trade, simple work is quite within the capacity of the amateur. For most work, a 9 in . wall suffices; in fact, for small erections, such as the lower part of a greenhouse, a $4 \frac{1}{2}$ in wall will be quite serviceable. Nothing should be attempted above 8 ft . in height, becausc the matter of scaffolding for higher buildings involves operations in which experience is essential. A brick wall must have a solid and level to act as guides. trench must be dug, in which to pour the concrete for the founda. tion. Upon this foundation are laid the brick footinge, consisting of two courses or rows of bricks. The foundation concrete should be wider than the lowest course of footings, and for a singla storey building may be 2 ft . wide and not less than 6 in . thick. This allows for two courses of footings built with bricke, and as these should be buried below ground-level, the bed of the concrete must be not less than $1 \mathrm{ft}$.3 in . deep. Before digging out the ground, stakes should be driven in to define the comers and angles of the trenches, both inside and outside, and, in.addition, lines or cords should be stretched tightly between the stakes so as

Bricklaging. Fig. 1. Laging lootings. Fif. 2. First courses of footings, showling lapping of bricks. Fig. 3. First course of wall, showing bonding and closers, and bow headers in front wall become stretchers in aide wall. Fig. 4. Commencing second course of wall. Fig. 5. Footings and quoins built up to four courses, showing bonding at gtopped end for doorway. Fig. B. Wall four courses bigh. Fig. 7. Testing brickwork with plumb-line

The ground should be dug out correctly to these lines, and pegs should be driven in along the midille of the trenches so that the tops of the pegs are al! at the correct level for the finished concrete bed, acting as a guide when filling. If the earth shows signs of falling in at the sides, keep it in place with rough boarils set vertically on edge and secured with short stalies or pegs. Make the bottom of the $t$ rench hard and firm. Prepare a convenient part of the ground on which to mix the concrete, and then shovel it into the trench, ramming it down with a ramnter, and taking care to teat the surface to ensure that it is level both across the trench and lengthways. A spirit-level on $\pi$ straight batten of wood, at least if ft . in length, is reputired in order to get the foundation concrete level. The pegs previously inserted should be accuratel! levelled by cominencing from one corner and adjusting the other pegs accordingly until all are level While the concrete is setting, the mortar-if lime is used-should be prepared.

First Stare in Building a Wall
Next ret lines along the sides of the work to lay the bottom course of footings by, ! in. from the centre line of the wall to be built. Put the lines on the outside and work from the inside. Spread a bed of mortar 18 in . wice in such quantity that when pressed down it will make a joint about $\ddagger$ in. thick. Then bed down the bricks in two rows of headers (Fig. 1). As the bedding proceeds the excess mortar that squeczes out at the sides should be picked up with the trowel and thrown on the bricks already bedded Lay the firat course thus all round the foundation and flush it up with mortar as the work proceeds, to fill the joints. 'This and the next course may be laid without putting any mortar on the bricks to form vertical joints.
Proceed similarly with the next course of footings, joining as shown in Fig. 2. The course will be $1: 3 . \frac{2}{2} \mathrm{in}$. wide, $6 \frac{3}{} \mathrm{in}$. each side of the centre of the wall. Flush up with mortar as before; that is, fill all joints with mortar.

On these two footing courses, which require only ordinary care in la!ing, begins the brickwork proper. Stretch two lines at right anglea as before, $4 \frac{1}{1} \mathrm{in}$. outside the centre lines of the walls, and work now on the outside. The first operation is to build up 4 courses of bricks at the intersection of the two lines, fo form the angle, and a similar quantity at the other end of the piece of wall to be now built. Fig. 3 shows the first course in plan, and Figa. 4 and 5 show the angle in elerntion. These corner or end picces must be plumbed ul) on buth faces with the plimb rule in order to ensure the wall being upright.

This done, the line is stretched from corner to corner at the level of the top) enge of the first course, forming a true line to work to when laying this course. The course being finished, the line is removed to a similar position on the second course, and so on till four coursea are built (Fig. 6). The operations are then repeated for nother our courses. First the corners are taken up, filled and plumbed, then the work lilled in course by course between
The bond illustrated is linglisla bond, the casiest to build and the strongest when built. (Diagrams showing the chief types of bond are given in Fig. 8.). Observe carefully the arrangement of bricks in the illustrations, noting the positions of headers and closers. The vertical joints, called in the trade perpends, must he correctly, that is vertically, over one another the whole height of the wall.
The damp course in amateur work is hest composed of a double course of slates or ordinary tarred roofing felt in long strips 9 in. wide, beddel in mortar and wit! mortar on it to receive and bed the course alove it. The damp course should be at least 6 in . above the level of surrounding ground and below the lowest woodwork, the purpose being to prevent dampness rising from the ground, is slates are impervious to moisture.

The amateurcan

supplement the in. formation given here and contirm it by watching $n$ bricklayer at work. The mortar can be thrown on and the l,ricks set in place very quickly, strik. ing them on the top with the handle of the trowel to levelthen. Special care must be taken hefore bedding each brick to apply a pat of mortar to the end or side to form the vertical joint, and also to llush up cach course with mortar to fill up the whole of the internal joint. Thesimplest way of linishing the oxternal mortar joints between the bricks is by striking them as the work proceeds. This is done simply by cutting off the excess of mortar that aqueezes out when the bricks are berlded, using the trowel as a knife placed flat on the face of the work, thus pressing the mortar with the trowel along the upper edge of the joint, until it is very slightly below the surface of the upper brick and flush with the face of the lower brick. For the inside surface of the wall a flush joint is better and is made by pressing the exuding wet mortar with the trowel, and making it flat or flush with the wall. The edges should be neatly trimmed off with a trowel, guided by a straight edge. A pointing trowel is best for amateur use on this work, being smaller and lighter than the ordinary bricklayer's trowel. When the mortar

Brick. Fig. 8. Kinds of bond in general use. A and $B$, English bond. $C$ and $D$, Flemish bond E. garden wall bond. F, stretching bond
has set for an hour or so the wall can if necessary be waslied down with clean water and a hard brush, to remove any surplus mortar from the face of the bricks and leave them clean and bright.

Vertical work next to n door-frame or a window must be jointed and honded in the same way as shown for the corner of the wall. Figs 6 and 7 show tho honding for left ordinary coveled with olteropping pants. and right hand ve- Overburut (buri ticals respectively Openings should he placed so that brick dimensions can be adhered to in the brickwork, i.e. stretchof wall ahould bo multiples either of $4 \frac{1}{2} \mathrm{in}$. or 9 in. it length. This avoids cutting of bricks Joints should not lie less than $z_{8} \mathrm{in}$. in thickness.

Bricks have to he cut to act as closers and for other purposes. This is done as follows

Brickuork : its use in the garden. Not only the dry wall, with its outcroppings of rock plants, is made
of brick, but also the piers of the pergola. Above, small brick courtgard laid at three different levels
(Fig. 9) : Mark a line on the brick where it has to be cut, then press a bricklayer's bolster or chisel on the line and strike it a light hlow. Repeat the operation on other sides, then lay the hrick on a smooth, firm surface and atrike the holster a firm, hard blow, thus cutting the brick. See Cement ; Concrete.

Brickwork in the Garden. Apart from wall use, bricks are effective in place of paving for small gardens and courts, for cottage approach paths, and for steps; also for cdging lily ponds, for floors in summer-houses, piers for pergolas and path-designing in sunk rose garilens.
In formal town gardens the rich warmth of red bricks economises labour, as it intensifines the colour value of flowers arranged in small, neat hedding sections, or in stonc vases, and does away with gravel or grass The contrast of stone or metal ornaments adde to beauty all the year round, and evergreen shrubs scem brighter ngainst brick-work.
For pergola piers, antique facing-bricks miny be used either in the yellowish or reddisi, purple range of colours. A grey or fawn mortar joint should be chosen, as white spoils the effect. For paths and practical steps, harder paving bricks can be ohfained: while for small surfaces, 6 in fireplace bricks may look more suitahle instead of those of the standard 9 in. length. When making dry walls. or wide ateps for a rock garden to the ordinary bricks can be used. Overburut lburn

Brick-work in the garden. Brick ateps arranked in expanding aemicircles lead to a seat of which the back and front are of brick
rreath of orange hlossom, or of orange hlossom and niyrtle Jewelry is not usually worn by the bride cxcept the bride. grooin's gift. No rings are worn on the occasion before the ceremony. If she carries a houquet that also is his gift
The bride walks "p the church on the arm of her father, or whocver is to give her away, and at the chancel steps the bridegroorn awnita her. She takes her place on his left. the veil over her ace, and when the cremony is ended she gocs out to the wall) bricks may be chosen to adil to the vestry on his lefl arm. In the vestry ahe signs pleasing irregularity of the colour scheme and her maiden name, and comes down the church diminish cost of material by more than half on her hushand's right arm with her veil for retaining walls where mortar joints are used.

The surface for paths should be even and laid on an ash foundation, which admits of quick drainage after rain. The bricks may he laill flat and lengthwise as in stuetcher courses of masonry.

Round a sundial, or other central ormanent, bricks may be laid withont mortar, so that mose or little rock plants can grow througli tho crevices. A wide terrace or kitchen garden path may have the middle of paving bricks or stones and t.he sides of bricks laid without mortar. This treatment is suitable for the Istter path when llowers are grown on either side, and it continues a decorative effect from the house or flower garden to an alcove or ornamental comer where brick-work is again amployed.

Before beginning to lay out any scheme, a plan should be carefully drawn to scale of the proposed brick-work. See Garden.

## Bridal Wreath. See Francoa

BRIDE. It is usual for a bride to wear a white wedding dress, though a colonred one is occasionally chosen, and many bricles are married in the clothes in which they are going nway. A widow who re-marries does not wear white. It is said that the bridal dress should inclucle :

Something old, and something new ;
Something lorrowed and sonething blue.
The veil may fulfil two of the requirements. for hrides often horrow an old and leantiful lace veil. This can be arranged under a thrown hack See Marriage; Wedding.
BRIDEGROOM. With the assiatance of his hest man the briderronm nakes the arrangenents for the wedding, as far as the church or place where it is held is concerned, and pays the expenscs incurred there. He must be ready to receive the hride on arrival, and is responsible for the arrangements for leaving the church and departure for the honeymoon. See Best Man.

BRIDESMAID. For a very quiet "edding bridesmaids may be limited to two or dispensed with altogether: but if it is to be a society function the number may vary from four to twelve. In this case the bride will see that the bridegroom's relatives are duly represented.

No tactful bride will allow her bridesmaids to wear colours that do not suit them or to he involved in expense beyond their means, and in planning the dresses she will hear this in mind. It is customary for the bridegroom to inake a present to each bridesmaid, and if honquets are carried he provides these too.

On the wedding day the bridesmaids arrive first at the church nnd await the coming of the bride. Upon her arrival they follow her up the church and atand behind her throughoul the ceremony. The principal bridesmaid takes the hride's gloves, houquet or prayer-book, and holds them until the service is over. The head hridesmaid follows bride and bridegroom into the vestry, and generally sigus the register. Finally, the bridesmaids leave the church behind the newly wedded pair.

## Bridge: The Principles of its Play

With Hints on the Three-handed and Two-handed Variants of the Game
Consult also the special article on Contract Bridge
Bridge is a development of whist, of which fresh cut is necessary to decide which of those the present form is properly known as rogal auction bridge, but, as this game has superneded all other variations, it is usually referred to aimply as bridge. The ordinary game is for four players, but it can be played hy three or by two.

Four players cut for partners, for choice of seats and for deal. The drawers of the two ligher cands are pastners against the drawers of the two lower cards. The cutter of the lowest card has the first deal and the choice of seats. In cutting, ace ranks as the lowest card and the other cards in order of their suit values Two players cutting cards of equal value, unless such cards are the two highest, cut again. Should they be the two lowest, a

## f wo deals. <br> Partners sit opposite one another. Thus in

 the diagram, A and 13 are partners against $Y$ and $Z, \%$ being the dealer and declarer.
## Y (dummy)

The cards are cut by B, and Z deals the cards one at a time in rotation, heginning with A, the player on his left. After all the cards are dealt, but not before, each player looks at his cards. The dealer has the first right of making $a$ bid. The object of the game is to make 30 points by tricks alone. 'Two games
won out of three constitute a ruhber, for which the winning side scores 250 points above the line. No third game is played if one side wins the first and speond game. Honours are scored, hut do not count towards gatne. 'The' ralue of tricks and honours varies with the suit declared as trumps. The suits in bridge rank and count thus:

Clube
Iliamonds
11 riats
spades
No trimpa
The score at bridge is divided into points, honours and penalties. It is kept on a sheet or Wock suitahly marked.

Little slain (i.e. where one side makes 12 out of the 13 tricks) scores 50 . Grand slam (i.e. where one aide makes all 1:3 tricks) scorea 100 Winners of rubber score an additional 2:0 points. The value of the trick declarations are subject to alteration by doubling.
The honoure are ace, king, qucen, jack and ten of the declared suit. At no trumps the aces score as honours.

Honours and penalties are scored ahove the line only and trick scores below the line. No one can score below the line except the peison left in with the final declaration and his partner (the dummy). They can only scorc helow the line if they make their contract, i.e. all the tricks they bid or more. 'The partners who are playing against the declarer are known as the adversaries. They can acore above the line only.

The following table summarises the system of scoring and is frequently printed on the backs of the scoring blocks:

| Trick Scored Ench t.rich ahove six counts |  | Spacles | Hearts 8 | $\underset{\substack{\text { Din- } \\ \text { monds } \\ 7}}{ }$ | Clubs is |
| :---: | :---: | :---: | :---: | :---: | :---: |
| HONOURS ScORES 3 (simple lionolims) | 301 | 18 | 10 | 14 | 19 |
| 4 (divided) .. | 10 | $31 ;$ | $3:$ | 28 | 24 |
| 5 (dlvided) . | - | 45 | 40 | 35 | 311 |
| $t$ (in one hand) | 100) | 72 | 64 | 50 | 18 |
| $t$ (in one hand and 1 in partner's, 5 honours in all | - | 81 | 72 | 03 | 54 |
| 5 (in one hand) | - | $\mathfrak{O}$ | 80 | 70 | 311 |

'To bid, the denler, \%, having lookal at his cards, mukes a declaration, or, if he elects to pass, simply says "No" or "No bid." The bilding then proceeds to $A, Y$ and $B$ in suc. cession, the final decision os to what are to be trumips reating with the player or the side who declares to win the greateat number of points. 'l'hus \% derlares one spade- 9 points. A can now declare two in any of the suits or one no trump- 10 points. Y can advance the bidding hy a call of two spades or anything over the value of 10 , and so on. When two declarations are equal in point value, the one which involves making the greater number of tricks overcalla the other. Thus four clulss will overcall thice hearts- 24 points

Under the American rule of "majority calling." now little followed in Great Britain. four clubs ( 24 points) would outhid three spades ( 27 prints).
A player may double his opponent's declaration when it comes round to his turn to call, and it is open to either of his opponents to re-double. Only one re-double is allowed. The double does not affect the value of the tricks so far as the bidding is concerned. Thus two hearts overcall two diamonds doubled. But doubling and re-doubling reopens the bidding and gives each player the chance of a fiesh call.

A player may not double his partner's declaration. Only the final deciarer, as the player of the two hands is called, can scoie
below the line. In order to do this he must fulfil his contract.

Penalty for failure to gain contract is 50 points per trick scored above the line to oppo. nents. If doubled 100 points per trick, and re-doublat 200 points per trick. If the declarer is successful in making his contract after it has been doubled he rereives a bonus of $B 0$ pointa for contract (scored above the line like honours), and 50 points per trick for each trick he obtains in excess of his contract. If redoubled he receives 100 pointa for contrict and 100 points per trick for each overtrick. Thus \% bids two spades and is doubled by $A$ He makes his contract and one over. He scores 54 below the line (value of three apmes doubled) and 100 nbove the line ( 50 for con. tract and 50 for overtriok), plus any honours he may holel.

Principles of Bidding. The aim of hidding is to discover the best combination in which the hands can be played to the advantage of yourself and your partner. No trunpes is the most important declaration, being the only call on which you can go game from a love score ly making $?$ tricks. One method of determining if you are strong enough to bicl no trumpsoriginally is known as the Rohertson rule. By it an ace counta 7 , a king 5 , a queen 3 , a jack si and a ten 1. When any such cards collectively total 21 with at least three suiti guarded, the hand is good 'enough for a first call of one no trumps. Other holdings which justify the same useful call are
Four aces (even without ot her court cards).
Three aces and other curds of value.
Three acces and two protectrd kings
T'liree aces, a king and "gunrded queen (i.c. quaen Two aces and good cir
Two acem and good cirds, such as king, queen. Jack, or king, jath, tell in one suit.
One are and " good all-mund hand-something of One ace with protectio
likellhood oi taking in the other three suits and lukellhood ot taking at least four tricks.
one hoe herading a long gult with two other suits
well gurndeul well minnded
and a proper protection ins liave two long sults
The suita are divided into major suita (apales and hearts) and minor suits (diamonda and clubs). A first bid in a major suit ahould show at least five of the ruit with top honours -nce, king or king, queen, jack. Don't bid on a suit of four except when youl have the four top honours. Even then some ouitaide strength is necesarary. And don't bid origin ally from length alone. A suit of six or seven headed by queen or king should be reserved for second round bidding. In cases where you hold great length, such as king, queen, to aeven or.cight, it is often arlvisable to bid three of the suit straightaway, not merely to indicite great length, but to prevent your opponenta and your partner from interfering with the call.
The first bid of a minor suit must alwaya show top honours. It may be made on four or even three (if the three be acc, king, (queen) 'Ihe object of the declaration of a short minor suit is to encourage your partner to make a stronger bid. It is informative. Bids made on the second or subsequent rounds of bidding do not convey the same information as original hids. They may be made on suits of five or six or more, which should he headed by queen.
Always hear in mind the difference letween original and secondary bids. You are justified in supporting your pirtner much more lightly over hia first call than in the case of "forced or secondary bid. If your partner hids two suita, support him in the one in which you hold the greater length, and if his first hid fits your hand and his second hid does not, put him hack into his firat call.
If dealer has passed, you are in the position of original declarer, and the remarks about his procedure apply to you. If dealer has called it suit which you can over call with one of a
higher suit you should have five tricks in it. If you over.call with a tivo contract, yoll ahould be able to make six tricks in your hand. If you go no trumpa over dealer. or a previous caller, you must hold a guand in the sulit which is called against you.

If $Z$ and $A$ have passed and you, as third hand decharer, are not very atming it is likely B has a good hand. The beat that you can do is to call one of the suit you want led in cas 13 goes no trumps. If, however, $\%$ and A have both made a bid, you will aupport your part ner's bid, unleas you have a much atmonger call yourself. Don't show a fresh suit unless you have reason to believe it is better than that bid by your partner. Ind be careful not to take your purtner from a major anit bid into a minor one.
If all three playem have pasued, fourth hand should rlso pass, unless he has a hatnd at least two tricks atronger than that which justifies an original bid of one.

Play of the Cards. Lean ly heait the following table of leads. They are most im. portant, as they convey definite information as to the contenta of your hand.

From all otlier coubinatlous land fourtl higheat.
When lending a suit that your partner has called, lead the highest of the suit, unless you have five, when you should lead your fourth best. Some players do not lead the highest when they hold four, and there are oc-asions when it pays not to do so. But as a general rule it is hest to lead your highest, even with four, and vith any lexwer number it is exsential for you to do so. When your partner has not called, lead your strongest anit against a suitcall, and your longeat igainst a no-trump call.

The Eleven Rule. The leas of the fourth best, except when you hold three honours. againat a no-trump bid is based upon the eleven rule. which it is most important to learn and understand. This rule is that when a player leads his fourth bext card of a suit, if the value of the card led the deducted from 11, the remainder gives the number of cards higher than the one led which are not in the leader's hand. Thus, suppose the seven of hearta is led, third hand holds queen, eight. four, and dummy has jack, six, five. By an application of the eleven rule, it is evident to the third phayer that the fourth player has one card, and one card only. of hearts higher than the seven. If the fourth hand has made the declaration of no trumps, there is a stmang supposition that his one high card is either the ace or king. Therefore, the third hand should pass the seven led and not put up his queen.

The following general hints may be given Lead through atrength and up to weakness Suppose you are leading, and dummy is fourth hand, lead up to dummy's weakness It will enable your partner to make a trick which he might not otherwise make. Dn not finease againat your partner. Iead the higheat. phay the lowest of a sequence. Force declarer's strong hand whenever possible Forcing is leading a card which the opponents must trump to win.
The full code of the laws of royal auction liridge (two long to be reprinted here) is pul). lished in most text books on the game, or can be obtained scparately. It is not necessary to learn thein by heart, but it is mont neces. sary to have a good working knowledge of them. Particular attention should be paid to renalties for revokes, leading out of turn. calling out of turn, and cards exposed during play or aleal.

Bridge for Three. Three handed auction, otherwise known as cut-throat or skip, is played by three players, all against all. The simplest method is for the three players to nit on three sides of the table, leaving the fourth seat vacant. and to keep their seats throughout the rubber. The cards of dunimy are then dealt to the vacant seat.
The dummy is alwaya dealt to the same hand and receives the first, second, or thind card, depending which player is dealing. The dealer inakes his declaration or passes, and the bidding continues as at auction bridge. The tinal declarer of the highest hid plays dummy's and his own hand, and shifts dummy's cards to a convenient prosition ficing him.
If a player double out of turn, he forfeita I(0) pointa to pach of his alversaries, and the player whose declaration has been so doubled shall have the right to say whether or not the double shall stand. The bidding is then resumed: but if the double has been disallowed, the said declaration cannot he doubled by the player on the right of the offender.

The rubber consists of four games. but when two games have heen won by the sume player the other or others are not played. When ihe decharer makes good his declaration, he scoren as at auction bridge ; when he fails to do so, he loses to each of his ndversaries.

## Variation in Scoring Rules

The scoring is the mame as at auction bridge, except with regard to honours, which are scored by each player severally; i.c. each player who has one honour in cluda scorea six : each player having two honours in clubs scorss 12 ; a player holding three honours in clubs acores 18: a player holding four honouns scores 48, and a player holding five honourn in clubs scores (i0), and similarly for the other suita. In a No trump declaration aces count 10 each. and $10 x$ ) if all four be held by one player. Ono hundred pointa are scored by each player for every game he wins, and the winner of the rubber adds a further 250 points to his score. At the conclusion of the rubber the total scones obtained by each player are added up мерarately, and each player wins fomm, or loses to, each other player the difference between his score and that of the said other player.

As generally played the bidling is a ganuble for dummo. The dealer generally opens with a bid of two no trumps if he has any cards of value at all, on the principle that whatever good cards he may find in dummy will help to establish his indifferent lot. His bid has the alvantage, if he is not doubled, of putting up second caller to three no trumps or three of a suit, which third hand may possibly lie able to doulse to the advantage of the dealer.

Among varietics of three-handed bridge a variation now widely played is the doaling of the first fous cards blind face down th the
middle of the table, the romaining 48 cards heing distributed in four 12 -card hands Final declarer, before examining his dummy, looks at the four blind cards and distributes them as he wishes. one to himself, one to dummy, and one to each adversary. This procedure given still more spirit to the bidding, and adds to its uncertainty.

Double Douinmy. In double dummy the players sit next-not opposite-to each other, and deal alternately. The deal is decided by cutting tho cards, the lowest card winning the deal and choice of seats. Four hands of 13 cards are dealt, two face downwards and the two dummies (ea:h opposite one player) face upwards on the table. The following is the position of players and dummies:

13's Dunimy
A's
Dummy $\square$ B
The dealer. 13, has the first declaration, and bidding proceods as at auction bridge. There is no blind calling in this game, for it is obvinus that each player knows exactly what carda are in his opponent's hand. Expert players frequently can declare the number of tricks they will make or lose, and write down the score without playing the cards; but leas practised players will always find ample opportunity for finerso and subtlety of play in playing their cards out.

When the declaration is left with $A$, the lead is from a closed hand through two open hands up to a closed hand. When $B$ is the seclarer, the lead is from A's dummy through an open and a closed one up to a closed liand. ()n account of this difference the cut for choice of seats has an added importance Some players agree to change seata niter each rubber. The scoring as to honours and tricks and penalties is us in ordinary auction bridge.
An excellent variation of ordinary double dummy is afforded by the use of card racks. These ingenious devices, which can be obtained from most stores, enable each player to conceal his dummy's cards from his adversary. The players sit at adjoining sides of the table with the racks in front of them at a convenient angle. The cards are dealt into four hands. Before the bidding begins each player picks up the hand opposite to him and places the cards in his rack. Bidding, playing. and scoring are as in double dumms.
The game is more intereating than ordinary double dummy, herause, although each player knows his opponent's 26 cards, he does not know how they are distributed hetween the two alversc hands. Another variation is to make the bidding take place before the dummics are looked nt and placed in the racks.

Blind Auction. The game of blind auction, firat described in the "Daily Mail" in 1919. was the invention of the late Colonel F. de B. Young, C.M.G. It is far more interesting and less cumbersome than double dummy bridge, and is played as follows

Thirteen cards are dealt to each of the two players, the remaining half of the pack being pliced faoe downwards. The dealer makea the first call, which his opponent can over-call or double, just as at auction. After the hidding is finished the game proceeds, and the result is scored exactly as at auction. This first hand is, of course, pure chance. Neither player knows what the other has got, as there are 26 cards unaccounted for, nad anything may happen. The strangest bids may aucceed. But after this first hand has been played, the remaining 26 cands are dealt, 13 to each player. The dealer bids first, as before, and the hidding and scoring are as in nuction.

Now comes in the test of memory and skill. A good player with a card memory will know every card that is in his opponent's hand from the cards that were played on the first round.

He will, thereione, be able to make his cal with absolute matliematical accuracy. He knows just how far he can bid with asfety and when his adversary has overstepped the mark and can he doubled effectively. This is an especially good game for novices, since it cultivates card memory and teaches the necessity of noticing every card.

Draw Auction. Another good two-handed game is draw auction. The carda arc dealt 13 to each player. The 27 th card is placed face upwards on the table, and the remaining cards are put beade it downwards, to form the pack. There is no bidding, the hands being played as at no trumps. The non-dealer leads for the first trick Each player must follow suit if he can.
The player winning the first trick takes the exposed card to replace the one played. His oppionent, who loses the trick. draws the unexposed card from the top of the pack and turns the next card face upwards for the winner of the second trick to take. This is repeated after each triok until the pack is exhausted.

Now begins the game proper. At the end of this prelininary skirmish each player holds 13 cards, and he makes his hid as at auction. His opponent can outbid hinı, or double the bid or раяs. Tricks are now stacked and scored as in the regular four-handed garne. The playing of the first 26 carils before the game begins enables the player to locate valuable cards, to build up his hand for the declaration, and to weaken an opponent's hand by forcing him to play out high cards. There is much opportunity for judgement in avoiding taking worthless exposel cards and forcing them on the adversary. Once the second stage is reached the players deal with known quantities and can bid with accuracy.

Briage Parly. Card table covered with black moire and equipped with The scoring pads
brightly decorated must be fixed before the gaine begins. ash trays and glarses
tugether also. This is important, for a goon player gets little enjoyment out of the game when inferior players are at the same table, and a mediocre player feels out of place when asked to play with a hridge expert. If there are only two or three tables and all the players are equally matched, the hostesa may ask her guests to arrange tables and partners by cutting before the game begins. When scveral hostesses combinc to form a bridge circle, and the play takes place in rotation at the various houses, much of the difficulty in arranging tables is olviated, as players get to know each other's merits at the game The hostess must be responsible for arranging the stakes, which

Folding card-tablea can be bought so reasonably that the household may be equipper with one or two. Unless smokers' stands are available, better than the small size, 24 in. hy 24 in ., is a card table 30 in . by 30 in .. as the little extra space at the corners accommodates ash trays without so much inconvenience to play. The most useful tables have racks for

## Improvind Upon Green Baize Tables

In order to bring the tubles into relation with the decorative scheme of the room, it is often necessary to cover the green cloth or baize tops of the tables. These removable covers are easily made in furnishing velvet or moiré, trimmed at the edge with tinsel galon. Or the tables can be permanently covered with hlack moire, as shown in the one illustrated. Two clean packs of cards nust be allowed for each table, and alan four scoring pads and pencils. These may be charmingly decorated. The pads may have puinted or stencilled covers, embiroidered, or worked in raffia (q. v.), while the pencils may be tasselled with silk or light wooden heads. Occasionally there are differences of opinion, which are best and most amicably settled by reference to a book of rules.

The average draw. ing-room cannot take more than two or at mont three card-tables to allow ample roont for chairs, etc. Gond light sliould fall on each table, and the ronm must le pleasantly airy and yet, in colder weather, sufficiently heated.

There is usually an adjournment for tea or light refreali. ments during the afternoon or evening. At a small party such refreshments
BRIDGE PARTY: How to Give. Many may be prepared on a side table. Otherwise hostesses find that a bridge party given every they are served in the dining-room, and the two or three weeks is a means of discharging their social olbigations and ensures a pleasant afternoon's or evening's entertainment. The invitations may be by telephone or by informal letter. For an afternoon party the hours are from 3 to $6 \mathrm{p} . \mathrm{m}$. or 6.30. For the evening, from 8.30 to $11.30 \mathrm{p} . \mathrm{m}$. If guests are asked a quarter of an hour hefore play begins, coffeeand ligueurs if liked-can be served, and there is less danger of play being held up by late artivals.

The hostess should make up her tables an that the various plajers are suitably arranged ; really gond players together, and those whose play is of an inferior calibre placed at tables
gueats at each table go at the conclusion of the rubber, sfter the hostess has in general invited them to do so. Any variety of sandwich, made with brown bread and butter, or white, or with bridge rolls, amall cakes and fruit salad in glasses, may be served with suitable drinks either for the afternoon or evening party. See At Home; Sandwich.
BRIDLE. The bridle is that part of the harness of a horse that fits on to the head and to which the reins are fastened. The bit is that part of the hridle that goes into the mouth, and to the rings attached to it are fastened the various straps that fit the head and connect with the reins. Bridles are made
of steel and leather, and their care is part of the duties of the groom or coachman. See Bit: Driving; Harness; Riding.

BRIGHT LINE BROWN EYE MOTH.
This name has been given to a stout-bodied moth with reddish-brown forewings which measure, w hen outspread, $1 \frac{1}{2}$ in from tipto tip. The paler hindwings arc darker towards the hind margin On the forewings there are several in. definite marks but towards
 caterpillar is a Rarden Deat the middle of the front half there is a kidney-shaped mark more or less yellow. This is the brown eye. The white line is near the outer margin, slightly waved, but in the middle forming a distinct W .

The pale green or light brown smooth cater pillar is dotted with black and more minutely with white: along each side is a yellow line and three greyish lines run down the back. It feeds throughout the summer on low-growing wild plants, but in the garden attacks turnips, cabbages, tomatocs, etc

BRIGET'S DISEASE. Nephritis or Bright's disease is the name given to inflammation of the kidneys, which may be acute or chronic. The principal causes are exposure to cold and wet, especially after alcoholic excess, poisons of fevers, e.g. scarlatinn or tonsillitis, or irritant poisons like carbolic acid, can tharides or turpentine. Acute nephritis may follow a large burn.

The onset miay le insidiuus, the patient feeling ill in an indefinite way, or headache or shortness of breath may be the first symptoms. In children the disease may be ushered in by convulsions. Within a few hours the characteristic puffiness of the face and eyelids or ankles and pallor of the skin are probably observed, while the urine becomes much darker and also contains albumin.
The acifte form of the disease is always scrious, because it causes accumulation of poisonous material in the syatem through the kidney being thrown out of action more or leas. The chief signs may be headache and vomiting or there may be drowsiness and convulsions, followed by unconsciousness. This condition is known as uraemia Sudden dropsy of the lungs with great difficulty in breathing and a copious liquid expectoration may occur at any time, and the doctor should be sent for at once.

During the attack milk should be the only food taken. A hot moist pack should be tried. l'rotecting one-half of the bed with a rubber sheet covered with a woollen blanket, the patient should be gently lifted on to this, and then thoroughly enveloped in several thick nesses of blankets wrung out in water as hot as he can bear. He may remain in the pack from 15 to 20 min . Convulsions in children would be treated with a warm bath.
In chronio Bright's disease two main varieties occur, the large white kidney and the small red kidney. Those who indulge constantly in alcohol are specially liable to the former, men more so than women. The commonest variety of the disease is the small red kidney, which in its primary form may be described as a premature ageing or wearing out of the kidney substance. The regular use of alcohol and over-eating (especially of meats) together with a sedentary habit of lifo, are probably the chief causes.

Though the disease cannot be cured, much can be donc to retard it, and with proper
treatment, and in particular with a certain amount of self-denial and control of his appetites, the patient may usually look forward to many years of fair health and activity. He will require to take regular easy outdoor exercise, avoiding over-fatigue. He should keep to a simple, nourishing, largely vegetarian diet, be moderate with his tea and coffee, and give up alcohol in every shape and form. The bowels and the skin must be kept active. Two or four grains of cascarn at night, or a teaspoonful of Epsom salts before breakfast, may be taken. To kecp the akin active, a daily bath at the temperature of $80^{\circ}$ to $90^{\circ}$ should be taken, followed by a brisk rub down with a rough towel. Plenty of plain water, mineral water, or weak leinonade should be drunk between meals to keep the kidneys well flushed out See Kidney

BRILL : Ways of Cooking. Steamed brill contains more flavour and nutriment than boiled. Wash, dry, and trim 1 lb . or more of cut brill. Rub over with a little lemon juice, and lay it in a sten mer, covering it with a piece of greased paper. Heat the water under the steamer, and boil steadily for about 30 min ., or until a knife can easily he slipped along between the bone and the flesh. Lift out carefully and place on a warmed fish-napkin, or fishdrainer, on a hot dish. Garnish with slices of lemon and serve with a tureen of fish sauce. One pound of brill is sufficient for 4 persons.
Brill is la Conant is as voury. Wash, dry and fillet ahout 2 lb . of brill. Lay four slices of fat bacon in a lireproof baking-diah, and place three thin slices of Spanish onion, with neatly cut pieces of brill on the top of them. Melt 1 oz. butter in a saucepan, stir into it $\frac{1}{2} \mathrm{oz}$. flour and spread this on the fish. Dust with browned crumbs and a little seasoning. Cut two more slices of bacon into fine shreds. and scatter these over the crumbs. Cover with a piece of greased paper and hake in a morlerately hot oven for about 20 min. . or until a skewer can be easily pushed into the fish. For the last 5 min remove the paper. Gamish with thinly cut slices of lemon and crossway lines of fincly chopped parsley. Sufficient for six or eight persons.
Grilled brill is easily propared. Fillet it, saving bones, etc., for fish-stock. Warm 1 oz . butter, and brush over the fillets and season them. Heat and grease the gridiron, lay on the fish, and grill for $10-12 \mathrm{~min}$., or until slightly browned. Place on a hot dish, with a little hutter rubbed over each piece, and a dust of pepper. Serve with parsley, anchovy, or lobster sauce. See Fish; Sauce

BRILLIANTINE. The threc different kinds of brilliantine-separable, inseparable, and solid can be made as follows: Separable brilliantine is composed of 12 oz . almond oil free from acidity, 20 drops perfume, and 6 oz . absolute alcohol shaken well together. Inaeparable brilliantine is made from 2 oz . castor oil, 8 oz. rectified alcohol ( 60 over-proof) and 60 drops perfume. Solid brilliantine is prepared from 4 o7. white vaseline and 10 drops perfume. If a green colour is required a small amount of chlorophyll, obtained from green leaves, is added. See Hair.
BRIMSTONE. Popular name for sulphur is brimstone, and in combination with treacle it is much used for skin eruptions. Brinstone in powdered form is mixed with treacle in the proportion of $\underline{\varrho}$ or. to a pound of treacle. The
dose is two teaspoonfuls each morning Solid brimstone, in the form of stioks, is placed in the water which dogs drink, as a blood purifier. The brimstone does not dissolve in the water, but it contains sulphurous gas in the interatices, which communicates a sulphurous taste to the water. Sec Sulphur

BRINE BATH. By using the Droitwich or other salts in the proportion of 10 lb to 30 gallons of water, brine baths can be prepared at home. They are useful in sciatica, lumbago, and ohronic rheumatism. The bath should he maintained at blood temperature $\left(98^{\circ}\right)$. The patient should stay in it for 15 to 30 min ., then be quickly dried and put to bed. See Bathing.

BRIOCEE : A Fancy Bread. For this yeast cake, put $\left\{l_{1}\right.$, Hour on a board, making a well in the centre. In the well dissolve $\frac{1}{2} o z$. yeast in a little tepid water, and then enough water to mix the whole into a soft paste. Knead well, form into a hall and alash the sidea with a knife. Leave in a warm place to set the sponge.

Now take $\frac{3}{3} \mathrm{lb}$. Hour, and into a well in the centre put a level teaspoonful of salt and of sugar and a teaspoonful of water. When dissolved add 4 oz butter (melted) and 3 beaten eggs. Mix and knead well. The sponge should now have risen to threc times its size. Spread it out on the paste and knead them together until full of air bubbles. Form into a cottage loaf, or into small $t$ wists and rings, brush with egg, and bake in a moderate oven on a liaking sheet. Currants, candied fruits, etc., may be added if desired. See Bread.

BRIQUETTE. Coal dust, with a binding material such as clay, tar, resin or sawdust, is made into briquettes or blocks of fuel. Coal-tar, pitch and ordinary coal tar are most generally used. but satisfactory briquettes have been made with clay. Resin is cxpensive as a binding agent and, like saw. dust, is too inflammable The blocks arc made either hy heating the pitch and coal dust together or by mixing the coal dust with tar without hert.

BRISKET: A Cut of Beef. For an appe tising method of stewing brisket or breast of beef use this recipe. Rub vinegar and salt over 4 or 5 lb . fresh brisket and leave for 2 hours before dressing. Cover with stock in a small stewpan and skim well after bringing to the boil. Simmer slowly for $\frac{8}{}$ hour, and then add a carrot, half a turnip, 2 strips celery, $1 \frac{1}{2}$ onions, 8 peppercorns, a few sprigs parsley and thyme, and seasoning to taste. Continue cooking slowly for 2 hours.

When just done, heat 1 oz . butter in a sauce. pan, witli 1 tablespoonful flour, and cook until the mixture becomes golden-brown in colour. atirring irequently. Take out meat and remove bones, then strain stock, and add sufficient water to make up ? pint. Pour this into pan containing the butter and Hour, stir it until the mixture reaches hoiling point, boil for 2 or 3 min ., and season with salt and pepper. Serve as a sauce separately, but garnish the meat with the vegetables. See Beef.

BRISTOL BOARD. The smooth-surfaced white cardboard known as Bristol board is used mostly by black-and-white artists. Since the same whiteners and amooth surface are exposed, however much of the board is scraped away, it is admirably suited for all kinds of pen-and-ink work. It is made in all sizes and thicknesses. It is often employed as a mount for pictures. See Mounting.

BRITANNIA METAL. In the manulac such as bacon or a butter sauco, to increase ture of tea and cotfee pots, dish-covers, spoons, sto. Britannia metal is largely employed, being silvery white with a bluish tinge It may be electro-plated with silver, but being, when of good quality, a hard alloy and capable of taking a high polish, it is often used in its own natural condition

Britannia metal articles must not be leftto dry. for examplo-on the hob of a fireplace or anywhere exposed to flame or a very high temperalure il damaged they may be repaired by soldering

As cleansing agents, liquid metal cleaners may be used, but there is nothing better than warm water with a little soda, or plain soap and water, followed by a very soft brush and a wash-leather with the least touch of putty powder See Electro Plating.

BROACH. Long and slightly tapered. these tools are invaluable for rapidly enlarging holes in metal, hardwood, or fibre. Broaches, which are sumetimes known as taper reamers, are made in numerous sizes, from a very fine one to in. It frequently happens that on a job such as fitting a joir of hinges, the screws are just a shade too large for the hole. In such a case a lew turns with a broach will enlarge the hole, and the job can be at once colupleted. These broaches are frequently fixed into wooden handles: but a better plan is to uso an adjustable handled tool holder

BROAD BEAN. Of this bean plant the two ohial types are the Longpod and the Windsor, and several varieties of each. The longpud beans are now chiefly grown. Inforniation on the cultivation of the broad lean is given in article hean (II.v.).

How to Cook. Broad beans are nutritious, but should be euten with soine fatty food,
such as bacon or a butter sauco, added after cooking, as it tends to harden the beans if put into the water when boiling commences. Young broad beans, when taken out of their thick, woolly pods, can be cooked in boiling water, to which a little sugar is added, until tender, probably 20 to 25 min They are then drained and served in a loot dish with parsley sauce and boiled hacon, served separately
For broad beans à la crème boil 1 pint of young broad beans until soft Then remove the whitish skins, and put the green beans in a stewpan with 1 oz butter, and dredge in 2 teasponnfuls flour and 1 oz grated cheese. Toss beans in this, and pour in $\&$ pint cream and milk mixed, or only milk. Add a dust of sugar, some seasoning, and 2 teaspoonfuls chopped paraley Stir gently until boiling, then heap them in a hot dish and garniah with sippets of toast

To make broad bean soup put a quart of shelled beans and a sliced medium-sized onion into a saucepan of boiling water, and boil until soft. Drain off and save water for stock, unless it is blackish. Remove tough, outer skins, and rub green part of beans through a hair or wire sieve. The former will inake the smouther soup, but the latter requires less time and labour.
Melt 1 oz. butter in a saucepan, into this stir 1 oz . Hour and $?$ pint milk and stock mixed. Boil and stir this mixture until it forms a sauce. Blend this with the beans, arding more milk or cream if necessary. It should be of the consistency of rich cream when finished. Season it with care, then strain it into a tureen, and serve it with

## Broadcast Receiving Sets

Main Factors to Consider in Their Choice
Other information is given in such arlicles as Aerial: Amplifice; Condenser: Eliminator ;
High Frcquency; Selectivity; Short Wave, etc.

Broadcast wireless sets are of twotypes, mains are desirable if satisfactory loudspeaker results and battery operated. Typical portable sets have two screen-grid high frequency stages, a rectifier, and two low frequenoy magnifiers. The screen-grid H.F. valves may consist of two choke coupled, or one choke coupled and one tuned stages The latter gives higher amplification, but necessitates an additional tuning control. Since geared drive condensers and natched stages are employed, the extra condenser does not necessitate greater operating skill

Signals are reccived on a frame aerial, wave chanying being carried out by a double throw switch, whish may also provide a means of disconnecting the valve filaments. The loudspeaker is normally of the adjustable cone type. The filament current is derived from an unspillable 2 volt accumulator, H.T. current fioin a 108 or 120 volt dry battery, and grid bias from a 9 or 18 volt unit

In a good design the screen-grid valves are biassed in order to decrease the anode current. Failure thus to apply a negative bias will entail a frequent renewal of the H.T. battery.

Portable sets give their maximum results when rotated so that the plane of the selfcontained aerial points in the direction of the broadcasting station. They are very selective, but for volume and range are inferior to a similar receiver working from an indoor or outdoor aerial and earth.

Non-portable battery operated receivers may comprise up to five valves, and are designed to work with an outdoor or indoor aerial. For head-phone reception a simple one or two valve set is adequate. Given an efficient rerial, a two valve set (rectifier and low frequency magnifier) will work a loudspeaker at distances up to 40 miles from a regional transmitter. Three valves or more
are to be obtaincd from more distant stations A well-designed three valve set may be expected to receive ten stations on the loud. speaker. Skill in inanipulation may increase the number. The type of aerial has a marked effect on range and volume. A detector and two low frequency magnifiers will give good long dintance reception with an outdoor acrial, whereas the addition of a high frequency
amplifying stage is usually necessary to ensure similar results on an indoor aerial Given an averace aerial and earth three valves should provide loudspenker volume up to distances of $70-80$ miles from a B.B.C. Regional atation, and 150 miles from Daventry 5 X X, but local conditions may increase or decrease the range.
Larger seta having one or two tuned high frequency stages, a rectifier, and two low frequenoy magnifers, make possible reception over long distances, and arc suitable for operating permanent magnet or mains energised coil-driven loudspeakers

Triple capacity diy cell H.T. batteries or H.T accumulators are essential in order to supply the anode current required for the effective operation of the valves. This current may amount to 20 milliampores, and at this rate of discharge the life of a triple capacity dry battery inay not exceed three months When the battery is partially run down, the set fails to give its maximum results, and distortion, low frequency howling, etc., are liable to occur. H.T. accumulators are more suitable for these larger sets.

All-mains reccivers obtain their low tension, high tension, and grid bias voltages entirely from the lighting mains. Differently constructed sets a re made for use on D.C. and A.C.

## Direct Current Type of Receiver

The D.C. type present greater problems in design than the AC. type, brcanse :
(a) Transformers cannot he employed to step un the mains voltage na in A.C. and consequently the H.T. voltnge aiter amonthing may be ton low to apernte the valves at their maxinum emeiency (of. 100-110 volt mains). Tlifs npplipe partlcularly (b) The wheh the out put valie is a super-ponire one of waterulains voltage has to be cut down by means flamients.
(c) Precautions are necessary to ensure completc isolation of the set from the majus.
1.C. receivers are generally designed for $100-110$ and $200-250$ volts $40-60$ cycle mains. The high tension and low tension voltages are obtained from a built-in unit, comprising a transformer with H.T. and L.T. windings, dry metal or valve rectifier, smoothing chokes and resistances. In high magnification receivers it is usual to interpose special filters between the mains unit and the set itself to obviate mains hum, and " motor-boating."
A.C. sets employ similar circuits to the battery operated types, but utilisc directly or indirectly heated valves. Owing to the high efficiency of A.C. screen-grid valves, receivers

Broadcast Receiving Set. Battery-operated four valve recelver employing a screen-grid high frequency stage. Apparatus viewed from above, looking towards back of front panel

Broadcast Receiving siet. Mains-operated inree vaive recester showing (left) complete A.C. maina unit for bigh-tension and low-tension current. The anit is connected by a plug to a lamp holder of the house lighting syatem
with two stages of high frequency amplifica tion require elaborate screening to ensure stability. The ease of obtaining high anode voltages facilitates the usc of mains energised coil-driven loudspeakers, as distinct from the less critical cone types. It is thus possible to achieve more realistic reproduction of the hroadcast programmes

It is n common practice to make mains sets elf-contained, the loudspeaker being placed bencath the receiver and mains unit. The wooden front of the cabinet usually acts as a baffle for the cone or diaphragm, and assists the adequate production of the bass notes.
Mains reccivers are connected up to any convenient wall-socket or lamp-holder, a length of flexible cord, terminating in a suitahle plug, being supplied for this purpose. In some cases the lighting system also forms the aerial, while in others an outdoor or indoor aerial is used. The former method is convenient in certain instances, e.g. in flats, or where it may be necessary to inove the receiver from one room to another. The flexible wire must be the sort intended for electric lighting or power, and not the less heavily insulated liind used for bells, etc

## Factors in Choosins a Set

The latest designs embody such refinements as concealed pilot lamps to indicate when the receiver is "on" and to illuminate the tuning scale. The latter is calibrated in wave lengths and not in degrces; the wave-length of the station being known, the scale is merely rotated until this figure comes opposite to the indicator. The tuning controls are of the thumb control type, and are arranged so that they can be adjusted simultaneously or separately.

Radio-Gram receivers have a switching device which enables the low frequency mag nifier to be employed in conjunction with a gramophonc pick-up. The more elaboratc ones include an electrically driven turntable. together with a pick-up and tone arm, so that it is jrossible to receive broadcasting or reproduce gramophone records at will.

The following factors are of importance in choosing a suitable set
(a) Accessibility with respect to the removal of the lves when they need replacement.
(b) Gond cabinet work and mechanical solidity
(c) Criap reproduction, with the high and low noter In adequate proportlons. Intelligibility of the speaking volce. Freedom imm reaonance. "boominess," backgmund nolses, etc.
(d) Simplicity of operation, tozether with soine means of adjustlua the volume without limpairing selectivity or of introduclnz distortion
(e) High aclectivity and wive-change switching the receiver is to be used for the recention of atations other than the local.

BROCADE. Brocades are always figured and usually in Horal patterns, and generally the pattern is woven. According to one classification brocades have their groundwork formed by the warp or lengthwise threads, and their ornamentation by the weft or crosswise threads. The name inplies a rich decora tive fabric, usually carried out in silk, artificial silk, or mixtures of silh and cotton, with or without metallic throads.

BROCCOLI: To Grow. For practical purposes broccoli may be called the winter type of cauliflower. Sowing is donc as with curly kale, and the gardener who requires broccoli from October to May should make three sowings at regular intervals during April and May. Broccoli should not be planted between potatoes. To guard against injury from quick thawing after frost, the plants should be bent over until the stems are almost parallel with the ground, inclining the heads to the noith if the rows run east and weat, and west if they run north and south.
Some varieties are suited for autumn, some for spring, as follows:
Autumn: Michaclmas White, Self-protecting, lutuinn Protecting Walcheren.
Early Winter: Christmis White, Snow's Winter White, Early Purple 8prouting.
Late Winter nnd Early Spring: Knight's Pro. ecting, Penzance, White spmuting, Leamington Late Purple Sprouting.

Broccoli : two varieties of this winter veretable apring. Right, Late Queen.

Late Spring and Larly Summer: Model, Jate Queen, Methiven's June, latest of All.

The following standard sorts would give a good succession if sown together early in Ipril: Walcheren, Snow's Winter White, Leamington and Latest of All, always por vided the winter was fairly open
How to Cook. Strip off the outer and all withered leaves, cutting the remainder leve with the flower. Soak well in cold salted water with heads downwards to draw out any insects. Then cook for $10-15 \mathrm{~min}$. in boiling salted water, the flower part downwards and the pan uncovered, to preserve the colour. Test by piercing with a skewer, and when tender drain well, put on a hot dish and serve with a tureen of melted butter. Broccoli breaks if boiled too fast. The colnur and crispness of this vegetable will be speedily lost unless it is at once taken out of the water when cooked

With cheese sauce boiled broccoli makes an cxcellent dressed vegetable. Lay the cooked heads neatly on a huttered au gratin dish and coat with cheese sauce. Dust the surface over with two tablespoonfuls of grated cheese, mixed with a amall tablespoonful of browned crumbs. Put dish in the oven and bake quichly until the checse is browned and serve at once. See Cablange: Caulillower; Curly Kale.

BROGUE. This heary-soled shoe has a tongue which folds over the instep to prevent water entering the eyelet holes. Brogues arc used when heavier sporting boots are unnecessary. Imitations of the real article are sold, with punched toc-cap and vamp, and sometimes with the fringed tongue

## Broiling. See Grilling

BROMIDE PAPER. Bromide papers of different surfaces. glossy, matt, and of different tints, white, cream, etc., are almost exclusively used for making the so-called gaslight prints and enlargements from photographic negatives.

The paper is so sensitive to light that an exposure of a second or two bchind a negative placed a few feet from an electric lamp or gas mantle is sufficient to print a picture on it It is too rapid to be printed by daylight. After exposure, a picture quickly appears in a developer, which, in two or three minutes, produces a print of black colour. All operations up to and inoluding fixing must be done by orange or yellow light.

One or two small picces of the paper are exposed for different times, and developed in order to find the correct time for which to expose the paper. If the picture comes up slowly and remains pale, the pajer has been exposed for too short a time; if it comes up quickly and soon becomes dark and foggy, the exposure has been too long. The paper should he exposed so that a bright and vigorous print is ohtained with ahout 2 min . development. Practically every bromide paper yields

Left, Purple Sprouting, sown in winter or early Left, Purpie Sprouting, sown
wn in apring or early sommer
first-rate results with amidol, metol, or metolhydroquinone devcloper.

The exposed sheet of paper is placed, coated side up and without previous wetting. in a dish and flooded with enough developer to cover it; or a number of pieces may be quickly slipped at intervals into a larger quantity of developer. When fully developed, as shown by its vigous and depth, each is rinsed in clean water for a fow seconds and lixed in a bath made by dissolving 4 oz of hypo and $\frac{1}{2}$ oz. potass. metabisulphite in 20 oz ol water.

Chemicals for this fixing bath may be bought as acid fixing salts. Each print is best fully inimersed under the surface of the bath for a second or two ; and as prints accumulate in the hath they must be moved about so as to separate them from one another and ensure their being fully fixed. This is best done with a rounded stick, so as to avoid contaminating the fingers with hypo. which must on no account be alluwed to get into the developer. Prints will be fixed in 10 or 15 min They are then washed for an hour in running water, or in successive lots of clean water which is renewed every 5 min . Dry by hanging up on a line with clips or by laying out on blotting paper.

The black colour of bromide prints may readily be changed to brown or sepia, or to red, blue, or green. Of thesc toning processes, the one which is most largely used is sepia toning (q.v.).

BROMIDES. There are several druge ol great use in modicine which owe their virtues to the possession of the chemical element called bromine. They are potassium bromide, sodium bromide, ammonium bromide. and hydrobromic acid. All these preparations have practically the same action and are used for sleeplessness, nervous excitability, palpitation, etc., but when the drug has to de taken over a long period sodium bromide is preferred to potassium bromide.

The bromides are given in whooping-cough, ammonium bromide being considered the best for the purpose. Diluted hydrobromic acid is often taken with quinine. It helps to dissolve it and also to prevent the disagreesble effects sometimes produced by quinine. Giddiness may be alleviated by one of the bromides. and if full doses are taken every 3 hours for several days before going on board ship, seasickness may be prevented or diminished. Sleeplessness due to worry and nervous excitement may be relieved by 30 grains of potassium bromide in half a glass of soda water. Another use is in irritable conditions of the pharynx and larynx. In epilepsy bromides are given over long periods.

Bromism is the condition produced by overdosage with bromides over a period and is characterised by mental dullness, heaviness of the legs, unsteady gait, drowsiness, anaemin, an acne eruption and other symptoms. The addition of a little arsenic to the mixture usually prevents any eruption when bromides are being taken.
BROMPTON STOCK. This is the popular name ut a variety of the genus Mathiola, a half-hardy, biennial flowering plant. The seed is sown in May. In cold districts it is wise to winter the planta in a frame and put them out in spring. The plants nverage about 18 in . in height, and the flowers are sweetly perfumed.
BRONCHITIS: Care and Cure. While rarely dangerous to healthy adults, bronchitis is serious for infants or old people, in consequence of its tendency to spread to the lungs. It may be defined as catarrial inflammation of the mucous membrane which lines the bronchial tubes or air passages of the lungs.
Acuts bronchitis is most common in spring and autumn ; it may develop from an ordinary
cold in the head or be part of some nilment, such as measles, influenza, or whooping cough, and is due to the invasion of the air passages by germs. The attack begins with symptoms of a cold in the head, including perhaps sore thrnat. There may be little or no fever. The extension of the catarrh downwards produces hoarseness and a raw feeling in the chest, behind the breastbone. The tubes feel irritable, and there is a hard barking cough which may become paroxysmal. The chest feels tight and oppressed. At first there is only a slight sticliy sputum, but in about $\pi$ week's time this becomes freer, and increases the patient's comfort.

In treating bronchitis the patient should be confined to his room, and it may be necessary to put him to bed. A hot bath or a hot mustard and water foot-bath and a mustard plaster npplied to the chest are useful. The inhalation of steam from a jug of ateaming water, to which a teasponnful of Friar's balsam has been added. helps to soothe the racking cough, the patient covering his head and the jug with a towel If there is difficulty in getting up the sputum, ipeca cuanha wine in 10 minim doses may be given three or four times a day in a little water.

When bronchitis descends into the lungs, affecting the tiny end branches of the bronchial tubes, the patient's restlessness and distress increase. the temperature becomes higher, he has much grenter difficulty in breathing, and the cough is more marked. The lips and the finger-tips are often livid. The immediate attention of the physician is essential.

## Emersency Treatment

In a child the condition may be ushered in by convulaions, and the child should be put in $\Omega$ warm bath. During the course of the illness the child maty suddenly become very blue and breathless ; there also the warm bath would be used and cold water thrown on the child's chest to induce decp hreaths. These measures are, of course, only pending the arrival of the doctor.
After several attacks of acute bronchitis the lungs, particularly in middle-aged persons, may lapse into a chronic oondition ; but more often chronic bronchitis is associated with some other condition, such as heart disense, emphysemas (barrolshaped chest), diseased states of the lung induced by dusty occupations, gout or chronic kidncy diseasc. Frequently the disease takes the form of a cough, which

Brompton Stock. Flowers and foliage of the double red variety, useful for beds and borders
develops regularly at the start of each winter and lasts until the following suminer.

Sufferers from chronic bronchitis should pay particular attention to keeping the bowels regular. Two to three grains of cascara taken at night are usually all that is required. For the morning cough a hot alkaline drink, such as the following, sometimes gives relief :

## Podium bicarbonate <br> Potassinm bicarhonate <br> Chloroform water

- Irams

1 dram
4 ounces
Take one tablespoonful, mixed with two tablespoonfuls of very hot water, immediately on waling.
A thorough rubbing of the chest with ordinary soap) liniment or hartshorn and oil, and then covering the chest with a warm jacket of flannel, is also advisable in chronic bronchitis. See Cough; Lunge.

BRONCHITIS KETTLE. Special kettes made to emit a great volume of steam, which moisture is useful in assisting the breathing in bronohitis and similar complaints, are made and sold for this purpose. In case one of these is not at hand, an ordina ry kettle can be used. Filled with water, this should be placed on the fire and allowed to boil freely. With thin cardboard or brown paper, or, if theso are absent, with ordinary newspaper, a large trumpet-shaped roll should be matle.

## Place the narrow end

of this over the spout of the kettle and the wide end near the patient's bed, which, for this purpose, must be fairly near the fire. The-roll can be supported hy putting a piece of tape round it and fastening the other end of this to an overbanging projection of some kind. This improvised kettle will be found very useful in attacks of croup (q.v.)
BRONZE, Genuine bronze is generally found in the home in the form of atathary and ornaments. It is an alloy, chiefly composed of copper and tin, and is harder and more durable than copper or brass. Bronze has a pleasing dark brown colour, and is capable of taking a high polish.
The so-called bronze powders are metallio colouring materials used in the same way as gilding preparations. The article to be treated is coated with gold size, after which the bronze powder is sprinkled evenly over the surface. Various tints are to be obtained, in addition to powders simulating gold, silver, aluminium, etc.
Bronze Collecting. When selected with taste, bronze figures or vessels are restful to the eye. A classical centrepiece, such as a good bronze replica of a full-length Mercury, may be appropriately flanked by a pair of unglazed Parian figures ; it would lose in effect if placed between pieces of highly decorated china.

Egyptian bronzes are often forgeries rather than replicas, except such things as sphinx paperweights, and have little decorative merit of their own. It is otherwiso with the statuary bronzes of the Renaissance, or some admirable modern works. These are in some instances availalile in replica, and artistic reproductions have to be distinguished from inferior castings which are turned out abroad in great numbers for cheap decoration.

Replicas of ancient Chinese and Japanese temple bowls, koros or incense-burners, lanterns, hells, and Buddhist images are desirable nequisitions. The modern school of Japanese bronzists has produced excellent work, including animal groups and figures, worthy to be set out with choice porcelain jars. Some Saracenic and Persian work, especially when damascened in silver, and certain bronze lamps and figures from Ceylon are also good.
The natural patina or crust of genuine old bronze is often initated in replicas, and such finishes are not to be rejected if carried out sincercly. The intentional production of tints and sheens, either by oxidation or by liquid varnishes, reaches its highest level in eastern hronzes. Their effects are sornetimes due to the admixture with the copper-tin base of silver and other metals, sometimes to the use of metallic pastes, which are burned in and polished. Imitation patina is produced by green varnishes, which are liable to flake. or by al ammoniac.
Art-bronze is a term applied to much metal work of a trivial kind, and is especially affected by producers of tasteless ornaments, and thin stampings used as furniture panels. The collector of bronzeware for its antiquarian intereat usually preserves his treasures in cabineta. They may include a great variety. from werpons of the Bronze Age to AngloSaxon buckles and brooches, and medieval bella cast before brass had displaced bronze.
Natural patina ought not to be scoured sway. Inartistic stains may be removed, without destroying the patination, by means of a half-lemon dipped in salt. Sometimes antique bronze when unearthed is found to be oxidized throughout, and in that condition cannot be cleaned at all.
BRONZING. By the process of bronzing any article made of metal, wood, plaster, or other material is given a hronze-coloured surface. Iron and steel are bronzed by exposing them to the vapours of hested aqua regis, and dipping them infe melted vaseline. Plaster and wood are coated with size, then a metallic bronze powder is applied.
Dilute aulphuric acid and dilute nitric acid produce a bronze colour on many metals. The most artistic effects are ohtained by the use of bronzing acids on brass or copper ware. The acids are obtainable from any dealer in such substances.
The brass object is first cleaned and polished, either by mechanical means, as with emery powder, or by dipping in dilute nitric acid and washing off in hot water. The work is dried in hot sawdust, and must not be touched with the hands. Make a rubber of fine wood-wool shavings or linen, wearing rubber finger-stalls on the finger-tips to prevent the hands getting atained. Slightly warm the work, then wipe it over once only with the bronzing acid Keep the work free from draughts, and move it about over, but not too near, a gas flame. A deeper colour can be obtained by using a stronger solution or by repeated and continued applications of the rubber, slways taking care to work evenly.

BROOCB. The simplest form is the safety pin; all other hrooches are elaborations of the same idea. For a valuable brooch a good safety catch is the best form of insurance against loss.
In the case of the brooch fitted with a hook or a point-protecting catch, a safety chain should be attached. There is little difficulty in attaching it to the brooch, provided there is a small aperture through which the jump ring can be passed and afterwards closed with a pair of pliers. Instead of a safety chain, an efficient catch known as a fish tail can be fitted by a jeweller without much trouble. It consists of a amall plate, shaped like a fish tail, as in Fig. 1, and operated by a smal hinge set close to the existing entch. Fig. 2
illustrates a good form of safety catch, known to jewellers as the Tiffinny catch
Should brooch pins lreak or come out, it is quite a simple operation to replace them. Retailers of jewellers sundrics stock hrooch pins of all sizes in metal and gold. Perhaps the best investment is to buy a packet of assorted metal pins. If the old pin has broken off and the joint por tion is still in tho brooch, it can be removed by tapping out the piece of wire on which it is hinged with a stout needle and a light hammer, or the side of a pair of pliers. Take from the packet a pin long enough for the brooch, and, holding the head in the pliers, carefully file from each side of the joint sufficient to allow the pin to fit the gap from which the broken piece has been removed. Then take a piece of brass wire and file it slightly taper, so that it will go into the hinge, and force it home, as indicated in Fig. 3. Afterwards, with a file, nick the wire on each side of the linge, as shown in Fig. 4. break it off, and finish by filing it flush.

## Care of Gem Brooches

Long bar brooches, if sct with stones, ahould not be used to fasten thick material, as the weight of the material may atrain the setting, so that the stones become loose and drop out. If the pin has got strained and lost its apring in this way, it can he temporarily restored. Hold the brooch in the left hand, and, with the thumb and firat finger of the right hand, gently bend back the pin close to the joint. All hronches set with stones should be examined periodically, to make aure the gems are tight and the settings in good order.
A brooch set with jewels may be cleaned with warm water, a few drops of cloudy ammonia and an old toothbrush. 1)o it in a hand-basin and not over a lavatory basin or sink. Should a stone be lost in this way, open the trap fitted in most waste-pipes, as the gen has probably been stopped in this. Mothers with young children should not wear brooches unless fitted with a point-protecting device.

Sometimes a brooch pin will turn up at the point, and on withdrawing will bring with it a thrend of the material. The point can easily

Broocb. Figs. 3 and 4. Fitting a new pin and nicking it with a fle previous to fling fush
be straightened out. Hold the pin llat on a hard surface and, with a stecl linitting needle, as though sharpening a pencil, presa atraight the distorted point. A pin that is blunt at the point may be sharjened with a few rubs on a piece of emery cloth.
BROODER. This is the name given to a heated chamber connected to one or more outer chambers or chicken runs. It is an adjunct to the chicken incubator, and is used in order to raise chickens artificially when it is not possible to make use of a sitting hen. See Chicken; Poultry.
BROODINESS : Row to Cure. This condition in a hen is characterised by a peculiar clucking noisc, accompanied by feverishness, indicating the desire to sit. Apart from clucking, the desire to sit is further evidenced by the hen sticking tight to the nest. She should either lie allowed to obey her instincts by being entrusted with a aitting of eggs, or broken of the habit

To break up a broody hen, as it is termed, is quite a simple matter if taken in hand in the early stages. At the first indication of hroodiness, remove the hen to a coop with a slatted Hoor, that is, a floor composed of Iathes nailed crossways two inches apart. The coup is raised from the ground by bricks placed at each corner so as to allow of a free current of air beneath

In such a coop it is impossible for a hen to sit with any degree of comfort, and, being obliged to roost willy nilly, she quickly loses the desire. A few days confinement will auffice to curc her, and in the course of a week or so she will resume laying. See Poultry

BROOM: The Plant. This name is given hoth to cytiaus and geniata, hardy apring and summer Howering shrubs of great garden value. They thrive particularly well on poor or light land. When planting brooms it is important to choose small plants which have been grown in Hower pots; large plants lifted from the open ground are liable to fail

Some of the brooms are tall shrubs suitable for grouping in the flower garden and shrubbery ; others are of low growth and may ic grown in the rock garden. Of the tall kinds, which bloom in spring or earlv summer. some of the most beantiful are Cytisus albus, white, praccox, cream, scoparius, the common yellow broom and its variety andreanus, bronze red and yellow. Beautiful low growing brooms are Catisus Ardoinci, yellow, kewensis, cream, and Beanii, yellow. The genistas are

in full beauty in summer-all have yellow flowers. The brooms come readily from seeds, which may be sown outside as soon as they are ripe. or in spring in a cold frame. Cuttings

Broom. A tavourite hardy broom (Cytisus andreanus),
bearng red and yollow flowers in easly summer
strike in sandy soil if inserted under a hand. light in summer or early autumn. Layers may be put down in autumn.
A greenhouse species, genista, much grown by market gardeners, is a neat shrub with small, sweet-smelling golden flowers, continuing in bloom for a long time. It is grown in soil composed of two parts loam, one part peat and sand. Propagation is by cuttings in sping, preferably in a propagator. Small pieces of the new wood root readily in sandy peat, the more so if a heel of older wood is taken with the cutting. The plants which result should have the points taken off when they are 6 in . high, in order to cause them to break, and the side shoots thus obtained should also be stopped when about 4 in . long; this ensures neat bushes with several branches.

From May to midsummer the plants may be kept in a cold frame, and watered and syringed regularly. From that time to October they will be better on a bed of ashes in the open. They should be housed in autumn. A winter temperature of $45^{\circ}$ to $55^{\circ}$ will suit them. After they have flowered they may be cut hard back, re-potted, and syringed. They will then break afresh, and, after the necessary cuttings have been taken, may be hardened in the frame.

BROOM : For Sweeping. Brooms are made of bass, white fibre, hursehair, bristle, and coconut fibre. The stocks or handles are of alder, birch, and beech, and with the exception of certain bass brooms, the knots are invariably set with pitch. The so-called hair broom, for household use, in best qualities is of pure bristle at least 4 in . in length. Other qualities are less economical in the long run.

Points to look for in a good broom are the long, springy flag-ended bristles and the even pitch-set knots, with the outer row of knots well spread. It may be found that the outer knots are small and close made of bristle, with the inner knots large and composed of inferior mixtures. These can be detected by placing the hand across the surface of the
broom and noting the greater readiness with which the bristle will spring back when released, as compared with the less springy substitute. The knots in a good hair broom are set outwards to obtain tho maximum spread for the sweeping surface.
If the tufts of hair are stuck in with pitch, known as pan work, the holes should be well filled and a neat ring of pitch be visible at the edge of each hole, and there should be no waste of space inside the outer row of knots. When not in use a broom should be stood up in a reverse position or hung up. The best carpet brooms are made of Venetian whisk, straight, stiff, and durable. In most homes the carpet sweeper has ousted the carpet broom for Hoor sweeping, but it is still employed for upholstered furniture. Superior makes are fitted with plush protectors at each end of the stock, thus minimising risk of scratching fragile furniture, polish, etc.

In the yard or outdoor broom pure bass serves best. For very hard wear these are faced with knots oì cane or whalebone. Water will not deteriorate bass, but stiffens and keeps it in condition, so it is suitable for washing-down purposes.
The common coconut fibre broom is a cheap substitute and valueless. For hard wear, as in stable use, whalebone is mixed to give an added stiffness and durability, and in the case of heavy scavenger brooms the front row of holes is filled with split cane.
To obviate slipshod attachment of the handle an attachment can be procured which will enable the broom to be used both ways, trebling the life of the bristles, and the twoway metal attachinent fits and secures any ordinary broom-handle.
For sweeping up the litter made by falling leaves, cut grass, and so on, the garden broom or besom is highly satisfactory.
Garden brooms are made from birch twigs, cut from the trees after the periodical clearing of woods which is constantly going on. The twigs selected are up to about four feet long, and these are bunched with the strong ends level, and then tightly bound together with strip or split cane, one strong binding at the end and two or more at intervals of a few inches. A stout staff with pointed end is then driven up through the tied ends to make a handle, which is fixed by a plug passing between the bindings and through a slot or hole previously cut in the handle. See Brush.

BROOM RACE. This is a useful article for the home, and will also commend itself for the ease with which it may be made,

Fig2

Fig. 3

Fig. 4

Fig」
and the small amount of material required Fig. 1 shows the rack complete, consisting of a wood back, with pegs to hold brushes and brooms. Details of the rack appear at Figs 2 to 5. A hardwood, such as birch or elm, could be used, or ordinary deal would be very suitable. The best finish will be with stain or varnish, or varnish alone.

The back, as at Fig. 2, is 1 ft .6 in . long by 6 in . wide, and should not be less than ${ }_{3} \mathrm{in}$. thick. The long pegs for the brooms, two of which will be required, are shown at Fig. 3, and must be cut from wood in. thick. A tenon 1 in . deep by $\{$ in. long is formed at the back end of these pegs for fixing to the back of the rack. The shorter pegs for hand brushes are seen in Fig. 4, and at the back end of each peg a tenon $\frac{1}{2} \mathrm{in}$. deep by $\frac{7}{3} \mathrm{in}$. long is formed. Figs. 3 and 4 show $\frac{1}{2}$-inch squares.
Mortises are cut through the back of the rack to receive the tenons on the ends of the pegs, and a chamfer about $\frac{i n}{} \mathrm{in}$. square is cut around the edges of the back, as at Figs. 2 and 5. The pegs are glued to the back. For hanging the broom rack, two holes should be bored through the back, so that it may be fixed to the wall with a couple of brass-headed nails
BROSE. This dish of Scottish origin may be prepared with pease meal. Put two tablespoonfuls of this into a basin and stir into it $1 \frac{1}{2}$ gills boiling water. Put the mixture into a saucepan and boil carefully for 5 min . Season with salt and pepper, add a piece of butter the size of a walnut and serve very hot with milk.
For another variety of brose, break sufficient stale brown bread into inch pieces to fill a $\frac{1}{2}$ pint measure, and stale white bread to fill a pint measure. Put these brown and white pieces into a double-pan, add 2 oz . of butter and $\frac{1}{2}$ pint of milk, then cook it until the bread is quite soft and the milk absorbed. Add salt or sugar to taste, and serve in hot porridge bowls. If the bread is very stale more milk will be necessary. It is best not stirred during cooking.

BROTH. The unclarified stock made from beef, mutton, veal, chicken, etc., is garnished for broth with neat cubes of the best parts of the meat, and vegetables used in its preparation, with the addition of a little iice or pearl barley boiled in it.

BROWN: In Clothing. For autumn and winter wear, brown in varying shades is always in fashion, as the colour is warm and looks well in heavy fabrics. For women there is also the advantage that it tones with most furs. For country, sports and travel wear, brown is a good choice, as it does not show dust, and smart accessories for both sexes, shoes, boots, knitted wear, scarves, etc., can be obtained in this range more easily than in any other colour. Lighter colours can be successfully dyed brown.

BROWN BOOTS : Their Care. In making brown leathers for boot uppers, it is essential that the boot maker should use skins which are free from defects. After tanning the raw skins it is customary to sort them over carefully, and to employ those which are at all defective for lower grade blacks. This influences the price of the finished boot or shoe, so that good brown boots are dearer than black.
After a few days' wear cheap brown boots lose their smart appearance. This may not be so noticeable in the case of cheap black footwear, as manufacturers can more readily
fake the uppers of the black boot after the latter has been made. But with brown hoots touching up can only be done on a small scale with a pigment finish. Such finishes consist of a pigment colour similar to those used in paint manufacture, and some binding substance like shellac. When this is applied to the defective grain surface of the leather, the tiny particles of pigment fill up seratch marks, etc., forming a smooth surface. After a little wear this finish hecomes ineffective, and the hoot begins to look shoddy.
Cleaning and Reviving. No polish should be applied to the surface of brown or coloured hoots until all the dust has been removed, otherwise the bright brown tone of the leather will gradually dull. If it is desired to revive the original colour, the following method has been found satisfactory. The boots are placed on trees and brushed with a warm solution of soft soap. Ordinary soap is useless for this purpose. This is then washed off with clean water, soft soap rubbed into the leather and allowed to remain until nearly dry, when the excess of dry soap should be wiped off with a damp rag and the boots allowed to dry thoroughly. If a good polish of the required shade is applied the brown boots should look like new.
Trouble is often occasioned hy grease spots on brown hoots. Apply a paste of fuller's er reth, which should be left to dry before wiping off. It absorbs most of the grease without taking out the colour, and a second application should complete the absorption. If water or rain spots are allowed to dry, the lenther is likely to be spotted with light patches. For these blemishes make a stiong decoction of shag tobacco, and lightly touch them with the liquid until they resume the requisite deeper shade. Then apply a good polish to the whole surface

## Black Boots from Brown

To convert brown boots into black needs anre if the job is to be undertaien at home First, all dirt should be removed with a clenn brush. Then polish is removed by going over the upper with a cloth or sponge soaked in netrol,-followed by $a$ similar application of methylated spirit. This, of course, must be done in the open, fivay from naked lights The boots are allowed to stand for some time in the open air, in order that all the petrol left in the leather may volatilise. The surface is next lightly rubbed with a cloth dipped in either $n$ weak soda solution or some weak ammonia, after which the uppers are wiped over with warm water
By this time all foreign matter should have been removed, and the cleaned surface is ready for the dye, which can be bought at any leather goods or oil and colour stores. Two applications or more will be needed, then the bonts are allowed to dry, slowly and thoroughly. They must not be put in front of a fire to dry. Finally, the uppers are blacked over with n good black boot polish
Brown Boot Polish. The pastes employed for shining brown leather boots have a basis of beeswax and turpentine, the yellow colour being given by an aniline dye such as bismarck brown or phosphine. It is sometimes necessary to remove stains and discolorntion before applying polish to brown boots. The beat clennaer is a thick cream of gum tragacanth to which 2 per cent. of oxalic acid has been adder. See Boot.

BROWN BREAD. Unfermented brown bread can be made in this manner. Mix well Ib. wholemeal with $\frac{1}{} \mathrm{lb}$. white flour, 1 tcaspoonful each salt and sieved carbonate of soda, and two teaspoonfuls sieved cream of tartar. Rub finely into these 2 oz . margarine, butter, or dripping, and mix to a soft dough with about $\frac{1}{2}$ pint milk. Knead quickly and lightly, and shape into two round loaves.

Gash rather deeply across the top, place on a Houred baking-tin, and bake in a quick oven for about 30 min ., or till well risen, lightly browned, and firm in the centre. If there is butter-milk or sour milk, use that for mixing. and only one teaspoonful of crenm of tartar. See Bread.
BROWN BREAD PUDDING. Make 4 oz . brown breadcrumbs by rubbing stale hread through a wire sieve. Put $1 \frac{1}{2}$ oz. hutter into $n$ basin. warm slightly, and add 2 oz. castor sugar. Beat these with a wooden apoon nnd stir the yolks of 2 eggs into the creamed mixture, then add crumbs, grated rind of a lemon or an orange, a few grains each of grated nut. meg and powdered cinnamon, and a gill of milk. Mix all together and stir in lightly the whipped whites of the eggs. Pour the mixture into a well-greased basin, twist a piece of greased paper over the top, and ateam the pudding gently for 1 hour. Turn ont to dish. and pour round the pudding hot jam or other aweet snuce

BROWN HOLLAND. This plain, unbleached linen fabric for children's dresses and the like is imitated also in cotton. The window holland, usually brown and emploved for blinds, is nlmost always of cotton, finished in a special mnnner to throw off dust.

BROWNING. For colouring soups, gravies, and puddings, this is sold in bottles, but may be made at home. Put 4 oz . white sugar into a saucepan and stirover a low fire till the sugar is melted. Boil gently, and when it turns a rich brown, pour into the pan $\frac{1}{2}$ a pint water. Boil gently until the consistency of warined treacle; stir occasionally, and skim if necessary. Cool, pour into a clean bottle, and cork for use. Well-made browning should be neither bitter, from overcooking, nor sweet, from insufficient colouring of the sugar.

## BROWN JOHNNIE PUDDING.

An excellent steamed pudding made by mixing 6 oz . each flour, finely chopped suet, and golden syrup with 1 teaspoonful ground ginger. Beat an egg frothy, mix with $\frac{1}{2}$ a gill milk, and beat these into the flour, etc. Have ready a thickly. greased basin, and the water boiling in the steamer.

Put one teaspoonful of bicarbonate of soda in a small basin, mix smoothly with two teaspoonfuls of milk, and stir thoroughly into the pudding mixture. Turn it at once into the hasin, twist a piece of grensed paper over the top, and steam for two hours. Turn out on to a hot dish, and pour round it some hot sweet sauce.

## BROWN PAPER.

 Brown paper is sold in shects, the most or dinary size being 29 in by 40 in ., with 24 sheets to the quirc. Three qualitics are obtainable, according to the thick.
## ness required.

BROWN ROT : To Prevent.
During the suminer and early
autumn fruit trees are frequently attacked by a disease which produces on the fruit soft brown areas. These increase in size until the whole fruit is affected.

Diseased fruits which become nttached to the tree gradually dry up and shrivel, and these produce a new crop of sporea and spread the disease.

The best preventive measure, as is pointed out in Leallet No. 86 issued by the Ministry of Agriculture. is the removal and destruction of all mummified fruits during winter. They should be collected, and either burned or deeply buried. All infected spurs, together with cankers on the stem, should be cut out.

When fruit is to he stored, the greatest care should be exercised in discarding all fruit showing signs of brown rot. for the disense will

Brown Rot. Left, apoles aflected by rot. Right Brown Rot. Leit, apples aflected by rot. Right.
fruiting spur, showing pustules of the same fungus By permission of II.M. Stationery Othice and
not only continue to develop in the affected individuals, but will spread to others. It is advisahle to spray with a tar-oil wash in winter and with Bardeaux mixture before the blossoms open and again as soon as they have falien. See Apple.

BROWN SCALE : How to Spray. Goose. berry, curriant. peach and nectarine are all linble to the attacks of the insect known as brown scale The insect leaves n pale scar when removed from a twig, and it has a preference for the older branches. The remedy is winter and apping washing, of which particulars are supplied in Leaflet No. 223 issued by the Ministry of Agriculture.

Complete pruning before spraying operations are commenced; and in old and badly infected trees remove as much of the old wond as possible. The spraying apparatus should have the nozzle fitted at an angle of about $\left.4^{\circ}\right)^{-}$degrees so that the spray may be conveniently directed to the undersides of the branches where the insects are usually more abundant.

The best winter wash is lime-sulphur. The concentrated lime-sulphur solution can be bought ready made, and should be diluted to winter strength-3 quarts of lime-sulphur ( $1 \cdot 3$ specific gravity) to 10 gal. water. A good paraffin emulaion is

Dissolve the
Brown Scale. Undersides of, left. larva and, right. young female, highly magnified; $m$., mouth: c. channels to respiratory tubes. Right, peach twig affected by brown scale soft soap in about a gallon of boiling water. Remove the soap solution from near the fire, and while still hot add the parnffin. Churn the mixture very thoroughly, add soft water to make $10 \mathrm{gal} .$, nod make sure that there is no paraffin lloating on the surface.

BRUISE : Its Treatment. The colonr of a bruise is due to the blood which has escaped from the vessels into the surrounding tissues. It is usually at first a bluish-black.

To prevent the further escape of blood intu the tissues, an ice bag or a series of towels wrung out in cold water should be pliceed over the part. The ordinary lcad water and opium lotion poured on a handkerchicf and
then bandaged loosely over the bruise is a good home remedy.
If the skin is broken, and oozing is taking place on the surface, wash the part well with running water for a few minutes and dust it thickly with boracio acid powder or paint with tincture of iodine. Then apply a piece
of boracic lint, and bandage as firmly as is comfortable. Place the lower part at rest ; if a lower limb, elevate on a pillow; or the upper, place in a aling. A hot bath taken soon aftel the injury will help to relieve pain and stiffness. After a few days massage the part gently. See First Aid : Sprain.

## BRUSHES FOR HOUSEHOLD AND GARDEN USE

## How to Choose and Keep Them in Good Condition

Further details will be found under such headings as Boot Brush; Clothes Brush; Paint Brush : Tooth Brush. Sec also Broom; Carpet Sweeper; Vacuum Cieancr

Brushes are divided into two kinds, simple and compound, according to the way they are made. The former consist of one tuft only, un example being the brushcs used by the artist ; and the latter of more than one tuft. among them being most of the brushes used in the home. Brushes in which the tufts are placed side by side are known as stock brushes.
The principal raw matcrial used in the manufacture of brushes is bristle, almost wholly pig or hog bristle. This is collected, partly sorted, and sold in lengths from $1 \frac{1}{6}$ to 7 in . It is dressed, comhed, and mixed before heing made up according to the particular class of work for which it is intended. Bristle s exceedingly springy, and will maintain this property under ordinary conditions until worn away by use. Hence the chief value of bristle for making brushes.

## Materials Other Than Bristle

Among other materials used are fibre (Mexican grass), Mexican whisk, Bahia bass, and horsehair. Fibre and drafts (horsehair) are the chief materials used for mixing with bristlea as well ay for substitutes. Skunk fur is used for a light dusting brush with an adjustable head convenient for edges of panelling and for lighting fixtures, as shown in the illustration. A finely cut rubber brush, arranged in a spiral round wire is excellent for cleaning bottles and vases.

For fancy brush handles and backs, roseavood, satinwood, und ebony lend themselves to an excellent finish. Owing chiefly to the increasing cost of bristlcs, imitations and substitutes aro plentiful and lead to unsatisfactory wear in some cuses.

Scrubbing-brushes made of a mixture of fibre and hass, and known us union, are cheap and serviceuble. The one illustrated with a long handle working on a swivel saves kneeling and stooping. Shoe, stove, and similar brushes arc made with the root end of bristles to obtain the required stiffness. Best mukes are wirc-drawn, with screwed-on backs. Small hand brushes bristled both sides are convenient for removing dust from cushions and
rugs. Racks for holding brooms and brushes are illustrated under the heading Broom.
Fibre and Bristle. High prices call for an examination of brushes used for decorating, A common fibre brush is intended for rough work where lime is used. Whether tied on the handle in two knots with wire or string, or nailed on with tin or leather, a good finish is usually an indication of a well-made brush. The sash brush or tool of more than a dozen sizes is best made in a forked handle, and bound with a string or copper wire. The bristles are held together with a cement of resin and oil, and pulled into the handle while they are hot.
The distemper or whitewash brush with two knots is an expensive article. Five to 6 in . bristle is used, and the wire, which should not be stinterl, may be secured by solder at the corners. All first quality distemper brushea are stamped pure bristle, or covered with a similar guarantee. Black Chinia bristle, while good in appearance, does not compare in usefulness with other bristles, mainly because it does not carry or hold paint or distemper.

A moderate ululteration of bristle with fibre and horsehair is quite acceptable for ordinary purposes. A popular brush, and one that has replaced many more expensive varietics, is the flat tin varnish. These are made of China bristle, and in sizes of an inch and upwards, and are intended for general use, including varnish work. They are usually bevelled at the top of the bristle, which gives them the appearance of a part-worn brush.

A common fault with all paint brushes is the presence of frec or loose hairs, which have not been caught by the cement or held by pressure, and one by one come out to spoil work and weaken the brush. Passing the hand over the top of the bristles, as if to test the spring, will cause these undesirable hairs to rise, and any considerable quantity denotes an unsound article. These loose hairs arc particularly objectionable in pastry brushes

In the process of making, paint brushes have probably been subjected to extieme heat and

Brush : two labour-saving patterns. Left, light brush of skunk fur, with adjustable head, for dusting lighting tixtures. Right, scrubbing brush with long bandle working on a swivel, which saves kneeling
other unhcalthy conditions. and manufac turers frequently issue instructions to pur chasers which should be strictly observed, or the maximum of wear will not be obtained. During intervals of work paint brushes should be suspended in the paint or distemper and not allowed to rest on the working end, otherwise they will become clogged and for a time unworkable. Before putting aside after use, they should be thoroughly cleaned and ready for use on the next occasion. Much can bo done by wiping out on old boards, and water will remove any remaining whitewash or disteniper:

Paint, varnish and enamel brushes must be suftened and squeezed out in a little turps or paraffin, and finished with $\Omega$ warm solution of soap and hot water, working on a stone sink or board and removing all traces of turpentine or paraffin, as this destroys any cement in the brush.
BRUSSELS CARPET. The floral designs in worsted Brussels are seldom in use, but the hair carpete, made from cowhair, and aold in natural, undyed grey or brownish inixture colouring, and also in many good ahader, are tasteful, durable and cheinp. Black or coloured borders to these squares look well in small living rooms and for bedrooms. For a stair and passage carpet it is more dependable in the undyed than in the dyed shades See Carpet.
BRUSSELS SPROUTS. The leaves at the top of the Brusacls sprouts stein are excellent as a vegetable, but should be left until all the sprouta have been gathered.
The seed is sown outcloors carly in April. and the seed. lings are planted finally in June or Juily. For an early autumn crop seeds are sown in a frame in February.

Loose sprouts are generally the resuit of over. crowding and tou light a soil, which, perhn pls, has been badly dug. Directly the lower leavea turn yellow, and part conprany with the stem underalight pressure, the sprouts may be removed, but there must be no wholesale
 clearance of the leaves. The stem is cleared of sprouts from the bottom upwarde.
The best varieties include Exhibition, Landon Market, Aigburth, and Standard. Medium-sized plants, with medium-sized sprouts of superior Havour, are given by such varieties as Matchless, Wroxton, Scrymger's Giant and Imported. Sinallest of all is Dwarf Gem. It is an excellent little variety that reaches inaturity much more guickly than large varieties. Moreover, while the larger varieties require at least $2 \underline{f} \mathrm{ft}$. each way to give of their best, 18 in . suffices for Dwarf Gen.

The enemies of Brussels sprouts are the name as the peats of other greens, with the addition of the cahbage enowy fly (q.v.).
How to Cook. The usual method of cooking this vegetable is by boiling. Trim, rinse under cold water and leave to soak for an hour in cold salted water. Drain them and
put into a saucepan of boiling salted water. If using hard water put in $n$ small saltapoonful of bicarbonate of soda, for hard water spoils the colour of green reget ables.

Boil quickly until they are soft througlt, but not broken, probnbly for about $15-20 \mathrm{~min}$., and then pour into colander, drain and return to pan. Add for 2 lh . sprouts $\frac{1}{2} \mathrm{oz}$. hutter, a little dust of pepper and $n$ few grains of grated nutmeg.

Brussels sprouts au gratin form an excellent supper or luncheon dish, prepared with 1 lb . cooked sprouts and checse sauce. See Au Gratin; Cheese Sauce.

BRUSSELS SPROUT SOUP. This delicate green purée can be made entirely with milk. Creami increases nutriment and richness, but is not essential.
Trim and wash 1 lb . Brussels sprouts and put in a saucepan of fastboiling salted water, with a small onion and a very small saltspoonful of bicarbonate of sods. Boil quickly until they are soft. Drain off water and with a wooden apoon rub them through a sieve. Put back these sieved ingredients, or purce, atir in one quart of boiling milk and reheat without letting it actually boil, or the colour will not be so good. Add one gill cream and season carefully. The soup should be is thick as good cream, so add more liquid, or a little thinly mixed cornflour, and rehoil it, even should the colour suffer, if the consistency is wrong.
BUBBLE AND SQUEAK. Use up $\ddagger \mathrm{lb}$. cold potatoes, 2 oz . fnt cooked bacon, $\ddagger \mathrm{lb}$. of cold cabbage or other cooked vegetahles, some pepper and salt, and some fat for frying. Nash potatoes. chop cabbage, cut bacon into small squares and inix all together with sessoning. Heat the fat in a frying pan, and fry the inixture until brown on both sides; then shape into a Hat cake. It should be served very hot.
BUCKET: For Household Use. The strength and durability of galvanised bucketa can best he judged by the weight. A common bucket with seamed sides weighs about 3 lb . a good quality riveted about 5 lb ., while a very strong contractor's bucket with a welded iron hoop around the rim or a similar hoop at the bottom weighs nhout 10 lb . These weights are for the 12 in. size.
Firc buckets, enamelled red or bluc, weigh about 4 lb ., and when usel for fire protection purposes should be hung on a bracket, and always kept full of water.

For home dairy purposes, enamelled buckets are used, but once chipped they should he discarded as there is a risk that a small prorticle of the enamel may get into the milk.

Wood pails for stable use made of oals have narrow galvanised iron hoops. They need to he well looked after, otherwise the wood shrinks or they develop leaks.
The cnamelled bucket, with or without lid, quichly becomes rusty if no nttention is paid to keeping it in gool condition and free from dirt. A convenient form of housemaid's pail has an exterior receptrole for a scrubbing brush, and a small one for holding the soap. Another pattern has an interior receptacle and a oinder sifter that facilitates the process of cleaning the grate.
Ordinary galvanised buckets are quietened by hinding the handle or bail with cord, or litting a rubber ring. An enamelled bucket that has been chipped can be tiented with
bath enamel applied to the damaged places, and put on in the same way as for a bath.
BUCKRAM. A stiff material made of very coarsc linen or cotton, and usually stiffened with glue, huckram is used to stiffen the edges of articles in dressmaking and fancy work, etc.. or as an interlining.
BUCKSKIN. Deerhide or sometimes sheepskin, tanned in a particular way and dressed with oil to render it Hexible, is used under the name of buckskin to make riding breeches nnd gloves.
Buckskin may be washed with sonp and wram water, rinsed and dried, but this dries nad stiffens by removing the oil dressing. An nunce of yellow ochre rubbed into a paste with a teaspoonful of salad oil, and then mixed

th coloured arc immune from the attack of birds. but by smartly jarring the attacked branches with a stick numbers miny be brought down into an upturned umbrella or shect, from which they may be collected and destroyed.

BUG. Although the word is frequently used in the American sense to indicate any kind of insect, it is npplied correctly to insects of the sub-order Hemiptera, which live by imbibing the juices of plants or animals. The bed hug is a well known example of the animal feeders, but the great majority-there are about $4 \overline{0} 0$ British species-confine their attentions to plants.

The plant-feeders in Great Ibritain seldom occur in sufficient force to cause appreciahle damage; but in other lands they include the mosquito-blight of the Indian tea-gardens, the chinch-bug that attacks corn, and the cottonstainer that depreciates the cotton crop.
The bug, or bed bug, is a flat, oval insect, a fifth to a quarter of an inch in length, with six legs and a pair of antonnae hefore the prominent eyes. Its colnur is chestnut-brown or a mahogany tint. It has n characteristic odour which helps to make it a pest. Introduced from abroad about three centuries ago, the hed bug spread rapidly and settled in wainscoting and heavy furniture. To-day, with our cleaner habits, it is less abundant; but the most scrupulously clean houses may be invaded by its walking in, or by its introduction with fumiture, either from factory or sale-room.

To allay the irritation set up by its attack, the affected part should be touched with liquid ammonia, sweet oil or tincture of iodine. Any article of furniture known to harhour the bug should have ita suspected corners and crevices painted with either of the petroleum oils applied with a painter's sash tool. Where the infestation has assumed more serious proportions, the room should be fumigated with sulphur, all crevices of windows and doors, as well as the chimney, being made tight, and the door kept closed for 24 hours after the sulphur has been ignited.

The bed hug has been convicted of acting at t:mes as carrier of the germs of relapsing fever, and it has been suspected of transmitting ot her diseases. Cockroaches eat bugs, and the same good office has been attributed to the minute reddish ant, which is itself a pest in some houses. See Ant; Apple; Cockroach.

BUGLE : How to Sound. The bugle is akin to the trumpet, but hins a shorter and more conical bore; it is used chiefly for calls in the army. The anunds that can be produced are the natural harmonic serics

These sound a tone lower, as the instrument stands in the key of B flat. It is always
written for, however, in C. Of the above sounds, the lowest $\mathbf{C}$ (fundamental) is of weak tone, and is not used. The B flat also is rather too Hat to be available, while the highest C is not employed for the army calls.
The instrument should be held firmly, but not too tightly, in the middle of its thickest portion, not too near the mouthpiece. The lips being placed to the mouthpiece in such a way that none of the breath is wasted by eacape at the side, the player utters the syllable "too," the tongue being hetween the lips and quickly drawn back. The first en deavourshould he to produce the middle $\mathbf{C}$ as a holding note When this can be done with certainty, it may be varied rhythmically by the device of tonguing (" too too "), and subsequently the other notes can be produced by means of increased pressure

BUHL. The chief characteristic of buhl, or houle, work is the application of tortoiseshell veneering on The surface is inlaid with delicate tracery in metal, especially brass, and these inlays are adorned with tortoiseshell tracery. Brass feet, bracket, edgings and other ornaments are

Buhl Work. End ol a commode made of pine with brass ebony and artoiseshel marginetry work
18th century

18 th century
Hu-dermission of the Director. Dictoria
also used, either to protect the corners and edges of the piece or for decorative purposes

Trouble with the brass inlay in buhl work is probably due to the perishing of the adhesive used in the laying. In the endeavour to press the hrass back into position a kink often develops, and this must he removed as far as possible by taking out sufficient brass to enable the inlay to be hammered on something hard slipped under.

Shellac cement, either heated or reduced to a thick consistency in methylated spirit, may answer the purpose. The cabinet naker's method is to use the best Scotch glue of good consistency, and full hot Have at hand some means of pressure that will apply to the position of the inlay-i.e. a weight, a handscrew, or even a strong 4 in . paperclip may answer ; also some flat pieces of wood and brown paper. Apply the glue, using no inore than is necessary, to the back of the brass, and press back into position with a hammer-head. Then lay the brown paper over, and the flat wood over this, before applying the weight or handscrew for compression. The brass must be held in position till the glue has set.

# Building: THE Legal Aspect <br> Important Points for the Prospective House Builder 

## The following article affords a valuable introduction to such entries as Architecture; Bungalow;

Cottage: Garage; House. See also Drains; Garden; Sanitation

The man who proposes to build his own house should first of all familiarise himself with the exact legal character of the intended property, and the obligations that may be laid upon him, particularly by local authorities.

In Great Britain certain acts of 1925 made various changes in the land laws, in the direction of greater simplicity. Land may be either freehold or leaschold. Freehold means that land and the house upon it are held in fee simple, and is the nearest thing in law to ahaolute personal ownership of land.

Leasehold means that while a man purchases the bricks and mortar of the house from the builder, he docs not purchase the land on which it stands, but hires it on lease for a stated number of years, 99 in most cases, but occasionally 999, at a fixed yearly rental. The ground landlord, besides retaining his proprietary interest in the land, acquires the same interest in the house built upon it, and at the end of the lease can, through his descendants, gain absolute possession of the house. Moreover, the tenant at the time may he obliged, if the house needs repairing, to execute those repairs at his own expense, and in the case of an ordinary dwelling house has no claim on the ground landlord for any part of the outlay.

The holder of a lease of agricultural land has the right to claim compensation from the ground landlord in respect of buildings that have improved the value of the land. But the only protection available to the non-agricultural leaseholder is by way of modifying clauses in his covenant with the ground landlord, entitling his heirs to get back from the latter a little of what they give him.

More often than not the ground landlord, owing to his tenant's indifference as to what may happen 100 years hence, succeeds in
imposing a restrictive covenant that lenves the leaseholder with little choice as to the kind of house he may build or the use he makes of it when built. Restrictive covenants are also attached to the sale of many freehold building estates, but these generally relate to atipulations as to the number of houses to the acre, the piohibition of offensive trades, building in front of a certain line and so on.

There are three methods open to the purchaser of a freehold house. He may pay the whole purchase price in cash; or he may obtain a fixed or jermanent mortgage on part of the value, subject to the mortgagee's right of foreclosing: or he may obtain an advance from a building society, repayable by instalments, plus intercat on the capital, each inonth, quarter or year, according to arrangement. The last is the method usually chosen by those who cannot put down the whole price.

## Terms of Contract

When the purchaser has made his arrangements with the builder the next step is the signing of a contract. With this goes the payment of a deposit, in most cases 10 per cent. of the total purchase money. The contract binds the builder to finish the house by an ngreed date, and the customer to completc the purchase on entering into possession on that date. In the interval a formal deed for the conveyance of the property is drawn up usually by the purchaser's solicitor, who submits it to the other party for approval. In small and straightforward transactions it often happens that the builder's solicitor acts for both parties, in order to keep down the costs; but when investigation of tithe is necessary, or any other point is involved on which dispute might afterwards arise, the purchaser will do well to have his ow n solicitor.

The charges of solicitors for advising vendors and purchasers of real property are regulated according to the amount of the purchase money. These charges, which are payable ly each of the two parties, may, however, le varicd by written agreement or reduced by one solicitor acting for both. Both a contract and a legal conveyance must be stamped The Stamp Act imposes a scale of charges which work out at ahout 5 s for every $£ 50$ of the value, if the latter exceeds $£ 500$. When a huilding society's financial help is required, the borrower is called upon to pay the surveyor's fee and expenses, and a snia! fee, amounting to lUs. per cent. as a rule, on the value of the loan.

## Authority of Local By-Laws

There remains to be considered the purchaser's relationship, to the local anthority. When the house is to be erected on a developed residentinl estate, he will find that such matters as the submission of plans for the local authority's approval have been arranged for, and the builder will see to it that the plans involve no breach of the local by-laws. But if the site is on undeveloped land, and the builder does not accept any responsibility for a breach of the local by-laws which the plans may involve, then the purchaser should study these by-laws very closely indeed By-laws, though they have in several instances heen greally modified, are still stringent enough to add considerably to the cost of the house, entailing heavier construction than is alisolutely necessary and limiting the range of materials

In any case the matter of future road charges aliould be carefully investigated. Very often a building firm developing an estate will undertake the construction of everything connected with it, including drainage and roads. The latter are made with the authority's approval; but even then the authority does not renounce its right to call upon the occupiers of houses on a particular rond to remake the road at their own expense in accordance with the authority's ideas. The builder may give a personal assurance that no such demand will be made for a number of years, but he will rarely give it in writing. and it is always as well to allow for this contingency in estimating the ultimate cost of the house. The only site that is immune from the danger of road cliarges is that fronting on a road that the local authority has already taken over and made up.

BUILDING SOCIETY. A building society exists primarily for the purpose of recciving money from its members and lending it to them or to others to enable them to buy or build houses. In the United Kingdom huilding societies must be registered, and the registrar of friendly societies examines their accounts. The funds of a society must he invested upon mortgages of real or personal property, or in trustee securities. Two-thirds of the money advanced on mortgage can be borrowed hy the society
To become a member of a building society it is usually necessary to buy one or more shares. For these payment can be niade by instalments and the member's liability is limited to the shares he holds. In addition, the societies receive money on deposit, paying interest on this according to the state of the money market, but usually giving a higher rate than the banks. Money on deprosit can he withdrawn often without notice, although in the case of large sums notice is required.

Money may be horrowed either on building society nortgage or on ordinary moitgage, the security given being a mortgage on the property. In the foriner case it is for any time not exceeding 1.5 y ears, monthly repayments of principal and payments of interest being inade. In the latter case, the principal is repaid by quarterly instalments, but these repayments do not begin until three years have elapsed. Interest is paid monthly, as in the case of
the other class The rate of interest varies and selecting bulbs. Hyacinths are graded und commences on the day the mortgage is executed After the first year it is charged on the balance of the principal which remains unpaid at the beginning of the year. An additional I per cent. is charged during the first three or four years of the mortgage.

An applicant for an advance should fill up a form of registration and pay a registration fee of ls. The property to be nortgaged is then surveycd. For this fees a verage a guinea for each $£ 500$ of the mortgage below $£ 1,000$, and a guinea per $£ 1,000$ above. Extra travelling expenses are liable to he charged for property more than five miles distant.

The officials of the society will, on receipt of the surveyor's report, decide whether or not the advance shall be made. If the decision is finvourahle, the entrance fecs on the shares necessary to make up the amount of the advance should then be paid. The title deeds or the abstract of the title should be handed to the society's solicitors, who, if the title is approved, will prepare the mortgage deed, and on its execution and the receipt of the law charges will pay the amount.
The scale of law charges is $£ 3$ is. for an advance not exceeding $£ 500$; $£ 44 \mathrm{~s}$. for one between $£ 500$ and $£ 1,000$; and $£ 1$ ls. extra for each $£ 500$ or fraction of $£ 5(0)$. Persons who wish to erect a house cannot, of course, obtain money upon it until something is in existence. In such cases it is usmally possible to arrange for the buider to wait for his money, or the hulk of it, until it can be olitained from. the building society. See Mortgage.
BULB : How to Grow. In the popular sense hulls include daffodil, hyacinth, narcissus, iris, tulip, crocus, lily, snowdrop, and many others, some of which are not really hulbs, but rhizomes or cornis. Bulbs should be lieavy in proportion to their size. Soundness may betested by pressing the thumb on the hollow at the base: this will be firm if the bulh is sound and soft if the hulb is unsound. Reject all soft, spongy hulbs. Flower grouth must be preceded by atrong, healthy ruot action, and the cultivator should give it every encouragement.
Both size and weight have to be conaidered in

Bulb. Above, two examples of indoor culture: left, single narcissus; right, white Dutch Roman hyacinth. Below, fritillaries grown out of doors
the free passage of water. The compost should be thoroughly mixed some time hefore it is required for potting. It should be moist but not sodden.

If new pots are used, they should be well soaked for several hours, and allowed to dry. Figa. 5 and 6 in the diagram show correct potting, with ample drainage, and the bulbs resting on a base of silver sand. Bulbs should not be planted deeply, as in Fig. 7, or too much above the badly drained soil, pictured
in l'ig. 8. To drain,
place n large piece of broken pol over the drainage hole, smaller pieces over and around it. and still smaller pieces above these, then some of the rougher parts of the compost.
Bulbs Grown in Water. Bulbs are also grown in glasses of water rainwater when possible. To keep it pure, a fow pieces of charcoal are put into the glass, as shown in the diagram It is not necesaary for the bulb to touch the water; it should rest just a bove the surface, as in Fig 1, not in the water ns in Fig. 2. Loss of water must lie marle good from time to time. Bulbs in glasses are best kept in a dark cupbonrd until they have made considerable ront growth, as shown in Figs. 3 and 4 of the diagran Staking is sometinies essential. and wire supports should be emploved.
Some bulhs, more especially the bunch-Howered narcissi, do well in bowls when placed among pebbles and water, but the more customary mothod for indoor culture is to plant in a mixture of shell and fibre.
is a first saze bull, and will command the best price for the particular variety. Nevertheless, a bult is often less than 2 in . through and still a first size bulb, as the varieties differ in respect of the size of their bulbs. The bulbs of daffodils, tulips, and lilies vary a good deal in size. If lily bulbs are shrivelled they should be laid in coconut tibre refuse about a fortnight before planting.

There is no better compost than three parts of sound loam, one part of thoroughly decom. posed leaf-mould, half part of decayed cow manure, and sufficient coarse sand to ensure
soil. Very little pruning is required. The Langley bullace is the best for gardens. See Damson; Plum
BULLDOG. The big head and wrinkled face of the hulldog are read by anme persons as the outward and visible signs of a savago

Bulldog. Champion of this breed, showing the massive ahoulders and widely aeparated front leas
disposition. Yet there is no dog that is safer and that will with a sweeter temper endure all the indignities that may be put upon him by a young child. As a house guard, his methods are his own : instead of warning off an intruder by barking, he prefers to adninister punishment silently, and he is not persuaded easily to relax his hold.
In selecting a bulldog, choose one whose body is broad and thick-set, and his head large even in proportion to his body and square-looking-as deep as broad; the thin, amall ears set high on the head, the upper part falling to the side. The mugh, broad nose should he black, the nostrils large and wide, separated by a sunk line. The thick, muscular neck should be short and arched; the chest broad and deep, keeping the short, straightboned forelegs far apart. The hind lega should be long and less massive; and the round, smooth tail should taper sharply in its short length from a thick base. His gait should be heavy and slouching. The maximum weight for a bulldog is 30 lb .
There is a toy race, known at shows as the ministure bulldog, which is in every respect save size a replica of the ordinary breed, hut its weight is limited to 22 lb . The French bulldog is apparently a variety of the smaller breed, but distinguished from it at a glance by its erect ears ; those of other bulldogs are always drooping. See Dog.
BULLET WOUND. The first-aid trentment of gunshot wounds may involve the treatment of haemorrhage, fracture, and shock. It calls for the greatest care to avoid further contamination of the wounds by dirt. thereby incressing the dangers of septic inflammation and tetanus.
Bleeding from the wound may be arrested by pressure as described under bleeding, or in the case of a limh by an improvised tourniquet.
Firm pressure should not be applied on the skull or over broken ribs. Simply apply cloths wrung out of clean, cold water. Such cloths should also be put on a wound of the abdomen, and then a towel pinned round or two broad-fold bandages. Fractures of the limbs should be fixed oy padded splints, and of the ribs by broad-fold bandages, before an attempt is made to remove the patient.

Wounds should be washed by pouring over them cold boracic lotion, if possible, or cold water, and then covered with boracic lint or clean rags. Shock is treated by kceping the
patient covered up, chating the limbs, upplying hot bottles, and giving hot drinks of tea or coffee, or, if all blecding from a linib be stopped. a little spirits and water.

In wounds of the trunk care will have to be taken in giving anything to drink at all till the doctor's arrival. A bullet may remain in the body without any bad reault whatever, though if it is easily removable it is desirable to take it out See Bandage; Bleeding: First-Aid; Fracture; Tourniquet.
BULL MASTIFF. Although a cross breed pure and simple the Bull Mastiff has been accepted by the Kennel Club in its classification, and this has enabled the breed to achieve prominence. At one time known as keeper's night dogs, their duty is the protection of person and property. A bull mastiff with its massive frame and stout build is necessarily a formidable foe. The prevailing colour is brindle, either light or dark, but fawn specimens are not uncommon. A dog of this breed should be massive in all proportions -the head heavy, the jaws level, and teeth sound and strong: the neck thick and well rounded, the chest deep, the ribs well sprung, the loins short and strong and the limbs big boned, atraight, well carried and well placed in relation to the body. Common faults are cowhocks, splay feet and weak quarters. Careful training is necessary.

BULL TERRIER. The modern examples of the breed have less of the bulldog atrain and more of the terrier of their original ancestry.

Except for his black nose and small black cyes, the bull terrier should be wholly white, with a close, short cost of stiff glossy hair. The head is long and Hat, wide between the aemi-erect ears and tapering to the nose. The jaws are long and powerful, and the nostrils open. The shoulders are muscular and alanting, the chest wide and deep, and the legs straight. The rather short tail tapers from a thick base to a fine point, and is carried without curl at an angle of $45^{\circ}$. The bull

Ball Terrier, a powerfully built breed of dog
terrier varies in height at shoulders from 12 in . to 18 in ., and in weight from 15 lb . up to 50 lb See Dog.

BUMBLE BEE. The bumble bee performs a useful service in the garden by fertilising flowers, but sometimes it causes injury, particularly to broad beans and antirrhinums The honey being secreted deep in the blossom, the bee has a difficult task to force its body down to the nectaries. It finds an easier way by puncturing the calyx and petals from outside, and then drawing up the sweetness from within. The result is that pods in embryo are often spoiled by the puncturing and fail to develop properly, with a consequent reduction of crops. Šee Bee.

BUMBLE FOOT. The heavier breeds of poultry are more particularly subject to the disease known as bumble foot. It consists
of a swelling in the hall of the foot which, soft at first, gradually hardens and, becoming full of pus, is very painful. The cause is com ${ }^{-}$ monly attributed to the fowl jumping to the ground from a high perch, hut it is also liable to arise from injury caused hy contact with hard substances, such as glass or rough stones

The symptoms are lameness and a disposition to squat down. To cure it, apply bread or linseed poultices, and then cut and expel the pus, afterwards applying a simple ointment. The foot should be bandaged for a ferr days, and the hird placed in a pen by itself where it cannot perch lut has to rest on straw. See Poultry.

BUMBLE PUPPY'. This children's game can be plaped by two or more persons. A pole should he planted firmly in an open piece of ground. The height of the pole varies with, the space availahle, as the taller the pole, the greater the space required, but it should not lic much shoiter than 10 ft .

From the top of the pole an old tennis-hall in a string or erocheted bag is suspended by a stout cord to about 3 ft . from the groundl. The firat player muat hold the hall out and strike it with a racket, his aim being to wind the cord round the pole before his opponent is able to hit the ball hack. When one or the other player succeeds in so winding it the game is won.

If there are more than two persons playing sides must be taken. The great rapidity of movement neceasary and the quick accord between hand and eye make it an excellent practice for lawn-tennis. The game is also called stick-tennis or apiro-pole.
A game of whist played regardless of rules is given the name of bumble puppy, which is also an alternative name for the old game of nine-holea.

BUN : Plain and Spiced. Of inuch the same consistency as bread made with yeast. sweetened, and currants or raisins adcled, for buns the dough is formed into rounds and browned well on top.

Spiced buns are alan marle with yeast. The following is a good recipe to be used for these or hot-cross huns: Sieve 1 lb . flour, $\frac{1}{2}$ teaspoonful mixed powdered apice, and a good pinch of salt into a warm basin, rubbing into them $t \mathrm{lb}$. of hutter. Then make a well in the centre of the paste. Put $?$ o7. compressed yeast into another warm hasin with a teaspoonful sugar and beat to a cream. Stir in $\frac{1}{2}$ pint lukewarm milk and 2 well-beaten eggs, and then pour all into the centre of the flour, etc Mix the whole lightly and beat until smooth : then cover the basin and put it into a warm place so that the dough may rise to twice its original size This should take ahout $1 \frac{1}{2}$ hours.

Clesn 3 o7. currants by rubbing them on a sieve with a little flour, and add to the risen dough, together with a little less than $\pm \mathrm{lb}$. castor sugar. Shape the dough into small huns and place on n greased, floured tin a little distance apart. For hot-cross buns mark a cross on each with the back of a knife. Ieave them in a warm place for $10-15 \mathrm{~min}$., when they should he almost double their original size. Then brush over with milk and hake in a hot oven for $10-15 \mathrm{~min}$ See Bath Bun; Rock Bun.

BUNG : Of a Barrel. In everyday use, a bung presents three problems? how to get it out, how to replace it, and what to do when it is not tight and allows the contents to leak.

The withdrawal of a tightly fitted hung is almost impossible without danaging it, but a sharp atecl spike. curved at one end and handled at the other, will sometimes prove effective. Careful prizing with a screwdriver is nccasionally successful, or three corkscrews inserted into the bung, ticd
together with string and then pulled. When be found helpful in securing a tight joint
all else fails the bung can lie driven through into the interior of the cask.
This necessitatcs the construction of a substitute Provided a sufficiently large piece of cork is available, fashion it into a hung by cutting the cork with a penknife. Otherwise a circular piece of wood, such as that from the end of an old comice pole, is easily shaped with a chisel and rasp. To obtain $n$ good fit, try the hung in the hole and give it a twist; this will show up the high spots on the bung. and by cutting these off a good fit ultimately reault $A$ diak of washlenther or cloth will tealed by in

## Bungalow: Plans and Building Details

Four Typical Examples of Attractive Dwellings Described and Illustrated
The reader may usefully turn to Architecture; Bricklaying; Cottage; House; and other articles dealing with constructional matters; as well as to Building; Drawing, erc.
For the purpuse of this article the word but wasteful in pasangea, and the hroaler type hungalow is assumed to mean a house with all of plan, compact as regards communication, its rooms on one floor, to be lived in all the but lavish in the height and spread of its roof. year round, and one that in construction and It is for these reasons that most examples quality of finish will bear comparison with save the amallest assume the $L$, the $U$, or the its higher-built neighbours. The bungalow $E$ shape, the additional cost of hips and can offer real advantages in reducing running valleys heing compensated for by the leseer and service ex-

Bungalow. Fig. 1. Bungalow at Stalnes, with verandah facing the Thames ; below, plan showling arrangement of rooms round a central saloon Desioned oll T. Davison, A.R.I.B.A
from which all the rooms are entered. The drawbacks of the first type are obvious; whether it is worth considering on account of the large gain in cubic contents-that is, costis for the occupier to decide. Fig. 1 illustrates the central-room type. This is a compact little riverside bungalow; in winter the many doors incidental to this type become a serions drawback. In Fig. 2, a cosy-looking bungalow of permanent construction, the same type of plan is rather more developed. There is a small vestibule to screen from outside draughts, and a comfortable sitting-room independent of the common living-room.

When we consider the second type of plan, in which the rooms are separated by communi cating passages, or hall, we at once come on the great difficulty of the bungalow designer He must compronise between a long, narrow building, which is economical of mof span Bung holes can be enlarged or made with a tool known as a bung horer, but a drill and a cabinet rasp will answer. Steel drums containing oil and wood preservative are much more convenient if patent comhined bung and pourer be substituted for the customary cork. A home-made substitute is simply made and consists of a bent tube, ahout $\frac{1}{2} \mathrm{in}$. diameter and an air inlet pipe about $\frac{1}{1} \mathrm{in}$. bore, and curved. Both are inserted into holes drilled in the cork bung. The drum can be sealed by inserting a cork into the mouth of the tube. See Barrel ; Cork

Four Typical Examples of Atwactive Dwelings Described and Wustrated ralleys heing compensated for by the leseer
sage is relatively hoth short and well lighted.
The L-shaperl type bungalow is shown in The L-shaperl type bungalow is
Fig. 4, $a$ well-arranged and welllighted plan, which is also compact and easy to roof. This example also possesses the excellent arrangement of placing the living rooms en suite, so that two moderate moms can, on occasion, be thrown into one large one if required.
All these examples, with the possible exception of Fig. 1, illus. trate bungalows which are meant for more or less constant residence. and built of permanent materials. They can thus be fairly compared with the average two-storey house, and offer distinct advantages. On the other hand, the week-end bungalow, for merely ata ying in, is so varicd in size. purpose, and construction, that it is impossible to generalise. Being built for a different atandard of life, the materials of ten are poor, and the general level of finish such as would not be tolerated in an ordinary house. Owing to the absence of a stair-
ronf span and
decreased pasdeoreased

Tho bungalow shown in Fig. 3 tends to the $U$ shape, and has the charm of that most sympathetio of all roofing, reed thatch. The ingenious disposition of the rooms will be noticed in this example since, although it contains four bedrooms, the winding pas-
ad well lighted.
case, it is usually easier to give any desired aspect to rooms than in the two-storey house This concession, however, is modified by the difficulty of gmuping hedrooms and, without excessive passage way, keeping their donors away from the entrance hall, a desirable point. Site and aspect uaually have greater influence upon the plan in the bungalow than in the house. The most accommodating site is one with access from the north or north-cast, which gives service quarters, etc., on the colder entrance side, with the living quarters to the south or southwest, overlooking the gardens and catching the mnxinum of annshine.

Whether bedroonis should face east or not is a mintter of personal choice. A small point that is often overlooked is the value of some suggestion of plinth or baso, lest our bungalow tend to look like the top portion of a house half sunk in the ground. For the arme reason the utmost should be made of any littlc difference in level, terrace, or steps.
The roof will usually be sprearling and low in pitch, if only for the sake of economs, and this, if well proportioned, combined with broad eaver, will de much to give a restful effect as well as a useful shadow. Chimneys. in the nature of things more numemus in the bungalow, should be grouped and arranged when possible to sit squarely on a ridge, or at least should hear some definite relation to the ronfing scheme rather than protrude apparently at random, as is so often scen. Scale should be carefully conaidered, and accessories such as railings, porches, trellis work, etc., are most useful in preserving this. The usual fault is to make them too clumsy and lacking in elegance. If the roof is of thatch it is better to form the gutters and downpipes of wood in the old manner

## Brick the Best Material

The moat general and, other things heing equal, most usually satisfactory material for the walls is brick. Whether this is finished with facing bricks good enough as regards texture and surface to he left, or whether cheaper bricks are to be used, and the outside to be finished with plaster or limewashed. depends upon tho materials obtainable and restrictions of oost. In any case, unless mugh.
plaster is to be applied outside. the walling of the building in order th ensure weather-proofness, should he hollow.
An economy that is perfectly antisfactory in one storey buildings is two walls of brick on edge with the through hearlers acting as bonders, or ties. This requires an external covering of plaster, etc., but effecta a saving in hricks, and is amply atrong ennugh to aupport the small "eights of $\Omega$ bungalow:
Many efforta have been made to popularise wood construction in England. It is worth

Fig. 2. Bungalow at Penshurst. Kent, built of brick, rourbcast, with tiled roof and renuine half-timber work in the gable. Above, plan
noting, however, that noting, however, that
in America, one of the great homes of building in wood, there has been a growing tendency to revert to brick construction. Wood construction usually implies a solid braced framework of wood, covered externally with overlapping boarding, the inside walls being plastered or covered with a sub. stitute, such as asbestos
sheeting, match, or pressed fibre hoarding. The main advantage of the wood house is the speed with which it can be erected compared to other forms of construction. In general, too, its initial cost is less, though a well-const ructed wood house is by no means much cheaper than a brick one, especially if solid foors and substantial foundations are employed. Its disadvantages are obvious-shorter life and greater upkeep; in fact, hefore building a wood house its yearly cost of upkeep and repairs should be ascertained and capitalised and added to the initial cost.
Pise-de-terre, that is. walls of earth rammed between shuttering until homogeneous, is a very old method of building. On account of its inherent weakness it is unsuited for lofty walls, and therefore more particularly applicable to the bungalow type. It alsn needs to be made of considerable thicliness, this latter failing being its grentest charm. Like the wood building, however, it requires ordinary brick foundations and chimneys, and some form of surface protection. Fig. 3 shows a bungalow of this material, in which the pleasing effect of the softened corners will be noticed. As, however, many soils are unsuitable for this method, the prospective builder will do well to obtain expert advice before deciding on his site.

## Use of Concrete for Walls

Concrete forms a fourth method of wall construction. This may be either cast in shuttering on the job, or the wall built of previously east blocks. Systems are innumerable. Probably one of those using cast blocks with two or more cavities in their thickness will make the beat wall. In general, concrete for domestic building is not now widely used. For inside walling, however, the thin wall of "breeze" concrete blocks has almost entirely superseded the division of plastered studding.

Assuming a raft of concrete over the site, the floors may be either hollow or solid. In the first case the board is laid on wood joists, on dwarf brick walls, a short distance above the surface concrete, having-what should be, but often is not-a well-ventilated space belon. The alternative is to lay the foor hoards solid on the concrete in mastic. on the principle of a wood block fioor. This

Bungalow. Fig. is. Bungalow at Heanlieu, Hants. The walls are made of pisé-de Dexioned bu Leonard Murlin, F. $\boldsymbol{H} /$ B A
method has heen rapidly gaining in favour of late years, owing to its convenience and greater safety from dry rot.

Setting aside such materials for the roof as ashestos compounds and corrugated iron, there remain slates, thateh, or tiles, which may be either flat, as in Fig. 2,
or the pantiles. If slates are or the pantiles. If slates are used, an endeavour should he made to obtain
one of the thicker varieties and to vary the colour. They usually look best over a whitewashed wall. If a sawn stone ridge is not used, the ordinary half-round ridge tiles, alternately tarred and whitewashed, make a good sulstitute.

Windows may be of casement form, either wood or steel, or the familiar boxed sash window. There is little difference in the cost between them, what there is leing rather in favour of the casement. If casement windows are used with shutters, these should open inwards, a fact which must be remembered when designing inside curtains.
Internal arrangements on different principles are indicated in the plans ac companying Figs. 1-4. Various detailed arrangements, which are common to house and bungalow, are discussed under the heading Architecture. Bungalows are naturally harder to heat $t h a n$ houses, and if a central heating system is used, special attention should lie paid to

Fig. 4. Bungalow in Nottingham, without chimnegs, as beating is
by gas. It is of stucco-faced brick blocks. Above, plan Desiuned b|l D. Howilt. I R.I B.A.

securing sufficient tall to the pipes More over, bungalow chimneys, on account of their lesser height, are rather more susceptible to down draughts, and trees or buildings arljacent must be considered. There will usually be found ample room for storage purposes in the roof. Rough hoarded and provided with a generous-sized trapdoor, it becomes a useful box-roon, etc.

## Comparison with a Small House

It is interesting to consider the relative merits and cost $\mathrm{o}^{\prime}$ a bungalow and a twostorey house. The average iden is that it is much chenper to obtain the same accommodation in bungalow form, that passages are eliminated along with staircase, and that by having one storey half the brickwork is saved. Such conclusions cannot be said to be justified. As to actual saving, the omission of stairs, upper flooring, joists, etc., is obviously in its favour, but the area of ground llooring is practically doubled. As regards walling, the gain is small, since the lower height is usually more than offset by the grenter perimeter. Chimney stacks, too, though less in height, tend to be more numerous and less easy to group Damp course foundations tell heavily against the bungalow, as also does increased roof area, with its consequent greater length of gutter and ridge On the other hand, there is greater speed in ercction, and certain advantages, such as decreased scaffolding and easier supervision. Many of these points do not apply to the very small and simple bungalow, which may, cven in initial cost, prove the cheaper. Ahove a certain size, however, the one-storey type tends to overtake and pass the house, though many will think the relatively small increase in first cost more than justilied by its inherent advantages.
I careful analysis made hy Mr. Edwin Gunn, FR.I.B.A., concerning the approximate cost of a bungalow and a two-storey cottage of almost identical accommodation gave a working result of 9 per cent. extra to the former in initial cost. This granted, however, the advantage of having all the rooms on one floor

is undoubtedly great and is increasing with the steady development of mechanical devices.
BUNION : How to Treat. A bunion is a swelling over the joints of the foot; it is usually found on the first joint of the great toe. It occurs with displacement of this toc towards the other toes by pressure of tight, badly shaped boots, or in cases of osteoarthritis. The resulting irritation causes thickening of the skin.

The first step towards a curc is the provision of a properly shaped hoot, that is to say,
straight on the inside. It may be necessary to have a boot specially made so that there is no pressure on the inflamed part. If the deformity is at all pronounced, a metal aplint may have to be worn

If inflammintion occurs, tincture of iodine may be painted on, one or two coats nightly for thren or four nights; but if there is suppuration, a doctor will have to let the matter out. See Corn ; Font
BUNSEN BURNER. Universally used in laboratories and workshops, the Bunsen burner may be called the foundation design of all gas cookers and domestic gas fires The principle of the burner is to utilise the velocity of a Buphthalmum. Name of the hardy jer jet of intlammable gas or vapour issuing from cnnial popularly known as ox-eye (q.a.).

## BUREAUX: ANTIQUE AND MODERN

## Practical Hints for Collectors and Handicraftsmen

Other articles of similar nature are Cabinet: Chair; Chest; Sidebard. See also Chippendale; Inlaying; Joint; Sheraton; Walnut, etc.

There are only a few bureaux of enrlier date than the reign of Queen Anne in existence, these being chiefly specimens from Cromvellian times Walnut bureaux are $\Omega$ familiar feature of Queen Anne furniture. They usually had a glazed case or a cabinet of drawers ahove, were fitted with a sloping lid, and surmounted by pediments of various kinds, which never entirely went out of fashion right through the 18 th century.

Bureaux were made by Chippendale and Hepplewhite. The former made many that had ahove a bookcase enclosed by two doors, or a china cabinet. Above the cornice the broken pediment is found, and sometimes in the centre a crown and feathers. The inside fittings followed the Queen Anne models as regards their arrangement, but with carved decoration or lacquer work. An oak bureau should cost less than one of walnut or mahogany, because the tro last-named woods were used for finer pieces. Mahogany bureaux over 150 yeara old are rare.

Secret drawers were often concealed in the complicated interiors of burenux. A place where one may be looked for is on either side of the central pigeon-hole, where a little decorative column is sometimes placed. That column hides the drawer, discovered by putting the hand through the central pigeon-hole to the back and feeling there for n secret spring which releases the column, which then comes away with a narrow drawer behind it. Another drawer-a very simple device-may be placed at the hack of two little brackets which are sometimes found to right and left of a central recess undernenth the row of pigeonholes. These small brackets simply come out as drawers.
Antique Patterns. The illustrations on this page show fine examples of hureaux. No. 1 is a somewhat unusual example. Made of walnut towards 1700, it stands on cabriole legs with hoofed feet. The top is fitted with eight small drawers, four pigeon-holes and in the centre a cupboard. The pillare on either side of the cuphoard should be noticed, as they form the backs of two secret slots, intended for hiding papers.

No. 2 is typical of the Chippendale period to which it belongs. The fine lacquer work ornamentation showing Chinese inspiration and influence and also the broken line of the pediment should be noted.

No. 3, of walnut, lias interior fittings not unlike those of No. 1; but the four long drawers in the body of the piece suggest a more practical design, which has been very considerably imitated since.

Apart from its decorative effect, a burcau takes up leas room than a writing-table, has deeper drawer space, and affords an opportunity of quickly enclosing a considerable amount of correapondence.

Making a Bureau. For the bureau shown on the next page, Fig. 5, mahogany stained to a rich plum colour, and either hright or dull polished, is successful, while waxed walnut has always a refined appearance Oak, stained and polished to a Jacohean or mut-brown colour, will leave little to be desired for Fig. 3, and birch. heech, and basewood are efficient substitures for a cheaper article, all these three taking stain well

For a medium sized article the np portioned width may be 2 ft . 6 in.. whilst a small size may be put at 2 ft . wide. The height to tahle top is 2 ft .6 in. and the enclosed slope rises from 10 in to 12 in. nbove this. The

depth back to front is 1 ft .5 in . over the side Two different styles of burean are pictured. and taking the onk or Jacobean (Fig. 3) it will he seen that the main construction consists of two parts. The case encloses drawers and pigcon-holes, heing separate from the base support, which is in the form of a atoul, with recessed top into which the case drops. A front elevation of this bureau is given nt Fig. 1, showing fairly deep drawer accommodation in the general dimensions marked, the width being 2 ft .6 in . The depth of 1 ft .5 in. marked olt the side elevation allows for ample servicc. If shallower drawers are desired. the stool could be increased in height by a couple of inches or so with good proportions. A sketch of parts which will be handy for reference is secn in Fig. 4, which shows clearly the chief joints and fittings.

The sides (A) are of $\$$ in. thick hardwood, or Fin. thick if faced The front ed ge is vertical for 1 ft .4 in ., and then is cut back to n point $9 \frac{1}{2} \mathrm{in}$. from the bact edge, to which it finishes at right angles and at a height of 2 ft .3 in . This 9 ? in. takes the top shelf, which should be of equal thickness with the sides.

The inner ahelf or table top (C), in line with which the fall will open out, is best dovetailgrooved into position, but could be tenoned or dowelled to sides. It is shown as of equal width with the sides, but could be of 11 in . width only, so that, when fitted, it projects 1 in. under the stationery box (inserted later), and gives a bcaring. The joint into sides is stopperl $\frac{1}{2}$ in. from the front edge of the sides, and the part pushed home.
The hearer rail (D, Fig. 4) is $2 \frac{1}{2} \mathrm{in}$. to 3 in. wide by 8 in . thick, and enters into the sides with a couple of tenons. A couple of similar rails can be dovetailed in at E , one at front and one at hack, instead of the full width bottom of the case.

The runners ( $F$ ) are tongued to the rails in addition to being grooved to the sides, and are a clean-up from stuff 3 in. wide. They should also he grooved as well as the inner edge of rails to receive dustboards(G). whichare

Bureau : antique examples. 1. Walnut bureau on cabriole legs and boof leet, late 17th century. 2. Piece at the Chippendale period ornamented with lacquer work. 3. Walnut bureau with shaped Interior Attings 1 and 3, courtesin of Gill \& Reloate. Lid. 2, Victoria and Allert Museum. S. Kensington

edges of the
sides and top shelf.
The ata. tionery case is practically n separate box for in. sertion, and optional in its arrangementof pigeon-holes and drawers, eto. 'The surround cant he of $\frac{3}{1}$ in. thick. ness, dovetailed or nailed to.
devirable to limit the drift of dust in course of service.

A check or short inner up right $(\mathrm{K})$ is fitted $\frac{3}{4}$ in. away from case sides on each side of the upper drawer, entering with a couple of tenons topand bottom; the resulting fin. space hetween serves for the slide (J) to travel in.

The slide supports the fall when down. It is made 3 in . wide, and noounted on a block (H) to make up the balance of height with the top drawer. The slide can be ensed from ifin. thickness, and should travel smoothly without play

J'he drawer fronta (L, M) are shown in lig. 3 ns bruken but can be mitred ul in manner indicated at Fign. 4 neat effect. The section is $t$ in. wide and is obtninable in 10 thick by eady for, and is obtrinable in 10 ft . longths endy for glueing and pinning as reglimed. The
 otoms 1 in ., all dovetailed together in the usual manner. Handles of the pear-drop variety, with bolt and nut fastening, are preferuhle for the Jacobean design (Fig. 1).
The back can be of $\frac{\mathrm{g}}{\mathrm{k}} \mathrm{in}$. or $\ddagger$ in. thickness, matched or plain, and may lic rebated in or screwed on. The grain should run horizontally.

The fall or Hap (as Fig. 3) call be framed up of $\frac{1}{2}$ in. thichness, with a panel $\frac{1}{2}$. net clamperl each end and screwed behind. A $\}$ in. by $\{$ in. section mould is mitred up to drop in of face. Alternatively the fall can be framed up of $\frac{3}{3}$ in. thickness with $\frac{1}{2}$ in panel grooved in. and the recess moulded on the solid. It will he rebated to lap partly over tho

## Burglar alarms for the Home

## How they can be Fitted and How they Work

The article on Burglary that follows gives other information about protecting the home against burglars. See also Alarm and the entries Battery; Circuit, and athers thal deal with electrical matters

An alarm should he workel automatically by the entrance of the intruder, and so wake the inmates. For this purpose the beat syatem is electrical.

For effective working a burglar alarm de. pends on the operation of a contact either hy the opening or shutting of a door or window. Every jossible means of entry should be fitted with an alarm contact, and the design is important, as the apparatur may stand a long time without attention. A rubbing contact tends to clean itaelf automatically, and is therefore better than a push contact.

Fig. I shows the door or window contact consisting of an arm carrying two contact
plates normally separated from each other these are forcel together by menns of a paw whenever a door opens beneath it. The device is fixed to the architrave over the door. Window contacts nre made on the same principle. Figs. 2 and 3 illustrate arrangements of contacta applied to a window and wo arranged that the circuit is completed if the window sash is moved.
One form of door or window contact is emberlded in the woodwork, and consists of a barrel and plunger normally preswer inwards by the door or window-sash. When this moves, a spring forces the plunger
outwards and makes contact between tivo
contact plates, thus ringing a bell. Burglar alarma are connected in the same way as an electric hell, but without a press in the circuit. If it is desired to disconnect the alarms it is best to introluce a switch in the main lead from the battery.

A nother method is to arrange a clock in the circuit, with adjustable contacts so that it automatically opens or closes the circuits during any prearranged hours. The clock may be electrically driven, or, alternatively, of the spring-driven type, but the latter nust be wound up regularly.

## Relay in the Alarm Circuit

An ingenious device consists of a relay in the alarm circuit. When a window or donr is opened the circuit is closed, the relay releases a catch that in turn releases a weight or apring sufficiently strong to close a switch in an electric lighting circuit, with the result that not only is the nlarm bell set a.ringing, but the house is illuminated at the same time.

Where it is intended to protect aparticular object of value, such as a safe, a spring contact is concealed heneath the floor covering, so that if the safe is moved the circuit is closed, and the alarm given.

The foregoing paragraphs have denlt exclusively with open-circuit systems which can easily be put out of action by cutting the wires at any point. In the closed cincuit alarm system the essential feature is that when in action the circuit is closed, a current of electricity flowing constantly along the wires and through the alarm contacts. The moment this circuit is opened, as by the opening of a window or door, or hy outting the wires, the aiarm bell rings. The ainateur must be particularly careful not to mix up the two systems of wiring: nor to use any apparatus unsuited to the conditions for closed circuits.

The wiring diagram, Fig. E, illustrates a typical alarm circuit; but us many contacts as needed will, of course, be wired on the same principle.

There are several methods of wiring on the closed system, two of which are illustrated. These show simple arrangements and only a few contacts; but given adequate battery power, any number of contacts can be intro. duced. Contacts on the closed system are connected in series, that is, the wire from the liattery goes to one terminal of the lirat contact, und continues from the other terminal of that contact to the second contact, and so on in serios, ultimately returning, via the bell or relay, to the hattery.

## Alarm Attached to a Door

Fig. 4 shows a single door contact at $A$, with a bell of the ordinary vibrating type, with the addition of a third terminal. this being in connexion with the contact poat. I hattery of Daniell cells is shown at C , and a switch at $D$, as a cut out for use when the ularm is not needed. When this switeh, $\mathbf{D}$, is closed, current Hows from the hattery, through the switch to terminal 1 on the bell, thence through the magnet coils to terminal 3 , through the contact $A$, and hack to the battery. This energises the bell's magnets, and attracts the armature, pulling it out of contact with the contact post, and maintaining it in this position until the circuit is broken. as by the opening of the door. When this happens and the circuit is broken, the bell armature fies buck and makes contact with the screw on the contact poost, the bell then rinying in the same way as an open circuit hell. It will continue to ring until the door is again closed.

This system suffers from the defect that if the door is again clused, or the severed wines reunited, the bell will cease to ring. For this reason a relay can be introduced with allvantage, as it can be used, as shown in Fig. 5, to close a local circuit to a continuous ringing
bell. In this case the Daniell cell, $C$, passes the nuts buried in tho current through the wire and contacts to the relay magnet coils, and then back to the cell. The relay being thus energised attracts the armature, $A$, of the relay, pulling it away from the contact screw, B. It thus acts as an automatic switch, for, on the opening of any contact, the current ceases to flow through the relay; the armature, A, flies back and makes contact with $B$, thus closing the local circuit through the bell. This being an ordinary continuous-ringing bell, it will keep on sounding its alarm although the door contact be again closed. The bell can only be stopped ringing by opening the switch $D$ and resetting the catch on the bell.
The ideal protection is obtained by combining hoth systems, fixing open and closed contacts at every point to lie protected. Separate wires are run for both sets of contacts, and if these wires are braided or intertwined, it is almost impossible to sever them without ringing the bell.
It should be noted that the expression window closed need not necessarily imply the entire closure of any window If it is desired to have some ventilation, all that need be done is to introduce a framework, covered or otherwise, between the window-sash and the top of the window framework. Or even a strut of wood between the sash and the contact. The window should be werlged to prevent the wind shaking it, as this would tend to relense the atrut and start the alarm ringing.

The battery for any closed circuit system has to be of $\Omega$ suitable type, as the current is flowing constantly. The battery that is in most extensive use for this work is the Daniell (q.v.). Other well-known batteries alao used are the Edison-Lalande. the Fuller and the Bunsen.

BURGLARY: How to Prevent. The best plan after installing an alarm system is to attend to such mechanical devices as will make entrance impossible or at least difficult.

Adequate protection is often provided by building in strong iron bars for bathroom, larder and frequently kitchen windows. Casement windows can have the protecting bars cranked or bent outwards, as in Fig. 1, to allow the window to open. Such bars are best inserted and securely cemented into the hrickwork. Window bara screwed to woodwork are readily prized out. If it is nesessary to fix such bars, they had better be affixed with coach-bolts,
the nuta buried in tho wondwork and covered with a wood plug, as in Fig. 2.

Locks, bolts, and fasteners should next receive attention. The sockets into which the latch of a lock catches can be reinforced with a strap of iron, securely screwed or bolted to the woodwork. The fastenings of the lock itself should also be examined and strengthened if need be. The keys of all ordinary locks should be left in place and sceured from turning by inserting a crossbar of metal through the bole in the handle of the koy and fastening the metal bar so that it cannot be removed or shaken out, or by a spring metal Intter cannot be pushed back. bent wire, as shown in Fig. 3. This prevents the safest way is to drill and tap a hole through the lock being picked or the key being turned. the meeting bars, and screw them together

Door holts are best if set diagonally and with a countersunk head metal screw
fastened to the door frame, with a socket fastened to the door. This arrangement is more difficult to undo with a wire through the letter-box, than the normal arrangement of horizontally placed bolts. Incidentally, protect the letter-box with a stout hard steel wire grating or letter-basket. Inother safeguard to a holt is to insert a hardwood plug into the hariel behind the holt, so that the

A sash window is best protected by drilling a hole through the inner or lower sash, and half-way into the upper; a piece of metal pushed into this hole effectively locts the two. The aame plan can be adopted when it is desired to leave the upper sush open, the hole in this case being drilled with the sash in the desired position. The metal peg should be practically flush to avoid its withdrawal by anyonc putting an arm through the opening.

Casement windows with wood sashes can be plugged in a similar way to ordinary sash windows. With metal casements probably

Burglar Alarm. Firs. 1-5. Diagrams illustrating appliances and electric circuits to give warning of attempts to open windows or doors

After all the doors and windows have been madc secure from within, one at least must be fastened from the outside. One way of doing this is to fit one or more carriage-locks, like $\Omega$ railway carriage door-lock, ainking it into the doorpost. This is actuated with a carriage key from the cxterior. The keyhole is covered with a knoh, and is unlikely to attract attention. See Bolt ; Lock, etc.
Burglary Insurance. A useful form of insurance is that against loss by hurglary, housebreaking, and theft of property from tha house. Burglary is a rolbery from a dwell. house by night. Night means between 9 p.l. and $6 \mathrm{a} . \mathrm{m}$. of the next day. Housebreaking is a rohbery from a dwelling-housc between 6 a.m. and 9.j.m.

Both offences connote a breaking in or a breaking out. If a thief finds a door or window open, and gets in that way, he ia not a burglay or houselireaker; hat, if ho steals anything, he has committed larceny from a dwelling. house. A householder ought to get a policy covering him against these risks. When a theft of any soit takes place, the insurance company should be informed at once, as well as the police.
In this kind of insurance, as well as all others, it is essential to insure up to the full value of tho property. If not, only a proportion of the loss-the same proportion that the total value of the goods insured bears to the amount insured will be praid for. See Insurance.

BURGUNDY. Burgundy is a wine from the Hante - Bourgoyne. Baswe - Buourgoyne. Maconnais and Beaujolais, in France. Fuller in body and of greater alcoholic strength than claret, it possesses a fine, clear. dark-red colour and charming bouquet. The wines which rank the higheat of all the Burgundy wines are Romanée Conti, Clos de Vougeot, Contact Contace Chambertin, Nuit St . Georges, Nilits - Prémeaux and Corton.

Many fine wines come from Pommard, Volnay, Savigny and from Beaune in the Côte-d'Or. The last named
is perhaps the best known amongst the cheaper Burgundies, although unfortunately many chemical decoctions are sold under the name of Beaune which have never come from Burgundy. A true Burgundy can always be known by its clear dark red colour and bouquet Safe Burgundies of certain vintages are Volnay, Pommard, Mercurey, Moulin-ì-Vent, and Beaujolais

Burgundy matures quickly, and a wine of 10 to 12 years old is in its prime. It should be slightly warmed before drinking; if brought to the dining room an hour or two before dinner it will get the right temperature. Bur. gundy should be decanted carefully so that the deposit does not get into the decanter.

BURGUNDY MIXTURE. A useful spray for potatoes, to prevent summer blight, is named Burgundy mixture. To make a 1 p.c. solution put 1 lb . copper sulphate in $\pi$ wooden tub containing 8 gal. of water and allow it to stand a few hours. When dissolved, put $1 \frac{1}{2} \mathrm{lb}$. sodn in $\frac{1}{2}$ gal. hot water and when dissolved cool down with it gal cold water Pour the 2 gal . of soda solution slowly into the large tub. Its method of application is identical with that of Bordeaux mixture. See Bordeaux Nixture; Potato.

BURN : How to Treat. Injury cnused by dry heat or Hame is called a burn; a scald is the result of moist heat. There are various degrees of burning. It may cause simple redness or greater redness and blistering, but leaves no scar on healing (first degree).

Destruction of all the layers of the skin mny be caused nlong with the nerve endings, so that there is less pain, but a deep and permanent scar remains (sccond degree). If the tissues underlying the skin are destroyod the result is deep scarring with deformity (third degree). Charring of the bone may nlan occur. The immediate effects are the pain and some degree of shock

The doctor should be suminoned al once if the burn is a! all severe, or if shock is present.
Pending his arrival shock should be trented

Children may very carefully he put in a warm bath: this will help the shock and facilitate the removal of the clothing from the burnt part. If any burnt clothing adheres to the part, it should be soaked thoroughly, and if it does not come away easily, it should be cutoround.

With regand to first-aid dressing, there are various suitable remedies; the one chosen will depend upon what is handy. Greasy applications should not be used except for slight burns, as they are usually difficult to remove. If blisters are small they should be left, but if large they should be pricked with $n$ clean needle or scissor-point. A good method of dealing with them is to thread a needle with white cotton and to boil these for a quarter of an hour in a clean pan. The needle is passed thmugh the blister from end to end, and the cotton cut, leaving about half an inch on either side. The fluid contained in the blister gradually drains away.

For burns of the tirst degrec one of the following can be used : A dusting powder of zinc oxide, 1 oz and boracic acid, 1 dram Vaseline or carbolised or boracic vaseline. Zine ointment. Bicarhonate of soda, inade into a thick paste and applied in a good layer. Olive oil. Lint soaked in a 1 p.c. solution of picric acid, or picric gauze, moistened Where blisters are present, lint or clean linen or cotton spread with boracic ointment or carbolised vaseline should be applied.

Paraffin preparations may be used for burns of the first and second degree If not available, the burn should be covered up with cloths sonked in boracic acid solution, or in the case of a limb it might be immersed in warm water in which a heaped tablespoonful of boracic acid has been dissolved till the doctor see. 3 it. The cloths should he kept moist with the solution, as if allowed to dry they adhere to any raw surface.

When much scarring takes place after $n$ burn, there is a tendency for the senr to contract. and if a joint is involved its movement mny be impaired: or where opposed surfaces are involved, they may adhere together. The greatest care should therefore be taken in carrying out to the letter the instructions given by the doctor regarding the position in which the parts are to be kept. See Ambrine; Bandage : Carron ()il: First aid: Scald.

BURNER : How to Keep Clean. In oil lamips for table or wall use the burner is generally made of several pieces of brass, oranty arranged. One part adapted to screw into the reservoir or oil container is called the body; nnother part, to guide and support the wick, is the wick tube, and a part to support the glass or shade is the gallery.

The wick tube generally has an extrat part to accommodate a shaft and $\operatorname{cog}$ whecls to raise and lower the wick. Oil burners for heating stoves are made on similar lines, but some burners have perforated metal cones in place of a chimney, and these vaporise the oil, which then burns his sides, and giving him hot drinks -tea or coffee, or a little diluted spirita, or a teaspoonful of anl volatile in a with a hot, blue flame
wineglass of water. The patient should be kept perfectly quiet and free from worry.
one or more atmospheric hurners. These automatically mix the air and gas in correct proportions to ensure a hot fame, although the hest makes are fitted with independent means of adjustment.

To obtain the best results from any form of burner, clennliness is essential. A dirty oil lamp always gives off a strong odour. See that all screw-threads on lamp bodies and fillers are sound, and that the requisite washers are present and in good order. Parafitin oil burners are eagily cleaned by removing the wick and boiling the burner for half an hour in strong sodla water, drying off over the fire.

Incandescent gas burners should be cleaned from time to time by removing them from the bracket or fitting, taking the burner apart. and blowing or brushing away all dust and accumulated dirt. If this cleaning is not done occasionally the nir passages beconie clogged with dirt, and a greater proportion of gas has to be burned. The same remarks apply to warming and cooking stoves. The burner is in this case generally made of cast iron When dirt or dust accumulates within the passages cast into the burner, it is removerl by hoiling in soda water, or by brushing. See Acetylene; Bunsen Burner: Gas; Lamp.

BURNING BUSH. Dictammus fraxinella, as the burning bush is known to botanists, is a herbaceous hardy perennial, 2 to 3 ft . high.

Burning Bush. Flower apikes and leaves of a garden plant with a particularly pleasant scent
It benrs alternate pinnate leaves and purplish red-veined Howers in summer, and has a pronounced and agreeable odour. During hot weather the plants exude a volutile, inflammable oil which may ignite if a lighted match is put to it. If stocli is wanted, it is best to break up one plant only and use small portions of the flealiy ronts.

Bursitis. Name applied to inflammation of the bursa. See Housemaid's Knee.

BUSHEL. The bushel is a measure of capacity used for grain, fruit, and other goods. The imperial hushel mensures 22182 cubic in., and contains 80 lb , or 8 gallons of water; but there are other bushels, generally of local signiticance In dry neasure the bushel contains 8 gallons or 4 pecks, and 8 bushels go to the quarter. The bushel of English wheat, rye, and maize contains ( $\mathrm{j}_{0} \mathrm{l} \mathrm{lb}$., the bushel of barley 50 lb ., and that of onts 39 lb . The bushel of foreign wheat is 62 lb . Sce Dry

## Measure: Quarter.

BUSH FRUIT. This term is usually applied to small fruits 'such as raspberries, currants and gooseberries, but larger fruits
also may be grown in bush form, e g. the apple. Bush fruits are commended to those with only limited space, and, given suitable soi and position, provide good crops with very little trouble November is the best time for planting. After-care is important, light hoeing and freedon from weeds being of great benefit. Under-cropping with low growing vegetables, if necessary, may be carried out alniost to the stemis of the trees.
BUTCHER'S BROOM. A native evergreen, found on the heaths, butcher's broom has angled, erect stems, and rigid, twisted spiny leaves, on the centre of which the greenish white flowers appear in early spring. They are followed by red berries in early winter. The height is 2 to 4 ft . This shrub is dioecious, i.e. male and female fowers are on separate plants. Both must be planted to ensure fruits. A good slırub for shady places.
BUTLER : His Duties. The butler is the head man-servant. He has charge of the wine cellar and the plate, supervises arrangement of meals, and directs the servants who wait at table It is the butler's duty to announce visitors whom the fontman has admitted and ushered in. If there is no valet, the butler looks after his master's wardrobe and secs that his clothes have been brushed and laid in readiness. At night he sees that the house has been properly closed up. The butler generally takes his meals in the housekeeper's room, and is responsible for the indoor men servants
BUTLER'S TRAY: To Make. The principal ohject of the butler's tray is to provide a corner where dishes can be placed while neals are served. It consists of an oblong tray on a stand, and has flaps on either side : when raised and fixed, these form an edging to prevent plates slipping off the tray. Holes cut in the llaps allow the fingers to pass through so as to carry the tray (Fig. 1). The stand is X -shaped and collapsible.

Another type, without Haps, and carried by means of fixed handles, is simply made either in mahogany, oak, or white deal. The top should be 2 ft . to 2 ft .6 in ., and 18 in . wide, using $\frac{3}{3}$ in. material. If deal is used, a piece should be olitained which is 9 in wide and double the length required. This is cut in two and the pieces glued together, so as to get the 18 in . of width required for the top.

Two battens about 2 in . wide are screwed to the underside (Fig. 2), the edges and corners

Butcher's Broom. Spray of foliage and berries of the evergreen beath plant. See above
being hevelled. These not only strengthen thetray but prevent the wood from warping through hot dishes being placed on the tray. A narrow edging should be fixed round the sides with round-headed hrass screws
A convenient height for thic stand is 2 ft .9 in . It is made in two separate frames, one fitting inside the other, so that one will be 2 in wider than the other. If the top is 2 ft . in length, the legs should be cut off 3 ft. 1 in. long, ! rom 1 cut off 3 ft. 1 in
widh heing if in . Pace all the legs together and mark across bored large enough to take the collar, which is them the centre, where a hole is hored to take the bolt, which should he as thin as possible so as not to weaken the legs; also mark the length. The legs have to be cut at an angle to conform to the top and floor.

Next, screw at the top of each pair of legs a cross-piece 3 in . wide, and another piece 6 in . from the bottom 2 in. wide, as in Fig. 3, allowing 2 in . difference between cach frame; the top pieces are bevelled at the same angle

the top pieces are bevelled at the sane angle be fixed after polishing.

## Butter and Butter Making Simple Methods for Use in the Home Dairy

Consult further Diet; Vitamin; and the entries in this work on Checse; Cream; Milk, etc. See also Churn ; Separator

Butter is essentially the fat of milk. fresh milk is allowed to stand for several hours, the fat in the form of cream rises to the surface the larger globules first, and the small ones only after a long period. The cream, alimmed from milk that has been allowed to stand, contains besides the fat also some of the curd (casein) of the milk and some of the watery part, of which the skinı milk principally consists. This method of obtaining cream for butter-making leaves still some of the milk fat anong the skim milk. The milk is placed overnight in large shallow basins and in the morning the cream is skimmed off.

A more effective separation is olbtained by the use of a machine called a separator. This revolves at a high speed, some 1,000 revolutions per minute, and, as the fat and the water are of different weight, the fat is driven in a layer to the top, and is drawn off by a tube fixed at the plane where the watery part ends and the fat laver begins. These machines are made in amall sizes, suitahle for lome use. In one of these small separators an iron enamelled stand and crank are screwed to a table, and on them rests the separator proper, consisting of an upper bowl-like part into which the inilk is poured. In the bottom of this bowl is a small hole plugged by a metal rod. This must not be removed until the separator is revolving at full speed.

Beneath this bowl, and fitting into it, is another small howl containing a number of inverted, cone-shaped disks fitting closely one over the other. These revolve when the crank linndle of the separator is turned, and by their rotation the fat or cream is separated from the watery part of the milk. The cream runs out through one spout and the separated inilk through another, and hoth arc collected in separate basins. After the separator has been used, it is taken apart and its component portions washed in boiling water to which a lump of washing soda has been added. It is then rinsed in clear hoiling water, dried and put together again. The crank-handle should be oiled two or three times a week.

Each day the cream reparated can be run into the same basin and then set aside to ripen or becone fit for churning. When the cream is two or three days old the buiter is of a richer colour and Havour. The beat temperature at which to churn the cream is about
$60^{\circ} \mathrm{F}$.; if it falls below this the churning has to continue longer lefore butter inaterialises. In hot weather it may he desirable to stand the churn in a hasin of cold water to which chips of ice should be adrled.

Churning and Washing. For use in small households, the best kind of churn is a glass jar with a screw top, through which passes a rod holding wooden paddles inside the jar and a handle for turning them, like that of a mincing machine or egg whisk. The churn and paddles must be scalded hefore use, and everpthing must be thoroughly clean. The top of the churn is taken off and the ripened cream poured into the jar. The top is then screwed on and the handle turned, slowly and steadily at first, and gradually quicker, until the revolutions of the paddle are almost sixty a minute The cream lecomes thicker until it is like a thick custard. After a few more turns of the paddle it becomes grainy and little tlecks of butter appear.
The churn is then opened and a cupful of cold water

Butter. Simple butter maker for bousebold use
Courtesy of the Slainest Kitchen
Equipment Co., Lid. thrown ill It is then screwed down again and the paddle gently turncd. After ahout six turnsthe grains of butter becone bigger, sticking together in clots, and most of the buttermilk sinksto the bottons of the churn. The churn is then opened and its contents poured into a basin. Clear water is put in a second basin, and by spoonfuls the butter is lifted out of the but. termilk and

Butter. Making butter pata : 1. Place butter on mould. 2. Cutaway surplus, firat top, then bottom balf. Butter. Making butter pats : 1. Place butter on mould. 2. Cut away surplus, frat top, then bottom balt.
3. When monlda are separated, the pat will come ont. 4. Pair of moulds. Eutter cooler in pottery a courtesy of Staines Kitchen Equipment Co., Ltd.: 5. courtesy of Selfridge at Co, LId.
placed in the water. The butter is squeezed and off. To serve as a hot vegetable, soak 1 ll . kneaded with wooden spouna to get rid of the butternilk. The washing water is changed repeatedly until it remains clear. If butter. milk is left in the butter it will not keep, and also has a sour Havour. When the last washing water has been drained off, the butter is sprinkled with fine salt and the latter well worked in ; this helps to preserve the butter.

The quantity of butter produced by a given quantity of milk varies. The average should not fall much below $\frac{1}{2} \mathrm{lb}$. from a gallon of milk. If too much water is left butter soon turns rancid. When the quantity made is for domestic use, the butter may be first prepared as described, and then renixed with a small quantity of fresh milk. If prepared for commercial purposes it must not contain more than 24 per cent. of water. The commendable points about milk-blended butter are that it has a pleasant flavour and a oreany consistence. It does not keep well, but in small quantities this is not so important.

Butter, heing easily contaminated, should be kept in the coolest part of the larder, away from meat, fish, onions, or other strong. smelling foods. When choosing salt hutter, test it by plunging a knife into it. If, when withdrawn, the knife has an unpleasant odour, the butter may be regarded as rancid.

Butter contains the food principle or vitamin also found in beef-fat, the yolk of egga, and in fish-oil. As a fond butter is a heat-producer. In an average diet about two ounces per day, including cooking, is enough. It can be prepared from the milk of goats, asses, etc., but the pronounced Havour does not commend these to people familiar with ordinary butter.

Butter Cooler. The various types include those made of porous pottery, the butter being placed on a tray which reats upon another containing water. The cover is placed over the butter and rests in the water, with the result that the porous pottery alisorbs a considerable amount of the water and so becomes cool. Butter coolers are also made in zinc.

BUTTER BEANS. Prepared and used similarly to haricot beans, these beans are largeı and pussess a more delicate Havour. The skins are somewhat indigestible and if desired may be removed by putting soaked beans in boiling water for a fow minutes, and then into cold, when the skins will easily come
beans overnight, then put into a saucepan of cold water, with a piece of dripping or a lump of fat Boil until tender (2-3 hours), replenishing with hot water, if necessary, and

In making a collection of buttertlies or moths two methods are adopted: to catch the mature insects with a net, and to rear the caterpillars. By the latter method more perfect specimens will, as a rule, be obtained.

The butterfly net is made of mosquito netting or leno, with a hem of stouter material around the mouth through which passes the cane frame. If made at home it is advisable to purchase a brass Y-tube. The lower arm of this fits on the end of a stick and the upper arms take the ends of a curved cane which, hefore bending, measures about 3 ft . The depth of the net-bag should be twice the width of its mouth, and should have a rounded bottom, the stick being the length of a walking-stick.

Armed with this net, the collector visits such places as he has onserved to be the haunts of buttertlics: flowery fields, green lanes, heaths, the borders of woods and the open rides through them. For butterllies this must be in sunshine, jreferably in the morning. Moths, being mostly night-fliers, must be sought after sunset. While many moths are attracted to light, others may be trapped by dipping rags in a boiled mixture of coarse foot-sugar dissolved in beer. The rags are pinned to trees, or a stripe of the sugar painted on the tree trunk. These baits are visited with a lantern; the moths will be captured easily, each in a separate glass-bottomed box, about $1 \frac{1}{2}$ in. in diameter.

Many kill their hutterflies whilst still in the net by nipping the forebody between finger and thumb; and if neatly
about $f$ hour before serving add salt and other seasoning to taste. They are excellent eaten with boiled bacon, or they can be served with tomato $o$ cheese sauce on hot buttered toast
To make rissoles, prepare $\frac{1}{2}$ pint beans as above, adding 1 teaspoonful mixed herbs with sensoning about $\&$ hour before done. Pass through sieve and mix with yolk of one egg and $\frac{1}{f}$ pint stale breadcrumbs Shape mixture into balls or flat cakes, coat with white of egg and more breadcrumbs, and fry golden brown.
A good thick soup) is made by soaking and skinning 1 pint benns and putting them into 3 pints cold water or unsalted stock, with celery, ollion, tomatoes, chopped parsley and pepper. (Salt must not be added until beans are tender) After hoiling pass the whole through a sieve, boil up and add 1 oz . hutter and more water or stock, if necessary. A ham-hone or bacon trimmings, adderl while soup is cooking, improves the llavour. See Beans: Haricot Beans

BUTTERCUP. The yellow buttercup of the meadows and pastures is a wild species of the Ranunculus, and is also known as the crowfoot. This is a very troublesome weed in gardens. It must either be spudded out or killed by dropping carholic acid on the crown of each plant. Another method is to dip an iron skewer into sulphuric acid and force it down the centre of the plant. The best reinedy, however, is thorough digging of the ground, picking out and destroying all the roots as digging proceeds.

## Butterfly and Moth Collecting

## Securing and Preserving Favourite Specimens

Following the entry Birds' Eggs, another articic that deals with a collecting hobby, the reader will find instructions about making a suitable cabinet for his exhibits

Butterfly Collecting. Glass-bottomed bos, 1t in. diameter, used for catching moths
performed this is effectual by compression of the chief nerve centres. Others put their captures into a cyanide killing bottle, or bring them home alive, each in its box.
Specially made entomological pins of various sizes are used for pinning, and these are obtained from the dealers by the ounce, $\frac{1}{2}$ or $\frac{\mathrm{oz}}{\mathrm{oz}}$ A pin of a si\%e proportioned to the stoutneas or slenderness of the insect's body is passed straight through the fore-body (thorax) and the protruding point inserted in the central groove of a corked setting board. The wings are then carefully arranged in the conventional manner, and secured in position by strips of thin card pinned to the cork surface, hut not through the wing. The antennae and fore legs are secured in a similar manner. The specimens should be allowed to remain un disturbed until the hind body has become stiff, which takes from 10 days to a fortnight A little disk of paper with the locality where talien and the date should be translixed by the pin under the insect.
Caterpillars for rearing may be obtained by noting plants whose leaves have been partiy enten; the spoiler may le hiding on the under side of the leaf or lower down the stem. The beating of trees $\rho$ r bushes over an open umbrella will yield many eaterpillars. At home these should be placed on $n$ sprig of the proper food in a breeding cage, which may be a bo: with a glass front and with perforated zinc or wire gauze at the back or topl The food can be kept fresh by having a small hottle of water with a hole bored through the cork large enough to take the sten of the plant.

In the cabinct drawer the insects should be arranged in vertical rows, each species with a neat label bearing the name below the speci-
another. It can be made in wood, metai, or other material. It is in woodwork that the butt joint is mostly used, and it is generally
mens, which should include one of each sex, an exampie sct with the lower side uppermost, and any others that show marked departure from the typical form, colour or markinge. The latter are known ns aberrations and varieties

The drawers of an insect eabinet are undivided, the bottom is lined with sheet cork to receive the points of the fine pins, and the framed glass lid fits airtight. - There are cells to contain camphor or powdered naphthalene, as without one of these deterrents the specimens will be reduced to dust by mites, look.
 secured by glue, nails, or screws.

## There are certaín

 essentials to success in making a simple butt joint. The work must be measured correctly, cut off square and true, and assembled and nailed together in proper order.In metal work, a butt joint is usually riveted, brazed, or welded, examples being the riveted butt joint of a girder or bridge and the welded butt joint of ordinary gas pipe. See Box ; Joint.
BUTTON. Small machines and supplies of button moulds are obtainable for making cloth-covered plain buttons, thus enabling the home dressmaker to turn them out neatly covered in any kind of self material.
Craft workers in metals can make enamelled and filigree buttons, and also original designs in beaten metal. Neat fingers and a hook are needed to plait strips of leather into buttons suitable for tweed coats.
The larger sized moulds, if for embroidered

Butterfly Collerting. Some requisites: 1. Breeding cage lor caterpīlars. 2. Setting board with specimen in position beneath.
thin paper for drying. 3. 8pecimens in position in cabinel drawer
buttons, may be covered by hand. Cut out a circle of material half again as lice or other oncmies. The calinet should stand clear of the wall-especially an outside wall-to ensure safety from damp.

Should a cabinet be considered too expensive an item on beginning the collection, the insects may be housed safely in storeboxes which can be obtained from any dealer for a few shillings. A very suitable cabinet for butterflies or moths can be made on the lines of the birds' egg cabinet described under that heading.

BUTTERFLY FLOWER. The schizanthus, or buttertly flower, is a greenhouse piant that blooms abundantly in summer. The best results are obtained by sowing the seeds under glass in September and repotting the seedlings us is necessary, finally placing them in 7 -in. pots. They develop inte fine plants and bloom in May and June. Seeds may also be sown in the greenhouse in spring. There are many varieties. The colours include rose, orange, and lilac, as well as white.
BUTTERMILK. This is useful in making liscuits, cakes, scones, etc. When comlined with bicarbonate of sorla, less cream of tartar is required than where fresh milk is used.

Butterscotch. Sce Toffee.
BUTT JOINT. The simplest of ail joints is the butt, which might bo described as the abutting of one piece of material on to
large as the mould, whip round the edge, pluce over mould, and draw up tightly, finishing off underneath. In most cases it is better to embroider the material, either in sills, wools, or beads, before it is cut up into oircles for covering the moulds ; but care must be taken to keep the design within the area of stuff that will show on the right side when the button is finished.

To sew buttons on firmly, stitch many times to and fro through the garment and the holes in the button or its shank or the material covering it. Finish before fastening ofl by winding the ootton tightly severaltimes round stitches, between the button and stuff. A thin material may be strengthened if a sma!! s quare of stuff is put on the wrong side of the

Buttonnole. 1. Making a round end. 2. Buttonhole with round end. 3. Buttonhole-stitch. 4. Making square end. 6. Buttonhole with square end. 6. With counded and square ends. See above.
garment and sewn in with it and the button For heavy coat buttons strain is avoided by a small button placed on other side ot the mateial and stitches taken through both huttons.
BUTTONHOLE : Bow to Make. Before cutting buttonholes important points to decide arc whether they are to run across of down; whether they will look better rounded at one end or square at both ends If the button is to rest at one side of the buttonhole when the yarment is fastened, then a round end at that side allows the button to fit in snugly.
To make certain that buttonholes are even, take a piece of light cardboard and make a notch in this, within one end, corresponding to the distance required between each buttonhole, and thus mark their positions. Buttonholes are usually sewn with $\Omega$ thick twist cut a little longer than the length required for one buttonhole. The starting of a new thread before the buttonhole is complete spoils the even effect. Take'z of a yard of twist for a ? in. buttonhole and proportionate lengths for a larger or smaller one. Usa buttonhole scissors for cutting and make a clean slit of the required length - Where the rounded end is to lie, hollow a little out with the scissors. If the material is woolly or liable to fray, it is necessary first to overcast all round with cotton Where the buttonhole is to be worked through a double thickness, it is important to tack round the position for the buttonhole, to keep the layers from slipping when working.

Commence stitching at the end farthest from edfe of material, and work from left to right Insert needle through buttonhole from back to front about $\frac{1}{8}$ in. from lower cut edge, and taking the rloubled silk that comes from the eye of the needle, put it under the protruding point of the needle from left to right: then draw the needle through, pulling it upwards so that the knot of the stitch conics exactly on the cut edge of the buttonhole. Repeat for the other stitches, making them exactly equal in length When the rounded extremity is reached the stitches must diverge like the points of a star. For a square end make a row of buttonhole stitches at right angles to the line of the buttonhole and have knotted ends inwards, but first make two or three straight stitches across the end. See diagrams below, also Appliqué.

BY-PASS: How to Test. The name is given to a mechanical device whereby a gas burner (for example) can be lighted up or turned down without matches. One type of construction is seen in the diagram and consists of a separate small passage-way. controlled direcily by the gas tap.

In the best makes of gas-burner the by-pass has $a$ regulating screw and locking nut. The lock nut is to hold the screw in place when the correct adjustment has been lound. If the by-pass llame is too small it wilk be blown out by the rush of gan from the burner, thus cnusing an escape which, in $n$ closed room, may have serious consequences; if too big, it will waste the gas and cause the mantle to be blackened and soot up.

With some makes of incan. descent burners the gas thp turns off the gas to the by-pass when the burier is fully lit, but re-admits
ges to the by-pass when the light is lowered Such burners need care. ful udjustment, or are linble to fail if turned on or off ton quickly.

The nozzle of the hy-pass tulse will become ohoked up with deposit after lengthy and continued use; it can be cleanerl by
wiping with a dry rag and pricking out the hole with a very fine wire, or a burner pricker. On most gas gey-

By-pass. Sectional diagram o incandescent gas burner, sinow sers the by-pass jet is controlled by a small tap, but the same principles of adjustment and cleaning apply.

cABBAGE. Growing treely in all soils, tho cabbnge is a very hardy plant. It can be sown to yield produce at most seasons, hut chiefly in spring, early summer, and autumin. If the hearts are not cut too low, but near the base of the lower leaves, the stump will throw up secondary sprouts.
It enjoys a deep, rich soil, but while the ground may with advantage be fertile, it should also be firm. especially for the spring orop. Yard manure of any kind is suitable. Sulphate of ammonia or nitrate of soda, 1 oz . per sq. yard, should loc applied occasionally in spring and summer.
Cabbages for late summer and autumn are sown in March and April, for spring in July and early in August. One ounce of seed should produce 1,000 plants. Like borecole, cabbago is transplanted. Large sorts arc planted out $2 \frac{1}{2} \mathrm{ft}$. all ways, medium sorts 2 ft ., small or very compact varieties, 18 in .

Some varieties of cabbage nre suitable for sowing in spring, others for sowing in July and August. Excellent soits to sow in summer are Harbinger, April, Flower of Spring, Mein's

Cabbage. Diagramg illuatrating points to be observed in planting. 1. Cut of tap root at a belore planting. 2. Place in hole and lever over soil with dibber (a). 8. Correctly planted cabbare. 4. Bady planted in dry soile. $\quad$. Method of planting in wef soils

No 1, Ellam s Early and Finperor, they will supply produce in spring and early summer. The following, if sown in March. will furnish cabbages in late summer and autumn Little Pixie, Tender and True, In perial, Enfield Market, and Winningstadt.
Colewort is a first-rate small cabbage to sow in April and May for autuinn produce the seedlings should be thinned out to 10 in . apart, not transplanted. Red or pickling cabbage is sown in August. Savoy cablogge, a valuablo hardy winter veretable, is sown in April and May The Drumhead cabbage, from an April sowing, yields firm hearts in late autunin.
The Portugal cabbage, or couve tronohuda, is valued for the sake of its thick midribs, which are almost as good as senkale, ns well as for the head of cabbage. It is grown from seeds sown under glass in March or out of doors in April.

Chou de Burghley, which produces a broccoli-like head, is sown under glass in March for an autumn supply, or out of doors in May for spring use.

Bolting or premature running to seed is most troublesome in the spring crop sown after midsummer; it is most likoly to occur when a dry autumn is follower by a wet winter. Sowing the right varietics at the right time nlanting on a lirm bed in October, and hoeing

Cabbage. Above, conical cabbage. Right, hardbearted cabbage of Drumbead variety
must never bo pouied down the sink without afterwards flushing it with water. It is better to pour it away outside if possible, since it often has a strong and somewhatobjcctionable odour:
Stuffed calsbage provides an excellent way of using up scraps of meat. Should there be no scraps in the larder use $\frac{1 \mathrm{~b}}{}$. of sausages, preferably pork. Wash and trim a savov cabbage, put it in a pan of boiling, salted "ater, and boil it until it is half donc, then drain it well. Cut it nearly in half, and remove a piece out of the centre.
If using sausages, remove the skins and mix with the meat a good dust of salt and pepper, 2 dessertspoonfuls chopped parsley 1 dessertspoonful ohopped onion, and 1 oz rice, whioh has first been boiled until tender in salted water. If scraps are being used, cut off all skin and gristle, chop the meat finely, and use it instead of the sausage-meat. Next press the mixture into the cavity in the cabbage, put the two halvos together, bind them round with a piece of tape, then wrap the whole in a pieco of muslin, put it in a pan with plenty of boiling salted water, and loil until the cabbage is tender. Take off the muslin and tape, arrange the cabbage in a hot dish, and pour round it some brown sance. This is sufficient for four persons.

CABBAGE APHIS. This is a pest fre. quently found in colonies on the outer leaves of
 the cabhage. It does not affect the hearts, ex cept by weak ening the con stitution of the plant. If the planta havo good soil to grow in and are stimulated by vigorous hoe. ing, no further steps are neerl ed. Should the pest threaten to gire them a serious check, it may be as wel! to use an insecticide; but this is only likely while:the and feeding in spring are measures which are plants are young; at a later stage the outer likely to prevent boiting. See Black Rot.

Cooking the Cabbage. To boil cabbage, first remove all discoloured leaves and the stump of the stalk. Halve the cabbage, or, if it is large, quarter it, and then remove a wedge shaped picce from the stalky centre. Wash the cabbage and let it soak in cold salted water ; then put it in n saucepan containing plenty of fast-boiling water, allowing to each quart of it a tablespoonfu of salt and a piece of soda the size of a large pea

Boil the cabbage quickly, the lid being off the pan, for 15 to 40 min . or until the leaves and smaller pieces of stalk are tender. The time needed will depend on the age and size of the cabbage. Strain off the water through a colander, pressing the cabbage firmly. Heat again in the saucepan with 1 oz . butter ; add season ing and serve in a hot vegetable-dish, cutting the cabbage across in portions.

The water in which greens have been boiled

By permisgion of II.M. Slationerll Ohice and lie Milistry of Auriculfure
thase of the cabhage moth burrow more into the hearts of the plant. In a normal year the pesta can be kept under control in n small garden by hand picking. During the periods when white buttertice are seen on the wing in some number, orops liable to attack should be examined about once every 7 to 10 days, and all clusters of eggs should be crushed.

It is unwise to use poisonous aprays on green vegetables, but syringing the plants, especially underneath the leaves, with paraffin cumblaion or with a solution of anlt, 2 oz . in 1 gallon of water, does good Paraffin emulsion is made by dissolving a handful of soft soap in a little hot water, adding an eggeupful of paraffin and 2 gallons of water. This treatment is necessary in July and August. If the above simple solutions do not prove sufficiently effective, the following auggestions are offered in Leaflet No. 109, issued by the Ministry ol Agriculture

Slaked lime in powder or lime and soot are sometimes dusted on the plants when damp Fences, etc., surrounding allotments should be searched for the chrysalides of white butterflies. When the ground is dug, a look out should be kept for the brown chrysalides of the cabbage moth, which should also be destroyed.

CABBAGE FLY. The larvae of a grey ty infest cahbages in summer and cause them to turn yellow and droop in the hot sun. Its naine is Anthomyia brassica,

Cabbage Fly larvae. highly magnifed or the cabbage fly and it must not be confused with the aphis or green fy. The male cabhage fly is quite a slate colour; the female is lighter. Spraying or the wholesale use of insecticides is not of much use. The only safe plan to prevent thic pests from spreading is to pull up infested plants and burn them, at the same time giving the ground a good dressing of lime.

CABBAGE MOTH. The cabbage moth is a dark brownish grey in colour ; the caterpillar varies in colour between green and brown.

It feeds
uponlettuee, mangold and various wild plants. but is especially fond of cabbage. Unless care is taken in dissecting
 and washing close hearts before cooking, the full-grown anterpillar may make its appearance at the table. The moths should be watched for in the evenings of June and July, when they are egg-laying. The eaterpillars feed from July to October, when they go under ground to pupate and pase the winter.

The most cffective method of dealing with this pest is to hunt for the caterpillars, which feed during the daytime as well as at night. The plants may be watered with sospsuds, a little paraffin oil being added; hut this should not be done if the cabbages are likely to be cut within a period of four or five weeks.

CABBAGE ROOT FLY. One of the most destructive of insect pests, the cabbage mot fly attacks cabbages and cauliflowers chiefly, but also sprouts, broccoli, and turnips, young regetables suffering more severely than older plants. If an affected plant be pulled up it will be noticed that most of the small lateral roots have been eaten away, and the maggota are to be found around the inain
root or in the soil elose by. It is in the maggot stage that the insect is injurious, the flies causing no direct harm.

A most ratisfactory method of control is to protect the plants by means of taried felt disks particulars of which are contained in the Ministry of Agriculture's Lerllet No 122. The disks act as a mech. anical device preventing the flies from laying thoir
surface of the disks free from soil. Once the plants have made good growth they have been tided over the most vulnerable period. and the soil can be earthed up over the diaks. is the latter are then no longer necessary
CABBAGE SNOWY FLY. Resenibling in appearance a minute moth, the eahbage snowy Hy is a lour-wingerl insect allied to the scale-insects. With wings fully spread it measures only $\frac{1}{\text { d }} \mathrm{in}$. across Bath boily and winga are coated with wax in a meal-like forno. and this is shaken off where their yellow elliptical eggs are laid, so that the presence of the latter is revealed by these dusty patches. In spring they may be seen Huttering about the cabbages and laying their eggs on the undersides of the leaves. The flat little larvae that emerge sack the juices of the plant, and the evidence of their presence is a yellow-
egge near the roots of the plants. The disks should beplaced quite flat on the ground round the steins of the plants directly the latter are planted out.

It is also advantagenus to earth the soil up slightly around the plants, so as to form a flattened rirge. It is important to keep the

## CABINETS: ORNAMENTAL AND USEFUL

## For the Connoisseur and the Amateur Woodworker

Related articles are those on Bookense; Bureau; Chair. Sce further Birds' EgR Cabinet; Coins; Corner Cupboard; Cutcery; also Antique Furniture; Cabinct Making

At first little more than an oblong hox, the cabinet, owing to the skill of the Flemish workmen in the 16th and 17th centuries, became a magnificent piece of furniture. The wood was carved, inlaid or polished, and the piece adorned with ivory, tortoiseshell, or precious stones. The doors were beautifully painted, sometimes on the inner sides as well as the outer. The interiors were often remarkable for their elaborate decorations, these taking the form of floors made of alternate aquares of ebony and ivory, and adorncd with columns and mirrors, the whole resembling a palace hall in miniature.

Cabinets were made in England in the 17th century. when walnut came into vogue Flemish influence was strong, but something was copied from Chinese cabinets, which were then being imported : hence the use of lacquer,

in
in which excellent work was done towards the end of the century. The stands were beautifully carved and sometimes silvered. In the 18th century some eabineta were made of mahogany, but lighter woods were still much favoured, satin and tulip among them. Annther development was the introduction of glass into the doors, these onbinets heing chiefly used for the display of ehina, glass, etc.

Making a Mahogany Cabinet. The cabinet shown in elevation in Fig. 1 could be carried out in mahogany, when it would go well with any furniture of the Chippendale type. It has an enclosed centre cupboard and two glazed cupboards at sides. A glazcd door might be fitted to the centre compartment also if deaired.

The base should be taken in hand first. The long rails at back and front are tenoned

Cabbage Root Fly, A fully Cabbare Root Fly, A. fully end of lafor. D, pupa.
 g patch on the other side of the leaf
Washes and sprays have been recommended for dealing with this pest, but sceing that it is always on the underside of a bmad. greasy leaf all liquids run off the upper surface without affecting them The only practicall romedy is to locate the larvae by means of the yellow patches, and then either to destroy thein by pressure or by cutting off the leaves and burning them.

into the outside legs, and the end rails are similarly tenoned to the legs. The two inside legs are bridle jointed to the front rails. A shallow groove the width of the leg is cut on the front of the rail. Fig. 3 (E), and the rest of the thickness of the rail is taken out of the leg. The rails may be shaped with the bow saw. The shoe for the legs is shown in Fig. 3 (A). A centre cross rail might he ndded to stiffen up the base. Mould-
ings are
mitredround as shown in Fig. 2, and supported by blocks glued to railsand mouldings at shor
intervals.

The construction of the carcass is shown in Fig. 2. The partitions may be dovetailed or tenoned to the top and bottom. If the latter plan is adopted the tenons should be uredged after glueing up. The top and lottom are lap dovetailed to the sides of the carcass. The back is mateh boarded, each board being fixed with two screws at top and bottom. The frieze box is of solid mahogany, the front corners being mitre dovetailed together and the back lap dovetailed. To allow for the width of the mouldings on front and sides the back rail of the frieze box is made a little wider. The top is fastened to the frieze by pocket screwing. The top moulding is shown
in Fig. 3 (B). The pediment has base and capping moulding as indicated in Fig. 3 (C) and (D).

The doors are mortised and tenoned together and then rebated. Slats are fitted for the bar mouldings, the ends being stuh tenoned, and the slats halved wherc they cross. An astragal moulding, or a plain rectangular one, may be used for the bars, which are glued on to the slats. The panel of the centre door is caul veneered. the pieces being first fitted and glued to a sheet of stiff paper
The shelves, which rest on fillets, are fitted so that the front edges come opposite the second and third bars from the bottom.

## CABINET MAKING IN THE HOME WORKSHOP

## The Tools Required and the Principles of Construction

Further practical guidance for the amateur on this subject will be found in the articles Anmateu Carpentry; Workshop, cte. See toa Bench; Joint; Tenon; also Chisel; Plane and other tools
Cabinet making includes the making of tool, and later, for fine work, may be added a all the finer articles of furniture, such as 6 in . or 8 in . dovetail saw. The bow saw is bureaux. It is thus distinguished from required for shaped work, and a compass carpentry, which refers to the constructional saw, with its long tapering blade, is useful forms of woodworking, such as roofing flooring, staircasing, etc.

Most articles of ordinary household furniture can be made by the man who understands tools and is fairly proficient in their use, and if to some knowledge of timber is added skill in the making of joints. the cabinet making that can be undertaken is only limited by congiderations of time and cost. or interior' shapes which the how saw cannot conveniently cut. With delicate shapes in thinner wood the ordinary fretsa $w$ is used.

Rough boards are first dealt with by the jack plane, and if a worker buys his timber in the rough he will also require a trying plane, which is requisitioned after the first operation with the jack plane. The smoothing planea smaller tool-is used to bring the board
Cabinet making differs from carpentry not only in regard to the character of the work, but also in the timber used. Speaking generally, the cabinet maker uses hardwoods, such as oak, mahogany and walnut, whilst the carpenter works in the softer woods of the pine, fir, and spruce families. Hardwoods are chosen for furniture because of their durability, the extra strain they can withatand, and their rich colour and pleasing grain. It is obvious that the working of oak is more laborious than the working of yellow pine, and also that surfaces which are to be polished must he brought to a higher degree of finish than boards which are to be pminted or varnished. Cahinet-work is finer, and calls for more careful workmanship than that necessary with carpentry; the material is more costly, and the aim is to produce something which is pleasing to the eye as well as of practical use.
Tools Required. A hand saw with blade of 24 in . or 26 in . is required for cutting boards lengthways. A smaller tool of the same type is the panel saw with an 18 in blade. A tenon saw of 12 in . is an cssential

! ? 3 feet of construction of the carcess. Fig. 3. Sections of mouldings and other working dramings. Sea text fur lettering

硅

2. Details rails

Cabinet Making. Figa. 1-3. Diagrams illustrating some of the principal joints used in making a table and a light bookcase

to a further degree of accuracy, and leaves it ready for scraping and glasspapering. Of other planes there is a great variety. many being of iron. The toothing plane, with the cutting-iron milled to resemble saw teeth, is used to roughen the surface of a board preparatory to veneering. The router is for grooving timber across the grain. In addition there are planes for rebating, for ploughing, for shooting shoulders and mitres, and the range of moulding planes

Other tools required include $n$ range of
 a ratchet brace and boring bits, a try square, marking gauge and cutting gauge, a couple of spokeshaves, oilstone, glue kettle, rasp. file, two screwdrivers (large and small). several bradawls, pincers, pliers, mallet and hanmers. A substantial bench is necessary: and a pair of hand cramps.

Principal Joints Used. Apart from a knowledge of joints, some of the general principles of cabinet construction should be clearly understood. A plain table of the simplest type, for example, is put together as Fig. 1. The legs (A) are mortised on their two inner faces to receive the tenons of the rails (B). If lower rails are to he introduced to strengthen the legs they will also be tenoned in, as at C. In the illusiration a stub tenon $(D)$ is shown on the top of the leg. This will enter a shallow mortise cut in the underside of
the top. The top itself will be glued down omitted; in heavier doors the tenon is usually and additionally held either by pocketscrewing through the rails or by fitting glued blocks in the angles formed by rails and top.

In the case of a table which is to be fitted with a drawcr, the method of construction usually followed s shown at Fig. 2 The ends ( E ) are tenoned to the leys, but at front, instead of the upright rail, as in Fig. 1, there is a top rail (F) and a drawer rail (G). The upper rail is dovetailed to both eg and end as indicated; the ower.rail is tenoned to the leg. Drawer runners, etc., will afterwards be added. When a shelf with n rail is wanted below, the usual method for a light table is to tenon the rails $(\mathrm{H})$ to the legs. The shelf (J) is cut at the corners to fit the legs, and screwed to the rails from underneath. A section of this is shown at K .
When articlen such as small hoolicases. light sideboards, etc., are built with solid ends (Fig. 3), dovetail housing is adopted as the method of securing rigidity. A section of the dovetail housed joint is shown at A. In the case of the illustrntion sketched, the top of each end would be cut to enter a doretail groove trenclied in the top. The lootton shelf would be similarly dovetail housed to the ends, the joint in each case being stopped back about $\} \mathrm{in}$. to mask it in front. The middle shelves might he plain housed, as adequate rigidity is secured by adopting the method of dovetailing at top and bottom. The shaped rail shown under the top and also helow the hottom shelf is tenoned to the ends and glue-hlocked hehind.

Carcass Construction. The term carcass is usually applied to the framed box whioh forms the akeleton of articles anch as wardrober, cabinets, cheats of drawers, and bookcases. Fig. 4 indicates the carcass of n small wardrolse. The carcass would atand on a framed hase, as shown, and have a loose frieze and cornice above. The top and hottom of carcass are dovetailed to the ends, the Intter being rebated for a framed back

Large articlea of furniture are often made up of two or more carcasses. A tall hookcasc or bureau will have separate carcasses for the lower cuphoard and the upper case, whilat a threedoor wardrobe will probably be made up in threo carcasses. The back of an enclosed article is sometimes matchboarded, but more usually framed up. Lighter itema are now frequently fitted with three-ply lmards. In the case of heavy furniture of the sideboard type, corner posts are added. To these framed ends are housed, and in front the carcass is connected by means of rails, dovetailed or tenoned in as in the case of a table.

Doors for cabinets, wardrobes, book cases and sidehoards are framed up of atiles and rails, mortised and tenoned together and rebated for their panels. Except in the case of very amill donss the thickness for atiles and rails is generally $\frac{7}{\text { f }} \mathrm{in}$. net. Wardrobeand bookcase donrs which have to carry glass will need to be heavier. The width of the framing varies from $1 \frac{1}{2} \mathrm{in}$. to 3 in ., according to the size of door. At Fig. 5 (A and B) are shown the mortised stile and tenoned rail of $n$ door. The tenon is indicated with a shoulder, as C , and the stile is, of course, mortised right through. For light dones the shoulder may be
wedged, as indicated by dotted linea at $C$.
In the case of a cabinet with double doors, the meeting atiles may have an applied astragal on the right-hand door, as $D$, or the atiles may be relonted to engage as $E$, a liead

Cabinet Making. Fig. 4. Details of carcass construction.
Flg. 5. Diagrams showing details of door construction. See text leing run up the edge of the righthand stile to soften the joint. On the beat work all astragal is rehated in as $F$. Fig. 5 also slows aome typical examples of door plaineat treatment in indicnted at G, n flat frame, with the panel sunk not mom than jom. in. it H the frame has a simple mould run in the solid. J,
again, slinws the frame rebated to take an applied moulding, whilat at $K$ the trentment adopted for heavier doors is indicated.

Working drawings for a dining-room calsinet are given on page 172, and otiler articles to which reference should be made are Bookcase, Burcaux, and Birda' Egg Cahinet. In the latter some leading features of cabinet construction are shown in detail, with large scale drawings.
CABINET PUDDING. For a hot puiding, well butter a plain mould and decorate the hottom with halvea of glace cherries. Break up ahout four atale sponge-cakes, and pack them loosely in the mould in layers, with $n$ fell chopped cherries or mixed candied fruita. Bring $\frac{1}{4} 10 \frac{1}{1}$ pint of milk to hoiling point, and beat up 2 egga; let the milk cool slightly, and then pour it gradually on to the egga, atirring all the time. Add aliout 2 tablespoonfuls sugar and a few drops of vanilla or other casence to the cuatard, then atrain it over the cake in the mould, not quite filling the latter Let it stand for at least $\frac{1}{2}$ hour. Cover the top of the mould with a piece of buttered paper, and steam it very gently for one hour. Turn it on to a hot dish and serve with it any good sweet sauce. If preferred this mixture can lie hakied.

For a cold cabinet pudding omament the bottom of a plain mould with cherries and angelica, cover these with a thin layer of clenr jelly, and leave it to set. Line the side of the mould with 3 oz.. of Sa voy biscuits, splitting the biacuita in half and arranging them alter nately with back and front to the mould. Put 2 oz. of broken

Cabriole Ler, late 17th century pattern

Next make a custard by benting up the yolks of $4 \mathrm{eggs}-\mathrm{or}$, if preferred, $\geq$ wholc eggs-and ndding $\frac{1}{2}$ pint milk. Pour this mixture into a jug, atand it in a raucepan of hoiling water over the fire, and stir until the custard thickens. Melt $\frac{1}{2}$ o7. leaf gelatine in a little hot water and strain it into the custard. When cooled, add $\frac{1}{2}$ gill of cream, with sugar and vanilla to taste. Mix all well together and pour it into the mould. When quite set turn it carefully out on to a glasy dish.

CABRIOLELEG. This carved leg found in certain styles of furniture
has a projecting rounded knee at the top and n gradually tapering lower part, which is often carved with representations of a hoof. n shell, or an animal's paw grosping $n$ hall. It is a feature of the Queen Anne styylc and was much used by Thomas Chippendale. In quite a different sense the word is used for a chair with upholalered back, arms, and seat, helonging to the Hepplewhite period. See Chair: Chippendale; Hepplewhite; Queen Anne.

CACHOU. By this name is known a small sweetment with aromatic flavouring which is alowly dissolved in the moutl, to diaguise the odour of intoxicating liquors, tobacco, etc. For this purpose enchous are generally carried n a small box.
CACTUS: How to Grow. If the cactiare to be grown in a room, a very light and sunny position in front of a window should be selected. In

the plants to flower, as in almost all cases the horsoms are exceedingly beantiful. The chief points to be noted are: In the first place, never give n cactus plant a lange pot-that is to say, always let it be rather smal for the size of the specimen. Second$l y$, begin to water the plants freely in April, but keep the soil rather dry
in winter. Thirdly. Cactus. Variety called Old Top. fight typical phyllocactus in bloom in the hot summer weatherlet the cacti simply bake in the sun, in order that all the shonts may become well ripenerl.
Perfect pot-drainage is essential. Fibrous loanm should form part of the soil, but nearly an cqual amount of sand and brick rubbish should le added: morenver, each pot should le one-third fult of drainage material. About April is the lest time to carry out the potting of cacti. Raising from seed is a very slow process. and by far the quickest method of propagation is hy cuttinga. Practically any part of the stem will grow if the piece has heen dried in the sun for several days before leing inserted in a mixture of losm, leas-mould, and small crocks. The cuttings are potted up as soon as they are rooted. The following are the principal kinds of cacti

## Cereus Echinocactus <br> Mamillaria Echinopals <br> Melocactus <br> Opuntla Pereskla <br> Phyllocactur <br> Rhlpenlis

piphyllum
Moat of the phyllocacti are very fre Howering, and a splendid whitebloomed
variety is alhus superlus. The well-known red, so often seen in cottage windows, is also another useful kind of phyllocactus. The epiphyllums, inany of which bloom in the hutumn and winter, are very graceful subjects. being crimson, pink or white in colour The genus cereus has amongst it sonie freehlossoming kinds.
CADDIS WORM. This insect is a very attractive inmate of the aquarium, owing to its habit of building a oylindrical case of sand grains, gravel, grass-stalks, small leaves, or gnail whells, each species selecting particular materials. They are the larvae of the caddia Hy There are about 150 British species, the larvae being found in ponds and streams Their long, pale bodies are soft, except the head, fore-body, and sir legs, which have a. horny skin. To protect the soft hind-body they construct cases by uniting their building materials by silk filaments, with which also the tube is lined These they drag over the bottom or haul up the stems of the water. weeds, upon which they feed principally. Some species ure carnivorous, and in the aquarium will destroy other aquatic insects.

When the larva is full hrown it moors its case to weeds or stones. spins a sillien web over each end of its tube, and changes to a nymplı with free legs. Ultimately it leaves its case and olimbs ont of the water, throws of the nymph-skin, and spreads the four hairy brown winge of the caddis fly. See Aquariun

Caddis Worm. Protective tubes made by these worms and attached to twirs
CAERPHITLY CHEESE. This cheese is considered to be specially suited to the needs of the underground workers. The moat popular kind of Cuerphilly is a cheese of the quickripening variety, available for consumption a fortnight to three weeks after manufacture. It is, therefore, of a perishable nature and deteriorates in quality after four to six weeks. becoming dry. This cheese is inade from morning's and cevening's milk.

CAFFEIN. Alknloid found in the dried leaves of tca, in the dried seeds of coffee, and in other vegetable preparations. The dose in medicine is 1 to 5 grains. Preparations in common use are cafficin citrate, dose 2 to 10 grains, and effervescing caffein citrate, dose (if) to 120 grains

The chief action of caffein, whether taken as a drug or in tea or coffee, is to stimulate mental activity. All the faculties become on the alert, the inagination is kcener, and thoughts work faster. It also wards of fatigue. If the dosing is continued, as in prolonged, excessive tea or cofiee drinking, an overwrought state of the whole nervous system results. Caffein has also a marked diuretic effect on the kidney tissues, increasing the flow of urine. The drug is therefore much used in heart dropsy, and other conditions in which it is desired to deplete the body of fluids through the kidneys. The effervescing caffein citrate is frequently prescribed.

Caffein is frequently used in heart disease. either alone or combined with other heart stimulants, such as strychinia; or it may he

Cairn Terrier, a small sporting dog
used in the form of colfee. When phenacetin is prescribed for headache, culfein citrate, 2 grains, may be combined with 8 or 10 grains of the former, with cafiein counteracting any depressing effect of the phenacetin on the heart, and also enhancing the efiect on the headache. Caffein is recommended for asthma.

## Cakes and How They Are Made

General Directions about Materials and Methods

## Further details will he found under the heading of various cakes, c.g. Dundec; Genoa. See also

 Raking; Decoration; IcingCake mixturea may be conveniently divided into four main groups: (a) Plain cakes, in which butter is rubbed into a relatively large quantity of Hour: (b) Richer cakes, in which the sugar and butter are creamed (i.e beaten to a cream) and Hour and other dry ingredienta added suhsequently; (c) Sponge mixtures, which contain no butter, and (d) Gingerbreads, in which the hutter, sugar, and syrup (or treacle) are melted together and poured into the dry ingredients.

Recipes covering each group are given below Variations of these proportions and methods may be preferied by sonie cooks, but the examples given have been found satis. factory in practice. It is to lee understond that wherever butter is mentioned, margarine may lve substituted if deained, or for fruit caken, a mixture of lard and butter.

Plain Cake Mixtures. A very plain mixture, suitable for an ondinary round cake or for amall oakea ( 12 to $\frac{1}{2}$ th Hour) may be prepared as follows: Rub 3 o\% butter into $\frac{1}{2} \mathrm{lb}$. Hour. Add $\ddagger \mathrm{lh}$. sugar and either $\ddagger \mathrm{ll}$. currants or a teaspoonful of curaway reeds. (Alterna. tively, teaspoonful of vanilla casence may be ailded after the egg and milk). Beat one egg, add to it rather less than a gill of milk. mix with dry ingredients, put into a greased cake tin and bake one hour in a morlerate oven. The 12 amall cakes require 20 to 25 min . in a quick oven. By using $\frac{t}{2}$ gill only of milk, a good rock cake mixture is obtained.

Another goond cake of this type is called Bachelor Cake. To make it, add a teaspoonful of haking socla to ${ }_{3}^{3} \mathrm{lb}$. of tlour. Then rub in 3 oz . butter. To the mixture add $\frac{1}{2}$ th. augar, 1 oz . each of cinnamon, allspice, and ginger, teaspuonful of ralt, 2 oz . chopped mixed peel, 2 oz. blanched and shredded almonds, $10 z$ caraway seeds, $\frac{1}{\underline{1}} \mathrm{lb}$. washed and dried curranta. $\ddagger \mathrm{lb}$. stoned raisins, and enough buttermilk to make the mixture into a moist dough After beating for 20 min . place the dough in a greased tin, anid bake for ahout 1 hour in a moderate oven.
Richer Cakes. A good sultana aake (Fig. 1) can be prepared as follows: Cream $\frac{1}{2} \mathrm{lb}$ hutter with 6 oz. castor sugar. Add giadu. ally and alternately 1 lb . Hour and a teaspoonful baking pouder and four well-beaten egga. (If self-raising flour is used no bakingpuwder is required) Stir in a gill of milk, a pinch of salt and either $\frac{3}{4} \mathrm{lh}$. sultanas or $\frac{1}{2} \mathrm{lb}$.

2 to 5 grains of the citrate heing given at bedtime and again during the night.

CAIRNGORM. Semi-precious stone of the quartz family. It is largely used in the mounting of Highland dress accoutrements ; also for jewelry, chiefly hrooches and buckles, seals and beads. In colour it varies from a pale sherry tint through all degrees of smoky brown to almost black

CAIRN TERRIER. This is an extremely popular variety, being a keen, aporty little dog. and one that is particularly suitalle for living within the family circle. Apart. from this it is used for ousting foxes from rocky caims where "bigger dog could not go Consequently he requires a strong muzzle for his size. I fair average weight is ahout 14 lb ., but the tendency is towards a smaller breed. The cairn is a short-legged, compactly built little dog with a rather foxy head, alert eyen, and small, pointed ears.

The outer cont is wiry and hard, and there should be a good under coat. The colour may be sandy, grey, brindled, or nearly hlacl:. Dark ears and muzzle on the lighter culours are appreciated Eyes are dark hazel. Sec Dog.
sultanas and $£ \mathrm{lb}$. finely chopped candied jeel, and heat thomughly. Put mixture into as cake tin lined with greased paper and hake from $1 \frac{f}{d}$ to 2 hours in a rather slow oven. If a metal skewer insorted into the cake comes out dry, the cake is done.
A rather inore elaborate cake of this type is known as Angel Cakc. To make it, cream 4 oz . butter with 4 oz. castor sugar, add 2 well. beaten egge and sift in $\frac{1}{2} \mathrm{lb}$. Hour mixed with 1 teaspoonful baking powier. Add $\ddagger \mathrm{lh}$. sultanas, 2 oz. each of preserved cherries (quartered) and choppled preserved pineapple. Nix well, and if the mass seems too dry, soften with a little milk, but be careful not to make it. too moist. Stir in a few drops of eraence of lemon, place in a cake-tin lined with wellhuttered paper and bake in a moderate oven for about is hours. The success of this cake depends on the thorough beating of the eggs and the gentle mixing of the flour.
A very rich cake, suitable for Birthday or Cliristmas Cake, can be marle, icod and decorated, as follows: Line a large cake-tin with greased paper (sce Fig. 2), and then put d lb. butter in a warm basin, heating it with a
 sugar, creaming the two ingredients together until they resemble whipped cream. Beat four egge to a froth, stir them gradually ints the mixture, and beat well. Sieve ilb. of tlour, half a level teaspoonful of salt and two teaspoonfuls of ground allspice, adding these lightly to the whole

Mix together 6 oz . currants, 6 oz . sultunas, 1 oz glacé cherries (quartered), (s oz. mixed chopped peel, 2 oz shredded blanched almonds, and the grated rind of a lemon. afferwards

Cake. Fig. 1. Good sultana cake, a recipe for making which is given in the adjoininR column

Cake: stages In making a rich cake. Fig. 2. Cake-tin greased and lined with paper. Fig. 3. Turning the baked cake on to a sleve to cool. Fir. 4. Almond paste apread on the top. Fig. 5. Cake covered
stirring them into the other ingredients Pour in 1 gill milk and 4 tablespoonfuls brandy, turn mixture into eake. lin, and smooth the surface quite level, using a knife dipped in hot water. To prevent the cake from burning undernenth, a layer of salt or sand about an inch thick may be put in the bottom of the haking tin. and covere-t with preasod paper. Then bake the cake in a moderate ouen or about $2!$ hours. and turn out on to ת sieve (see Fig 3)

When it commences to brown, lay a piece of thick paper over the top, letting it rest on the exlge of the band that stands up above the tin. When culd, cover top of cake lirst with almond paste (q.v.) and then with myal icing (Figs. 4-6), nnd decorate it with caramelised fruits.
 Anished cake decorated with ornamental flowers in icing The latter nrc prepa onf augar in arepared by boiling $\frac{3}{} \mathrm{lb}$. of water to moisten it, and stirring it over the fire until it becomes golden-brown in colour, and adding a few drops of lemon-juice. Take some greengages and apricnts, cut into halves, and some whole grapes: dry these thoroughly and drop them into the caramel mixture immediatcly after it has ceased to boil. When well conted, put the fruits carefully aside to dry, and then arrange them on top of the cake. Instead of the fruit decoration, suger flowers may be userl, made with an icing tuhe, and coloured (Fig. 6).
For $n$ child's birthday cake, candles in tiny holders, the number denoting the age of the child, may form part of the decoration.

The necessary ingredients for royal icing are 2 lb . of icing sugar. 4 whites of eggs, and the juice of 2 leminns. Rut the icing sugar through a hair sieve into a basin, nake $n$ well in the centre, and put in the slightly beaten white of egg. Mix in a little of the sugar fron the sides, then add half the strained lemon juice, and nix the whole to a rather moist paste, adding more lemon juice ns required. If the lemons are large, all the juice inay not be needed. Use the icing at once, smoothing it over with a large knife, dipping the Intter in cold water occasionally.

Rich cakes should alwnya be made a month or more before they are required for use; theyshould be packed (when cold) in several layers of greaseproof paper kept in a dry and airtight place.
A Madeira mixture may be prepared as follows. Take 3 eggs and their weight in sugar and self-raising flour and the weight of 2 egga in butter, and Havouring to taste. Cream butter and sugar, addl eggs and llour gradually and alternately, stir in flavouring cssence and beat very thoroughly. Put mixture in a calietin lined with greased paper and bako at once in a moderate oven from 1! to $1 \frac{1}{4}$ hours.
To make layer or sandwich cakes use 2 eggs and their weight in butter, sugar and selfmising flour and mix as for Madeira cake. Bake layer cake (Fig. 7) for a hout 1 hour in a rather slow oven. For Sandwich Cake, or Victoria Sandwich, divide mixture into two equal parts and bake in sandwich tins (greased
and tloured) for ahout 15 mill. in a brisk oven Layer calie should be cut through twice and spread ivith jam (preferably raspherry or apricot) or with whipped cream, sweetened and thavoured as desired. One cxcellent filling is made with minced Brazil nuts and sweetened whipped cream. A sinuple icing can be made by heating (not hoiling) I lb icing sugar with rather lese than a gill of water and a teaspoonful of the desired flavouring Pour over cate while warm and ornament with glacé cherries and walnuts or angelica.

Sponge Cake Mixture. One way of preparing this is to take 2 or 3 eggs and their weight in sugar and flour. Whisk eggs and sugar for about 15 min. and fold tlour in lightly and thoroughly. Have ready a tin lined with buttered paper and sprinkled with sugar, put mixture in at once and bate in a hrisk oven for about 3 hour For jamsand wich. divide mixture into two parts and bake in sand wich tins. This should take about 15 min in a brisk oven. It is very imporiant that this mixture should be made quickly and put into oven at once, and that oven door should not be opened until it is nearly done.

Gingerbread. A good plain gingerbread is prepared as follows: Melt $\frac{1}{\mathrm{lb}}$. sugar. $\frac{1}{2} \mathrm{lb}$. margarine, and teacupful of golden syrup in a saucepan over the firc. Beat up 2 eggs, and when the melted syrup is cool, add them to it and bent all together. Sieve together 1 lb . Hour and 2 teaspoonfuls of ground ginger, make a well in the centre, nad into it pour the syrup, etc., mixing and benting the whole thoroughly.

Dissolve $\frac{1}{2}$ flat teaspoonful hicarbonate of soda in $\frac{1}{2}$ gill of milk, mix it with the other ingredients, and tarn the mixture into a greased cake-tin. Bake the cake in a moderntely hot oven for 1 to I? hours, then turn it on to a sieve and leave until cold.

The temperature of the oven should always be fairly high before calies arc put in In a gas oven the burners should be left full on for about 10 min . previously and turned down about half way when cake is put in, i.e rather less than half way for a 'brisk' oven and rather more than hall way for a 'slow' oven. The oven door should not be opened for at least 20 min . after a cake has been put in, and when baking sponge cake, not until cake is likely to be done. The oven, it is to be noted, should be hotter for small and light cakes than for fruit cakes.

To make a cake level for icing, a slice is sometimes cut of the top and cake turned upside down; but if mixture be kept higher at sides of tin than in the middle before putting in oven, the necessity for this is obviated to a great extent. Another method is to place a sheet of paper lightly neross the side lining paper (which should always be higher than tin) as soon as cake has risen and brow ned slightly.

CAKE STAND: How to Make. Silver or plated silver stands having two or three tiers, and fitted with chinil or glass plates, are useful for the table.

Floor cake stands vary from $2 \frac{1}{2}$ to 3 ft . in height, and arc made in metal and wood.

Cake. Fig. 7. Layer cake with jam flling. the top iced and decorated with walnuts and glace cherrnes

The shelves ( $F$ ) are cut from wood $\frac{1}{2}$ in thick, and tenons similar to those shown at Fig. 4 are formed at each end for framing into the uprights (A) A rim (G) is fitted above. each shelf to keep the china plates in position. These rims should le cut from wood $\frac{1}{3}$ in thick. They atand $\frac{1}{} \mathrm{in}$. in from the outer edges of the shelves, as shown at Fig. 4 The inner diameter of the rims must he large enuagh to fit the rims at the buttom of the platos, which will prohably le about 6 in The enges of the rinis could be be celled as shown. The rims

Some of thesc fold up into small compass and have two or three tiers. To mntch the furniture of the room, stands are made of walnut, plain and inlaid mahogany, fumed oak, and other less expensive woods. One of the handsomest is madc of black mahogany inlaid with English gilt, and having a jingoda design. Other Chinesc designs are introduced on lacquered stands in colours to suit the scheme of the room.

A threetier cake stand is shoum in Fig. 1. There are threc shelves carricd by side framework, which is provided with suitable feet at the botiom. The framework is connected by a crossbar at the lottom and a handle at the top. The vood selected sliould, if possible, match the surroundings in which the stand will he placed, aak (fumed and wax polished) or any of the polished cabinet woorls being suitable.
The dimensions given in the diagrams are suitable for china plates about $0 \frac{1}{2} \mathrm{in}$. in diameter, so that, if larger or much smaller plates are to be used, the dimensions given should he altered accordingly. The framework at each side oonsists of two uprights (A) which are 2 ft .9 in . long by $\mathrm{f}^{\mathrm{f}} \mathrm{in}$. square ; a foot (B) nnd a top rail (C), which are cut from wood $\mathcal{i n}$. thick to the shape and dimensions shown in Figa 2 and 3 The uprightsare tenoned into the feet and top rails, as shown at Fig. 2, the length of the uprights between the shoulders of the tenons being $2 \mathrm{ft} .7 \frac{\mathrm{f}}{\mathrm{g}} \mathrm{in}$. The bottom crossbar (D) is $11 \frac{1}{2} \mathrm{in}$. long by $\frac{8}{8} \mathrm{in}$. thick. This bar is tenoned into the feet ( $B$ ), the length lietween the shoulders of the tenons lreing $10 \frac{1}{2}$ in. The handle ( E ) is shaped as shown at Fig. 3 from wood $\frac{3}{3}$ in. thick. It is notched $\frac{1}{8}$ in. over the top rail ( C ) and is fixed with scrowis driven through the rails. This completes the construction for the framework.
 are glued to the shelves. It is usual to cover
the shelres inside the rims with haize. In fixing the shend insie thes joith baize. In fixing CALAMINE. This is another carhonate, and prepared calamine. which is used in medicine. is got from it by crushing and pulverising. The common cala. mine ointment. which is much used in inllamed conditions of the akin for its slight astringent effect, is piepared by mixing one part of calamine with five parts of benzonted fard. Colaminc may also be used as a lution.

## CALANDRINIA.

 The annual kinda may be sown under glass in March or ont of doors in Ipril; they need well-drained soil and a aunns spot. Grandiflora ( 18 in. ), rose, and speciosa (!) in.) crimson purple, should be grown. Unibellata has magenta flowers.CALCEOLARIA
laria is groirn in pots for green house decoration

in May and June: the thowers are brillinntly coloured and make $n$ atriking display Seeds are sown in May and June in pots of fincly sifted sandy soil, and the plants are grown in a cold, shady frame during the summer. In autumn they are placed in the greenhouse, a temperature of 15 to 50 degroes being suitable.
The dwarl shrubliy calceolaria, in yellow, bronze and other shades of colour, is a favourite summer bedding plant ; it is not quite hardy except in warm, sheltered places, and is propayated by cuttings set in bnxes of soil in a frame in September. Planting is clone in May Golden Gcm is a favourite variety. There are several charming small-Howered calccolarins which arc invaluable for the greenhousc in summer ; chief among them are integrifolia, amplexicautia, Burbidgei, and Clibrani The John Innes strain of calcenlaria provides plants 18-24 in. high, which bear amall flowers in many colours. The shrubby kinds are in creased by cuttings taken in late summer, the others from sceds sown in May.
The seed is very small and, in the case of choice varictics, is expensive. The compost is of Inam, pent and silver sand placed in a box on a Inyer of broken crock, as shown in $c$ and d, Fig. I, and moistened by sinking the loox in water. The seed is spread over the surface and covered with $n$ little of the finest silver sand, as in $b$, Fig 1. The box is kept in semi-shade in the greenfionse covered with a shect of glass, as in $a$, Fig. 1, and when the plants are up they are renoved to a frame, as in Fig. 2, liept there woll watered until potted when the leaves are about an inch long, as in Fig 3, and later transferred to a llowering pot, as in Fig. 4. A good mixture is one part each of loan and clecayed hotbed manure to half a part of silver sand. Propagation of the shrubby varieties is by cuttings talien late in autumn with long heels sliced almost perpendicu. larly from the parent plant, as in Fig. 5, and inserted in a cold frame, Fig. 6.
The plants should be grown in a warm, moist position close to the glass. They last well in a cool atmosphere, but are very susceptible to fog. When they liave died down for the period of rest, they should loc kiept very dry, or the bulhs will rot.

CALCULUS. A stone-like concretion known as calculus is found in the human hody. especially in cavities which act as reservoirs. Thus, in the gall hadder, biliary calculus or gall stone occurs; in the pelvis of the kidney, renal calculum; in the hadder, vesical or urinary calculus.

The innterial of which a calculus is composed is frequently found to have gathered round a nucleus, e.g. blood clot, dried nuous, or a amall foreign body. Such a concretion may give rise to few or no symptoms until it begins to miakr its way down the duct which empties the reservoir, when it may cause excruciating pain, as in hiliary and renal colic. It may liccome stuck or impreted in the duct. See Gallatone ; Kidney, etc.

## Calendars for Household Use

## Examples that are Easy to Make and Useful

Bent Iron Work; Passe Partout; Stencilling are among the entrics that those interested in making a calendar may consult with advantage

A calendar is quite simple to minke. The punched in the top of the suede through necessary material, in the shape of cardmoard which a narrow ribbon is threaded to form or suitahle paper, having bcen ohtained, all that is necessary is to tako a copy of the calendar for the previous year, and to move hack ald the dates by one, cxcept for a leap year, when they must be altered by two. This the Sundays in January, instead of reading 4, 11, 18,25 , will read $3,10,17,24$. This done, with

Calendar. Fig. 1. Diagram sbowink how a bird calendar can be made from velvet and cardhoard so that room is left to fix a arranged calendar after the stoncilling is completed Appropriate atencils-a blue bird, a squiriel, a ship, etc.-can be hought to be used with watercolour, and a small Jap brush An alternative is to paste a photograph or a coloured print-outlining either with a black or coloured border, put in with pen or brush-on the mount. A amaller mounting board may be used and a booklet calendar fixed by two short lengthe of narrow ribbon to hang below the board. A strip of firm paper ahould be pasted at the back of board and booklet in order to hold the ends of the connecting ribbons in place.
Stencils many be used ou coloured suède. Trake a piece about 7 in. by 3 in., place it on a llat board and stencil, on the suèdo side of the leather, the small design chosen. Mandarin inks or liquid stencil colours may be used. A border is painted or inked round the piece of suede, and appropriate words written. with the same onlouring material, above the tab calendar. Aholeis

Calendar. Figs. 2 5. Perpetual calendar in boz form, with
a loop at the back and tied in a amall bow in front. The lower end of the calendar may be fringed or the corners trimmed.

Lucky black cats, squirrels or birds, may be cut out of velvet and pasted on cardboard mounts cut to the ahapes of the animals. A paper pattern should first be innde by the help of a transfer. Glass beads may be used for eges, fastened by wires at the back, the visible ends of the wires being covered with a dab of black paint to form the pupils of the eyes. The calendars can be gummed on the animals Original designs can be drawn on the cardbonrd and cut out to form the pattern from which to cut the velvet covering. The latter may be touched up with paint to improve the outline.

A calendar on which the figure of a bird is the main feature is shown in Fig. 1. A piece of cardboard is cut into a circle except for an cxtension at the bottom, as shown in the illustration, nnd is painted black. The figure of a parrot is then outlined, the upper part being on the circle, while the tail part, which is below it, is fitted with a backing of cardhoard. A piece of blue velvet is pasted on to the figure, cxcept that in one place, as shown in the diagram, a piece of green is substituted The bird is npparently supported on a bough, mund which claws. also of cardbonrd, must bc cut, and these should be covered with yellow cloth. Finally the calendar proper can be hung on to the tail. and the whole suapenderl by a ribbon. Following the samc design, other colours and figures can he used.

Perpetual Calendars. A perpetual oalendar is illuatrated in Fig. 2, details of construction being given in Fige. 3, 4, and 5. The work is simple; the side pieces are gronved to receive the font and back, the former being cut out and glazed. The top and basc can be cut from the solid or built up from several layers.
The rollers are shaperd its shown, and carry the linen band on which are marked the numerals 1 to 31 . The upper and lowe mollers have the names of the months and the days of the week respectively marked upon them. Tho work is completed hy staining or polishing.

Another perpetual calendar is introduced into a linen sampler embroidered in cross. stitch, as seen -in the illustration, Fig. 6, with $\boldsymbol{a}$ diagram, Fig. 7. showing back of calendar.

First take the atrips of ribbon to match the colour of linen used and trace with a pencil on each, very neatly, the days, dates and months. Outline thesc in black silk. Next draw the design on the linen and embroider the anmpler in cmos-stitch (q.v.), using delicate, old-world pinks, blues and greens. The little lady has yellow hair, pink and blue dress, vellow and green llowers. Blue French knots

Fig. 2

form her eges and her face and arms are out. lined in pale pink. The zig-zag deagn is in black, pinks, blues and yellows The slots for the day, dateand month, are firgt buttonholed and then cut so that the strips may be inscrted. The sampler is backed with cardbnard, slots being cut oxactly to correapond with those in frunt to allow the strips to be moved round. Join each strip to makc $n$ ring at the back (see dingram) and frame in a passe-partout frame

CALF. The llesh of the calf is known as veal, and is a very delicately-Havnured white ment. The brains, head, heart, tongre, liver, sweetbread and kidneys of the calf are alan used for the tiable, while jelly is made of the feet. The tongue, liver, and kidneys arc smaller, more ten der and delicately flavoured than those of the bullock, but the method of cooking them is practically identical. See

Brains; Liver; Sweetbread: Venl.

Calendar. Fig. A. Perpetual calendar on an embroidered sampler in cross-stitch. Fig. 7 (above). Back of calendar

CALF: The Leather. If tho pelt is to be turned into old-faghioned calf leather it is tanned by steeping in an infusion of bark or other vegetable produce containing tannin. The leather, according to methods of finishing. will be cither calf for boot uppers, gloves, etc.

There is inother process of dealing with the velt, and that is by immersing in a bath of chromium salta, which produces chrome leather. This may be finished black, when it hecomes hox calf, or a shade of brown or yellow, known as willow calf.
Another finish is velvet calf. In this process the natural grain is carefully removed in the buffing machine, leaving the surface with a fine velvety nap. In wax calf the finish is on the flesh side, and the grain or outer surface of the akin hecomes the inner surface. This is employed for heavy bonts, for shooting, fishing, and for agricultural bonts. It is said to withstand the effect of stable and field wear better thnn chrome leather.
Calf uppers of heavy boots should be freed fom all dirt and thoroughly dried after use

They should be treed to preserve the shape. and before wear given an application of dubbin if the weather is wet, or of good blacking if it is dry.
Patent calf is perhaps the most reliable patent leather that can be purchased. This is perfectly waterproof, and here again to assist the patent surface to be maintained it should be fed occasionally with a little castor oil lightly rubbed over and then wiped dry with a soft rag.
Russia leather owes its characteristic odour to the birch bark with which it is tanned. Like most other fine leathers, the original has been imitated, and much of the so-called Russia leather is tanned with other materials. and then scented with birch tar oil.
In dressing calf a certain amount of acid is a boorbed which has to be removed by washing. When the leather is required for book. binding this elimination has to be very thorough, otherwise the acid will in course of time cause the leather to deteriorate and mt away. See Boot: Leather.
CALF'S FOOT JELLY. Wash 2 calf's feet thoroughly in boiling water, chopping each into 4 pieces. Put these into a saucepan with cold water to cover them, and allow them to boil for 5 min . Lift out the 2 feot, throw away the water, and replace the feet in the saucepan with 5 pints of hot water, boiling it gently for 5 to 6 hours and keeping the stock well skimmed. By this time the liquid will be reduced to about 1 quart. Strain off, let it get cold, when it will be a jelly, and then remove grease from the surface, finally wiping it with a clean cloth dipped in boiling water.
Turn the jelly into a clean pan, add $\downarrow$ pint of sherry, 6 oz. loaf sugar, the thinly-pared rind and strained juice of 3 lemons, 3 cloves, 1 in . of cinnamon, and the washed, crushed shells of 2 eggs and their lightly-whisked whites. Whisk all these ingredients over a moderate heat until the jelly boils up to the top, of the pan. Let it sink again and rehoil it. Do this twice; then allow it to settle for 10 min . by the side of the fire, kecping it covered. Strain it into a basin through a clean, coarse teacloth kept solely for this purpose, first scalded by pouring boiling water through it. Pour the jelly back again through the cloth two or three times if at all cloudy. Next pour the clear jelly into a wet mould, or moulds, and leave till set.
It is wise to test the stifiness of this jelly by cooling a little of it quickly If too stiff add a little more sherry, water, or lemon-juice. If wished, omit the wine and use more water and lemon-juice, or add brandy or port wine in place of sherry. If a clear jelly is not required leave out the shells and whites of the eggs, and after boiling the jelly for a few minutes, strain it through a hair sieve or a fine strainer. This is sufficient for about a quart of jelly.
CALF'S HEAD. Wash the head thoroughly and trim, making sure that the eye, the inner part of the ear, and all the soft, bony parts from the nose have been removed. Leave it to soak in cold, salted water for 2 hours; then lay it in a saucepan, with enough cold water to cover it, and boil it for 10 min . Throw away this water, put back the head with fresh water, and add 1 onion, 1 carrot, 1 turnip, and a few sticks of celery, all cut into small pieces, a emall bunch of herbs, 6 peppercorns, 2 cloves, and 3 allspice, the last nanued being tied up in a small piece of muslin.
Let all these simmer for 3 to 4 hours, or until the meat is perfectly tender and comes away from the bones. Skim the stock well, lift out the head on to a hot dish, and serve whole with hot maltre d'hôtel sauce poured over. Alternatively, cut the meat off the bones into large, neat picces, arrange on a hot dish and pour over the sauce, garnishing the head with sippets of toast and cut lemon.

Another way of treating calf's head which has been boiled is to cut it into slices in. thick, sprinkling the pieces on both sides with grated nutmeg, flour, and ralt. Fry these a light brown, then put each piece into a stewpan. Mix a teaspoonful of four with a little water till smooth and add it to the butter in which the head was fried, afterwards pouring in gradually $\frac{1}{d}$ pint stock together with a wineglassful sherry and a tablespoonful Worcestershire sauce. Season the whole with a little cayenne and a tablespoonful lemonjuice, pour the sauce over the meat, and let all simmer for a quarter of an liour.

Calf's head is often served with tomato sauce. This dish is made from a boned, cooked
 macaroni. Divide the macaroni into piecen about in. long, and boil rapidly in salted water until tender. Cut the meat into small slices, pour the tomato sauce into a stewpan, and add to it the strained macaroni and the meat. Sicason it to taste, and heat thoroughly. A calf's head makes a good brawn, and mock turtle soup can also be made with it. See Brawn; Mock Turtle Soup.
CALICO. The name is derived from the Indian port of Calicut, from which a large part of the calicoes worn in the western world used to bo shipped.
What makes one calico better than another is the quality of the raw cotton used to begin with, the fineness of the threads from which it is woven and the number or closeness of those threads. Cotton cambrics, jaconettes, long-cloths and nadapolams are included under this heading. Calicoes may be bleached, unbleached, or partly bleached, or printed, by machine or hand, in most colours. See Cotton.

## Californian Bluebell. See Nemophila.

CALIFORNIAN POPPY. The eschscholtzia, or Californian poppy, is commonly seen bearing deep orange towers with a yellow

Californian Poppy. Flower of the
Californan PoppJ. Flower of the
Californian Tree Poppy, Romneza
range scarlet ; and frilled pink
This showy annual is raised from seeds sown in the open in spring and autumn, and the scedlings thinned to about 9 in. apart. A light, friable soil and a sunny site are most suitable. In many gardens self-sown seedlings are numerous

CALIPERS: For Measuring. These instruments are generally made of metal with firm joints; that is, the joint is so constructed that the calipers, when set to any given measurement, will not readily be displacod. They are made in various forms, those shown here being from 3 in . to 24 in . in length. The outside calipers are pearshaped and adapted for

Calipers. Diegram showing how they should be used for making inside and outride messuromonte
measuring the diameter or thickness o a rod or bar. The inside calipers, used for measuring the bore of a tube or the diameter inside a ring, have outwardly turned ends or jaws.

The method of using is illustrated It is cssential for accurate measurement that the calipers should be held erect and the jaws kept at right angles to the axial line of the work. Inside calipers are hcld in a similar nianner. with the centre of the joint on the axial line of the bore of the work The distance outside the jaws is then compared with a ruler to olitain the dimension. In the case of outside calipers the dimension inside the jaws is taken. Improved calipers for very fine measurements have a acrew adjustment. Spring calipers can be easily and quickly adjusted with considerable accuracy, by means of the screw nut. Thread calipers for measuring the diameter of screw threads have extra wide jaws, while odd leg or jenny calipers are for scribing the centres on a bar or for other marking out and measuring purposes.

CAIL : Elow to Pay. In the country and smaller towns it is customary for the older residents to call first upon newcomers. They may call because asked to do so by a mutual friend, or, quite correctly, as an act of courtesy, without introduction. If invited to meet the newcomer at the house of a friend, they would be almost bound to call at an early opportunity, unless they wish to alight both friend and newcomer.
This rule is obviously impossible in the larger towns, and therefore a ncwly arrived person has to take the initiative in such matters. She will usually have some kind of social introduction to one or two people, and will duly leave cards on them, or should her social circle be very large, she may send her secretary to leave carda. In India and most of the British dominions and dependencies this also applies. The newcomer will leave his or her card on the residents (as a rule the card is merely put into the letter-box or into a special box for the purpose fixed to the gate of the drive) and will write his name in the book at Government Houso, and such as desire the acquaintance will then take steps to improve it.

Leaving Cards. Usually the time for calling is from 3 to 6 p.m., from 3 to 4 being the most formal hour for mere acquaintances. When the lady called on is not at home, the caller should leave one of her own cards, and if married one or two of her husband's, one of his being for the lady of the house and the other if she is married for her hushand. After a first call it is usual to leave only one of the husband's cards.
"Not at home" is often a polite formula, and may mean that the lady of the house is in but is not receiving. This must not be taken as a slight, and the caller, unless on very intimate terms with the mistress, should not ask any questions of the servant, but leave her cards. A man should not call on a lady unless she invites him to do so It is usual for men to leave their hats and sticks in the hall, and not take them into the drawing-room.

The caller should not present cards to a servant when the mistress is at home, but should follow to the drawing-room door, where the name should be given, if unknown, to the servant. After shaking hands, the visitor should sit down near the hostess without

A formal call should only last about a quarter of an hour. It is usual to offer tea, but the offer is not usually accepted unless tea is already being served in the room. Women do not rise when other visitors are introduced unless they wish to show particularly courteous
attention. A man would get up at the eame time as his hostess, who always rises to greet a visitor of cither xpx. The same rule applies when a guest is leaving.

Etiquette of Introduction. When introducing, a man must always be introduced to a woman, whatever their respective rank or position, and, in the case of people of the same sex. the less important is introduced to the more important. An unmarried lady is always introduced to a married one, unless the former is of superior rank. The rule is to how only on being formally introduced, but this is not usually adhered to if the people are introduced by the hostess as personal friends of her own, when it would seem frigid not to shake hands. If jeople have only bowed they do not usually shake hands, but bow again, at parting Cards should be left or a call returned within a week or ten days. See At Home; Etiquette.

CALLIOPSIS. The daisy-like flowers of the calliopsis (or coreopsis) are orange, yellow, crimson, and brown, growing on stems $1 \frac{1}{2} \mathbf{f t}$. high. The annual varieties are sown out of doors in March-April, where they are to bloom in summer. Several kinds are perennial, but as they are liable to perish after having llowered it is wise to sow seeds annually in June; the best are auriculata superba, grandiflora and lanceolata, all three bearing yellow flowers

CALL SIGN. In wirelcss telcgraphy this is an identification signal by which a transmitting station may be readily recognized, thus facilitating the transmission and reception of messages in Morse code. Call signs are also used by broadcasting stations.
CALOMEL Calomel or mencurous chloride is a white, practically tasteless powder frequently used in medicines for its purgative action. It also acts as an intestinal antiseptic. Calomel is usually given at night, dose from one-half a grain to 5 grains, when the constipation is accompanied by headache, heavily coated tongue, and feeling of fullness in the pit of the stomach.
A saline such as Epsom or Carlshad salts or back draught (compound mixture of senna) is usually given in the morning following. It clears away bile from the gall bladder. In various forms it is used in syphilis; combined with glycerin and solution of lime it forms hack wash, which may be used as a lotion for sores of this complaint. It may be applied as a dry powder to relicve itching.

Calomel, the mercurous chloride, should not be confused with corrosive sublimate, or mercuric chloride, which is much more poisonous. See IBlack Draught.

CALUMBA. The dried root of the calumba plant, which is obtained in E. Africa, is used for medicinal purposes, being a bitter stomachic, increasing appetite and aiding digestion. As it contains no tannin it does not form a black, inky mixture with imon, in this way resembling quassia. Useful preparations are the infusion, which is made with cold water, dose $\frac{1}{2}$ to 1 oz ., and the tincture dose $\frac{1}{2}$ to 1 dram. In anaemia the following may be given, a tablespoonful being taken in water thrice daily after food :

As another illustration of the use of calumba in medicine, the following may be given to increase or stimulate the appetite, the dose being one tablespoonful in a wineglass of water, taken thrice daily just before foud :

## Nitrohydrochloric acid (dilutc) <br> Syrup of oranges

CAM : In Mechanics. The cam is a projection on the side of a revolving mechanism, such as a shaft, which causes any fitment
that is brought into constant contact with be distinguished by the presence of certain its profile to perform a reciprocating motion. stronger hairs of a darker hrown. Camels With internal combustion engine design the grow two kinds of hair, one relatively short cam is used for other purposes than the operat- and downy, grown on the body; the other
longer and coarser, on the liaunches, hump. and mane. The long hair is combed out as far as possible but a littie remains

The hair of camels is collected in Central and Northern Asia, and manufactured in the same way as wool in Great Britain and other countries The natural colour is fawn made into un dyed blankets, dress. ing-gown cloths, etc. See Wool

Camel Hair Brush. Thebest paint brushes in this hair are made with a knot of camel hair securely tied and pulled into a tin ferrule, which ing of the valve gear, such as the operating is then in most cases fitted with a long of the oil pump, and also of the water pump handle of plain coloured or ebonised wood. that is sometimes fitted to assist the cooling Camel hair is of a soft, silky nature, and tho system. In these cases the shape of its profile end of the brush being pointed, the smallest differs considerably from the cam employed quantity of anything in liquid form can le for valve gear work, inasmuch as its action is applied. To clean the brush after use, a littlc more gradual, a steady reciprocating movement paraffin should he worked into the hair, the being all that is required, as illustrated at $A$. B shows a cam with equal sides and a rest period at the top, i.e. a period of the cam's rotation during whioh the part being operated remains stationary This design gives a quick opening, a long rest period at full open, and a quick closing. It C is given a cam having a moderately quick opening, a shorter rest period and a slower closing. D shows a cam with equal-sided faces and no rest period at the top. Generally apeaking, it may be noted that the more rapidly a cam performs its lifting function, the more severe will be the blow given to the part to be lifted at the beginning of the operation. See Motor Cycle; Valve.

CAMBRIAN WARE. The term loosely comprises all the ceramic products of the Swansea works down to 1870, but collectors prize the opaque china, not true porcelain, produced after 1802, and decorated with painted shells, butterflies, birds and flowers, or with local landscapes. Swansea china, a softpaste porcelain made after 1814, often bears decorations in the same style. There are also saltglaze stonewares and cream-wares, represented by jugs, tea-sets and other patterns, as well as mantel. piece figures, unglazed buff reliefs, some Egyptian black, and imitations of Etruscan ware. Milk. maid-and-cow figures are charming and characteristic examples. See China; Pottery.

CAMBRIC. Cambrics are made both in cotton and in linen. They are of light-weight, fine and closely woven, and much used for making handker. chiefs. Linen cambrics are cooler to the touch than cotton and stand more washing. See Handkerchief.

CAMEL HAIR. Very soft and warm to the touch, camel hair can sometimes

Cambrian Ware. Some of the princlpal marks on Swansea china. 1. Impressed mark, rare on china, common on pottery. 2. Impressed mark common on early
examples.
mat. 5 .
Common marks. B. Impressed mark, late period. 7. Transier mark, latest period
brush squeezed out and washed in warm water and the hair pointed with the fingers
Camel hair pencila are made of knots fixed in quills of birds' feathers varying in size hetreen those obtained from the goose and the lark; the smallest si\%es are found in a child's paintbox. Handles are supplied to fit into the quills.

Another use for camel hair is in the thin. flat brush made for damping paper for the letter copying press. The brush for painting the throat with iodine or other preparation is also composed of camel hair, the knot being pulled into a large quill, which is sometimes bent to facilitate reaching the inside of the throat. Care should be taken to see that the knot of hair is securely fastened, See Brush.
CAMELLIA. This evergreen shrub is generally grown under glass, hut it is fairly hardy and may be planted out of doors in warm sheltered spots. In the greenhouse camellia is grown in larger flower pots or in a bed of prepared soil. Thorough drainage is neccssary, and a suitable soil compost consists of peat and loam with and added freely. If grown in pots the plants should be set out of donrs in the summer and replaced under glass in September A temperature of $50-55$ degrees is suitable.
Healthy plants have a habit of setting far ton many buds. It is best to reduce the number, before the buds have developed, to not more than one on each shoot

After fowering, the plants should be pruned, hut only sufficiently to preserve the shape of the bush Crowding shoots may be thinned and atrag. gling oncs shortened.
Propagation is effected by means of gralting under glass in spring. If re potting be necessary it

should be done directly the flowers are over, but should never be undertaken unless the pots are obviously crowded with roots. Cimellias should bo sponged occasionally for "hite scale, and fumigated for green fiy if necessary

Good varieties are alba plena, white: Comtersa Lavinia Maggi, white with deep rose
stripes: fimbriata, whito; Lady Hume's Blush, flesh pink: Mathotiana, glowing red : C. H. Hovey, crimson ; Donckelaari, crimson and white: Reine des Bcautés, rose: Thos. Moore, carmine.

CAMEMBERT. This is a popular variety of soft cheese. In France, its native country, it is usually made from whole milk of a quality similar to that given by Shorthorns. Often, however, separated or perfectly sweet skimmed milk is mixed with the new in proportion of 1 to 5. Usually made from Sept. to May, these cheescs are small; they weigh from 10 to 13 oz ., about $5 \frac{1}{4}$ gallons of mixed new and skim milk being required for each dozen. See Cheese.

CAMEO. This is a piece of relief carving in stone, such as sardonyx, chalcedony, ngato. The layers of colour peculiar to these stoncs are utilised to form a backiground, after the front portions lave been carved away. Cameos are also made from a variety of shell consisting of two layers. one of which is pink and the other white. The dosign is carved in the upper or white later, while the lower or pink layer forms the background.

The value of the cameo depends on the beauty of its carving. A genuine cameo should be carved entirely out of one pieco of material ; many imitations consist of a badly carved subject cemented to a background of a different coloured material. Cameos may be cleaned by washing in warm soapy water and gently brushing with an old tooth brush.

## Cameras for the Amateur Photographer

## Hints on the Choice and Use of the Best Modern Types

For the principles of Camera Work see Photography; their detailed application is described under Developing; Enlarging; Filnt: Plate: Printing, etc. Other aspects are discussed under Cinema; Telephotography, etc.
There have been continuous developments at a time. They are available in a wider range in camera design since photography became a popular hobby, the general trend leing towarda greater compartness coupled with increased efficiency. Better lenses and more precise adjustments have made it possible to produce with the modern pocket camera crisp sharp negatives that will enlarge to any reasonable sizc. Cameras taking smaller negatives than the once almost universal $\ddagger$ plate ( $4 \ddagger \times 3 \downarrow \mathrm{in}$.) are theretore now popular. The $3 \ddagger \times 2 \ddagger$ in is now the most popular size, but Vest Pocliet (2! $x / \frac{15}{8} \mathrm{in}$.) is widely used. Other popular sizes are $4 \frac{1}{4} \times 2 \frac{1}{i n}$. and Postcand ( $5 \frac{1}{2} \times 3 \frac{1}{i n}$ ).
Most modern cameras can be loaded in daylight. The majority of them take roll film ; canteras primarily intended for glass-plates (which have to be loaded in a dark room) can be made daylight loading by fitting a film-pack adapter and using film packs Daylight loading films are the most convenient form of material when a number of pictures are to he taken. Glass plates are preferred by those who wish usually to make only one or two exposures

Camera. Fig. 1. "Brownie " simple boz-form camera for snapshots in good light, with portrait attachment for close-up photos Courtesn of Kodat. Ild.
at a time. They arc available in a wider range
of speeds and colour sensitiveness than roll films, but are equalled in this by cut film, a molern material used in plate slides.

With practico and intelligent application of the principles of photography good negatives may be niade with the cheapest camera and the simplest lens. It is only necessary to realize the limitations of the lens, and not to attempt subjects which are not within its scope. The leginner who blindly snaps at a fast-moving motor-car, or even people walking in a street, with a cheap caniera and its neces sarily slow lens is making failure inevitable The more expensive camoras are fitted with faster lenses, admitting more light, and there fore pernitting shorter exposures, i.e. quicker snaןshots.
Three Main Types. There are threc main types of cameras : box form, folding pocket, and reflex. Cinematographic cameras are dealt with in the article on the Cinema.
The hox form is the simplest type, repre sented by the box "Brownie" (Fig. 1, to take pictures $34 \times 2 t$ in., or $4 \frac{1}{4} \times 2 \frac{1}{2}$ in.). A simple lens is fitted so that snaps can be taken only in fairly bright light, but the camera is so simple and solidly constructed that a very high proportion of good pictures results. Interior construction and shutter mechanism are seen in Figs. 2 and 3. A somewhat more expensive form in the "All-1)istance" (Fig 4) which, with a special type of lens gives sharp images at distances from 3 feet upwards without a portrait attachinent. It includes a direct vision-finder, seen on the right of the camera, and a film-registering device which keeps the film flat without tension during exposure. The lens is hooded, and so prevents
light fog due to glare from the sky, or other causes of diffusion of light in the lens, a frequent cause of foggy-looking negatives.

Folding pocket cameras are made in all sizcs from the V.P.K. (vest pocket Kodak Fig. 5), $2 \frac{1}{2} \mathrm{in}$. $x 16$ in., to $5!$ if. $\times 3 \frac{1}{4}$ in. (postcard pic tures). Some are self-erecting, the lens front being automatically pulled into position as the basehoard is

Camera. Fig. ; ${ }^{1 \text { nterior of No. } 2}$ box "Brownie;" Fig. 3. Shutter
mechanism, A, B, and C
pulled down; in other types the base is pulled down and the lens front slid out on runners, as the example given in Fig. G, which takes roll film 21 in. $\times 3 \pm$ in., has a two-position lens giving accurate focussing at all distances between 3 ft . and 9 ft . and 9 ft . and infinity, and a three-speed shutter The wire frame in front folds out ns a direct view-finder.
Various types of lenses and shutters are fitterl to folding cameras, from the simplest to the most expensive. A good modium priced camera equipped with a $f 6.3$ lens will enable snaps to bo taken successfully even on dull days. Simple box cameras are fixed focusonly objects more than, say, 10 ft . away will be sharp unlesa a supplementary lens, a portruit attachment, is used. Folding cameras usually

Camera. Fig. 4. Box-form with "All-Distance" Camera. Fig. 4. Box-form with "All-Distance"
lens giving clear focus from 3 feet to inflity Courtesy of Ension, Led.
have $\pi$ focussing attachment; by setting a pointer at the appropriate distance on a scale the lens-to-film-distance is idjusted.

The Siand Camera. The types of canteras named above are primarily hand cameras, though most of thens are fitted with a bush for attaching to a tripod when time exposures are to le given. The hand or stand cantera is a type that takes plates, cut films or film-packs, and has a proper ground-glass screen for focussing the image when used upon a tripod, in addition to a pointer and scale for use when the camera is used in the hand. This type of camera is one which is largely used by the more practised amateur, since it enables him to use colour sensitive plates (orthochromatic or panchromstic), which give better colour rendeings than the ordinary roll film

Most cameras of this pattern fold up small enough for the pocket, plates being carried in dark slides, or n larger number of flat films in a film-pack with adapter. The example shown in Fig 7 will take plates or flat films of various sizes from $3 \frac{1}{2} \times 2 \frac{1}{2}$ in. to $\frac{1}{t}$-plate It has $n$ double extension, by means of which the front and its lens can be racked out for focussing near objects, and a rising and falling front. It is asually fitted with a better type of lens than the fixed-focus camera, e.g. an anastigmat of 17.7 or f 6.3 aperture.

The Reflex Camera. With the reflex camern (Fig. 8) focussing is done visually up to the moment of exposure on a screen at the top of the camern. The Gmflex is fitted with a very fast lens and a shutter giving exposures from is to Forn second, so that it can be used for high speed subjects which would be blorred with an ordinary camera
The general principles of a reflex cannera are illustrated in Fig. 0. $P$ is the plate holder ; I is the revolving back for horizontal or verlical pictures; $F$ is the focal-plane shutter; $M$ is the hinged mirror which swings to the dotted position during exposure of the plate ; $G$ is the ground glass upon which the object is viewed; $H$ is the viewing hood; $L$ is the lid to cover hood when folded down; $R$ is the rising and falling front ; $S$ is the sky shade and lens cover: ' I are the sliding guides and racks; V is the focussing pinion

The focal-plane shutter consists of a blind running close in front of the plate and having in it a slit, the width of which can be adjusted. The blind is wound with a spring, and when released passes very rapidly in front of the plate, giving an exposure which may be as short as rôd of a second

Choice and Use of a Camera. The choice of a camern depends upon the amount of moncy an amateur can nfford, and upon the kind of work it is desired to do. The lens is the most important part of the camera. The best lenses are known as anastigmats, next to them come the rapid rectilinesrs (known also as doublet or R.R. lenses), and after them come the single lenses, the chenpest form, which do excellent work when properly used
If the would-be photographer wishes to do ordinary snapshot work he cannot do better than choose the best roll-film camera he can afford, deciding the size of original negative desired (always remembering that it may be enlarged), and the quality of the lens. Better use a small size with a good anastigmat lens than a larger size with a single lens.

In ordinary use in temperate climates, cameras, either hand or stand, will last for

Figs. 5 and 6. Roll-flm types. Left, Fest Pocket Kodak with time and instantaneous shutter. Right, Ensign with "All-Distance " lens and 3-speed shutter Courtcsll of Kodali, Led., and Ensign. Led
years without nceding any repair. The only care which they require, other than abstinence from rough liandling, is occasional wiping of dust from the inside of the bellon's with $\Omega$ damp cloth.

In all the patterns of the hand camera which have bcen described, with the exception of the rellex, the user has to do two things in order to get a satisfactory picture. Onc is to hold the camern so that the exact picture required is seen in the finder. For this purpose it is best to use the direct-vision finder rather than the misleading, so-called "brilliant" finder generally found ahove the lens at the camera front.
The second essential is to obtain a sharp picture. With a tripod camern the actual picture is viewed on a ground-glass, and the lens moved in or out and adjusted by using a smaller stop until the necessary sharpness of definition is seen. With most hand cameras the distance of the principal part of the subject has to be judged by the eye, and the lens then racked in or out until i pointer on the focussing scale comcs opposite the mark corresponding with the judged distance. Some experience is necessary to judge distances with sufficient correctness.

The smaller the camers and the smaller the stop in the lens the easier it is to obtain a sharp picture, even though the distance of the subject has not been quite correctly judged.
A cause of failure among many beginners is

Camora. Fir. 8 (left). "Graflez" model of reflez camera with bigh speed lens and shutter and focussing mirror. Fig. 9 (above). Sectional diagram of reflex Courtesu of Kodali, Ltd.

causing a certain muscular vibration, the effect of which in the picture is slight fuzziness. In the use of a very small camera it is always advisable to press it gently against some rigid supiort when making un exposure

Even the chenpest hand cameras allow of much better pictures being taken if used on $n$ light tripod. If this is done, a longer exposure can be giren by using what are called the time and bulb adjustments of the shutter, marked respectively $T$ and $B$ on the shutter scale Set to T , the shutter is opened by pressing the trigger and remains open until the trigger is

Camera. Fig. 7. Folding plate nond fim-pack or cut-fim type for advanced work, with rising front and anastigmatic lens Courtesus of Ensiun, Led
agnin pressed. Sct at $B$, the shutter remains open as long as the trigger is kept pressed. By using these adjustments, fully exposed pictures may be taken, even in a very dull light and with the slow lenses fitted to the most inexpensive camerns. But the subject must not contain objects in movement.
CAMOMILE. This is a fnmily of hardy rock and border plants. The flowers are white, silvery grey, and yellow, and the planta, which are mostly summer-flowering, do not need any special cultivation. Anthemis Biebersteinii grey leaves and yellow flowers, 12 inches, and macedonici, white flowers, 6 inches, are suitable for the rockery. Kelwayi and tinctoria grow 2 feet high and are valuable border Howers.
Carnomile Tea. The dried flower-heads of the camomile are sometimes infused at home to make camomile tea. It is made as follows. Soak 1 oz . of the dried Howers in a pint of boiling water in a covered pan for 15 min. Then strain off the liquid and add sugar
to tasto. It acts as a mild tonic and is good for sleeplessness. If given hot it pronotes perspiration. and administered warm acts as an emetic. The infusion obtained from a chomist is of a unitorm strength, and the dose is 1 to 407. 'The drug is used in this way as a tonic and stomachic, as it is an aromatic bitter

A camomile poultice is an old household remedy for inflammation and sprains. For this purpose the flower-heads aro put in a bag and boiling water is poured over them. The oil, in doses of $\&$ to 3 minims, is a stimulant and antispasmodic, like other volatile oils.

CAMIPANULA. Some of the most delightful hardy tlowers for borders and for the rock garden are found among the bellflowers or campanulas : $\Omega$ few are suitable for the greenhouse. The border kinds flourish in sunny or slightly shady places and in ordinary soil which has been dug deeply and manured. llanting may be done in autumn or spring. The best perennial oampanulas for the hardy Hower, border are persicifolia and its varieties Telliam Beauty, blue, and Snow King, white, $2-3$ feet ; glomerata, blue. 18 inches; Hendersoni, mauve-blue, 12 inches: lactiflora, palest blue, 2-3 feet; latifolia macrantha, purple, :3-4 feet : latiloba, blue, 2 feet, and its white variety Theso may be raised from seeds sown in fine soil in a frame in spring or by detaching and replanting rooted pieces in summer. lictiflora may perish after flowering; it is wiso to raise seedlings every ycar or to take care of self-sown seedlings.

The campanulas suitable for the rock garden thrive in moist, gritty soil in slight shade. The best are pusilla, blue, and its variety Miss Willmott. paie blue; muralis, purple blue; G. F Wilson, purple-blue: pulla, purple: garganica, lavender blue; carpatica, blue. The last named is more vigorous than the others. reaching a height of 12 inches when in bloom.
Some of the rock garden campanulas are difficult and must be grown in very gritty, thoroughly drained soil such as is provided by a moraine. Among them are Allionii, cenisia, Rainerii, and Zoysii. Seeds sown in spring in pots of very fine soil placed in a frame provide the best means of propagation.
The chimney bellflower (campanula pyramidalis) is a handsome plant, 3-4 feet high, suitable for planting out of doors or for cultivation in pots. Seeds are sown in March under glass to provide flowering plants the following year.
 Campanula blue. and its white variety, $a l b a$, make charming plants for the room, window, or greenhouse ; they should be sown in suspended pots, for they are of droop.

Campanula. Bell-like flowers of C. Allionii, a rockery plact. Above, C. carpatica, grown as a pot placit
ing growth. They are easily raised from secds in spring and need a compost of loam, lealmould and sand.

The popular Canterbury Bells are varieties of campanula medium. There are single, double, and cup and saucer rarieties in white, pale rose, purple, lavender-blue and other shades. The plants are trented as biennials : sceds are sown in boxes of fine soil in a frame in May. The seedlings are planted on a reserve border when large enough, and are put out in autumn or spring when they are to bloom the following summer. They are useless after having flowered. Plants which do not bloom in the year following seed sowing should not be disturbed : they will Hower exceptionally well the next yoar. See Canterbury Bell.

CAMPHOR. Camphor is a pungent crys. talline substance ohtained by the distillation of the wood of the camphor laurel. The commonest preparations used in inedicine are:
Camphor water-dose, 1 to 2 oz.
Spirit of camphor-dose, 5 to 20 minims.
Compound tincture of camphor (paregoric)-dose,
to 1 lludd dram. This contains opium.
Liniment of camphor and ammonia.
Rubbed directly on the skin camphor has a stimulating effect, dilating the superficial blood reosels, and leading to an immediate feeling of warmth. As this passes off partial loss of sensation in the skin follows. It is for these effects that camphor liniments are so commonly used in chronic rheumatisni, sprains, bruises, neuralgia, etc.

Internally caniphor has a stimulating effect on the stomach, increasing both its muscular movements and the outpouring of gastric juices. It is also a heart stimulant, frequently prescribed when the pulse is thin and feeble. As it has a mild diaphoretic action on the skin. camphor is added to many cough and cold mixtures. The compound tincture of camphor was a common household remedy for colic and diarrhoea. It should not be forgotten that this preparation contains opium.

Spirit of enmphor may be taken at the beginning of a cold, 10 dmps on a lump of sugar. Camphor balls arc used for rubbing on chapped skin It is of service in relieving itching, and for this purpose the spirit may be dabbed on, or camphor water may be used as the basis of a lotion, e.g. zino oxide 1 dram, glycerin 1 dram, camphor water 1 oz. ; to be shaken well before applying.

Camphor Balls. Owing to its high cost camphor is comparatively little used in the home, but its effioacy in keeping away moths and other insects from clothing has long been recognized. Three or four camphor cubes about ${ }_{3}{ }^{3} \mathrm{in}$. square placed in the drawer or trunk in which the clothes are kept will preserve them from all the ravayes of insects. To protect dried botanical specimens a little powdered camphor should be dusted between the leaves of the specimen book.

Camphor is useful in insect powders. Equal parts of camphor and boracic acid is an excellent powder for dusting on animals to prevent attacks by fleas. The addition of pyrethrum powder in the proportion of about three of pyrethrum to one of mixed camphor and boracic acid forms an insect powder which is good against practically all insects. A cheap substitute for camphor, sold under the name of moth-balls, or carbon-balls, is not composed of camphor at all, but of naphtha. lene. A handful of naphthalene balls will protect stored clothes from moth, and the powdered form of naphthalene will take the place of camphor in insect powders.

CAMPHORATED CHALK. A popular dentifrice is made by mixing camphor with precipitated chalk in the proportion of camphor 1 oz . to chalk 9 oz . The camphor is first reduced to a fine powder in a mortar by rubbing it with a few drops of rectified spirits of wine or spirit of camphor. The spirit
soon evaporates when the chalk is stirred in. It is advisable to keep camphorated chalk in a bottle to prevent evaporation of the camphor See Chalk: Teeth.

CAMPHORATED OIL. This is another name for the liniment of camphor, which formerly was official, and consisted of 1 oz . of camphor dissolved in 4 oz . of olive oil. It is used as a stimulating liniment, and is especially useful for chest complaints in children. The official liniment now contains ammonia, and is known as the liniment of camphor and ammonia. Camphorated oil is preferable for young children, however Camphor in sterilised olive oil (camphor 1 part, olive oil 5 parts) is used as a heart stimulant in pneumonia, intluenza, and other diseases. It is injected under the skin in doses of from 10 to 30 minims, and has proved most useful See Camphor.

CAMPINE FOWL. Owing to its economical qualities this fowl is much esteemed by many poultry keepers in Great Britain. It is a prolific layer of good-sized white eggs, and when fattened makes a plump, though rather small, table bird. There are two colours, gold and silver. See Poultry.

CAMPION. There are both annual and perennial kinds of Campion (silene); they flourish in ordinary soil in a sunny position.

Campion. Flower heads of Silene armeria, a pretty
The most popular annuals nee varieties of Silene pendula; they are grown chiefly for spring bedding, as a groundwork to beds of bulbs. Bonetti, deep rose, and Douhle Saltnon, pink, are two good ones. Seeds are sown on a narrow border in July, and the seedlings planted finally in October. Seeds may be sown in April to provide summerflowering plants. Silene armeria, 12-15 inches. has rose-coloured flowers in summer; seeds are sown in April.

Of the perennial kinds the most useful are Silene alpestris, white, 6 inches, and schafta, rose, 6 inches; both are suitable for the rock garden. Silene acaulis, which forms a moss-like cushion and bears rose pink flowers in April, is difficult ; it is most likely to bloom if grown in gritty soil in the moraine. Silene maritima flore pleno is an attractive plant 6 inches high, which bears double white blooms in summer. Sceds sown in fine soil in a frame in spring provide an easy method of propagation ; the stock can also be increased by division in autumn or spring.
CAMP STOOL. In the folding camp stool, types of which are shown in Figs. 1 and 2, the seat is usually of canvas and the legs are pivoted. The commonest type is that in Fig. 1. The canvas is stretched when the legs are open and folded when closed.
Fig. 2 has a wood seat, and the joints at the tops of the legs have to be made to suit, for the seat must fold over, instend of collapsing like the canvas stool. One pair of legs are

Camp Stool. Figs. 1-5. Easily made stools and details of
pivoted to the seat and the other pair are detachable from it, so that it can tum over as if hinged. The pivoted joints generally swivel on a rivet. Another way is to use a screw, as in Fig. 3, instead of a rivet. The piece of wood nearest the head of the screw should be sufficiently slack to swivel with. out turning the screw, and the thread of the latter should be immovable in the other piece of wood The lower parts of the lega are united by cross pieces, varietics of which are shown in Figs. 1 and 2.

Slats on the legs or hack are screwed on. They are often a little longer than the actual distunce over the lega, partly to avoid short grain beyond the screw holes and partly to "void flush surface where one part shows end grain and the other side grain. Another reason is that the projecting ends act as stops for the folding parts.

The round rod connecting the lower ends of the legs in Fig. 2 is glied into a bored holc (Fig. 4), or may be secured by a wire nail. The hole is not bored entirely through the leg. In seats of the kind shown in Fig. 1 the tope of the legs are generally tenoned into the rail the canvas is tacked to (Fig. 5). The tenon may or may not go completely througk. The wood is usually bireh or beech.

CAMSHAFT. The shaft that drives the cams operating the valves (inlet and exhaust) of an internal combustion engine is known as the camshaft. Except in very large engines the cams are usually formed ns part of the rhaft. In the casc of the overhead camshaft, it is so designed that one cam operates two valves. See Cani; Motor Cycle; Valve.

CANADA BAISAM. From this resinous substance, obtained from a Canadian tree, Canada balsam cement is macle. It is used for mounting microscopic objects and mending broken glass. The cement is a thick, glassy liquid prepared by dissolving 3 oz of Canada halsam in a bottle containing 3 oz . of henzol. thie contents being slaken until the balsam has dissolved. The anlution niay be obtained ready prepared from most firms dealing in microscope accessories.

CANAPE. These may be either rounds or fancy-shaperl pieces of bread and butter, cut very thinly, and served with savouries. Cut shapes in tonsted or fried bread are sumetimes known as canapés, but are more often called croûtons.

CANARY. In buying a singing canary it is important to make sure of two thingsthat one is getting a cock bird, and that it is young. A healthy singing pet should live at least 10 years, and mary even reach twice that age, but its length of life will naturally depend on the constitution with
which it starts and on the carc it receives in $\Omega$ week. A piece of cuttlefish bone should be the matters of food and housing. The hest stuck in the wires for tho hird to exercise time to buy a singing hird is in the summer or autumn, when the young birds of the season's brecding are on the market. To be certain of the sex it is necessary to hear the bird sing; for, so far as appearances go, cock and hen canaries are so much alike that only expert fanciers can distinguish them, and even they cannot always be certain.
The plumage should be very close and neat and the legs and feet quite amooth, with delicate claws; if the legs look rough and horny, owing to the projection of the erlges of the scales covering them, and if the claws are long and coarse, the hirll is either aged or has a poor constitution, the overgrowth of horn early in life heing a bad sign. The birl should also be active and restless in its move ments, and alwnys ready to burst into song. The colour is quite immaterial, though most penple prefer a pure yellow bird.

## Best Sinsind Canaries

The smaller breeds of canaries are the best for pets, as they arc more active and hardy than the large kinds, and their song is not so loud and piercing. In fact, the best singing canaries are the small Rollers. These have a beautiful soft running song, without the high notes, which are often rather too prominent in that of the ordinary canary.
To keep a canary in condition, unc should buy as large a cage as space and funds permit. and this should be of the pattern with slips of glass round the bottom to prevent seed being scattered about the ronni. The best shape is oblong, and the cage should be hung in a room where the temperature does not vary much, placed well out of any draught, out of reach of the cat, if one is kept, and not above the gas.

The food should be canary and rape aeed, and the latter should be the brown summer rape, at any rate for Rollers. A few grains of hemp may be given daily as a treat; but this is too fattening a seed to be given at discretion. A spray of millet to peck at makes a change. The only delicacies that should be allowed are green food or fruit, which should be given daily. In summer groundsel, chickweed, Howering grass, or dandelion can generally be had; tender lettuce and watercress are also gond, and a slice of ripe apple is much appreciated. But too much of this raw fond should not be given, as if stale it is injurious; nor should any be used in a frosted state in winter. When the hird is moulting it may have a piece of stale sponge-cake daily, but not at other times.

Sand should always be available so that the bird can select the grit it requires for grinding its food; it is usual to cover the drawer of the cage with this, but as long as a teaspoonful or so of sand is put down whenever the cage is cleaned, the drawer can be just as well covered with sawdust or cedar litter. It is best to cover the drawer of the cage with paper bc. fore putting the litter on, and the cage should be cleaned out after the bird has had its bath, which it should have at least twice

put out in late spring, not in autumin. Moreover, in an aviary there should always be at least three hens to every cock, with a proportionate number of nests. If they are jimperly boused, they will bear the winter as well as British finches

CANARY: A White Wine. Wine produced in the Canary Islands was formerly drunk in England under this name The best is called Bidogne or Vidonia winc. It is a dry, white winc somewhat resembling Madeira, but with less body and perfume. The name Canary was formerly applied gencrally to dry white wines, many of them inixed with sugar and cinnamon.

CANARY CREEPER. Grown as an annual. the canary creeper is popular for training over trellises, up porches and above

Canary Creeper. $\begin{gathered}\text { Sprays of flowers and leaves of the } \\ \text { quickrowing creeper }\end{gathered}$
window-boxes. The secds are best sown under glass in spring. in pots or hoxes, and the young plants sct out in May or June. The plants grow fast in moist fertile soil, and soon come into bloom. The llovers are amall and a bright pale ycllow in colour, and are produced very freely. For rapidly covering fences, concealing ugly spots in newly formed gardens, this creeper has few equals.

CANARY GRASS. A hardy perennial, canary grass or phalaris, of 3-4 ft. high, has various names in different localities. Thus it is known as bride's laces, French grass, gardener's garters, lady grass, lady's garters, lady's laces, painted grass, ribbon grass, silver grass, sword grass. It is a fickle waterside plant, which frequently reverts to type. It thrives in any soil which contains plenty of moisture, and can bo propagated by division in spring. In a variegated form the leaves are strijed with white or pink. The species Canariensis is not often cultivated Its seeds are the well known shining canary seed of bird-lovers.

Canary Seed. When ripened and dried this is sonietimes given, slone or forming part of a mixture. to canaries and other birds.

CANARY PUDDING. Well grease some small moulds place 3 oz . each of butter and castor augar in a basin, and beat them to a cream. Mix together 6 oz . of Hour, one teaspoonful of baking powder, and the grated rind of a lemon. Well beat two egga, and then beat them into the butter and sugar. Add the flour, etc., lightly, also the strained juice of a lemon, and lastly 2 tablespoonfuls of milk. Half-fill the moulds with the mixture, cover them with a piece of greased paper, and steam them for of an hour. Turn them out and serve with jam sauce.

CANCER. For malignant tumours of all kinds the general name of cancer is often used, such tumours having the characteristics of growing again when removed, of reappcaring as secondary growths in organs perhaps far distant from that attacked hy the original growth, of leading to wasting and great general wealiness, and of eventually killing the patient

Cancer of the throat is said to be frequent in smokers, and thesc may have induced chronic catarrh by tobacen smoke. A jagged tooth may produce cancer of the tongue. In countries where the men eat their food hot cancer of the stoniach is common, whereas it is almost unknown amongst the women, who eat their fond cold Cancer of the stomach occurs usually on that part of its lining which would be irritated by hot liquids.

The chief signs of cancer are a rapidly developing tumour or the formation of an ulcer. with a hard Hattish hase, and irregular, hard edges. Contrary to common belief, pain is not a common early symptom, though it may be very severc in the late stages. The treatment of cancer is the extirpation of the growth by opcration, and if this is done early enough the likelihond is that the discase will not recur. Unfortunately too many people put off seeking advice about lumps or sores or haemorrhages till the disease has obtained a wide hold on the parts affected or has heen disseminated to distant parts.

Radium and X-rays have produced good rusults, but, with the exception, perhaps, of roclent ulcer, the proper treatment of cancer is carly operation. The other forms of treatment find their proper aphere in those cases which unfortunately have been allowed to get heyond a point where operation is of any use. They may prolong life, but can to little more.

Relief of Cancer. To mitigate the ravages of cancer much research work has been done, chiefly by the Imperial Cancer Research Fund, 8, Queen Strect, Bloornsbury Square, London, W.C.I, and the Jritish Empire Cancer Campaign at 12, Grosvenor Crescent, London, S.IV.I. For sufferers there is a National Society for the Rclief of Cancer, at 15, Ranelagh Road, London. S.W.I, and Cancer Hospitals in Fulham Load, London, S. W. 3. and Nassau Strect, London, W.I.

CANDELABRUM. A holder for two or more candles, the branches of the candelabrum may be attached to a bracket for fixing on a wall, or to a standard for placing on a table. The wall canclelabrum with two or three branches has been extensively adapted for electric light, the bulbs being shaded by scrcens of silk fixed vertically.

Brass candelabra are often lacquered, in which case they should be simply wiped with a soft cloth, and only sponged with warm soapy water; any attempt at polishing will destroy the lacquer. If medallions of Wedgwood ware or china are let in, do not loosen the cement with which they are fixed by too hot water or much rubhing.

CANDIED PEEL. There are three kinds of candied peel, viz. citron, lemon, and orange, and the method of preparation is practically the same for each.

In the following $S$. American recipe for preparing candied peel at home, rinds left over from jellies, etc., can he utilised. Soalk the rinds from $\&$ oranges or lemons in slightly salted cold water for 3 days. Then drain, rinse, and boil the rinds in freah water until they are quite tender. Make a strong syrup) by loiling together 2 hreakfastcupfuls of white sugar and onc breakfastcupful of water for 5 min., keeping the pan uncovered.

Put the conked rinds into a brsin, pour over them the boiling syrup, cover the basin and let it stand for 2 days. Ifter that time strain off and hoil the syrup). Put in the rinds again and boil them until they look semi-transparent.

Probably they will need $1 \overline{5}$ or 20 min. hoiling Talie out the rinds, lay them on llat tins, put a little of the syrup in the hollow centre of each piece, turning them up like cups, sprinkle all over with castor sugar, and dry them in a cool oven. If they are not dried in one day, continue on the next. Keep the rinds in airtight tins, using them as required. Besides its use for flavouring calies, puddings and other sweet diahes, pee! can be cut into shapies for the decoration of shortbread.

CANDLE. The cheaper sorts of candles are generally minde of paraffin shale wax. Others are of stearin, which is pure white, harder, and more opaque than the paraftin cand!e and burns longer, hut is more easily hroken. On the other hand it can withstand hot weather when the paraltin loses its shape A inedium grade is manufactured from an admisture of the two, and costs very little more than paraflin. Tallow candles, which are a dirty yellow in colour, are now chielly used by plumbers and in engineering works, having leern superseded in the household ly the cheaper and more serviceable wax candle. Spermaceti, which is obtained from the cachalot whale, is employed in the nanufacture of the most expensive candles.

For photographic purposes, carringe lamps, and invalid food heaters, the candles in usc are similar in composition to the domestic was candles, lut are made with a special wick, which generates little heat; othcrwise, being burnt in a small enclosed space, the was would quickly dissolve.

Candles are sold by weight, the various size units, sixes, eights, 12 's, ctc., indicating the number of candles going to the pound. The usual sizes for domestic use are sixes to 14's. All sizes are equally economical, as the smaller thie candle the smaller is the wick inserted, and therefore a given weight of candles of any size will burn the same time as a similar weight of any other size. Candles, it should be noted, improve with leeping; if the was in allowed to harden, they will last longer and give a better light.

Decorative Uses. Coloured candles arc used in room and table decoration, in silver, glass, or other ornamental candlesticks. The
 four lights, c. 180010 Courtesy of Chapple \& Montell, London

Candleshade. Stages in cutting out parchment to make an ornamental shade best coloured candles are solidly dyed, and and quarters of the silk are made to correspond not surface tinted, and taper in shape. They with those of the frame. Attach the silk to may be obtained in many shades to tone the covered wire by sewing, the raw edges with any colour scheme Candles are often being tumed inside.
used for dining-table lighting in preference to other methods of illumination. Miniature candles in various colours are used to border a birtliday cake.
Self-fitting candles are usual in white, but if a colonied candle will not tit the candlestick,

Candleshade. Lelt. candleshield consisting of orange silk stretched on a homemade wire frame, decorated with a daisy stencil and edged witb gold galon. Above, candleshade made from drawing paper
immerse thie end of the former in a cup of warm water, and while the wax is still soft, push it into the candlestick.
Candle grease may be removed from clothes by placing a piece of blotting-paper over tho grease mark and pressing it with a hot iron. In obstinate cases fresh pieces of paper should be placed under the imn until all the spots have disappeared. See Night Light.

CANDLESHADE : How to Make. Silk shades may be made on wire frames with thin silk and necessary trimmings. Fluted or square shades are a change from the usual round shape; or the shield type of shade can be used when the candles are placed on shelf or bureau, or for electric candle lampa in wall lighting.
To make a round or square silk shade first cut narrow strips $\frac{1}{2} \mathrm{in}$. wide, either selvedge, or crossway; if there is plenty of material available choose the latter. Cover the whole wire frame by tightly binding with the strips of silk; when starting a new sttip, sew securely to prevent the material slipping. When the frame is completely covered, cut pieces of silk sufficiently deep to allow neatening at top and bottom. The length of silk depends whether it is to be perfectly plain or to be gathered or pleated on the fraine For the Intter method, measure round the bottom of the frame, and allow about as much again for the gatherings.

A good trimming is a tiny ruching (see Bag) of the silk sewn on the edges of the frame, or coloured wooden beads of different shapes may he threaded to hang from the frame in a kind of fringe, or a very narrow silk fringe to mateh the shade may be used on the lower edge. Such shades are suitable for electric candle lamps

Silk shields may be plain or designs may be painted or stencilled on them. The edge should be fastened with a cord or narrow gimp. Mandarin inks are the hest colouring mediun to use for sliades as they are transparent. Stencilled designs may be outlined in embroid. ery silks, as in the shade illustrated Parchment shiclds can be hought cheaply, and decorated hy means of oil-paint transfers.

When making round parchment and paper shades, the stiffness of the medium may render a frame unnecessary, and the shade, when completed, is placed on a holder with adjustable clip. Although the word parchment is used, real parchment or vellum is not often employed for shades, owing partly to the cost and the limited supply, partly to the fact that more skill is required to work on vellum. To ob. tain the pattern, use any suitable paper ; pencil a circle round an ordinary meatplate for outer cipcle and round a cup or small saucer for the small circle The distance between the two circumferences gives the depth of the shade. Cut this wide circle in half, and there will then be patterns for two candleshades.

Amongst the simplest and cheapest kinds of candleshades are those fashioned of cartridge paper. These may have plain tops and coloured borders, or may be hand-painted with Chinese designs of dragona or birds, or illustrating the Willow pattern. The choice of colouring and design must he influencerl by the room and candlestick. See Lampshade.
CANDLESTICK. In places in the country where neither gas nor electricity is available the candle is still the only illuminant for the bedroom, which

Mark the lialves and quarters of the strips of silk with a contrasting cotton, alsn the top and hottom rims of the frame. Run a gathering thread at both top and bottom edges of silk, join to form a circular strip, and gather the silk and place it in position on the frame, raking care that the halves

Candlesticks in mood, that on the left of oak, the other being turned complete from a plece of cocus Courtens of Georue Adums
is usually provided with standard candleaticks for dressing-table and mantolshelf. In addition a candlestick with a base for holding the matchibox is placed on the hall table early in the evening for each person in the house.

Where candles are not $a$ necessity, the candlestick is used for its ornamental quality, enlianced by coloured candle or sharle. Very tall standarda are made in polished or acquered woods, or severe designs are carried out in metals, and faceted mirror glass The

Candlestick: antique examples. 1. English, late 18th century candlesticks, that on the left being of gilver gilt, the other two ol silver. 2. Brass church candlestick, early 16 th centurg. 3. Flemish brass double candlestick, 16th centurg. 4. English patterns: left, late $17 \mathrm{th}^{2}$ century : right, Cromwellian
1.3. by nermission of the Director. Vieloria and Albert Museum
older types in pewter had a base shaped like a bell and a grease tray half-way down the stem. Later models of brass, copper, or silver had bases square, round or oval with columns surmounted with a capital to form the socket, or with grooved or spiral stems. These are particularly suitable for dining-table use and in crystal glass are also popular and sometimes adapted for electric lamp candlea
Wooden candlesticks of simple yet pleasing pattern are readily turned by the amateur who has a small lathe or a mandrel. Those shown in the previous page, worked in oak and cocus woorl reapectively, were madc on a Verschoyle mandrel (See Lathe). The larger of the two is $10 \frac{1}{2} \mathrm{in}$. high; the base (turned separately) is 48 in . across. The other pattern is turned complete from $n$ piece of cocus. It is 8 in . high, the hase measuring 3\} in. Sec Mandrel; Wood Turning
Bedroom Candlesticks. Portable candle sticks of plain coloured pottery with a screening back are a good choice for bedroom use, as they protect the wick from draughts, and also serve to arrest grease splashes Candlesticks in silver or other metal which have no special fittings such as these should possess a wide tray to catch any grease as it falls. A good deal of trouble in cleaning is saved if a Hat glass disk, with a hole for the insertion of the candlc, is placed on top of the candlestick

CANDY. The accepted definition of this term is a sweetmeat made of hoiled sugar, with numerous tlavourings and colourings added. See Sugar Stick

CANDYTUFT. The annual varieties of candytuft are favourite odging Howers for beds and horders They are of various colours,
 crimson. purple, rose, lav. cnder, etc The plants are of the easiest possible cultivation and make a brave showfor several weeks Seeds are sown in April where the plants are to bloom in summer and the seedlings slooutd be thinned to about 6 inches a part.
Candytuft. Flowers of the
Derennial Lttle Gem variety
There ale some charning fowers among the perennial condytufts. They look best in the rock garden, where they will drape the houlders with shects of hloom in spring. They llourish best in well drained soil and should le planted in autumn or spring. The lest sorts are Iberis sempervirens, garreyiana, and gilsraltarica, all with white Howers. One named Little Gen is of compact growth and suitable for small rock gardens. Cuttings taken in June and placed in pots of sandy soil in a frame will soon form roots.

## Cane: The Material and its Uses

## Hints on Making and Repairing Cane Furniture

Bamboo; Basket; Rush are other articles in this group. See also Armchair; Chair; Table, etc.

By retson of its qualities of lightness and strength, cane has many uses in preference to wood, whether in the form of circular rod or split into strips. Large diameters of rod are used for the framework of light chairs and tables, for oric-
 ket bat handlos, and similar purposes. Walking - sticks and fishing.rods are often of cane Small canes arc used similarly to willow for wicker. work articles. Naturally tlexible, cane is still more easily bent hy soaking in hot or cold water, or by the Cane. Fir. 1. Principal varieties cane used for furnitare

Cane furniture has much to reconmend it for in addition to its durability it is easily and quiokly cleaned. It does not collect dust so readily as upholstery, and may be washed with warm water and a scrubbing brush, or with the garden hose. It is important that cane furniture should not be too springy, since the spring only lasts a short time, and in order to obtain it a good deal of strength has to be sacrificed.
The weight is another test of quality, the heavier furniture betokening a strong frame. When buying cane furniture special attention should be paid to the finish round the top and arms of the chairs, etc. In properly made cane all this is woven and has no piait or beading fixed on with tacks.

There are different varietics of cane, as scen in Fig. 1. The outer skin is retained for all purposes where strength is clesired. The cane used for the back and seat of chairs is narrow strip, consisting chiefly of the outer dry heat, which prevents cracking and splitting when sharp bends liave to be formed
The split cane is used for purposcs where the whole cane would not be sufficiently flexible or would be needlessly thick. One of ita chief uses is for the seats of chairs. It can also be very closely woven to form a kind of fabric. The hard outer skin gives great tensile strength to very thin and narrow strips. The interior, or pulp cane, is also strong, and is used in strips for winding round the nailed-togcther framework of cane chairs and other articles.

The woven fibre is manufactured into furniture which shows to great advantage when coloured. Besides its use as garden furniture, woven cane of this type can be utilised in nurseries, bedrooms, and country living-rooms, as it can be procured or painted to tone with any colour scheme. The table illustrated is glass-topped in green glass to tone with shot green and gold paint used for the woven cane.
 of wider cane is put round on top of the seat
skin, and can be bought from most hasket makers and furniture repairers.

How to Re-cane Chairs. In the course of time chairs require re-caning, as the cane gets strained and slack and breaks in places. Thic new cane should be soaked in water for about 24 hours before using. This not only makes it more pliable, but it gets swollen by the water and dries and shrinks after the worli is completed, and this strnins it tighter than would otherwise be possible.
The work usually commences lyy removing the old cane from the seat 1 portion may be

Cane. Glass-tonped coffee table in Lloyd Loom woven fibre, and procurable in many colours
cut out and kept as a pattern for reference in case there is trouble in lacing correctly. All round near its inner edge the seat has a row of holes, about $\frac{3}{\pi}$ in. dinineter, and $\frac{5}{5} \mathrm{in}$. apart. In some of these wood pegs will be found wedging the cane, and these must be punched out. Commence the new lacing by putting in double strips of cane from back to front of the seat, as in Fig. 2, the rounding or glossy side of the strips being kept uppermost. The dotted lines show how the strips pass beneath from one hole to the next. A steel awl and a number of tapering wond pegs (Fig. 3) are used for temporarily holding the cane at each hole, while it is strained across the seat to the next.
Then the lacing at right angles to this is put in similarly, except that it goes under and over alternately, as shown in Fig. 5. This separates the double strips slightly. The next stage is to insert single diagonal strips. These also pass beneath the edge from one hole to the next. Details of crossing are shown in Figs. 5 and 6. As seats are not square, it is not always possible to get geometrical accuracy around the edges, and canes must be put through the most convenient holcs.

When all the lacing is done, alternate holes are permanently pegged, and an edging
to cover the holes. It is pegged in at the corner holes, and tied down (Fig. 7) with cane at the alternate holes, which have not leen pegged, the cane passing from one hole to another leeneath the seat. Where lengths have to he joined the cane is tied with an ordinary linot, as in Fig. 8.

Making a Pulp Cane Chair. The pulp cane chair in Fig. 9 consists of a framework, as in Fig. 10, of thick cane or villow rod, roughly fitted toget her and nailed in the first place and afterwards strengthened, as well as given a neat appearance, by the pulp cane binding which is wound around the joints and rods, and forms a woven or laced fabric in the spaces which have to be filled There is a great deal of variety in such chairs, both in design and details of construction.

In the framework of these chairs two rods are often used side by side instead of one They need not depend entirely on the binding for holding them together, for they can be nailed. Smnller members joining main ones, as in Fig. 11, are nailed first and bound after.
Where joints occur, the parts are usually cut nore or less to fit each other. Fig. 12 shows an end of one rod hollowed to lit the side of another. A nail would usually be driven as shown, and afterwards strands of split cane might he wound round both. Rods crossing

fig. 9

CANKER : In the Garden. This disease affects fruit trecs. chiefly npples and pears Predisposing causes are undrained soil, careless or late pruning, or the attacks of insects Frequently where a branch has been torn off by the wind or sawn off roughly, the bark fails to gow over it. and an entrance is left for the fungus spores Apple canker is evident around the fruit spurs, and as soon as it is detected the branch afficted should he cut far lack from it and burneal. The fruit of cankered times is often cracked and worthless See Appla; Pear.

The tern canker is sometimes used synonymously with roup in ©owls, but it is in reality a development of diphtheritic roup in its last stages. See Roup

CANNA, or Indian Shot. These handsome plants may be grown in pots in the greenhouse or in flower beds out of doors in immer: The broad foliage is green, brown, ol hronze, and the flowers are of many colnurs.

Cannas are not hardy, and need to be wintered under cover The strong, thick rootatocks form large masses, which can he taken out of the beds in autumn with soil adhering and stored in a frostproof place for the winter. These clamps can be divided in spring. It is usual to pot each division, and to plunge the pots in hottom heat, but thovean be started in a warm frame or grcenhoirse. When they have hegun to grow they should be hardened off in a cold frame,
Cane. Figs. 9-15. Processes in the construction of a chair in pulp cane
hard. Germination is hastened by soaling the: seeds in water for 12 hours, then sowing in a warm greenhouse. The seed niay be covcred with half inch of soil.
When grown in pots the plant needs a rich, porous compost A mixture of three pails loam. one part lenf-mould, and two partis decayed manure, with plenty of sand, suits it It should he well watered, and when the flower spikes push up, liberal doses of liquid manure should be applied.

CANTALOUP. A small ribbed variety of the musk-melon, it was originallo cultivaterl at Cantalupo, near Rome, and so ohtained its name. A good wny of serving it is to embed it in crished ice for 10 hours or more. then cut it in halves or thick: slices, and remore the secds. leaving on the rind Serve with a lump of ice in each portion, and hand salt and fine white sugni, some people preferring to eat it with salt. See Melon.

CANTERBURYBELL (Campanula medium). This is a great farourite among hiarly horder plants: if the dead flowers ure

Canterbury Bell. Spray of bily-like fiowers of this vigorous and hardy garden plant
picked off regularly the plants will blnom throughout the summer from early July. The Canterbury hell is useless after it has flowered, therefore $\Omega$ fresh stock of plants must be raised each year. Seeds are sown in May in a box of fine soil in a frame, and in due course the seedlings are planted on a reserve border: there they remain until October, when they are set where they are to flower the following year. Any plants which do not bloom then should be left undisturbed: they will form giant specimens the next year.

There are many varietics of Canterbury bell -single, double and cup and saucer flowers in purple, rose, lavender, white and other ahades. All thrive in ordinary soil that has been well cultivated. Those who have no room for raising seedlings may buy plants in autumn or spring.

CANTHARIDES. The drug knoirn as cantharides, or Spanish Aly , is prepared from a dried beetle found in Spain, Russia, and Southern Europe. Preparations used are tho plaster, tincture, and an ointment.

Its intense irritant action makes the drug valuable for external use to produce redness or blistering of the skin, and so relieve deepseated pain and inflammation, e.g. in such conditions as pleurisy and sciatica.

A mixture of one part of cantliaridine ointment and two of soft paraffin is recommended as a pomade to stimulate the growth of hair.

It should be discontinued for a short time if is a mistake to have canvas shocs tightly much irritation is produced
In poisoning, give an emetic of mustard and water, and then white of egg. No fatty substances should be employed. See Blister: Hair: Poisoning.
CANVAS: Its Domestic Uses. Nany different kinda are made, and the name is

Cavas for embroidery. Leib single-tbread canvas; centre, donblethread or Penelope canvas: both actual size. Right, canvas used as the rroundwork lor wool rars
cloths woven from hemp, flax, and cotton libres. In packing-canvas nothing beats the uld-fashioned hemp for durability, but it is so much dearer than jute-hessian that it is little used. Jute frays more ensily than hemp and does not stand sunlight or damp во well
Green rot-proof cotton canvas, as used for cart and rick-covers, trunk coveringe, boat and motor car covers, in addition to being waterproof is immune against insect pesta, for its green colour is due to salts of copper. Sailcloth and tent-cloth, hoth olose-woven fabrics, and made from linen or cotton, are often called canvas ; the linen kinds are the stronger and more expensive. What are known as tailors' canvases or padilings are used in bisting, stiffening and inter-lining garments, and it is important that these should not shrink or stretch if the garment is to retain its shape. Canvases for interlining are made also in hair

Artist's canvas is a special flax fabric made for oil puintings. Fancy cottons made in square and sometimes open-work weaves are described as canvases. Wool canvas is a rather open-textured fabric. Ordinary tarpaulin is a tarred canvas.

Double-thread canvas has two threads running vertically and two horizontally close together, so that there is a small square space between the threads This canvas is employed for the coarser varieties of tapestry, and it is the chief groundwork for cross-stitcl. When stiffened it is used for tops of stools, and cushion covers, worked in silk and wool respectively. It is also uscd for bead purposes and hags. There are also two varieties used for homemade rugs, the first size with a mesh a bout $\$$ in for ordinary rug wool, and the larger size cinvias for cable wool. On the latter, though not much in use, home-miade rugs can be made to resemble sheep-skin rugs. Finer enshroidery is worked on single thread canvas See Bead; Cross-stitch: Hessian; Waterprooting.

CANVAS SHOES. Canvas or stout linen is employed for making the uppers of a rariety of shoes and also for cricket and sports boots. The soles of canvas shoes may be of leather, ns in cricket shoes In this case the canvas or linen drill should be of strong texture, and the soles should be made of well-tanned leather so that it will hold the spikes without bending or warping, a common fault with cheapquality cricket shoes.

Canvas shoes for tennis and sports wear are soled generally with rubber, which is either attached by stitching or solutioned to the uppers. It is in this attachment of the soles to the uppers that the variation in the quality of plimsolls is most apparent. In a poor quality, cheaply made, the sole will frequently after a few days' wear part comprang with the upper,
fitting. Not only does the canvas or cotton not stretch with the movement of the foot, ns is the case with leather, but it actually contracts and shrinks when wetted Rope-soled canvas sandals are worn for bathing.

In cleaning white canvas shoes the pipeclay should be wetted and a thin coating well rubbed in. Care should be taken not to soak
the fabric too much or it will sbrink in drying. They should preferably be dried in the sun.

CAPACITY. Electrostatic capacity is mensured by the quantity of cleotricity which has to be transferred from one isolated conductor to another to produce a potential difference of one volt. The unit of capacity is the farad, and is the capacity of a condenser which requires $n$ charge of one coulomil to increaso its potential by onc volt. A microfarad (mid.) is one millionth of a farad. See Condenser; Diclectric.

## Cape. Sec Cloak.

CAPE GOOSEBERRY. The true Cape Gooseberry is Physalis edulis, from South Afrioa, which provides edible fruits in that country. In British gardens other kinds arc grown for the anke of their large orangered oniamen tal "fruits" "hiol cluster onsteins about 2 feet high. Thesc "fruits" are really enlarged calyces within which the truc fruits are found They are popularly known $\begin{gathered}\text { a } \\ \text { Chinesc }\end{gathered}$ and Chinese lanterns, and are most decora. tive in the garden and in vases indoors

when cut. Physalis Franchetti and Bunyardii provide the finest fruits. Buth are hardy perennials suitahle fur planting out of doors in well drained soil and a sunny place. They may be increased ly division in ear'y autumn or by عowing seeds in a box of soil in a frame, or out of duors in spring.

CAPER. This name is given to the small, dull-green, unopened flower-buds of a trailing shrul, which grows wild in Greecr, N. Ifricn, and various parts ol S. Europe. It is cultivated to a small extent in Great Britain.

The bud is picked long before the llower is ready to bloom, and the further it is from that stago the more pungent the condiment

After the buds have been picked and left in vinegar for a time they are sorted into sizes by sifting them through sieves with mieshes of varying sizes, then loottled and namod accordingly, being classilied as nonparcil, capuchins, capotes, etc. Capers are used for farnishing purposes and for flavouring sauces.

Caper Sauce. This may to either white or brown To make the white sauce, melt 1 oz . butter in a small saucepan, add 1 oz flour, and cook them together for about 3 min . over a slow lieat without browning them. Next add gradually a pint of hot stock, stir it till it hoils, Then cook it gently for 5 min. Take 2 tablespoonfuls of capers, cut them in halves, add them and 2 teaspoonfuls of caper vinegar 10 the sauce. Seuson it to taste with pepper and salt, and it is ready to serve. If the sauce is to be served with boiled fish, use fish stock

Fur the hrown sauce, take 1 pint of any gond brown sauce, season it carefully with salt, pepper and grated nutmeg, and hoil for 15 min . with 2 tablespioonfuls of caper vinegaratid add to it one tablespoonful of halved capers.

CAPERCAILZIE. This game-bird is also called capercailie, woud-grouse, or cock-of-thewoods For roasting it in first prepared and trussed us for a turkey or fowl, and inside is placed 4 oz of raw beefsteak, which is, taken uut after the cooking and may bo used in the preparation of patties, mince, etc. A few slices of fat bacon are laid over the lireast of the bird, with slits cut in the rind to prevent them ourling. The bird is then put in a linkingtin and roasted in the oven or before a clear bright fire for about one hour, with frequent basting with milk. When it is abuut threeparts couked, remove the slices of bacon-save them also for some cold-meat dish-dredge a light dust of flour over the bird, baste it, and let it thoroughly finish cooking.

Tu serve, remove the slowers, strings, etc., pour round a few sponfuls of clear, hot gravy, and garnish the dish with tufts of washed watercress that have been seasoned with a few dropse of salad-oil and a little salt and pepper. Extra gravy and bread sance ' $q$ v.) should accompany the bird. A bird will be eufficient for about seven or eight persons.

CAPON. This term refers to a cockerel, apecially treated when voung and reared for the table, not for brecding purposes. It becomes specially large, and is plumper and better flavoured than ordinary fowls. Capons are trussed and cooked in the same way as directed for fowls. Sce Boning

## Cappings and Cornices

## Some Typical Moulds and How they are Fitted

Such entries as Bookcase; Cabinet; Cuphoard may usefully be read in association with the one below. Sec also Dowelling; Moulding

When setting out an article which is alout to be constructed, special regard must be paid to the importance and finish that a suitable capping or cornice is capable of imparting to the assembled effect. Too frequently any section that may be ready to hand is worked in without the slightest attention to its suitability.

In fitting cappings, these may he finislied with plain square edges, or the edges may be rounded, nosed, or thumb-moulded; or, again, the edges may be beaded or have a bevel taken off the upper or lower edge accond. ing as this is below or above the edge when fixed in position. Generally speaking, however, a three or more membered mould will give a
distinctly enhaneed effect The simplest form of capping is that used as a terminal tinish for posta, and frequently employed in the construction of bedstead ends As indicated in Fig. 1, the caps on a 2 in . by 2 in . post tinish about 4 in . by 4 in . square by $\frac{7}{8}$ in. thick with a Hat top This portion is improved by a raised and rounded finish. for which purpose a 4 in . by 4 in square of $\}$ in. thickness is glued on to the flat, or the detail can be finished from material $1 \frac{1}{8} \mathrm{in}$. thick net. These cappings are best fixed with a stub tenon cut on top of post to enter $"$ corresponding mortise in capping, but threc small dowels can be utilised instead. One dorel is a mistake, as the capping will be liahle to tivist out of the square.

The capping mould, often seen at the back section is sometimes completed by glueing $\Omega$ of a hall table or dinner wagon or on the top of lining slip behind in the angle formed by the a washing-stand back, is sonetimes fixed to pitch of the mould in other instances it

Capping. Patterns described in the tezt, showing in section mothods of attachment and other details By arrangement wilh Evans Bros., Lid., London
the face of the rail, and in other instances (when below the level of the eye) is fitted to the topedge of rail. In the former case it may be glued and pinned into position, but is hetter screved from thi back (Fig. 2), and either mitred or returned on itself at cnds with the chisel. Better work nay have the section rebated into the face of rail, as indicated by clotted line. When fitted to top edge, the eapping is dowelled on as Fig. 3, flush at back, and with a projection of $\frac{7}{8}$ in or $\frac{7}{8}$ in. at front, according to the section in use. The bead grooved in below the capping mould in Fig 2 is often added when a shelf is not provided above the tiles or marble panel of a washstand back. If well above the cye, the capping (Fig. 3) might be screwed instead of being dowelled into position.

## Methods of Fixing Moulds

The cornice mould of a well-made article of minor dimensions would probably be worked on the edges of a solid top of $\frac{3}{3} \mathrm{in}$. or $\frac{7}{8} \mathrm{in}$. thickncss, whilst in common, hastily constructed work it is often merely glued on or pinned on. A neat method is that indieated in the section, Fig. 4. The mould is let into the fricze rail about $f$ in., and a $\frac{z}{8}$ in. top fitted into the rebate formed by the rise of the mould beyond the top edge of rail. Another method is shown at Fig. 5, the mould being tongued to a lining slip behind it to form a rebate for a dustboard to drop in and be screwed. Either of these methods could be npplied to a wall cabinet as well as to cupboards of larger size.

In some forms of cabinet work the cornice and frieze may be built up in the manner indicated at Fig. 6, the top being housed into the frieze rail, and the frieze mould mitred at corners out of slips about $2 \frac{1}{4} \mathrm{in}$. by $\frac{1}{4} \mathrm{in}$., glued to under edge of frame. Stock moulds miny be obtained from the furnishing wood yards, the whole section of which, as at Fig. 7, is cut out of 1 in . material or less, to be glued into position on the cornice framing. Such a
will be held by angle blocks at intervals of 9 in . or so apart. The top is shown as screwed down to the framing, and the method with lining slip is suitable for an article such as a china cabinet. Below eye-level a solid $\frac{z}{8} \mathrm{in}$. or $\frac{1}{3}$ in. top to overlap had best be provifled, to be glue-blocked under into position. The entry-holes of screws are unsightly, and, even when well-stopped, tend to show through the surface finish owing to shrinkage of the wood.
Another fixing for the upper mould is that given at Fig. 8, the top being made to project beyond the carcass sufficiently to cover the pitch of the section below it, which is glued into position above and helow Such a section would be suitable for a divarf linen cupboard of Jacobean type, or could be adopted in the construction of a mantel.
An instance of a solid top mould is given at Fig. ?, the rail under being rebated to receive a lining flat of $\frac{s}{8} \mathrm{in}$. material or so, thus extending the mould with a sort of frieze effect. l'raming and top are glue-blocked behind, and the eection is very suitable for an oak' cuphoard. In the section at Fig. 10 this method is developed, the arrangement being useful where it is desired to achieve a carved friezc effect after the Jacobean style.

## Attachment of Loose Cornices

Loose cornices separately made to be casily detachable from bulky pieces of furniture (such as a wardrobe) are usually fixed into position by means of glued blocks on the upper part of carcass. Cornice and frieze moulds are mounted upon a separate framing. In cheap work the framing nay be found to be merely mitred and nailed together at front and sides, with a glued block in the inner angle. A back rail is nailed and glue-blocked at back to hold the whole thing square, a stretcher rail being also similarly fitted in centre. The cornice mould is glue.blocked into position and nailed, and a dustboard is usually omitted, as indicated in the part plan (Fig li).

A slietch of a loose cornice is given at Fig. 12 showing it in position on wardrobe carcass as viewed from above. Height over all may work out at 4 f in. to 6 in , according to detail. The method of dovetriling front and side rails of framing is given at Fig. 13, and from this it. will be seen that the mould is mounted higher than the front and side rails to form a rebate for the dustboard top. The side rails have the back rail fixed to them by means of a housed dovetail, and the stretcher rail between front and back rails by means of a dovetail into each. If properly done the whole thing should be thoroughly firm when glued up. The throughdovetailing is masked by means of facing slips of the hardwood in use ( 1 in. thick or so), glued on after mitreing at corners. The width of these slips is determined by the height of the cornice mould which beds upon the top edge of them.

Another effective method is to pitch the cornice high (Fig. 14) and rehate it to receive the dustboard.

When fixing a cornice mould, in cramping up after glueing it will be necessary to use a suitable block to fill the space caused by the pitch or projection of the members between the jaws of the hand-screw. Where the Hat member, often dentilled, exists a square slip of necessary size will suffice, but in other cases it may be necessary to scribe the block to prevent it slipping when pressure is applied. It may be found that use can be made of a spare cut of the mould in use for that purpose, possibly with a layer of felt between to avoid bruising any points of contact.
CAPSICUM. This plant is grown for the sake of its red and yellow fruits, so much in demand for pickles and flavouring. It is raised from seeds sown in a lieated glasshouse in March; the scedlings may be grown in (i-inch pots or planted out of doors in a sunny place in lunc. They flower in July, and yield pors ready for picking eatly in September. They are very ornamental when in full fruit.

Chilli or Chili pepper is obtained from capsicum, and cayenne pepper is the ripe fruit dried and ground. Fresh red or green chillies are procurable at certain seasons. Capsicums are sometimes stufled with forcemeat and served as a sa voury. (See Cayenne; Chilli.)

In medicine capsicum is valuable because it stimulates the flow of salivary nnd gastric juice, thus promoting appetite and digestion, and correcting dyspepsia. It relieves liatulence, and $\frac{1}{1}$ to 1 grain may be given in $n$ purgative pill to prevent griping. For theso purposes the tincture may also the employed in doses of 5 to 15 minims, in a mixture.

For chilblains one may rub on either capsicum ointment or the B. P.C. stronger tincture of capsicum; but these preparations should not be used if the skin is broken. The liniment of capsicunt may le used in painful affections like lumbago and sciatica. Capsicum wool and capsicum gangee tissue act like thermogene and are warm and stimulating.

CARAFE. Glass water-bottles for bedroom use have a tumbler to match. Bottles or carafes of old green and wine-coloured glass, with old-fashioned stoppers, are obtained or copied for table use. For cleaning the carafe, shot, which may be bought at any oilshop, pieces of charcoal, or of raw chopped potato with warm water, may be slaken in the carafe. For rinsing, cold water must always be used. See Glass.

CARAMBOLA. This is the fruit of an evergreen tree widely grown in India. The fruit is yellow, about the size of an orange, and full of juice, but acid. It is caten as a preserve.

## Caramel, See Browning; Toffee.

CARAMEL PUDDING. Both the custard and the rice caramel puddings given here are popular with children, and very wholesome.

To make the first, put $\& \mathrm{lb}$. lump sugar and $\ddagger$ pint water in a small saucepan, and let them boil until the mixture turns a golden colour like toffee. Pour it quickly into a plain dry mould, coat the inside of it all over by turning the mould round, and then leave it until it is cold. Put 4 yolks and 2 whites of egge in a basin and beat them, frothing them as little as possible.

Bring pint milk to boiling point. When it has cooled slightly, pour it gradually on to the eggs, and add to the mixture a tablespoon ful of castor sugar and a few drops of vanilla. Strain this custard into the mould, covering the top with buttered paper. Steam the pudding very slowly for about an hour or until it is quite set. The water should hardly bubble, for unless the custard is cooked very slowly, it will be full of holes and spoilt.
If the pudding is to be served hot, let it stand for a minute before taking it out of the saucepan. Then turn it very carefully on to a hot dish. If it is to be served cold, let it stand for an hour or more before turning it out. If preferred, 3 whole egge can bo used instead of 4 yolks and 2 whites.

Sugar, rice, milk and eggs are the ingredients for a more substantial caramel pudding. Make the same quantity of caramel mixture as is given in the first recipe, and with it line a plain mould thoroughly.

Put $\boldsymbol{L}^{2}$ oz rice in a saucepan with a pint milk and let it aimmer very gently for about an hour until the rice is tender and has absorbed the milk. Neat beat up 2 eggs, add them and 1 oz sugar to the rice. Turn the mixture into the prepared mould, twist a piece of buttered paper over the top, and steam the pudding for about three-quarters of an hour. Then turn it out on to a hot dish, when the caramel will run all round the dish like sauce.

CARANISL SAUCE. Put 1 oz . loal sugar into a steel pan, or one not lined with tin, and let it melt and cook till it is a rich brown. Add 1 pint water and 6 oz . more sugar, and boil these until a little forms a strong thread between the thumb and finger when tested. Flavour with vanilla, and stir in a teaspoonful of corntlour mixed thinly with cold milk. Stir and boil for five min., then strain it. It should be served with hot puddinge.

CARAT. Carat is a term used by goldsmiths as a measure of purity of gold. Fine gold is 24 carats; 22 carat is 22 parts gold and 2 parts alloy, either copper or silver or both ; 18 carat is 18 parts gold and 6 parts alloy, and bu on down to 0 carat; 8 carat and 14 carat are not recognized in England.

CARAVAN. The horse-drawn caravan is largely used for holiday tours, while a lighter type is towed by a motor-car. Caravans used as permanent residences are in many places subject to special by-laws. See Holiday; Motor-Car ; Sanitation; Tent.

CARAWAY. The seeds of the caraway plant, with their strong aromatic flavour, are used for flavouring cakes. The essential oil of caraway seeds forms important ingredients in various tonics, condiments, wines and cordials. See Seed Cake.

CARBIDE. The chief use of carbide of calcium is in the production of acetylene gas.

Carbide can be bought in $\frac{1}{1} \mathrm{lb}$. and 7 lb . tins, and in iron drums or barrels holding from 28 lb . to 2 cwt . It greedily absorbs moisture, and will take it up out of the atmosphere. Hence, when a drum is once opened it is advisable to empty the entire contents at once into some form of special storage bin with an airtight lid. If the storage bin is not closed properly a white, powdery crust will form on the top of the carbide ; this crust is, of course, so much waste.

As acetylene gas is explosive, and may be given off accidentally or without being noticed
from a store of carbide, a licence to keep carbide must be obtained from the local authority if it is desired to store more than 28 lb . at a lime. See Acetylene.
CARBOLIC ACID. The drug is generally used in the liquid form. It is used as an antiseptic, and at the same time relieves pain, but if employed as the liquid acid, or if lotions are too strong or left on too long, the skin and other tissues are destroyed.

Carbolic acid lotion may be in the strength of 1 in $20,40,60$, or 100 . If the lotion is made at home, hot water should be used in order to ensure thorough mixing; and the lotion should be kept in a poison bottle. It may be used for washing wounds or sores, but is also applied on lint or gauze which has been wrung out of it. When the dressing is to be covered with gutta-percha tissue or oiled silk only the weaker lotions should be used. The 1 in 100 lotion may also be used as a gargle in sore throat and usually brings much ease, but it should not, of course, be swallowed. This strength could also be sponged on the skin to relieve itching.
Carbolic oil is often used for burns, but to be useful it must be fresh. The glycerin of carbolic acid is better, and this is also a useful application in boils and carbuncles. A few drops of this instilled into the ear may be helpful in relief of pain.

Lozenges and pastilles may be obtaincd from the chemist for use in sore throat or septic conditions of the mouth. If a little cotton-wool be rolled on the end of a match and dipped in the liquefied acid it may relievc toothache if it is gently rubbed round a cavity in a tooth. Someone should do this for the sufferer, and should use cotton-wool or a rag to protect the cheek and gum.
Polsoning by Carbolic Acid. In poisoning there is intense burning of the throat and mouth, whitening of mouth and lips, and the characteristic smell of the poison. The doctor should be sent for, and in the meantime 1 oz of Epsom salts dissolved in a tumbler of water may be given, with demulcent drinks later.
Sometimes symptoms of carbolic acid poisoning, noted chiefly by a sudden darkening of the urine, may develop when large skin surfaces are being treated with carbolio acid antiseptio dressings. Here the treatment consists of the immediate substitution of some other antiseptic for the carbolic, and the taking of half a teaspoonful of Epsom salts in half a wineglass of water four times a day.

Household Uses. The chief use of carbolio acid in the ordinary household is as a dis. infectant, and for that purpose it remains a favourite, although a good grade of coal-tar disinfectant is much more efficient, besides being relatively non-poisonous.

Carbolic acid should always be kept in a labelled bollle and.in a locked cupboard, owing to its poisonous nature.
For use a 1 in 20 solution is convenient, and this is made by adding about 4 oz . of the pure carbolic acid into a $\frac{1}{2}$ gallon of water, and shaking up well.
In cases of infectious illness, all infected bed-linen, blankets, and underclothes should be soaked in this solation for about 12 hours before being washed. The spreading of colds would be lessened if all soiled handkerchiefs were similarly treated before being washed.
The sheet hung over the door of the sick-room in cases of infectious illness is frequently moistened with carbolic solution. When required the fluid may be used in a scent spray for freshening the air of the sick-room. Floors which have been soiled with infected material should be washed over with the carbolic solution. For sweetening drains, sinks, and water closets, the solution should be swilled over the appliance, and allowed to remain in contact for two hours. See Disinfectant; Poisoning.

CARBOLIC SOAP. Carbo'ic soap consists of an ordinary soap to which a small proportion of carbolic acid has been added, but it actually contains so little of the ac:d that its disinfectant action is small and must not he too greatly relied upon. Carbolic soap has, however, a definitc use. The smell is particularly wholesome and cleanly and will replace offensive odours

CARBONIC ACID. Carbonic acid gas is given off in breathing, combustion, fermentation, and putrefaction. The proportion of the gas in pure air is about $4 \frac{1}{2}$ parts in 10,000 : more than this can be tolerated, but if the amount in the air of a room exceeds that limit, drowsiness and faintness are produced. (See Ventilation.)

Aerated waters are charged with carbonic acid gas, which process gives them their piquancy.

Poisoning by carbonic acid gas occurs sometimes when people sleep close to lime kilns, when a charcoal or other fire is lighted in a room without a chimney, in the holds of ships, and especially in coal-mines by the after-damp or choke-damp. A condition of asphyxia is produced. Remove the patient to the open air without delay ; practise artificial respiration, and if possible give oxygen. If the patient recovers, the effects of the poisoning soon pass awray.
CARBONIC ACID SNOW. This is one of the most successful agents for removing birthmarks, warts, and for the treatment of lupus and other skin affections. It is prepared from liquefied carbonic acid gas, and the snow should only be applied by a doctor.

CARBONIC MONOEDIDE. Known also as carbonic oxide, this is a highly poisonous gas present in ordinary coal and water gases. It is also formed when any substance is burned in a quantity of air insufficient for complete combustion. Coke and charcoal stoves sometimes give it out in dangerous quantities. A slight escape of gas in the house may gradually produce symptoms of carbonic oxide puisoning. There is a considerable percentage of carbon monoxide present in ordinary coal gas, and the greatest care should be taken to see that all gas connexions and fittings are absolutely gastight. The action of the gas when breathed in is to form a compound in the blood which ultimately ends in asphyxia. The gas burns with the characteristic blue flame which is seen in a very hot fire or charcoal stove. The formation of carbon monoxide in this way, indeed, has been a very frequent cause of death where charcoal has been burnt in rooms which are insufficiently ventilated.

No brazier or similar heating apparalus should ever be used in a closed room. For a similar reason, the use of a geyser in a bathroom is dangerous unless adequate ventilation is ensured.
The gas is not readily displaced from the blood by oxygen; hence resuscitation by artificial respiration is sometimes very difficult. The symptoms are great weakness, a throbbing headache, nausea, and giddiness. Later thene may be convulsions and then unconsciousness. Send at once for the doctor. Until he arrives practise artificial respiration. This may often have to be continued for several hours. See Artificial Respiration.

CARBON PAPER. Prepared with carbon, or other material, so that it reproduces on paper or other substances placed beneath it a copy of any design or outlines, it is chiefly used in typewriting to obtain a duplicate, and for a similar purpose when the writing is done with pen or pencil. Other uses include the transference of a design on paper to the surface of some other material such as wood, leather, or canvas, which has subsequently to be modelled, shaped or worked upon The carbon paper used for typewriting purposes is not so sensitive
as that for penoil use, as the force of blow struck by the type face is considerably greater than the pressure exerted in hand writing.
Pen copying carbon paper is very clean in use and produces excellent duplicates, when the original is written with a fairly fine or hard nib The best results are obtained from carbon papers by keeping them llat and free from dust and excessive warmth, which tends to dry them up. See Typewriter. of making photographs from ordinary negatives on sensitive tissue. This tissue consist. of paper coated with a mixture of gelatine and a pigment, some 30 different colours being a vailable. The tissues and other carbon materials are made by the Autotype Company. It is best for the amateur to buy the tissue ready sensitised.

In making a print, the tissue is exposed (behind the negative) to daylight. The negative must have an opaque border, made by pasting narrow atrips of black paper round its edges. As the tissue is of deep colour, the action of light upon it cannot be seen ; it is necessary to ascertain the required time of exposure by means of an actinometer. From the appearance of the negative it is fairly easy to judge how many sections of the P.O.P. must be exposed in succession to match the tint in order to give the correct exposure to the tissue under the negative.
The action of the light on the tissue is to make part of the gelatine insoluble in hot water. Un. fortunately, the
action of light
is chiefly on the surface of the tissue, which liecomes covered over almost all parts with a skin of insoluble gelatine. The varying amount of insoluble gelatine which, with the pigment held fast by them, will finally form the picture lie underneath this skin, together with all the soluble gelatine which is to be dissolved away.

## Transferring the Tissue Coatins

The tissue coating has just to be transposed to another piece of paper, so that the soluble parts are on the surfacc. This is done by soaking the exposed piece of tissue in cold water along with a piece of transfer paper, which is paper coated with hardened gelatine. After soaking for a minute or two, the dark surface of the tissue and the gelatine surface of the transfer paper are brought together under the water, then laid on a sheet of glass or other flat surface, and pressed together with a squeegee, which is a stout strip of rubber mounted in a wooden handle. The two sheets are then left for about 15 min , and the print is then rearly to be developed.
The developer is simply water at a temperature of about $100^{\circ} \mathrm{F}$. On soaking the pair of papers, which have been squeegeed together in this hot water the mixture of gelatine and pigment soon begins to ooze out from the edges. As soon as this is seen to be taking place the original paper of the tissue can be readily stripped away, leaving the picture, as yet invisible or very nearly so, on the transfer paper. On further soaking in the hot water the dark coating of pigment dissolves away revealing the outlines and light and shade of the picture. It is best to assist the process of development somewhat by pouring hot water over the print from a cup. In this way parts

CARBON PRINTING. This is a process
such as heavy shadowa may be lightened by extra treatment, or by using slightly hotter water. In all, development should not require more than 5 to 10 min . When the picture is seen to be of the correct depth and clearness in the lightest parts it is laid carefully, face up, in a dish of cold water, and is then soaked for about 5 min . in a hardening solution nade by dissolving loz. of alum in 20 oz . of water. A washing of 5 min . in running water is given before drying.

Owing to the transfer of the tissue coating to a fresh support the picture obtaincd from an ordinary negative becomes reversed. This may be overcomc by making a reversed negative, or, in the case of film negatives, by printing with the tissuc in contact with the plain side of the negative.
Carbon prints are of a very high degree of permanence, sinco only permanent pig. ments are used in making the tissues. Morcover, the only chemical, bichromate, is very completely washed out in the hot doveloping water. For good results on bought tissue, negatives of good contrast and quality are necessary Sec Negative Photograjhy.

The action on the coating of gelatine and pigment is that they are rendered insoluble proportionately to the silver in the bromide print.

This form of carbon printing has several very positive advantages. There is no need for daylight; the whole process, including the making of the bromide print, is done by artificial light. There is no reversal of the drawing of the picture, but at the same time a reversed picture can easily be made.
For working the process two stock solutions are required. The following is the stock solution A for the sensitising bath
Potussilum bichromate
Potassium ferricyanido Potarsium bronido
Water
102
1
10
20
20
The stock solution $B$ for the acid bath is made up as follows: Acetle acid, glacial
Hydrachloric acid, puro
Formaline, solution as sold
The sensitising bath is made by mixing some of the A solution with three times its bulk of water. The acid bath is made by adding 1 oz . of the B solution to 32 oz . of
 water The sensitising bath may be used a large number of times in succes. sion, but it is best to throw away the acid bath after each day's use. To make a carbro print, a sheet of pigmented paper is immersed in the sensitising bath and turned over once or twico in about 3 min . Meanwhile bromide print should have
CARBORUNDUM. A manufactured been soaking in clean water. There is nothing
article composed of silicon and carbon, carborundum is used as an abrasive in the form of wheels, flat slabs or stones, and in various other shapes suited to the sharpening of many kinds of tools and appliances. Carborundum powder is made in various grades, and is a splendid grinding compound.

It is also obtainable in the form of a sheet or cloth, the carborundum being applicd to it in the same way as emery cloth Long strips of this material, made in the form of an endless belt, are used for grinding amall articles or cleaning the scalc from a casting.
A carborundum combination sharpening stone is a handy form of oilatone, ns it has a coarso face for rapid cutting on one side and a fine face for whetting on the other.

Carvers' slips for the sharpening of gouges and other carving tools, and the points, slips, and sticks of different shape are invaluable for finishing off dies or any small, àccurate metal work, as they can be used as a fine file.

When using carborundum powder or cloth remember that it is an excellent abrasive; therefore, when the work is finished, every care must be taken to see that all trace of the powder is cleaned off the work.

CARERO PROCESS. The Carbro process is a method of carbon printing which is very much simpler to work, yet yields results identical with those of the carbon process. In it pigmented paper of any of the large variety of colours used in carbon printing is exposed, not to light under a negative, but simply to contact with a bromide print or enlargement after having heen soaked in a certain mixture of chemicals.
special about the bromide print except that it should be printed with a white margin. If it is not made with this margin, the sheet of pigmented paper must be about $\frac{1}{2}$ in. larger than the bromide print.

At the end of 3 min . the pigmented paper is drained from the sensitising bath and laid face up in the acid hath, where it is allowed to stay for a time ranging from 15 to 25 sec . The longer timc of immersion yields carbro prints of less contrast. While the pigmented paper is in this bath, the bromide print is taken from the water and laid face up on a level sheet of glass. The sensitised pigmented paper is then taken straight from the acid bath and laid, coated aide down, upon the bromide print. The two are immediately pressed into contact by means of a squeegee. The pair of papers is then placed between sheets of greaseproof paper and allowed to remain in contact for about 15 min

## Special Method of Developing

During this time a shect of transfer paper is soaked in clean cold water, and when the 15 min . have expired the pigmented paper and bromide print are gently pulled apart, and the former laid, coated side down, on the transfer paper, squeegeed into contact and left between blotting hoards for about 20 min . At the end of this time the original sheet of paper which was coated with the pigment is stripped away, by immersing the pair in water at about $100^{\circ} \mathrm{F}$., leaving the picture on the transfer paper, though hidden in the mass of pigment. The further development of the picture is exactly the same as in carhon printing. The bromide print undergoes a bleaching action
by contact with the sensitised pigmented paper. It is washed in several changes of water for half an hour, and then restored to its original state by placing it in an ordinary developer, such as M.Q. or amidol. After a further wash of a few minutes, the bromide print may be used at once for making other carbro prints, or be dricd for future use. See Carbon Printing.
CARBUNCLIT. The commonest sitcs for a carbuncle or local gangrene of the tissues underlying the skin s.re the back, the nape of the neck, the shoulders and the buttocks. The chief differences between a boil and a carbuncle are that the latter may be an inch or more in diameter, is inclined to spread, and in the later stages has three or four openingss in its surface leading down to the core, whercas a boil is usually much smaller, docs not spread, and the skin is broken in but one place.

A carbuncle is most likely to occur in one who is in a debilitated and generally run-down state of health, perhaps as the result of chronic disease or of living in insanitary surroundings or of insufficient food. A blow or a squeeze may be the exciting cause. A typical carbuncle begins as a hardish, painful swelling under the skin. Soon it becomes softer and doughy, and then later the purplish red skin gives way, and the core may be seen beneath as a greyish white slough.

Unlike a boil, a carbuncle requires immo. diate treatment at the hands of a surgeon. The name carbuncle has been sometimes wrongly applied to malignant pustule or anthrax. See Boil.

CARBURETTER: Details and Working. A carburetter is a device used on internal combustion engines to ensure a proper explosive mixture in the engine. Broadly speak ing, for petrol an explosive mixture consists of one volume petrol vapour to twenty volumes of air. Should the mixture be too strong it will not explode rapidly, thereby creating loss of power in the engine, as well as causing the engine to get unduly hot. On the other hand, should the mixture be too weak, the resultant symptoms would still be loss of power, but probably accompanied by popping in the silencer, caused by late firing of the weak mixture.
With few exceptions, the method of pro ducing an explosive mixture is carried out by spraying the petrol from a fine jet, by drawing the air at a high velocity through a choke tube, in the centre of which this jet is placed. The suction is due to the fact that the pressure of the air at the restricted part of the passage, that is the choke tube, is decreased at tho same time that the velocity is increased. The petrol as it issues from the jet into the stream of air is broken up into very fine globules. See Fig. 1, which also shows the functioning of the simplest type of carburetter.
To obtain perfect carburation at all engine speeds is by no means easy of accomplishment, for there is no perfect carburetter, i.e. one capable of giving correct mixture under every varying condition of engine requirement and atmospheric changes. A rich, slow-burning mixture is necessary for starting and slow running; a slightly rich, quick-burning
mixture when accelerating; a fairly weak and may be controlled by hand or automixture for fast running on the level: and a matically, generally the former. They are rich, slower-burning mixture for hill climbing. With varying claims to these essentials there are dozens of different makes on the market.
Carburetters, as a whole, may be said to be of either the single or multiple jet pattern With the former one main jet is employed to serve the dcmands of the engine at all engine speeds, the pilot, or slow-running jet, only coming into operation when the throttle is closed. The necessary adjustment of the mixture to the needs of the moment with the single-jot type is usually provided for by means of the throttle, which is 80 arranged that
more air is admitted at high engine speeds.
The multiple-jet carburetter is one in which three or more jets are so arranged as to be uncovered one at a time, by the opening of the throttle, as more power is wanted. Another popular type which may be said to be closely allied to the multiple-jet family is that in which the proportioning of both the air and petrol are automatically controlled, an ordinary butterfly throttle being employed to govern the engine speed. Briefly, this type has a tapered needle which fits into the petrol orifice, the base of the needle being secured to a piston Valve; this valve also covers Mirture of to Engine the air port of the carburetter, and is operated by the suction of the engine, which is so arranged an to create a vacuum at the back of the valve, hercby drawing it off its seating more or less as the cngine speed varies.
When tuning a carburetter, the same results may be obtained by different methods. A weak mixture may be corrected by fitting either a larger jet or a smaller choke tube. Whether the former or the latter will result in giving as much power with petrol economy will be found by test. Broadly speaking, a change of jet is preerable to a change of choke tube, because the latter may seriously restict the area called for by the particular engine being dealt with. Further, as the air velocity would be much higher with a small choke tube than a largo one at a given engine speed, it follows that the suction on the jet would also be greater, in fact most likely out of proportion to the extra air control, whether of automatic or mechanical design. On the other hand, should the mixture be too rich, which is traceable by licavy petrol consumption and a hot engine, always try a larger choke tube first; and even should this cause missing and bad acceleration, it may be accepted as a step in the right direction, following on by trying jets of different sizes before changing the choke tube.

To overcome some of the difficulties of carburation an additional independently controlled air passage may be provided. Thus extra air valves are sometimes fitted between the carburetter and the engine,

Carbaretter. Fig. 2. Panctured float caraing flooding Carbaretter. Fig. 2. Punctured iont caraing fooding
only intended for occasional use, and the carburetter is controlled independently during normal running. The so-called air valve on two-lever motor-cycle carburetters need only be operated occasionally, for example, when starting.

Carburetter Troubles. These are generally due to piartial or complete stoppages caused by dirt choking up the gauze filter or the jets themsclves: tracing and curing such troubles is a simple matter Fuel supply from modern pumps with highly efficient filtering systems has greatly reduced the occurrence of clirt in petrol tanks and carburetters and its consequent troubles.

Water in the carburetter gencrally produces a complete stopping of the engine ; in clearing water out of the carburetter the petrol tank should be inspected at the same time, othcrwise the trouble will recur immediatcly. Flooding at the jet may be due to dirt under the needle, wear of the needle and its scating (Fig. 3) or a punctured float (Fig. 2). Flooding means waste. bad running and risk of fire. See Bowden Control ; Motor Car.

CARDAMINE. Most of the species of cardamine or bitter cress are weeds, but pratensis (Lady's Smock) and its double variety, 12 inches, are pretty early summer flowers of pale lilac shade. Propagation is by division in spring.

CARDAMOM. The small dark brown capsules of an E. Indian plant known as cardamoms are highly prized in tropical countries as a condiment for flavouring curries and also sweetmeats. In Europe they enter into the preparation of numerous curry powlers, cordials, sauces, and for spicing cakes.

Cardan Shaft. See Propeller Shaft.
CARDBOARD. Strips of thin cardboard will serve instead of wood to light the fire. An old hatbox packed with hay, straw, or saw. dust inakes an excellent hotbox in an emergency. A piece of cardboard fitted in the bottom of an old bucket will render it serviceable for dry material.

CARDIGAN JACKET. The cardigan jacket is a knitted woollen coat, buttoning in front. A couple of side pockets and Hat bindings for the edges and buttonholes are desirable. Fitting close, the cardigan can be worn in winter in addition to ordinary clothes.

Cardinal Flower. The popular name of the red-flowered Lobelia cardinalis. See Lobelia.

CARDOON. Closely related to the globe artichoke, the blanched stalks and main root of the cardoon are eaten instead of the unde. veloped flower-head. It is hardly suitable for small gardens, but in large ones it is often grown in trenches like celery, but given more room. The trenches should be larger, and be 4 ft . apart, with the plants 3 ft . apart.

The seeds may be sown under glass in March and the plants put out in May. Another way is to sow in the open ground in April for the current year's yield. The plants are generally strong enough for blanching in August, when the leaves aro drawn together, bound round with straw to the tips, and covered with earth. They blanch in about two months. Recipes suitable for cooking celery (q.v.) may be used for the cardoon.

CARDS: For Visiting. Visiting cards should be stamped with a copper-plate die in script. A usual size is $3 \frac{1}{2}$ by $2 \frac{1}{2} \mathrm{in}$. for ladies
and 3 by $1 \frac{1}{2}$ in for men. The name, placed in the middle of the card, is prefixed by the title (if any) or Mr., Mrs., or Miss An address and telephone number may be put in the left-hand botton, corner, if desired, and should be in a smaller script.

Cards are not sent in upon arrival at a house for a visit, except in business interviews On leaving after a call has been made, a lady may leave on the hall-table one of her own cards and one of her husband's, or of any male relative with whom she resides, e.g. her father or son. If her hostess is married or has a male rclative living in the house, the caller may leave tivo of her husband's cards as well as her own.
When no call is made, cards may be left at the door upon the following occasions After invitations to a formal dinner, dance, At Horne, or any similar function : if the lady of the house is not at home when a call is made ; when one is inquiring in cases of illness : and to intimate a change of address.
Business cards may have the profession or trade in brackets under the name, with some essential details, which, however, must be few and as short as possible. The name of the newspaper, in the case of a journalist, or of the firm with which the owner of the card is connected, may be put upon a card.

A very narrow black edge may be used upon the card to indicate mourning; but this is no longer usual. See Call; Etiquette
CARDS, PLAYING. Bridge, whist, poker cribbage and other popular indoor games are played with packs of cards. A full pack contains 52 cards, but some games, e.g. bezique, are played with a smaller number, certain cards being removed. There is an excise duty of 3 d . a pack on playing cards in Great Britain. See Bezique; Bridge: Crib bage; Nap; Poker. Whist, etc.

CARD TABLE : How to Make. For card playing tables are made in all the woods used by cabinet makers, and are covered with green baize One type consists of a square of wood supported on legs which can be folded up, enabling the table to be put away in the minimum of space

There exist some fine specimens of antique card tables, chiefly of walnut and other light wonds. The one shown in our illustration dates from the early 18 th century. The top is of oak veneered with walnut, the carved walnut legs being graceful specimens of the long cabriole with ball and claw fent. The top is covered with green cloth, the under surface of the hinged portion being treated with green moroceo leather. When open it shows a top of four equal sides interspaced by four oval concaves for money and counters, and a plain circular panel at each corner to hold candle. aticks The underframing is hinged so as to

Card Table of oak, veneered with walnut, of an early 18th century English make
Victoria and Albert Museum, S. Kensingtun
permit two of the !egs to support the leal when open, just as in the ordinary Hap-leaf table of to day.

Figs. 1 and 9 show a simple folding card table A suitable size is 2 ft . by 2 ft ., the finishing height being anything between 2 it. 3 in and 2 ft 6 in For a longer and narrower top a size 2 ft 6 in . by 1 ft .8 in . is of service.
Mahogany is the best wood lor the top. Pine or oali may be used Elevations of the opened table are given at Figs. 1 and 2. The top may bo put together with hard. wond tongued joints and clamped at ends with 2 in clamps, the only finish to also being slightly rounded, say. 1 in . by 1 in . of each length on the angle. In another way, a deal top can be grooved and tongued up, and have the edges finished with slips of 1 in. by 1 in material mitred and screwed or nailed on all edges and finally rounded off.

I better specimen of work would the to frame up the top, which could then be of material in lengths of 4 in width, with the grain alternately reversed and grooved into a framing 2 in. wide. the latter being mortised and tenoned together right through and wedged. The underside will be battened on with pieces 1 ft 9 in by 2 in . by $\}$ in. or $\}$ in net screwed on As shown on the plan, Fig 3, the position for these battens may be 4 in. from outer edges of top, which will make them 12 in . apart.
The trestles are made of material $1 \frac{1}{2} \mathrm{in}$. by 1 in ., finished with the edges slightly rounded. These are pivoted together (Fig. 2, B) either with a lengtl of 1 in . dowel (hardwood) or with tapped and nutted $\frac{3}{\frac{3}{3}}$ in iron rod. An alternative method of pivoting is to sink a nut into the end grain of a tightly butted length of 1 in by 1 in. wood (say, beech, birch, or satin walnut, if oak is not available), and enter the bolts, through the trestle lengths, into the nuts after the manner indicated at Fig. 8. For these trestles four pieces, to finish 2 ft . 10 in . in length, will serve, the pivoting point being found 1 ft . 7 f in. from lower end or
the edges being to round them, the corners 1 ft . $2 \frac{1}{2}$ in. Irom topend, and not in the middle

Card Table. Kigs. 1-9. Diagrams show construction of a lolding card table Two lengtb
Two stiffening rails (A) are screwed to the crossed pieces, say, $1 \frac{d}{d} \mathrm{in}$. by 1 in ., or 1 in . by 1 in . will serve, fixed at about 3 in to 4 in. up, and the same may be done to the part above the pivot. At the top end of each trestle pair a length of $\frac{1}{4}$ in hardwood dowel is fitted to holes tightly, and wedged or pinned. The centres for these holes will be found by noting the position of the part at C, Fig. 2, the top end of trestle lengths being finished by rounding off the end grain

In Fig 9 a perspective view of the table opened out is given From this it will be seen that the top is attached to the dowel rail at $1)$ by means of a pair of sockets, such as arc used for a bolt to shoot into, two suitable kinds being indicated at Figs. 4 and 5, to be screwed to battens. These sockets servo as hinges to pivot the top and allow it to shut down on to the dowel rail at E , attachment teing by means of a couple of hooked plates, as at Fig. 7, to be screwed on, or a couple of coat hooks, as at Fig. 6, will serve.

It would be possible to replace the dowel
 If these are drilled each end for pinning and with brass sockets and hooks, the effect would be smarter. In folding the table fiat for standing against a wall the parts $\mathbf{D}$ and E approach $F$ and $G$ respectively, and the top lies upon them. See Bridge Party.

## Card Tricks for Home Amusement

## Some Examples Needing only Sleight of Hand

This article contains information that will usefully supplement that given under the headings Children's Party; Evening Party. See also Conjuring

The tricks described here require no apparatus, no conjuring skill, and yet will provide plenty of amusement.

A slight manipulation with a pack, or with a number of packs preferal:ly, will enable any one to puzzle an audience completely. Prepare a pack of cards by placing all the odd cards together, the $1,3,5$, etc of each suit, calling the jack and king as odd, and all the even cards together, and place the two halves of the pack on top of each other. It is perfectly safe to show the cards to the company, for it is most unlikely anyone will see how they have been divided. Now ask anyone to choose a card, and note which half of the pack it is chosen from, the oild or even half. Return the card yourself, making clear you are not looking at it, but return it to the half from which it was not originally chosen. Then deal all the cards, face upwards, in rapid succession, announcing that you will stop at the chosen card. Naturally, it is the only odd card in the even half, or vice versa.

Another trick is absurdly simple, but its very simplicity l, affles nine people out of ten Six cards are laid solemnly on the foor, and the performer announces that he will make any one of the cards selected by the company disappear. A card is chosen, the performer turns up his sleeves and slowly picks up the cards. He holds them for a few minutes in his hands, and then alowly puts them back on the floor, when the indicated card is found to have disappeared. The explanation is rarely guessed by any who do not know the trick. In picking up the aclected card the performer runs his thumb, which he has casually moistened with his tongue, down the side of it, and the next card adheres to it. The cards when picked up should be carefully alined up and given a firm squeeze before being laid down again, so that the two carda should stick firmly together.
The four knaves trick is performed in this way. The performer runs through the pack and picks out the four knaves, keeping up a
running story ol four knaves who are gong to rob a house The story is purely to distract the audience, and to hide the modus operandi of the trick. The four knaves are held out fanwise in the left hand and the fact fully impressed on the audience that they are four knaves. The fan is closed and placed on top of the pack, face dounwards. The performer then takes the top card of the pack, which is also the top card of the four, and places it, without showing it to the audience about a quarter way down, telling a suitable story about this knave robbing the upper part of the house
The next is similarly placed about half-way down, the third of the way down, and the last left on the top of the pack. The performe then gives the cards a sharp double linock which, he informs his watchers, has so frightened the three knaves in the pack that they have all hurried to the top of the pack to join the knave there. As he does so he turns over the four top cards and shows the four knaves. The explanation is that belind the back card of the fan of jacks are three other cards Properly squared up with the jack they do not show, and when the fan is closed and placed on the top of the pack, it is these three cards which are placed, one after another, in the pack, leaving the four jacks in position

It in always a good plan to prepare for the next trick while the audience is thinking about the last. During such an interval make a quiet mental note of the two top cards of the pack, and then ask anyone to divide the pack into three heaps, and announce that you will name the top cards of all three heaps. The usual method of dividing a pack into three heaps is by cutting off almut one-third to forn one heap and dividing the remainder into two equal heaps. So, the two top cards of one heap are known, and the top cards of the other two are not. Let the known heap be called $A$, and the other two heaps $B$ and $C$, and suppose that the two top cards in $A$ arc the ace of diamonds and four of clubs.

## How the Trick is Performed

The performer calls out that the top card of heap C is the ace of diamonds, and picks it up. Without showing it to the audience he says "Correct," and states what the top card of $B$ is. The card he names is the top card of $C$ he already holds. He picks up the top card of B, calls out "Correct," as before, and names as the top card of $A$ the card from $B$ he has just picked up. As he picks the top card off A he holds all three cards, which have been correctly named, so that the audience can see them. The object of knowing the second card of the heap $A$ is so that the trick may be repeated on demand to prove there is no trickery in it

The trick shown in the illustration almost explains itself, and its very simplicity usually prevents the secret from being discovered. The four aces are apparently placed on the table as shown, and the rest of the pack dropped on top of them, and shuffled all thoroughly together. One of the company should be then asked to find the four aces. The ace of hearts is missing, and is produced from any place where the performer has previously hidden it

The cleverness of the following trick lies in the fact that though the victim apparently chooses a card at random from out of the pack. the card is in reality chosen by the performer. The trick consists in clever question and state ment by the periormer, enabling him to elim. inate every card in the pack save the one chosen. The performer knows the position of one card in the pack. It is immaterial whether it is the top or botton card, or the seventh card down from the top, say, so long as he knows its actual position. For the sake of explanation, one will suppose he knows the top card-the three of spades By question and answer he forces his victim to name it.

A Series of Questions. The questions are imilar to the following you prefer in suite. red or black ?" If the other asys "Red," the performer says, "That lenves the two black suits, spades and clubs," and continues as helow. If he answers "Black," the perormer says: "Very well and which of the two black suite do you prefer, spades or clubs?" If the "iotim answers performer continues with his question. "Clubs," the pays "aves spades," and continues, "And now which cards of a suit do you prefer, those cards from the ten to the ace, or those from the nine to the two?" If the victim chooses the nine to the two, the performer continues as below. If he chooses the ten to the ace the performer replies, "That leaves the nine to the two of spades. Divide them into two parts the nine to the four inclusive, and the three and the two. Which will you have?" If the victim, as he most likely will, says the nine to the four, the performer replies, "That leaves only two cards, the three and the two of spades. Which will you have?" If the victim says the three of spades, the performer quietly asks him to turn up the top card of the pack. If he chooses the two, he says, "And that leaves the three, does it not?" The victim agrees, nnd the performer turns up the top card-the threc of spades.
The end of the trick should never be ex plained, as it always causes intense astonish. ment, to those who do not know it, how the chosen card should be on the top of the pack (or, of course, any other position known in advance to the jerformer). He is firmly convinced that he himself has chosen this one card out of the 52 in the pack. The whole essentials of the trick consist in taking or leaving each suit and each set of cards in turn or not, as necessary, according to the colour, denomination, and size of the known card.

CARIES: In the Teeth. Dental caries is a slow progressive destruction or rotting of the hard substance of the tonth, caused primarily by acid acting on the outer part of the tooth.

The foods which become decomposed in such a way as to form acid are sugara and cooked starches. These, known collectively as carbohydrates, encourage the multiplication of acid-forming parasites or bacteria, more especially in the crevices of, or between, the teeth or wherever the action of the tongue, lips and saliva does not easily remove them The enamel benenth the carbohydrate and
bacteria is softened or dissolved by the acid formed, and broken down. The destruction of the tooth generally proceeds more rapidly when the enamel is broken through

For the prevention of caries it is particularly desirable that the food at the end of a meal should be of a cleansing nature, so that the mouth will be left free from the carbohydrates previously caten. This means that artificially prepared carbohydrates, e.g. sweets, breail and jam, or sweet biscuits, should never be allowed to terminate a meal, but should be followed by some natural food such as uncooked Íruit, or vegetables like celery. If these foods are undesirable, as, for example, with very young children, withhold highly sweetened foods altogether, and substitute hard, unsweetened foods, such as toasted bread or crusty bread and butter. See Teeth
CARMINATIVE. Peppermint, cloves. allspice, cinnamon, cascarilla, bitter orange. alcohol, etc., used to relieve flatulency and intestinal colic, are exainples of the remedies termed carminatives. By stimulating the stomach and the intestines into more forceful movements they help to expel the gas which has accumulated in the digeative tract.

For babics dill water may be used in teaapoonful doses, and a little bicarbonate of soda may be added with advantage. For others, peppermint water, which is more pungent, is useful, the dose being one to four tablespoonfuls, and here also bicarbonate of soda, perhaps half a teaspoonful, should le added; or soda mint tablets might be taken, See Cascara; Indigestion.
CARMINE. Being a particularly fine sed colouring, carmine is much used for cooking and confectionery purposes. It is practically the anme as cochineal, and both are valualile, not only on account of their colour, but because they are absolutely harmless and devoid of flavour. A small hottle of carmine will last an ordinary household a long time, as a few drops give a good deep pink. Two or three drops at most are ample for a pint of cornflour blancmange. See Cochineal.

CARNATION. There are four chief types of carnation--the border carnation, which is grown in flower beds out of doora and blooms in summer; the perpetual-flowaring carnation, which is cultivated in pots under glass and blooms all the year round, though chiefly in autumn, winter and spring; the annual carnation which flowers in summer from seeds sown in spring; and the Malmaison.

The border carnation is a fine old English flower of which many oharming new varietics have been raised in recent years. It flourishes best in well-drained soil; on heavy land it is a good plan to raise the camation hed 6 or 8 in . above the ground level, so that the plants are not waterlogged in winter. Well-dug soil with which a little decayed manure and mortar rubble liave been mixed suits them. In most gardens planting is best done in September or October, in very cold districts the plants are wintered in a frame and planted in March

Border carnations are propagated by layer ing the shoots in July. The layers will be well rooted by the midतle or end of September, and may then be taken up and replanted at 15 in. apart to form a new hed of carnations; they will bloom the following year Large plants can be obtained by leaving the layers undisturbed. It is not necessary to layer border carnations overy year; they may le left untouched for at least two or three years. Such plants will bear large quantities of flowers. Another way of raising a stock of border carnations is to sow seeds in a box of soil in a fraine or greenhouse in March. When the seedlings are well developed they are planted out of doors, preferably where they are to bloom, at 18 in . apart. It is necessary to sow seeds of a really good strain to obtain a large percentage of double blooms. Carnations
$1940$

grown in this way yield more flowers than those raised fresh from layers cach year Border carnations can also be increased by cuttings, though these are less certain than layers. Some of tha best varieties of horder carnations are : Crystal Clove, whito; Royal Clove, pink: Bookham Clove, crimson: Margaret Keep, hluah pink; and Steerforth, white marked with crimson. All the ahove varieties are fragrant

Other border carmations of brilliant colouring are Mary Murray, yellow ; Dr. Raymond Crawfurd, orange buif: Miss Josephs, old rose; Yvonne Thomas, lavender; Fair Fllen, white marlied with lavender; Jessie Murray, white marked with mallve; Mrs E Charrington, white marked with lilac; Grenadier, scarlet ; J. J. Keen, apricot and rose ; Linliman, yellow and scarlet; Pasquin, vellow, pink and lavender.

Perpetual-flowering carnations are grown in immense quantities under glass to supply

Malmaison carnations are little grown nowadays. They need similar conditions to the perpetual-flowering carnations. They are grown in flower pots 8 in . in diameter, and are increased by layering in summer.

Annual Carnations. Carnations which bloom the same year in which seeds are sown are useful as pot plants in the greenliouse and or filling sumı mer flower beds. The best strain ol sced vields a good percentage of double flowers of various col. ours. The seeds are sown in FebruaryMarch under

Carnation : three types. 1. Perpetual flowering carnation. 2. Bloom of the Malmaison. 3. Border carnation

CARP. Like all fresh-whter fish, carp requires to be cleaned as soon as possible after it is taken out of the water, or it acquires a rank, muddy flavour. Carp is perhaps nicest if stuffed and baked, or it can be filleted and fried or plainly grilled.

To stulf and bake a earp, mix together 3 tahleapoonfuls fresh white brearlcrumbs, 1 tablespoonful chopped suet, 2 teasponfuls finely chopped parsley, and I terspoonfu! powdered herbs A little minced shallot may also be added. Add a seasoning of salt and pepper, and bind all with a beaten egg Press this stuffing into the cavity made by cleaning the fish, and sew the edges together with coarse Hiread Brush the fish over with benten egg, and diedge it well with crumbs

Grease a fireproof baking-dish, and ourl the lish in it so that the tail can be fastened in the mouth with a skewer made from a pointed match Put ahout $1 \frac{1}{2} \mathrm{oz}$. of butter or dripping in with the fish for hasting purposes. It will take about an hour to cook. Serve it in the dish in which it was cooked, emoving the string and skewer A lish sauce can In poured round it, or merely the fish juice and butter in the dish can be used to moisten it

Fried carp is also good After cleaning it, with a sharp linife reminve the llesli from the bones, and cut cach fillet into convenientsized pieces. To improve the llavour, lay tho fillets to soak for an hour in a mixture made

Carp. Stuffed carp ready for serving. It may be garnished as shown or a fish sauce noured round
of a tablespoonfuls olive oil, 1 tablespoonful vinegar or lemon juice, 1 tenspoonful each chopped parsley and onion or shallot, and salt and pepper.
Turn the pieces now and then. Then drain them from the marinade, dredge well with Hour, and fry thein in hot dripping until well browned. Serve the fillete with a garnish of cut lemon, anchory sauce, and any roe taken from then, which must be egged, crumbed, and fried seprarately.
Carpentry. This term refers to the con structional forms of woodiv.orking, e.g. roofing, llooring, etc. See Amateur Carpentry.

## Carpets and Carpet Repairing

## Selecting and Laying them to the Best Advantage

Sce the articles on Bedroom: Dining Room and other rooms of the house; also Colour Scheme;

## Linolcum, etc., and the colour plate herewith

The first thing for the buyer to decide is the approximate amount he is prepared to spend on $\pi$ carpet. This being settled, the choice of qualities is sutomatically narrowed down.

If a thick carpet is required, the purchaser will probably first turn to hand-knotted car pets, which may be either British, Europenn, or Oriental. Thie cheapest hand-made carpets are Indian. Beautiful designs are seen in Oriental productions of good quality, especially in Chinese. Modern hand-made French carpets are flat, being woven after the style of the old Aubusson. If any doubt is entertained as to the knot, the intending purchaser should bend open the pile, across the width, when the tuft of yarn will be seen, firmly knotted, or, more strictly speaking, looped round the warp threads. Even this, however, is no guarantec that the carpet is hand-knotted, for there are power-looms capable of imitating very closely the Oriental knot. This is not saying that such earpete are
necesarily inferior to hand-knotted carpeta of corresponding quality; indeed, they may be as good or better; only the buyer should not le put off with a machine-made carpet if he is secking a hand-made one. The machinemade will be appreciahly cheaper.

The carpet should also be examined to ascertain its pitch, that is, the number of tufts in any unit of lengthand width of tise fabric. Hand-tufted carpets vary generally from 9 to 100 tufts to the square inch, though there are qualities even finer than the latter. Brondly speaking, the coarser the pitch, the heavier will be the fabric: also, tho coarser will the design appear. The finer carpets. though lighter, will be more expensive, owing to the slower production and higher cost of weaving.
Axminster and Wilton Pile. Apart from hand-tufted carpets, depth of pilc alid luxurious tread can be obtained in many qualities of machine-made Axminster and

Wilton Axminster, with its comparatively thick woollen yarn, lends itself in particular to the production of soft and heavy qualitics The depth of thic pile can be gnuged not only by pressure of hand or foot, but also by opening up the pile between the rows across tho width of the fabric, and noting the height which the tuft stands up from the back Heavy qualitica are nlan made in Wilton.
purposes; but, although the loops have a certain resilience, the fabric has not the same richness as Axminster and Wilton Hair carpets are the best known lonp-pile fabrics and are exccllent in natural colour for stairs and as a background for Oriental rugs. These carpets are also a good choice for hedrooms and are obtainable in many sliados by the yard and seamless

Carpet. Example of a modern picture carpet. The design being known as "Banks of the Stream." and carried out In many aoft pastel ahades. The carpet is of hand-made British workmanship

Courtesy of waring if fillow. I.ld.

Below thesc in value comes a variety of qualities in Axminster, Wilton and chenille, which form the bulk of the avcrage carpet dealer's stock, the retail prices of which will he within the means of the average bouseholder. These comprise the standard qualities in the three fabrics mentioned, all of which have either a tufted or cut pile surface, and give a comfortable, if not luxurious effect.

In Axminster the pattern is formed by tufts of woollen yam that are cut off and inserted double in the bolly of the carpet. It is practically unlimited in colour effect, and is made in all widths from 12 or even 15 ft . down wards, that is, both in seamless carpets, in hody, borter, and stair, and in sewn carpets made up in 27 in. breadths. The most typical and popular Axminster quality is about if in thick with about 45 tufts to the square inch.

Wilton is made of worsted yarns, the velvety surface being obtained by the cutting of the warp threads that form the pattern after they have been looped over the wires in the loom. This type of carpet is limited in colour, but is susceptible of finer effects of design than Axminster, owing to the greater closeness of pitch. A typical quality of this fabric is alrout $\frac{7}{8}$ in. thick, utilising five or sir colours, and with about 90 tufts to the square inch It is made in widths up to 54 in ., and also in seamless carpets.

In chenille Axminster the pile consists of chenille fur, which is inserted as one of the wefts and woven on to the loody of the carpet. The design is apt to show a certain irregularity (not necessarily unpleasing), and the pitch is coarser than in tufted Axminster or Wilton. Chenille carpets are generally seamless, and a standard quality is about five rows of fur to the inch. They are to be ohtained in excellent colourings.
Loop-pile Carpets. Below these medium qualities thers are cherper guades of Axıninster, Wilton, and chenille, and there are aiso she Brussels, tapestry, and ingrain fabrics Brussels is a loop-pile fabric, made in much the same way as Wilton, but with the loops left uncut. The clean but rather hard surface makes it a suitable floor-covering for some

Ingrain Carpets. Scotch, or art squares, are of a different class of manufacture, the design being obtained by combinations of the warp and weft threads The surface of the fabric is flat, and cven in the heavier qualities it cannot be regarded as a luxurious carpet.

What has bcen said so far applies to carpets with a surface composed of worsted or woollen yarns, combined with a backing of woollen, cotton, linen, or jute warp and weft. Carpets, however, are also made solely of jute. The lower cost of this material cnables a carpet to be produced at a cheap price, but dyes are lces satisfactory and the fabric lacks resiltence. Coir, or coco-fibre, carpets are obtainable in attraotive de-ibns and colourings for lungalows or usc on stone floors.

Decorative Considerations Colour is often the first consideration with the purchaser of a carpet, and rightly $s o$, as tiles, walls, curtains. ctc., may have to be matched or pleasantly contrasted in the scheme of a room.

In the first place, the carpet should be regarded as the base of a dccorative scheme, and in most cases should be darker in tone than any other part of the room, because it presents the largest mass of colour and because it forms a background to the furniture. This is not to be interpreted as ruling out all light-ground carpets; but such can only be employed with discretion, and in association with appropriate wall treatments and furniture. A well. lit room can stand a darker and richer carpet than one with small or few windows, where a carpet with fairly light ground colour may be Inid with the object of aiding the lighting of the room by reflection.

In most effective schemes three or four harmoniously contrasting colours are employed A room decorated strictly on the self-colour or tone on tone principle, as, for instance, with a carpet in three or four shades of blue, blue walls, blue woodwork, and blue curtains, might be harmonious in a sense, but not pleasing. The proper use of semi-complementary colours is one of the secrets of an effective colour scheme.

The choice bet ween a plain or self-patterned and a multi-coloured carpet is largely a matter
of taste. In the caso of the lormer the selection of a colour scheme is to some extent simplified. It is certain that it is not desirable to have too much pattern in a room; that, for instance, a figured carpet, figured curtains and figured wallpaper would be most difficult to harmonise, and unrestful. Broadly speaking, the prevailing colour of the walls and curtains should contrast harmoniously with the prevailing colour of the carpet, while there should be notes of some of the colours of the carpet in other details of the room.

The question of design may be of minor importance compared with the consideration of colour ; but the right selection of a pattern is of high value in successful furnishing, as the adoption of a scheme in a room in which consistency and harmony are carried out in colour and also in design leads to perfection in interior decoration.

A definite and pronounced style, if adopted for the carpet, should be carried through the rest of the decoration. For instance, if geometrical patterns are liked, these go best with quite modern furniture, wall and window schemes. Carpets are obtninable representing every hnown period; and if a householder wishes to furnish his room completely in the Adam, Louis XVI, or in any Oriental style, he can do so by tahing a little trouble.

Choice, however, is not limited to definite periods or to very striking designs. Many carpets of unobtrusive and harmonionsly blended patterns and colourings tone perfectly with curtains and furniture of different styles, provided that the cobur scheme is right. It may be sound advice to a liouscholder who has to choose a carpet for a room with decorations of a nondescript or even a mixed character to select a plain carpet or one in a good Oricntal style. Picturc carpets are made in Ixminster, ot more expensivo ones are hand-made, as secn in the illustration herewith.

Care of Carpets. One of the problems which may occur is whether to fit the carpet to the room, or to have a bordered square with a margin of floor hetween the edge of the carpet and the skirting. The former choice may be more cosy, and looks well with a plain pile or hair carpet, but the latter is clcaner and more economical, enabling the room to be swept more easily, and the square can be changed end for end to equalise the wear. Oval and round carpets suit many rooms.

Carpets should be be cleaned with a vacuum cleaner or brushed regularly with a carpet sweeper, or a broom that is not too hard.

The Laying of Carpets. The tloot should be perfectly clean before the carpet is laid After removing any old nails from the boards they should be scrubbed with soft soap and warm water, and allowed to dry thoroughly before the carpet is laid. This is an importanit point, and it is advisable when possible to do the scrubbing a fow days beforehand, and to have a fire lighted in the room for a few hours to ensure thorough airing. If the carpet is laid over damp boards it is liable to rot.

The character of the surround must be decided upon, and it must be dealt with before laying the main carpet. If the surround is to consist of the plain boards, stained and polished, this must be done several days beforeliand to ensure thorough drying of the stain. The width of the surround should allow for it to extend for 2 in . bencath the main carpet, and before applying the stain the oxact width to be stained should be marked on the lloor with chalk.

When the surround is made of linoleum it is a good plan to use an underlay of tarred paper. This prevents damp from rising through the linoleum, and it also prevents moisture from injuring the flooring.

The tirst precaution in laying the carpet is to put a suitable underlay in position. This
keeps the carpet Irum direct contact with the the same thickness as those used in the floor, makes it wear very much longer, and also gives an impression of softness and comfort that is absent when the carpet is placed directly over the boards The underlay can vary considerably in character, and is, as a rule, not fixed firmly to the floor or only held in position by means of a few small tin-tacks. The best underlay is a plain and inexpensive grey felt.

Once the underlay is securely arranged the main carpet must be rolled and placed in position. A chalk mark should be made to indicate to where it must extend In the case of a valuable or very thick pile carpet it is desirable to call in an expert, who has the tools necessary for stretching the carpet properly. Failing this, care must be exercised by the amateur to stretch the carpet well. Only a amall portion should be unrolled at a time, and the roll used to pull and stretch the carpet after the free edges of one side have been fixed. The best kind of caruet nail is a patent brass nail which passes through the carpet and into a brass groove, socurely holding the carpet in position. It is quite easily drawn up without tearing the carpet when the latter is removed for shaking.

Fitted Carpets. In the caso of a fitted carpet completely covering the floor, the dimensions of the room must be carefully noted. If possible, an expert should be sent for to make exact measurements; but if this is impracticablo for any reason, then a rough plan should be made of the room. The outside measurements, by the floor along the skirting-boards, should be taken, also the measurements of fireplacc, any recesses, etc. These dimensions, together with the measurement of the room diagonally from corner to corner, would enable a carpet manufacturer to make up a carpet in the exact size required. If an expert is not available to fix the carpet, care must be taken after fixing the underlay to stretch the carpet to its utinost and to fasten it down securely. To ensure this a wide brush such as painters use can be shorn of its bristles, and then used by pushing it along the surface of the carpet to press and stretch the carpet properly, so that it. lies perfectly flat upon the floor.

Carpet nails as deacribed above should be used at cach corner and across the doorway. In other parts of the room the carpet will be held in position sufficiently by the weight of the various pieces of furniture.

Stair carpets need care in laying over under. felt or stair pads. Sufficient stair carpet should be bought to allow of at least an extra $\frac{1}{2}$ yd. for each flight of stairs. This extra length makes it possible to rearrange the carpet about four times a year, so that the wear is distributed evenly over the whole length; without it, the carpet will quickly show signs of wear at the edge where the tread falls on each step.
The extra length of carpet can be folded up smoothly under the last step or under the tread of the carpet of the top landing at the head of the flight of stairs. In laying a stair carpet it is advisable to start at the top, securely nailing down the top edges. The carpet is then gradually unrolled, drawn down and fixed in position by means of the stair rods. Each step is gradually covered in this way and the carpet drawn taut, so that it lies perfectly even and straight over each tread of the staircase.
Repairing Carpets. When a carpet is in need of repair this work may be entrusted to the firm from which it was purchased; but if amateur workers should desire to attempt repairs themselves, the following hints may be useful. A supply of the raw material is necessary; cotton, linen, jute, and worsted or woollen yarns, the latter in the same shades and of approximately
the same thickness as those used in the
manufacture of the carpet, should be obtained. and stout needles of a suitable size

If the back of the fabric has been de stroyed, it will be necessary in the first instance to sew in carefully threads repre senting warp and weft. This done, the pilc surface may be sewn on, in different stylen. according to the nature of the fabric. Occasional stitches present no difficulty, but if a patch of even 3 or. 4 sq in . in a patterned pile carpet has been burnt, considerable care and skill will be required to restore the correct design and colour.

In the case of a Brussels or tapestry carpet the missing threads are replaced by others sewn round wires, which represent the original wires in the loom. With Wilton or Axminster the tufts are sewn into the back, and cut off with scissors on a level with the existing pile surface. Tapestry velvet can be treated similarly.

Chenille Axminster occasionally suffers from breakage of the fine cotton threads which hold down the fur of the pile If the fur is not lost or destroyed, it can easily be sewn down again ; but if it is lost, it is hardly possible to obtain any of the correct pattern of the fur, and the next best thing s to sew in tufts as in Wilton or Axminater.
Repairs to a machinc-knotted carpet, or to one which shows the pattern on the back, to be done oorrectly involves sewing the tuft yarn right through the body of the fabric Repairs to the coarser types of hand-tufted carpets may also he made in this way, but repairs to a fine Persian carpet should not be attempted by the amateur. For cleaning car pets special soaps are used. See Soay.

CARPET BAG. A carpet bag takes its name from the material of which it is made and is used for the transport of workmen's tools, cricket and sport.
 away, bringing the end joint of webbing way from the sown-up sides of the bag. The joins C D can then be covered with leather or webbing stitched in place. A canvas lining should be cut to a similar pattern and sewn to the top of the carpet prior to attaching the binding. Handles can be affixed where de. sired.

Cricket and other carpet bags can be recovered by unpicking all the stitches. flattening out the old material and cutting a new piece of carpet to correspond. This is then sewn up in the same way as the old oarpet and attached to the frame. work. In many cases cricket bags have a stiffener of card or leather; the purpose of this addition being to keep the buttom in shape.

CARPET BEDDING. Plants which are dwart in habit, or are kept dwarf by clipping. are arranged in formal beds ao that the diversity of colour of Hower or foliage given the beil a carpet-like appearance. The art of wo arranging them is called carpet lxedding. This operation is usunlly carried out by the aid of a wooden bench or form upon which the gardener can kneel or sit.

Clever gardeners can work out most ntricate designs in the varying colours of bedding plants. The plants need continually clipping and cutting back, or the bed becomes ragged and loses its trim, neat aspect The chicf kinds used arc alternanthera, echeveria, mesembryanthemuin cordifolium variegatum, herniaria, sempervivum, golden leather. and sagina.

The diagrams on this page are typical examples of carpet bodding, and although the make-up of the beds is largely a matter of individual taste. the suggestions given may be accepted as giving a pleasing diversity of pattern and colour. Fig. 1 shows an ivy leaf; $A$, silver foliage with dot plants if dark-leaved nasturtium; $B$ and $C$, vermilinu and gold, rose and carmine, or mauve and purple. Fig. 2 shows a corntlower: A. maroon : B , gold or silver foliage with petals in two shades of blue. Fig. 8 shows a maple leaf : A. dull gold with dot plants of scarlet crimson; B, Californian bluebell or pale bluc violas; C, gold, scarlet. crimson, or deep blue. See Bedding.

CARPET SWEEPER. A carpet-sweeper consists of a circular brush enclosed in a wooden box on wheels and fitted with a long handle. The dust is collected in the box, which should have rubber comers to prevent. damage to furniture.

A carpet sweeper will last for years, and do its work easily and effectually, if it is kept in proper order. Fach day, after use, the dust

Carpet Bedding. Figs. 1-8. Diagram showing several different deaigns which oan be employed in laying out formal beds. See article above
$B_{y}$ apeciul arrangement wilh Amalrer Gardentag
and Huff accumulated in the box must be removed, and the brush itself kept free from hair, cotton, etc In most kinds an automatic comb is fitted for accomplishing this In time bits of hair, thread, etc., will get wound round the axle of the sweeper between the wheels When this is the case the frame work should be drawn away from the axle, and the brush taken out so that the axle may be cleaned. See Vacuum Cleaner.

CARRIAGE. In general this word is used for any vehicle used for carrying, but more especially it means a vchicle drawn by a horse or horses and owned by a private individual Carriages are called by different names, according to their shape, size, and other conditions.

Carriage Licence:. In Great Britain a tax is charged upon carriages kept by private persons. For four-wheeled vehicles drawn by one horse this is 2ls. a year, but if drawn by two horses it is 42s. Two-wheeled velicles pay 15s. a year. Vehicles used for business purposes are charged nothing, but a tax of 15s. a year is paid by the owners of cabs plying for hire. Carriage licences can be obtained from any post office.

CARRIER: Of Disease. In medioine this is the name applied to persons who are found to be carrying in their bodies virulent micro-organiams which are capable of producing disease in other people if communicated to them. Thus diphtheria and cercbro-spinal fever carriers have the microbes of these diseases in their throats, and these people may not themselves have suffered from the disease which they carry, or only so inildly that it has been overlooked. Enteric fever carriers are persons who have recovered from the disease but who continue to pass the germs in their stools
When a case of diphtheria (q.v.) arises all residents in the house should be examined to ascertain whether or not they are carriers.

CARRIER : The Legal Aspect. There aro two kinds of carrier, the common carrier and the special carrier. A common carrier holds himself out to carry goods from one fixed place to other fixed places on payment of his customary charges. A special carrier undertakes special journeys on terms arranged for each journey. A railway company is a common carrier, a furniture remover a special carrier.

A common carrier is bound to accept for carriage and to carry all goods of the kind he professes to carry so long as he has room for them and the consignor will pay the usua! charges. Apart from any special term, he is liable for their safety and safe delivery, quite apart from his negligence, except for acts of God and the King's enemies. Thus, if they should be stolen by armed thieves, or damaged by someone else's negligence, he is liablc.

Railway companics are only liable for goods sent at owner's risk if the goods are lost or damaged by the misconduct of their servants. See Parcel Post.

CARRIER PIGEON. Noted for its stately grace and dignified bearing, the carrier pigeon is held in high esteem by fanciers. No pigeon commands higher prices, as much as $£ 200$ having been paid for a show specimen. Possibly, on account of its name, many wrongly attribute to the carrier the characteristics of the homer; but although at one period it possibly possessed them, they are non-existent in the English carrier of to-day See Pigeon.

CARRIER WAVE. A continuous wave of constant frequency which is radiated all the time broadoasting is being transmitted. The carrier wave is modulated or varied by sound vibrations picked up by the miorophone in the broadcasting studio. See Microphone.

CARRON OII. A soothing application for burns and scalds, first used at the Carron
ironworks, Stirlingshire, received the name of Carron oil. It is prepared ly shaking together equal parts of lime-water and linseed oil. when a thick cream is obtained. This is freely applicd to lint or soft rags, and placed upon the burn or scald. Carron oil is improved by the addition of 1 or 2 per cent. of an antiseptic. such as carbolic acid or eucalyptus oil.

CARROT. This valuable root vegetablc thrives best in deep, well-drained soil: but heavy land can be made suitable by cultivation and by adding sand, sweepings from garden paths, grit, and leaf-mould. Lumpy soil will produce ill-shaped roots. As the seeds are small. the ground surface must be well broken down with fork and rake before they are sown.
The main crop of winter roots is obtained by sowing seeds thinly in shallow drills 10 in apart in April. The sceds are covered suffciently by passing the rake over the drills. The seedlings must be thinned out gradually until

Carrot. Early Gem carrots, a prolific and proftable variety. Above, rights, banch of Long Reds
they are 6 in . apart: the final thinnings will be large enough to use in the kitchen. During the summer months the soil between the rows must be hoed frequently to kecp down weeds. In October or carly November the roots are lifted and stored in sand or soil at the foot of a wall or fence. Often they are placed in boxes in a shed, but in such conditions their flavour deteriorates.

A sowing of an early varicty in July will yield small roots of excellent flavour in autumn and early winter. 'To provide young carrots in summer, seeds should be sown on a warm sheltered border in March. By sowing on soil placed on. a hotbed in a frame in November, and during the winter, a succession of small early roots is obtained.

- On deep, well-tilled soil the long-rooted varieties, e.g. New Intermediate and Long Surrey, may be sown. For ordinary garden soil James's Internediate and Scarlet Intermediate are more suitable. Uf the small- rooted sorts for sowing in March and again in July, French Short Horm, Early Gem, and Scarlet Horn should be chosen. Varieties to sow in a frame in winter are Parisian Forcing, Farly Nantes, and Inimitable Forcing.

How to Cook. The carrot contains no starch, but a large amount of saccharine matter, and is of great value as a flavouring vegetable. loung carrots are most

wholesome, and the fine colour of the outer portion lends a decoralive touch to stews.

Carrots should never the peeled. After they are washed take a sharp knife and lightly scraje off the outer coating, scraping from crown to root. It is best not to do this until the last moment. or the flavour is weakened. Young carrots re quire about $\frac{1}{2}$ an liour's cooking. and old ones about 1 hour's.

If to be stored during the winter, put them, if possible, on a slate slab, cover ing them with sand. Carrots when used tor garnishing purposes are cleancd and cut into various designs, after which they are boiled in slightly salted water. Grated carrots are often used in Christmas puddings and added raw to salarls.

To boil carrots, cut off the green tops and rootlets of 2 lb . of carrots; scrub, then scrape the carrots downwards until they are quitc clean, taking care to cut out all specks. Lay them in cold water, cutting them, if large, lengthways into quarters. Place them in boil. ing salted water, and boil them until tender. Pierce them with a skewer to make sure they are soft. Drain off all water, and serve them either plain with butter and pepper, or with melted butter sauce, or chop finely, reheat in the saucepan. and serve with 1 oz . of butter and a dusting of pepper. In the last case the mixture is pressed into a mould and case the mixture is preased into
turned out into a vegetable dish.

Carrot. 1. Insafliciently thinned. and, 2 amply thinned plants. 8. How to sow orrrots : a, hole levered with c, seed sown on top with fine soil: c, seed sown on top and covered with ane trom trost in arrots stored awn from frost in fine moil or eand

Young carrots, boiled whole, may be served with rarsley sauce made from a lump of butter the size of an egg, half a handful of finely. chopped parsley, the juice of balf a lemon, and a little seasoning. Toss these ingredients in a pan over the fire for a few minutes, and then pour the whole over the carrots, serving at once.

Carrots with mint-glaze are excellent. To prepare them, wash and scrape about 3 or 4 medium-sized, well-coloured carrots. Slice these into $f$ in. thick rounds, and boil them for 10 to 15 $\min$. Then drain off this water and in its place put 2 tablespoonfuls white sugar and 2 oz . butter. Stir in 1 tablespoonful washed, finely chopped, fresh mint leaves, cover the pan, and let its contents simmer until the vegetable is tender and has a glazed appearance. Then arrange in a hot dish, pour over any juice, and add salt and pepper. A pretty dish is made if a border of cooked peas is added.

CARROT FLY. Carrots are frcquently much injured by the larvae or maggots of the carrot fly. which hore into and feed upon the

roots, causing them to become brown or rusty. and finally rotten. In some eases the growth of small roots is entircly checked. It has been noticed that the pest is worse in dry seasons.
In appearance the carrot tily is shiny black or dark greenish-hlack in colour and ahout $\frac{1}{2}$ in. long, with $n$ wing expanse of nearly $\frac{1}{2}$ in The maggot is yellowish, about $\ddagger \mathrm{in}$. long
The tlies appear in spring, and may be seen upon the lower leaves of trees and bushes, especially near brooks and streams. When the carrot roots are well eatablished the Hies lay eggs upon them just below the surface of the ground. When young, the maggots especi ally attack the outer parta of the carrot.

When it is noticed that the tops of carrots change colour prematurely, the roots should be examined and the infested parts forked up and destroyed As a preventive measure spraying with paraftin emulsion is recommencled. A paraffin emulsion may be made and applied as follows :
Dissolve 1 lh . of soft suap in 1 gal . of boiling water, and, whille still hot, add 1 pt . of paraflin and churn the imixture thoroughly
When required for use add 1 gal . of the inixture to 9 pal, of water, using rain water or water which is not very harel.
Spray the carrota soon after the seeds have germimated and immediately after they have been thinned.
Sawdust impregnated with paraftin laid alongside the plants helps to keep away the Hies in carly summer. Pressing the carth close round the stems after thinning the seedlings tends to prevent the llies from egg laying
In localities where the attack of the Hy is very prevalent, a supply of carrots can usually he maintained loy sowing early varieties in a sheltered position in March, for early use and again in July for autumn and winter.

CARROT PUDDING. Several puddinys of which carrots are a constituent are some times known as carrot puddings. One of these is Victoria pudding, while another is made as follows: Mix together with a little inilk 4 oz . of grated carrots, the same quantity of suct, flour, and currants, 3 large tablespoon fuls of golden syrup, and the grated rind of a quarter of a lemon. Steam the whole in a hasin for $1 \underline{1}$ bours, and turn out to serve.

CARROTSOUFFLE. An excellent sulffle is made with cold cooked carrots. Rub sufficient through a tine sieve to fill a break last cup. Molt 1 oz . butter in a saucepan. stirring into it 1 oz . llour. When well blended, add the sieved carrots and stir the mixture over the fire until it boils. Cool it for a minute or so, then bent in the yolks of 2 eggs, and wenson all these ingredients carefully. A tiny pinch of powdered mace is an improvement.
lut the whites of the eggs on to a plate, and heat them with a knife to a very stiff froth. Fuld theme whites very lightly, but thoroughly,
into the carrot mixture, then turn it either into a buttered fireproof soufflécase or a greased pie dish, or into some small fluted paper soufflé cases. These must only be about two-thirds full, unless a greased paper band is tied round outside the mould to support the mixture as it rises. Bake these souffés in a quick oven for about $15 \mathrm{~min} .$, and, when cooked, add a dus of tinely chopped parsley over the top.

CARROT SOUP. In a good recipe for carmot soup only the red part of the carrots should he used. Melt 1 oz. of butter or good dripping in a saucepan, add to it 1 heaped breakfastcupful of the chopped red parts of raw carrots. Turn the pieces about in the hutter for 10 min., taling care that they do not colour in the least. Next add 1 quart of stock, and boil the soup gently until the carrots are quite soft, which will depend on their age. Rub the soup through a hair or fine wire sieve, put it back into the saucepan. which must first be rinsed with cold water. and let it re-hoil. Mix a level tablespoonful of cornflour smoothly and thinly with a little cold stock or water. dedd it to the boiling soup, and stir it until it re-hoils, then let it cook gently for ahout 15 min ., removing all grease from the surface.
Season the soup carefully with salt, pepper, a few grains of nutmeg, and $\frac{1}{d}$ a teaspoonful of
castor sugar lastly, add about $\frac{1}{2}$ a tencupful of carefuily-hoiled rice. Serve the soup in a hot tureen If no atock is available use water, adding, if liked, a litt'e meat extract. This is also linown as Crécy soup.

CARVERS. This term is applied to the knife and fork that are used for carving fool They differ in shape and make according 10 whether they are meat carvers, game carvers or fish carvers. Meat carvers have long blades, 8 to 10 in. in length, a usual size for household purposes being 8 in . Carvers for ham and other cold meats are best with long narrow blades. The essentials are a good halance, : well-proportioned handle and a keen cdge. The two former are provided by the inakers the latter can be developed at home with the aid of a table stecl or sharpener

Fish carvers are preferably made o! silver hut cheaper patterns are made in electro-plate

Game carvers are shorter in the hlade than meat carvers, have longer handles and n different halance. They are usually inade o good-class steel, either plain or rustless The former take a very keen edge. For carving poultry and game, patent sécateurs are also used Fashioned like large curved-bladed scissors, they are equally effective for disjoint ing an uncooked fowl, or for carving at table Sise Cutlery: Fork Kinife; Steel

## Carving for the Home Table

## Correct Ways of Cutting Meit, Poultry and Fish

## See also the entry Boning the usual curs and ioints provided by the rctailer and given under Bacon; Beef: Mutton, cic.

The correct carving for table of meal, middle is reached, when the slices should poultry, and fish has considerable influence be only $\frac{1}{2}$ in. thick. When the middle is past, on the flavour, which may be spoiled by again serve slices alout 1 in., until the tail is indifferent carving, and is also moreeconomical reacherl. One side of the salmon is now clear
For meat and poultry there are three neces sary implements : a good sharp knife with a fairly thin blade, a strong, two-pronged fork. and a steel, which, however, is only required in case of emergency, for the knife should be well sharpened before it is placed on the table or the sidehoard.
A good carver will consider the prarticular tastes of those he is serving, and also take care to cut the meat neatly so that it is not dis. figured if brought for the second time to the table The cook may make the carver's task easier by placing the joint or bird on a dish quite large enough, and also) hy refraining from filling this with gravy
It is better when a dish is much garnished to remove the joint on to a llat dish, conven ently placed, to obtain full control for carving
Figs 1 and 2 slow how, with a pair of forks, the centre bone s removed from n fried sole. It is not oonsidered correct to fillet a fried sole, as the llesh adheres to the forks, but in the case of a grilled sole, by all means, yes. Always rememher to cut the fins off with pair of scissors before cooking. It makes the dish look much more appetising. When carving a salmon a void break ing the llakes, and cut crossways. Run the knife along the hackhone first, then right through the belly. Carve from the head in slices about 1 in. thick, until the

Carving. Figs. 1 and 2. Separating the backbone neatly from the flesb of a fried or grilled sole by means of two forks

slice of the breast should be served with each leg. The fork should never be dug into the lireast of the hird.
Small birds, like plover, quail and snipe, are served whole. Woodcock, partridge, grouse, and pigeon are usually cut into halves.
The carving of a turkey is a similar operation to that for a fow. Remove the leg (Fig. 10) place the bird on its back, and start carving from the centre of the breast towards the side. The logs should be cut into slices and served with pieces of breast and stufting.
The carving of a goose is similar to that of turkey. With a woast gosling remove the legs as in the case of turliey, then cut the wings away, leaving the breast. Carve the breast

Carving. Figs. 3 and 4. When carving a surloln loosen the meat from the chine and then carve downward. Fig. 5. For a ham, make an incision at the knuckle and carve towards it. Fig. 6. For a ler of mutton, make an inclsion and carve fairly thick slices. Fig. 7.
the long cut. Then carve the opposite side of the shoulder. giving a slice with the long cut. Which will inake a good portion. A small piece of the oyster should be served, this being regarded as $n$ great delicacy It should be remembered to out down the bone in a rather slanting manner.

In dealing with liare or rablit, separate the legs and shoulders. and cut the back part into portions. If a knife is inserted into the joint, and the back raised up, the opern. tion is simple.

To carve a fowl, or a pheas. wisy up the slices should he out alternately ant, hold the bird firmly on a dish by inserting from right and left sides, or they would eventually become as large as a plate.

With a leg of pork the method is naturally similar to ham, but it is advisable to remove the crackling. Then the slices can be cut as thin as required.

Thicker slices of a leg of mutton (Fig. 6) sliould be carved than for beef. First make an incision at the knuckle. Continue until a hone at the top of the leg is reached. Then cut left and right sides alternately.
The heat way to carve a saddle of nutton is to run the linife along the chine bone, and under the meat along the riks. Cut down to the bone on the cross, then slices from the outside, which is called the flap. This will make the piece V-shaped. Two slices of crosa-out and a piece of fat are generally sufficient for a meal. .

Commence carving a shoulder of mutton (Fig. 7) from the blade bone to the angle bone; this is called

Carving. Figs. 8 and 8. For a fowl, remove lers leaving wings intact to enable the carver to quarter the bird. Fia. 10. When carving a torkey, first separate a ler from the carcass and then carve slices from the breast

Courtesy of $d$ Lnons \& Co.. Lid.
the carving fork into its leg, then loosen the lege by cutting skin, following the natural curve of leg. Now turn fowl on breast and out sharply through backhone. Remove legs from wing (Fig 8). Now cut, wings in tive
 and cutting to wards and through the wish. hone, then repeat operation: by fol lowing the first incision and cutting right through the breast the fowl is quartered. The portions call be increased by cut ting the wings from the hreast with winglets at tached, making two portions, and dividing each leg into two. A sinall a teasjoonful of the liquid extract, may be taken at bedtime, of smaller doses, 10 to $\because 0$ drops of the liquid, or a grain of the dried extract, may be taken before each meal, 3 times a day.

The aromatic syrup may also be used in appropriate doses To cover the exceed ingly bitter raste of the liquid extract it may be inixed with an by inserting kinife equal amount of liquid extract of liquorice and in centre (Fig. 9) taken with a little tincture of orange or chloro

CASCARILLA. This dried bark has aromatic bitter properties, and two medical preparations are made from it. The infusion dose $\frac{1}{2}$ to 1 oz , which does not keep well, especially in warm weather; and the tincture dose $\underline{d}$ to 1 dram. It stimulates appetite and digestion and makes a useful tonic in con valescence from an acute illness. A tablespoonful of the following may be taken thrice daily in a wineglassful of water, at or after meals: Tincture of cascarilla, 6 drams; tincture of orange, 3 drams ; syrup of orange. 4 drams; chloroform water to 6 oz . See Appetite; liet.

CASE HARDENING. This process con sists in increasing the carbon content of the surface of a steel relatively low in carbon,
so that by being heated and then quenched it can le hardened like other atcel. Simple case hardening may lee carried out by any amateur $A s$ an example, suppose a new cone has been made from ordinary mild steel, and that it is desired to harden the surface. When sufficiently heated and surrounded by carbonaceous material, mild steel

Casement. Fir. 1. Metal casement window Figs. 2 and 3 Fastener
and stag lor wooden casement
will absorh cartion, and the longer the time the steel is in the carbonaceous material, the deeper becomes the case hardening effect.

Having obtaincd a metal box, take some clean old bones, crush them up as finely as possible, sprinkle a layer of the bone dust on the bottom of the box, place the cone in position, and pack it all round until it is huried in bone dust. Fix on the lid by means of a catch. or wire it on with steel wire. If a very hot fire can be raised in the kitchen stove, this may be used as a furnace wherein to heat the box thoroughly and its contents This must be kept glowing red-hot for half an hour or so, when it may be removed from the fire, the lid knocked off, and the contents dropped on to the hearth. The cone can then he picked up with a pair of tongs or pliers and dropped into cold water.
If several pieces are to be case hardened, it saves much trouble to purchase one of the ready mixed carburising compounds sold for the purpose. See Hardening.

CASEIN. Organic substance contained in milk and cheese, being the essential ingredient of the latter. Casein can be desiccated and prepared as a substitute for eggs in baking, as the basis of an enamel paint, and as a substitute for glue in the making of cement. See Cheese.

CASEMENT: Of the House. In domestic architecture the casement is a window in which the sash is lung upon hinges to open like a door. The expression, the casement, is generally understood as referring to that part of the window that opens and shuts. By casement window is meant a vindow of the cottage type, and as a rule made with inultiple panes of glass.

Commercial casement windows are made in a wide variety of pattems and sizes: those commonly in use measure 20 in ., 39 i in., and $58 \frac{1}{2}$ in. in over-all width, and either 3 ft ., 4 ft ., or 5 ft . $1 \frac{1}{2} \mathrm{in}$. in height. The total area in square fect of all the casement windows in a room should never be less than 10 p.c. of the flonr area: and preferably more than this for efficient lighting and ventilation. Various combinations of the nindows enable requirements to be met. By having one casement to open on the left hand and another on the right hand, with possibly a transom or top hung casement, at least one window can be
open in any weather (Fig. 1). The one that opens with its back to the wind or rain very seldom permits the weather to enter the room.

The modern tendency is to use the casement window in preference to the sliding sash type; it is made either in wood or metal. The latter has many advantages, for metal windows are wind and weather proof: they are not affected by moisture, and they never jamb or stick in their frames Another advantage is the greater glass space in a framc of given size, metal framing not leing so wide ns wood

Exist ing window openings can often be converted for casements by removing the

showing wedqe shaped slot for fastener
important when fitting the Instenes that it should draw the sash closely against the stopping, for which purpose the rubbing plate is generally made tapering or wedge-shaped. When newly fitted the fastener should draw the window up tight when the lastener is just at the hottom of the wedge-shaped part. This allows for future wear.

Fittings that have been in use for some time may have worn, and the fastening is then insecure, allowing the window to rattle and admit a draught This is remedied by resctting the fastener, recessing it further into the frame, or hy packing out the rubhing piece See Blinds; Burglary; Curtain; Window. etc

CASEMENT CURTANN. These curtains are madc of the same depth as the casement. and drawn along rods fixed to the frame They are provided with rings sewn on to the base of a hem about 1 in deep, and made with a drawtape. which allows a perfcctly even distribution of the fullness.

The rods should be accurately measured and have proper brackets The rings should lie threaded twice with a cord, so that they can be drawn or undrawn. Each ensement will have its own curtain, and if, as is usually the casc in a bay-uindow, there is a row of lights above the casements, these should be provided with curtains In this way light can be regulated more easily than by the single pair

The use of thesc curtains is not conlined to casement windows they are employed in place of blinds for small нash-windows, and also in full-sized sash-windows. one pair of curtains being allowed for each sash. They are made of various washing materials of casement cloth, cretonne, shantung or Bolton shceting. The term casement curtains is sometines loosely used for any short curtains, but here it applies only to curtains as shown in Fig. 1 on this page, which are fixed within the window frame. Sec Curtain

CASHMERE. Real cashmere is a superlativcly soft wool or hair forming the under coat of the Kashmir goats of Tibet and the Central Asinn platenu

Many goods made not from goat hair, but from fine wool. are customarily known by this name. Cashmere stockings and socks are ordinarily made from tine-spun merino wool Cashmere suitings and dress materials are made from the finer qualities of worsted The real cashmere wool is used in high-grade knitted wear See Shawl.

## Cash on Delivery. See C.O.D

CASSAREEP. The juice of the cassava. root, with the addition of several native spices, yields the condiment known as cassareep. It is introduced largely into a West Indian pepper-pot, and enters into the composition of many sauces

## Cassava. See Tapioca

## Casseroles and Casserole Cookery <br> An Economical Method which Conserves the Flavour of Food

Sec Beef; Chicken; Game and also the articles on allied methods of cooking, e.g. Braising; Stewing
This process is slower than that required by ordinary utensils, but, on the other hand, less fuel is required, the food is cooked evenly, and none of the valuable juices are allowed to escape in stcam. It is on this account the most wholesorne form of cookery. Owing to the elimination of waste, even inferior cuts of meat can be used with advantage. French cooks were the first to realize the advantages of casserole cookery, and it is extensively used in that country. Braising is carried on to perfection in a casscrole.

Quite a number of dishes can be cooked in a casserole, and are best brought to the table thercin. This saves re-dishing, ensures the food being served really hot, and reduces the labour of washing up. Also, it is a most convenient method of cookery for the busy house.
wife, as the fond is cooked without constant attention and can be kept hot for a long period for any late comer to a menl

A useful casserole which can le placed on a gas boiling burner, turned low to a blue Hame, has an outer casing with a turned-in rim. forming a cavity into which heat ascends until the food inside the casserole is cooked.
Casserole of Chicken. Fowls cooked in this way can be successfully made tender and succulent even when they would be otherwise tough. Cut a fowl into neat joints and season each with pepper, salt, and a pinch of pounded mace. Put some slices of broon at the bottom of the casserole and lay the chicken or fowl on these. Having sprinkled over them a linelyminced onion, pour over all half-pint of white stock. This done, the casserole can be covered

Casserote Fig. 1 Lasserole ai chicken. ior coosing a tougb burd
buil together, stirring till smooth. Your this over the tail, and add 2 carrots 1 turnip, and 2 onions. all prepared and cut up small
A bouquet gami and a little spice, with a few peppercorns, should be tied in a muslin bag and put in with the vagetables Simmer gently over the fire or in the oven trom 2 to $2 \frac{1}{2}$ hours, pouring in a little more stock if required Before serving, the gravy must be cleared from fat and the spices and bouquet removed (Fig 3)

Cod with Artichokes. Among the fisl, that can be cooked in a casserole are cod haldock. hake, plaice, salmon, sole, turbut and whiting. A good way and placed in a moderate oven for an hour, or with cod is to flake $1 \mathrm{lb} .$, peel 4 Jerusalem arti it can be p!aced on the hot-plate of a range chokes. and put them into the casserole with and the contents simmered for an hour. If a gas stove is used a thin iron plate or an asbestos mat put over the stove will enable the casserole to simmet thereon This recipe can also be used lor other poultry or for game The cassero!e illustrated (Fig. 1) is of ylass with a plated silver mount for table use.
Ways with Meat. Onc of the beef dishes that can be cooked in a casserole is the shin Take 1 lb . of this and, after wiping it, cut it into small pieces and add four slices of fat

Casserole. Fig. 2. Beel casserole served In an earthenware diah. Fir. 3. Casserole of ortail. to which carrot, turnip and onion are added. the whole cooked in a china digh
bacon Then place it in the casserole with two finely-minced onions, a scraped carrot cut into small pieces, some mustirooms or mush room ketchup, and a pint of stock Bring it to the buil and let it simmer for three or more hours. Strain the gravy and add a dessertspoonful of Hour smoothly mixed with cold water, or, if preferred, with a glass of claret The beef can then be returned to the casserole and again allowed to simmer. Fig 2 shows this dish ready to be served in the casserole. Oxtail is also an excellent choice for cassorule cooking. Having cleaned the tail and cut into pieces, fry them in 2 oz of butter or dripping When the pieces are a rich brown, put them into a casserole, and cook in the remaining fat $1 \frac{1}{2}$ oz of fine flour, then, by degrees, add $1 \frac{1}{2}$ pints of good brown stock, and let all

Casserole. Fig. 4. Appetising breakfast dish of flsh baricot beans and egrs, served in a klass casserole

3 pint milk, 1 oz. butter, a dessertspoonful minced onion, pepper and salt to tuste. Cook gently in the oven until the artichokes are soft, then add sufficient melted butter sauce to cover, bring to the boil, add a squeeze of lemonjuice and garnish with Gnely-chopped parsley before serving in the casserole

Earthenware for Vegetables. As regards vegetables, cabbages, cauliflowers, spring greens, spinach, turnip tops, green peas, celery, brussels sprouts, and Frenoh beana

While casting in iron can only be done effectively in a foundry. the non-ferrous metals like lead and brass offer plenty of scope for the amateur who lias provided himself with the necessary tools. Which are neither numerous nor coatly. Such work has a particular attraction for many, and it is ruite unlike any other mechanical prucess. For casting in lead, one or two iron ladles, a wire skimmer or spoon for removing the dross and a few simple modelling touls are all that are necessary. The lead can be purchased from most ironmongers or plumbers, as can the fine plaster of Paris used for the moulds. For casting in brass or aluminium a furnace is necessary The addition of a few plumbago crucibles, a pair of crucible tongs, moulding sand, and flasks or moulding boxes, complete the equipment.
larly good braised in a casserole First parboil the celery for 10 min in salterl water and then drain it. Place in the cassarole with sufficient boiling brown stack to cover the celery and put in the oven till tender. Serve with chopped parsley and a chopped, hardboiled egg sprinkled over the top Fruit cooked in syrup, to be afterwards served cold, is better stewed in a casserole, as not only is the Ilavour consersed better, but also the colour and shape

Beforc being used, a casserole, it of earthenware, should be toughened or scasoned by filling it with cold water to which a liandful of salt has been added Bring the water slowly to the boil, and then leave it to cool in the casserole Another method is to melt some fat in the pan, smcar it well all over the inside and out, and bake it in a cool oren. A casserole is best used in the oven or on the hot-plate of a kitchener, and should never be placed directly over a fire or a fully-turned-on gas-jet. Glass casseroles should be used in the oven only The food in these is cooked not only by the hot air of the oven, but also by radiation of the glass
Breakfast dishes are appetisingly served in glass ware A good recipe is made from I lb. of left-over cod or haddock, two boiled and mashed potatoes, I lb. haricot beans, boiled and pressed through a sieve, and four poached eggs. Make $\frac{1}{2}$ pint anchovy sauce, place with faked fish in casserole, add potat() nnd put beans on top of these, also several dabs of butter. Heat slowly in oven and before serving place poached eggs on top (Fig. \&).

To clean casscroles, wash them inside and out with hot soapy water to which a little soda has been added, and rinse them with warm water In case of very dirty pans. fill them with cold water containing a little soda and place them on a hot-plate to heat the water and so loosen the dirt. Stains may be removed with sifted ashes or silver-sand.

CASSIA. A group of trees and shrubs of which only cassia corymbosa is commouly grown in British gardens. This is an evergreen shrub, 6 ft . or more high, which bears yellow, pea-shaped flowers freely in summer; it is not hardy and must be kept in a warm greenhouse for the winter. It will cover the back wall of a greenhouse if planted in a horder of loany soil, or it may be grown in large pots and used in Hower beds in summer. Propagation is by cutting under glass in spring.

Oriental varieties of the same shrub provide the purgative senna leaves of conimerce. Further species include the Hashish, or Turkish dream drug.
The bark of the cassia used in cookery resembles cinnamon in appearance, smell and taste. See Cinnamon.

## Casting in Iron, Lead and Brass <br> Methods and Equipment for the Amateur Metal Worker

A knowledge of this subicet will help materially in making many of the articles described in this work See also Lathe; Metal Work: cte.

Casting in Lead, For first attempts at casting the amateur will be well advised to used lead or type-metal. Wuoden moulds can be used, and the lead melted in an iron ladle over the kitchen fire. Cast lead panels or plaques can be noodelled in wax or plasticine, and cast in plaster moulds, the lead casting being carcfully scraped wherever any rough edges or faulty places develop Almost any simple article can be made after lirst planing up some soft wooden blocks of appropriate size.

In making a wood mould of an artiole to be cast, sume skill in woodworking is required, since the mould must be a replica of the article itself in reverse, and a core must bo provided if the article is hollow. The following system avoids a great deal of this trouble.

Fig. 1. Plaster mould for casting a toy soldier. Left a hollow balf mould : right, the other ball, with the casting in place
model, somewhat smaller than the linished model, then to coat the exterior with dental modelling wax, and shape this to the desired form with modelling tools. Three or four wires are then driven partly into the model in the least conspicuous piaces, and the compo and produces excellent results. The first sitc model coated with plaster as hefore, thing required is a replica of the desired casting: this can be an existing object, such as a toy soldier, or the article can be modelled in wax or plasticine. However it is made or obtained, the remaining processes arc the same. The object is rubbed over with vascline, then slightly warmed to ensure the vaseline flowing into every crevice, and the surplus is wiped off. Next stand the object on a piece of glass, a tile, or a smooth board, well greased, and make up some plaster of Paris into a thick paste. This is best done by putting some cold water in a howl and sprinkling the plaster on to it, stirring the water gently all the time and always in the same direction. Continue adding plaster until the mixture is thick and sticky (like clotted cream, but not so thick)
Heap the plaster up and around one-half of the model, keeping the plaster in place with a temporary wall of clay or plasticine which has been previously built up. Allow the plaster to set, which will take about twenty min or less, remove the clay and the model, and clean up the surface of the plaster to a tlat face, using an old table-knife. Drill two or three holes into the body of the plaster, and fix into it little wooden pegs with rounded ends. These should protrude about $\frac{1}{2}$ in. from the face of the plaster, and enable the two halves of the plaster mould to be put together in proper register. Replace the model, vaséline the face of the plaster, and well vaseline the pege. Then huild ul the other half of the mould with plaster as before. The result is as in Fig. 1.

To cast from such moulds, remove the model, wipe off si much of the oil from the vaseline as possible, and coat the interior with powdered blacklead. Then tie the two pieces of the mould together with atring and pour in the lead from what will be the bottom of the model. Some elaborate models will require the moulds in three, four, or more parta to enable them to be removed from the casting without heing damaged.

When it is desired to make a hollow lead casting, it can be done in one of two ways. An ordinary mould can be made, the lead poured in, and immediately poured out again As the skin or surface in contact with the mould is the first to chill and set, only the inteitor parts will be molten, hence a more or less hollow casting is the result. A similar method is used commercially for casting lead toys and for similar purposes. Disadvantages are unequal thickness in the casting, frequent distortion, and a tendency for holes to form in the outer surface.

A better plan is to make rough plaster chimey whe the
except that the whole model is entirely covered, the only openings being the venthole for the exit of air and the gate or entrance for the molten metal.
When the plaster is quite dry it is placed in a dish in a hot oven with the gate downwards, the heat melting the wax, which Hows out of the mould into the dish. The planter core remains in position, as it is held firmly by the wires. A space must be hollowed out in the wall of the mould around the gate o form a trough into which the molten lead may be poured. The lead Hows into the space hitherto occupied by the was, and when cool the mould is broken open and the casting removed. The plaster in the interior can be chipped out with a amall chisel, and the holes inade by the pegs closed up with a spot of solder.

It will syatem requires an opening soniewhere in the casting to enable the plaster to be removed : generally this can be arranged under the feet or at the hack. When using plaster or metal moulds it is desirable thoroughly to warm them before introducing the molten metal.

Casting in Brass. A simple furnace suitable for melt ing brass or small quantities of iron is illustrated in Fig. 2, and can radily be made from bricks. The furnace is 18 in . square, built with nine courses of bricks set in cement on a concrete foundation 4 in. of a wooden core or box 6 in. square: the tiue is similarly cored with a $3 f$ in. diameter wooden block. At the hack of the furnace other bricks are set up to support the chimney, which is made from 4 in diameter stove pipe, and is 24 ft. high, for which reason it is desirable to place the furnace outside the house and against a solid brick wall to which the

Casting. Fig. 3. Furnace damper. Fig 4. Simple gas-heated furnace

The grate is inade from a regula. stock cast iron fire grate and is supported on two bars of iron built into the brickwork. The top of the furnace is closed by a fire brick 12 in square and 2 in . thick. All joints åre made airtight with fire clay. In use, a fire is made with gas coke worked up thoroughly hot, the furnace again filled with coke and the crucible set in position on top of the fire The lid is then placed on the furnace top and luted or made airtight with fireclay A damper: at the top of the chimney is a convenience in regulating the fire, and is operated by a long wire. as in Fig. 3.
Such a furnace should melt 5 lb . of cast iron in of an hour, brass being melted in inuch less time. After every hicat the fire grate must be pulled out and the slag cleaned away with a rake or scraper. as if allowed to cool off it will adhere to the lining of the furnace and be difficult to remove.

Where gas is available a very simple furnace can be rigged up by using the gas blow pipe as a heating medium. The furnace is simply built up from fireclay bricks, well jointed with fireclay and provided with a lid and a hottom of the same material, as in Fig. 4. The lid has a small and slanting hole ahout $1 \frac{1}{6}$ in. in diameter cored through, and a hole is left in the side of the furnace to receive the nozzle of the blow pipe. The gas is then turned on and lighted, the bellows operated steadily, and the gas adjusted until the flame entirely fills the furnace and thick. The interior is lined with fircclay, squeeze it tight and on opening the hand if解 poured in when wet, and is formed by means to pieces, it can be used for moulding, other-

through the fine sieve. After mixing, damp the material to make it cling together. Moulding boxes can be made from wood 1 in

Casting. Figa. 8-8. Moulding bor, pattern and core or canting an alaminium candleatick
thick, just like an ordinary lidless box but with triangular corner pieces glued and nailed to the inner corners as in Fig. 6. The boxes can be any size to suit the work and are made up solid and then sawn asunder. The ends should have dowel pins or guides to make them register properly; the parts are kept together with a hook and eye on each side. Note the holes (A and B) drilled to act as a gate for pouring in the metal, and for a vent which allows the steam or gases to escape: when the metal overflows at this latter hole it indicates that the mould is full.
In use, the wooden frame is laid on a wooden baseboard and filled with damp moulding sand rammed in tight and levelled off flush with the sides. The model or pattern is now pressed into the sand until half the pattern is embedded, and the surface is then finished of leve! with the sides. Place the top box on the lower one, sprinkle the surface of the sand in the lower box with dry parting sand, that is finely powdered fire-brick dust, and then fill the top box and ram home the sand.

## Preparing the Mould for the Metal

Separate the two, remove the model or pattern by rapping it with a stick, dust the surfaces with fine charcoal, cut a passage way to the gate, and another to the vent, also drive a knitting needle through the sand in one or two places from the cavity formed by the pattern, these to act as additional air vents. Replace the top box, and clamp them both together, then pour in the molten metal. The brass casting will come out much cleaner if a little powdered resin is spinkled over the mould faces prior to replacing the top box.
The amateur can use new brass obtained from the metal merchants. Ornamental drawer handles, door fastenings, keyhule plates, and similar cabinet fittings may be cast in brass. A number of small models might be cast together in the same box. the cavities being joined by a channel to allow the multen metal to flow from one to another. The thin bonding piece thus produced is easily removed when the casting is cold. Alu.
minium is cast in much the same way, but larger pouring gates and ample air vents are needed. The metal should not be over. heated and should be poured as soon as properly melted.
Plaster casts can be madc in plaster or wood moulds. The plaster is mixed to the consistency of thin cream and poured in the same way as if it wero metal. The moulds must be well oiled with lubricating oil prior to putting in the plaster. The surplus oil is poured out before casting.

Fig 7 is a pattern of a short candlestick cast in aluminium. It should have the base recessed so that it will stand steadily on n surface that might not be quite flat : the top should be hollowed slightly, so that the melted greasc will not run over the edge. If the pattern were made thus, however, it could not be lifted from the sand of the mould, so the preliminary pattern differs a little from the finished article.

In Fig. 7 the outline shows the pattern itself, and the heavy dotted lines show the details of recessing the base and candle holder. The candle-stick is best finished by turning in a lathe, and therefore a piece is shown projecting from the base, to be held in a self-cen tring chuck, or for a carrier to be put on it and the candlestick held between the centres of the lathe.

The projecting piece at the other end is termed a print, and will not appear in the casting, as it pro. duces the hole for the candle. The faces of both ends are slightly conical to allow the pattern to leave the sand easily.
A core is required, as shown separately in Fig. 7, and in position in Fig 8. It should be of the diameter of the print. Its length should
 be that of the projecting print plus the depth of the hole required in the top of the candlestick. shown by the dotted lines. This core can be made out of ordinary bath-brick sawn and filed to the required shape. When the pattern has been taken from the sand, the core

is placed in the impression which was left by the print and butting aqainst its end (Fig. 8). The melted meta will How round the core, and this will pro. duce the hole for the candle. The print should not be made any shorter than shown, or the

Castle Nat. Laft, aut removed. Right nut in place on bolt with aplit pin inferted but not fally bent over
melted metal might float it up. When the casting is taken from the mould, a metal plug can be fitted to the hole, so that the work can be centred to run true in the lathe, and it can be turned all over. The base can be turned flat and recessed, and then with a pointed tool the projecting piece can be parted off.

CAST IRON. Although one of the cheapest metals, cast iron is of little use to the amateur worker, except in the form of small castings for the construction of little engines and other mechanism. It is widely used for all kinds of domestic appliances, from drain pipes to gas stoves, and, being brittle, must not be struck with a hammer. It can only be satisfactorily repaired by autogenous or acetylene welding. In drilling holes a handclrill or brace and a sharp twist drill are employed, but no lubricant must be used upon the drill: if it shows a tendency to heat, it should be cooled with a few drops of water.

CASTLE NUT. This is the name that is given to an engineer's nut having a projecting portion which is slotted: it is secured by a split pin, inserted through a hole drilled in the bolt. The provision of six slots enables the nut to be tightened up to a nicety, is of a turn sufficing to bring a slot opposite the hole in the bolt.
To unscrew a castle nut, the split pin must first be removed by bending the ends of the pin and straightening them as much as possible with the pliers. The pin is pulled out with a pair of pliers or a split pin extractor. The nut can then be removed with a spanner.
CASTLE PUDDING. Whether baked or steamed, this is usually made in small moulds or cups. Choose two good sized eggs, lay them on the scales where the weights are usually put, and weigh against them first butter, then flour, and lastly castor or granulated sugar. the former being best.

Beat the butter and sugar to a cream and add the eggs one by one, beating each well in. Next add the flour and a good saltspoonful of baking-powder. Stir these lightly in : lastly add two tablespoonfuls of milk. Turn the mixture into some well-buttered moulds and cither steam them for about 45 min . or bake them, when they will only take from 25 to 35 min . Turn them out on to a hot dish, and make a little hollow in the top of each and put in a small spoonful of jam.

CASTOR: How to Fis. The kinds of castors mostly used comprise the socket, screw and plate sorts : to these may be added bedstead log and truck castors and glides.
In dealing with a socket castor (Fig. 1), not only must height be

Cator. Fig. 1. Socket cator. Fig. 2. Screw cator. Fig. 8. Roller-
bearing plate castor. Fig. 4. Ball castor. Fig. 5. Diagram illastrating how to replace the castor on the leg of a bedstead carefully observed. but the diameter of the socket at its mouth, because any difference in this part will mean either packing for a size too large, or paring the wood if tonsmall, in buth cases inadvisable to attempt. It often nocurs that a screw castor (Fig. 2) will break, and that the atump of the screw will remain in the wood;
this should he removed by the hel ${ }_{i}$ of a.strong pair of pincers.

Plate castors (Fig. 3) are standardised into sizes, and made with either iron bowl or wheel. or wood, the last named being better for domeatic use These heing attached by screws in the plate, are easily fixed, and simple to attach to any chest or piece of furniture for the first time.

Ball-bearing castors may be procured in either ancket or screw patterns, the object of such lieing to make movement more rapid and easy ; but whether such casturs are satisfactory is an open question Glides are ex. tremely useful if in the correct position, and con be driven home by means of a hammer with a piece of wood to protect the plide. Glides are nade circular or trinngular but the former is recommended as being best. Fig. 4 shows a cominon type of ball castor made in n number of sizes for chairs, tables, etc.

To replace a bedstead castor (Fig 5), first remove the old castor, taking care that the pin of the bedstead is straight and the edge of the hurr at the end filed off before attempting to fix the new castor. If the chill or casting at the foot has been allowed to hecome worn so as to have sposiled the seating against which the castor is to work, it may be found helpful to place an iron washer under the castor to form a now sating, but this should not be done imless absolutely necessary. The castur being in place, add a small washer on the top and then rivet over the peg, which will, if sufficient turnover be given. retain the castor in its working position
T'o fix a set of socket castors where none has previously been used will need careful and accurate use of chisel and gouge. laking precaution that the tapered wood end of the ley, be it either table or chair, is exact in the length of the taper, as well as being correct in the extent of its tapering. Use $a$ screw gimlet for each screw hole so as to give every screw a good start, and be careful, especinlly in dealing with oak and mahogany, in both of which it is easy to get a split, to turn the screw gantly and quite straight. It must also be remembered that the outside of the socket should tie Hush at its mouth with the wood of the leg as it enters when in place. See Armchair: Chair; etc.

CASTOR : For Table Service, A pepper castor is often called a pepper pot. Sugar castors are made of silver or electro-plaie, or of glass with a silver sprinkler top. Remove the top from the pot when cleaning it, and it it is all silver, empty the sugar out. Caked sugar is removed from a glass pot by filling it with hot water and letting it stand. See Pepper Pot ; Silver.

CASTOR OIL. This oil is a good purgative, especially for children. In doses from half th, two tablespoonfuls it is often taken by adults.
Varying from 15 drops for a three months infant to a teaspoonful or more for a two or three year old child, castor oil is a remedy which can usually be preseribed with benelit at the onset of most infantile disorders. In stead of plain oil, the B.P. mixture of castor oil may be taken. The dose is one to four trblespoonfuls.

Where in a grown person there is diarrhoea, caused by the irritation of undigested food in the intestines, one to two tablespoonfuls of castor oil, to which has been added 10 to 15 drops of tincture of opium (laudanum), is sometimes a very effective cure.

To disguise the taste it may be takien floating on a layer of peppermint water, and covered with a thin layer of brandy. See Constipation.

CASTOR OIL PLANT. This is the common name of Ricinus communis, a member of the spurge family, which is grown for the sake of its large. handsome leaves and some-
times used in sub-tropical flower heds for the The plant correctly named Aralin Sieboldii is summer. There are varieties with leaves of also called the castor oil plant. different colours, e.g. Gihsonii, bronze, and cambodgiensis, dark crimson. The planta are raised from seeds sown in loamy soil in a warm greenhouse in Fehrnary, the seedlings being poited finally in 5 -inch pots and planted out early in June. They may be placed in larger pots and grown for conservatory decoration.

## Cats: Varieties and Characteristics

## With Hints on the Care of these Domestic Pets

Other articles in this group deal with Dog: Rahbit and other animals kept in the household

When only one or two cats are kept, no hardness of the wood, and a piece of old special accommodation need be set apart blanket utilised as the actual berliding. An old for them. but if catting on a more extensive scale is desired, $n$ hox-room or light and airy attic makes $a$ suitable abode, while a substantially huilt wooden house makes an ideal garden, backyard, or general out-of-doors cattery. Cats stand any reasonable amount of cold, but damp and draughts are fatal to success. if not indeed to the animals them selves A sunny room or a cattery situated in a sunny aspect is a big asset in cat-keeping, as folinity loves sunlight, and one of $\pi$ cat's greatest pleasures is to lie on a shelf or other resting-place at the window, and while enjoving the sunlight, taling a keen interest in all that it sees outside.

Whether hept in a special room or cattcry, or simply as a house cat, the animal should have its own bed. Which may be a basket with a hlanket in it, but a roomy hox, raised a few inches from the ground, and thus above floor draughts, is preferable. A cube sugar-box makes an ideal sleeping-place. The lid should be removed, and the box placed on its side; the upper side then forms a roof which keeps off draughts, while if a broad spar of wood is nailed along what is now the front of the box at the bottom, the bedding will be kept in place and the lower draughts excluded. Neither straw nor hay makes suitable bedding material. Some layers of newspaper can be placed on the bottom of the box to break the
 pillow or not ton coarse canvas bag can be filled with clean wood shavings, and if these are not too tightly packed, they malie $n$ cosy and comfortable bed
Sanitary hoxes or pans should be placed in an out-of the way corner, but always where the cat can get to them with ease. Weil-broken peat moss or ashes from the ranges make the hest sanitary earth. Sawdust alone is not to be recommended, as it sticks to the cat's paws and cost, is carried outside the hox, and usually some is licked off the coat and swallowed Sawdust mixed with the ashes inakes a friable and ahsorbent material, but sawdust alone should be aroided. If the pans are emptied and their contents renewed every dav, they will never smell : apart from that, a cat will not use a dirty sanitary bos, and it is the neglect of that necessary clcanliness which engendery bad liabits.
As soon as it can leave the nest. prent the tiniest kitten will seck instinctively for some earthy material, and if a shallow pan is placed close to the nest, and kept in the one place so that they know where to go, kittens will never give their owners any trouble in that respeet. A pot or box of coarse grass should he giown and with regular watering it will keep freah indefinitely: Cats cat a lot of grass, as it acts as an intermal cleansing agent, and is particularly necessary where long-hairel ents
are liept, as their swallowed fur is apt to gather in and stop up the intestines

All cats indulge in claw-sharpening, and for this purpose they should havo a log or piece of rough wood into which they can stick their claws. It it is rough enough to catch their claws, and heavy enough not to move when they are using it. cats will never scratch lurniture A flat piece of rough wood on which a cat can sit and clarv is the best form of sharpener.

## Varied Dietaries

When house scraps do not suffice to feed the feline fanily practically any of the proprietary dog foods can be requisitioned for the feline menu: that is, any of the broken-up or kibbled foods, and not the actual dog bis. cuits. Cod'n head, well boiled, and sufficient of the liquid poured over it for the lood to nbsorb without being sloppy, and then the flesh of the heads taken awry from the bones ind mixed up with the soaked food, make a nourishing and appretising meal. Or a sheep's pluck, namely, the lights, liver, and herrt, can te secured from the butcher, well boiled. the liquid poured over the food in the snme manner as the cod's head liquid, and the llesh itsell cut up and added Rabbit is a size-making dietary, and horse flesh is excellent, but the latter should be guaranteed pure.

Kittens should be fod on any of the proprietary infant or puppy foods, and should lie taught to lap when they aro about tliree weeks old 'The strain on the mother cat is thus lessened, and the digestive upscts caused by the sudilen tranalerence from the matemal to other food is avoided when the bittens are completely weaned. Cow's milk is neirly always injurious to kittens, because of the preservatives it contains, and for the same resson it disagrees with many ndult cats. luoth cats and kittens should be allowed abundance of clean water to drink

Varieties of Cats. Cuts are classified in two main divisions-Persians, or longhairs, as they are usually called, and shorthairs. The latter include the varjous British varietics as well as Manx, Siamese, Abyssinians, and Russian Blues.

Blues are the most popular of all the feline tribe and the most remunerative for the average cat-lover. Any shade of blue is permissible, but soundness and evenness of colour are essential There must be no dark patches, no tabby markings, and no white hairs. Blacks are jet-like cats, and the most difficult point is to get the colour a rich black to the roots of the cont B!ue and black kittens frequently have white hairs acattered over their bodies, and are often rusty or brownish in their top conts. These blemishes usually disappenr with the kitten coats, and if the roots of the cost are sound in colour, the white-haired bittens make the best-coloured adults.

## The Eyes of Coloured Cats

Creams should be a rich cream or straw colour, the paler the better, but there must be no suapicion of a washed out or whity appearance. Reds should be as rich orange or recl as nossible, but they and creams atill have a tendency to show tabby markings, and the majority of the reds are more or less shaded. Als these varjeties should have orange, a mber, or hazel eyes. White should be pure white with no creamy tinge, and their eyes must be blue, a deep sapphire being the ideal. Some white cats have odd eyes ; that is, one blue and the other orange, and these cata are quite good for breeding from.
Chinchillas, which should have green eyes, should be one clear sparkling silver from nose to tail, that exquisite appearance being attained by each hair being tipped with silvery-grey, the ground colour being white. Brown. red, and silver tabbies should have orange eyes. 13rowns and reds have respective
ground colours of sable and orangc, with markings of black nad red respectively, while silver talibies have a ground colour oi silver with deep hlack markings. The word "tabby" is often interpreted as meaning a female cat, but what it really stands for is the maried or atrined cats, as distinct from the patched ones, which 'atter are tortoiseshell a nd tortoiseshell and white. 'Tortoiseshella should have patches of red, cream, and black, the richer the colour and the more distinct the patches the better, while tortoise-and whites are tortoiseshells witl whte, but the white must not predominate Both varietiea should have orange, a mber, or hazel eyes
The British shorthnirs are self-blue black, white, red, and cream, though creams and reds are very seldom seen. There are also brown. red, and silver tabbies, and tortoiseshells and tortoise-and-whites. The British shorthair is built on finer lines than the Persinn, and is not so cobby, the head is not so round, the nose is slightly longer: the neck should be long and graceful, the legs of medium length, without the clumsy appenrance of the Persian: and the tail long, thick at the base, and ta pering towards the end The coat should be close and s mooth and never woolly. Rusaian Blues are sealakin-coated blue shorthairs, lankily or snakily built, with long narrow heads and laces nud green eyes. The real spalakin

texture and pile of cost is their first casential ; a woolly texture means a cross with a Persian Manx are tailless cats, with very cobby bodies, long hind legs, a round rump, big head with well-cleveloped cheeks, and a rabbit-like coat.
Colour or markings are of no importance in Manx. Abyssinians or bunny cats are found in two varjeties: browns and silvers. 'I'he one should be rich rufus brown and the other pale silver in ground colour, with rabbit-like ticking. They arc more finely built than British shorthairs, but not quite so snaky as Russian blues. Siamese, or the royal cats of Siam, have pale craam coloured bodies, with seal-brown faces, tails, and legs. Their eyes should be blue, and their coats have a woolly texture. Siamese kittens are white when born, and in aged cata the beautiful cram body colour has a tendency to darken anil smudge. Occasionally Sianmese are bred with blue instead of self-brown points.
Care of Persian Cats. Because they are less common and more pictureqque, Peraians, especially the blue variety, assure u greater certainty of profit, but the market for Siamese and Russian blues is almost equally keen. Except that they require regular grooming if
their coata are not to become nuatted and dishevelled. Persians are no more trouble to keep than are shorthairs.

Persinns should never bo wnshed, except by the experienced cattiat: with the exception of the white variety being prepared for a show, washing is never necessary Persians should be groomed with a long-hristled brush, and in long siveeps from the root to the end of the coat If the brushing is done in short staccato dabs, the hair is liable to become broken. A rub over with s short-bristled brush, followed by a hand grooming, is all the toilet that shorthairs demand. Bran heated in the oven, then rubbed into the coat and brushed out, is an excellent dry-clean for dark coloured cats.

White fuller's earth is the best cleanser for white or light-coloured cats

CATALEPSY. Catalepsy is a state of morbid sleep in which the patient's body and limbs remain in any position in which they are placed, while the power of voluntary morement is lost It cecurs in persons who are hypnotised A severe form of prolonged catalepsy is known as a trance

Callses which may bring on an attack are suilden fright, shock, or any deep mental emotion or prolanged depression. Generally the attack is sudden, the patient fainting away and becoming pale and death-like. She generally stays in whatever position she may be placed, with perhaps wide upen oyes The temperature falls, the heart weats slowly, and the breathing becomes shallow. The face may be set in a fixed smile, and the pupit is dilated.

The attack may end in a few minutea or last for several hours, and may continue for drys and even weeks. To s layman the patient often has all the appearance of being dead. A cataleptic pationt requires the care of a skilled physician.

CATALPA. With its nearly heart shaped leaves and clusters of summer flowers which are white narked with purple and yellow catialja bignonioides, or Indian bean, makes a charming lawn tree. It thrives well in town gardens. The yellow-leaved variety, aurei, is very attractive. Propagation is by sceds.

CAT AND MOUSE. At least 12 players are required for the game known as cat and mouse. All of these except two sit in two rows, facing each other, learing it gangway letwcen them and room to pass bet ween their liacks and the walls or furniture. The other two players are the eat und mouse. They stand, blindfolded, at either end of the gangway. The cat calls meow! The mouse squealis in answer, and then the cat has to chase him between and around the rows of players. If the cat has no idea of the wherealiouts of the mouse, he may call meow ! rgain, and the mollse has to answer, however near to the cat he may be When caught. the mouse becomes cat and chooses his own mouse.

CATARACT : In the Eye. Cataract is opacity of the lens of the eye, causing nore or less blindness. It niay develop from no apparent cause with the advance of age (senile cataract), usually after 50 , or in diabetes, or may be due to accidental injury to the lens Sometimes it is preaent from birth.
As a rule the first symptom is a group of tiny stationary speriks before the eye The general vision gradually grows dimmer, and the sufferer may note that hie sees best when the light is not particularly bright. But n bright light may not be disturbing. or may the even more agreeable.
As the condition advances vision is diminished, till at last there is usually only perception of light but none of objects. The cataract is then said to be ripe, and the pmoses may take months or even years When the cataract has reached this stage
the treatment consists of removing it entirely, and making up for its absence by wearing a glass lens in front of the eye. In this way excellent vision is nearly always obtained.

While the cataract is ripening reading may be made easier by shaping a cone of cardi. board, with its base shaped to fit over the socket of the eye and the further end brought down to a diameter of $t \mathrm{in}$. or less. The inside is blackened. The better eye is used. See Eye.

CATARRE. Infiammation of a mucous membrane, e.g. the lining of the nose, the bladder or the gastro-intestinal tract. The word has in view the increase of the discharge from the mucous membrane concerned, as in the running nose, but it is retained in cases where the discharge is scanty or absent; for example, the dry catarrh of the bronchial tubes, apt to affect old emphysematous men, in which there is a very distressing cough with little expectoration. The name is also sometimes used for inflammation in the walls of the air vesicles of the lungs. See Bronchitis ; Cold ; Conjunctivitis; Cough, etc.

Catchfly. This is a name given to several species of lychnis (q.v.).

CAMERING: For the Home. In the country, with most perishable commoditios, so to speak, at the door, catering resolves itself into carefully thought-out menus, taking due consideration of the days when it is possible to get fish, to make a change in the planning of courses from poultry, eggs, vegetables, etc., and keeping an eye on the store room. which should always be kept well stocked with tinned and bottled food in case of emergency.

On fish days, for instance, a boiled fish course might be served at luncheon, and a fried one be included in the dinner menu; the next day, for breakfast, kedgeree or fish cakes, or a fish salad, or curried fish at luncheon, might use up the remains of the boiled fish, and kippers or dried haddocks might supplement eggs for breakfast the morning after.

The caterer for a small family in a town, buying such provisions as fruit, cakes, bacon, fish, etc., may be well advised to carry them away in the shopping basket, because hooked orders are often not dealt with until late in the day. Moreover, unleas top prices are paid for special reserve stocks, the finest market value has been carried off by careful housewives, and only the second best is left. Other advantages of personal catering are that it enables the buyer to see the particular bargains of the day, and to get better service by tactful praise or complaint.

## The Week's Menus Planned in Advance

Some people find it answers to plan a week's menus in advance, leaving one or two blank spaces for speoial dishes which may present themselves to the cook's imagination as suited to the doing up of left-orers, according to quantity, so that as many things as possible towands the week's catering may be got in on one day. Friday is a good day to choose for this scheme, because of the extra week-end shopping that is necessary anyhow, and because things in bulk, such as groceries and vegetablea, that are ordered on Friday, do not keep on arriving through the busy Saturday and are known to be safcly in the house, leaving only the perishable goods to be brought in.

When giving a party, a few days beforehand plan and write down the menu; then, taking each course in turn, make a list of things with the quantities of each that will have to be bought. The special things can be chosen at the caterer's convenience, and each item ticked off on the list as it is purchased, so that nothing is forgotten. See Breakfast : Dinner; Luncheon.

CATRRPILLAR: In the Garden. It is said that the caterpillar consumes on an
average half its own weight in a day, and certainly there are no worse pests in a garden. From the moment they emerge from the egg until they settle down to the chrysalis state they steadily devour leaves and shoots. Caterpillars are the offapring of common butterflies and moths, and by killing these winged insects a step forward is made in preventing the destruction caused by their progeny. They are dealt with in the notes concerning the trees and plants which they damage.

Means of Destruction. Hand-picking of caterpillars, killing of butterflies and moths, crushing of eggs which are found in clusters on the underside of leaver, are the surest means of riddance. Syringing or spraying with soft soap and paraffin solution, in the proportion of one gallon of suds to a wineglassful of paraffin, is a deterrent: but care must be taken to spray the underside of leaves to make it effective. Fruit trees should be grease-banded at the end of September, in order to trap wingless female moths, which crawl up the trunks and deposit egge at the base of dormant buds, from whence caterpillars come in the spring, attacking. growth with disastrous results. See Butterly: Cabbage: Caterpillar.

CATRARTIC. Any drug known as cathartic is used to open and clear the bowels, which is done by increasing the peristaltic movements of the intestines and by rendering their contents more liquid. Cathartics are graded according to the effect they produce.
The mildest aperients or laxatives, such as sulphur. prunes or liquid paraffin, merely produce softened motions. These are semi-fluid, however, if castor oil, senna, calomel, aloes, etc., are given. It should be understood at the same time that these drugs in sufficiently small doses will have simply a laxative action, without producing a reaction in the shape of constipation, which is apt to occur when they are given in large enough doses to act briskly. They can therefore be utilised in chronic constipation.

None but the milder cathartics should be given to children, old or debilitated people, except under medical advice. The entire lip. The hybrids far outnumber brisker cathartics tend to produce griping the species, those of the labiata group being and are usually combined with an aromatic, the finest. e.g. ginger, in order to prevent this. See Aperient ; Constipation.

CATBITER. This is a long, hollow instrument used to tap certain cavities of the body through narrow passages. One form is used to draw off fluid from the urinary bladder. Of various sizes, catheters may be rigid, made of metal, or semi-rigid, of a varnished woven network, or soft, made of soft rubber. Frequently on account of enlargenent of the prostate gland elderly men have constantly to use catheters.

The greatest care must be taken not to introduce dirt and infection into the bladder. If a soft rubber catheter can be passed, it should be boiled for a few minutes before use, washed in running water after use, dried, and kept in a clean, dry receptacle till the next occasion.

Before use the catheter is placed in warm water, and lubricated before it is inserted with clean vaseline if necessary. After use it is washed thoroughly in running water, inside and out, backwards and forwards, using a little methylated spirit if there is difficulty in removing grease. It is thoroughly dried and is then placed in its receptacle. The hands and
third group also has the
two-leaved stem, but has an
the end of the penis should be thoroughly washed before using the catheter.
If the semi-rigid type of catheter is used, this should be soaked for an hour before use in a 1 to 2,000 solution of perchloride of mercury, and then lubricated with the carbolised oil. After use it should be well washed in cold water, then soaked for ten minutes in the perchloride of mercury solution, and finally carefully dried with a clean towel, and put a way in a clean box until an hour before it is next required. This type must never be boiled.

CATEODE. In an electric primary battery cathode is the name given to the negative plate or element. The positive pole or terminal of a cell is joined to this negative element. which becomes the starting point of the current to the outside circuit.

In an indirectly heated wireless valve the cathode is the cylinder surrounding the heater element. The cathode is coated with oxides, which give a free emission of electrons at a comparatively low temperature, and is normally connected to a point in the circuit having a zero or in some cases a positive potential in relation to earth. See Accumulator; Battery : Cell : Electrode ; Valve.

CATMWEYA. One of the chief groups of hot-house orchids consisting of some fifty species and innumerable hybrids; many have large and particularly handsome flowers.

The labiata group of about 20 species has a single broad ascending leaf, and the flowers are large, usually lilac or rose-purple with a richly coloured lip and some yellow in the throat. This group includes Cattleya labiata, the original species introduced about a century ago; Mossias and Mendelii, blooming in spring; Dowiana, Gaskelliana and Warsce. wiczii, flowering in summer and early autumn: Percivaliana, Schroederae and Trianae, which flower in winter. New hybrids, raised in large numbers by orchid growers, are now chiefly cultivated.

In the slender bulbed or diphyllous group, the flowers are smaller and have a three-loved lip, the stems bearing a pair of spreading leaves at the summit. $\Lambda$ third group also has the Cattleyas are casily grown in a suitable house, and a succession of bloom can be maintained practically throughout the year. Artificial heat is generally required, except perhaps in the height of summer. The following temperatures ( $F$.) should be aimed at :
W0inter: $55^{\circ}$ th $60^{\circ}$ at night ; $60^{\circ}$ by day ; $65^{\circ}$ to $70{ }^{\circ}$ च'th sü.

8prink and autumin: $60^{\circ}$ to $65^{\circ}$ at night; $05^{\circ}$ to $70^{\circ}$ ly day; $70^{\circ}$ to $75^{\circ}$ with sun.
$5^{\circ}$ to $80^{\circ}$ with to $18^{\circ}$ at night ; $70^{\circ}$ to $75^{\circ}$ by day : $75^{\circ}$ to $80^{\circ}$ with sun.
These plants do best in pots in a fibrous compost, which must be sufficiently open to allow of the free passage of surplus water, abundance of water being required during active growth. The compost may consist of decayed leaf-mould and fibre in equal proportions with a little chopped sphagnum moss. The pots should be about half-filled with clean crocks. The proper time for potting or adding new compost is when the plants begin to produce new roots.

Cattleyas differ in their time of flowering, especially in the C. labiata group, some of which bloom immediately the young growths
are completed, others after a short rest in the autuinn, while the remainder wait until the following spring; a little more water should be given as soon as the buds begin to push in the sheaths See Orchid Pron. Cat'le-a.

CAUL. A caul may be bought separately, or a piece of it should be sent with a joint of lamb. Pieces of caul are used in which to wrap cutlets that have been spread with sone farce or forcemeat before they are grilled or fried. Chopped mixtures of meat, game, etc., are wrapped up in pieces of caul previous to baking them. The caul forms a protection to the food, and by the melting of the fat, of which it is mainly composed, the meat is tasted and kept moist

CAULDRON. Originally made in wrought or cast iron, cauldrons now survive in the form of coal receptacles. These are stamped from sheet iron. A coat of dull black paint speedily restores their appearance if worn. See Coal Box.

CAULIFLOWER. "What is the difference between cauliflower and broccoli"? is a question which is asked frequently. Both are varieties of the same species of wild plant (brassica oleracea), but broccoli is hardy, cauliflower is not. Cauliflower, which has Whiter "heads" than broccoli, and is considered to be of finer Havour, is available only in the summer and early autumn, whereas broccoli is in season from autumn until late spring and early summer.

To provide the earliest crops in May and June, seeds are sown in a box of soil in August ; the seedlings are potted, kept in a cold frame during the winter, and planted on a sheltered border in March. The frame must be ventilated freely in mild weather and covered with mats in severe frost. It may be necessary to protect the plants occasionally with bracken or straw should severe weather set in after they are planted out of doors
Suitable varieties for sowing in August are Best of All, Early Snowball, First Crop, Magnum Bonum and All the Year Round. A sowing of these varieties in a warm greenhouse in January, the seedlings being planted out in March-April, will provide a succession of produce.
The chief sowing is made on a propared seed bed out of doors in April or in boxes of soil in a frame or greenhouse in March. Beforo they become crowded the seedlings must be transplanted to a reserve border in rows 8 in . apart. In June they will be large enough to plant out finally at about 24 in . apart. Good maincrop varieties to sow in March-April are Autumn Queen, Autumn Giant, Early Giant, and Walcheren.

Cauliflowers need deeply dug, rich soil to ensure free development, and watering is necessary in dry weather in summer. Any

Caulifiower. Three heads of the Walcheren variety
with leaves cat as propared for cootring
check to growth is likcly to lead to indifferent results. They are not a success in poor. shallow soil.
The cauliflower is subject to attack by clubroot, gall-weevil, and the grub of the cabbage root-fly. In a blind plant no vestige of a heart nppears, but in its place there is a small cluster of pale leaflings. Such plants are useless A check to growth, perhaps due to drought, is the principal cause
How to Cook. To prepare a cauliflower. for boiling, after trimming off the leaves and stump, notch the stalk deeply so that a piece can be removed from its centre. Lay the caulillower in a deep basin with cold, salted water and a dash of vinegar. This soaking is necessary to extract any caterpillars.

After the soaking, to prevent scum settling on the flower, place it head downwards in a saucepan of boiling salted water. Select a pan that is sufficiently small to keep it in position ; if too large it usually turns over so that the Hower is uppermost.
Care is needed not to over-boil this veget able. Test the flower by finger pressuro or with a skewer. Time for cooking depends on age and size A small one may only require 15 min ., a large one as much as 40 min . A fish slice is useful for raising and draining the cauliHower when cooked, then place it in a hot vegetable dish, straining over it plain melted butter sauce, or else serve it plain with a small lump of butter on top and a dust of seasoning.
Caullifower au Gratin. Put a hot, boiled cauliflower on a hot au gratin dish or a picdish. Squeeze the cauliflower gently together in a clean cloth with the hands, so as to press it into a neat shape. Melt 1 oz. butter in a saucepan, stir $\frac{1}{2}$ oz. flour smoothly into it, add $1 \frac{1}{2}$ gills milk, and stir over the fire until the sauce boils and thickens. Add 1 oz grated cheese, and pepper and salt to taste.
Pour this sauce all over the canliflower, sprinkle 1 oz more grated cheese over the top, and lastly a few browned crumbs, with a few bits of butter here and there. Put the dish in the oven until the cheese is nicely browned, then serve it at once. This sauce will be sufficient for a small cauliflower.
The dish is as practicable made with the remains of a cold boiled cauliflower as with a fresh one. If the dish is required in a hurry, it can be browned under the grid An alternative is to break the sprigs of cauliflower and place a layer to each layer of cheeso sauce. Twice the quantity of the sauce is required for this method: which makes a richer dish.

CAUSTIC. Caustics are substances which burn. Fuming nitric acid, glacial acetic acid, arsenic, nitrate of silver, carbonic snow, the electro cautery, and Pacquelin's cautery, a hollow metal point heated red-hot by benzine blown into $i t$, are the chief caustics and cauteries used in medicine. Warts mny be removed by nitric acid or glacial acetic acid, applied on the end of a match, otherwise the use of these agents should be left to the doctor.

CAUSTIC SODA. Being much stronger than ordinary washing soda, caustic soda is often used for cleaning sinks, pots and pans, and for other domestic purposes. It is a coarse white powder or in the form of pencils or sticks which become moist after keeping, and has a strong burning effect on the skin. For domestic use the proportion is 1 oz . in a pint of water.

In cases of poisoning, large draughts of water should be given mixed with acids such as vinegar, citric acid, lemon-juice or tartaric acid; then give white of egg and olive oil.

CAVIARE. There are several kinds of caviare, which is a delicacy made from the salted roes of sturgeon and other fish of the same family. It should be eaten fresh, when it is a greenish-grey tint, succulent, and in shape like small pearls. Those who appreciate
caviare eat it quite plain with crisp, dry toast and salt, cayenne, and perhaps a dash of lemon- juice. It is not suitable for hot savouries, and is best kept on ice till required. It should never be touched with metal, bone spoons or wooden skewers alone being permissible.
Caviare Prawn Crouttons. These are made by stamping out a dozen rounds of bread, each the size of a five-shilling piece and about in. thick. Fry them a golden brown in oz. of butter, and leave them until they are cold. Place a teaspoonful of caviare on each crouton, lay a shelled prawn on top, and use a few thin shreds of gherkin as a garnish Arrange each croutton on a tiny plate, and serve one to each person.
CAYENNJ. Cayenne is a red, pungent, intensely hot powder, sold and used as cayenne pepper. It is prepared from the fruit of several varieties of the capsicum. See Capsicum ; Chilli ; Chutney.
CEANOTEUS. The mountain sweet or Californian lilac is a group of leaf-losing and evergreen shrubs of great decorative value.

Most of them need the shelter of a wall; a few are hardy enough to be planted in the open garden except in cold districts. The flowers of most of them are of some shade of bluc. The chief favourites for the open garden are hybrids between Ceanothus americanus and Ceanothus azureus: there they grow from 2-4 feet high and flower in July-August. The best of them are Gloire de Versailles, blue, Ceres, rose, Indigo, dark blue, and Rose Perle, rose. They should be pruned in spring by shortening the shoots or branches of the previous year's growth.
Ceanothus veitchianus is a beautiful blueflowered shrub, in full beauty in May, for planting against a sunny wall, where it will grow 6 feet or more high. Others suitable for a sunny wall are divaricatus, papillosus, and thyrsiflorus, all having blue flowers in AprilMay. When the flowers are over these wall shrubs ought to be pruned by shortening the side shoots of the previous year's growth to within a few buds of the base. They flourish in ordinary well-drained garden soil and are increased by cuttings set in a !rame in July. Pron. Cē'-a-no'-thus.

CEDAR : The Tree. The cedar of Lebanon attains to a great age and size and forms a magnificent tree in time.

The Mount Atlas cedar forms a beautiful pyramid when planted with plenty of room to develop and with shelter while young. The foliage is less sombre than the cedar of Iebanon. The so-called blue cedar, atlantica
glauca, is very handsome. The deodar cedar dens dcodara) is a most graceful tree for gardens Cedars need plenty of room and thrive hest in well drained loamy soil.

CEDAR: The Wood. Of the several varieties of cedar, the one grown in England is an ornamental tree the timber of which is seldom used, and is not of much value. The pencil cedar of N. America is the wood used for lead pencils. It is light reddish brown in colour, with a fragrant smell, and has close, straight grain, easy to work and easily split. IV. Indian cedar is darker in colour, and has

some resemblance to mahogany The Himaayan cedar is a valuable timber trec in India
Cigar boxes are made of cedar It was formerly used a great deal for wardrobes, boxes and drawers, because motlis and other insects dislike its smell and tastc. It is used for some parts of pleasure boats; for, though soft and brittle, it is more durable than some woods when exposed to alternate wetness and dryness. The trunk of the cedar tree, owing to its low branches, decreases in diameter too rapidly to allow long planks to be cut from it. See Wood

In England the plaster ceiling, as we know coming upon the same joist, as they would be it, was developed in Elizabethan times. The more liable to tear away from their nails, and patterns of these ceilings are often rich in design, the monotony of the surface being broken by the ornament of slight or heavy projections, often elaborated with pendants Towards the end of the 17 th century the character of the ceiling began to alter. The constructional beams were no longer hidden, but were used in combination with crossbeanis and curvilinear ribs of equal heaviness to break up the surface into a series of recessed divisions or bays. Ornament was concentrated on and near these beams and ribs, and its character became bolder and more massive. This style was succeeded by a reversion to the Hatter surface decorated in low relief.

Ceilings are a feature in houses built by the Adam brothers. and some of these have been taken down and removed. The brothers seized upon the llat style then in vogue, and perfected it by substituting an intelligible classic design for the somewhat confused essays of their contemporaries. In these, panels are suggested only, with slight lines and rings of leaves and araliesque. The moulds of the ornamental clevices of Robert Adam are preserved and used for many modern ceilings.

Apart from such ornament niodern decorators use colour in ceilings; sometimes to tone with the walls when these arc in pale colours, or with the frieze only when the walls are panelled; sometimes in contrast, as for example when a ceiling is stippled in golden yellows to enhance walls of plain colour with mouldings enriched with gold metallic paint.

The inner covering or roof of a room is generally finished in plaster work, or may be constructed of boards, 3 -ply panelling, or building boards such as beaver board and the like. Plaster ceilings are built up on a groundwork of laths, the boards being nailed directly to the ceiling joists or rafters; but it is frequently better to employ special battens so as to utilise the boards to the best advantage A good ceiling should be artistic in appearance, homogeneous and dustproof, preferably linished white or in some light colour.
Lath - and - Plaster Ceilings. A lath-andplaster ceiling is formed by nailing laths to the underside of the joists, as in Fig. 1, with a space of approximately in between one lath and the next to form a key for the plaster, which should be pushed up through the spaces and grip the edges of the laths. It is important to have straight-grained, wellseasoned laths in order to avoid breakage or rotting after fixing. Rent laths, shaped by cleavage of the wood, are better than sawn, since they contain more continuous fibres, and are, therefore, stronger. Usually, however, sawn laths are employed, and those known as "lath and a half" in thickness should be olitained.

In commencing the work, some 10 or 1 ? laths, 4 ft. long, are nailed in position, then a similar number of 3 ft . laths, and so on. This is to prevent all the joints at the lath ends
allow the ceiling to crack in a straight line from side to side of the room. In a new house the partitions running in the same direction as the joists are left incomplete wherever possible until the lathing has been carried from end to end of the building. By this means a great deal of lath cutting is avoided. Partitions running at right angles to the joists are built to the required height in the first instance, and are generally used as structural supports to the joist ends. The laths run parallel to these latter partitions, and do not have to be cut for them.

## The Three Coats of Plaster

The plastering is applied to the ceiling in three coats, all composed of lime and sand, but mixed in different proportions. The lime is pure chalk lime, and is prepared by slaking lumps of quicklime in tubs containing excess of water, and then straining the liquid.

The first coat (Fig. 1, A), known as the scratch, pricking-up, or rendering coat, is made of coarse stuff composed of one part of lime with three parts of sand by measure, with ! lb. of long, clean ox-hair to every cubic yard. In good work the floating, or second coat (B), is applied after the pricking-up coat is thoroughly dry, to avoid breaking the key of the mortar, i.c. the connexion between the mortar bclow the laths and that pricked up into the spaces between them. Floating and pricking-up are sometimes performed in one coat, but the attention devoted to obtaining a level surface (floating) detracts from the elfort necessary in forming a good key by vigorous trowel work.
The third finishing, skim, or setting coat (Fig. 1, C), is of fine stuff composed of lime putty (q.v.) and washed sand in equal proportions, and is applied after the under coats have dried and settled into position. A setting coat

Ceiling. Fig. 1. Diagram showing construction of a lath-and-plaster ceiling A. Kendering coat. B. Floating coat. C. Setting coat. D. Cornice. Bracket. F. Ground. G. Ornamental work cast in nieces and fred to $F$.
lime putty to hasten its setting properties The proportions of lime-putty and plaster vary considerably at the discretion of the plasterer, but one part of plaster might be added to three of putty. No extra sand is added for the plaster of Paris, and in some cases the gauged stuff is left free of sand altogether, since plaster of Paris and other hard-setting gypsum plasters are not able to work with such large quantities of sand as lime mortar.
The employment of sheets ol asbestos com pounds, compressed wood pulp or three-ply boards, beaver board, and the like, permits of ceilings being formed without the delay involved in waiting for plaster to set and dry out The sheets are cut to the required sizes, and nailed at their edges to small wooden battens fixed in position at suitable distances on the underside of the floor ioists The exposed surface of the ceiling sheets is usually whitened or distempered, and the joints covered with slats of wood, arranged to form panelled patterns of ribs across the surface.
Ceilings in country houses are Irequently made with the plaster in narrow strips between the floor joists in order to present an oldfaghioned appearance by contrasting the colour of the wood with that of the plaster Small rough strips of wood are nailed to the sides of the joists to receive the ends of the laths, and after the plastering is complete small moulded strips are sometimes fixed to the joists to cover the joint betwcen the wood and the plastet.
Where plastering has to be applied to a broad wooden surface, special precautions have to be Iaken to ensure a key. In cheap work the beam is roughened with a great number of small gashes made with the corner of a broad chisel, an adze, or a hatchet, in such a manner that the chip is not detached, but is forced to stand out from the surface As an alternative, broad-headed or clout nails are partly driven into the beam. If laths are used they must not be fixed direct to the face of the beam, but to rough battens nailed upon it in such a manner as will keep the back of the lathing from $t$ to $\frac{1}{2} \mathrm{in}$. from the bean to allow room for the key of plaster which oozes round the lath

Lathing should never he fixed direct to the underside of a boarded floor, but always to the joists, otherwise the spring of the flooring boards will crack the plaster. The laths must be supported at every 15 in . of their length, or the plaster will be apt to crack.

Repairing a Ceiling. Among the tools which will be found of use in making or repairing a ceiling is the hawk, a wooden board about 12 in. square with a short handle projecting beneath it, used for holding a supply of material preparatory to depositing it on the ceiling with a trowel. The setting coat is applied with a wooden hand foat, which works better if it is kept thoroughly clean and wet, fiec from lumps of dried plaster. The angle float is used for working in the corners between the wall and ceiling. A lath hammer is useful if much of this work is to be done, as by its aid the laths can be trimmed to length. The ama teur will probably feel disposed to tackle the repair of an existing ceiling before launching out on new work. Fig. 2 shows a typical hole in a ceiling. Certain precautions are desirable, includ ing the following. First break away all loose plaster around the

Celing. Firs. 2 5. Stages in mending a broken ceillng, the laths being repaired and covered with two coats of plaster, one rough and one fine
the plaster work, and can be covered with plaster of Paris.

A better plan is to get up into the roof, brush off all luose and dirty material from the back of the ceiling and pour over it sufficient water to saturate the hack of the ceiling. Then immediately apply a grouting of liquid plaster of Paris, pouring it all over the damaged parts. It will set very quickly and make a sound key to hold the ceiling in place. This method depends for success upon the complete removal of all dust and loose stuff from the ceiling. The strutting must not be moveduntil this plaster has thoroughly set, and is dry and hard.

Cracked ceilings are best repaired by scrapingout the cracks with a chisel or scraper to enlarge the hole sufficiently to take the plaster or lime-putty which is used damaged part. Then examine the lathing, and to make goud. The edges of the cracks must be if any of it is broken, cut the laths out by saturated with water to ensure a sound joint. chopping them off with a chisel, half-way across a joist, to provide a fixing for the laths which are to take their place. These can then be cut and fitted (Fig. 3). Next prepare the coarse stuff, and thoroughly brush allay any dust and loose pieces of plaster, especially around the walls of the hole. Thoroughly damp the laths and the surrounding plaster work and then apply the coarse stuff with a trowel. The plaster has to be thrown at the laths rather than merely put up against them, the object being to force some of the coarse stuff through the spaces between the laths so that it can grip securely (Fig. 4).
The finishing coats (Fig. 5) arc then applied. When applying the first force it up hard against the existing work and keep it damp for some hours by brushing it with water. When a moulded ceiling has broken away from the laths it can often be made good by strutting it up with uprights of wood, bearing upon boards placed on the ceiling, the whole driven up tight with wedges under the feet of the struts. Screws with large washers about 1 in . in diameter can then be driven into the joists about 10 in . apart. These will draw into
saturated with water to ensure a sound boint.
Spots and dirty marks on ceilings can be removed with a weak solution of starch and water, painted on, allowed to dry, and afterwards rubbed briskly with a coarse Hannel.

The cmbellishment of an existing or a new ceiling can be carried out with fibrous plaster ornanients ohtainable ready-made, and only requiring to be secured in place with strong plaster. Cornices and mouldings are generally worked in plaster.

CELERIAC. Turnip-rooted celery, as it is sometimes called, finds less favour in Great Britain than in the other countries of Europe. The edible part is the enlarged base of the stem which is well shown in the illustration. The plants are raised from seeds sown in a heated glasshouse in Fehruary-March: the scedlings are treated as advised for celery and arc planted 18 inches apart in June in rich soil. In August the roots are covered lightly with soil, and in early autumn they are lifted and stored in soil or sand until required.

To cook celerinc, wash and trim a root, put into boiling water and boil till tender, skin it,
cut it into slices and serve with white sauce.

# Celery: From Garden to Kitchen 

## The Culture and Cooking of a Favourite Vegetable

This article contains also recipes for special celery dishes and information on celery pests. Sce furiher Fcrtiliser; Trenching

Celery stands almost a lone among vegetables in being equally palatable either when cooked or in its natural condition. There are two types in common cultivation, the red and the white Opinions differ, but the white has perhaps the advantage in being earlier, the red in vigour and flavour, so that it is customary to grow both. Good white varieties are Giant White, White Gem, and White Queen. A1, Sulham Prize and Standard Bearer are some of the hest red varieties. Early celery may be planted between rows of peas: late celery may follow early peas and broad beans. Those who want celery in August or Septeniber should sow in gentle bottom heat in February or put the pans of boxes on a shelf in a mildly heated house. A fine surface compost
is deairable. A covering of half an inch will be ample. The scedlings must be transplanted at 3 inches apart in boxes filled with a mixture of loam and leaf-mould. When nicely rooted they arc hardened off in a frame and planted out of doors in May.

Seeds to provide the main winter crop are sown in boxes of light soil in a slightly heated greenhouse or frame in March. When the seedlings are large enough they are planted in a bed of rich soil at 4 inches apart in a frame and from these are transferred to the open garden in June.

Trenching. Trenches are not essential, but they provide a convenient means both of feeding and blanching the plant. To prepare a trench, remove the top soil, break up
the under soil, and liberally interlard it with decayed manure.

A trench for one row of celery may be not less than $\frac{1}{2}$ a yard wide, and for two rows 2 ft . wide, the plants in this case being set in opposite vacancies. If the plants are grown in single rows in a series of trenches, the latter should be 4 ft . apart, and run north and south.

The depth of the trenches when finished should be 9 or 10 in ., allowance being made for returning just enough of the top soil to cover the roots.

The Cuthill method of trenching, which has produced the finest celery in the world, consists in digging a trench two spades deep and 5 to 6 ft . wide, banking up the mould on either side. Fill in with a foot in depth of strong manure, such as decomposed cow dung, and cover it over with three or four inclies of mould for planting in ; or, if the ground is very tich, half the quantity of manure.

Finc celery, especially for early supplies, can be obtained without trenching, being, mercly planted in a slight hollow in rich, well-tilled soil. The blanching is mainly done with brown paper, or with special blanching bands, but a little earth is generally drawn up to the base. The trench system is lietter for winter celery.

If there is plenty of ground available, the trenches may be made a month or so before planting, and as soon as the ridges have loeen formed at the sides of the trenches lettuces may be planted on them. As the celery grows, any sucker shoots that spring up should be picked out. The plants will grow the faster if water and liquid manure can be supplied.

When the plant is half-grown, 1 oz of nitrate of soda in a gallon of water, $\frac{1}{2}$ oz. phosphate of potash in a gallon of water, and $\frac{1}{2}$ oz. each of superphosphate and nitrate of soda (or sulphate of ammonia) in a gallon of water,

Celeriac. Stalks and roots of the turnip-rooted
used alternately, will work wonders. Anothes good change is 2 oz. Peruvian guano per yard of trench, dusted on the soil in showery weather.

When the plants are a foot high, a loop of raffia nay be slipped around them, and when they have grown another 6 in ., a second adiled, fixing one near the bottom, and one, not very tight!y, near the top; in this case this should lie done before the earthing, in order to lieep, the soil out of the centres. For earthing up, the soil should be just damp, not sodden or moist at the top and dry below, or running to seed may follow.

The earthing should be thorough, even though it is not completed in one operation. When several rows are grown in each trench, temporary divisions will have to be made with boards of the width of the trench while the earth is being packed among the plants. If there are slugs about, lime should be userl freely. By the time eart hing is completed-and that should be in advance of severe frost-the earth should be level with the topmost tip of leaf. Celery blanches in 6 or 7 weeks from the time of being eartherl.

Celerg. Diagrams illustrating method ol culture. 1. Trench properly prepared: a, sloping sides: $l$, good soil ; $c$. manure; $d$, cast ont soil, with catch crops krowing at $e$
3. First earthing-up

First earthing-ud 4 Final earthing-ud
How to Cook. Celery should he carefully washed, the outer stalks should be pulled off, and all the green tops, except the very young ones, cut away. When to be served raw, the head should be split lengthwise into four or more pieces, or every stalk separated, and served in a celery glass lialf full of cold water

Head of Celery For cooking purposes, celery may be dried and stored. The sticks are cut in strips 1 in. long, left in a cool oven for a day or two until hard and crisp, then packed in airtight bottles, and when required for flavouring crushed to a prowder with a rolling-pin. Celery seeds are also used for flavouring.
To stew celery, the sticks are simmered in slightly salted "ater for about 45 min . They are then drained and served with white or brown sauce. Cooked celery is also good When dipped in batter and fried. Cardoon (q.v.) may be cooked in the same way.

In order to make celery and macaroni stew, $1 \frac{1}{2}$ heads celery and 1 oz. macaroni should be boiled for 35 min . in separate pans each containing salted water Theyare then drained and dropped piece by piece into 1 gill hot white sauce. A sprinkling of pepper and salt is added, and the whole allowed to simmer for 20 min . Prepared in this way, but cheese sauce sulstituted for white sauce, celery and macaroni, or celery alone, arc also excellent au gratin. (See Cauliflower.)

Another good way of utilising celery is in a sauce for serving with boiled poultry. In this case wash and ohop 2 small heads of celery, putting the pieces in a sancepan with sufficient cold water to cover them Cook these slowly for a little less than $f$ hour, stirring frequently; then add some white sance made from J oz, butter, $1 \frac{1}{2} \mathrm{oz}$. flour, 1 pint milk,
and a little pepper and salt, and stir until the mixture boils.
To make celery soup with a large head 2 pints of white stock or water and $\frac{1}{2}$ pint of milk are required. The white part only should be used Two rashers lean bacon, two onions, $1 \frac{1}{2}$ tablespoonfuts flour, 1 oz . margarine. with salt and pepper, are also needed

The bacon is cut into pieces 1 in long, and the onion and celery sliced fincly. The vegetablea should then be fried in the margarine in a large saucepan. The bacon, stock, and sensoning are added, and the whole simmered for about 45 min until the celery is tender. The contents of the pan should be rubbed through a fine sieve and the purée returned to the pan. the milk added, and the whole brought to the boil. The soup is then thickened by the addition of the llour, mixed to a paste with a little cold milk, and the whole cooked for about 5 min ., stirring all the time.
Celery Diseases. The most troublesome disease to which celery is liable is leaf spot or blight ; one cause of the prevalence of this is bad seed. It is wise to buy seed of the hest strain which has been treated in the way advised by the Ministry of Agriculture as a means of preventing leaf spot. If any doubt exists the seeds should be steeped for threc hours in a solution of formalin, one part in 600 parts of water. Holding a leaf up to the light and looking through it enables the grower to recognize this disense which gives rise to dark spots on the leaves and may eventually render the plants useless. Spruying with Bordeaux mixture immediately diseased leaves are noticed is advised If only a small number ol plants is grown all the diseased parts should be cut off and burnt.

This fungicide is also recommended as a preventive of celery rust. It is of
 the celergleal: magnifled

Celerg. Buccesslul methad al bianching celerg gromn on the gronnd level by wrapping the stalks in paper collars which exclude the anolight

The hest preventive measures are to spray the plants occasionally in late spring and early summer with paraffin emulsion for the purpose of keeping off the llies. Paraffin emulsion is made by dissolving a handful of soft soap in a little hot water, adding an eggcupful of paraffin and two gallons of water. Some good is done by cutting off those parts of the leaves attacked and burning them It is most necessary that unused parts of diseased plants and those attacked by pesta be not left lying about or thrown on the rubbish heap; they should be burnt CELL: In Electricity. This apparatus is used to generate a current of clec tricity by means of chemical decomposition A simple cell is composed of two elements, a positive and a negative, inmersed in a liquid known as the electrolyte A single accumulator is also known great importance to spray early; once these as a cell. The so-called dry cell has the diseases are firmly established on the plants it electrolyte in the form of a paste
is a!most impossible to destroy them
The attacks of the celery Hy usually begin in April and may last into December. The larvae live upon the juicy substance between the upper and lower skins of the leaf. which eventually shrivels up, with the result that the stalks and stems of the plant cannot grow and fill out properly. l'arsnips suffer in the same way from these pests.

Celery Leaf Spot or Blight : the chiel celery diseasc. 1 Plant attacked by blight. 2. Effect on leal. 3. Inlected fruits

Cells are generally classed under two headings, viz., primary cells, which generate current, and storage cells or accumulators, See Accumulator ; Battery : Daniell Cell.

CELLAR. The hest situation for the cellar is on the north side of the house, and it should be partially or wholly underground if advantage is to be taken of the non-conducting properties of the carth in preserving the cellar from heat in summer. Houses built on soft soil may have cellars economically formed in the basement botween the foundations of the walls. The maintenance of an equable and low temperature is import. ant when a cellar is used for storing Sea Coal Cellar; Wine Cellar.
CELLARETTE.
Some sideboards have a druver lined with zinc or other metal and divided into compartments, one for each bottle of winc, etc. Originally the cellarette was distinct from the sideboard, and was placed beneath it. Fine examples were made of rosewoodand mahogany. some being oval or octagonal in shape. They were bound with brass bands and, in addition, had a receptacle for ice
'CMLTO : How to Play. The violoncello is the bass member of the violin family, and for orchestral purposes is usually supplemented by the double-bass, an octave lower. Its beautiful tone makes it a favourite instrument for amateur players, and a capable per former is always in request. In appearance it resembles the violin, but it is played from between the knees of the performer its lower end being supported on a stem sufficiently long to prevent the bow touching his body when either of the outer strings is played.

The four stringe are tuned in perfect fifths, thus:

The strings are of gut, the two lowest being covered with silver or copper wire. They are played with a bow, which is drawn across them at right ang!ea about an inch from the bridge. In piano playing it should be rather nearer the finger-board, but in the opposite direction in forte playing. For orescendo increase the speed and pressure of the stroke, the process being reversed for diminuendo. Besides the $F$ and $G$ clefs, the $C$ clef, on the fourth line, is used as for the bassoon.

A start should be made by trying to produce a good, steady tone from the open strings. To this end it is necessary to pay chief attention to the use of the bow, which should be firmly grasped by the fingers, yet so as not to interfere with the freedom of the wrist. When a satisfactory tone has been acquired, the study of stopped notes follows, by practising different intervals, 2nds, 3rds, etc.

Owing to the length of the strings and the consequently wider distances to be reached by the fingers, the principle of the fingering differs from that on the violin. Broadly stated, it consists in the use of the next finger for a semitone and of the next finger but one for a whole tone, though this procedure is not invariable, especially in the higher positions, as will be seen by the exercises given in tutors for the instrument.

In order to reach the higher notes, the left hand is gradually shifted nearer the ribs of the 'cello. When the index finger is used to produce a second above the open note, the hand is in the first position; the second position is when it reaches a third above the open note, and 80 on. Thus on the A string the index finger will play $B$ in the first position, and $C, D, E$, $F$, etc., in successively higher positions.

Sometimes a false nut is made by placing the thumb across two adjacent strings, and then fingering according to the method on the violin. This is useful for high notes; but players prefer the ordinary stopping, as the tone is stronger and more equal.

After use the 'cello should be wiped with a dry duster to remove any particles of resin from the belly, and it should be kept in its case, so as to preserve it from the dust, which otherwise will certainly find its way through the $f$ holes, to the detriment of the instrument.

CBLLULIIIS. The term is used to describe a rapidly dangerous variety of inflam. mation of the soft tissues underlying the skin or lying between the muscles. The cause is always some pus-forming germ which either enters the tissue through a wound or is brought there in the blood stream, e.g. the microbe of erysipelas. It is more liable to affect debilitated persons, e.g. those suffering from diabetes or chronic kidney disease.

The first symptom is a rapid swelling of the whole part, with redness, tenderness, pain, and some fever. On pressing the finger against the skin a small pit or depression is formed which may remain for some moments after
the pressure is removed. In the next stage the whole of the skin over the part involved becomes dark red, tense, and firm from the swelling of the tissues underneath.
The inflammation in cellulitis rapidly spreads, so that when beginning above the wrist, for example, within a day or two the whole arm may be hard, brawny, and greatly increased in size. Unless vigorous treatment is instituted the tissues under the skin become gangrenous, and the skin itself becomes purple or blackish, and then gives way. By this time the patient is usually in a very low state, with high fever, rapid, irregular pulse, and all the signs of severe constitutional disturbance. He should be under medical care at once.
CELLULOID. Largely used as an imitative substitute for ivory, celluloid is manufactured in rods and sheets, the latter more or less transparent. The material is elastic, readily machined and worked, takes a high polish and is capable of exhibiting very beau-

Cement: Its Varieties and Uses

## Methods of Use Clearly Explained for the Amateur

This article may be read in association with those on Brick ; Bungalow; Cottage; House, etc. See also Concrete; Lime; Mortar

Materials known in the building trades as cement include numerous varieties of lime and Portland cement. The former requires different treatment, and is dealt with separately, the following notes referring to Portland cement, which in appearance is a greyishgreen material in the form of a fine powder. It should be perfectly even in grain and free from lumps, the presence of the latter inclicating that the cement has got damp and has deteriorated.

Cement sets or goes hard by the action of water. a process known as hydration. It becomes harder and more durable in combination with certain other materials. Mixed with an equal or greater bulk of sand, the material is more practically useful, and is known as mortar. When the aggregate is in comparatively large pieces, such as broken brick or gravel, the resulting mixture is known as concrete.

It is vitally important for good work that the cement be uniformly distributed through the sand or aggregate, and that the water be uniformly applied and dispersed. While cement imperfectly mixed is thus a source of danger, when properly handled it is one of the finest of building materials, and has great possibilities for the amateur constructor. It can be cast in moulds, or worked up with a trowel on existing brickwork or lathing: a whole house can be built with it, and all kinds of garden seats, rollers, sundial columns, ornamental figures, etc., eithercastor moulded while the cement is workable.
Cement can be purchased in small quantities at an ironmonger's, but it is nore economical to purchase a sack of cement from a builder's merchant. This weighs about 200 lb . As the strength of cement depends largely upon its correct manufacture, it is always advisable to
buy the best quality.

The nmateur may begin by taking a handful of cement and gradually damping it with a little water, stirring the powder about so that the water is evenly distributed throughout. At first the cement will be crumbly ; a little more water added to it causes the mass to hang together, and to retain its shape if moulded with the hand. Continue the experiment by adding a little more water to the cement and keep mixing it until the material feels slimy or greasy. This state is known as a fat cement, and is the best state in which to work it with a trowel. Now leave the material for a few minutes, and it will be found to have set. It will not be dry : indeed, it takes several days or even longer for the water to dry out. The point to notice is that the cement has undergone a chemical change, and setting has reached its maximum strength. The whole purpose of wetting is to bring this about, and the cement is then left to dry out. If it is knocked about with a trowel before it has dried and more water added, the material will mix up and look very much as it did before setting, but its real strength will have gone.

How to Mlx Cement. The best way to mix $n$ small quantity of cement is as follows. Provide a strong solid board or table about 4 ft . square upon which to mix the materials. The grading or proportioning of the materials is known as gauging ; the gauging is done by bulk,
 or measure, and not by weight. Suppose
thecement is wanted in the form of mortar. Take one pailfulof cement and empty it on one corner of the board. Then take a pailful of clean, well-sifted sand and spread it over the board with a trowel. Sprinkle about $\frac{1}{3}$ of the cement over the sand, put another pailful of sand on the cement, and sprinkle another \& of the cement over it. Finally, add the remaining sand, and the rest of the cement. Turn it all over with a shovel, and rake it over
until the grey colour of the cement is seen to be evenly mixed with the sand

The complete mixing must he done dry, and a good result is obtained by using two mixing boards, shovelling from one into a sieve on the other, and sifting the mixture. When properly mixed, sprinkle with water from a watering can with a rosehead, and keep stirring until the whole mass is well mixed and in a workable condition. For casting in moulds use it moist ; for bricklaying and rendering, or any trowel or moulding work, use it fat

Cementing Large Areas. The application of cement to bricklaying is dealt with in the article Brick (q.v.). The repair of cracks in floors and walls, as well as the coating or facing of a wall with cement, known as rendering, is done generally as follows, using the mortar as described For cement facings on brickwork, chip out all loose material, rake out the old mortar from the joints between the bricks with a chisel to a depth of $\frac{1}{t}$ inch, thoroughly wet the wall, and then smack on the cement by a sort of throwing action, so that it is forced hard on to the brickwork; and smooth it over with the trowel, and keep the cement damp for some hours by spraying it with a little water to a void cracks due to a too rapid drying Floors are dealt with after the same method
A now lloor laid in cement is generally composed of several inches of concrete and faced with a 1 in. thickness of granolithic cement, made by mixing cement, sand, and fine granite chippings in equal proportions When dealing with large areas it is a convenience to break them up into sections by laying battens of wood on the concrete about 3 ft . apart and filling in between them with the cement facing, removing the battens and filling in the gaps as the work proceeds. Considerable skill is required to trowel up and lloat off a flat floor. A long straight lath resting on the tops of two adjacent section battens, and worked about in different direc tions, will greatly aid this work by producing a level surface, only needing floating off
Cement can lie applied in the form of a wash to the surface of brickwork, old cement or plaster work. It consists of a mixture of cqual parts of cement and sand, and is applied in a liquid form with an old whitewash brush
Casting and Moulding. The casting of cement is carried out in shaped wooden moulds ; alternatively, those made of plaster of Paris can be used. The cement is rammed into the mould by hand in a damp condition, and the mould can be taken to pieces and removed from the casting as soon as the cement has set sufficiently. It should then be soaked with water and left to set hard and dry off. Very good results are obtained by using cement and and in equal proportions. Moulding in cement is carried out more or less on the lines of clay modelling by shaping the material with sweeps or boards cut to a template, or by means of trowels of different shapes, and wooden or other modelling tools.

Keen's cement, made from alum and gypsum, is used in plastering (q.v.). It rets very hard and is useful for repairing damaged surfaces.

CEMENT : For Mending. For uniting the hroken edges of china objects a cement such as the following is required. Soak 1 oz of isinglass in $\mathbf{2} \mathbf{~ o z}$ of water overnight; then place the mass in an earthenware jampot ; put this in a saucepan containing a small amount of water, and heat until the isinglass has dissolved. Next udd $\mathbf{l}$ oz. of strong acetic acid, stir well, and pour the cement into smiall bottles.

For use, the bottle containing the cement is placed in hot water until the cement liquefies. The edges of the broken china object, having been warmed, are smeared with the cement, then brought together and kept in position until the cement has set.

For mending knife handles, mix together flowers of sulphur 1 oz , powdered resin $\xlongequal{2}$ oz. kaolin 1 oz , and fill the hollow handle. Next heat the tang of the knife nearly to redness, and press it into the handle, holding it in position until it is cold.

For sticking leather patohes on hoots the following cement is used. Dissolve by continuous shaking gutta-percha raspings, 1 oz., in carbon bisulphide 5 oz . 'The surfaces of the leather patch and the boot are cleaned hy means of fine sand-paper, the cement is spread upon the surfaces to be united and allowed to evaporate. Then the patch is placed in position and smoothed with a knife handle or rubhed with a warm iron. See Canada Balsam ; Crockery, etc.

CENTIGRADE. This is one of the chief ways of measuring heat by a thermometer On a centigrade therinometer freezing point is marked 0 degrees and boiling point 100 To convert centigrade degrees into Fahrenheit multiply by ${ }^{5}$ and add 32 . Thus 300 centi grade $=\frac{9}{5} \times 30(3)+32=572^{\circ}$ Fahrenheit. To convert Fahrenheit degrecs intocentigrade sub. tract 32 and multiply by $\frac{\dot{3}}{6}$. See Fahrenheit Thermoneter.

CENTIPEDE. Millipedes and centipedes are found in all parts of Great Britain Millipedes are injurious in the garden, feeding oll roots of all kinds, while centipedes are harmless to plants. Of the latter the variety mostly found in the garden is long and slender and is common in leaf-mould. Sce Millipede

## Central heating for the Home

## A Typical System and How it Operates

See Anthracite; Gas; also Boiler; $\begin{gathered}\text { Range, and other entries dealing with the heating } \\ \text { apparatus of the housc }\end{gathered}$

The heating of a huilding by radiators or pipes supplied with hot water or steam from a single boiler is known as central heating. Several systems are in use For domestic purposes the onc or two-pipe drop systems for low pressure hot water are probably the most satisfactory.

With a central heating installation only one fire requires attention, while a good boiler does not need stoking more than two or three times a day, and will remain alight all night. The heat transmitted by the radiators is healthy, mild, and agreeable, and there are no noxious fumes. The temperature can be regulated at will, and any individual radiator can be put out of action when not needed, or hrought at once into service by merely turning a tap. The following notes refer to small domestic installations suitable for the average dwelling house of eight to ten rooms.

There are two distinct methods of low pressure hot water heating. The object of the first is to warm the whole house and in maintain it at an equable temperature. The second is designed for local heating: that is to say, the bulk of the heat is applied to the warining of one or two principal ronms, the others being warmed as required Coinbination systems, where one fire suffices for cooking, hot water supply, and heating. are now uvailable, and the type of kitchen range illustrated in Fig. 1 will serve several radiators

Central Heating. Fig. 1. Combined boiler and cooking range, which also supplies bath water Courtesy of Natlonal lladiator Co., L.td.
in addition to providing domestic hot water and ample cooking facilitics for the average dwelling house

A central heating boiler may be heated by coal, colic, wood, oil, or gas. Anthracite and coke arc the most satisfactory nolid fuels. Gas may prove expensive for continuous heating, which is the essential feature of a central heating installation Oil is economical for large installations, but for small private houses the initial cost of the oil-

Fig. 2. Independent boiler for supplying a number of radiators. Fig. 3. Efficient type of radiator for central beating
Courlesu of National Radiator Co.. t.id
hurning plant is gencrally considered prohibitive, and in any case auxiliary power, such as electricity, compressed air or steam is necessary for atomising the oil. The heat necessary to maintain the system oncc it has been raised to its highest temperature is that required to make up the heat logt from the rooms. This is the secret of the efficiency of the independent central heating system.

A typical boiler is illustrated in Fig. 2. It is made up of four panels connected at top and bottom by hollow headers. The panels com. prise a series of small upright waterways. The fire and ashpit are surrounded by a waterjacket. This boiler also functions as a radiator, and will warm the kitchen or living room, where it is situated

Dampers are provided to regulate the fire by controlling the entrance of air, the opening of the ashpit draught door increasing the heat of the fire, and vice versa.
The size of the boiler must be sufficient to maintain all the radiators constantly at full heat. When reckoning the size of an installa tion, allowance must be made for the geographical position of the house. A dwelling on a hilltop, expored to the full force of a winter gale, obviously requires more heating
than a building of identical sizo in a sheltered required on this level, they prsition The area and position of the glass windows also play an important part, the loss by radiation through the glass windows being very considerable Taking a fair average, the following sizes of radiators are required to maintain a temperature of about $65^{\circ}$ The figures represent sq. ft . of radiator surface:
Small bedrooms
Larger bedrooms
Pasage way
Entrance hall
Dining monm
Draw!
Dowm
required on this level, they
are connected by the down pipe $F$. then through pipe G. It will be seen that any of the radiators can be shut off by closing the valve, but without impeding the flow in the pipe. The pipe should be galvanised wrought iron steam quality, and it in in the bore.

A smaller bore expansion pipe is connected to a small cast iron or galvanised ex.

The tutal may be put roughly at 200 sq . ft. of radiator surface To this must be added an amount to cover the losses in the connecting pipes, which can be greatly reduced by lagging the pipes wherever possible with asbestos or ither non-conductor of heat. The above hypothetical installation woald require is boiler containing about $10 \frac{1}{\mathrm{sq}} \mathrm{g}$. ft . of heating surface, and measuring about 36 in . high. 15 in wide, and 20 in . deep.

Having decided upon the boiler, the radiatnrs can be selected necording to their capacity

Central Reating. Fis. 4. Diagram ahowing low pressure hot weter drop aystoin. 800 toat lor lettering
The latest type of radiator has small fluted columns, as shown in Fig. 3. The smallest size may be a four-column $5 \frac{1}{2}$ in. wide or thereabouts, composed of six sections 24 in. high. A pattern suitable for the larger bed. rooms would measure about 30 in . high, and be composed of ten sections. For the largest rooms a six-column type can be chosen, having, say, eleven sections 36 in . high or 13 or 14 sections 30 in . high, according to the space available. A long low radiator is sometimes more convenient than one of fewer sections but greater height

Such radiatore as those illustrated in Fig. 3 are made of cast iron, with the internal waterways formed when cast. The sections are connected by taper threaded internal nipples. lilet and outlet connexions as well as a tapping for the air release valve are provided.

The pipo system has next to bo planned. Desirable features are compact pianning. minimum lengths of piping and gradual easy falls to all pipes. In the drop system (Fig 4), the heated water ascends by the flow pipe to a cross-pieco HP at the highest point of the avstem; branches aro taken as at AB to the return pipes CD. The radiators are con. nected by short branches, as at $H$ and J with a valve on the top inlet of the radiator. On the gmund floor, when radiators are
pansion tank M, another pipe being taken from the top of the tank as an overflow on to the roof. A safety valve should, however, be fitted to the boiler and maintained in porfect working order.

Connexions are made where necessary by means of the standard elbows, tees, and bends, screwed on tightly and the joints made water-tight with red lead or, other jointing material Various types of valves are available for controlling the supply of hot water to the radiators. The air release valves are simple plug-cocks and are screwed into the radiators.
The position of the boiler will be governed by convenience. It should be well away from woodwork or inflammable material, placed on a good solid fireproof floor, such as a bed of cement concrete $\delta$ in. thick. The need of carrying the smoks pipe either through the wall to the outside air or into a conveniently situated tlue must not be lost sight of. Otherwise the boiler is best placed in the most convenient position in the house, from whence the flow pipes can rise with as few bends as possible, consistent with an allowance for the expansion of the pipes when heated.

CENTRE. Centres are used on lathes and other tools to assist in supporting the work, and to locate it truly on the centre line of the shaft. The centre itself is in various forms; the point centre is pointed in shape, the cup or hollow centre is inverted, and the vee-centre has a $V$-shaped slot cut across at right-angles. Many small bench drilling machines are provided with such centres.

Centre to Centre. This expression is frequently found in descriptions of "how to make "articles. It means that measurements are taken from the centre line of one part to the centre line of the other part. It is the most

Centre. Implemonts used in iathe work ; top, point oentre : middle, vee centre; bottom, cup centre
accurate way of marking out a job For example, floor joists may be specifled as being 15 in . centres, meaning that their centre lines are 15 in . apart. Such joists are "frequently 2 in . thick, but as they are only rough sawn, it would not be satisfactory to measure the gap between two joists, as this would vary slightly one from another, and the ultimate result would be unsatisfactory.

The word is also used in connexion with the naking of chocolates. See Chocolate.

CENTRE PUNCE. A centre punch is one having a sharp.pointed end, made of tool-steel, either hexagonal or circular in section. It is used for marking the centre of a hole, for dotting a line on metal prior to cutting it, and sundry other similar jobs. It is used by holding it ereot upon the work, with the point exactly on the centre. A sharp blow is then struck with a hammer on the head of the punch; this makes an indentation in the metal and thus marks the centre. The point should be kept sharp by grinding.

An automatio centre punch has a spring-actuated self-contained hammer which strikes the blow when the punch is pressed hard on the work. They are very convenient in use. Bell centre punches are handy for marking the centre on the end of a metal bar. A centre punch or several of different sizes are essentials to almost everyone desirous of working in metal.
CERAMICS. Under this Cluded the plastic arts of the potter and the worker in clay fabrics. Thus the name includes chinaware (porcelain), faience, pottery (earthen and stone wares) and terra. cotta Ornamental bricks and tiles are also branches of ceramic art. Owing to the fact that great potters experimented with many clay fabrics in making their wares, china marks are sometimes used on both earthenware and chinaware. See China: Faience; Pottery.

CERTAL. Foods made from cereals, i.e. from grains such as wheat, barley, oats, etc., provide the starchy substances which are neccssary for life and health. Besides supply. ing starch, wheat flour and oatmeal furnish a fair amount of proteid or flesh-forming food, and oat meal alsocontributes asubstantial amount of fat as compared with the meagre quantity con. tained in other cereals. Mineral salts are also represented in cereal foods, chiefly in the form of phosplastes of potassium and magnesium: but the amount of these in fine flour is small as compared with that in wholemeal flour.

Rice contains little else than starch, and what little of the other food constituents it does contain are generally removed by boiling it. The proper way to cook it is by thorough steaming. Oswego, corn flour and hominy are obtained from snaize by acting on it with caustic potash. See Barley; Bread; Diet; Flour ; Oatmeal ; Rice, etc.

Cerebro-spinal Meningitis. This is the medical term for the disease better known as spotted fever (q.v.).

CFREUS. Several species of cereus bloom at night, hence its alternative name of torch thistle.

Among the best sorts is the rat-tail cactus, (flagelliformis), so called owing to its slender wiry growth: it bears pink flowers in spring, and is a desirable plant for a hanging basket or for growing in a window. Fulgidus, with its scarlet flowers in early summer, is good for a small house. Grandiflorus bears large white flowers, often nearly a foot across, and is fragrant on summer nights.

These plants require a very porous soil. and it is usual to add shattered bricks to the loam when preparing a compost for them. The pots may be filled nearly one-third with crocks for drainage. In summer they should have a light, sunny position in the green house
or window; in winter they must be kept under glass safe from frost and given very little water. They are propagated by inserting portions of the matured leaves or stems in sandy soil in summer. See Cactus
CERTIFICATE. Certain documents that are issued by public and other bodies, usually containing evidence ahout a person's status or proficiency, are known as certificates. Copics of certificates of birtha and marriages are required for various purposes, e.g. insur ance. These are usually obtained where the birth is registered or the marriage celehrated ; but if not they can be obtained from the Registrar General, Somerset House, London, W.C., or the Registrar General in Edinhurgh

As regards marriage certificates, copies can be obtained from the incumbent of the church in which the marriage was celebrated. Death certificates, signed by a medical man, are also issued and are necessary for burials and cremations, as they are for the proving of wills. Copies can be obtained for a small charge.

Certificates are given by various bodies, hoth those that examine in education generally, such as the joint board of Oxford and Canbridge, and bodies that specialise in one suhject only, e.g. music. Certificates from medical men testifying to sound bealth are also re quired from applicants for various public and other positions. See Birth; Death; Marriage.

CESSPOOL. This is a receptacle for the sediment from a drain. Cesspools are of tivo kinds; those adapted for all kinds of drainage, and others intended for sink and hath wastes only. Many old houses in the country have nothing more than an open pond to deal with this class of sewage, but its presence is a menace to health and should be destroyed.
The drainage of the pond is generally accomplished by cutting trenches to conduct the water on to the land, previously filling in the trench with coke or gravel and covering with turf, if the land is pasture. The bottom of the pond should then be covered with un slaked lime, and a few days afterwards the sediment and soft material should be dug out, carted away and deposited in shallow heaps on the land as remote from dwelling-houses as possible.
The drains to the pool must be removed or stopped up with concrete, unless they are to le used for the new cesspool, in which case they must be tested before use. If the pond is to be used as such, the bottom should be cemented over, or covered with a layer of clay 6 in . thick, then a layer of straw, and finally another $\boldsymbol{6}$ in. layer of clay, well rammed and consolidated.
Points to observe in making a cesspool are to place it as remote from the dwelling as

Ceaspool. Sectional diagram showing the correct method of lining and connecting a cesspool for house dralnage
cossible, never less than 70 feet, or any greater distance as prescribed hy the local authorities, and equally remote from springs, wells or brook. The drain to the cesspoo ahould fall gradually towards it. The outlet from the cesspool should fall as rapidly as possible, and discharge into an automatic distributor, or into trenches filled in with coke or gravel, and covered with turf.

The cesspool itself is preferably excavated to a depth of 6 or 8 ft or more, the botton made up with 6 in of concrete, the walls built of brickwork, filled in at the back with concrete, and rendered with a $l$ in thickness of strong cement mortar, gauged 1 of cement to 2 of sand. The top can be briclied over, or covered in with old railway slcepers and turfed over, leaving an opening large enough to adinit a ladder and giving room for the in gresa and exit of a man for cleaning purposes.
This opening should be covered with a cast iron manhole. To jrevent any smell working back into the house, an interceptor trap and ventilating pipe must be built into a inanhole formed between the drain and the cesspool The outlet pipe from the cesspool should be 2 in . below the level of the inlet pipe, which should terminate in a downward direotion by fixing a bend a little before the end. See Brick; Cement ; Drain ; Sanitation.

CHARLIS. A class of delicate, thin white wines, sometimes incorrectly described as white Burgundies, is known as Chablis.
This wine may be served with fish. A refreshing drink for hot weather is Chablis cup made from the following recipe: Dissolve 4 lumps of sugar in a $\&$ pint of boiling water. Put this into a bowl with a slice of lemon-rind, and after about $\ddagger$ an hour add a bottle of Chablis, a wineglassful of sherry and $\frac{1}{2}$ pint water. Mix well, and after straining add a bottle of soda or seltzer water, a sprig of verbena, and a fcw strawberries. Ice and scrve in small glasses. See Burgundy; Wine

CHAFING. Wherever there is pressure on the skin, or where two skin surfaces rub against one another, chafing may occur. Wash the part several times a day with warm oft water and soap, dry carefully by dabbing the part with a soft towel, and dust the skin with powdered talc.

Where excessive perspiration is the cause of chafing, this scented jowder will be found agreeable :

Oil of rose geraniun
Salicylic acid
l'owdered zinc oleate
Powdered starch
See Blister; Foot; Skin, etc.
CHAFING DISH : How to Use. A dish in which light cookery can be done at table s useful at breakfast or for late suppers. Chafing dishes are usually made of silver or electro-plate and possess an outer vessel to contain water, an inner pan with handle and $\&$ cover, stand, and a heating stove. The last named is often a spirit lamp, but clectric chafing dishes are obtainable with a disk stove with two heats

For frying and quick cooking, the inner pan of a chafing dish should be placed directly over the lamp; but when gentle heat is required, as, for instance, in the preparation of such dishes as scrambled eggs and stewed oysters, the hot-water pan should be placed beneath the

cooking-pan. It is important that all utensils belonging to a chafing dish should be kept scrupulously clean, and the food served quite hot. When a spirit lamp is not in use, keep the cap on, otherwise the spirit will evaporate. A toaster is an invaluable adjunct to a chafing dish outfit. It is best to have all food to be cooked in the chafing dish prepared hefore hand. Such food as sausages, fishcakes, rissoles, savoury haildock or kipper, can be ready cooked and reheated in a little butter or a suitably prepared sauce. See Sa voury : Supper.

CHAIN: Its Home Uses. Chandelier chain is stamped from sheet brass by machinery and has many uses. Ladder chain is applic-
 able to similar purposes, and can be used with small sprocket wheels for driving toy engines.
Jack chain is another machine-made form in brass, galvanised iron, or bright iron, and with single or double coils. It is useful for all kinds of light work

Bicycle Chain. All the above chains are neerely in the nature of a tether; but others are used to transmit nower, like the bicycle chain, which consists of side plates or links, rollers and crossbars or rivets There are several makes of such chains, of which the improved Renold is illustrated. This method of construction is applied to cycle and to motor cycle chains from
Chain. Component parta of imchain
$\frac{B}{8}$ in. to $\frac{z}{z}$ in pitch
imum life and service fron To obtain maximu roller chain, they must be luhricated freely. If the machine has an oil-bath chain case, make sure that a sufficient oil level is maintained to bring the bottom side of the chain into the oil; otherwise remove the chain about every three months, thoroughly clean it by immersing in a tray of paraffin, wipe dry, and then immerse it in melted chain lubricant, working the chain about to get the lubricant into the bearings. An important matter with a chain is to run it at the correct tension. It should not be run dead tight, hut when the top side of the chain is tight, it should be possible to move the bottom side up and down a hout in See Bicycle; Motor Cycle.

Chain. Measure of length. It is 22 yd or $\mathrm{ij}(\mathrm{ft}$. in length and is divided into 100 links each of 7.92 in . Ten chains make a furlong

CHAIN STITCH. In needlework therc are three varieties of chain stitch-namelv, machine stitch, embroidery, and crochet ; all of these have the common purpose of link ing together stitches that are comprised in the form of a chain. See Crochet ; Finbinidery ; Sewing Machine.

## Chairs: Choosing, Making and Mending

Advice for the Collector and the Craftsman

Related articles include Adam Stylc; Armehair: Chippendale: Dining Room ; Drawing Room Sheraton, ete. Sec also Baby Chair; Cahinet Making; Easy Chair

Most British households possess at east one chair. the Windsor, which expresses the development of this piece of furniture from stool to chair.
The two features which distinguish all Windsor chairs and are peculiar to them are the saddle-shaped seat and the fact that the hack is structurally separate from the lower part. These two features are seen in no other chairs in the world. The Windsor is British and one of the very tew pieces of furniture which is not a derivative from forcign sources Old ones of undoubted authenticity can therefore be more easily ohtained in England than anywhere else. Those made of yew are the best.

Old Windsors. A William and Mary Windsor has a crest rail with its upper profile bow. shaped There is probably a crown in the middle. Some of the rails beneath the seat and the uprights of the back may be twisted or of barley sugar pattern. In a Quecn Anne the centre splat of the back is probably fiddle shaped and the legs cabriole. Later, this chair may show Prince of Wales's feathers. This type in varied forms appeared for quite 100 years. The arch back, which can bc identified by its name, has horseshoe arms. The front stretcher beneath the sest is curved away towards the back legs
Wheel back is a very common form, so called because the centre splat of the back contains a perforated shape resemblines a wheel It is probably derived from the well-known Hepplewhito feature. V-stretcher backs are so called because for extra strength two strctchers are put into the back of the chair in a V-shape, the point of which is formed by the stretchers meeting in a specially made tailpiece of the sent. The other ends of the two stretchers are fixed into the crest of the back
The chairs of the 17 th century, genuinc specimens of which are rare, but have been widely copied, are those belonging to the periods of James I, Charles I, the Commonwealth and the Restoration. In this category may also be placed those of Willinm and Mary, but they are not so distinctively English ns are the earlier ones.

Chairs by the Great Makers, Chippendale chairs are so called because they are in the styles followed by Thomas Chippendale, mostly adaptations from the French of the period of Louis XV.
The average collector may take it that Chippendale chairs were usually made of mahogany, with a wide seat in front narrowing towards the back; they stand on legs aquare or mainly square in section, have a bow. ahaped crest-rail, and a perforated, decorative convex back. Many so.called Chippendale chaira have cabriole or club legs, with ball and claw feet ; it is doubtful whether Chippendale himself made many chairs with such legs. The decoration was by means of carving Inlay was rarely used. The mahogany was heavy and of close grain. Ribbon back, Gothic and Chinese Chippendale chairs are among the styles which are specially valued by collectors

Hepplewbito chairs are also principally made of mahogany, and the wheat-ear is a favourite form of carved decoration. Many are painted, and the typical specimens have either a shicld or heart-shaped open back and show the wave-line, a serpentine curve in furnitura. The front line of his chair-seats is often bow-shaped, and the arms are held by curved supports Sherston chaira have thin, tapering
egs, angular backa, and are rather small as a rule in the seat They are often of satinwond and the decoration painted or inlaid 'The crest rails are straight, or nearly strnight. with slight breaks. Late in life Sheraton was influenced by the Empire period.
The chairs designed by Robert and James Adam are not within reach of the ordinary collector. They are both carved and painted and genuine examples usually fetch very high prices.
As chairs of any kind were not conmon in England before the reign of Charles 11, it will be seen that numbers ol so-called Jacobean chairs which are offered as antiques must of neces. sity be spurious.
The oak chairs of the time of James I have heary framework, both legs and back heing of timber square in section, and held together by rails simply mortised into the uprights. Panelled backs were common, and carved ornnment had little or no modelling Where chairs had arins they were simply acrolled, over supports which were

= were upholstered They were often inlaid as well as carved, and the ball and claw foot was first seen about the end of this reign.

Making a Chair. A change for the ordinary Windsor chair is that shown in Fig. 1. White deal could be used for a cheap variety

The main dimensions arc 18 in . from the floor to the seat, and 3 ft . 2 in to the top of the back In plan, the seat should be 1 ft . 2 in. at the back, increasing to 1 ft . 5 in . at the front and 1 ft 3 in from back to front The rake of the back should he similar to that in Fig 16 tion of the stretcher, one of the most important contributions to chair maling in this period.
Practically the whole Queen Anne period produced chairs in walnut wood The stretcher work disappeared, the cabriole lcg came in and the knees were frequently carved with a shell Backs ware still high, and there wis a concave centre splat resembling a fiddle in shape in the back. Many clisirs of this period
ports, thes twisted formation being also scen on the rails and legs Cane panels werc often used for the backs In the time of William and Mary walnut was commonly used ; and the twisted rails gave place to gracelully designed turning. A feature was the elabora-
also possible in waxed oak The chair (Figs 2 and 3) has a total height of 2 ft . 11 in , height of back being 1 ft .6 in ., and of seat (at bach) 1 ft . 5 in., the front of seat being $\frac{t}{2}$ in higher. Width of back at top is 1 ft .2 l in. diminishing to $1 \mathrm{ft} .1 \frac{1}{2} \mathrm{in}$. at seat, depth (back to front) of seat being $1 \mathrm{ft} .1 \frac{1}{2} \mathrm{in}$.

In setting out the back legs the most econo mical methorl is to mark them out close to gether on a narrow board of a sufficient thick ness to allow of cleaning up to the following detail dimensions. 'Total length finished 2 ft .83 in . to joint of top rail, an additional I in being allowerl for the tenon here. Thir face should finish 1 in. in width throughout the back leg, but the thickness will vary between $1 \frac{1}{}$ in net at the seat height and 1 in net at ground. The upper portion of back leg can be lessence to ? in thickness with D sertion. The rake at reat height is $2 \ddagger$ in

The top hack rail has broken corners, and in style will go well with furniture of Queen Anne or Chippendale character. This piece finishes 2$\}$ in. wide net, and should be carefully shaped to the outline indicated. In setting out, the best way will be to allow $\frac{1}{2} \mathrm{in}$. radius for the quadrant internal breaks, and strike the parallel outer shapings at Id in. radius. The rail may be flat. but in practically all chairs of similar type the effect is improved by working to n curve, which in this case could be $\frac{1}{2}$ in apring (i.c. depth) only. The lower edge of rail will refuire mortising or grooving $f$ in repme mortising or grooving $f$ in the dinishing receick the back panel or spla the finishing thickness being $\frac{7}{8}$ in net to $1 \frac{1}{6}$. $2 \frac{1}{2}$ in at top over all, narrowing The lower rail of back is fitted 1 ft .1 in . 1 ft .1 in or 1 ft . $1 \frac{1}{2}$ in. helow. clear of top rail and, if curved. should An enlarged set-out of the back correspond with the latter in depth. finishing size being a clean up from $l$ in. by $l$ in. and should be tenoned into position

The back panel can be of $\frac{8}{8}$ in. thickness, or slightly leas. and is $3 \frac{1}{2} \mathrm{in}$. wide. shaped back to about $2 \frac{1}{2}$ in., an extra $\frac{1}{2}$ in. full being allowed in length for stithos top and hottom. The quar. tored effect indicoted at Fig. 4 is
well worth carrying mapped in I in. squares is shown at Fig. 4. out in veneer, and is The seat is framed up of pieces $1 \frac{1}{2}$ in. wide not difficult to lay if by $\overrightarrow{3} \mathrm{in}$. net, usually dowelled together, and is the meeting edges fixed to the back legs by notching and by a are clcanly cut with hardwood peg right through. The back rail of the grain to match seat is often allowed a trifle extra width and is up nicely. A front shaped. The seat is caned in the ordinary elevation and side way 'The legs can be worked from lengths view of this chair of $1 \frac{1}{2} \mathrm{in}$ material to finish 1 i in at top, tapering are given at Fig. 3. to $f$ in, helow which the swell for toe can be The back, it will be $1 \frac{1}{\mathrm{l}} \mathrm{in}$. by $\frac{7}{8}$ in high, this latter projecting noticed. tapers slightly more at front than at back of legs. Fig. 5. Example of single chair belonging to dining room guite. Figs. 6, 7. Front and side elevations of dining room chair. Fiz. 8. Diagrams of tramemork of seat, and method of plotting design of chair back. Fig. 8. Back of chalr serviceable and graceful type of chair for dining-room purposes. Oak is most suitable, but both beech and birch are serviceable if well stained so that they do not quickly wear white. Choose only the pick of wellseasoned wood, fairly straight and regular in grain, and free from knots, shakes, and bruises that would tend to weaken its resistance to a strain that is often considerable. The general height for a standard chair-seat is fixed conveniently at 1 ft .6 in ., but is often found to be 1 ft . $5 \frac{1}{2} \mathrm{in}$. to top of front rail, after levelling and a loose-pad seat, such as that shown at Fig. 12, if well stuffed, will add a trifle to this. Should it be desired to provide a stufied or spring seat, the seat rail will need to be lower in order to allow for moulding up

For the standard or small chair the width across the front is a full 1 ft .6 in ., and across the back it is from $1 \mathrm{ft} .2 \frac{1}{2} \mathrm{in}$. to 1 ft .3 in . The depth of seat, front to back over rails, is 1 ft. 5 in for the person of average height, but in special cases for a tall person a depth of 1 ft .6 in . to 1 ft .7 in . will be found more comfortable. A fairly high back is shown, height from seat rail to top of capping on back legs being 1 ft .11 in ., the top back rail entering the back legs 1 in . lower at a height of 1 ft . 10 in . The back may be made 2 in. lower without detriment to proportion. Width at top of back over uprights or hack legs is the same as at ground level, $1 \mathrm{ft} .2 \frac{1}{2}$ in. to 1 ft .3 in Where armchairs are provided they are often termed carving chairs, and at times the seat is increased in height to 1 ft .7 in The width across front of seat is a full 1 ft . $9 \frac{1}{2} \mathrm{in}$., and at back is 1 ft . $5 \frac{1}{2} \mathrm{in}$. Depth, back to front over rails, should be the same as for standard chair. The height of back can be 2 in . in excess of that of the standard chair; width of back is uniform

The standard chair is shown in elevation (front and sides) at Figs. 6 and 7, with main dimensions marked. These will be of assistance in making a full-size set-out on lining paper
which in all cases should be done, and to and where the front legs project on the inner facilitate which a pencilled extract of following sizes will save constant reference to letterpress The back is shown to enlarged scale at Fig. $\theta$ The back legs (A) finish $1 \frac{1}{2}$ in. wide on face throughout, and thickness at seat height is 18 in ., which is tapered to 1 in . net at top and at ground respectively.
The method of setting out this part of the work is shown at Fig. 8, A, plotted out in 1 in. divisions of width and 2 in . divisions of height, the height of seat rail being noted at 1 ft .6 in ., where the rake or depth of curve is 13 in ., measuring from a line touching topand bottom of back leg. Some economy of wood can be effected by settingout
egsclose together on the same board.
The top back rail (B) takes a piece 1 ft .3 in . by 31 in. includ. ing tenons and paring, and when finished will measure 3 in. wide The lower rail (C), is in wide finishes like the top rail $\frac{7}{}$ in. thick. Both rails can be tlat, but the general appearance and comfort to back will be improved by working the rails to a curve in the manner indicated at Fig. 8, B, out of thicker material. The centre panel (D, Fig. 9) can be 21 in . to 3 in . by 会 in. thick, stubbed into rails top and bottom, taking a length of 1 ft .3 in . including joints. The narrow bars or uprights (E) on each side of panel finish $\frac{7}{4} \mathrm{in}$. by f in. thick. By way of embellishment, three flutes can be worked on the back lega, and two scratched beads on the bars close to the edge will improve them. Height of rail (C) above seat-rail is a full 3 in .
The reat-frame rails, shown enlarged on plan at Fig. 8, C, finish 2$\} \mathrm{in}$. by $1 \frac{1}{8}$ to $1 \frac{\mathrm{in}}{\mathrm{i}} \mathrm{i}$. thick. and will require careful tenoning into back and front legs. The joint is cut in line with the rails, and entered so as to give as long a tenon as poss:ble, mitred to meet. A section of front and side rails is given at Fig. 8, D, showing a $\frac{A}{B} \mathrm{in}$. rebate for seat-frame $\frac{7}{i} \mathrm{in}$. or in. deep with the outer edge rounded. The front legs should not be less than $1 \frac{1}{\frac{1}{2}}$ in. by $1 \frac{1}{\frac{1}{2}} \mathrm{in}$. and might finish $\frac{1}{} \mathrm{in}$. larger for a firm chair. They are shown as tapered with the lower 11 in . shaped to form a toe as a relief from plainness. In framing up it will be noticed that the back legs are joined square with the back rail, whilst the front legs finish at sides in line with the side rails of seat, but not quite Hush with them-say in. projection uith the projection rounded away at edge.

## Supports for the Movable Seat

The interior angles of seat are stiffened by the fixing of braces cut out in 1 in . material 3 in. by 3 in. to shape, and screwed into position tlush with the bottom of rebate so that they give extra support to the pad frame. An improved finish to the seat-frame is secured by moulding the top edges ovolo at front and sides. The back seat rail is not rebated.

The pad-seat is upholstered on a separate frame, and is indicated by dotted line on plan, Fig. 8, C. This frame should be preferably of birch dowelled together or bridled and screwed, and is made a full $\frac{1}{i n}$. smaller than the rebated opening to receive it, as an allowance for the covering material. material should be that of the depth of rebate
and where the front legs project on the inner fit. Upholstery of pad-frame could be carried out in hide, but a change would be velvet or mohair. Tapestry may also be used.
The underframing shows three rails, one high up connecting the two front legs, and one rail to connect each pair of front and back legs. The arrangement stiffens the chair considerably, and with the front rail as shown, has the

Chair. Fig. 10. Light drawing room ohair. Figa.
11-14. Bhowing detalls of joints, bsok, and seat
advantage over the ordinary H-pattern framing of not tempting the sitter to put his foot upon it. No rail is necessary between the back legs, but it can be added if desired. Size for the rails may be about $1 \frac{1}{8} \mathrm{in}$. by $\frac{8}{8} \mathrm{in}$., or the front one may be wider, say $1 \frac{1}{8} \mathrm{in}$.

Drawling Room Chalrs. Since drawing room chairs are lighter in construction than dining room and other types, it is essential if the chair is to last any time that all the material should be sound and of good quality and that the maximum amount of strength be obtained by good workmanship and careful planning of the joints, etc. The best plan is to make a full-size drawing of the chair, giving side and front views and a plan of the seat (Figs. 11, 12, 16 and 18). The setting-out of the back legs requires careful attention to get the correct rake (notice that a straight, perpendicular portion is always left where the side seat rails join them).

The method to mark out the back on the wood is as follows: Prepare the wood the total length and thickness required, and wide enough to take the rake, and square up the front edge. At this edge mark the position of the straight portion required for the seat rail joint (the edge being already square and straight) and mark the remainder of the leg and back from this point. The chairs should be finished with french polish.

Fig. 10 is a light chair to be made in mahogany with a loose seat (Fig. 12). This style
would do cqually well for any living room. the upholstery being varied accordingly. The main dimensions can be scaled out from Fig. 11, using the 3 in . squares as a scall. (thus the height of the back is 3 ft ., and two pieces 4 in . wide will be required from which to cut the back legs). At their widest part on the front side these should measure $1 \frac{1}{8} \mathrm{in}$., tapering downwards to $\frac{18}{5} \mathrm{in}$., and upwards to $\frac{g}{\text { g in }}$.

The front legs at the top are $1 \frac{1}{8} \mathrm{in}$. and taper to $\frac{7}{6} \mathrm{in}$. Note that these are bevelled away to line up with the side rails, which are necessarily at an angle caused by the front of the chair being wider than the back. The front and two side rails are rebated $\frac{z}{8} \mathrm{in}$. on the inner edge to take the loose seat and a moulding is worked on the edge (see Fig. 14). The rebate is continued on the leg and the moulding worked on it after the chair is glued together. All the rails are tenoned into the legs and the joints strengthened with angle brackets (Fig. 12). The top rail of the back is mortised to take the uprights (Fig. 13) and the intermediate rails stub-tenoned.

The centre back portion is cut from a piece of $\frac{1}{2} \mathrm{in}$. material, the triangular shapes being cut out. When glueing the chair up, glue the back and front first and allow to set before fixing the side rails. The loose seat can be made from any of the cheaper hardwoods and is either halved or mortised together. An allowance of $\frac{1}{8} \mathrm{in}$. should be left all round to allow for the thickness of the material with which it is covered.

For a drawing room this type of chair looks well covered in striped material-either self-striped satin, or a vari-coloured taffeta. Irocarle or damask is suitable, or a loosc cover can be casily made to match those of other chairs, etc., in any living room. Rep. is suitable for a dining room chair of this make, or any good fabric with a geometrical design. Damask may also be used if the other furniture in the dining room is of the light character with which this chair would be a good choice

## Mahodany Chair with Stulfed Seat

Fig. 15 is a chair of similar character but having a stuff over seat and an under framing. It is set out and proceeded with similar to Fig. 10. A wide and shallow rebate is worked on the rails over which the material is tacked (Fig. 17). The front legs are easily rebated after glueing up. The lower side rails are of $\frac{1}{\frac{1}{2}} \mathrm{in}$. material and are $\frac{7}{7} \mathrm{in}$. wide, they are tenoncd into the legs. Note that the shoulders of both joints will be at an angle. The joining rail is dovetailed into the side rails. When preparing the top back rail, which is dowellod into the uprights, the dowel holes should be bored before cutting the rounded portion, as it would otherwise be liable to split away (Fig. 19) Half-inch beech dowel is the best to use. The slats are stub-tenoned between the two rails, and are in wide at the top and taper to about $\frac{1}{2} \mathrm{in}$. Use $\frac{1}{2}$ in material for these.

Chalr Repalring. This is often easily done. At Fig. 20 two common leg break. ages are shown. Always repair such breakages before the fractured edges have got rubbed. The part, will then fit closely : whereas, if there is delay, the ragged edges may get injured and a neat joint may be difficult to effect.
The front leg is re. paired by means of a long dowel inserted (Fig. 21) First cut off

Chaif. Figs. 20-80. Diagrams illustrating how various breakages oan be easily monded. Eee text
the small turned fragment which is attached to pared to permit of the wedged tenon acting like the top square block of the leg. Use a fine a dovetailed joint. After the four seat rails tenon saw. and cut across at AA. Warm the broken surfaces, glue the little part which has been removed to the main body of the leg, and lay the work aside till the glue is set. Now bore both parts of leg (square portion and turned piece) for a long dowel (B), which should be of beech or oak not less than $\frac{8}{4} \mathrm{in}$. in diameter. The dowel must go well up into the square block and at least 2 inches into the turned leg beyond the fracture. Glue everything well, and the leg will be stronger than before.
The back leg is repaired with screws, as at Fig. 22. If any of the splinters are loose. glue them down so that the parts will fit quite closely. Hold these together, and, at the angle indicated in the diagram, carefully bore holes for two screws, one at each side (aee CC'). Countersink for the heads. It is well to use a tine bradawl first, and then a gimlet. The screws must be of a fairly tine gauge, and either $1 \frac{1}{\mathrm{in}}$. or $1 \frac{1}{2} \mathrm{in}$. in length. Try the screws. and, if all is right. warm the broken surfaces; apply thin hot glue and screw up. At the two ends of the joint (DD) insert a couple of ncedle-points. The holes countersunk for the screw heads are filled with a cement made with beeswax and resin. This is stained to the colour of the wood, and when trimmed off and rubled over with polish the repair stould be satisfactory.

## The Repair of Frame Joints

Chair frame joints frequently work loose on account of the glue giving way. Seat rails are tenoned to the legs, and when the tenons beconie loose the leg is unsteady. The inside angles of chairs are usually braced, either with a strut wedged in, as Fig. 23, or with a brace screwed on, as Fig. 24. If the bracing works loose the leg will probably be insecure. The joints of a chair with wood seat can be repaired with little trouble; but in the case of an upholstered seat, it is well to allow the repair to stand over until the chair needs to be re-upholstered. In this latter case it may be stripped, and then re-covered after the joints have been repaired.

Knock the parts loose and scrape off all the old glue. As the tenons may have become a little too small, owing to shrinkage, they should be wedged in order to tighten them. As the tenons do not go right through the leg they will have to be blind-wedged, as Fig. 25. That is, two cuts are made in the tenon and narrow wedges inserted. When the tenon is glued and driven home with the mallet, the wedges increase its width and thus ensure a tight fit. 'The mortise holes in the leg may be gently:
have been glued up the braces or struts are glued and screwed in position. Work of this sort usually requires to be cramped up with a regular joiner's cramp, the method of using which is shown in Fig. 26. The eramping is very important, as the glue will not hold satisfactorily unless the parts have been put under heavy pressure.

Kitchen chairs, which are frequently used for purposes for which they were never intended, have a habit of falling to pieces, but if properly repaired they will be as good as new. Taking Fig. 27 as a typical example, the best plan is to knock all the parts separate, marking each, so that its correct place is known. Clean off the old glue, and, if any of the leg joints fit rather loose, take a paring off the ends, so that a thicker portion will make the entry. A broken stretcher rail may be repaired in the way already described for a back leg (aee Fig. 22). It may, however, be less trouble to make or buy a new stretcher. Glue the rails to legs, and then glue and knock the four legs into the seat, using the cramp if possible. See that all four legs are level.
Coming to the back, if the tenons of the two outer uprights are loose they will have to be wedged (Fig. 28). The wedges are driven in from the underside. If the top pin which enters the shaped rail is broken, cut it off, and

Chair Bed, shown in two positions: open for use at night, and closed to form an eary chair
Courtesy of Oplsmann \& Co.o. Led.
fixed to the seat. The holes in the top rai are then glued, and this part coaxed on with the mallet. It is usual to wait and see that everything is correct and in line before driving in the wedges used to strengthen the outer uprights

The arms of kitchen armehairs often come loose owing to the breaking of the screw which holds them Punch out the head of this serew. The other end may be withdrawn with the screwdriver if a nick is first made across it with a file. The new screw should be insertod so that the smooth shank will pass the line of joint (see Fig. 30). It will then run no risk of breaking, and the countersunk hole may be filled with a stopping of some kind.
CRAIR BED. This is usually an arınchair, generally provided with an iron framework, which unfolds so that it can be used as a bedstead. The chair legs and seat remain in their normal positions, and the article is extended by turning over the upper part of the seat and lowering the back. The extremitios of the extensions are supported on extra legs which fold. It is fitted with cushions, usually three in number, which serve as a mattress. It may be entirely of iron or may have wooden or brass lege.
The illustrations show snother form of chair bed. When folded this has the appearance of an upholstered easy chair. The seat and back are folded down, as shown, to convert it into a bed. See Bed Sitting Room

CRAIR RAIL. This is a wooden moulding fixed to the walls to prevent damage by chair backs. It can take the place of the dado, and if different shade or colour of wall covering is used above and below the rail, the result can be made very pleasing. The moulding can be obtained in the white, i.e. not stained or painted, and when ordering allowance should be made for waste in mitring corners. There will usually be at least 10 corners, and 2 ft . extra should be obtained.

Start on the longest lengths of wall first : the short lengths and odd corners can be fitted with the moulding left over. The mitres for the corners should be cut neatly with a tenon saw, and with the aid of mitre box or board. When making the joints for the fireplace and bay window corners, do not forget to cut outside corners, or some of the moulding will be wasted in recutting. If it is necessary to join some of the lengths, do not mercly lay them end to end. Cut each end at
an angle of $45^{\circ}$, so that they can be o v erlapped. Such a joint will scarce ly be noticed when glass papered and painted.
Cut nails should be used to fix the rail to the wall and a suit able height is 36 to 39 in. from the floor. Punch the heads of the nails well in and cover with plaster of Paris; putty is sometimes used, but it shrinks in drying, and is unsightly. The rail should be treated to match the other wood work of the room. The moulding can also be obtained in oak, ma hogany, or walnut.

CRAIIS: In the Soil. Chalk is not so good as lime for heavy soils, but on light, sandy land it is to be preferred, because of its slower action. For this purpose it should be finely ground and put on the land in winter. Caicareous soils with solid chalk a few inches below the surface dry out quickly, and the best way to keep trees and plants flourishing in such land is to mulch the surface in early summer
So far as soil treatment is concerned, a great deal can be done by breaking up some of the chalk with a pick or strong fork, and using rotting or charred turf, or burnt clay, if procurable, as freely as possible. A good deal of it should be packed below and around the roots of each tree See Gardening; Rose ; Soil.
CHALR STONES. These are gout stones or tophi, which form beneath the skin in gouty patients, frequent sites being on the ear or knuckles. They are composed of urate of soda. See Gout.

CRAMBERMADD. In a hotel the chambermaid's duties are similar to a housemaid's in a private house. She attends to the bedrooms and bathrooms, and the passages and staircases in that part of the house where these rooms are situated. She brings hot water if it is not laid on, draws the window blinds, and calls visitors. She makes the beds, cleans the rooms, lays and lights fires.
CBAMBBERTLN. One of the most famou of all the red Burgundy wines is Chambertin. It possesses a fine, clear, dark red colour, and fulfils on the palate the promise held out by its charming bouquet. Soft and velvety, it is never sugary or "spirity." It is a warm, generous, and at the same time delicate wine. See Burgundy; Wine

CHAMFERING. The object of chamfer ing may be either for decorative purposes or to lighten the appearance, or sometimes simply to remove a sharp edge. It is usually at an angle of $45^{\circ}$ with the main surface, though it may be worked at any angle which the particular nature of the work requires.
The commonest form of chamfering and the quickest to carry out is when it is run along the entire edge without stopping (Fig. 1), in which case the work is done with an ordinary plane. In a type more frequently used the chamfer is run for a certain length and then stopped a short distance before reaching the end. Figs. 2 to 6 are typical examples of stops employed; Figs. 3 and 6 are more suitable for oak work. Frequent use is found on the insido edges of framings, such as panelling, and work for ecclesiastical purposes makes great use of chamfering.
In cases where the stop is flat, such as Fig. 6, the flat side of a chisel is used to cut the wood, and the reverse side for such as Figs. 2 or 3. As it is impossible to use an ordinary plane for the whole length of a stop chamfer, the ends have to be cut with a chisel or a bull-nose plane, which is capable of working very close to the ends, as there is only a very short distance between the cutter and the

front of the plane. Where a great deal of chamfering is to be done, a special chamfer plane (Fig. 7) is often used, the advantage of which is that it can work right up to the stope, and automatically regulates the depth of the chamfer
When a very deep chamfer has to be cut, it is advisable to make several saw cuts at various points along the cdge (not quite down to the finished depth), to obviate the tendency of the wood to split out when removing the bulk of the waste with the chisel; for should the wood start to split, the sp!it cannot run farther than the next saw cut. The chamfer is finished off with a chisel and plane. Finally a scraper is used, and then glasspaper.

Sometimes the tool known as a chamfer shave is used for chamfering. In appear-
 Heidsieck, Irroy, Moēt and Chandon, Perrier Jouet, Pol Roger, Pommery and Louis Roederer.

The champagnes shipped to Britain are generally dry, and styled brut or nature, which should mean that they contain no added sugar or liqueur. They are obtainable in half bottles, pints, quart bottles, magnums (double bottles holding 4 re puted pints), and jeroboams (double magnums). Cham. pagne keeps better in bulk.

Ice should never be put into it as it spoils the fla vour The bottle should be placed in an ice pail for 10 to 20 min . before serving. At a dinner party where various wines are served champagne is usually given with game or entrées and after. The best glass for champagne is tulipshaped with a deep stem ance it is like a spokeshave (q.v.), and used in the same way. It is capable of producing splayed and stopped chamfers.

CEAMOIS LEATEER. For cleaning windows and glassware, and as a polisher for metal ware generally, nothing is better than so-called chamois leather. It is really made from sheepskin, which after being freed from the wool is split into two layers. The top layer, or grain, is made into a variety of coloured leathers; the under layer, or flesh split, is used for chamois leather. It is treated with fish oil, and during oxidation the colour changes from white to dark ycllow. The skins are pressed and washed to free them from excess of oil, and the leather is then bleached and finally buffed to give it a fine nap.

The two characteristics of chamois or oil leather are its softness and its resistance to the action of water. For this reason the name washleather has been given it, and washable gloves are made of it.

In washing these gloves a simple method is to wear them, while a good washing in warm, soapy water is given, working them about on the hands so as to remove grease and dirt. Wash again in clean, warm, soapy water, and if a little soap is allowed to remain in them when they are hung up they dry more satisfactorily.

A cleaning leather is the better for frequent washing in soap and warm water with a little borax, afterwards insing in cold water. Then squeeze it, pull the leather out flat, and spread on a board or table. When almost dry, pass it through the hands and stretch it out until it is flat, repeatedly smoothing the surface. In this way the leather will dry soft. See Glove ; Leather.

CBAMLPAGNE. This sparkling wine re quires to be looked after very carefully. If there be the least sediment or deposit the wine requires to be filtered into fresh bottles. The wine matures quickly, and is at its best after from 8 to 15 years, although there are instances of champagne having retained its excellence after 40 years. Champagne is known by the name of the shippers. Amongst the leading brands are Ayala, Bol. inger, Clicquot, Goulet, cease to bear children: and as the change
froquently affects the mind as well as the body, especial care of the health is always called for. The age at which the change occurs is generally between 45 and 50 , but may be either earlier or later in certain cases The child-bearing period usually lasts about. 30 years.
The manner in which the climacteric occurs is irregular In some cases inenstruation sud. denly ceases, but in most it first becomes irregular, remains on for two or three years, and then finally stops. Fxcessive bleeding at the periods or blceding in the intervai should not be accepted by any woman as due to this cause alone without consulting her dootor.
Amongst the symptoms common ut this time perhaps the most unpleasant are flushings of the face and limbs, frequently preceded by chilly sensations, and followed by profuse perspiration. Some women are prone to corpulence while others become thin Osteoarthritis is another of the evils to which women are exposed Nervous symptoms are frequent, while headache is rather common, but often due to the need for glasses Other symptoms are backache and indigestion.
The first thing necessary for a woman who is suffering from the troubles incident to the change of life is to realize that they are natural, and that they will pass away in the course of a few years. This will ease her mind. At the same time, however, she should realize that some increased attention to her health is advisable for a fow months, or even years. The following aperient is useful :
Confection of senna .. .. .. .. .. I oz.
Confectlou of sulphur
Mix well. Take one teaspoonful at night when necessary.
As an alternative, one to three grains of cascara or a liquid preparation of cascara may be taken at bed time. The following simple dinner pill may be tried:
$\underset{\text { Extract of inux vomica }}{\text { Aloln }} \quad . . \quad .$.

| 8 |
| :--- |
| 3 |

Make into 12 pills. Take one pill after the evening meal when required.

If the appetite is poor, a tonic may be wseful. Strong tea, indigestible foods, and alcohol in any form must be avoided. Warm baths at bedtime, two or three times a weok, are soothing to the nerves.

Many women are prono to be emotional : they should strive constantly to control them. selves and, generally speaking, to take a cheerful view of life, which does so much to banish worry and anxiety. The troublesome Hushings are often relieved by bromides, and the following may be taken:

Cinnanuon water (enough to make) 6 oz .
Make into a mixture. Take two tablespoonfuls after the midday and evening meals when required.

It has to be pointed out that bromides are only to be taken when really requirod; if their frequent use is necessary, it should be under the oye of the doctor. Flushings are also helped by taking ichthyol. Beginning with a tablet of $2 \frac{1}{\frac{1}{g}}$ grains, the dose is increased gradually till in about three weeks time four tablets are being taken thrice daily. If at any time there is a persistent taste of the drug in the mouth sufficient has been taken. Iron may be required in some cases where there is shortness of breath and want of general tone due to anaemia, and may be taken in the form of Blaud's pills or in a mixture. See Anaemia.

CRLAPERON. Originally a hood worn by matrons, the word chaperon came to be applied to a married woman who took charge of an unmarried girl on social occasions.

A hostess often gives dances and dinner parties to which it is understood that clisperons are not invited, the hostess Lerself acting in that capacity to any unmarried girls prasent. At important aocial functions girls are chaperoned at least during their first. season.

CBARACTER : The Legal Aspect. it is usual for mistresses when engaging i servant to ask for a charactor, that is. somothing from a former employer about the antecedents and qualifications of the person requiring the situation. A character of this kind should never be given unless asked for.

Even if what a mistress says in giving a character is in fact untrue, yet if she says it honestly she will be protected by the law so long as she is not actuated by spite or malice.

Beware of giving a false character. If a mistress dismisses a servant whom she knows to be a thief, and out of gond nature writes that she is honest, and in her now place she steals, her old mistress is liable to the new mistress. A servant who obtains a situation by a forged or false character is liable to fine or imprisonment. So is anyone who knowingly gives a servant a false character, by means of which the servant obtains another situation. See Servant

CRARADES : How to Play. This game ts suitable for any number of players above 7 or 8. Two persons pick up sides, and one side then goes out of the room and chooses a word of two or more syllables. each syllable teing a soparate and complete word, e.g. sel-fish (sell fish). The syllables are then acted in two scenes and the whole word in the final scene

The usual method of procedure is for the syllable to be spoken by one of the players, though there is no need for the scene itaelf to give any direct representation of the word. Another method is for the syllable to be acted, though not necessarily spoken. Thus, in the example chosen, the first scene might show a shop, with a brisk trade, and the second might represent a party of fishermen coming home with their catch, while the whole word should not be difficult to act ; two children playing could easily convey the necessary effect. At the end of the performance the audience has to guess the word chosen.

The game is more successful if a fen words have been selected beforchand and a possible scenario drawn up, otherwise the time occu. pied in discussion by the acting party is apt to be wearisome to the inembers of the audience.

Historical charades is a picturesque variant of this game. The word to be guessed is the name of some person famous in history or fiction, and a short name is generally chosen, as upon its length depends the number of scenes to be enactod. Each scene depicto an incident in the life of some other celebrity whose initial letter occurs in the name selected for the charade.

No names are introduced by the actors that will give the subject away. About five people can comfortably take part in the scenes. No theatrical costumes, scenery, or other property are necessary ; the house can furnish all that is required in the shape of a few shawls, scarves, sheets, hats, coats, and walking. sticks. See Children's Party.

CRARCOAL : Its Domestic Uses. Al. though charcoal has a limited use in the house, it has excellent deodorant properties, as well as the power of taking the colour out of certain solutions. It is produced by partly burning certain kinds of wood and bones, the former varicty being known as wood charcoal, and the latter as animal charcoal

Wond charcoal finds one of its chief uses in the garden. A fow pieces mixed with the mould in which plants are potted keeps it sweet. For a similar reason a picce should be placed in the water of the glasses in which
bulbs are grown. Stakes driven into moist ground resist decomposition for long periods if the ends are first put into a fire and so partly converted into charcoal. Similarly, casks charred inside resist fermentation better than uncharred casks
Mixed with any foul inaterial charcoal helps to destroy the odour. It has been found to absorb any smell that may arise when clothes are put away in a wardrobe or chest of (lrawers. For this purpose somo moderate sized pieoes should be placed among the clothes. Powdered charcoal serves as a tooth-powder, neutralising some of the effects of decay.

Some coloured liquids, e.g. red wine and fruit juices, lose their colour when filtered through powdered charcoal. Charcoal should not be used to purify drinking water.

CHARLOTIE RUSSE. A jelly mould is lined with a little jelly at the bottom and when nearly set glacé cherries are pushed through

## Charlotto Rasse, a delioious party sweot

it to the bottom of the mould and sponge cakes or savoy fingers placed round the sides. A dessertsjoonful of castor sugar and half a clessertspoonful of gelatine should be dissolved in a $\frac{1}{2}$ pint of milk over gentle heat. Tho milk is then strained and a few drops of vanilla cssence added; also, if desired, a tableapoonful of sherry. Half a pint of cream should be well whipped and the strained milk stirred in when cool. The mixture is poured into the mould and left in a cool place or on ice until it has set. when it is turned out

CRARPIE. Shredded linen used for the dressing of wounds is termed charpie. It is made of Hax between layers of gauze, and used to form part of the first field dressing of the soldier; but gauze is now deemed to be sufficient. The shredding makes the dressing more absorbent and protective, but these purposes are usually achieved by the use of gauze or lint and absorbent cotton-wool. See Bandage ; First Aid.

CBARR: How to Cook. Amongst fresh water fish charr is highly nutritious. It should be washed well and dried before cooking To fry it, cut the fish into steaks, coat with egg and breadcrumbs, and fry in hot fat, or the fish may be first dipped in batter.
Charr inay be broiled or grilled. Cut the fish into steaks about 1 in . thick, season with pepper and salt, wrap in pieces of oiled paper, and gently broil them over a clear fire To grill charr with a gas fire, place it on a greased grid-iron and put this under the griller, which must not be turned on full. Charr cooked in any of these ways should be garnished with lemon or parsley, and served with melted butter sance.
CEARTREUSE. There are three kinds of this celebrated liqueur. The white variety is the mildest; the green is the most potent and highly prized, especially in France : the yellow is the liqueur most widely used in all countries. Chartreuse is distilled from certain aromatic plants. See Liqueur.
CBARWOMAN. A charwoman is a worker who goes out by the day or hour to clean private hnuses, offices and shops. She may be paid by the week, day, half-day or hour, and her pay may include or exclude food.

A charwoman must be insured under the health insurance scheme, but not against
unemployment. If she works tor a single employer he is responsible for the weekly pay. ments. If, however, she works for a number of employers the one who employs her on Monday is, strictly speaking, responsible. In some cases, however, the employers agree to take it in turn to pay the employer's share of the prem:um.

If a charwoman is employed regularly-for instance, once a week, or once a fortnight or month-she is a workman within the ineaning of the Workmen's Compensation Acts and the employer is liable for compensation if she is injured by an accident arising out of and in the course of her employment. It is wise, therefore. to include her as a servant when insuring against risks under this act. If employed only on odd occasions she does not come within the act. See Insurance.

CRAUDFROID SAUCE. A gencral favourite for coating meat made up into cold entrées, chaudfroid sauce requires skilful cooking to be of the right consistency. To make the white variety, heat up pint white sauce, adding to it 3 sheets of gelatine, previously dissolved in a little white stock, and 2 or 3 tablespoonfuls of cream. Strain the whole through a tammy cloth, and use the sauce when it is just on the point of setting.

Brown chaudfroid sauce is made from $\{$ pint good brown sauce, $1 \frac{1}{\text { tablespoonfuls liquid }}$ aspic, and 2 oz meat glaze. The glaze is dis. solved in the sauce before the aspic is added, and the whole strained and used when cooling. See Sauce.

CHAUFFEUR. The driver of a motor car is termed a chauffeur, and certain qualifica. tions are required for the post. He must be in possession of a driving certificate, which ehould be free from endorsement, and in view of the responsible nature of his work he must be of good personal character. He should also have the technical knowledge required to do his own repairs and to keep the car in proper condition.

He ranks as a skilled mechanic, and is generally an outdoor servant. Both men and women are employed.

The employer is liable for injury or damage to person or property caused by his chauffeur's negligent driving or handling of the car while on his master's business. But if the chauffeur takes the car out for his own purposes-e.g. to call on one of his own friends, or for a joy. ride with the housemaid-and does damage while so engaged, the employer is not liable The latter nust always insure against accidents to third persons and property caused by his car when driven by his chauffeur.

A chauffeur must be insured under the national health insurance scheme and the employer is responsible for the weekly payments. Unless the chauffeur is a woman, the cmployer must take out a licence enabling him to keep a male servant. This costs 15 s. a year. See Insurance; Motor Car: Negligence : Servant.

CEEDDAR : A Mild Cheese. This is one of the cheapest varieties of cheese. There are several methods of making Cheddar, besides the noted west of England way, other varieties coming from Ayrshire and Canada.

Cheddar cheese is usually made from morning's and evening's milk that has been ripened. The correct degree of ripeness is difficult to gauge, and the inexperienced maker can only determine it accurately by tests. One way of ripening the milk is to keep it at such a temperature during the night that enough acidity will develop to ripen the morning's milk partially when this is added. The other method is to add a ripening or souring agent, such as a starter, to the milk in the morning, and allowing it to remain until sufficient acidity is obtained. The former method is satisfactory with careful handling, but the employment of a good starter will give more reliable results.

## Cheese and Cheese Making

## Some Practical Bints for the Small Dairy

Our Encyclopedia contains articles on the various kinds of cheese, e.g. Cheshire and Stilton. This entry is followed by a number of entries on cheese dishes. See also Diet; Milk

Cheese is a valuable food-stuff, more especially double cheese, which is made from whole milk, and contains a large percentage of protein and fat. Unfortunately it is diffioult to digest. It should be eaten with bread or biscuit in order to ensure that it is thoroughly masticated and sufficiently broken up before being swallowed. Soft, fresh cream cheeses are more easily digestod than most other varieties. Cheese is a more concentrated form of nourishment than the best beef. Lean meat has about 70 p.c. of water, whereas good cheese contains only about 30 p.c. Fortunately, for those with a tendency to indigestion, cheese can be eaten with impunity if grated or pulverised. Puddings and other dishes of milk, eggs, and grated cheese are extremely nourishing.
The standard English cheeses, such as Cheddar, Cheshire, und Derby, are too large for the smallholder to make, as he does not usually have more than 7 to 10 gallons of milk daily, and only a portion of this is available for cheese-making. In addition the utensils required for making the larger cheoses are somewhat expensive.

Hygienic Making Conditions. It is essential that the milk intended for cheese-making should be perfectly clean and in good condition. Almost. any clean, airy, and well. sheltered building having a good floor is suitable for cheese-making purposes, and if a cellar is available in which to ripen the pressed cheeses, so much the better. If a dairy has to be built, it should be of brick, with a cement tloor falling to a channel which leads to a suitable gully placed outaide the ${ }^{-}$dairy and
communicating with a proper drain. If pressed and ripened cheeses are to be made, a similar building, to be used as a curing-room, should be erected in line with the dairy, but sunk about 2 ft . in the ground, and provided with a floor of cement. A series of shelves, on which to place the cheeses, should be put round the ripening-room, and the walls of both rooms should be limewashed at least twice each ycar. When not required for cheese, the making-room would do duty as a butter dairy.

A suitable size for the making-room is 10 ft . by 8 ft ., and for the ripening-room, 8 ft . by 8 ft . The roof inay be of tiles, thatch, or galvanised sheeting, lined underneath with boards. All ventilators and windows should be made to open and close as desired, so that the rooms can be kept at a suitable temperature. In order to save expense, both rooms may be made of wood placed on three or four courses of brick to prevent rotting. If built of wood, the outside walls would need to be double, with an air space between. The inaking-room should usually be kept at a temperature of $62^{\circ} \mathrm{F}$. to $66^{\circ} \mathrm{F}$., and the curing-room from $58^{\circ} \mathrm{F}$. to $62^{\circ} \mathrm{F}$.

Cheese-Making Requisites. A table 6 ft . long by $2 \frac{1}{2} \mathrm{ft}$. wide, with raised sides and ends, and lined with tinned sheeting, is necessary. This table should slope to one corner, and be provided with an outlet and pipe to allow of proper drainage of the whey from the cheeses into a pail below. One or two well-made oak tubs in which to coagulate the milk are required; they should be of a
capacity of 6 gallons each, and be provided
with close-fitting wooden lids The maker will need a large knife with which to cut the curd a milk-strainer, curd-ladle, skimmingdish, and thermometer, cheese-moulds. boards, straw mats, measures, choese-draining rack, set of wall shelves on one side of the wall, measur-ing-glasees, pails, and brushes: alno weights up to 28 lb . with which 10 press cheeses, and ${ }^{\text {a }}$ supply of rennet extract. The measuring-glass, I oz. size, should be sub-divided into drams.

Method of Making. A pressed cheese, which is crasmy in texture with a distinct chcesc flavour and very palatable when ripe, is quickly made. Six gallons of fresh, sweet milk are required for one cheose of standard size The circular cheese-moulds should be $6 \nmid \mathrm{in}$ deep by 6$\}$ in. diameter, strongly made of tin. and perforated all round. In addition, the moulds should be provided with a circular tin disk and wooden follower.

The milk is first raised to a temperature of $90^{\circ}$ F., and rennet, in the proportion of I dram to 3 gal., is added to bring about coagulation. The rennet is diluted with six times its volume of water, and then stirred into the milk. The milk is then stirred deeply from 3 th 4 min., after which the surface is kept gently moving to prevent the fat from rising. until coagulation sets in. The tub or vat is then covered with the rooden lid until coagulation is completed. The approximate time to cut the curd may be reckoned by multiplying by $2 \frac{1}{2}$ the time taken for coagulation to appear after the rennet is added, thus: Time of adding rennet. 8 a.m. Time coagulation commenced, 8.15 a.m.$15 \mathrm{~min} . \times 2 \frac{1}{2}=37 \frac{1}{2} \mathrm{~min}$. Time to cut curd 8.52 a.m. The curd-as the coagulated inilk is termed-is ready for cutting when it feels firm and springy, and splits with a clean fracture when a finger is inserted and lifted upward through the curd.
A large knife, long enough to reach to the bottom of the vat or tub, is taken, and the curd carefully cut in cubes $\frac{f}{} \mathrm{in}$. to $\frac{1}{2} \mathrm{in}$. in size, tho horizontal cut being made with a skimming dish. After cutting, the curd is gently stirred by hand, care being taken to remove particles adhering to the vat.

The temperature is now raised to $106^{\circ} \mathrm{F}$. If a jacketed vat is used this is done by passing hot water into the jacket. The temperature should not be raised faster than $1^{\circ}$ in 3 min., and the curd should be kept stirred during the process. If the cheese is made in a tub or unjacketed vat, the following procedure is adopted : If there are 6 gal . of curd in the tub and the temperature is $86^{\circ} \mathrm{F}$., it has to be raised $20^{\circ}$ to $106^{\circ}$. This temperature is attained in 4 steps of $5^{\circ}$ each. The first step therefore, is to raise each of the $6 \mathrm{gal} 5^{\circ}$.

## Heating the Whey

A cheese cloth is laid over the vat and pressed down on the curd; a supply of whey is then ladled off into a bucket and the temperature of this raised by the immersion of the bucket in hot water. The temperature to which the whey should be heated is estimated thus: If 2 gal . of whey have bcen taken off, these 2 gal . must be raised $15^{\circ}$ to $101^{\circ}$; if only 1 gal . had been taken, then the temperature would have to be raized $30^{\circ}$ to $116^{\circ}$. The temperature of whey should never be raised above $120^{\circ}$.

When this heated whey has been returned to the tub, the mean temperature of the whole 6 gal will be $91^{\circ}$, i.e. the first increase of $5^{\circ}$ will have been effected. The three further stages in the process of raising the temperature to $106^{\circ}$ are carried out in the same way. The stirring of the curd should be continued until the curd becomes tough and bright, and the particles, when pressed together in the hand fall apart and do not crush. The curd is then allowed to pitch and the whey is poured off through a straining cloth.

The curd is now spread evenly over the bottom of the vat, and salt in the proportion of 1 oz . to 2 gal . of milk is mixed into it. The
curd is then carefully packed into the mould, ripened lor renneting. If no test lor acidity is at ntersals until the curd has a slightly aoid which should previously have heen lined available this must be judged, but carc should taste and smell, when it may be cut into slices with a chocse cloth, and put to press with be taken that the milk is not over ripe or the 2 cwt. pressure. It is turned tho same checse will work too quickly evening and returned to press until the following morning In the morning the cheese a talien from the prese seven in a calico bandage and again returned to the prese io 1 hour, after which it should be placed in a is added at the rate of ono drain (mixed with
 four gallons of milk, and the whole should be well stirred for 3 $\min$ To prevent wasto the cream should be gently stirred in just before the milk begins to curdle. The curd is Soft Cheese. A soft cheese which is usuready for cutting when ally designated Cambridge cheese is made it breaks cleanly over from whole milk and is in demand during warm weather.
 'I'wo cheeses can be made from a little mure than 6 quarts of milk. It is un ivise to mako larger quantities than required for speedy consump) tion, as this checsc deteriorates quickly The teinperature at renneting should be from $92^{\circ}$ to 95 F About 1 dram ol rennet should be added to the quantity of
 milk mentioned, and the cheese tub should be care. ully covered. It s advisable to use is amaller tub when making not more than four cheeses. The rennet should be diluted and be stirred infor 4 min . When the curd os apt and the
Sairly dry draughty room lor two days and then in the ripening room. It will be ready for use in about three weeks, when the weight will usually be about $6 \frac{1}{2} \mathrm{lb}$.

Unscalded Cheese. A checse not unlike Welsh Caerphilly is quickly made and digestible but does not keep well as it is unscalded. It is a popular cheese for consumption with salads in hot wenther

This checse is made from mixed morning's and evening's milk As an insertedfinger, the curd retains a large percentago of which is usually moisture (the whey), very little acidity is 40 to 45 min required, and, unlike the varieties requiring after renneting longer periods of ripening, it can be made in It is now out cold weather. Five gallons of whole milk into pieces about will make a cheeso weighing about 7 lb . the size of $\frac{1}{2}$ in The moulds for these oheeses should bc cuhes, this procers flat. $9 \frac{1}{2} \mathrm{in}$. by 2 in ., with removable bands taking 10 to 15 whioh sink down as the cheese presses min., during Where a number of these cheeses are made which time the they are piled one on top of the other when put whey should be to press, and only the top one requires a stirred gently follower or board. Small moulds to make When the curd 1 or 2 lb . cheeses can also lie obtained and are is evenly cut and very convenient, as any number fiom 4 to 12 cheeses can be pressed at the same time with a large board placed between each layer. milk is at once atroined into the cheese gat octle lor or tub and well stirred to get rid of the odour whey is now of the cows and to lower the temperature drawn off. With slightly; in cold weather it is covered to small quantities maintain the desired temperature so that a (e.g. 5 gal.$)$ this certain amount of acidity will develop to ripen is best done by the morning's milk when added. In warm pouring off the weather it is unnecessary to cover the evening's whey through a milk. When a starter is used, the evening's cloth (over milk should be cooled down to $70^{\circ} \mathrm{F}$. as soon another vessel) ns obtained, to check acidity, and stirred and then gently tipping the curd into the cloth whey is on the surface, the curd may be occasionally during the evening to prevent and tying up into a bundle. It is now left for removed with a skimming dish and placed the cream rising. Neat morning, when thic 20 min ., and then cut into 3 in . cubes and the in the moulds in thin slices, a portion of temperature of the milk bas been raised, a whole moved and turned to assist drainage. unbroken curd being set aside to forin a smooth amall quantity of starter may be added to It should then be tied up again for another 20 upper surface on the oheese. The moulds are produce enough acidity, so that when the min, after whioh the pieces should be pulled in two pieces, the bottom portion holding a morving's milk is added the milk is sufficiently apart and again ticd up. This should be done threaded straw mat, which prevents the curd
secaping, whilc the upper one is pierced with draining holes They are about $7 \frac{1}{2} \mathrm{in}$. long by 5 in . wide and 6 in . deep, and should be made of elm wood. Moulds made of tin should not be used, as in these the curd rapidly loses heat, and drainage is thereby retarded. With tin moulds the curd settles into a flat cake, but with wooden moulds the curd adheres to the sides, causing the cheese to settle in the middle first. thus producing a curl in the curd.
These cheeses are not turned at all, and are ready for use $w$ hen the wooden moulds can be removed without the cheeses losing shape, each chcesc weighing well over a pound. They are consumed fresh, being sold along with the straw mat upon which they have been drained,

Cheese Hopper. Small yellowish. white maggots, known as cheese hoppers, some times swarm in cheese where care has not been taken for its protection against insects. They are the grubs of a tiny black fly (Piophila casei) which lays its eggs upon cheese. Maggots have the mouth formed for sucking, and to reduce solid food to a condition in which they can absorb it they have to discharge upon it a fluid that will dissolve it. In this process chemical changes take place that may be highly injurious to the human system. The part of the cheese attacked should be cut away and destroyed.
Cheese Mite. Flour, linseed, and other household stores, as well as cheese, are attacked by Tyroglyphus siro, or the cheesc mite. It get.s into cracks in the rind of whole cheese, or in air cavities of cut surfaces, and reduces the food to powder. Some consider that the presence of the mites improves the flavour of the cheese. Under the microscope, the powder resulting from their activity is seen to consist of dead mites, cast skins, etc. The injured portions should be cut out and the sound part scraped thoroughly, to get rid of mites, the rind getting attention as well as the edible portion

CHESSE CAKE. For the lemon-cheese filling these require 2 oz. sugar, 1 oz . butter, 3 oz flour, 1 egg, 1 tablespoonful milk, $\frac{1}{2}$ teaspoonful baking-powder, a pinch of salt and a little lemon flavouring. Crean the

Cheese Cakes made with pafi paskry, the contres boing filled with jam and a lemon-choose mixture
butter and sugar, and add a well-beaten egg and the sifted flour. Beat well, and stir in the baking-powder and essence. Line some deep patty tins with puff pastry (q.v.), then put in each tin 1 teaspoonful each of raspberry jam and the mixture, and bake in a hot oven for about 15 min .

CHBESE CROQUETTE. Either vermi. celli, macaroni, or spaghetti may be used for cheese croquettes. To prepare them, boil together $\&$ pt. each of milk and water, adding 2 tablespoonfuls of spaghetti broken into short lengths. Boil these for about 10 min . or until the spaghetti is tender, and in a separate saucepan melt 1 oz . butter, stirring into it $\frac{1}{2} \mathrm{oz}$. Hour, and then the cooked spaghetti and milk and water. Stir and cook the whole gently until it boils and thickens, then mix in 2 oz grated cheese, and season it well.

Turn the mixture out on a plate to cool, and when cold enough to handle form it into cven-sized balls Beat up an ogg on a plate brush some of it over cach ball, and then roll it in breadcrumbs. Heat some frying fat in a deep pan, and when it begins to smoke put in the balls, a few at a time, and fry them a golden brown. After Iraining them, serve on a paper doily garnished with parsley.

CFIEESE FONDU. An appetising supper dish is prepared by mixing 3 tablespoonfuls of grated cheese and the same quantity of milk into 3 well-beaten eggs. Sicason the whole carefulty. Thickly butter three little fireproof dishes and pour enough of the mixture into these to fill them about three-parts full. Bake these gently until they are lightly set and delicately browned, and serve them immediately in the dishes in which they were baked. Thin rolled brown bread and butter or thin fingers of dry toast should be served with this dish.

CRIDESE FRIMIER. Mix 3 oz . of flour with a dust of salt, and in a separate basin beat the yolk of an egg with $\frac{1}{2}$ gill milk and

2 tablespoonfuls melted margarine Stir these into the flour and beat the mixture well Cut 6 oz stale cheese into small strips or fingers, season with salt, pepper, and a few drops of vinegar. Beat the white of an egg to a stiff froth and fold it lightly into the batter, dipping the pieces of cheese in this and sliding them gently into a pan containing smoking-hot frying fat. Fry the pieces till they are golden brown in colour, turning them once to make sure that they are cooked on both sides Drain them well, heap them on a hot dish, and serve them at once.

CFISESE PUDDING. As this pudding sinks rapidly after leaving the oven, it requircs to be served at once. To make it, stalk $\frac{1}{} \mathrm{lb}$. tomatoes, dip them for a few seconds in boiling water, and then peel them. Slice each tomato thickly and lay the slices in a greased pie-dish. Mix 6 oz. grated cheese with 3 oz. fresh breadcrumbs, and in a separate basin beat 2 cggs to a froth, mixing them with $\frac{1}{3}$ pint milk. Stir these into the cheese and crumbs, adding as much more milk as is necessary to make the mixture the consistency of a thick batter. Season it carefully and pour it into the dish over the tomatoes. Bake the pudding in a noderately hot oven until it is set, well puffed-up, and browned.

CHEESE SAUCE. A sauce for serving with au gratin dishes, or with stewed celery or seakale. It is prepared as follows: Melt 1 oz. butter or margarine in a saucepan, stir in $\frac{1}{2}$ oz. flour and, when smooth, add slowly $\frac{1}{1}$ pint milk (or pint milk and $\frac{1}{3}$ water). Continue stirring until mixture boils, then add $1 \frac{1}{2} \mathrm{oz}$. grated cheese, preferably Parmesan, salt and pepper to taste, and, if liked, a little grated nutmeg. When serving an au gratin dish, mix a similar quantity of grated cheese with a tablespoonful of browned crumbs, sprinkle this over the sauce, add a few smal pieces of butter, and bake the dish in a
quick oven until the cheese melts and browns. See Au Gratin.

CRESESE STRAWS. These are firequently used as a savoury instead of cheese. Mix together 2 oz flour, 3 oz . grated checscl'armesan if possiblo-and add a few grains of cayenne and salt. Into these lightly rub 2 oz butter, and mix to a stiff paste with the raw yolk of an egg beaten up with 2 teaspoonfuls of cold water. Knead and roll out into a strip about 4 in . wide and $\frac{1}{8} \mathrm{in}$. thici: Cut the mixture into narrow strips like large matches and bake them on a tin lined with greased paper in a quick oven till they are a delicate biscuit colour. They burn very easily, so need care; they are also very brittle and require gentle handling. They keep for at least a week in a tin, and can be re-warmed

CEDESSE TOAST. This savoury is made by boiling six almonds for 2 min., skinning and slıredding them, and then frying them a light brown in a little salad oil. Coarsely chop 1 tablespoonful of chutney, put it into a small pan, and add to it the fried almonds, $\because$ tablespoonfuls grated stale cheese, and a little salt and pepper. Heat all these ingredients thoroughly and serve heaped up on small rounds of hot buttered toast. Small pieces of fried bread may be used instead of toast.

CRESSE TURNOVER. Thesc can be caten immediately after making, or reheated the following day Mix together 1 oz . of boiled rice, 2 oz . of grated checse, an egg, and 1 tablespoonful of thick cream, and season the whole with salt and red pepper. Make $\frac{1}{1} \mathrm{l}$. of pastry ( q v.), roll it out thinly, and cut it into six neat rounds On each of these pile a tablespoonful of the mixture, damping the cdges of one side of each and folding the pastry over to make semicircles. Have ready a pan of deep fat heated to boiling point, drop in the turnovers, and fry them to a golden brown, afterwards sprinkling them with salt and serving very hot.

CBIF' : A Professional Cook. The chef is the principal cook of an hotel or restaurant. or of a house where a considerable staff is maintained. He must be a master-cook who has had experience in a first-class kitchen, and should be provided with a diploma from a recognized school. He-or she-must be able to compose a menu, and to take the principal part in or direct its preparation ; he is expected to be capable of devising new dishes, and not to be entirely dependent on the recipes of any cookery book.

It is possible to secure a complete profcssional training in the properties and qualities of different foods, and in the science of their preparation, at various places.

A chef's cap is made of white duck, $t$ will, or linen. It is of no special size, and can be mado by cutting a round of material 22 or 23 in . across, and pleating it into a band, 2 in . deep, and folded to the exact size of the head.

CBIELSEA BUN. This is made from 4 oz of Hour, oz. butter (melt ed), a little more than $\ddagger$ oz. yeast, $\frac{1}{\frac{1}{2}}$ teacupful of milk, and about 1 oz sugar. Cream a pinch of the sugar and the yeast together, pour the milk over the melted butter, and mix all together with the warmed flour to a light dough, kneading it well. Leave it to rise, then repeat the kneading process, and roll the dough into a square. Spread it orer with $1 \frac{1}{2}$ oz currants and oz. sugar, roll it up, and cut it into 5 or 6 pieces. Let these stand for a few minutes, coat with a little beaten egg, and then bake the buns in a hot oven for about 15 min .

CRISLSEA CAKE. The ingredients required for a Chelsea cake are 10 o7. Hour, 4 oz . butter, 6 oz castor sugar, 5 eggs , $\frac{1}{2}$ gill milk, and a teaspoonful baking-powder, and vanilla to taste. Sieve together the flour
baking-powder, and a pinch of salt, and cream together the butter and sugar. To the latter add the eggs, beating each in scparately, then the flour, etc., and lastly the vanilla and milk. Put the mixture in an oblong baking-tin lined with two layers of buttered paper, and bake it in a moderately hot oven or about an hour.
In the meantime, prepare a filling for the cake by chopping up 2 tablespoonfuls of dried and shelled walnuts, and pounding them in a mortar with the same quantity of ground almonds, a tablespoonful of apricot jam, and a little lemon-juice and orange-flower water. Add enough sieved icing sugar to mix the whole to a smooth paste. Slit the cake into halves and put the icing between them.
Make a little white icing and pour it over the top and sides. Decorate with halves of walnuts and preserved rose or violet petals.
CBISLSEA CBINA. True Chelsea is always soft-paste, 'easily marked by a knife, and as most imitations are in hard porcelain,

Chelsoa Cbins. Examples of the delioatoly coloured and graoefally thabioned old English ware. The oharacterigtio Agures represeat: left, Justioe, and right, Diana
due to a method of manufacture which begins with the formation of a caterpillar of cut fringe.
Ordinary cloths are made by one weaving but chenille fabrics are made by two. First o all a fabric is woven in bands of colour, and then that fabric is slit lengthwise into narrow strips, so providing the caterpillar-a furry coloured strip of fringe supported by length wise threads, arranged to hold the fur securely. This caterpillar is re-woven across a thinner set of threads, and the colours form the pattern seen in the completed cloth

Chenille may be cotton, wool, silk, or other material. Cotton chenille is made into selfcoloured window curtains, and their colour has a peculiar bloom, due to the method of making. Wool chenille is made into a variety of seam less Axminster carpet squares. Chenille in various colourings is also extensively used for embroidery, knitting, and crochet work.
The pile of chenille can be made either long or short. The article is generally decorative rather than durable, although good wear is given by the best qualities if fairly treated. It should be realized that chenille is less able to stand severe treatment than velvet fabrics of mor substantial construction, and the articles should be used with care, especially in cleaning. Rough hand ling is likely to break the light warp thread which form the support of the caterpillar or pull out the fur from its foundation.

Cotton chenille window curtains can be washed in a lather of good soap flakes; as the surface is bushy and rough, handling is to be the presence of a forged mark, either the avoided: it is advisable to steep them well, triangle or the anchor, should not deceive.
Chelsea ware began with undecorated groups in translucent white, like skimmed milk, and passed thence to four-sided bottles and octagonal tea-ware, decorated with Aesop's fables or Japanese designs. After producing hexagonal jars, dishes in the form of birds and regetables and the like, Sères and Dresden influence introduced rich ground colours, especially pea-greens, turquoise, and the peculiar Chelsea claret, with panel paintings of pastoral scenes and Oriental birds. Besides the figures and groups, knife-handles, stick knobs, scent-flasks, etc., were much favoured.
Careful imitations were formerly made at Coalport and Paris, and there are many inferior modern forgeries. These may often be detected by their gaudy colouring, the flesh tints of the cupids, and the tell-tale gilding of the anchor. See China.

CEISLSEA PENSIONER. The name is given to a prescription for rheumatism and gout which was. obtained from a Chelsea pensioner. It has been subject to many alterations, but the following is probably the original prescription: Powdered guaiacum, 1 dram; powdered rhubarb root, 2 drams; cream of tartar, 1 oz ; sufphur, 2 oz . : and one nutmeg, grated. These powders are mixed together and then made into a paste or electuary by incorporating honey 12 oz . The electuary is taken in doses of from one to two teaspoonfuls, night and morning. siee Rheumatism.
C:IFNTLLE. The name is derived from the French word for caterpillar. Chenille trimmings and furnishing fabrics all have a vertain velvetiness of appearance, and this is
rinse thoroughly, and dry in a good current of air. Wool chenille curtains and table-covers can be dry-cleaned more safely than washed.

CRISQUE. A cheque is a negotiable instrument-that is, it can pass from hand to hand like cash unless it is marked " not negotiable." Thus, if a cheque is stolen or obtained by fraud, anyone who takes it in payment of an account or cashes it and does so in good faith without notice of the frand or the theft, and before it is overdue, has a good

The cherry tree flourishes best on well drained land, on a subsoi! of sand or chalk ; there, in time, it develops into a large tree and is long.lived. It may, however, be grown on ordinary soil that is well cultivated. When cherries are planted in small numbers in gardens the difficulty of protecting the fruit from birds has to be considered, for unless the trees are netted the birds will spoil the crop. For this reason amateurs should plant bush or pyramid trees in preference to standards which take up a lot of room and cannot be netted conveniently.

Another detail of importance is this: all varieties of cherries are considered to be selfsterile and unless several are planted together the blossoms will not be cross-fertilised, and thus the chances of a successful crop are remote. For this reason it is useless to plant solitary cherry trees unless there are a number of others in the immediate neighbourhoor.
title to it and can enforce payment. A cheque is overdue when it has been more than a reasonable time in circulation and a chequc over a week old may well be overdue.
A cheque may be made payable either to a named person or 'order,' or to a named person or 'bearer.' The payee of an order cheque cannot transfer it to anyone else or obtain the money for it without writing his name on the back-'indorsing' it-but a bearer cheque passes from hand to hand by delivery without indorsement. If the person to whom a cheque is transferred is not paid by the person who transferred to him. he can sue the drawer.
If someone forges a man's signature as drawer of a cheque and his bank pays it, the bank must bear the loss, however clever the forgery ; but if a man makes a cheque payable to Jones or order, and someone forges Joncs's name and caslies the cheque the bank can charge it against the drawer's account. The bank is supposed to know the signature of its customers, but not the signatures of persons in whose favour its customers draw clieques.

Crossed Cheques. A precaution frequently taken in writing out a cheque is to cross it by drawing two parallel lines across it thus $\geqslant$. A cheque so crossed may be indorsed by the payce in the usual way ; it cannot, however, be exchanged for cash at the bank, but must be paid into a banking account If in addition the name of the payec's bank is written between the lines of the crossing the cheque can only be paid into that bank. The addition of the words " $a / c$ payee" to the crossing means that the cheque cannot be indorsed to any third person by the payee.
Another method of protecting a cheque is to write on it the words ' not negotiable' either with or without a crossing. If a cheque so marked is indorsed by the payee to some third person, that person and any subsequent indorsee can have no better title to the cheque than the person from whom he received it Thus if such a cheque is stolen or obtained by fraud, the holder cannot recover on it, even though he took it in ignorance of the theft or fraud and for value.
Always present a cheque the same day it is received if possible. A banker is bound to honour (i.e. pay) a customer's cheques drawn on him so long as he has money enough in his account. If the bank dishonours a customer's cheque when there is money to mect it, the customer can recover damages, which may be very heavy if he is engaged in trade or busincss.

Cheroot. See Cigar.

# Cherries: The Fruit and its Varieties 

## With Methods of Preparing Them for the Table

## See articles on other fruits, e.g. Apple; Plum; and for cultivation Grafting; Pruning, etc. Other

 uses of cherries are deacribed in the shorter entries that follow this maln headingThe matter is complicated by the fact that onme varieties of cherry are inter-sterile. tha is to say, the flowers can be cross-fertilised only by certain other varieties.
The result of experiments has been to classify most varieties into six separate groups: those in one group will not crossfertilise others in the same group, but they will cross-fertilise those from any other group. When making a choice of varieties. therefore, it is wise to choose one from each of the following groups rather than two from the same group.
A. Knight's Early Black, Black Eagle Early Rivers and Belford Prolific. B. Frog more Bigarrean, Bigarreau de Schrecken and Waterloo. C. Emiperor Francis and Napolcon. I). Governor Wood and Fiton. E. Kentish Bigarreau.
Other cherries are less difficult of management, and if a mixed collection is planted
 left, clusters of small red morello cherrles, much used in cooking
simmer gently until tender in an enamelled pan or cassemole, with to every pound of truit $\frac{1}{2}$ pint water and $1 \frac{1}{2}$ table. spoonfuls sugar
Stuffed cherries make pretty dessert sweets. and are prepared by rolling some almond paste into neat little halls, making a slit in the cherries, and insert ing a ball in each. The cherry is then molled in the hand to mako it round, sprinkled with castor sugar and put into a tiny paper case.

Owing to their decorative appearance, cherry swcets are liked for parties. Cherry jelly is a favourite. To prepare this, wash and pick 1 lb . cherries, remove the
natislactory crups may be expected. Among them are Noble. White Heart, Black Heart. FHorence and Gcant d'Hedelfingen.
13isha and standard cherry trees are grown in the open garden, standards at 30 ft . apart, bushes at 12 ft . apart Fan-trained trees are suifable for planting against a wall facing south, west or east: they should be 18 ft apart
The sweot cherries, which comprise all those varictiea named above, bear their fruit chiefly on spury-short, sturdy shoots bearing blossom huds. The principal pruning is done in early August when summer laterals or side shoots which are likely to crowd the tree are stopped at about six leaves from the base. These shoots are again shortened in winter

As cherry trees become older fruit spurs usually form freely and little pruning is nceded. In fact, severe pruning does harm and may lead to an attack of gumming."
Standard cherry trees need less pruning than bushes or pyramids; the branches are thiuned out in autumn to prevent overcrowding. The growth of cherry trees on a wall must be limited and the summer and winter pruning of the side shoots is necessary. Cherry trees which grow luxuriantly but do not produce fruit should be lifted and root pruned early in November ; that is a better practice than prining the branches severely.
The morello cherry, which is so valuable lor coroking purposes, flourishes best on a west or north wall. It needs quite different pruning from the swcet cherries. This takes place in Inte summer as soon as the fruit is gathered. and consists in cutting out parts of the old whonts to make room for those of the past summer's growth.
Pests and Diseases. Black fly usually infests the leaves of cherry trees in early summer. They should be sprayed frequently with an insecticide immediately the peat is tirst seen. Gumming is a malady which is difficult to denl with. Its presence is indicated by an exudation of a sticky gurn-like substance Irum the branches. Planting in wet, heavy, ill-drained land and severe pruning are pre. disposing causes. If the silver leaf discase, recognized by the silvery grey appearance of the leaves, attacks a cherry tree it ought to be uprooted and burnt.

How to Cook. The cherry, whether it is fresh. preserved, or crystallised, is a favourite fruit with cooks. and may be used in a variety of ways. It is best stoned before being cooked. If a cherry-stoner is not at hand, the fruit may be stoned by pushing a smooth, thick quill thruugh each cherry from the stalk end. In this way the stone is pushed out and the fruit left intact To stew cherries, let them
stones, and put the fruit in a saucepan containing \& pint water and $\boldsymbol{i}_{\mathrm{oz}}^{\mathrm{oz}}$. sugar. Simmer these until the cherries are tender, then atrain and add water to make up to the original quantity. Put in the strained juice of half a kmon, together with oz. gelatine. and stir the whole over the tire until the gelatine has dissolved.

Strain all the juice into a basin, and when it is cold and nearly setting, add enough cochineal to produce a pretty pink colour. Put the cherries into a glass dish, pour the liquid over them, and then lase the jelly to set in a cold place. This may be decorited with cream. angelica, crystallised iolets and cherries.
A good blancmange for children's parties is made from a quait of milk, 4 oz . each cornflour and cherries, 6 oz. sugar, and a little vanilla cssence. Put the milk into a saucepan and boil it, then add the cornflour mixed to a smooth paste with a little extra milk. the fire until it thick. ens, and cook it very gently for 6 to 8 min stirring all the time, then add 4 oz sugar and a few dmps vanilla cssence.

Stew the cherries in sufficient water to cover then until they are tender, adding another $\underline{\text { oz. sugar. Kinse a mould with cold water, }}$ and arrange a few of the cherries at the hottom ; then pour in some of the cornflour mixture, and lastly the rest of the cherries mixed with the remaining cornflour. Leave the hlanemange to sct.

Another decorative party dish is made from 1 lb . cherries, 3 gills water, the juice of $\frac{1}{2}$ a lemon, 4 oz sugar, toz. gelatine, I gill creain, and a little cochineal or carmine. Remove the stalks, wash the cherries thoroughly, and then cut them into halves and take out the stones. Put them in a pan with the water, sugar, and lemon juice, and simmer the whole until tender. Then strain off the juice and measure it, and if it is less than 3 gills make up the amount with water, afterwards putting it into a pan with the gelatine, and stirring it over a slow heat until it has quite melted.

Add a few drops of cochineal or carmine, put the cherries into a border mould rinsed out with water, and strain the juice over them, leaving the whole in a cold place to set. Turn out into a glass dish, and fill the centre with whipped cream, sweetened and Havoured with
vanilla. A tew whole cherrices may be placed round the top of the mould.
CHERRY BRANDY. This is a cordial which is good when home-made and when the best materials are used

A simple method is to fill a bottle full with cherries, not overripe and using half inorello and half black cherries; pour in brandy to the neck, cork it up well, and let it stand for a month. See Brandy.

CHERRY CAKE. By those who do not care for currants cherry cake is generally appreciated. To make it, sieve logether

Cherry Cake, cut lo hall to show the rlace cherries and candied peel with which it is Glavoured

I lb. flour and 2 level teaspoonfuls of baking. powder. Beat $\frac{1}{2} \mathrm{lb}$. butter or margarine and the same quantity of castor sugar to a soft cream, using less butter if a plain cake is desired. Into this mixture whisk 3 beaten egga, then fold in the flour lightly, adding 1 oz . chopped candied peel and 2 to 3 dozen glacé cherries cut into halves or quarters and well Houred. Stir in about 3 table. spoonluls milk, and bake the cake in a tin lined with greased paper in a moderately hot oven for about $1 \frac{1}{2}$ hours. This mixture might also be baked in small fancy patty pans for about 20 min See Cake.

CHERRY CIDER. The in gredients required are $\frac{1}{b} \mathrm{lb}$. stoned ripe cherries, a pint of boiling water, and a thin piece of lemon rind Bruise the cherries, pour the boiling water over them, and then add the lemon rind. A few bruised cherry stone kernels will be found to improve the flavour greatly. Soak the fruit in this way for 4 or 5 hours, then strain and sweeten the liquor with 2 oz . of sifted sugar before bottling it.

CHERRY JAM. As it is deficient in pectose, the substance that forms jelly, jam made with cherries requires the addition of apple or red currant juice to make it set To each lb. of sound fruit allow ? 1 lb . of sugar, 1 gill of red currant or apple juice, and two shredded sweet almonds. Put the sugar and the fruit juice in the preserving pan, and let it dissolve slowly by the lire.

Boil the mixture for 5 min ., add the ripe; sound fruit, removing the stalks and as many stones as possible, and lastly add the shredded almonds. Boil the jam gently until the fruit is tender, and the juice jellies when tested on a plate. Keep it well stirred and skimmed during the boiling. When cooked, pour off into dry, warmed jars, and tie down at once.

Cherry Laurel. See Laurel.
CHERRY PIE or Heliotrope. A nonevergreen shirul) with fragrant lilac-coloured Howers, the cherry pie or heliotrope grows
fast from seed sown in heat towards the end of winter, and can therefore be used in beds the same season. The reed may be sown in a hox or pan put in a warm glasshnuse in February, and the plants pricked off and hardened in $n$ cold frame, then planted out in June Any fertile, friable garden soil suits them.

Cuttings can be made of the young shoots in spring, inserted in sandy soil and placed in heat. During the winter the plants need very little water, but must be given air

Young plants bought in small pots in June should be planted in a sloping position about 18 in apart, and the side shoots pegged down from time to time as they extend

The greenhouse culture of cherry pie is easy. A suitable soil consists of loan with a quarter of leal-soil, a quarter of spent hotbed manure, and a fair amount of sand. Propaga tion is either from seed or by cuttings of the young shoots in spring.

When planted on a warin greenhouse border, cherry pie will very quickly cover considerable space on a wall, nad it will scent the whole house. All the attention it will need will be judicious watering, periodical tying-in, and occasional pruning. Standard plants can be secured by depriving the main stems of strong plants of all lateral shoots, and growing on until the plant has renched the requisite height.

Cherry Pie. Plant of beliotrope, of the Miss Nightinale variety in full flower

The following are some of the best varicties: Miss Nightingale, violet blue; Rose Clair, dark Whe; White Lady, palest blue: President Garfield, mauve-purple ; and The Speaker. violet-purple.

CHERRY PUDDING. To nake ns ordinary cherry pudiling, grease a small pudding-basin, sprinkling on the bottom of it a thin layer of brown sugar to form a caramel, and lining the busin with a good suet crust. (See Apple Pudding.) Remove the stones and atalks from 1 lb . cherries, and till the basin with them, adding 2 or 3 trblespoonfuls of sugar. Pour in a little water to moisten the fruit,

Cherry Pudding. A baked caramel-covered pudding made with cherries and euet crust
and then cover it with a layer of suet-crust. Bake the pudding in a moderate oven for $1 \frac{1}{2}$ hours, and turn it out of the basin before serving.

Cherry Sandwich Pudding. This is made by parhoiling 1 lb of black cherries in a syrup made by boiling 3 oz . granulated sugar in a saucepan, with a gill of water

Cherry Sandwich Pudding served with the syrap esulting from parboiling the cherries

When the cherries are tender, drain them, and reserve the syrup. Then beat 5 oz . margarine and the same quantity of sugar to a cream, add a pinch of ground cinnamon and the beaten yolks of 2 eggs , and stir in 5 oz . breadcrumbs, 4 tablespoonfuls of milk, and the stiffy whisked whites of the eggs. Put a layer of this mixture in a greased pie-dish, and on this place a layer of cooked cherries, then some more mixture, and so on until the dish is full. Bake in a hot oven for $\frac{1}{2}$ hour.
then turn it out on to a hot dish, and pour the syrup over it.

CHERRY WOOD. One of the chief uses for the wood of the cherry tree is in making tobacco pipes. It is valuable also for turned and fancy articles, and in small cabinet work. The colour of cherry wood is brown with u reddish tinge ; it has a smooth and fine grain easy to work, and takes a good polish. It is hard, but not very durable as it splits rather easily. See Pipe

CHERVIL. The kind mostly grown is the common chervil, the aromatic leaves of which are used for salads und garnishes, particularly those of the curled variety, which are more crisped. The chervil is an annual, and thrives in any ordinary soil, producing leaves fit for gathering in ahout two months from the time of sowing. It may be sown successionally from March onwards, and thinned to about 6 in. apart.

CHESHIRE CHEESE. Both as regards texture and flavour, Cheshire chcese possesses distinct characteristics, for while it is very open-grained it is yet mild, soft and full in Havour. It is perhaps the softest of the hardpressed varieties There are threc types of Cheshire cheese, known as early ripening, mediun ripening, and slow ripening. The cheese may also be coloured or uncoloured. See Chcese.

## Chess: The Pieces and Their Play <br> First Principles of an Ancient Game

The game of chess is played between two opponents, moving in turn, on a board of (i4 squares, arranged in 8 rows of 8 equares each. These squares are coloured alternately white and black (at times other colours, but always conventionally called white and black); and there must always be a white square in the corner to the right of each player. The opponents have 16 men each (also known as white and black) on the two rows of squares nearest to them, namely 8 pieces on the back row and 8 pawns on the row just in front. This is the position when a game starts.

The pieces on the back row are of tive different kinds. The king and queen stand in the centre, the queen being on a square of her own colour ; a bishop next each of them ; a knight next each bishop; and a rook (or castle) next each knight. The pieces on the hing's side of the hoard are known as king's bishop, king's knight. king's rook; the pieces on the queen's side of the hoard as queen's bishop, queen's knight, queen's rook. The pawns, who occupy the next row to the back onc, are called after the pieces standing behind them-king's pawn, king's bishop's paimn, commonly written KP, KBP, etc.
The notation of the chess

Chess. Fig. 1. Board set out with men placed in position ready to start the game

The theoretical object of a game of cheas is the capture of the hostile king, which brings the game to a close. When the king is liable to be captured on the opponent's next move. he is said to he in check; and if he cannot move out of check, he is said to be mated, and the game is over. Now and again situations arise where neither king is mated and the game has no decisive result

All the chessmen alike capture an opposing man by being put down on the square occupieed by that man, which is then removed from the board; but there is a considerable variety in the nature of their moves. 'Ihe king has the shortest and simplest move, being one square only in any direction-horizontal, vertical, or diagonal In Fig. 3, supposing the king stands on the square marked $X$, he can move to any of the dotted squares immediately surrounding it. As he cannot be captured, however, with. out ending the game, it follows that he cannot move into check and cannot stand on a square next the opposing king.

The queen's move is a prolongation of the king's move in each direction up to the edge of the board Standing on $X$, she can go not only to each dotted square, but also to any of board that is current among English-speaking the squares along the arrows shown in Fig. 3 peoples is derived from the names of the The rook has the horizontal and vertical moves pieces, cach vertical row, or file, being called of the queen, but the bishop has her diagonal after the piece standing on it. Thus, in moves only.
Fig. 2, white's extreme left-hand file is Neither queen, rook, nor bishop has the the queen's rook's, or QR , file. The squares power of jumping over a piece, whether friendly on which the pieces originally stand are QRI or hostile. The knight, on the other hand, can. (or QR square), QKt1, and so on: the The knight's move may be roughly described squares on the next horizontal row, or ns one square in $n$ horizontal or vertical rank, are QR2, QKt? and so on. From black's standpoint the figure is reversed, so that his $\mathbf{Q}$ side pieces arc to his right, his K side pieces to his left. A move is recorded, in this notation, in the form $K-K 2,(Q-Q R 4$, P-K3, etc., indicating both the man moved and the square to which it moves.
direction, followed by one in a diagonal direction away from where he previously stood. Thus, in the left-hand section of Fig. 4, if the knight stood at $X$, he could move to any of the dotted squares in a circle round it, regard less of whether the squares immediately next him were occupied by friendly or hostile men

From this jumping power ol the knight it sound development. Now development means Ki4, 1'—K4; 2 Kt—K133, Kt- (Q13:3: :; Pfollows that in the original position of the men (Fig. 1) the linights alone of the preses can move the others having to wait until the pawns have heen moverl.
The pawn's ordinary move is one square forward in $n$ vertical direction It does not however, capture an opposing man in this way, but by a move ono square forward diagonally. Thus if a pawn stands at $X$ in the right-hand section of Fig. 4 its ondinary move is to a, its capturing moves are to $b$ or c. On its first move in the game each pawn has the privilege, at the player's option, of a double move, i.e to $d$ in the diagram Both the single and the double move of the pawn are dependent on the absence of any obstruction in the path. There is also another limitation to the double move. If, in the diagram, a hostile pawn (but only a pawn, brought ahout as follows:1 P-K4, P-K4. not $a$ piece) stood on either of the squares $2 \mathrm{Kt}-\mathrm{Kl} 33, \mathrm{Kt}-\mathrm{Q} 133 ; 3 \mathrm{~B}-\mathrm{B} 4, \mathrm{~B}-\mathrm{B4} ; 4$ marked $e$ and $f$, then, in spite of the fact that a pawn on $X$ moved to $d$, the hostile pawn could capture it on a, liefore it reached d. This is called taking en passant. or in passing. On reaching the further side of the hoard in safety, a pawn becomes promoted to queen, rook, bishop, or knight, at the option of the player.
The move known as castling is $\Omega$ joint move of the ling and une of the rooks. It can only occur once in the game on each side, and then only if neither king nor rook has moved pre viously and no piece stands between them This operntion consists in bringing the rook up to the near side of the king, and simul taneously jumping the king over the rook to the square next heyond him. In this the king may not pass over $n$ square where he would be lisble to capture
In power the queen is easily first : the rook is second, the bishop third, but only a little and that not alwnys, above the knight (which in certain positions, indeed. is the more powerful of the two pieccs): while the pawn is the wenkest of the chessmen, with the exception that its potentiality of promotion even to $\Omega$ queen gives it a force much ahove its normal. In the absence of a queen on the board, a pawn which cannot be prevented from queening is obviously most powerful as compared with the remaining pieces Owing to the peculiar fenture of the king, whose capture would end the game, his value cannot well he eatimated
Types of Opening. There is no royal road to the openings at chess; and, though there are many excellent text-books, it is of little use to learn by heart the varintions which they give, without understanding the principles of

Chess. Fig. 3. Diarramshowing possible mores of king, queen, fook and bishod trom X. Fir. 4. Left, moves of a knight ; Right, those of a pawn

#### Abstract

getting the forces into play where they will

 (1) have increased powers and (2) restrain the powers of the enemy's forces 'The advanco of the two central painns releases hoth bishops and the queen The knights can como out independently of the pawns, and so the wry is the pawns, and so the wny iscleared for the rooks to operate in the centre, the king being got out of the way by castling. Thus we might get such a system of developing moves for ono side as P-K4, P-Q4, Kt -K B33, Kt-QB3, B-QBt B-K B4, castles, Q-K2 (or Q2), QR-Q1, KRKI, when every piece would be developed But clearly both sides could not deploy their forces thus without coming into direct conflict in the centre of the board 'I'he alternation of moves between the two must modify the development.

A typical opening is P-Q3, P-Q:3; $5 \mathrm{Kt}-133, \mathrm{Kt}-\mathrm{B}: 3$ 'This is a variation of the opening known as the Giuoco Piano, or Slow Ganie it is optiona now for both sides to castle, to bring out the $Q$ and $Q R$. and to move both rooks into the centre : but such procedure woulil not neres. sarily be the hest

A very different type of opening is seen in the various gambits A gambit implies the sacrifice of a pawn, and sometimes more, in the oprening. Here, for instance, is the Muzio Gam. bit, us illustrated in a game played by Morphy at the uge of 20: 1 P-K4, PK4: $2 \mathrm{P}-\mathrm{KB4}, \mathrm{P} \times \mathrm{P}$ (i.e. $P$ takes P): $3 \mathrm{Kt}-\mathrm{KB}$. P-KKt4 : 4 B B4, PKt5 ; 5 Castles, $\mathrm{P} \times \mathrm{Kt}$; 6 $\mathrm{Q} \times \mathrm{P}, \mathrm{Q}-\mathrm{B} 3 ; 7 \mathrm{P}$-K5. $\mathrm{Q} \times \mathrm{P} ; 8 \mathrm{P}-\mathrm{Q} 3, \mathrm{~B}-1 \mathrm{l} 3$; Q Kt-B3. White has given upa knight and a pawn for the sake of quick development and a very threatening attack, against which any alip by Black may lend to disaster.
Nowadays neither of these forms of the opening is in favour with the leading masters at chess: but they amples of two extrences in Modern practice devotes what are known as the

Cbess Board. Figs 1-4. Diagrams of board completed and in process of making
(lt, P×P: $4 \mathrm{Kt} \times \mathrm{P}$ ) The openings are intended to put the player in a good position for the middle game which, is the principal part of a chess match.

CHESS BOARD : How to Make. Fig. I shows a chess bnard which can be inexpensively made. The base of the hoard should be of three-ply wood surrounded by a fairly hold moulding; the base is rebated into the moulding, and the latter is mitred at the corner, while the facc of the hoard is covernd with the chequered playing squares.
With the playing space formed with $1 \frac{1}{2}$ in chequered squares the base will be 1 ft. square. in addition to which allowancc must be made for rebating the base into the moulding. so that the piece of three-ply wood required for the base must be $12 \frac{1}{2}$ in square, and it should be about in. thick The playing space consists of eight rows of chequered squares with eight squares in each row, sixty four in all. Half of the squares must lee cut from a light wond, and the other half from a dark wood. Holly and ebony will give the best effect.

To cut the chequered squares accurately and quickly, provide five strips of light woud, about 14 in . long by $1 \frac{1}{2} \mathrm{in}$. wide by $\frac{1}{8} \mathrm{in}$. thick, and four dark strips ul similar dimen sions. The stripy should then be glued up in the order shown at Fig ${ }^{2}$. After tho glue dry, one end of the gluedup strips should be cut quite square, and from it eight strips $1 \frac{1}{2}$ in wide ano cut, from which the com plete playing space may be formed. The chequered strips are fixed to the hase with glue as shown at Fig 3. care being taken to gluc the edges of the strips together as well as to glue the strips to the base. When the chequered strips are arranged correctly it will be found that there will be " surplus light square at one end of one strip and at the opposite end of the next strip, and so on, but there must be removed before the strips are glued to the base.
The moulding, which is mitred around the base, should be 18 in . wide by $l \mathrm{in}$. deep, and of a section similar to that shown at Fig. 4. Mahogany could be used for the moulding, and a piece of the section shown could be very easily worked by hand. A rebate or a groove is cut in the inner edge of the mould. ing, into which the base fits; the corners are unitred, and the moulding is fixed with glue. The best method of finishing the board will be by french polishing.

CHEST: In Human Beings. The important part played by the chest is sufficiently indicated by its position and the organis which it contains. Ailmente of the chest are of common occurrence and injuries to it may involve the lungs or the heart. and call for surgical treatment.

In men chest measuremient is regarded as a test of strength and stamina. Recruits for the army and navy, for example, must reach a certain standard in this respect. Tho chest measurement in most men varies from 33 to 40 in.

This region may be the scat of aneurian and of various tumours. Injuries of the chest may be slight and have no worse consequence than a bruise or a broken rib; or they may be anvere and result in damage to the lung,
the heart, or the covering membranes All scvere injuries require the attention of a surgeon. Until he arrives it is inportant that the patient should be kept warm, and in a state of complete rest.

First aid consists in tying a broad-fold triangular bandage mund the chest, the middle of the bandnge being placed over the broken ribs A similar bandage is then applied overlapping the first above or below, depending on the site of the fracture. A broad strip of flannel or a soft towel may bo used instead. and these are fastened with safety-pins The object is to restrict as far as possible the morements of the chest, but it is important that the bandage should not be firm enough to hurt.
Probably the most commun cause of pain in the chort is flatulent indigestion, and this often erronenusly icads the sufferer to bolieve that his heart is affected It is a mistake for anyone to try to make his own diagnosis The explanation of the cause of such pain must come from the doctor; in the meantime the patient should be placed at rest in the easiest position, and hot fomentations or a hotwatcr bag applied over the painful area.

Care of the Chest. Bestles indicatiny a good physique, a deep, well-expanded chest is a help to wearing clothes with distinction. Chest development by proper breathing can be augmented by the following exercises:

1. Stand with bead bent forward, shoulders and arms relaved : raise arms sidewiays ond atraighten back, letting the head an back with mouth open The cffort of the movement is concentrated between the shoulder blades, and the expansion of the chest Repest 6 timcs.
. Knecl and sit back on heels with hands clasped bchind, Head well back and chest expanded. Stil keepins head well back, hend the upper body iorwari until the chest almost touches floor in front of knees. Then relax upher body completely Gradually atraighten the back, the cheat and head being the las warts to be completely raised. and finlsh with ches well expmand
Exercise with a bainboo cane held hehind the shoulder blardes is helpful. especially if seated tailor fashion on the floor, as this position renders it impussible to hollow the back, and the shoulders must do their proper work in helping chest expansion. Send the cane to the right by straightening the right arm, and then to the left by straightening the left arm. Then raise the cane with both hands over the head and bring down to first position. See Adenoids: Bandage ; Breathing.

## Chests: Antique and Modern Pieces

Information of Value to both Connoisseur and Woodworker
The reader may usefully consult the many entrics that give practical advice to the amateur woodworker, e.g., Amateur Carpentry; Cabinet; Cabinet Making; Joint: Mortise

The chest is a development of the box. being neally a large box with a hinged lid. In addition to their obvious use for holding clothing and other personal and househnold possessions at home and when travelling, chestes were often, in the Middle Ages, used as seats.

These chests, however magnificent, were essentially boxes, but later they were raised from the ground by the addition of feet, and were used less than formerly for travelling purposes. Some were beautifully carved and ornamented with heraldic designs. Another class of chests, known as tilting coffers, were carved with representations of tournaments, or with figures of inythical monsters or heroes of chivalry. Examples are in the Victoria and Albert Musenm, S. Kensington.
Existing antique cheats are chiefly of the 16th, 17th and 18th centuries, although there are $a$ few of even earlier date, at which time they were a common article of furniture, serv.

wainscoting, way followed; thus earilier chests were carved in linenfold pattern, while the Jacobean cheats often repmoluce the pilastered and recessed oaken mantelpieces of that time. The three antique chests illustrated are of oak, the wood chiefly used for them in the 16 th and 17 th centuries and earlier, while mahngany and walnut were the woods selected for chests in the 18 th .
Fig. 1 is a finely carved specimen of English work dating from the 13 th century. Fig. 3 is $\Omega$ beautiful piece of work. This oak is heavily moulded and is inlaid with mother-of-pearl and ivury. Fig. 2 is a coffer of Inte 17 th century make showing a plainer style. It will be noticed that it is well raised on

Making a Chest. Fig. 4 shows a chest which can be made by the amateur, and will be suitable for the hall or for a dining room. The wond should be oak, stained to a rich
nut-brown colour and oiled, waxed, or Irench pulished to harmonise with the surrounding furniture In a quieter way some suggestion of an old effect can be obtained by finishing with red polish mixed with a small quantity of vegetable black Thuse who preter to make use of some other wood may be able to serve their purpose with birch or American whitewood, or something might be done with antin walnut. ash. or pine as subatitutes

Chest. sig. 4. simpie uning room caest which can following the instractions given below

The top rail (13. Fig. 7) is fitted from a piece 4 ft by 4 in . by $1 \frac{1}{8}$ in or $\frac{?}{\mathrm{l}} \mathrm{in}$., to be grooved for panels and for the entry of the inner uprights. It has shouldered tenons at each end The bottom rail (C) finishes 3 in by $1 \frac{1}{8}$ in. or $\frac{7}{8}$ in. The two inner up. rights (I)) take pieces 1 ft .4 in to finish 3 in. by $1 \frac{1}{8} \mathrm{in}$. or $\frac{7}{6} \mathrm{in}$. and are stubbed to rails top and bottom. The three panels ( E ) are allowed a size of $1 \mathrm{ft} .4 \mathrm{in} . \mathrm{by}$ 1 ft .2 in. hy ${ }_{8}^{5}$ in net for fitting These may be treated as plain or bevelled

mdicated witn three pancls at Fig 8 For this the stiles (II) take wo pieces 4 it 1 in by 3 in by $\frac{1}{6}$, and rails (.) four pieces ift 8 in by 3in hy i in.,to lse mortised and temoned together and pinned or wedged The framework is also grooved for the pianels to be fitted thush, Fig. !, allowance for panela heing 1 ft. 6 in by 1 tt. 3 in. hy of in lig. I3 shows fitting of back, and I'ig. 14 the jointing of front and end panels to prosto and inner uprights.

A Simple Siand. Those who would prefer to raise the chest ahove the ground, in order that the top may form an attrac tive side table, may con struct a stand similar to that indicated at Fig 10 The idea is usclul, too, for anyone already in posses sion of a chest of which the lower pait is dilapi dated, or where the plinth or legs have been short ened, making the whole thing rather squat. Such a stand can be 12 in high, and made with a

I'he detuil lor the panels shown in Fig. 4 is wel top, so that the cuest may drop in snugly. one that is casily nitred up of $f$-in. mould.

The two uppor end rails (F) are fitted from
 huttom rails (G) finish 3 in . wide to agree with the front. Both are tenoned to uprights and pinned-with panels grooved in, taking 1 ft . 9 in by 1 ft .4 in . by in net. The back is rehated into position behind and acrewed. It can be made up of threc hoards with the grain reversed and glued up, or (preferably) tongued and glued, using hardwnod longues. The botton is pieced up in the same manner and rebated to enter housings in front and ends. It may either be acrewed or glue-blocked under.

The lid should he tongued together, if marle up of lengths to the required width, 1 ft .10 in . a lining (Fig B) serewed on under can lap over the top edges of box at front and ends and serve ns a stop for drifting dust. The top, however, is best framed up in the manner

Details for making this stand, with secure joints for the rails and legs, are shown in Figs 11 and 12
legs (or uprights) take four pieces 12 in . by $1 \frac{1}{2} \mathrm{in}$. by $1 \frac{1}{2} \mathrm{in}$., or may be linished $1 \frac{1}{\mathrm{~g}} \mathrm{in}$. preferred. They may stand four square on the ground, hut are indicated at Fig. 10 as with 2 in . Hat ball feet dowelled in, of the type known as bun shape. The rails can be nllowed 4 ft .3 in . by 3 in . by $1 \frac{1}{\mathrm{~g}} \mathrm{in}$. for front and back, and 1 it .10 in . by 3 in . by $1 \frac{1}{\mathrm{t}} \mathrm{in}$. for ends, to be dovetailed inter uprights and he stilfened with braces in the angles as at Fig. 12 The brackets under provide some little finishing effect. They can be cut 3 in. by 3 in by $k$ in., to be dowelled and screwed into position. The mould, forming a lip edging behind which the chest (less its legs) will bed can be a $1 \frac{1}{2} \mathrm{in}$. by $\frac{\mathrm{in} \text {. section, glued and serewed }}{}$ as shown in Fig. 12. The cutting list is given

## The Chest of Drawers

## Construction, Renovation and Small Repairs

## See further Cabinet; Drawer; Dressing Table ; Tallboy; Wardrobe; also the preceding article Chest, and the entries dealing with the methods of the amatcur woodworker

A chest of drawers is in essence a chest into has there a further drawer, and the whole is which drawers have been fitted. For it the supported on five heautifully carved legs, three chest in ordinary use was made larger and the front cut away to admit the drawers

The early chests of drawers were of oak, and of walnut, veneered on oak or pine, dating from the time of William and Mary and Anne. The beautiful effects of the drawer-fronts were olitained by cutting and laying the wond in various directions. later in the 18th century mahogany became fashionable for these chests, and many fine specimens are in that wood. They are made by Sheraton, Chippendale and other great designers.

Of the two illustrations of antique chests given herewith, the first is of pino and oak veneered with walnut and lignum vitae. It follows tho conventional atyle in having two small drawers and two larger ones in the upper part of the piece, but the hottom is more claborate than is usually the case. The chest
in Iront, and two lehind, which in their turn rest on a plinth or stand. On each drawer are brass escutcheons and drop handles. The second is an example of Dutch work of about the same date. The supports of old cheats of drawers vary. Some are supported on a plintlı and carved legs respectively, but others rest upon short legs of a plainer kind.

A Man's Dressing Chest. The type of chest of drawers illustrated in Fig. 3 requires only a small space, and will be of special use to the man who likes a convenient glass for shaving. Tne chest is 3 ft . 6 in . high, having a useful set of drawers ranging from 4 in . to 7 in . deep. The glass is thus at a suitable height, and the whole article is not only neat and compact, but easily made hy those who have an average amount of cahinet-work skill. Oak is the most suitable wood to use, or, if inahogany be
preierred, the lower corner brackets should eft out and the leg pirtion tapered
The four posts should be prepared first. These are $1 \frac{1}{2}$ in square and are mortised to take the side rails and drawer rails, the top front rail lieing dovetailed as in Fig. G This dingram shows the top portion of a front leg with the top removed, the view being taken from inside the job. The prats are grooved to take the side panels, and the hack legs are also rebated for the back as in Fig. 5. The ends are glued together first and allowed to set hefore glueing the remainder If the job is to be atained a dark colour, it is advisable to put a little stain round the edges of the panels, so that in the event of their slirinking no white edges will become visible. The top dividing drawer rail is stub-tenoned between the two top rails, and all the rails except the botton are grooved to take the dust-hoards, as in Fig 6. The hottom one is rebated to take the bottom board, and is 1 in. thick. The draver rails measure $2 f$ in. by $\}$ in., and the runners $1 \%$ in by in.

Having put the carcass together, the runners may be fixed. These are also grooved for the dust-boards, and are fixed at the front by stub-tenons fitting into the grooves of the drawer rails (Fig. 6), and at the back anc screwed to the back prosts around which they are cut Note that thesc runners are in no way fixed to the side panels. To the tops of the runners the guides are screwed, being lengths of 1 in. squares, as Fig. 6 shows.

## How to Make the Drawers

The drawer fronts finish $Z$ in. thick, and the sides and hack if in., and all the parts are fitted separately to size. Fig. 7 shows the correct setting out for the dovetails An important point to notice is that the groove for the bottom is contained within the lower dovetail, so that this will not show a gap when the drawer is together. The total width of the back mensures from the top of the groove to the dotted line (Fig. 7), the top being rounded na shown. The bottom is fixed in a groove run along the drawer front. and at the side in grooved tillets with a rounded upper edge, as in Fig. 8; these are glued to the drawer sides. At the back, the bottom is screwed or nailed to the drawer back. It is usual to allow the bottom to stand out from the back, as shown so that if the bottom shirinks the screws can be talien out and the hottom pushed forward.

The top is moulded at the front and sides and overhangs 1 in. at the back to allow for the wall skirting. It measurcs 2 ft. $4 t$ in. long by 193 in . wide, nnd is fixed by screwing fmm undernenth. The aldition of the lower angle hrackets (glued and screwed) completes the lower part of the chest. The mirror supports are $1 \frac{1}{i} \mathrm{in}$. square, and are tenoned into the top, the rail being dowelled into them also the side brackets. The frame is mortised together and the glass fixed with wedges glued to the rebate (Fig. 9). The back board is screwed on, as shown. The glass swings on special brass movements made for this purpose The handles, of the drawers, if the jol, is in oak, should preferably be of the clrop type.

ConvertIng a Painted Chest. An old painted chest of drawers such as that illustrated in Fig. 10 is to he found in almost every house. If the paint has become worn, a practical plan is to strip the paint off and mount the chest on a stand. decorating the drawer fronts with mitred mouldings, and thus producing an attractive Jacobean chest (Fig. 11).
The plinth is usually attached with glue and nails, and strengthened underneath with corner blocks. These latter should he knocked off with a chisel before removing the plinth. The old handles, too, should be taken off The paint should then he cleanly stripper off, using one of the well.known strippers Every hit of paint should be got off, as when
later the job is stained any paint left on would prevent the stain from taking.

Any necessary repaiss may now he done to the chest, including lilling in the holes left liy the removal of handles andthe whole thuroughly glass-papererl, finishing olf trith No. I! Mouldings can lie purchased at a cabinet maker's store; either oak or deal is suitable For the chest illustrated about 60 ft. would be required. Mark out on the drawer fronts the position of the mouldings, and at the jutting portions glue on small slips of woorl $\frac{3}{16}$ in thick, round which the moulding is mitred (Fig. 14). The moulding inglued and pinned. and care must hie taken to iemove all surplus glue. The drawer stops must be removed and fixed further back to allow
the moulding to ntand on Iy alightly forward from the carcass of the chest

The stand may now be procecded with. Allowance must be made at the front and two sides for the moulding shown (Fig. 13), inside which the chest stands. The stand is mortisel together as in Fig. 12, using 2 in. stuff for the top rails and $\frac{1}{2}$ in for the hottom rails. When $t$ his has heen glued together and is quite dry. clean off the top and place the chest upon it in the required position, and lix the moulding round ; this will cnsure its fitting accurately. The moulding should he glued and pinned to the stand only, so that the chest is always free to he lifted off. The joh is now ready for staining: dark walnut water stain is the best to use. Afterwards polish it with wax, and tinally fix the brass drop handles.

Repairing a Chest. The illustration (Fig. 15) is an example of an old mahogany chest of drawers of the general type that any amateur might lie called upon to repair. The chest top is vencered with one sheet of mottled mahogany. the grain of which runs lengthways of the chest. The veneor is laid
unon yellow pine top (or core as it is termed), and this top has clamped ends similar to a draw. ing hoard. The edges of the top are cross-banded by glueing on ${ }_{a}^{3}$ in. solid mahogany strips, these being alterwards rounded off to give a finish to the work.
The caroass ends are of solid mahogany of the straight - grained varicty, commonly called bay wood. The front of the chest immediately under the top shows a

Chest of Drawera. 1. Example of English desirn, made in the late 17tn or eary fotu century. It is of plae and oak, veneered with walnut and lignum vitae. 2. Antique Dutch chest of drawars, with bowed front

wide bearer rail, veneered with mahognny glue hardens would he obtained by using two curl vencers, jointed up to olitain the handscrews or G cramps, which would span neccasary width across the carcass front. across the drawer front. The edge of the bead The draiers have their fmnts vencered with should be hodicd up with french polish before mahogany curls, and small projecting cock lixing in pusition.
heads have been litted into rebates at the ends, At the top edge ol the drawer (Fig. 16 B) is but are simply glucd on to the top and bottom shown the method of letting in a small piece edges. The plinth or lower part of the chest of new wood to replace a bruised or damaged has been made in a separate portion, screwed portion, where it is not thought desiabibe to to the carcass.

One of the commonest repairs to an old chest re-fixing the lock, etc. The new piece is made of drawers is the renewal of a cock bead which to a dovetail shape and laid on to the existing has accidentally heen damaged by splintering head: then a mark is scratched around it with a piece out of the drawer, or the replacing of a needle or sharp penknife point. This will give a amall portion which has bcen broken during the exact size and angles of the new ploce, and romoval operations. Fig. 16 (A) showa a new the recess may be anwn and carefully pared out length of heading made out of a piece of old with a chisel. The new piece sliould be made mahogany. It is ready to be glued to the rather thicker than required, so that after bottom, and its mitred ends have heen cut fixing, a ahaving or two may be removed, this and tried in position. The lower edge of the leaving all Hush. The top edge will then have drawer should he carefully scraped to remove to be glass-papered, stained and polished in all trace of the old glue. The necessary pres- the required colour.

Owing to constant friction, tho lower edge of the drawer sides hecomes worn away as in. dicated by the line .lrawn on the side of Fig. $16(\mathrm{C})$. This allows the drawer to sag and thmes the front out of truth with the face of the chest. This shows an unequal margin of the cock bead. and alan canses the drawer to rint hadly. Drawery that have their lower edgen hadly worn should lie turned bottom upwards on the bench and the won portions planed away as indicated by the line at Fig. 16 . The planing will not

Chest of Drawers. Figs. 10-14. Palnted chest of drawers and diagrams showing bow it can be transformed into a piece of furniture in Jacobean style
interfere with the drawer bottom, which stands clear of the lower edge of the side by anything from in to in. A new piece. preferably of hardwood, is glued on to the existing drawer side and cramped in position. After, say, 24 hours, the surplus material may be planed off the newly-jointed piece. taking care to mark it out and make it parallel to the top edge of the drawer.

In other cases it may be found that the runner or piece that supports the drawer shows signs of considerable wear, and the remindy for this is to replace the worn runner with a new one. Runners are fixed in two ways, and it will be found that in most' of the old chesta a groove has been cut across the carcass end, as illustrated in Fig. 17, to receive the entire thickness of the edge of runner. This groove is generally ahout $\frac{1}{t}$ in deep, and the unner is simply glued into it. The end of the runner has a small tenon to engage the back edge of the front bearer. The partitions or dust-boards fit into the grooved edges of the bearer and the runners, and preclude any possibility of the runners working out of the grooves cut in the carcasy ends

## Another Method of Fixins a Runner

The lower part of Fig. 17 illustrates the second methor of fixing a new runner, and in this case no groove has been cut in the carcass end. The tenon on the runner is glued into the bearer gruove, the opposite end notched out and prepared to receive a screw. A dab of glue is applied to the carcass end as indicater hy the arrow. If the back edge of the runner be glued along its entire length, it does not allow for any contraction or expansion in the carcass end, and this will often cause a fractured or open end joint.

Fig. 18 slinurs such a fractured end, and, as it is practically impossible to knock the chest asunder and re-joint the end, it is necessary to glue into the crack or joint a small strip of wood with its end section wedge-shaped. If the fracture follows the general contour of the grain and a straight strip cannot be conveniently applied, the atrip will have to be cut into short lengths of say, 6 in ., so that they can be easily bent to the shape. Care must be taken to joint up the ends of the strips so as to leave no open joints. The job is thell cleaned off level and polished.

Another common repair is a broken foot Fig. 19 is a part sketch of a plinth which has been taken off the carcass and turned up side down The repair is carried out by cutting away the broken portion of the old font, until the new joint is in alinement with the top of the straight portion. This will allow the bull-nose plane to be brought into opera tion, so as to plane up the major portion of the joint, after which the existing mitie and comer block are scraped by using a toothing plane blade which has been temporarily reinoved fmm its stock. A new piece of woud is planed true on its lower edge, and the end is nitred This piece is glued in position and handscrewed down, whilst two ordinary screws hre inserted from the back of the corner block to secure it. When the glue has thoroughly set, the new piece is cut to the desired shape with a bow saw, as shown hy the dotted line. A fine sprig or panel pin may be driven in the edge of the shaping, as suggested in sketch. after the foot has been out to shape.
Fig. 20 shows how to effect a repair to a piece of braken veneer which has formed a cross-hand on the wide top benrer of the chest. Using a ateel rule as a guide to the penknife blade, a deep incision is made and the old piece of veneer removed. This may be accomplished by damping a piece of rag and placing it upon the damaged veneer. A hot iron is now applied to the rag, and the steam sn generated will soften the old veneer and glue to auch an extent that it may easily be peeled awny.
A now piece of mahogany curl veneer is fitted to replace the damaged part and is laid by the caul method. The caul in this case may be a piece of yollow pine wood which has been planed up and rubbed over with raw linseed oil. It is heated in front of a fire, and a piecc of clean white paper is placed hetween the caul and the glued veneer. The pressure is applied to the work by the handscrew, as shown. The work will in due course be levelled up with the steel scraper, after which it is glass-papered and
 polished. If
old curl veneers which have been cut forsome years he used, it will save much time and match. ing up when the polishing is commenced.

Fig. 21 re-
presents one
corner of the
chest where
the crosa-banded mould and the veneered top have been broken away. To repait this a cut is made across the corner and the old veneer removed by the methorl above deacribed. A suitably grained piece of veneer is selected and laid in position by the caul and handscrew mothod. A day later, a piece is glued to the oross-banded edge, and in due course it is rounded of to shape with a block plane.
The polishing and colouring up of the repaired portions of antique furniture call for great care on the part of the worker.
CHESTERFIELD SOFA. Stuffed all over, back as well as sides, to seat two or threc persons, this comfortable atyle of sofa is sometimes supplied with added loose cushions, which should he soft and resilient, while in some makes one end is adjustable to cnsure greater length for reclining.

In selecting a chesterfield it is necessary to get a good quality guaranteed by the name of the firm to be of gond workmanship, since it is not possible, even for an expert, to judge of the durability of the sofa in its finished atate, but any basic faults will quickly show through. The framework of beech or birch, the hracing of the frame, the spiral springs, the wehbing, all lie hidden beneath the upholstery, and it is upon these unseen parts that the lasting quality of the sofa depends The frame must be of well-seasoned timber, hirch being used in the best work; the spiral springs must be of well-tempered steel, and the workmanship should be of the highest standard.
The covering can be of various materials. according to the room in which the sofa is placed. For a lounge or living-roon, velreteen, velvet cord, tapestry, a durable nioquette, or a similar fabric of heavy weave, are suitable; for a drawing room, damask or veivet. This sofa is not suitably covered with any fragile material as it is usually selected for comfort and service.

How to Make. Dinensions for the chesterfield shown in Fig. 1 may vary slightly in length for individual requirements, 5 ft . 6 in. over all when finished being about the smallest useful size; 6 ft .6 in . the size most frequently met with; and sizes up to 8 ft . or 9 ft . for halls, institutions or ballrooms. The length for framework (Fig. 2) in the present case is put at 5 ft .6 in .; height to top of end posts, Ift $10 \frac{1}{2} \mathrm{in}$. or 2 ft ., to include castors : height of front rail (seat), 8 in . : and depth of sent, front to hack $\rho$ ver all, 2 ft. 6 in . to 3 ft . for a laige size. Settec frames of the chesterfield aize vary in detail according to the chatacter of the furniture they go with, but for a fixed end settee, the franie (Fig. 2), of which

Chest of Drawerg. Fig. 15. Example of an old mabogany veneered chest of drawers, a common type to require repair. Flgs. 16-21. Diagrams illustrating bow various simple repairs can be eflected
make. The woods generally used for fiames are beech and bircli, but pine or American whitewood could lee used for parts, the show

Fig. 3 gives a diagram of an adjustable head. The sectional view shows the head ercet with dotted line of stuffing, together with a dotted line of head lowered to a reclining position. All that is necessary to operate the action is to lift the head slightly, which disengages it from a bottom stop-rod, and allows the head to revolve to a lower angle, where it is stoppled by the extension piece hearing against a rail fixed for the purpos finm side to side of the box seat. The whorl limiu which these head scrolls are sliaped sliould be about $2 \frac{1}{2} \mathrm{in}$. thick, preferably of handiwod. to counteract any undue strail.
wood (in this case tho legs) being in onk, walnut or inahogany, as an improvement upon staining to match exist. ing fumiture.

In making a start with the setfec frame the front prosts ( 1 ) will be cut from 4 in by ( in., the rounded or scroll portion being made $\quad 11$ lop an extension piece to project $1 \frac{1}{2} \mathrm{in}$. or so, dorrelled on. This post is flush with front of settee, but in soinc instances is slinped or set back a few inclics from the front edge of seat rail, separate stumps (eitlier tumed or tapered) being jointed into the sent framing. The front rail ol seat (B) is $\$ \mathrm{ill}$. by 3 in ., preferably tenoned into ןosiion, but sometimes dowelled It is shown as straight, but is often whaped to break forward ns at $X$ (Fig. 2). The end (C) and back seat rails can lic somewhat lighter, 3 in . or $3 \cdot \frac{2}{2}$ en fill by ill. The scat frame should be boxed in at ends ancd or dowelled at front; shaped por. to a height of about $\bar{\delta} \mathrm{in}$. clear above ground. fions at comer are separntely worked and dowelled into position.

For the back legs (D) $\mathbf{2}$ in. by 2 in. matcrial will be required, the legs being continued to tho ground. If preferred they may finish into the back seat rail and have separate shaped legs dowelled or bridled into the sent framing. The top lack rail (E), 4 in . by 2 in ., has the centre upright at back (F) tenoned into it and into the sent rail, size for this and the centie stretcher (G) being 3 in by 2 in., the latter being dovetailed and serewed to the seat rails from lelow. The stretcher is sometimes aliaped with a dip or bend in the centre, or its place may be taken by one or two stout iron rods similarly slinped and werewed between the seat framing back to front. The stuffing or tacking rails (H) are made to finish 1f in lyy lif in.

## How the Adiustalle End is Made

I framo made to the foregoing sizes will be fairly stout for the size ( 5 ft ( i in.) mentioncd with lised end. I chesterlield settee frane, however, is nowndays usually made with one or hoth ends adjustable to let down to the seatlovel and serve as a lounge. In this manner the framing of Fig. 2 would have a similar upright to 1 built into the hack framework, as shown in dotted line ( $J$ ), and a separate head framing on the lines of $A, E, H$, hinged to let down. There are several head adjusting actions on the market, some of which are obtaimable through cabinet makers' sundriesmen; but, as a rule, they are somewhat complicated for the ainatcur to deal with Detajls of one are shown which would be of assistance to the average worker in making his settee with drop end, the best way leeing to inalic a smaller model in thin wood, so that the method of action is clearly understood. lefore cutting up good material

Chesterfield Sols Fig. 1. A comfortable sols which can be made by following the directions given in this article. Figs. 2-5. Working diarrams, including details of alternative dron end
tapered block, P, glued to the bux end will serve as a guide for the horn to slip bsick to its position after being lifted:
An enlargement of the end viers of the rods on the lower portion of the scroll (Fig. 5) indicates the stop rod $\mathbf{N}$, bedded ints, the bos sides to about two-thirds of its thickness, and the pivot rod M, passing through scroll and sccured by burring over on a washer, which may be thin and slightly sunk. The position of sheet iton braclicts is made clear at L, Fig. $\overline{\mathrm{J}}$. By a little manipulation it would be possible to obtaill an angle of adjustment for the hearl midway between the extreme points indicated by the foregoing, fixing being in the course of the dotted line near L, Fig. jo Sce Divan Ottoman : Settee: Upholstery

CHESTNUT (Spanish). The Spanish or swect chestnut, with green serrated leaves, grows up to ( 60 ft . in height. When ripe, the nuts are brown and glossy, but sweet and not bitter like those of the liorse chestnut (q.v.). This tree likes $n$ loamy soil with sand rather than clay. Propagation is by nuts sown in autumn or spring.

CHESTNUT: The Wood. 'Therc are tivu rarietios of wood, differing very much in chirracter, produced respectively by the horse chestuut and the sweet or Spanish chestnut. The lirst is a light. solt, spongy wood, which loses nenrly half its weight and a considerable nenount of its bulk in seasoning. It is used for turning bobbins and other small articles. Ior carving, packing cases and also lor mugh outdoor boarding where durability need not be considered.

The swoet chestnut is a more valuable woon, and is the onc in general use, being ensy to work. Comparntively hard and heavy, it somotimes serves ns a substitute for onk. In rough earpentry it is employed 'or fencing. palinge, pilcs, beams; also for colfins, door and window sills, in cabinet making and for fretwork. Ladders. small casks and hoops are amongst the innumeratile articles that are made with the wood of the Spanish chestnut.

CHESTNUT : In Cookery. Of all nuts the chestnut contains the least oil, is pmbably the most digestible, and many dishes une made with it. It is also employed in atuffing lor poultry and in sauce. To buil chestnuta, make an incision in the skin of each nut and put them into a saucepan of salted, boiling watcr. Buil thein for about $\frac{1}{2}$ hour, drain, and iemove the shells nad re-heat the nuts in a little butter.
If chestnuts are boiled for a few minutes beforo being roasted on a shovel over a goord fire, they will be cooked through to the centre instead of being done merely on the outside. as is so often the case with roasting
A savoury dish is prepared by mixing. onc cupful of boiled chestnuts, mashed and sieved, with the same quantity of mashed potatues, 1 oz . of butter or margarine, a teaapoonful of grated onion, and a little salt and pepper. Butter an au gratin dish thickly, fill it with the mixture, nad sprinkle the top with breaderumbs, together with 2 oz. of butter divided into small lumps. This quantity is sufficient for one or two jersons only
Chestnut Sweets. In order to minke chest. nut charlottc, cut some sponge cakc into a round about 2 in . thick, spreading the outside colges with a little royal icing, and fixing around it about 2 dozen savoy finger biscuits. While these are setting, put 1 lb chestnuts into boiling water, boil them for 10 min ., then remove the outer shells and inner husks.

Break the nuts into picces, put them in is pint of milk, together with 2 in . of vanilla pood, and stew them gently until they are soft. Then rub the chestnuts through a wire sieve, and mix the puree with is little castor sugar to taste, it gill of cream (whipped), 1 teaspoonful
lemon-juice and 3 oz nurrons glacés each sut in aboul eight pieces.

Put the mixture into the prepared casc, whip. sweeten and flavour annther gill of cream. and force it over the top of the mixture, using a large rose pipe and raising the centre well Decorate the top with pieces of glacé cherries and eryatallised flower petals.

Another attrantive rweet for a party is chestnut trifle. The ingnerlients are $A$ square sponge zakes, I lb cheatnuts, a little white wine, anme apricot jam, \& gill cream and sume custaid. Buil the cheat-nuts. akin and mash half, and nix them with 3 tahlesperonfuls of apricent jain. Leave the remainder of the nuts in hat water. Cut the sponge cakes open, spread them with the nut and jan mixture, and arrange them in a glass dish, sonking them with two tahlcsponnfuls of wine, or fruit syrup may be used in place of wine.

Cover the whole with a good thick custard. and when the latter is set. shell the remainder of the nuts and press them through a large-hnled sieve so that they fall like threads over the custard, leatving jlain $n$ round central apace.

These give character to the trifle. The central spare is then filled with whipped cream. See Christmas: Marron Glacé ; Royal Icing: Sauce: Stuffinц.

CHEVAL GLASS. The name is applied to a mirror swung between uprights which form a stand. The mirmr frame is made of 1 in. stuff, it in wide inoluding the moulding and is mortised tugether. The rebate for the glass is on the same level as the quirk of the m:sulding (Fig. 2), so that both the tenon shoulders will be level. the moulding on the mortised pieces being cut away. When ordering the glass allow the size to be $\frac{1}{16}$ in. small all round. Hig. 2 shows how the glass is secured by glueing wedge-shaped pieces to the rebate.

Glue the frame together and clean up and prepare material for the back. The panelsare ${ }_{1}{ }^{3}$ in. in. thick and the crosspieces $\frac{8}{8}$ in., thesc being grooved to take the panels. The vertical rail is in two pieces, tenoned into the other at the centre, and hoth are screwed to the frame.
As it is necessary for the panels to fit right on to the frame the rails are cut away, at the ends, on the underside, just the depth of the bottom flange, as in Fig 4. Screw these in position and fit the panels, rounding off the edges to give a lighter appearancc, and mark-

Cheral Giass in waluut, Queen Anne style
Courtesy of Harrods. Lid. on the inside their relative positions, so that they may bo replaced in the same places.

The uprights for the atand are 1$\}$ in. aquare and are chamfered at the edges as shown, the top being out to a finial shape. They are tenoned into the feet as in Fig. 5, the tenons being wedged from the underneath to give greater atrength. The feet are cut from a block of wood each ineasuring 16 by 3 by lif in. The corner lirackets are fixed after the uprights are glued, and fit into small grooves out to take them. The rails joining the uprights together are tenoned; the length is obtained from the mirror frame, an extranallowance being made so that this will swing

Irerly without touching The small centre ornament is stub-tenoned into the rails and

CHEVIOT CLOTH. Scottish tweed manufacturers used to make their coarser tweeds exclusively from Cheviot wool, and in order to make softer

The frame should be carefully polished before fixing the glass.

To fix the glass lay the frame flat on a lable and put the glass in position, being careful that it is right down in every part. Glue the wedges all round about 3 in . apart (the wedges are each about 1 in . long) and allow to remain until quite dry. The mirror is hung upon special brass movements which screw to the frame and stand. By turning a thumb. screw the glass is made to remain in any position. See Dressing Table; Mirror.
Chickens: Their Incubation and Rearing Advice on Raising Birds for Egg Production and the Table
Further information will be found under the heodings Coop; Incubator; Poultry. Sec also
Boning; Casscrole; Curry; EgR; Fowl; Soup and other cookery corries
Boning; Casserole; Curry; ERR; Fowl; Soup and other cookery entries
In the incubation of eggs, whether naturally hen should be allowed off the nest once a day under a hen or artificially in an incubator, for food and water, regularly at the same hour the first easential to success is strongly ferti- every morning. Sometimes a hen will refuse lised eggs. Where the number of chickens to leave the nest, in which event she must be deaired is not large the broody hen will suffice, but for more extensive operations an incubator is a necessity.
In the selection of a broody hen great care is necersary, as it does not always follow that because a hen clucks and takes to the nest she will prove reliable. Birds with nonsitting blood in their veins should be avoided. Pullets, too, are not always to be relied upon, and it is advisable to choose birds that are two years old or over. In sitting a hen nighttime should always be chosen. The nest should be made on the ground in a sheltered corner of a shed or outbuilding, and so placed that no other hens can have access to it. It is hest made by scooping out a saucer-shaped hollow, pressing it evenly down and lining it with straw.

The number of egga to be set will depend on the size of the hen. A small bird will cover 10 ; a large onc 15 . While sitting, the
gently lifted off. After this has been done a few times she will act for herself. She may remain off for a hout 20 min .

The food of a sitting hen should consist of maize, clean fresh water and grit being always within her reach. Should any eggs get accidentally soiled they must be cleansed with tepid water, and the nest material, if similarly soiled, should be renewed All being well, the cbickens should make their appearance on or about the twenty-first day.

Artificial Incubation. This is a more complex proposition, everything, apart from the eggs, depending on the capabilities of the machine used and the cere exercised in working it. In a amall way a 50 -egg machine may be quite large enough, but when it is desired to incubate a large number of chickens. one of at least $500-\mathrm{egg}$ capacity will be needed. For the average poultry-kecper, however, a $100 \cdot \mathrm{egg}$ machine will supply every need.

The mechanism and working of an incu bator is explained in the article on Incubators A good machine having been obtained, the first thing to be considered is where to locate it. A cellar offers many advantages; but wherever it is placed, the temperature must he even there must be no dircct draughts and no fire The machine should atand perfectly level and as firm as possible to ensure againat vibration. The mode of working the incubator will vary according to the principle on which it is constructed, but every maker sends out full instructions. The temperature is the same in all cases, namely, for hens cggs , from $103^{\circ}$ to $104^{\circ}$, reduced to $102 \frac{1}{2}^{\circ}$ the last seven days: and for goose and duck eggs, $102^{\circ}$ throughout. The eggs require to be turned regularly once a day, and it is as well to keep the large end uppermost. As the chickens hatch they are allowed to dry, and then removed to the brooder

Testing the Eggs. In both natural and artiticial incubation, the eggs should be tested for fertility by means of an cgg-tester An infertile egg will be perfectly clear, while all egg in which the germ has started to incubate and dried will appear thick and cloudy. A rotten or addled egg will appear black, but the fertile egg will exhibit small veins radiating from a dark red centre. The testing operation should take place on or about the seventh day, when all infertile eggs should be removed, and if in an incubator, replaced.

Immediately the young chick emerges from its shell, whether it is hatched under a hen or in an incubator, it requires air and warnth to dry completely ito down and to expand its lungs. Unless the hen is very nervous and resents interference, the shells should be removed from the nest as the chicks hatch, as otherwise an empty shell may cover up the chipperd air-hole of a hatching chick and smother it before it has time to free itself

There 18 not the same necessity for so much care with an incubator, as the eggs are less crowded, and in some cases there is an arrange ment by which the young chicks in struggling towards the light drop into the drying chamber In other makes the chickens will need to be lifted into the drying box or drawer shortly after they free themselves from the shell, and as soon as they are properly dry, and if they scem strong enough, they can be again shifted into the warm foster-mother or brooder Chickens hatched under a hen may be safely left with her in the nest for 12-24 hours from the time they leave the shell, but if she is clumsy or nervous it may be advisable to remove them earlier.

A coop having been prepared and previously disinfected by lime-washing or other method, the hen and her brood may be carefully removed to their new home. The hen should be lifted from the nest first, and the chicks carried in that, or an old hat, basket, or even the lonse pocket of a coat. In cold weather it is an advantage to use a small rather than a large coop, as the hen will have less mom to scratch about, and will brood the chickens better. It should face south and he protccted from cold winds by a hedge, fence or wall. if possible.

Day-old Chlcks. Many chicks are sold when 24 hours old. It is a good plan to place them on arrival in a brooder heatert to as near $95^{\circ} \mathrm{F}$. as possible for an hour or two. If no brooder is available, the birds inay be placed in a flannel lined basket reason ably near a fire. They should then be given a feed of warm stecped oatmeal or biscuit meal, and a little warm milk to drink. If the chicks have travelled a considerable distance, the best results will usually be obtained by rearing them under liroody hens, if a vailable. One or two chichs only should be given to a hen at first, and if she takes kindly to these the remainder may be alipped
under her wings. The ben should have heen sitting on "pot "eggs for some days before the arrival of the chicks
Management of a Brooder. The brooder or foster-mother is used when it is not always posaible to make use of a sitting hen. The ordinary brooder usually consista of a heated chamber which is connected with one or more outer chambers or chicken-runs It is of the greatest importance thint the brooder should be so constructed that the temperature is always kept equable thiroughout, and should be completely free from fumes at all times This latter specially applics to those corners of the brooder into which the young chicks are likely to crowd. Finally, it is essential that hrooders should be kept quite free from damp.

In most brooders the heating medium consists of a lamp, and in some types this lamp is placed outside the heated chamber und is rendered lireproof by the piovision of a jacket made of ashestos. In another type the brooding chamber is heated by means of a hot water tank, or by a circulating hotwater tube, which is run all rolund the inner walls. In a third type of brooder a hot-air tank is litted. This tank is heated by means of a lamp. The position of the lamp should in any case be so chosen that the fumes rising from it can be carricd away immediately.
$r$ Tho heat should be gencrated in such a way that the floor is properly warmed. Otherwise, if there is not a proper provision for warmth at floor-level, the chickens naturally crowd together in order to keep warm, nnd the strongest will climb on the backs of the weakest and either crush or suffocate thom. One way of making provision for such bottom heat is by means of a lamp which is placed in the centsc of the brooding chamber. The inner roof of this chamber is made of metal and forms a radiator. The heat which rises from the lamp strikes this metal roof and is reflected down to the chickens.

The newly hatched chickens should not be transferred to the brooder until the latter has been properly warmed. The brooding chamber should be prepared for their reception by heating it for one or two days. This heating will get rid of any damp which might have accumulated owing to winter storage or from any other cause Any dampness would
mean a targe mortality in the young chickens For the first week that the chickens are in the brooder the temperature should be kept as near $\left(\mathrm{GH}^{\circ}\right.$ as possible luring the second week this temperature may be gradually owered to $85^{\circ}$, and during the thind week to $80^{\circ}$, while during the fourth and the following weeks it should lie kept near $70^{\circ}$ 'Too much heat is as bad as too little A part from the use of the therinometer it is generally presible to tell to within a small degree whethet the temperature is too hot or too cold II the temperature is too low the chickens will invariably huddle into the corners of the browder or round the inmp and will utter plaintive cries: if the brooder is too warm they will gasp for breath and lie buddled about in a listless fashion on the lloor. Over. crowding of the brooder inust always be carefully avoiderl. As a genera rule, it will always be advisable to keep well within the number of chictiens specifierl by the inaker of the appliance as its full capacity

## Benefits of Scratchin\& for Food

The covered run adjoining the broorling chamber is usually converted into a scratching medium by littering the lloor thickly with cut chaff, a mony which dry chick food is scattered. This is an important pait of the rearing of chickens, since scratching for the food induces exerciae, generates natural warmth, and so keeps the chickens in fit condition to withstand any sudden changes of temperature, which are not always possible to guard against quickly. On sunny days, when the chickens can be conlined to the outer run, the brooding chamber should be opened up and exposed to the rays of the sun. As the season advances and the chickens outgrow the necessity for a heated brooder, generally at 4,5, or 6 weeks, they may be tiansferied with safety to a cold brooder

The ordinary cold brooder comprises nothing more than $n$ slceping compartinent and a coverel outer run. The sleeping chamber should be well ventilated, but it should be so constructed that no currents of air can play directly upon the inmates, and there should be just enough room to enable the chickens to huddle together comfortably for warmth. The floor of the cold brooller should be of

Cbicken. Oil-heated foster-mother or brooder, a useful appliance for rearing chickens when a sitting hen is not available. Adjoinlar the brooding chamber is a covered run

Courlesy of Sprall's loatent, LId
earth, above which a good Inyer of cut chat or peat moss litter is placed. and the floor of the outer chamber should be covered in a similar fashion

Feeding the Chicks. Chopped hard-boiled aggs and hreadcrumbs may be given 24 hours from the time they hatch, and this may he repeated 3 or 4 hours later At 48 hours old they can have fine chick leed, which will encourage them to scratch and excreise. Sawdust, sañd. or peat moss litter broken up fine, laid on the floor of the coop, when they are moved into it. will greatly encourage them to scratch, and will prevent them getting cramp. A wooden floor is always anlvisable if there is danger from rats, and will also keep them dry

From 2 days old they should be ferl every 2 or 3 hours from dawn to dark, and fresi, water may be given in a shallow pan, too shallow for them to drown themselves in If there is any danger from cats, rats or other vermin, it is advisable to attach a small wire run to the coop

## The Importance of Exercise

The ben should not be allowed to leave the coop at first, but the chicks can in this way obtain ample air and excreise without danger from vermin, or the possibility of the mother giving them too much exercise. It must be soen that the chicks have no difliculty in returning to their mother, and any difference in the height of the coop from the ground must be regulated by a brich or piece of wood.

The same carc should be taken with the foster-mother or brooder, and in both cases the chicks should always be shut in at night The coop must be cleaned regularly and all stale food and refuse matter removed. After the first 3 days an unlimited supply of fresh, clear water can be given. Special jars are obtainable which automatically regulate the supply of water, but mako it difficult for the chick to foul it or drown itself. Fine limestone grit in ama! pannikins should also be given If the weather is cold and damn and there is a tendency to diarrhoea, boiled rice once or twice a day will help to check it.

A grass orchard or small paddock or lawn is excellent for rearing chicks, as they will then have plenty of fresh green food, and ample shado ir very hot weather When possible, ground that has not had other poultry rumning on it for at least 6 months should be used The young chickens will then be healthy and less pronc to discase.
The feeding should he supplemented by coarser grain and chick feed as the chickens grow. Biscuit meal with a little meat meal may also be given. Some poultry raisers prefer to scald and give this slight!!y moist. whilst others-and this is the better mothod -dry it after scalding by mixing it with a little meal, such as Sussex ground oats. Dry foeding is much employed, i.e. a dry mash placed in pans or boxes, with a plentiful supply of fresh water always available. In a warm, dry season the chicks may be taken from the hen or foster-mother at 6 weeks old, but it is often better to leave them till 2 months old, unless the hen begins to lay again, when she may preck them.

Pullets and Cockerels. As soon as the sex of the chickens becomes apparent, e.g. from 2 to 3 months, according to the rariety, they should to separated and kept in different runs. From then onwards they are termed cockerel or pullet, and though they reach maturity from ©-8 monthis, these terms are applied until they attain their second year. Frame, not fat, is the aim of all successful chicken-raisers, and especially is this applied to pullets, many breeders using only grain and green food for these until they approach laying, when a wet or dry mash may be used once a day. Cockerels thrive on tit-bits of all kinds, scraps of moat.
etc. A mash of I part meat meal, I part pea or maize meal, I part supers and I part bran will he found very uscful. Susses ground oats. wet or dry, unay he given as a change.

Wheat, oats, barley and buckwheat are the favourite grains for rearing. but it is better to give a feed of one variety. with periodical changes to others, than to give all varicties in one mixture. Maize or Indian corn is fatten ing and warming, and should be used when it is clesired to supply these curalities. Cleanliness, regular and suitable feeding, dry housing, air and exercise are necessary in rearing of chickens

How to Cook. Chicken may be cooked in many ways, roasting and hoiling being the conmonest 'To roast, $35-45 \mathrm{~min}$ ahould be allowed, and the oven must be hot for the firat 10 min of cooking, and maintained at a molerato heat for the remainder of the time.
Sausage-meat or veal forcemeat can be used for stuffing the chicken, and its nddition makes the dish go farther The breast of the hird should he stuffed with the forcemeat, and a greased paper placed over it.
'The chicken should be trussenl. and small alices of hacon laid carefully over the breast It should be placed in a baking-tin in the oven, with some good beef dripping, and frequently hasted while cooking. When half. cooked, turn the bird over nud brown the back, then after 10 min . turn the breast uppermost again. While the hirr is roasting, the liver and gizzard should he put to simmer in ahout $\frac{1}{2}$ pint of well-scasoned stock for the making of the gravy.

When the clicken is cooked, skewers and string used in trussing should be removed, and the bird placed on n hot dish. 'The fat should be drained of the baking-tin, and the prepared stock poured into the tin and boiled up for a few minutes. It may be coloured with gravy colouring and more seasoning added. The gravy should be strained into a saucetureen, and hread sauce sorved separately, while whtercress, washed and drained may form a garnish

## Improving the Flavour

'T'o boil a chicken, first truss it, then rub it all over with half a lemon, and tic over the breast 1 slice of fat bacon, cutting a few alita in the latter to prevent it from curling up. Wrap the bird in a piece of buttered paper; then wash and prepare $\xlongequal{2}$ onions. "t carrot, a tumip, and 2 sticks of celer!, cutting all thesc into halves and putting them in a large stewpan, together with n bunch of mixed herbs, 3 cloves, and 4 peppercorns tied in a piece of muslin. Pour in enough hot water to lill the pan nbout half full, and put it over a noolerate fire. When the stock boils. put in the chicken and let it simnter very gontly for 1 to $1 \frac{1}{2}$ hours Then take the bacon from the breast, remove the greased paper, and wipe the bird with a clean cloth to rid it of greasc. Serve the chicken on a hot dish with egg sauce poured over it.
Chicken may also be fried, a good method being to cut the fowl into nent joints and remove the skin, afterwards dipping them into a mixture consisting of 2 tablespoonfuls of thour, I teaspoonful of salt, and a dust of pepper and cayenne. Mclt 2 oz. of bcef dripping in a small frying pan, put in the pieces of chicken, and fry them until they are golden brown on cach side. Keep them hot while 5 or 6 neatly cut pieccs of bread are ficel in the same fat; then slice three tomatoes, fry them for a couple of minutes, and lay them on the slices of bread. placing a piece of chicken on top of each Garnish the whole with small bunches of well washed watercress and chopped parsley.

Ideas for Re-cooking. The remains of roasted or boiled chicken can le minced. To I Ih. of finely chopped chicken allow' 2 oz . margarine, 2 oz. flour. I pint stock, and some poached
eggs. The stock can be prepared from the hones and trimmings of the chicken. Stir the flour into the margarinc melted in a saucepan, add the stock, and simmer the whole for a hout 15 min Seasoning should lie added, and the chicken then placed in the stock. Leave the pan by the ride of the lire until the bird is thoroughly heated, and serve it garnished with poached eggs, allowing one egg to ench person and one or two over. Finely chopped hoiled ham can be mixed with the chicken if desired in the proportion of 4 oz of ham to 1 lh . of chicken

The iemains of a cooked chicken may also be dovilled for breakfast or supper, using a tablespoonful each of salad oil, tomato sauce, chutney, and vinegar, 2 ahallots peeled and finely chopped, and a dessertapoonfirl of lemon juice. Cut up the chicken into convenientsized pieces, pour the salad oil (or oiled butter) on a plate, and dip each piecc of chicken in it, sprinkling over them on hoth sides ahout a teaspoonful of pepper and salt nixal l'ut the pieces on a gridiron, and grill them before a clear fire for 7 or 10 min ., turning occasionally, and taking care not to burn them.
l'ut the shallots in a stewpan with the vinegar, and cook them over a fire for 10 min with the lid off, then ould the chutney, tomato sauce, lemon juice, about is grains of cayenne, and a saltspoonful of aalt. Stir all together, and boil for 5 min . Serve the chicken arranged on a hot dish, with the sauce poised round.
Invalid Cookery. Specially suited for inclusion in an invalid diet is a gruel made as follows. Chop ${ }^{3} \mathrm{II}$. chicken meat vory linely Soak a little less than $\frac{f 1 b}{}$. breaderumbs in sufficient milk to cover them, and then rub them through a sicve into a saucepan contain. ing the chopped chicken, $1 \frac{1}{2}$ pints chicken atock, and a little scasoning. Boil the gruel for a couple of minutes, when it should be very thick, and serve it immediately.

Another easily digested and nourishing dish is chicken jelly. A small chicken should be boiled until tender, the meat then sliced and placed round the sides and hottom of a mould The bones and remains of the chicken should he put back on the stove with the liquor in which the chicken was boiled, and slightly seasoned. These should be simmered slowly over gentle heat for two hours. The stoct shoukd be atrained and poured into the mould When cold, the jelly should be turned out.

A suitable dish for invalids is chicken mousse made by mincing 6 oz. raw chicken, pounding it well, and adding to it $\frac{t}{2} \mathrm{oz}$ margarine and $\frac{1}{2}$ gill of thick white sauce. Continue the pounding process, and add 2 eggs, one by one, mixing and pounding them well with the other ingredients. Season the whole, put it through a sieve, and then atir in 1 gill of unsweetened condensed milk. Grease a large inould, three parts fill it with the inixture, and then cover it with a greased paper. Place it in a steamer and steam it for about 1 hour, then turn it out on to a hot dish, coat it with white sauce and decorate it with parsley.

CHICKENPOX. Onc of the commonest fevers of childhood is chickenpox, which occurs chietly in epidemics and is extremely contagious, so that inmediate isolation of the patient is always necessary. It is commonest in children up to six years of age, but nlso occurs among older school children, and grown-up people may contract the disease if they did not have it when young. As a rule a person can only have it once.

The first symptoms are slight fever, pains in the limbs and sonnetimes sicliness, occurring 11 to 19 days after infection. Within 24 hours a rash appears on the body, or on the face and scalp; the small, hard red pimples form blisters iilled with clear, transparent fuid. In a few days these dry into erusts and drop
off, rarely leaving any scar unless the ohild has been allowed to scratch or pick at them The pimples or vesicles niay break out inside the mouth in some cases and cause pain in swallowing
The chie! dangers to guard againat are inflammation of the kidneys and hronchopneumonia, so that the patient, after being isolated from the rest of the fanily or the school, must be protected from chills and draughts, and kept in bed till the crusts have formed. Custards, puddings, and other light milk diet are the rule, but ot herwise no special irentment is required. If the itching about the face is troublesome, the following lotion will give relief, and should be applied with a pad of cotton-wool

## Carbolic acid (illycerin <br> llectilled spirits of wine witer <br> $1^{1 \text { tcas,monflil }}$ <br> a tablesioun?ula <br> ${ }^{1}$ pint

CHICKWEED. The mouse ear chichweed (Cerastium vulgatum) is a common and iroublesome annual weed which sows itself frcely in gardens Cerastium tomentosum (anow in summer) is a vigorous, low-growing. spreading plant with grey leaves and white llowers in early summer; it is very attractive in a sunny place but must he kept in bounds by severc cutting back when the blooms are over. Cerastium Biebersteinii is similar but has larger Howers

CHICORY or Succory. The ehicory plant is a hardy perennial bearing toothed hue flowers in summer. It thrives in ordinary soil, and the

seed is sown in $\frac{1}{2}$-in. deep drills, 8 inches apart, ahout midsummer to provide roots for forcing.

The seed. lings are thin. ned to 6 or 8 inches apart. In autumn the roots are lifted as they are needed for forcing If placed in hoxes of soil, below the surface, in a cellar or other sightly warm dark place they will start into fresh growth. As it con. tains both sugar and starch, the root of the chicory plant has a food value, and when ground it is widely used for mixing with colfee. The usual proportion is one part of chicory to four parts of coffee. It is alsn employed to darken the colour of soups and gravies. The tr, to winter salad, or may be cooked for use as a vegetable. See Idulteration; Coffee; Salad.

CHIFFON : In Dress. This soft-finished, inther open-textured silk of light weight is used with lace or for fragile dresses and scarves, etc., in either plain colours or patterned variotics. Light and pliable silks of other descriptions are sometimes ealled by the additional name of chiffon. This there are chiffon velvet and chifion taffeta.
CHIFFONIER or Cheffonier. Of French origin and descended from the eabinet. chifioniers became popular in Great Britain
in Victorian times, and were chielly made in rosewood or inahogany, fitted vith knobs and handles of brass. They are still seen. usually taking the place of a small sideloard The doors are well panelled, with brass beading along the edges, while the feet are often in the shape of claws. In the finer pieces sphinxes and other figures in gilded bronze serve for supports to the article. See Sideboard

CHIGNON. Word used to denote a roll of hair in the nape of the neck. The ladiee of the 18th century padded this roll of hair With a stiff cushion of false hair. It was then powdered and pinned in position with pronglike pins and curls were attached to it. A century later women in dressing their hair threw it forward over their faces: they then pinned on the chignon pad and dressed the hack hair over it, tucking the ends under the chignon. Sec Hnir

CFILBLAINS : How To Cure. Hue to exposure to cold, chilblains painfully alfect the fingers and toes in the form of purplish inflammations of the akin, rometimes running on to blisters and ulcers As a rule, the sufferer's circulation is not very active, or he may he run-down. There is intense aching and tingling, with swelling and purpling of the akin. When blisters form and break, leaving ulcerating surfaces underneath, the chilblains are said to be broken.

The patient must see that gloves and boots are worn loose, socks thick and all-wonl, and frequently changed. The fent should be

## The Child: Its Care and Training

## Dietary, Hygiene and Legal Status

The first ycar of life is deale with under Baby. See also Adenoids; Croup; Measles and other complaints to which children are suhlect. Children's Party; Doll, ete., may a!so he read

All healthy voung animals, the human included. are playful and active during waling hours, and noed a large proportion of rest in consequence. During the second and third years 12 hours' slecp at night, say, from 6 p.m to 6 a. 1 n ., with a couple of hours during the morning and another hour or two in the afternoon, is a healthy allowance, though individua children vary a little in their requirementa As the child grows older and his interesty increase. the daytime hours of sleep become shorter, but a rest after the midday ineal should be encouraged up to $\overline{1}$ or ( j yeary of age. Early bedtime houra are most important throughout. Children from 10 to 13 years of age should have 11 hours' slecp, and from 13 to 16 or 18 at least nine hours.

From the earliest age they sloould be trained to slecp alone, in their own cots or beds. A hair mattress is the best, though during the second year, when control over the bladder is still imperfect, bran, which is easily and chenply renewed, may be used. The bed-eloth ing should be as light as is compatible with warinth, blankets being supplemented in cold weather with an ciderdown instead of a heavy quilt. For very young children it is advisuble in winter time to warm the cot beforehand with a hot-water bottle, which should be re noved when the child is put to bed. Light woollen sleoping suits, with long slecves, should the used for boys and girls, at least during the cold season.

The importance of fresh air in the bedroom cannot be over-emphasised. Fresh, cool, cir culating air has a stimulating and beneficial effect on the body, and, as children spend such a large part of their time asleep, effective ventila tion of the bedroom should alwavs be secured, So long as the hed is protected from direct dranghts, the bedroom window should ahways be kept well open. An exception may be made in very foggy weather. In very cold weather the air of the room nay be maintained at a
suitable temperature (about $55^{\circ}-60^{\circ} \mathrm{F}$.) by
placed in warm water at night and dried briskly. A hot-water bottle in bed is not desirable, but if it is used it must not be placed near the feet. If the hands aro cold warm them by rubbing together or washing in almost cold water.

The circulation should be stimulated by regular outdoor exercise and a generous diet. Cod-liver oil should be taken, or cod-liver oil and inalt. A teaspoonful of tho syrup of the hypophosphates of iron, quinine, and strychnia thice times a day, after meals, is an excellent tonic for an adult. Benefit may accrue from taking calcium lactate in 15 grain doses (5 grains for a child) thrice daily for two or three days at $n$ time. If the taste is ohjected 10, add as many drops of the liquid extract of liquorice.
la soon as the redness and swelling appear the affected parts should be prainted with tincture of iodine or campliorated alcohol rubbed in. They are then powdered with hismuth, salicylate, 1 part, and stareh, I part If the heat and irritation persist it is well to apply zinc ointment or an ointment of ichthyol 30 per cent. in vaseline.

If iblisters form and bieak. cover the whole part with a piece of lint, spread $\frac{1}{b}$ in. thick with boracic ointment, nud handage tightly; or this ointment may be used: linch tar, I dram: zinc oxide, 21 drams: vaseline, 5 drames For washing the sores, especially if they are suppurnting, there is nothing better than equal parts of hydrngen peroxide and warm water. See Boot: Foot: Hand
artificial heat, such as a fire or radiator. Winter and summer, whencver conditions are possible a daytime aleep ahould be arranged for in the open air

The Child's Diet. By the age of 2 or $2 \frac{1}{2}$ the first dentition should be completo, so that during the second year the diet must be gradually modified to train the child's powers of mastication and digestion. Theo meals a day should be the rule throughout early child hond, with no more than a little milk and water, soup. or something equally digestible at bedtime.

From the second year, one pint of milk. for drinking and cooking, in tho daily dietary is enough. Too much slop, food should not be givon, but at breakfast and tea chewing should be encouraged by serving dry buttered tonst, rusks, unsweotened bisenita, outcakes, and such-like. Small quantities of jain (without pips or akins in the case of young children), syrup, or honey can be added, or atewed or fresh fruit, ripe apple or mashed banana, for inatance. Well-cooked porridge served with milk is wholesome, but whould not be given constantly. Meat or fish dishes at breadifast are not necessary for young children, though bread lightly cooked in bacon fat is good occasionally. Milk. cocon. or weak chocolate are suitable drinks for bicakfast and tea Tea and cofioc are best withheld until after 9 or 10 years of age

At the midday meal small quantities (1 or 2 oz .) of meat or fish or a lightly cooked egg should be given. Until dentition is complete the meat should be cut up into fairly smal pieces, and varicties should be limited to mutton, chicken, rabbit, underdone beef or tripe. Small portions of boiled potato, cauliHower, or well-cooked eabbage may be given from I yoar, also a little carrot, turnip, onion or parsnip, provided they are mashed.

Vegetable proteins, such as peas, bears, and lentils, which are very wholesome, but rather more diflieult of digestion, are best withheld
until after the second or third year. All varicties of milk pudding, junket, jellics, steamed or boiled suct pudding with syrup, also baked apple or sieved stewed fruits, may be given from one yoar, provided the ohild is of average development. Beyond two yeara more variety may be allowed, also light home-made pastry. Fresh fruit and vegetables, a certain amount of which is always neccssary in the diet, may be given occasionally in the forin of a finelychopped salad

From 7 or 8 years onwards, when the child begins to go to school, supper, if a light tea be given, about 4 o'clock, needs to be a more substantial meal. Meat is not advisable, but soup, fish, or a well-made egg or cheese dish may be added, with milk pudding or fruit. This should be given at least an hour befone bedtime.

## Foods for Growing Children

From the age of 10 or 11 years onwards, $n$ period of rapid growth and development, both boys and girls need a plentiful supply of whole. some food, but meat once a day is enough. At no age should anything between meals be allowed except water to drink, and the best time for this is half an hour or an hour before meals. Drinking at meal times should he limited, and the habit of sipping between mouthfuls that some children are allowed to acquire is certainly a had one. Highly seasoned dishes, sauces, pickles, vinegar curries, or fricd foods should not be given to children. A few wholesome sweets or plain chocolate may be allowed, preforably as an adjunct to a meal.
Children should be given to understand they arc expected to eat what is set before them. A small percentage of children display idiosyncrasies towards certain artioles of food, such ds fish, egge, or some varicties of fruit. Skin rashes, maybe vomiting, with fever, follow ingestion of these particular foods. If such be the case they should be omitted from the diet, and medical advice ohtained if necessary
The Use of Aperients. A word may here be said about the use of aperients. The child should be trained from infancy to empty the lower bowel daily, preferably after the first meal of the day. The atomach and intestines have natural, rhythmic movements of their own which need to he respected and cultivated. An unnecessury dose of purgative medicine may upset this delicate neuro muscular mechanisin for indefinite periods.
Washing and Bathing. For the first few years of life a daily warm hath, preferably at bedtime, is the easiest and most rationa means of keoping a child clean ; but beyond the age of 4 or 5 a hot bath once or twice a week is enough. From early age, however the child should be trained to the use of cold water. Unless contra-indicated on medical grounds, the body each morning should he first lathered and then sponged all over with tepid water, the temperature of the latter being gradually reduced until water from the ordinary cold tap is used Rub hriskly with a bath towel afterwards.

As a general rule quite young children soon learn to appreciate this proccsa, which has a stimulating and invigorating effect on the whole body, and no doubt tends to increase resistance to catnrrhal infections. Provided the reaction aftervards be brisk, healthy boy: and girls should take a cold (i.e. $70^{\circ} \mathrm{F}$ or helow) plunge bath each morning, followed up by simple gymnastic exercises for a fow minutes When the hot hath is not due at night, ex posed parts of the hody sloould be washed before going to bed
Tecth must be cleaned moming and after the last meal at night, the latter being the more important. If particles of food, eapecially starchy varictiea such as bread and biscuits, remain around the teeth during the night,
fermentative changes take place and the enamel of the teeth is injured. Examination by a dentist at regular intervals-about once cvery six months-is most important. The hygienc of the nose is also very important. Children should be taught as young as possible to blow the nose and use a pocket-handkerchief. If the nasal cavities become blocked the child tends to develop a habit of mouth breathing, which is one of the factors in the development of adenoids and their attendant cuils.

As children approach the age of puberty it is desirable that they be given simple instruc tion about sexual life and its results. One of the parents is the most suitable person to do this; but if he or she feels unequal to the task, there are excellent little broks to be had dealing with the subject, or the services of it sympithetic teacher may be enlisted. Girls should also be told beforehand the nature of the menstrual perinds, which usually start from 13 to 14 years of age

The Legal Side. A father is the guardian of his legitimate children. But if the father and mother do not live together, and there is $a$ dispute as to which of them shall have the custody of the children, the court will take account of the children's welfare, and of nothing else. Unless the mother has been guilty of adultery, or is a drunkard, or there is some other reason why she is not fit to have the custody of then, children of tender years are practically always handel over to the mother. She may even be appointed their legal guardian and the father entirely ousted when he is unfit to be guardian, as, if he has been cruel to them, or is a conlirmed drunkard and wastrel, or is living with another woman, or brings his children into contact with immoral persons

## The Father's Ridhts in Religion

'I'he father has a right to say in what re ligious faith his children shall be brought up, but even this right is subject to the qualification that the interest of the ohildren is the chief consideration. If he has allowed them to he brought up in one faith, and then turns round and says that they must ohange, the court will not allow it if the judge finds that it would unsettle the children in their religion and possibly result in their growing up in an irreligious atmosphere. This right of a father to dictate the religion of his children continues even niter his death

Any agreement before marriago as to the religion in which the children shall be brought up is worthless, for the father can still insist on all the children being brought up in what ever religion he choosea, subject to the qualification stated above.

A child's earnings belong to the child, not to its parents 1 child earning money who lives with his parents is entitled to bargain how much he will pay for his kecp, and the parent has no right to demand his wages and make him an allowance for yocket-money. A child's misdeeds are his own, and he alone is responsible for them. So that a father cannot be called upon to pay, for example, for windows broken by his son. The father (mother if no father) is responsible for a child of school age attending school, and may be fined if the ohild fails to attend.

A father cannot be compelled to maintain a child capable of supporting himself or herself; but if a child of any age is, by reason of infirmity, whether mental or bodily, incapable of self-support and becomes a charge on the rates, the poor law nuthorities may summon the parent and obtain a magistrate's order that the parent shall assist in defraying the cost of maintenance. A father is bound to provide a child under 16 with sufficient food, olothing, and medical attendance; and if he does not, is liable to be summoned for neglect,
and fined or iniprisoned. The mother of an illegitimate child stands in the place of the father of a legitimate one.

Baby Farming. Any person who, for pay. ment, takes charge of children apart from the parents, must notify the local nuthorities within 48 hours of 80 receiving any child. If the child dies, or is transferred else wherc, or if the baby farmer changes her (or his) ouldress the fact must also be notified

These local authorities can appoint inspectors to visit the homes and regulate the number of infants which can be kept in them Persons are not allowed to keep children if their premises arc insanitary, or if they have been convicted of previous offences. They must have no insurable interest in the lives of the children kept by them. False or misleading statements relating to matters to be notified aro offences. Penalties for offending against the Act are imprisonment for not more than six montlis, or a fine not excceding $\mathbf{£ 2 5}$. English law also forhids persons to insure the lives of children, except under rigid limitations

Child Labour. In Great Britain local nuthorities have power to make by-lawa restricting the employment of children of achool age; and to regulate street triding by chililren. Any rules made can be ancertained at the office of the town, or urban, district council. Under the age of 12 children must not take part in public performances held in premises licensed for music and dancing or the sale of liquor; if over 12 years of age, they may be permitted on application to the local authority.

It is a legal offence for children under the age of 14 to be found on licensed premises, and for anyone to scll cigarettes to any peraon under the age of 16, whether for his own use or not. The police have powers to seize cigarettes or cigarette papers in the possession of any person, apparently under 16, whom they find smoking in a strect or other public place.

Juvenile Courts. These are held for the hearing of offences by children. Parents may be ordered to pay the fine imposed on the ohiklren. Children are prohibited from secing certain cinematograph films unless accompanied by an adult, and in the case of other films are excluded altogether. The chief legislation on children and their protection is found in the Children Aot of 1908, the Educa. tion Act of 1921 (England and Wales), and certain other enactments of like nature

CHILDBIRTH. The expectant mother, besides making a sufficiently early arrangement with a doctor and nurse, must make other necessary preparations, for although childbirth is a perfectly natural and physiological process, it exposes the natient to the risk of infection by microbes. The room in which she is confined should, thercfore, be thoroughly clean.

When there is a choice of rooms, let the one chosen be as large and airy as possible, and provided with a fireplace. The hedsteal ahould be plain and easily cleaned, and should be placed so as to permit of easy access from either side, screens being used to prevent draught. It ahould have a good spring matt reas and over this a clean liair one. A mackintosh or waterproof-shect is placed over the latter, or, where this is not available, scueral layers of olean hrown puper. Over this is placed a blanket and then a sheet. The bed is to be protected by putting a sheet of mackintosh below the hips and covering it with $n$ draw. sheet, which consista of a piece of sheeting folded to the breadth of about a yaril.

Labour takes place in three stages. In the case of a first baby the whole procers occupies on an average 16 hours, but it may be shorter, as it usually is in subsequent confinements, or much longer. The doctor should always be summoned at once when labourbegins.

It may be useful here to mention some of the more necessary things which should be procured in anticipation of a confinement : one or preferably two mackintosh or waterprool shects, drawsheets, at least three ahdominal binders for the mother, two or three dozen sanitary napkins of the largest size, 1 or 2 lb of absorbent cotton wool, some stout linen thread cut into lengths of about 10 in . or atrong narrow tape clean lint or linen, a bottle of lysol, large and small safety pins, a clean nail-brush, antiseptic dusting powder, a pot of vareline, clean scisors, and two basins. Three or four lengths of thread are tied together at each end to form a ligature, and two such are required. They should be boiled for half an hour before use, or in an emergency dipperl in lysol solution. Lint and other dressings may be baked in a hot oven for half an hour. care being taken not to scorch them Alidominal binders, towels, sheets, etc.. should be freshly laundered and put away. See Baby

## CHILDREN'S PARTY. To be successlul.

 a children's party requires an organized programme. It is easier to entertain children under 11 by themselves, as they like to play games and to have the undivided attention of sympathetic grown-ups while older children often get bored with romping. It is usually a mistake to in vite any child under five cxcept to a real nursery partyOn the invitations, sent out about 10 days beforehand, the hour of leaving should be stated, to avoid any confusion in the fetch. ing arrangements. Some hostesses engage a conjuror, a ventriloquist, or have a private cinema show, as a second part of their entertainment, finishing about 9.30 , the older children staying on after that to conclude the party with dancing

For a younger children's party beginning at 3.30 , a room in which to play games should be cleared of everything except a gramophone or a piano and chairs. The nore brightly this room is decorated the more quickly everyone gets the right spirit for a party On arrival, most children are apt to be serious, and something must be done lirst to helj, them to get over their shyness. A jolly game such as musical chairs, or one of its variants, is a good start, while presents-trifles from a $6 d$ store provided to send everyone away happy at the finish also make for success. The old-frashioned bran tub is voted rather messy for indoors, and the lucky dip has taken its place This is simply a large laundry basket or hox prettily disguised and filled with toys. A cloth is spread over the top, and each child puts a hand under this and drags out a parcel.. Or the presents may be hidden about the room in which tea has been served, and the party end with a treasure hunt.

## Making the Tea Table Attractive

Refreshments are most important at all children's parties. The table should be gay with a variety of cakes, fruits, and sweets. For small children there should not be too many rich things, but different layer and iced sponge cakes and varieties of fancy breads and buttered rolls. Fruit salad in pretty individual glasses always pleases. At a winter party crackers are an attraction. A large selection of coloured balloons are also useful, and can be given, one to each child, after serving as decorations, at the end of the party.

After tea all the old-fashioned games will go merrily. The great thing is to change a game directly it shows signs of tlagging. When halt a dozen children have been caught in blind man's buff it is well to start its variant. One person is ioindfolded and given a stick to hold The others take hands and dance round him in a circle until he bangs on the floor as a signal to stop. He then points the stick at somebody and says, Make the noise of a cat, dog, or any other animal that occurs to him. The person
addressed has to take hold of the stick and obey the order, while the blind man tries to identify the voice If he succeeds in guessing rightly he changes places with that person. After this game may come musical bumps, hunt the slipper, or any other game that may be suggested. Most children will like some dancing to a gramophone. Competitions also, with prizes, always seem successful. A favourite is to give each child a balloon that has not been blown up, together with a short piece of tape; stand the children in a ring and at the starting signal they begin to blow up the balloons, a prize going to the biggest, after everyone has either tied up their attempt, or burst it in the effort to win the prize.

Illustrations of fairy storics and nursery rhymes can be cut out of cheap paper cditions, the names removed, the pictures pasted on cardboard, and the child who guesses the most correctly is the winner Where a hostess is specialising in a young children's party, a marionette or a Punch and Judy show, which can be hired through the entertainment department of a big store, will be sure to prove a great success as a finishing touch to a party of this kind

For older children; at a later hour, there would he either a sit down or buffet supper. If the latter, it is well to have small tahles, with chairs, scattered about the dining room to put glasses, etc., on. Most children delight in a stand-up supper; it has all the joy of the picnic, and hoys feel pleasantly unrestricted as to what they may consume. After supper, should there be no entertainer, dancing is the rule: sometimes the party is a bigger success when the guests are in lancy dress. In some houses the children have a passion for charades, and love to get them up secretly with some of their friends before the day of the party. Any costumes that arc to be worn should be put out ready in bedrooms beforehand, and a stage-manager chosen to superintend.

A summer party is pleasantly and quite easily arranged where there is a large garden, and all sorts of outdoor games can be played. Sports can be organized, with three legged, wheelharrow, obstacle, egg-and-spoon, and sack races. Tea is served either in the house or in a marquee, and in the evening there can be a dance with supper and an orchestra in a marquee lit by Chinese lanterns. Sec Charader; Christmas; Fancy Dress.

CHILL. Exposure of the body to a draught of cold air or to dampness may bring on a chill. The patient feels shivery, may be nauseated or sick: there may be severe headache, a degree or more of fever, and he feels he is in for some
illness. In a few hours all symptoms may pass off: on the other hand, congestion of some internal organ may follow, when the chill is said to have settled in the lungs or liver, etc. The commonest results of a chill are a cold in the head and bronchitis (q.v.). A hot mustard fout-bath, warm drinks, and hot-water bottles in the hed, the patient being put between blankets, are the immediate remedies for a chill. See Cold.

CHILLI. The dried pod of the capsicurn plant is used in making curries, chutneys, and in pickling. In the green state it is eaten as a pickle. Chilli vinegar is used as a relish with tish. To make it 75 fresh chillies are used to $1 \frac{1}{2}$ pints of vinegar, the vinegar being boiled and, when cold, poured over the chillies. The whole must be tightly corked and left for two or three weeks, when it will be ready for use.

CHIMNEY. In building a new house it is well to remember how much the chimneys will influence its appearance, both at close view and at a distance when they become perhaps the most important detail of outline against the sky.

British architects are again taking an interest in chimneys and are not only designing them so scientifically in small houses that ugly pots and cowls are unnecessary to make the chimneys draw properly, but also with such an eye to decorative value that they may be now, as in Tudor times, ornaments which enhance the whole building. Elizabethan architects made such a feature of chimneys that they frequently designed them as part of the outer walls; the bases of such chimneys, when reproduced in modern houscs, make provision in the interiors for inglenooks

Colour of brick used for the stacks is considered carefully. Dark red bricks may be selected for chimneys on a stone-tiled roof a lighter shade of red on dark red tiles, and mellow tints for the plain brick chimneys suitable for thatched rools.

Ornamental brickwork was also used with discretion in Tudor times. It is shown as adapted to a modern small house on the beautiful chimneys in Fig. 1. A good outline on a gabled roof is also achieved by bringing three chimneys into one stacl;, as in Fig. 2, while a round chimney is a charming architectural feature in Fig. 3, where the brickwork is enriched with spiral stringing composed of projecting bricks.

Smoky Chimneys. An insufficient supply of air to the fire is the cause of many a smoky chimney; it is discovered by opening a door or window, which is effective in curing the

Chimney. 1. Ornamental brickwork, typical of the Tudor period, used witn goojerfect on tne chimneys of a modern house. 2. Three chimneys brought into one stack. 3. Spiral atringing an a ronnd chimney

smoke nuisance by introducing a curient of cold air. Remedies in such cases are to fit the ventilating bricks near the cciling and through an outside wall to the open air. Another method is to lit a ventilating llue under the lloor and terininating in a grating, provided with a regulating shutter, in the hearth or near to the fireplace.
The real troulile prolanbly lies in the chimney itself or in the stove. The chimmey may be choked with soot and broken pieces of mortar that have got lomse and fallen down, and the services of the chimney-sweep are required. When the stove allows cold nir to work into the thue or chimney it causes a down-draught Being heavier than air, the amoke can only tre carried out through the chimney if the diaught caused by the hented air rising in the chimney is strong enough to carry it allay. Therefore any cxcess of cold air must be stopped

## Eliminating a Down Drausht

The means for cloing this include attention to the pointing of the joints in the lorickwork, as the chimney must be nirtight except for the openings at the lop, and bottom. Treatment of the chimney in the region around the tireplace may include the partial lricking "p of the llue, reducing the actual opening to a space not larger than 9 in . square. If this is done, and the new brickifork is so arranged that the Hue makes an ensy turn and does not go stiaight up, it will almost always effect a cure.
The most fiequent cause of smoky chimnoys is the shortness of the chimney stack. lixtending the height of a chinmey raises it nbove the level of the surrounding roofs, a very important matter, as a roof sets up eddy currenta in the air which neaty alwiry have a tendency to blow down a chimney. A second adiantage of a taller chimney is the extra drauglit it causes. This is due partly to the added height and paitly to the restricted dianeter of its opening. Ill manner of shapes of pots have heen devised, but none aic entirely effective, although the lousre and lent-top pots, as well ns some of the revolving cowls, have substantial claims to success. iWhen a considerable height-say, $f$ or 7 ft .-is udded to a chimney, and a galvanised iron lallhov or pot of that character is used, it is just na well to provide some light iron stay rorls to prevent its leing blown array in a gale.

When every experlient in the "ay of ex lending the height of the chimney has proved a failure, attention must be given to the stove and its surround The ordinary cast-iron register stove may not be fitting perfectly airtight, to the bickwork at lhe back, and any lcaks must be made good with cement or fireelay Kitchen ranges are prone to this trouble as after lengthy use the mortar may have failed: when the brickwork is no longer a tight fit up to and around the stove hack, it may he remedied in the samo way.

## How to Deal with a Larse Flue

Large opell ranges can only be treated effectively ly making n hlower of metal or glass to restrict the opening. Dog grates and the old-fashioned open fires with a luge chimney shaft are very diflicult indeed is corrcct. Perhaps the neatest method is to enclose the chimmey opening with an iron plate having a small hole through it to accom. modate an ornamental linod or honnet. A separate sont door must lie litterl to allow the chimney to be cleaned
It is a legal offence to allow a chimey to cutch lire. Various tientments are prescribed for deuling with a cliimney on fire The simpleat and most effectivo is to close all doors and windows and to stop up the top of the chimmey by means of wet sacks, bricks, or anything handy that can he preased into service. If the bottom of the chimney can he closed, this also has a retarding effect on the fire. It is customary to throw salt in large quantities on the lire in the grate or down thic chinncy from the top, while a patent ex tinguisher inay be used when it can he brought to hear directly upon the fire in the chimney.

The heat way to prevent $\pi$ fire in the chim. ney is to keep the fire itself in moderation, to have the chimmey swept at frequent intervals, and to avoid the buming of Inrge quantities of paper that may lie carried up the flue and set fire to the sont.
Chimney Sweeping. When a visit from the sweep is thought necessary, certain preliminaries are desirable. Megin by removing and putting a way all white covers in the room. Take everything off the mantelpiece, as the sweep will need it clear to fix his black curtain. Sweep the hearth and grate perfectly frec of all ashes and cinclers, and spread a thick layer of nevspapers all around the fireplace. 'T'lic housewife knows from oxperience that some aweeps are ticly workers, and if such a man is coming no other preparations are necessary. But in the casc of an untried man, it is advisable to take down white curtains and to cover all fumiture with dust sheets.
While sweeping is in progress go outsicle and see that the brushes go right up the climney and are visible alove it. Fiome sweeps aio careless a bout brushing right up, and neglect of this means that soot will fall later When the sireep has gone take a hearthiruali and sweep out from the lower part of the chimney, just ahove the grate, the loose soot which falls from ahove and collects there Then put the room in ordei Again. Sce Firc.

## Chimney Bellfower. See Campanula

CHIMNEY PIECE. Since the chimncy piece enihraces the whole protective st ructure round a fireplace, from floor to cciling, its. decorative treatment is $\pi$ matter of importance. One has to remenilser, in this connexion, that the grate is always an int egrial part of the chimney piece, and that one cannot deaign or alter the latter without considering the former.

There are ways of converting a Victorian ohimney piecc into n modern one without great expiense. The marhle shelf can be painted after the surface lins heen well rubled down nnd finished off with a final coat of eggshell enamel. But this leaves the claborate supports atill visible, and on the whole the more eflective $\begin{aligned} \text { ransformation can be brought }\end{aligned}$ alout by encasing the entire structure in woor. lext the grate has to be dealt with. The straight up and down lines of the wand encaacment cali for a rectangular instead of a hoiseshoe shape, and this can be got by placing it piece of shect iron, cut in the centre to the reguired form, across the opening, finished off by a plain moulding. Copper can le usod instead of sheet iron with tine cffect when dark oak is selected for the casing, or another ide: is stainless steel, with $n$ surround of black marble and curb in place of a fender. The removal of the hars of the fireplace and the substi. tution of a barless grate will complete the work

Where it is a matter of creating, not merely adapting, a clumney picce, there are certain general principles which should govern the choice of $n$ design. In the first place, the size and character of the room should dictate the nature of this feature. In a small room the mantelshelf can be entirely dispensed with or restricted to 3 or 4 in . in width-suflicient perliaps, to carry a pair of good candleaticks and one good piece of pottery or china It should always le remembered that there is nothing more diaturbing to the ensemble of a chimney piece than a mantel crowled with

Cbimney Piece.
Old oak chimney piece beautifully carved and built to match a Jacobean panelled room

ormaments. When brichs are used the colour and design of the bricksork is of sufficient interest to hold the eye without disturbing detail alove. The illustration of a modern brick fireplace suitable for a hall shows perfection of treat. ment. A mirror in an antique gilt frame or a good oil paint. ing, cither landscape or a lower piecc, inset as a panel can be usefully introduced in cases where space and sur roundings permit.

If the house owner should be fortunate enough to possess a hall or a living room with an inglenook, there is unusual scope for artistic treatment. Nothing lonks letter than a surround of good bricks at the sicles and on the chimney breast. These should harmonise with the hearth, of whichsince an open dog grate generally takes the place of the shut-in fireplace-a good deal will be scen. Tiles require careful solection. They look well in Chinese or hlue delft designs in small fireplaces, and with amusing figures on them are a bright touch for the nursery chimncy piece designed without a mantelshelf, the tiles being carried up to the frieze. Lustre tiles in harmonious colourings, with hearth and kerb to tone, are also suitable lor a Hat treatment.

The more architectural the chimney piecc, the less need for overloading it with extraneons ornaments. For a panelled room the beautiful treatment of the Jacohean chimney piece illustrated gives some idea of richness combined with simplicity. The Tudor arch of the fireplace made in nood, but In rger ones are in marble. can also he adapted, in a room where Adam atyle lireplaces arc adapted for rooms panelling is not introduced, to $n$ simple overmantel treatment of a plaster relief in a line design.

Chimney pieces in the 18 th century werc delicntely carved in low relief or inlaid with the central interest of the rooms. Some were colourd maibles. See Bow II are.

## China and China Collecting

## The Quest and Care of Old and Modern Pieces

Other entrics to be consulted include Crockery; Faienc:; Pottery and those on the various kinds of china, c.g., Chelsca; Crown Derhy; Sẻvres, cte.

Modern china is so good decoratively that, decoration nud colouring fiom Nankin poree whet her required for ornament or use, many lain to modern Copenhagen. Others, again, people prefer it to old pieces for their homes, as they can select it to liring out an exact note of colour desired in a room. There is also not the same worry over breakages. On the other hand, china collecting is an interesting hohby when the amateur does not think that any list of old china, however indifiement. is better worth huying and hoarding than a beautiful piece of modern work.

Old English chinn, if porcelain be meant. covers a period of about a century prior to the Great Exhibition of 1851. But many collectors roam farther afield, and regard all the products of the kiln, in every age and place, as fit objects for study More thrifty and practical lovers of old china, content to explore patiently the byways which still exist, may in time nccumulate quite desirable and instructive possessions. Some may specialise in memorial ware recalling historic personages and events. Others may concentrate on bluc-and-white, tracing the course of

Chimney Piece. Typical Adam style chimney piece, barmonising courlexy of conullit tife with classical decorative schemes, as in the onc above. The Idam brothers employed Italian cruftsmen to work on marble mantelpieces
c.
faience, painted on the enamel in emulation of the achievements of Chinese ceramic artists. It is distinguishable from true china by the lark hue of the hody, often perceptible beneath the mughnesses of the base.

It was the use loy mediernl Chinese potters of fusible felspathic rock, similar to chinastone, in conjunction with infusible china clay, that led to the invention of true porcelain This is conted or glazed with a mixture of the felspar and lime, the whole being fired at a high temperature. It is vitrcous and resonant. breaks with a shell-like fracture and camot be seratched by steel. The secret of this haril porcelain was discovered in Europe 200 years ago at Dresden; in England its production was practically confined to Plymouth and Bristol

The old Seves ware on the other hand, was a soft paste porcelain, employing artificial fusible frits, having a granular fracture, and a surface that crumbles under the file. This was the parent of Bow and Chelsea. A great advance was made in England lyy introducing hone-ash. When this was used with a mixture of chinastone and china clay, without the old soft-paste frits, there resulted the bone porcelain, of which, since about 1800, the best linglish china wares have licen made
An intermediate form, called stoneware. is partially vitrified hy hard tiring, and when thin may lie semi-translucent. Its main defect is a tendency to crack with sualden changes of temperature. It was produced in the 17th century by John Dwight at Fulhan Out of it developed Staffordshire salt glaze, and afterwards Werlgwood black basalts and jasper ware. W'ith these fabrics may be classed ionstone china, semi-porcelain, opague china. and other efforts to secure a durable material withont incurring tho risk and cost of intense liring.
In the 19th century the Creat Exhibition of 185 I served ns a turning joint Parian or ungla\%ed statuary porcelain had just been invented, Nintons had reproduced Della Kohbia and P'alissy ware, and Irish iridescent porcelain was being made at lBellcek. To the previous half-century belong many of the ald heirlooms treasured in present-day homes. including examples bearing the famons names of Spode and Copeland, Havenport and Adams, Conlport, Swansea, and the llintons, not to speak of the new wares introduced by factorica established long before, such as Iongton Hall. where Stationlshire porcelain originated
Old Chelsea and Bow. To the 18th century belong many landmarks in the progress of the ait But among all the productions of that age lovers of old china are the fondest of Chelsea warc. liecause of its charm and historic appical. Owing to its remoteness fiom our own day it is not abundant, and the homes of Chelseal and Bow china are no more.

Some 18 th century factorics, notably Worcester, Derlyy. Wedgwood, and Sévies, are still active. No European ware earlier than the French soft-paste of the end of the 17th century ranks as porcelain. Such fabrica as Greek vases, Rhodian howls, Samian ware, Persinn glass-glazed dishes, ancient Egypitian faience, and neolithic pottery, wre a collector's or student's separate studies.

Large quantities of inexpensive porcelain are turned out in present day China and Japan for the export market, some of which arc effective. Examples of the great periods of oriental porcelain, from the Sung and Ming dynastics to Kang hisi and the 18 th century emperors, together with Arita porcelaincommonly called Imari ware-and other fabrics of Japan, tend to become rare and costly.

China Marks. The various devices used by potters for identifying work, whether it he porcelain, stoneware, or earthenware, are
 1751-69. 8. Chelsea-Derby, 1769-80. 9. Crown Derby, 1780-1815. 10. Bloor, 1815-39. 11. Derby, modern. 12. Chinese ${ }^{8}$-charaoter mark 1723-36. 13 and 14. Plymouth, 1788-72. 15 and 16. Bristol, 1770-77. 17, 18, 18. Worcester. 1751-83. 20. Cbinese dedicatory mark meaning 23. Séves, 1754 24. Dresden-Meissen 17ia 25 Cone

26 Japancse labric mark, Imari ware, 1800 usually painted, stamped, or incised upon the have become discoloured by hard water can base before the final firing. They may be cleansed by rubhing fine emery-paper over denote the place of manufacture, such as the stains, and afterwards washing them with Swansea, the master potter, suoh as Spode, the workman or decorator, such as G. T. for George Tinworth, or the date, as in some periods of Sevrcs.
On Chinesc porcelain the datemarks usually consist of two charactess, meaning period made, together with two for the emperor's name, making a four-character mark. Sometimes two othery, denoting the dynasty, are added, thus forming a sixcharacter mark Japanese wares differ from Chinese in usually having potters' marks, which are sometimes dated, and nssociated with armorial hearings.
Much old work was unmarked. while, on the other hand. the presence of a standard mark on certain pieces may be actually proof of their being lakes There arc marks of indication, apart from trade devices, which connoisscurs regard as surer tests. Such are the grain of the surface, the tint and imperfections of the glaze, the roughnesses on the base, the glassy moons seen in Chelsea ware before 1757, or the substance itaelf, as revealed by fractures.

Often undecorated pieces, after being produced in a famous factory, have been sent clsew here, either by their makers or by dealers, to be decorated and tinished, and in such cases the marks, original or copicd, have led to much uncertainty. Thus Chelsea imported genuine hodies from China for completion, and Siveres biscuit pieces were at one time sent to Coalport for the same purpose.

How to Wash. In washing china, plenty of hot watcr. space, and clean, dry towels are essential For ordinary household china a good sonp powder should be used in a large howl of hot water If the china is greasy, $n$ handful of soda should be thrown into the water The water should be changed as soon as it becomes cool and cloudy or greasy. Alter washing rinse the china in clean water.
The washing-up bowl must not be crowded with articles, as this leads to ohippings and cracks. A dish-mop on a stick is the most suitable appliance for washing plates and dishes. A dishcluth that is used in the hand is better for cups and small articles A rubber scraper is useful for greasy dishes.

In the washing of china to which value is att nched, a folded towel or thick, clean duster ahould be placed at the bottom of the bowl to protect the articles from the risk of getting clipped or cracked Neither sodn nor soap powder containing soda should be used when there is gilt or much red colouring on the china, as the action of the soda is sometimes injurious to such ornamentation. A few drops of
ammonia or a dessert spoonful of borax should be used instead. If the chinn is badly stained a little powdered fuller's earth should be applied on a cloth. For sufety the lewest possible articles should be placed at one lime in the bowl A small log's hair paint brush may be used to clean raised ornament or porcelain figures. Such aiticles should not be allowed to become really dirty, and should be rinsed after being washed, and then drained and dried. Tea stains can be removed from ohina cups by being rubbed with crushed salt on the dish. cloth. Flower bowls and toilet jugs that
trong soda-and water In putting awny china in the cupboard, sancers and plates should be stacked in separate piles that are not too high. Cups and jugs, when not hung on hooks, should have the handles facing outwards in order to avoid accidents.

Packing of China. When packing china no piecc should be in direct contact with any other, or with the walls of the packing case, and the packing material should be resilient and shock-absorbent. There must not be any gaps in the packing material, which should fill all spaces between the china. These requirements are met by the use of snwdust, old crumpled newspapers, straw or felt. Complete the work by filling in all gaps with more paper and atraw, and have a layer on top at least 2 in thick. Finally nail or screw on the lid. Give the box a good shake to ascertain if the contents are safc. If a rattling or clinking sound is heard, it will show that some of the china has been displaced, and this will necessitate repacking.
When packing china or any other articles for removal, it is well to remember that the removal contractor will not accept responsi. bility for anything that is not packed by his own men.
CHINA ASTER. One of the easient Howers for amateurs to grow, the China aster is a universal favourite in all gardens. Seedlings miay be raised outside in April, but stronger plants are obtained by sowing in a frame or greenhouse in February or March, always provided damping off is avoided. The seedlings

Cbina Aster. Bowl of double blossoms of various colours, purple to pink and white Courlesh of Sulton \& Sons. Led
 pink $\begin{aligned} & \text { Rose. } \\ & \text { monthly or China rose }\end{aligned}$ makes a good hedge. See Rose
ure planted out of doors in May. Great care must be taken not to over-water the small plants. There are many types and varicties of the annual aster with single or double flowers. The prim double blooms of the Victoria aster are still popular for exhibition and bedding, but for decorative effect and for cutting the Ostrich Plume, anemone Howered and Comet varieties are superior. The singlc Chinn aster is also charming. In each type there ate varieties of ruse, purple, mauve, socalled scarlet and other shades. If sown in May in the open, potted in mid.Sept., three in an 8 in. pot, and placed in a cuol greenhouse, Victoria and other dwarf types will bloom throughout the autumn

Asters attacked by the black-leg diseasc, whioh turns the base of the stem black, should be uprooted and burnt. If this trouble has been experienced grow the plants on a fresh site, lime the soil and spray them with liver of sulphur, 1 oz in 2 gallons of water.

CHINA ROSE. The popular name China rose is given to Rosa Indica sempertlorens, or the monthly rose, so called because of the continuity of bloom. In mild districts, if planted against a sunny wall, the old pink monthly rose will bloom more or less all the year. China roses do well in beds in a sunny plare: they should be pruncd lighitly. The best varieties are Armosa, pink; Comtessodu Cayla, reddiah yellow; Laurette Mesaimy, rose and vellow; White Pet, white. The variety Fell e nberg, which is rosered, is more vigorous and

CHINA TEA. There are about a dozen varieties of China tea, divided into two classes -green and black. It is paler in colour and less highly flavoured than Indian and Ceylon teas, and not infrequently it has n perfumed taste and aroma. It may generally be described ns being a delicate, fragrant variety of tea. It is sometimes medically advised for people with weaker digestions. See Tca.

CHINCHILLA: The Fur. The fur of the ohinchilla, which is soft and thick, from to light grey in colour, darkly mottled on the back, and slinding into dusky white below. As the chinchilla is becoming extinct and the skins are very small, they are very valuable. Becnuse of its fragile nature, combined with its bad wearing qualities, chinchilla ranks amongat the most expensive of furs. Sce Fur.
CHINE. When trimming the brond piece of bone at the end of a loin of nutton or ribs of beel or pork, the butcher is fre. quently asked to chine

1 and 7 British Museum; 3.6 and 8, Victoria \& Ałbert Museam; 2, courlestl of Royal Crown Derby Porcelain Co., Ltd.
it, or saw off the chine-Lone it should be noted that, as this piece ol hone will have been weighed in and charged for, it should be delivered with the joint for use in the stockpot or stew

A chine of pork is a favourite joint for roast ing: it is the piece between the head and shoulder, and should be carefully jointed before cooking. Or, if liked, the chine may he slightly salted, boiled, and sent to table with a pease pudding and some green vegetable. It needs to be cooked slowly in plenty of water and skimmed thoroughly to rid it of any superfluous fat. Chine of pork should be salted for a few days before it is cooked

CHINE. Satins, taffetas, ribbons, and also cotton materials are described as chind when printed in a blurred and shadowy-coloured design. The printing is done upon the warph, or lengthwise, threads before the cloth is woven. The weft threads are not printed, and they half conceal the design, tone down the colouring, and account for the softncso of effect

CHINESE STYLE : In Furniture. The threc ornamental features used in Chinese furniture are the cloud form, the dragon and the fret. All three may occur on the same piece of furniture the commonest is the cloud form, and it may be found practically alone in phairs, settces, and joes tables. To the unpractised eye the cloud form looks nore like a conventional spiral suggested by the smail whell. The dragon and the fret, much conventionalised, are more easily recognized in forms approximating io those their names would suggest Chinese fumiture is commonly made of darli rosewood prolished to a patina resembling hone.

The Chinese atyle in English furniture became popular in England when Thomas Chippendale took it up and exploited it with his Chinese Chippendale furniture, examples of which are rare and valunhle This furniture contains what to English people appear as more typically Chincse features than those alrcady mentioned, many of them oltained from architecture The principal one is the pagoda form, which Chippendale and other cabinet makers of his day employed in curved chair and settec backs, cabinets, beds, and wardrobes

Chinese Sigle. Lacquered and gilt bedstead in the form of a paroda : Englisb, c. 1760
Victoria \& Albert Museum, S. Keusington
 then, but quite frequently being applied by glue to the solid. Occasionally a conventional rendering of the dragon's head will be seen carved on the terminals of chair arms.

Nluch of the so-called Chineso furniture used in England in the late 17 th and 18th centuries was made of lacquered panels im ported into Holland and England and made up into cabinets on earved and gilt or silvered stands This style had much intuence on that of Chippendale (q.v.). See Decoration.

CHINTZ. Being a glazed cotton material, printed in several colours, usually 31 in . in width, and dust-resistant, chintz is suitable for bedroom upholstery. It may be used for linings for langing wardrobes, and ottomans. Old English designs are best in this fabrie with its suggestion of coolness and cleanliness.

Being a stiff material, chintz requires much minnipulation in upholstery work, especially when making loose covers. Careful planning is therefore advisable before starting to cut it out. Instend of gathering or folding the surplus material into pleats, as in the case of thin cretonne, a dart should be made by cutting awny the material where any fullness occurs and sewing the edges into a fine point.

In laundering chintz it is advisable to add bran water to the first washing water. Bran water is made by boiling for about half an hour $\frac{1}{2}$ pint of hran (placed in a muslin bag) in a quart of water. This addition helps to stiffen the material and to revive the colours of the pattern. Chintz should be starched in boiling. water starch. See Upholstery.
CHIONODOXA (Glory of the Snow). A pretty spring flowering bulb suitable for planting in the rock garden or in grass. Luciliae, blue and white, and sardensis, blue, are the chief sorts. The bulbs should be set 2 in deep in September. Pron Cio"-no-düksa.

CHIP CARVING. This art, which is done with a sharp-pointed knife, has nothing whatever to do with the shaping of the article, the pattern consisting of simple $V$-shaped grooves or excavalions cut in the surface just as lettering or figures niay be eut in a flat surface of stone. Designs, which are usually geometrical, are produced in this way in order to ornament what would otherwise he plain surfaces.

Examples of various cuts alo illustrated in Fig. 2. Before commencing on actual worli it is hest to practise on waste pieces of wood Draw pencil lines and try to follow them accur ately with the knife or with a chiscl. Is scen in Fig. 2 , the $V$-shaped trench may have square ends, sloping down at the same angle as the sides, or may curve or narrow up to a point at the ends. In other cases the excnvation may be a small triangle with its three sides sloping to a point at the bottom. A number of these are gencrally cut in a series forming straight lines of the pattern. Examples are shown in Fig. 1.

Nore elaborate forms of chip carving are shown in Fig. 3. The method is the same in detail, but the complexity of the design is increased. Two trenches side by side may have only a ridge between, corrosponding with a single line on the surface, or there may be a flat hetween them necessitating lwo linps in drawing the pattern.

After the desion has been draun on the "ood the lines are followed with the knife sloping. so that when at the correct depth the edge of the knife is midway between the surface lines. First one side is cut, and then the slope of the tool is reversed for cutting the other Instead of reversing the knifo it is often more convenient to turn the work round. In a long trench the chip can he removed when the
second side has been incised, but in the case of a triangle, or square end of course, a third incision is necessary to release the chip.
Matcrial for chip carving should be evenly grained, quite free from kinots or splits, and soft enough to cut easily without imposing too giest $\pi$ strain on the hand while manipulating the knife Lime and American whitewood are both excellent for the purpose: they are light in colour, pleasant to handle. and the white wood is particularly amemable to treatment with water stoin. Articles adapted for ohip carving include wall bracketa, medicine and other cabinets, and occasional tables: the tumeiy departinent of any large store is a hnppy hunting ground for suitable subjects Similar articles are also available with a design ready traced upon them. Varieties of chip carving knives are shown in Fig. 4, the one most commonly employed heing that which is bent in relation to the handle

A straight cut may rult with the grain on across it or diagonally, and in either casm the knife can travel along it in the direction which suits the grain. In following a curved line it may be necessary to reverse the direction of cutting once or twice to avoid tearing up the grain In a diagonal cut the linife muat trave one way on one side of the trelich and come back the opposite way on the other.

The bread board shown in Fig. 5 is a simplu example of chip-carving and may be made by any woodworker. It measures 1 ft. 2 in over all, and should be cut from $\frac{3}{3} \mathrm{in}$. or 1 in material, sycanore or becch heing suitable. The full size design may be set out from the particulars given at Fig. (f, the main lines running to the centre as shown. It is Iransferied to the wond by meane of carbon paper The principal lines should be veined. The cige should be finished with a pronounced chamfer Sec l'retwork; Woodcarving

CHIPPENDALE STYLE. Thomas Chiゃ pendale, a cabinet maker, who died in 177!), gave his name to a style of furniture which has lieen generally admired for its beauty of design. Gentine specimens command very ligh prices, while good imitations are valued One authority lins laid down the following useful hints for recognizing Chippendale

Cbippendale Style. Mahopany banging shelves showing influence of Chinese design. made c. 1750-60. Right, characteristic fref patterns used in lurniture decoration

Hu permission of the Dircelor, Vieloria \& Alher

furniture: "Chippendale furniture is made tahles, basin slands, wine cooleis, mirror most frequently entirely of mahogany with frames, writing-tables, brackets, wardrobes, carved enrichment and no inlay. Its construc- bureaux, secretaires, tallboys, candle stands, tion is sturdy but its omamentation often exceedingly light and fragile. Most of it shows skilful exploitation of curvilinear forms. Fretted or pierecd ornamentalion is common, and in general the atyle of the decoration follows Lonis XV' models. In colour old Chippendale furniture is inclined to brown, often hecoming decp chocolate with an almost metallic-looking patina It is never a hot red.'

The following articles are found in old Chip pendale: chairs, stools, setters, commodes, dining tables, side tables, hodkcases, card

Chippendale Style Left, portion of mahorany book case, showing use of fret. Above, typical armebair with cabriole lers and claw and ball feet
Courtixy of llarlug \& Gilloni, 1.1,l
clock cases, olina cabinets, lire screens, tei caldics, bedstends, and chests of drawers.
la far as can lie ascertained, Chippendale never made a sidehoard, as uc underatand the term, and evell his side tables rarely have a drawer in them. Spanish mahogany, which was carefully selected, was used by him for most of his pieces, but some of his designs were carried out in carved and gilt wood. Chippen. dale's chairs and tables had square or cabriole legs, the latter not infrequently terminating in a claw and hall foot. Foliage and scralls, t. Tophies of musical instruments, and frat work carved out of the solid wood and cut separ-ately-not applied, as was the custom with reproductions-are some of the fentures which characterise his cabinets. Mirror framed were divided into compartments by acrolls. Rigures and animals were introduced

Chinese Chippendale. Ifter the middle of the 18th century Chipmendale varied his furniture designs to fall into line with the prevailing Chinese mode. We have the lattice work backs of cliairs, pagodas on tops of bonkcuses and cabinets, fretioork of Eastern patterns. and other details which give the style to Chineac Chippendale

Later in the century French designs came into fashion, and Chippendale's work accoid ingly became more rococo. We have the interlaced riband-liacked chairs sometimes with a free treatment of the lover's knot ornament, and generally scrolls and foliage were carved with a lighter hand See Antiques; Chair: Chinese Style: Table, etc; also illus. p. 163

CHIPS : A Potato Dish. The secret of making chips lies in having the fat so hot that a hlue vapour rises from the pan, and in well draining the potatoes beforc frying After peeling the potatoes wash them well in cold water, as this washes awny the starch and prevents the chips aticking together in the pan. Slice the potatoes lengthwise. Wipe them dry with a clean cloth, then put them in a wire baskel, plunging the latter into a saucepan containing sufficient hot fat to cover the potntoes. Fry them until they are orisp and lightly browned, turning occasionally to make sure that hoth sides are cooked

wide, the most useful s being $\frac{f}{f}, \frac{3}{4}, \frac{1}{2}, ~\{$, and $t$ in and $1 f$ in. wide A variety of the same class is a long. thin paring chiscl (Fig. 2), intended for paring or cutting across the grain and working in deep holes Both are rectangular in section, and are also made with hevelled edges.
Mortise chisels (Fig. 1) are extra strong. and made from $\frac{1}{6}$ in. to $\frac{1}{2}$ in. in width, for cutting mortises. 1 drawer-lock chisel. indispensable for culting recesses for drawer locks, is an all-stecl double-ended tool.

Good chisels should be clean and straight, all bright parta of uniform colour and texture, and the bevelled end straight and evenly ground. The carver shape of handle shown in Figs 3 and 4 is smooth in contour, and generally made of boxwond. The plain beechwood or ash handles, as in Fig. 2, are larger in diameter, and give n good grip. Mortise chisel handles are more tapered

Before a chisel can be used it must be sharpened or set. This is done by first grinding the bevel to a uniformly flat surface and square at the end. When grinding a chisel the grindstone should be turned to-
cqually. Lift out the basket, and drain the potatoes in this for a minute before turning them on to a soft paper so that they may finishi draining. See Potato.

CEIIROPODY The treatment of the feet in order to keep them healthy and confortable is a very important detail of the toilet, and the instruments employed for the purpose nust be scrupulously clean. Scissors, files, scalpels, etc., should be placed in boiling water and then soaked in a solution of disinfectant.

The toe-nails should be kept well trimmed, but they ought not to be cut too short. They must not be cut in a curve like finger-nails, but straight ; if cut down at the corners they develop a tendency to grow in at the sides. which is injurious and painful. If an ingrowing toe-nail makes its appenrance, $n$ notch should be cut in the free edge of the nail. As the toe-nail grows this notch will fill up, and the pressure of the nail at the side of the toe will be relieved.

If the sport at which the nail is growing in is very painful, a little piece of cotton-wool that has been dipped in boric powder should be gently pressed under the nail. This nust be renewed daily, and will raise the nail so that the edge does not cut into the tlesh. See Bunion; Corn ; Foot. Pron. Chi rop'ody.

CEISEL: How to Use. In woodwork chisels are most important among the cutting tools. Those known as firmer chisels (Figs. 3 and 4) are most genernlly employed, and are sold in eleven sizes, from ${ }_{1}^{1} \mathrm{i}$ in. to $1 \frac{1}{2} \mathrm{in}$.
wards the operator. The chisel should he held firmly and squarely on the stone near enough to the top edge of the latter to allow the tool to be in a nearly horizontal position, with the bevel lying flat upon it. Holding the tool two low, so that the handle points downwards, will cause the water from the stone to run on the hands of the operator. The chisel should be constantly moved across the edge of the stone to wear the Intter evenly. It is then rubbed along the face of a good-sized oilstone, at a slightly steeper angle than that of the bevel (Fig. 7) This produces a shorter

Cbisel. Fir. 8. Enlarred view of the cutting edge when corrictly set, showing the smaller bevel lormed by rubbing the edge on ollstone hat on its back few strokes on and rubhing it off (Fig. 8). A few strokes on both sides, putting on little pressure, will result in a perfectly clean and sharp edge. Chisels must be maintained in this state by rubbing on the oilstone from time to time as they become dull or blunt.

The quality of work done with a chisel depends upon the correct handling of the toolHowever good a chisel or sharp the edge, no
satisfactory work can be done unless the fiandle is properly held Gencrally speaking a chisel should be used with both hands. The right grasps the liandle and directs the course of the tool, and also supplies the energy for its propulsion (Figs. 5 and 6). The left is used to grusp the blade near to the cutting part further to control and direct the cut. By far the greatest amount of work is done in one of four ways. These are: chiselling with the grain of the wood, paring across the grain, paring acrass the end grain and at right angles, and by oblique cutting partly ncross and partly with the grain.
In chiselling with the grain the tool is held at a small angle and simply propelled forwards, laking care not to let it dig in, by making judicious use of the left hand In paring horizontally across the grain, work from one side of the job towards the centrc: reverse the job and work from the other side, and linally clean up the surface flat and tiue, making diagonal cuts to nid in the Hattening. Test the work with a square at frequent intervals.
When paring across the end grain the tool is held upright and the cutting edge applied near the end and side of the wood, starting the cut with a slight side-tilt on the chisel, and bringing it up straight as the cut proceeds. The right shoulder should be elose to the top of the chisel handle, and the whole strength of the arni, shoulder, and liack put into the cut. One shonld never attempt to cut off too much at a time; repented light strokes produce better results. In oblique paring always work downhill-that is, cut with and across the grain. Do not attempt to cut against or up the grain, as the result will be ragged work and splita in the wood.

The not of using the chisel is only acquired by practice, and the amateur is advised to begin with simple johs, such as the shaping of a hexngonal pieco of unod, say 6 in . across the flate and 1 in. thick. If accurately chiselled to shape, and square and true on all its faces, this will be ample evidence that he has passed his novitiate. See Amateur Carpentry; Bench; Wond Carving, etc.

CHIVE : Its Culture and Use. The plant grows in a thick cluster of small bulbs with grass-like, hollow leaves. If an old clump is pulled to pieces in spring, and the separate plants are set $n$ few inches apart in a line in n fairly fertile soil, freali clumps are soon formed Where no old clumps are available, seed should he procured and sown, as if for

Cbive. A plant of chives, valued for its milld onion flavorr in salads and soups
onions (q.v.). The clumps reguire to be renewed about every third year. The leaves are cut close to the ground occasionally in order to ensure a full supply of young ones
Use In Cookery. The chive is a very useful varicty of the onion tribe Though small, it lias an exceedingly powerful Havour and should be used in cookery with caution The young leaves are often minced, and when freshly cut the flavour is delicate and forms an important inyredient in French salads They are also used as a pot-herb, and chive sance is much liked with roast meat or grills

To make this sauce, put a gill of fresh breadcrumbs into a saucepan with 2 oz. butter. Cook them over the fire until a pale gold, when $\frac{d}{d}$ pint stock and 3 tablespoonfuls tinely minced chives should lee added. Stir while it boils for 5 min ., season it with salt, pepper and a tiny dust of grated nutmeg, and it is ready to serve.

CHLORAL or Chloral Hydrate. On account of its soothing effect on the nerves and power of inducing sleep, chloral or chloral hydrate is often prescribed. Nevertheless, it exercises a depressing effect on the heart, and must be used with the greatest caution: if taken for any length of time it may result in a chloral habit that will be very difficult to shake off. It should not be taken by anyone suffering from kidney disease, and never except on a physician's prescription

CHIORODYNE. For relieving pain chlorodyne is a proprietary remedy very commonly used. It is useful in colic either with or without diarrhoes, and when this appears to be due to indigestible food a dose of castor oil should be given at the same time. It may also help an irritable dry cough. It should not be given to infants or children without medical advice. The symptoms of poisoning are those of opiun, and the treatment is the same. See Poisoning.
CHLOROFORM. This drug is widely used in medicine on account of its properties of inducing loss of consciousness and preventing pain and shock during surgical operations or in childbirth.

The compound tincture of chloroform and morphine is somewhat similar to chlorodyne, and is used in the same way. The dose is from 5 to 15 minims. Chloroform water is a pleasant diluent for other medicines, as it has a somewhat pungent odour. The dose is fluid oz.
Chloroform liniment is frequently used as A BC liniment, which is a mixture of the liniments of aconite, belladonna, and chloroform. This may be rubbed on the part, or it may be applied on lint covererl over with gutta-percha tissue. It may be used in muscular rheumatism or in neuralgia

Spirit of chloroform may be used in flatulent dyspepsia, and may be comlined for this purpose with a third of a teaspoonful of bicarbonate of soda dissolved in a little water. It is also used in cough mixtures. A single dose is from 30 to 40 minims; a repeater dose is from 5 to 20

CHLOROSIS. Women and girls who follow indoor occupations are liable, under certain conditions, to suffer from chlorosis, which is a form of anaemia and is also known as green sickness. The patient becomes breathless on exertion, as in climbing stairs The complexion may not sliow any marked change, but more frequently it has a greenish tinge. Constipation and digestive troubles are common. Examination of the blood shows a large diminution of its colouring matter, haemonglobin. The treatment consists in the administration of iron, a convenient form heing freshly made Blaud's pills, increasing from one to three, thrice daily, and frequent doses of Epsom salts. See Anarinia.

## Chocolate Making at home

## Recipes for Some Popular Varieties of Confections

Other articles dealing with Sweer-making include Fudge: Swests; Toffee. See also Cocoa; Decoration; Ieing; Sugar, cte

With additional cocoa-butter and fine sugar carefully incorprated cocoa becomes chocolate. Without the sugar it is known as unswectened block cocon, of which only the best should be used. Table cocoa must not be used for swectmaking.

Although impossible to make first-rate chocolnte without machinery, a good eating chocolate may le propared as follows. Put 1 lb . of unswectenerl block cocos in a small pan and place this inside another containing water. Slowly melt the cocoa over gentle heat, stiring well, and taking care that no svater comes over. Arld 1 lb . icing sugar, stir while this melts, and then thoroughly mix the two together. Run in 4 oz . melted cocoabutter, and beat the mixture vigorously
The contents must not be allowed to rise above blood-heat. Remove the pan from the warm water, add essence to taste, vanilla, kirsch, maraschino, etc, and keep stirring and beating till the chocolate becomes almost solid. Allow it to stand for several hours, then remelt it as required, never letting it get much over $88^{\circ} \mathrm{F}$. or $31^{\circ} \mathrm{C}$.
If the chocolate is to be poured into tin moulds, these must be warmed to be of the same temperature as the chocolate, and should be clean and lorightly polished to get nice glassy sweets. Once moulded, the chocolate should be cooled as rapidly as possible: otherwise it will be spotted and dull in appearance

Milk chocolate is prepared as ordinary chocolate, but with the addition of 4 oz . full-cream milk powder to the amount mentioned above

Harel nuts, shelled, blanched, and well roasted in the oven, are used for nut chocolate. The hazels, while still slightly warm, should
be stirred through the chocolate just lemore pouring, which in this case should be as nearly as possible at its setting point.
I great variety of chocolates are prepared by dipping sweets, known as centres, in a specially prepared chocolate. These centres, which inay be either of a hard or soft nature, are made of fondlant, variously coloured and flavoured, and also of fruit paste, caramel, nougat, marzipan, and nther inixtures. Effective decorations can be devised from angelica, artificially coloured nuts and sugars, and crystallised flowers.

The prepared chocoflate required for dipping is known as couverture, and it has to be melted down with the greatest care, for therein lies the secret of success. The correct temperature, too, when once attained, nust be preserved throughout. With too hot a couverture, the sweets becone grey; if too cold, the couverture is muddy, the dipping slow and tedinus, the coating heavy, and the finished sweet of unattractive appearance.

In dipping centres, wire forks or loops should be used. The pan with the chocolate, set in another contnining warm water, should he in front of the dipper, with the centres on the left and highly glazed papers or brightly polished tins, on which to place the finished sweets, on the right. The centre is dropped into the chocolate with the left hand, and picked up with the fork in the right; the fork is tapped on the side of the pan to spread the coating evenly and remove any surplus, then drawn along the side to prevent "feet" on the sweets, and the covered centie laid on the paper or tin, Unless to be otherwise decorated, each sweet is ornamented with n twirl or line.

Cbocolate Confectionery making. 1. The cream or other centre is dipped in liquid chocolate, and then as in 2, placed on tin to be decorated with a whirl, made, as in 3, with a little chocolate twisted round with a sweet fork. 4. In making a trofete the chocolate and whipped cream are mixed; the sweet is then rolled in the bands and dipped in chocolate powder
made with the fork as the dipped centre is laid on the paper. All manner of centres may be dipped thus.

After each of the centres has lieen dipped, the chocolate in the pan should he well stirred otherwise therc will he layers at different temperatures and the swcets will be streaky Couverture which runs very freely is too warm. It should set almost immedintely the sweet is placed on the paper and show a gloss. The dipping sloould be done in a dry room, with a temperature of about $\mathrm{f}_{\mathrm{j}}{ }^{\circ} \mathbf{F}$ Only the best cocoa-butter should lie used.
Almond centics are propined hy shelling $\frac{1}{2} \mathrm{lb}$. swect almonds and putting them on a baking-tin in the oven until they are slightly browned. When they are quite cold, dip, them in couverture, and leave them on an oiled tin to harden.

Chocolate truffes are rich, soft chocolate centres dipperl ip grained chocolate or dark, unsweetened chocolate powder. For each ounce of chocolate allow one talilespoonful of cream and a teaspoonful of coffec or vanilla essence. Nould the trufles with two terspoons and toss thein in the grained chocolate until they are coated; linish by placing them in fancy sweet cases.

Nougat centres are prepared by putting ( $\mathbf{o z}$. strained honey and 2 oz. glucose into a small pan, and setting the latter inside another containing hot nater. Stir the inixture till it is quite hot. In another pan hoil 1 lh lump sugar with $\frac{1}{2}$ pint water, and also a pinch of cream of tartar, to $\because 90^{\circ} \mathrm{F}$. While this is boiling beat up the whites of three eggs to a stiff snow, which should just be ready when the sugar reaches the requisite degree. Add the boiling sugar to the egg whites, stirring vigorously all the time

Next add the honcy and glucose, place all together in a double hoiler (one large pan inside another will (lo), and keep on heating gently and stirring vigorously till it becomes quite stiff. Idd a few blanched almonds and ghacé cherries, warmed and cut up, and pour the whole into $n$ tin or wooden firme lined with wafer paper. Cover it with wafer paper, place a honrd on the top, then a heavy weight: let it remain thus for 24 hours, then cut it up.

Orange crea $\quad$ II centiea are made by adding to the grated ind and juice of a carcfully sclected, deep coloured orange
sufficient icing sugar to make a stift paste Idd to this a $\frac{1}{2}$ teaspoonful of citric acid dissolved in a few drops of "ater, and mix all well logether. Form the inixture into small balls, or other shapes, and dip them.
To prepare Turkish delight centres, dissolve very slowly together 1 oz . of ground gelatine, 4 oz . of glucose, 1 lb . of honey, the juice of one lemon, and a full $\frac{1}{2}$ pint of warm water. Bring these carefully to the boil, stirring all the time, and boil for 10 min . Flavour and colour the mixture according to taste, and put it out into bright tins, rinsed out with cold water. When cold cut it up into squares.

Marzipan equares are made by dividing I Ih. of warmed almond-paste into three parts. leaving one white, and colouring the others pale ycllow and pink. Flavour the white with vanilla, the yellow with lemon, and the pink with rose or raspleerry. Roll them into sheels, and lay one above another. Cut them up into aguares and set them out to dry before dipping
Fruit Centres. To prepare Iruit-paste centres, bring to the boil a little apricot jam, stirring it all the time. lemove it from the

Chocolate Cake, covered with chocolate icing and decorated with pistachio and other nuts
gas or lire, inix in an equal quantity of tinely cut preserved pineapple, and drop the mixture with a spoon in small drops on some glazed paper. When these are set, stick them together in pairs with stiff jam or jelly, and allow them to dry thoroughly.
Chocolate fruit dominoes can he made by finely chopping a cupful of shelled walnuts, halif a cupful of ligs, and the same quantity of stoned dnten, and adding to thiem the grated rind of an orange, a tablespoonful of orange juice, and a square of melted, unsweetened chocolate. Tum the mixture on to n hoard sprinkled with powdered sugar, and roll it out to one-third of an inch in thiciness. Cut the paste into the shape of dominoes, using a sharp knife : coat these thinly with melted chocolate, and decorate with small pieces of hlanched almonds.

The ingredients required to mako chocolate caramels are $\$ 11$. chocolate (scraped fine), I cupful brown sugar. 2 cupfuls Sreacle, I cupfu
inilk, and I piece butter the size of an egg Boil these in a porcelain saucepan, stirring all the time, till the candy hardens when droppell into water. This sliould take about hour Stir in I tablespoonful of vanilin extract when the saucepan has been taken off the fire and the mixture has stopped bubbling. Pour in n aliallow, oiled tin : Icave candy to set and marl: into squares.

CHOCOLATE : The Beverage. When pussible, this should he made with a French chocolatière, which, by reason of a small heater device that passes through its lid, enables the chocolate to be casily whisked while cooking. A good drinking cliocolnte can be made by grating two large bars of plain cliocolate into a pan, and adding to them 1 heaped tablespoonful of white augar and a teaspoonful of the hest comflour or arrowroot. Nix these ingredients smoothly with a breakfastenpful of water, and let the whole boil gently for 5 min Then stir in I breakfastcupful of milk, bring it to the boil and serve it in cups, alding, if liked, a spoonful of whipped cream on the top of each. See Cocoa

CHOCOLATE BISCUIT. These are ex cellent for afternoon ten To preparc them, dissolve 2 oz grated chocolate in a small tablespmonful of water. Put 2 oz. margarine in n hasin, work it up with n wooden spoon, and add 3 oz castor sugat, beating the mixture to the consistency of cream. Mix in the dissolved chocolate, beat in an egg, then add the vanilla and lastly if oz. sifted llour, stirted in lightly Tum the mixture on to a lloured board, and toll it out into a thin sheet. Cut it into shapes, and bake these oll a gieased tin in a moderate oven for 12 to 15 min .

CHOCOLATE CAKE. First of all \& 16 cach of butter and castor sugar are creanlied together. Then the volks of $\geq$ eggs are beaten in, 3 oz . each of grated cliocolate and lour. and $\frac{1}{2}$ teaspoonful of laking powder

Chocolate Cream Mould. set in an ornamental shape and turned out in a glass dish
adder, and tirally the whites of the 2 eggs heaten to a froth. The mixture is haked in a moderate oven for 1 hour and may he covered with chocolate icing if desired, top and sides sprinkled with chopped nuts and centre decorated with pistachio nuts.

## CHOCOLATE CREAM MOULD,

favourite party sweet is made from $1 \frac{1}{2}$ oz. grated chncolate, 2 oz. sugar, $\frac{1}{2}$ oz. gelatine, and $\frac{1}{2}$ pint of slightly whipped cream. Put the gelatinc into a saucepan with enough water to melt it, and add the chocolate and sugar, together with a little milk. stirring the whole till dissolved. Whip the crean slightly, mix it with the rest of the ingredients, after they have cocoled alightly, and put all into a wet mould to set.

CHOCOLATE ECLAIR. These iced cakes are made with $\frac{1}{2}$ pint water, 3 eggs, 4 oz . flour, 1 oz . sugar, 2 oz . margarine, a pinch of salt, a little whipped cream and anme glacé icing. Put the watcr, salt, sugar, and margarinc into a saucepan over thie fire, and, when thicy hoil, add the llour. Stir the nisture until it beconies
a soft paste and leaves the sides of the saucepan. Then take the pan from the fire, and add the eggs separately, beating each in well. With a forcing tube lay the paste out in shapes measuring about 4 in . long on an ungreased baking-tin. Bake these for 20 min. in a moderate oven, and when they are cold split them open at the side, and fill them with whipped creain sweetened and flavoured with vanilla. Ice the top of the éclairs with glacé icing This quantity is sufficient for about ien éclairs.

CHOCOLATE ICING. In making a simple chocolate icing, $\frac{1}{2} \mathrm{lb}$. icing sugar and 3 oz . grated chocolate are mixed together with 2 tableapoonfuls of hot water or milk. A ylacé for fancy cakes requires more sugar. Cook 2 oz. grated vanilla chocolate in $\&$ pint of water in a pan, then add 1 lb . icing sugar with 3 tableapoonfuls warm water. The nixture should be poured warm over the cakes

CHOCOLATE PUDDING. A baked pudding requires 1 pint milk, 3 cggs, 2 tablespoonfuls each grated chocolate and castor sugar, a few drops vanilla, and 1 oz . cornflour l'ut the grated chocolate in a saucepan with f pint of the milk, and boil the two together until they form a smooth paste. Then mix the cornHour with 2 tablespoonfuls of the cold milk, and add it, with the rest of the milk, to the chocolate, and stir the whole till it loils. Draw the pan to the side of the fire and beat up the 3 yolks of eggs and stir them into the cooled mixture, flavouring with the vanilla. Pour the whole into a buttered pie-dish, bake $\frac{1}{2}$ hour, and then beat up the whites of 2 eggs to a stiff froth. Add half the sugar lightly, and heap it over the top of the pudding, sprinkling the rest of the sugar over all. Bake the pudding very slowly.

CHOCOLATE ROLL. Cream together 3 oz . each sugar and hutter, and aieve together $f$ lb. Ilour and 1 teaspoonful haking powder.

Cbocolate Roll. An attractive $S$ wiss roll for alterRon tea covered with chocolate

To the former mixture add 3 eggs, beating each in separately, and lastly fold in the flour and haking powder, together with a little milk if required. Pour the mixture into a shallow greased tin and cook for 10 min . in hot oven.

In the meantime, put $\{\mathrm{lb}$. jam into a saucepan to warm, and when the sponge is ready, sprend it with the jam, and roll it up immediately. When the cake is cool, ice it uith chocolate butter prepared with $\ddagger \mathrm{lb}$. butter, 9 oz. icing angar, 2 oz. grated chocolate, 2 tablespoonfuls milk, and a little vanilla Havouring. Cream the sugar and butter, and add the chocolate (dissolved in the milk) and a few dmps of vanilla. Pour the icing into an icing bag and force it fmo a shell-shaped icing tube in straight lines from olle end of the roll to the other.

CHOKE This is an electrical apparatus consisting of an inductive winding which offers a path of high imperiance to the flow of alternating currents, the impedance or A.C. resistance increasing with the frequency.

High-frequency chokes, as used in wireless receiving apparatus consist of a great number of turns of fine wire, wound so as to have a bow distributed or self-capacity : they may be employed for coupling purposes in high-frequency amplifiers or in circuits of the capacity reaction type Special heavy duty high-irequency chokes are sometimes used in mains eliminators to isolate the receiver from stray high-írequency currente, which may produce diatortion and other troubles

A good H.F. choke may be constructed by taking a 1 in . diameter ebonite former having six slota, each slut being $\frac{1}{b}$ in wide and $\frac{1}{2}$ in deep. These slots should be spaced $\frac{1}{1}$ in. apart and filled with No. 36 S.S.C. copper wire.

Low-frequency chokes have an irun or nickel alloy core, and are employed in lowfrequency magnifiers, and alan for smonthing purposes in minins units. A suitable value for an output filter, or smoothing choke, is 20 ) henries at normal working currents, and the winding should have a D.C resistance not exceeding 500 ohms. See Eliminator : Filter, Inductance ; Impedance : Reaction.

CHORING. One of the commonest causes of choking is when a fish bone gets stuck in the throat or when a morsel of food goes down the wrong way. Artificial teeth may get fixed at the back of the throat or in the gullet, obst ructing the air passages, and fragments of child ren's toys have been a source of danger.

Unless the patient is unconscious he should be made to kneel on a chair with the head downward and the body weight supported on the hands on the floor. In this position he should attempt to cough the obstruction out of the windpipe, while at the asme time he should be given a fou smart blows between the shoulder blailes. If these means are notsufficient to remove the obstruction, the mouth should be prizel open by some hard object thrust between the back teeth, such as the handle of a spoon guarded by a handkerchief Then someone should thrust his forefinger well to the back of the throat as far as possible, and sweep it across the base of the tongue in an attempt to dislodge the obstruction. If there is any difficulty in affording relief, the doctor should be sent for at once. Artificial respiration may be necessary if breathing has ceased. See Artificial Respiration : Asphyxia.

CHOP : How to Cook. The accepted meaning of achop is a small cut of mutton, lamb, pork, or veal taken from the luin. When cut from the tail end it is known as a chump chop. Chopa cut from a very fat loin are westeful, and as the price is high a good butcher will trim them carefully. They are beat grilled or broiled. Lamb chops are cooked a, those of mutton: they are more delicate in flavour, but should be well done, while many people prefer a mutton chop. slightly underdone See Grilling: Mutton

CHOPPER. Two types of ohopper are in general use-the long, nariow pattern used for chopping wood, and a broader-bladed kind for chopping meat. A French kitchen knife, however, with its fine point and deep hilt, is better than the straightblacled knife, and two or three of theae are most desirable implements to have in the kitchen.

All that a chopper requires to keep it in good order is an occasional grinding. The edge can be kept in good trim

Chopper. Above is shown the broad-bladed implement used for chopping meat: below, the narrow pattern employed for wood chopping
by whetting it on an wilstone slip. A wripe over with an oily rag prevents the blade going rusty : a loon mund the handle makea the chopper easy to hang up.

The correct method of chopping meat intu small pieces is to hold the point of the chopper or knife firmly down on the ohopping-hoard with the left hand. and with the right work the handle up and down. now and then collecting together and tuming over the tood being chopped with the left hand, thus ensuring speed. See Parsley: Suet

CHOPPING BOARD. Desirable qualities in a ohopping board are rigidity, solidity. a smooth surface, and toughness to resist wear. It should, therefore, be made of " solid piece of hardwond, such as heech, birch, or maple. Convenient sizes are 14 in long, 12 in . wide, and 2 in or more in thicknese Four holes, about $i$ in diameter, drilled near the corners on the under side of the block and filled with ordinary bottle corks, leaving $\frac{1}{1}$ in protruding, ensure the board resting firmly and, by providing a certain amount of resiliency, facilitate the chopping.

Chorea. This is the medical name of the complaint known as St Vitus's Dance (q.v.).

CHOW CHOW. A clever and kind. hearted dog, devoted to his owners and endearing himself to their children, the chow is

Chow Chow. Cbampion of the Chinese breed ol dog
a spirited gurdian of tho house and a distinct ornament to it. With his handsome cont of dark red, black, vellow, white, or blue, he wears a fur ruff around his neck, and the plume that serves for a tail is ourled far over his hack. His small, pointed ears are carried stifly erect, his dark eyes are almond shaped, muzzle broad, and tongue blue-black. His weight is about 40 lb ; that of his mate a few pounds less See Dog.

CEOOWDER. Cod or fresh hadidock may be used, if lb. heing cut up into small pieces witin $f \mathrm{lb}$. each of peeled onions and potatocs, cut in $\frac{1}{2}$. cubes Trim and cut 3 oz. of pickled pork into the same sized pieces, and fry the pork and onions until they are a light brown. Put potatocs. fish, onions and pork in a casserole in layers, adding 2 sliced tomatoes, and seasoning and powdered herher hetween each layer. Putato should be on the upl.

Pour in 1 pint of stock, cover it and simmer for 20 min .

Heat $\frac{1}{2}$ pint of milk and break into it three watet llowers extending the full width of the front biscuits lant these stand for 3 min Stir int, the chowder. boil it once. and serve it in the casserule.

CHRISTENING. This term is used, osperially by certain Nonconformist budies, for the religious rite more generally known as haptism.

Christening Robe. The usual length is $4 t$ in.. and 3 yards of double width nuterial is sufficient Ancfiective robe can be made by utilising a piece of Brussels or Honitun lace in pancl form from the yoke to the edge of skirt. Tiny tucks and insertion finish the rest of the skirt A benutiful gown can be made with solf.cmbroidery- $\Omega$ finc spray of

## Christmas and its Merrymaking

## Preparation of Seasonable Fare and Suitable Decorations

Further information will be found in such articles as Artificial Flowers: Cracker. Sce also Children's Parly and entries on Card Tricks: Coniuring

Preparations for Christmas are a serious or joyous matter according to the spirit in which they are tackled It is far better to give simpler presents, fare, decorations and general entertainment than to attempt expensive elaboration, which will not make for happiness owing to strainel nerves or over-taxed resources.
Most children love assisting with anything to do with Christmas festivities; also they like preparing presents, secret alopping and doing up their prorels. In the latter connexion the continental hathit of packing up gifte in special coloured and patterned papers, with tinsel or hollysprigged ribbons and attractive reasonable labels and seals, is one which delights children. and thesc little extra bits of de coration cost only a few pence. Purcels sent out or arriving in Christmas wrappinge with merry labels b earing the instruction "Not to be opened til! Decen. ber $25, "$ are much more exciting than drab brown paper packages

The modern chilat is apt to be incredulous of Santa Claus and of Futher Christmas himself hut is willing to do a little makeI elieve for the ocrasion. Therefore, in many houscholds on Christmas Eve, whensmall people have given up the futile effort to lie awake in il the arrival of Santa Claus, the stocking is filled and Christinas gifts are placed on the table by the bedside. This also has the advantage of keeping children busy until the elders are prepared to start the day; whereas, if the gifts arc to be placed on the breakfast table, the whole house is astir before dawn. It is usunl, especially where there are children, to have the Christinas dinner served in the middle of the day. 'This has advantages when evening refieshments have been cleverly plamed to take the form of a helpyourself supper of ready-prepared dishes, as it allows the staff to have the cvening off with their friends. If the Christmas party is a family gathering, prohably after dinner games suitable to all siges will be included in the programme. Everyone enjoys a few conjuring tricks, if the host is able to do a sliort series of these. In addition it is well that $n$ fow records of propular dance successes should be forthco:ning for the gramophone.

The Christmas menu may be simplified to grapefruit. consommé, flavoured and coloured by tomato and served in cups, roast turkeychosen with due consideration for the size of the party-atuffed with cheatnuts in the body and sausage ment in the crop, accompanied hy cranberty sance, celery, of salal and linked potatoes, and followed by those essential featurcs of a Clirist mas dinnei, plum pudding, mince pies and special dessert It is often found better to carve the turkey in the kitchen beforeland, arranging it nicely on a dish to the kept hot until scrved. Some. times roast goose is preferred to turkey. If not too fat, garnish the goose with chipolata sausnges and serve with rpple sauce

The table should be charmingly laid and decorated with as much colour in the schenc an taste permits. The big howl of Iruit, surrounded by acsarlet or silvered candles. in glass or silver candlesticks, and by smaller sweet dishes with brilliantly coloured crackers inter. apersed, can be recommended where Howers are where Howers are
frosted Christ mana hard to obtain. A small frosted Christman
tree on a centre piece of silver paper, outlined with holly leaves, or a snow man guarding a big bundle of crackers may lic liked. If a tablecloth is urad it should be a festive one, or mats of lace are always right, or an embroidered runner is suitable for a long, narrow table. Place cards and menu holders carried out in seasonable designs add a finish. ing touch of gaiety.

Christmas Decorations. Some people like to decorate their houses throughout, others are content with an arrangement of evergreens in dining room or hall and sprigs of holly for the table.

With many decorations ahout great care should be taken to sec that there is no danger from the fire or any candles. The latter should only be used for the table or high up on a chimney piece out of possible danger of heing knocked over. Wall decors-

Christmas. Fig. 4. Wall decoration of paper-covered hoops joined by coains. Fis. 5. Tuese are held up at intervals by wands topped by big brusbes made of strifs of coloured paper

On the apex of the trec the Angel of Pence is symbolised as a fairy doll, with glittering crown and wings and sprcading galuze akirta. A pretty touch is to let strands of tinsel fringing fa! np. parently from the doll's hands to festoon the hranches. The girls generally dras lots for the fairy doll at the cnd of the proceerlings Large toys and presents, if to be given at the same time, should be placed at the base of the tree. The tree should be lighled up a few minutes before the children are ndmitted, and all other lights turned off. In many houses it is kepit until New Year's Five, when it is lighted up again about a quarter of an hour before midnight (o) welcome the New Year.

## CHRISTMAS CARDS.

 There are not many households that do not send out and receive a few Christmasto form the neck, and keep the twist tight The loose end of the paper will form the body Having cut a atrip of paper, 2 in . wide and 4 in . long, the elastic way of the paper, $t$ wist it up very tightly to form a rope. With a stiletto or sharp-pointed scissors make a hole through the body just liclow the neck. If the rope of paper is inserted into the hole at one side and twisted. it will pass right through and form the arms The legs are made similarly from a strip of paper the same width and ahout 5 in. long, and are run through the body 1 in. below the arms. 'The doll is then made ns in Fig. 6, rendy lor dreasing.

For the skirt, cut lengths, 9 in. by 4 in ., of two colours of the crinkled paper. Paste the ends of each together and put one of the rings so made inside the other. Slit the top of both narrowly to a depth of about $\}$ in. to form the fringe, then alip in the little figure and gather the skirt closely and evenly round it, so that the base of the fringe comes just below the arms. Bind it round firmly with a doubled strip of paper about $\ddagger$ in. wide to make the belt. Press the fringe down so that the under colour ahows, and stretch out the bottom of the skirt to its fullest extent. The top skirt should now be cut up nearly to the waist, into strips $\frac{1}{2}$ in. wide. All that is needed to complete the ligure is n bow of narmw paper pasted on the head and the face inked in. Such little figures made without lege ean be mounted on sticks.
Christmas Tree. For the children the most exciting decoration is often a Christmas tree. Sometimes this is of cut out painted plywood set into an imitation plywood tub. Toys, etc., are hung on the tree by means of tiny screwed. in hooks, and the tree is set flat against the will. It obviates mess, but is rather a poor njology for the regulation fir

With any candle-lighted Christmas tree there is risk of fire, for which reason a long pole with a sponge at the end should be kept ready with a pail of water to extinguish the candles as they burn down. Because of this risk, many people prefer the tree lighted with coloured electric bulbs.

A fir tree standing about 6 ft . high takes two persons several hours to trim effectively. Ornaments mado from silver, gold, and coloured paper should fill up odd spaces and trim the tub, or whatever the tree is placed in. Special shining ornaments are sold by the dozen and can be wired on the branclies effec tively, with chocolate animals in silver paper, baskets of swcets, little dolls, niniature fumiture. cruckers, and light worden toys.
cards. They are often elaborate and heautiful, but the personal card with printed namo and address of sender, either specially designed or chosen from stock patterns, is increasingly popular. Miniature calendars are also frequently used. If the envelopes are left unscalerl, Christinas cards can be posted at printed paper rates.
CHRISTMAS PUDDING. The basin in which a plum pudding is biled must be quite dry and well greased. Fill it up well and tightly with the pudding mixture, and tie down over it a sealded and floured pudding. cloth, leaving a fold to allow for swelling.

A pudding for six or more persons requires boiling for at lenst 8 hours. Small ones require less in proportion, 3-4 hours sufticing for a 1 lb . pudding; but, in any ease, long boiling does no harm. If several puddinga are to be cooked in the same sauccpan, put them into boiling water at intervals of a minute, so that the water is not cooled too much, and replenish with boiling water as it boils awny. Puddings can be made months before use and stored in a cool, dry place; to re-heat them let them stand in boiling water for 2 hours or more.
The following is a recipe for a gond rich pudding. Mix well together 4 oz . Hour, 3 lb . breaderumbs, $n$ small teaspionful salt. $\frac{1}{2}$ lh.

Cbristmas pudding turned out ready to serve and decorated with DJwdered surar and a sprig of holly
chopped beef suet. and a flat emspoonful all spice Stone $\mid \mathrm{lb}$. raisins or use $\hat{d} \mathrm{lb}$. of seeded wash and piok over carefully $\} \mathrm{lb}$. each of currants and sultanas and atir them into the Hour, ctc Add 3 oz ench of candied orange and lornore peel and $\mid$ oz citron, cut into thin strips, 2 oz. ruughly chopped siveot nimonds and, if desircd, 2 nz glace cherries Mlix in alan ] Ib. moist sugar, and the grated rind and juice of $\frac{1}{2}$ a lemon. Beat up 3 egge, and mix "ith them 2 dablespuonfula rum, 1 tiablespoonful brandy, and 4 tablespoonfula ale or stout Pour this liquid on to the other ingredients. and the more thoronghly it is atirred the tetter. Lenve it for about an hour, and it is then ready to be put in the basin and boiled. This will make a pudding which will be large enough for 10-12 persons.

Hor a plainer puddings ehop 1 lb . of beef auet very fincly. Clcan and pick over $\frac{1}{2}$ thench of curriants and sultanas, nad stune and chop roughly $\frac{1 b}{}$ baisins. Mix them in a larga bisin with $\frac{1}{2}$ th noist sugar, $\frac{1}{} \mathrm{lb}$. Ilour, $\frac{1}{2} \mathrm{lh}$ breaderumbs. a little salt and a saltspoonful

Cbristmas Rose. Cluster of fowers and leaves
of Eelleborus niger
of allapice. Ped and core $\{\mathrm{lb}$. apples and chop them tinely, or put them thmugh the mincer. Blanch anil shred $1 \frac{1}{2}$ oz. sweet almonds, and cut 2 oz mixed peel into thin strips. Add these to the other ingredients, with the grated rind and juice of $\frac{d}{}$ an orange and $\frac{1}{2}$ a lemon, and mix well in. Beat up 3 egge, strain them on to the other ingredients, and mix. Ald $\ddagger \mathrm{pt}$. of stout, and enough milk to matio the mixture drop from the spoon. Let it stand for an hour, then put into basins, tie down, and boil. If mude into one pudding, this will be enough for 10-12 persons.

To serve n Christmas pudding, turn it out on a very hot dish and pour over it brandy sauce, or hand round brindy butter separately. Alternatively, jour a little brandy over the pudding just before bringing it to tablc, and set it alight. Decornte it with a sprig of holly. Ready-made puddings are sold by most hrocers and provision dealers, and all they require is $n$ few hours' immersion in hot water. See Brandy Butter; Brandy Sauce.

CHRISTMAS ROSE. Helleborus niger, commonly called Christmas rose, is n nember of the buttercup family. It is $n$ hardy perennial which thrives in partial shade in deep sandy lonmy soil. When transplanting becomes necessary it should be done in July; the clumps ought to be broken into several moderate-sized pieces. The finest varicty is named altifolius (maximus). The blooms are protected by covering thom with a handlight.

## Chrysanthemums and Their Culture

## The Characteristics of Many Different Varieties

In addition to the entries on Aster und other favourite flowers, consule general appropriate articles as Borders; Greenhouse, etc. ; also gardening notes under headings of the various months, c.g. April

Few llowors equal the chrysanthemum in will bloom freely in early nutumn. During popularity, for even in small gardens beautiful the summer months the soil between the diaplays of bloum can be obtained with very little trouble during the monthe of September, Octuber and November. It will llourish in beds and borders, but still more under glass, where the flowering period is prolonged into winter. so that it is practically the last of the great plants to bloom. No plant better withstands impurities in the air, and consequently the chrysanthemum is successfully oultivated in town gardens.
There are many types of chrysanthemum: some of them are suitable for cultivation uut of doors, others in pots under glass Among them are several hardy border perennials, e.g. the shasta daisy or hardy marguerite (varieties of chrysanthemums maximum and (cucanthemum) which bear large white bloums on long stems in summer, and the moon daisy (chryanthemum uliginosums), a tall plant with greenish-white fowers in September Japanese, incurved, decorative aud single Hlowered ohrysanthemums are gmwn in pots to supply blooms under glase in autumn and winter. Early or border chrysanthemums flower out of donns from August to October. Annual chrysanthemums, of which seeds are sown out of doors in March, llower in summer.
The horder chrysanthemum is hardy in all except cold districts, is easily managed and hlooms profusely in late suminer and autumn. It is a llower for every garden. Present-day varieties are innumerahle, and every yenr fresh ones are introduced: they bear double or single blooms in crimson, rose, yellow, jink. orange, bronze, and many other shadea of colour.

A start should be made by purchasing small plants in May and setting them out at 18 in. apart in a sunny place. Ortinary soil which has been well dug suits them; some clecayed stable manure and a scattering of bonemeal should be mixed in. In á fort night's time the top of each plant should be pinched off to make it branch out; the fresh shonts should le stopped again in June, but not after that month or the blossoming season will be too late. This treatment will ensure the development of well branched planta that
 plants should be hoed frequently, and it will be necessary to stake the planta securely in order to prevent the shoots being broken or becoming misshapen.

Although most of the plants will pass through an ordinary winter safely, especially if covered with old ashes, it is wise to lift a fow of them, cut down the stems, and set them in boxes of soil in a cold frame; in early spring fresh shoots will grow, and thesc are used an cuttings to increase the stock. They whould be severed slighitly below the soil surfíce, trimmed just beneath a joint, and inserted in jots or boses of sandy soil in the frame. If the latter is kept closerl and the soil moistened occasionally the outtings will form roots in 3 or 4 weeks. They will be ready to plant out of doors M May,
Border
Border chrysanthemuma may be left out of doors undisturbed for two or cven three years if large plants bearing an abundance of bloom are wanted.

The following are some of the best varieties. llowering in August September
Afterglow, terra-cotta : Charlotte Harley, crinnNon: Cranford, yellow: Crimson Circle, redl: dimald Dame, yellow ; Oumen Gold. Yellow ; Mme. Deskranges. White: Miss Matfie. yellow; Mrs. Thnope. ned: Suracen, amler: Shlrley Bronze, bmize jellow.

Raising Specimen Blooms. For the oulture of large hlooms the plants, grown in pots under glass, should be out down immediately the llowers have faderl, and the shoots growing through the soil will form the cuttings for new stock. Place the cuttings round the edges of pots containing a mixture of sandy loam, first dropping a pinoh of silver sand into each hole. Put them under a handlight or propayator in a greenhouse temperature of $50^{\circ} \mathrm{F}$

Well-inown growers who specialise in the chrysanthemum may be relied upon to supply excellent young plants in the spring. They must be given plenty of air, and they must not be grown in a temperature higher than $50^{\circ}$. Their proper place is in an airy house close to the light. A 3 -in. pot may be used, and the compost should consist of four parts loam, two parts leaf-mould or well-rotted manure. and one part silver sand

It is a good plan to make the potting soil fairly moist, and it is then unneccssary to water the plants for a day or tivo. By the beginning of April the plants will be well rooted, and should be put into 6 -in. prots, the compost being rougher and a trifle heavier The newly potted planta should be put back in the frame and kept fairly close for a day or two until the roots have begun to push out into the new material: but the pota must not be crowded. When the planta are again grow. ing well give them a sheltered position in the garden, and do not allow to become dry.
The final potting, which is clone in Juno, is a detail of importance. Flower-pots, 9 in. iride, are suitable for most varieties. The compost should consist of pieces of loan (old turf) twóthirds, well decaved manure one-

Chrysanthemam. Double variety of border plant
thirl with a scattering of sand and onished brick, and a sprinkling of superphospliate of lime or special chrysanthemun eertiliser. 'The compost must be made firm with a woodeu rammer and a space of about 1 in . left at the top when potting is finished. The best position for the plants is on a sunny gravel wulk. Each plant must le staked.

Different varieties need different treatment in respect of stopping and taking the buds. Often the chrysanthemum produces a flower bud in May: this, which is known as the i,reak hud, perishes and fresh shoots which will form the branches grow from beneath it. If this break bud does not form, the top of the plant must be pinched off to cause the development of other shoots. Usually not more than two or three of these are allowed to grow.

In August each one will bear a flower bud which is called the first crown. If the variety produces its best blooms from first orown buds, these нге "taken" by remoring the small shoots that grow bencath them.
If, however, the variety yields its best blooms from second crown buds, one of the small shoots beneath cach first crown bud is allowed to grow; the bud itself will perish. Each of the new shoots will, in due course. produce a flower-bud-t he second crown

Amateurs will get the best results from most varieties by stopping the plants in April or

Chryganthemum. Diagrams illustrating the method of raising from outtings. 1. Poor, and 2, good cuttings. 3 and 4. Incorrect and correct places to make cuttings. 5. The fish is served frequently well. in the casserole and garnished with little branched plants are sippets of toast. ohtained Stopping should not be done after June. The yhoots must be ataked and tied with great care. The final potting is done in June.

There are soine beautiful singleflowered varieties wihich bloom under glass in lateautumn: they need the same treatment as the decoratives. A fow of tho best are enumerated below:
Ceddic Muson. crimaon: Exinouth P'Ink Pusilier, hright crinusn: Godfrey's Trlumbh, yel low: Mary Richarilan. terra cotta: I'hyllia Comper yellow: Nanlown Ruading.

May, and taking the first crown buds in Auguat. If the shoots beneath the second crown buds are allowed to grow they will subsequently bear buds which are called terminals because they terminate the season's growth. Amateurs who grow for large blooms should consult the chrysanthemum catalogues which give the correct bud to take for each variety.

When the buds are developing the plants must be fed once a week alternately with weak soot water and with one of the special chrysan. themum fertilisers used according to the directions supplied. Towards the end of September the plants are placed under glass where the hlooms will open from November. onwards. The glass house must be ventilnted very freely in mild weather.

The Japanese varieties are grown to provide the largest blooms : not more than from one to three are left on ench plant. The following are first-rate varietien

Dawn of Day, reddish vellow: Duchess of York, rose-purple: Helena Maraerison, nink Indy Talbot, primroac : Loulsa Porkett, white : Majestic Edith Cavell , maronze yellow Michn. reddiah bronze roae: Mrs. K. C. Pulling, yellow ; Peace, yellow Princesa Mary, yellow: Queen Mary, white: T. W. Pockett, silvery pink, very large: Vlacount Chinda. yellow: W. Turner, illite : W. Ligby, ycllow.

Many new varietien are introduced each уеar.
Incurved varieties which need similar treatment to the Japanese are now little grown except for exhibition. A few of the beat are
Buttercup, yellow: C. H. Curtia, yellow ; Lady ranbel, blush; Ondine, white tinged witll green

Decorative chrysanthemums are splendid Howers for amateurs: they are douhle and of medium size. One plant will produce six or more blooms. The plants should be stopped in April or in June, the firat crown buds being "taken." They can be planted out of doors for the summer and carefilly lifted and repotted in September, though they do better if grown in pots throughout the season. They bloom under glass in late autumn. A few attractive varieties are
Aldyth, crimson ; Baldcock's Crimson: Blunche Poltevine, whlte: Cisshury PInk; Denember Gold, jellow: Dr. Finguchard, rose plnk: Exinouth Crimson, H. W. Thorpe, white; Jesn Pattison, copper salmon: Mmic. E. IRoger. greenish; Mra. R. F. Felton, crlinson; R. H. Pearson. yellow Wellington Wack, primrose.
These varieties can be grown to form large apecimen plants, each bearing from 40 blooms upwards. Cuttings should be taken as early as

Other types of chryaninthemum are the pon pon, anemone-flowered, and thread-petalled. The latest novelty is the cascade chrysan themum, which is of somewhat drooping growth, bears small single llowers and misies a most decorative pot plant.

Aphis or tly attacks chrysanthemums, but can be destroyed by using one of the numerous proprietary insecticides. Earwigs maydamagethe huds; they should be trapped in small flowerpots filled with hav and placed, invertêd. on the chrysunthemum stioks; the traps must be shaken over hot water every morning.
Rust and mildew are plant diseases which may dainage chrysinthemums. On the first sign of infection the plants should be spraycd with liver of sulplıur, 1 oz. in 2 gallons of water. The leaf mining maggot often disfigures the leaves by boring. Maggats can he deatroyed by pinching the affected parts of the leaf between the finger and thumb.

CBUBB: The Fish. Casserole cooking is

Cbuck. Figs. 1-2. Showing construction of taper screw and prong chuck

CHUCK : Its Uses. In its simplest form this is a body piece adapted to screw on to the spindle of a lathe or mandrel nose, as it is termed. Projecting from the end of the body is a tapered and coarse-threaded screw, on to which is screwed the piece of wood to be turned; such a tool is known as a screw chuck (Fig 1). When the work is long, like a baluster rail, and is supported at the ot her end by the tailstock, n prong ohuck (Fig. 2) is the proper tool to use.
A drill chuck has movahle jaws actuated by a screwed part of the body, a usual and chenp pattern like that illustrated in Fig. 3 being commonly found on hand drills, braces, and small drilling machines

A useful and inexpensive variety of chuck. known as a dog chuck, is shown in Fig. 4. The work is held by the short set screws; the posts, or doge, in which they turn can lie inserted in any of the holes in the borly or faceplate. Such a chuck can be used on " simple lathe, and will also le found of service for holding work under a drilling machine, or while otherwise working upon it.
A popular chuck for amateur une is a thrce jaw self-centring scroll chuck (Fig. if). This tool automatically centres the work. Two sets of jaws enable a wide range of interna or external work to he hield very securely
Chucks should always bo kept clean and free from chips. especially the working parts. threads before screwing the chuck on to the mandrel nose, no any chips or dirt in the threads will make it jam or run out of truth. See Centre: Lathe; Mandrel; Metal Turning;

## Vood Tuming.

CHURN : For Making Butter. One of the simpleat churns consists of a glass jar or vessel with a nickel-plated screw cap, and a wooden beater actuated by means of bevel the best way with this freshwater fish, which gears and a crank hundle. It is readily somewhat resembles a carp. The fish abould be washed in vinegar and water and thell sliced: 2 or 3 small onions are sliced and fried in butter, and 1 pint fish stuck added. vith a rlessertspoonful of mixell herbs and seasoning. The fish is allowed to simmer in this for 1 hour, then lifted out, and kept

cleaned and requires little attention heyond occasiona! oiling of the gears and spindle.

The barrel type of chum consints of a solid hardwood fraine provided with roller or other bearings, on which is supported a steel shaft rotated by a crank handle. A hardwood barrel with a remov. able lid at one end is attached to the shaft, and is rotated

end-over-end crank handle isturned The method of fitting and securing the lid is of importance in this class of churn. In some, a num lier of screw clamps are used to press the lid home in another, $n$ cam actuation is used to hold the lid in posi tion. Some harrel churns are supplied without a dash or benter; others have various forms of patent devices, such as the diaphragm.

Churns should be kept in a condition of scrupulaus cleanliness. and preferably in a cool and equable temperature. There is virtually nothing to go wrong or to require special attention in a good churn. Sce Butter.

CHUTNEY: The Condiment. Taken as a relish with hot or cold meat dishes. chutney is an Indian condiment, of which there are many varictien, such an Bomhay, Madras. and mango chutneys. The ingredients include raisins or mangoces, cayenne pepper, ginger, spices, and lemon. Several kinds of chutney can be inade at home with applea, tomatoen, marrows, etc., recipes for these being given under their separate headings.

## Cicatrix. See Scar.

CIDER : How to Make. The apples should be gathered in dry weather, of as even a degree of ripeness as possible, but just before they are quite ripe. Decayed, damaged, or worm-eaten apples must he rernoved and the atalks picked olf. Keep the apples about 14 days in a dry, well-ventilated place, and make the cider in cool weather. The making is done in three processes, the apples are crushed to a pulp or pomace, the juice squeezed out, and linally fermented.

For crushing, take a very atrong, ironhooped tub, about 18 in . in diameter, put in enough apples to cover the bottom, and pulp them by means of a heavy hardwood bruiser, not unlike that used hy a strect pavior. Pound a few apples at a time, and see that the bottom of the tuh is well supported on the ground so as not to risk splitting it. The pulp should le continually removed from the tub as crushing proceeds.

For pressing, a strong huireloth or coarse canvas sheet-a cloth called netting shading is the best-3 to 4 ft square is used. The pulp is spread evenly over ahout 18 in . square in the middle, and when alrout 3 ins deep the sides of the cloth are folded over the pulp; then another cloth is placed on top of this and more pulp packed in that. In this way, a cheese, as it is called, is huilt up, the number of canvas sheets depending on the size of the press.
The simplest form of press consists of two linged hoards, the pressing leverage on top being obtained by using a soout pole; this is a erude way of pressing, but has been used hy cottagers. Wooden presses are made very like those used for copying letters; so long ns the bare iron does not come in contact with the apple juice, the latter might serve as presses for a small cheese. The press has to atund in a tray or tuh to catch the juice, and from this tray or tuh the juice is run into a cask.

If one man pounds the apples while another does the pressing they can between them make

Churn. Left, showing and-over-end diaphragm churn romed in order to show the dash or beater
remor Courlesu of Thomas Bradford \& Co. . l.ld

10 to 11 gallons a dav, and this amount will take ahout 180 lb . of apples, or less with a good press. It is not ahoolutely essential that the pulp should lie pressed the same day as it is made; some keep it 24 hours, as it is raid to improve the vield: but there is danger of vinegar acid forming by too long exposure to the air and. in any case, the extra yield is doubtful.
As a rule apple juice is left to ilself to ferment, the yeasts present on the akin at crushing being suflicient, as in the case of the grape ; but in small fermentations it is usual to start the fermentation with a little brewers' yeast. This is advisable, because it can never lie foretold how long apple juice will take to ferment; sometimes fermentation is complete in 10 days, sometimes not under six weeks.

Having collected. say. 10 gallons in a cask, inix 2 oz . fresh brewers yenst with $\because \mathbf{o z}$. honey and 1 oz. Hour, place it in a muslin hag, and suspend the lagg in the cask liy a piece of string. The cask must be supporterl on a stand so that a tub can be placed undemeath to collect the veasty frolh which works out of the bunghole, and the cask must be topped-up) occasionally to keep it full and allow the scum to overflow

As fermentation ceases and the cider shows signs of clearing. it is runs slowly and carefully into n clean cask. which is then bunged down and kept in a cellar at a temperature between 50 and $60^{c} \mathrm{~F}$. If the fermentation is very tumultuous, or if the cider is required sweet. the Iransferring to another cask (called racking) should take place earlier and lx repated tivo or three times, avoiding neration as much as possible. This tencla to stop fermentation and prevent the cider getting torn thin. 'Ihe rate of fermentation should be watched hy using a saccharometer and the casks should be treated with a sulphur matoh after cleaning. Sce Apple.

Cider Cup. To make cider cup, wlice 2 in . of cucumber very thinly, and put the pieces in a jug, together with I oz. cartor angar and a sprig of mint, pouring over them half wineglass. ful of alierry and a guart of cider. Then add 2 bottles of soda-water. Cover the jug, place it in ice or in a very cold place, and leave it for alout 2 hours. Then strain out the mint and cucumber, and the beverage is ready for use.

CIGAR: Choice and Varieties. It is not prossible to judge a cigar by the outside. The outside wrapper is very often made of tine leaf, and the inside filler of wheap leaf, or of scraps of leaf an! stalk rolled up together The only way to judge the filler of the cigar hefore smoking it is to cut through the cigar lengthwise. But if the cigar comes from a factory with a famous name, one can assume that the inside is of the samc puality as the outside. Then the proint to look for is an
oiliness or glisteningness of the wrapper. Spouts on the leaf are causod either by sunburn, or insect-bites on the leaf. They suggest by appearance that the cigar is not first rate hut, actually, they do not affect its amoking qualities at all.
If you place a cigar to your car and erackle it. all that it tella you is whether the cigar in very dry or not. and the crackiling may split the leaf! Some people prefer their cigars very dry, but the majority like them of medium dryncas. The smell of a cigar is a partial indication of its smoking quality : but a cigat which smells good does not necessurily smoke gorid.
As to the ash, if this remains firm for a long time while the cigar is heing amoked, it meana that the filler is comprised of long leaves, neatly arranged and rolled. It indicatea care in inanufacture, but is not a guarante of well-matured leaf. When the ash of a cigar is Hicked off, the point ahould be sharp and bright, not ragged and dull. A sharp and bright point indicates a well-matured leaf

Keeping Cigars. The proper keeping of cigurs is important. Choice tohacco leaf is extremely sensitive to atmosphere, and to odous in the atmosphere, and will readily absurb them and affect its own taste. Paint, for instance, and especialiy wet paint, will ruin any cigar or tobacco placed nenr it. Salt sen-nir will completely spoil n fine cigar. 'Therefor cigary inust be kept in airtight hoxes. Cedar-wood is the best matcrial for the box.

If cigars ares subjected to sudden heat they thmo off their natural moisture and essential nils which give the character and bouquet to the cigar. In appearance the cigar is not changed: fout in smoking quality it has becume very different. That is why cigars have to he kept at a fairly even, medium, and dry temperature in order to retain their condition. The best tempernture is between $60^{\circ}$ and $65^{\circ}$ Fahrenhcit. A fine cigar should be c:arefully lightexl-lighted all mund, so that it will hurn evenly and not raggedly. When cigars burn down one side first it is usually due to carcleas lighting.
The shape of acigar is a matter of individual fancy. Many people prefer the torpedo sliape ass a matter of appearance, of of comfort in holding the cigar between the lips; but in the shaping of such a cigar much good lasf hay to cut away to waste, and this makes the cigar expensive in proportion to the amount of leaf it contains. A straight shapie avoids this waste of cutting, and many of the linest Havanes ane mude in that form

CIGAR CASE. The cases which are made to hold it few cigars for carrying in the pocket are usually either of tewher or of metal. the former being lighter and, generally speating, more earvicuable, while in a metal case the cigas are more effectuslly protected from getting crushed or broken. Some leather cases have the edges reinforced with melal, and ot hers are padied to make them stiffer and less llexible. The most useful type in leather is made in two portions, one part containing the cigars, the other sliding down over the first, rand so making the case practically airtight. Nince this case does not require to he folded, the leather used can be much stronger, and a double thickness on either side lessens the risk of crushiag and overheating the cigars.

A metal case affords coinplete protection, hesides heing airtight. 'I'he chief diandvantages are the size and weight. The lightest type is fitted with grooves to take three or four cigars. The hollowing ont of the gronves makes for lightness, keeps the cigars separate, and so prevents the outer leaf from being damaged. A very small case is made to talie a single cigar. Aluminium is of little use for a cigar case, as it is a good heat conductor,
and may spoil the aroma of the cigars in a very short time. The ideal case is of silver, a metal which is lighter and harder than gold

CIGARETTE. The main varieties of cigarette are Virginian, made from blendings of leaf from Virginia and Carolina; Turkish and Egyptian, manufactured from leaf grown in Asia Minor and Greece; and Havana, made from the cuttings of Cuban leaf used in the rolling of Havana cigars. Cigarettes are also made from Rhodesian tobacco. Mixtures of Virginian and Turkish are also sold, generally under the title of Turkish blend or Egyptian blend. Turkish leaf is considerably more expensive than leaf from Virginia and Carolina.
Cigarcttes, like any other form of tobacco, are easily affected and spoilt by strong odours around them. They should be kept in condition in an airtight box, preferably of cedarwond. The best cigarettes aro rolled in very fine and pure rice paper, as thin as possible, so that no taste of burning paper shall apoil the taste of the tobacco smoke. Cheap cigarettes are rolled in inferior paper, to which saltpetre or other chemical is sometimes added to make it burn quickly. Many pcople prefer a cork tip, for the reason that it prevents fragments of leaf from entering the mouth
Some smokers prefer to make their cignrettes, and this is quite simply and easily done by hand All the outfit required is some light Virginia tobacco, which is mostly used, and a small packet of ricc-paper, which is sold either with or without a gummed cdge, some smokers preferring to dispense with the gum.
Cigarette Holder. The variety usually offered in cigarette holders is very wide, for they are manufactured not only in gold, silver, meerschaum, amber, and ivory, but more extensively in vulcanite, horn and bone, imitation amber and other compositions, or simply of wood

Among the more expensive sorts is the plain tube of real amber of varying length, with gold rin, and the silver-mounted meerschaum with amber mouthpiece. Ivory, tortoiseshell, and mother-of-pearl holders usually have gold mounts.

Plain holders are made of horn or bone in great variety as well as in polished wood, and the cheapeat of all are of cardboard with a quill mouthpiece. Imitation meerschaum and amberctte offer another variety, and compositions figure largely in the manufacture of many others, particularly the tube or trumpetshaped kinds, which are produced in many colours. The length varies from 2 in . to 6 in., or even longer, the average being about 3 in. to $4 \frac{1}{2} \mathrm{in}$. See Tobacco.

CIGARETTE CASE. The metals em ployed in making cigarette cases include gunmetal, as well as gold, silver, and platinum. The outer surface may be plain, but is more often engraved. Silver is largely used, and many beautiful cases are made from tortoise shell. Cheaper varieties nre of nickel, white metal, or papier mâché, frequently decorated with enamiel pictures. Most cases are flat, but some, especially those made of silver, are slightly elliptical.

Cigarette cases are also made of leather, and many smokers prefer this medium, as a larger number of cigarettes can be carried in a flexible leather case than in the rigid metal one. This also allows of several kinds of cigarettes being packed into one case

CINCHONA BARK. Quinine is found in the bark of the cinchona tree, which grows in S. America and elsewhere. The oflicial dose of cinchona bark is 3 to 15 grains, and more in malaria cases. The powder form may disagree with the stomach. Common preparations are given in the following doses

[^1]The action of cinchonn is practically that of quinine. The liquid extract of red bark is rccommended for inspiring in dipsomaniacs a distaste for alcohol. See Quinine

CINDERS. The cinders from as coal fire need never be thrown away. First of all they should be sifted through a fine sieve. The fine dust that passes through can he dug into the garden soil, while the coarser cinders should be used again mixed with coal. If the fire is meraly to be kept in till necded, a shovelful of cinders will keep it going. Fine cinders make effective garden paths; they lighten a heavy soil and make excellent drainage material in garden pots, and for the garden generally. Mixed with cement, a good concrete results. In country districts where no proper drainage exists, it is useful to filter waste

Waters, such as those from the kitchen sink through cinders contained in an old perforated pail. The solid materinls, such as grease, are retained by the cinders, and after a couple of days' use the cinders should be burnt and the pnil replenished. See Ashes: Path.

CINDER SIFTER. The cinder sicve usually measures 12 in . to 15 in . in diameter, and is made with japanned metal or wooden rim and blacked iron wire bottom of fairly close mesh. A heavier inake of about 18 in to 20 in diameter has an oak rim 4 in. to 5 in . deep and a straight mesh. In a superior make the strands are separately soldered to the cross supports. Apart from their use for cinders, such sieves are service able in the garden for sifting mould, earth and gravel.

## Cinematography in the home

## Mechanism of the Camera and Projector

Other articles dealing with domestic amusements, both indoor and outdoor, include Billiards; Bowls: Conjuring; Croquet. See also Camera; Gamophone

It is only recently that the taking and showing of cinema pictures has become a fascinating hobby within the means of the private individual. Previously the weight and cost of apparatus and the expense of using it were prohibitive. These obstacles have been removed by adopting a new kind of "reversible" film of narrower width, which allows the negative taken in the camera to be converted into the positive for showing on the screen. With the standard
a great variety of short moving pictures is the secret of success and pleassure with the amateur cine camera.

Along with the introduction of 16 mm . film has come an immense simplification of the cine camera. Cranking by hand, with the necessity of mounting the camera on a stout tripod, is dispensed with Instead, the amateur's cine camera is a neat little instrument which can be carried in a sling case or
film of 35 mm . (1才in.) width. as used for the picture theatres, the making of film for showing would cost about 5d. per ft., and as 1 ft . yielda enough pictures for only one second on the screen, the making of films of one's own works out at the rate of 25 s . for one minute's performance.
The pioneers in amateur cinematography, the Kodak Co. and Messrs. Pathé, introduced film of 16 mm . and 94 mm width respectively. The former has very largely become the standard width for amateur film. A spool of 100 ft . (equivalent to 250 ft . of standard film in length of performance) may be bought or about 25 s . incluaive of development and speed conversion into the positivelopment and speeds: the

Cinematorraphy; Fif. 3. The Autokinecam" which can be used at three different speeds
speeds : the (Fig. 3), which has three
speeds: the normal of 16 pictures per
sec. ; fast ( 64 pictures) for "slow-motion"" Thus for this expenditure one can talio a film asting over 4 minutes on the acreen This may not seem very long, but it is sufficient for filming from 30 to 40 different subjects. Experience has shown that a subject or scene with plenty of movement in it will be adequately rendered in from 6 to 7 seconds on the screen. A longer period tends to be wearisome :
 contains a clockwork motor which drives the film when a button is pressed There arc many leading makes, of which Kodak, Ensign, Bell and Howell, Zeiss Ikon, Agfa and Pathé are the chief.

Fig 1 shows the lateat CineKodal, BB Junior, measuring only 7 by 43 by 21 in. Fig. 2 shows the mechanism of a Cine-Kodak by which the film is wound from one spool past the lens and back again on to another under the action of the clockwork on the far side of the camers (not shown in the photograph). Another type of instrument is the Ensign " Autokinecam " pictures on the screen, and slow (8 pictures per sec.) for comic rapid effects.

How to Use the Cine Camera. In use, the cine camera is even simpler than an ordinary hand camera The lenses with which it is fitted are of such short focus that practically everything is rendered sharp on the film. It is only for subjects very close to the

Figs. 1 2. The Cine-Kodak BB Junior, and interior shqwing film winding mesbanism Courlesy of Kodali, LLC even in the coat pocket, yet

camera-and they can he as close as 1 ft .that the focussing adjustment needs to be set. Practically every camera can be loaded with film in daylight almost as easily as a fresh apool is put into an ordinary film camera

The only thing which the amateur oinematographer has to decide for bimself is the amount of light allowed to act on each little area of film according to the subject and strength of the light. This is done by altering the aperture of the lens, for it is plain that the conditions are altogether different from those in ordinary hand camera photography where the nmount of light is chiefly regulated by the time of exposure. In a cine camera running at the normal speed of 16 pictures per sec., and fitted with the common type of shutter for covering the film whilst it is moving, the time during which each section of film receives light through the lens is 1-32nd of a socond. In taking cine pictures, " finding the exposure" is simply ascertaining the lens stop at which the film is correctly exposed in 1-32nd of a second. This is very easily done with the aid of tahles supplied with the cameras or of meters designed for the purpose. A beach scenc in summer, for example, will allow of the use of a small stop such as that marked f 16, whereas a portrait in winter will require f 3.5, which is about 20 times as fast. Most cine cameras are fitted with a lens of this great speed, allowing of pictures being taken

jectancar to the camera usually disappointing. ine to get ns close os figures, anima possible to the moving the camera the or sports events, and to stop the camera the instant " movement" passes
out of the field of view. In taking filnis of scenes at home-one of the most fascinating branches of amateir cinematography-it is aluays of advantage to plan things in advance, devising occupations and providing accessories which leave no dead intervals.

The user of a cine camera may also be his own producer of story filnss. Some exceedingly good films of this kind have been produced by amateurs, particularly by members of the many societies formed for this purpose.

The conversion of the exposed film into the positive for projection is a somewhat complicated operation which is best left to the makers of the film. There is no secret ahout the process, but it calls for experience and appliances which few cine amateurs can ncquire As already stated, the charge for carrying out the process is included in the price of the film, nnd the leading makers of lilm have stations throughout the world where films are "processed" in a few days and returned to the user mounted on a spool ready for insertion in the projector.

In the case of some makes of film the principle adopted is to finish of the exposed film as a negative and to print a positive from it. This is not so good a system as that just mentioned, for the process of reversal from negative to positive has a refining effect on the grain of the picture, with the result that such pictures can be shown on a greater scale of magnification without any appearance of coarse grain on the screen.

The Home Cinema. Projection machines for home use are now made in most convenient form for showing a moving picture of size from 3 to 10 ft . width simply by connecting the apparatus to an electric lamp-holder. The current provides the light and also the power for driving the film through the machine. In Fig. 4, which represents the Kodascope Model C, are seen the two spools, the motor and, on left, the casing containing the lamp. Fig. 5 shows a nother excellent projector, the Ensign "Silent Sixteen," also taking a spool of 400 ft . of film, sufficing for a performance of over 15 minutes. The owner of one of these little machines is not limited to showing his own films, for the Kodak Co. and other firms maintain a library from which films of all descriptions, including reproductions of famons films, may be hired for a small sum. It should be mentioned that all the film of 16 mm . width is made on so-called "safety" or "nonflam" base, viz, of aceto-cellulose instead of the highly combustible nitro-cellulose used for standard film. Nitro-film is material which burats into a blaze at the touch of a flame.

Accto-filin, while by no means incombustible, burns slowly, being rather lcss inflammable than a corresponding band of paper.
