As the amateur cinematographer becomes proficient he will be anxious to edit and title his films or try his hand at the making of cartoon films. This work is greatly simplified by an apparatus such as the Ensign Title Mnker (Fig. 6), which is n kind of portable studio, litted with stage for the arrangement of letters and drawings, and with lamps for illumination. The cinc camera is put in place on the top and photographs the subjectniatter displayed below. The short lengths of title film so made are inserted in the longer films to which they refer by cutting the latter and joining the new piece with some celluloid cement

Moving pictures in natural colours can also be taken This is the lntest development of amateur cinematograply, and is known as Kodacolor. A special film is supplied for the process, viz., one with a nicroscopically tine lens pattern embossed on the back. It is used in a Cine-Kodak litted with a lens of extreme aperture ( f 1.9 .) and a three-colour filter (Fig. 7). Suhjects are photographed in the usual way except that sunshine is absolutely necessary. The exposed film is "processed " by the Kodak Co, and is then sliown

Fig. 7. Loading a Cline-Kodak with special flm for colour picture
Courtesy of Kodali, I.14
on the acreen by nid of an ordinary Kodascope fitted with a three-colour filter similar to that used on the camera. Most admirable moving pictures in the full colours of Nature are produced by this remarkable process, the practice of which is entirely simple though the method ly which the colours are obtained is highly complicated.

CINERARIA. This is one of the showiest of all greenhouse flowers, and is in full beauty in spring nad carly summer. There are largellowered and small-flowered varieties in innumernble hright colours. The latter, of which there are star-flowered and cactus-flowered types, are very decorative: they form plants 2 ft . or so high which bear a profusion of bloom. The large-flowered sorts hear one large head of bloom and grow about 12 in . high. I new type, intermediate between the two other types, has now been raised.

Cinerarias are grown from sceds sown in May in pots or pans of light sifted soil in greenhouse or frame: the plants will flower the following year and are thrown away nfter the blooms are over, a fresh supply of
plants being raised annually. When large pictorial methods of denoting the various enough to handle, the seedlings are put in parts are used. Some of the chief symbols are 3 -in. pots and later on into pots 5 in wide. During the summer months they should be grown in a cold ahady frame, the pots being set on ashes.: They must have cool moist conditions. In September they are hrought into the greenhouse : a temperature of $45^{\circ}$ to $50^{\circ}$ is high enough. If large plants are wanted repotting into $6-\mathrm{in}$. or 7 -in. pots should le done in February.

A suitable soil compost consists of loam two-thirds, leaf-mould and decayed manure one-third, with a free sprinkling of sand. The plants must be kept frec from greenfly by fumigating occasionally, or by using an insecticide.

CINNAMON. The bark of a tropical tree, cinnamon is used he a condiment and stimulates digestion. Cinnamon water in tablespoonful doses half an hour after meals is sometimes used in flatulent indigestion; or compound cinnamon powder might be used in doses of 10-40 grains. The dose of the hark is 10 : 30 grains, and the powdered bark has been suggeated as a prophylactic in Corinan
measles and ineasles, ohildren exposed to infection being given as much as will lie on a sixpence or a shilling with the morning and evening meals. The dose of cinnamon oil is $\frac{1}{2}$ to 3 minims. It may be used, dropped on sugar, in catarrh and influenza. It is also used as an application for toothache and for warts.

Cinnamon sugar is uselul in the litchen. Put 4 sticks or rolls of cinnamion in a mortar with $\frac{1}{2} \mathrm{lb}$. loaf sugar. Pound them linely and rul) them through a coarse hair-sicve. Put the powder into a hottle and keep it tightly corked. Use it for adding to cakes, etc.

CINNAMON BUN. These are made with $\frac{1}{2} \mathrm{lb}$. flour, $\frac{1}{2} \mathrm{lb}$. barley flour, 2 teaspoonfuly cream of tartar, 1 teaspoonful bicarbonate of soda, 3 oz sugar, 2 tablespoonfula molasses, 3 oz margarine, 2 teaspoonfuls grome cinnamon, and 1 gill milk. Mix together all the dry ingredients. Melt the margarine and the molasses, warm the milk, and blend the soda with a little extra milk. Add it to the milk and mix the whole to a atiff dough. Shape the buns quickly and then bake them in a hot oven for 20 minutes. This should make from 15 to 20 buns.

CINNAMON CAKE. Iced or plain, this makes a ohange for afternoon tea. To prepare it, beat up 2 oz butter with $\ddagger \mathrm{Ib}$. sifted sugar, and when the two are well creamed, ada to them a little less than 6 oz . flour, \& teaspoonful baking-powder, 2 beaten eggs, $\frac{1}{2}$ gill milk, 2 good saltapoonfula each of powdered cinnamon and nutmeg, and a pinch of salt. Turn the mixture into a well.greased tin and bake for about $?$ hour in moderate oven.

## Cinquefoil. See Potentilla.

CIRCUIT. In electricity this is the path traversed by the electric current. If the positive and negative terminals of a galvanic battery or accumulator be connected by a wire, a circuit is formed, the current Howing from one terminal through the wire, back to the other terminal, and through the battery. See Battery; Bell; Burglar Alarm; Dpnamo ; Electric Lighting.

CIRCUIT DIAGRAM. This is a graphic representation of the internal or external connexions of a wireless receiver or other electrical apparatus, in which symbolic rather than

hown in the illustration. See Wiring.
CIRCULATION : Of the Blood. In the human body the blood flows continuously in a circle, being purified at one stage of the journey and then redistributed.

From the limbs, head, chest and abdomen it finda its way into the right upper chamber (right auricle) of the heart. When the heart beats, the walls of this chamber. contract down, forcing the blood through a valve into the right lower chamber or ventricle. This ventricle has thick muscular walls, and when it in its turn contracts, the blood is forced into the pulmonary aitery and reaches a network of thin-walled little vessels, called capillarics, threaded nmongst the air cells of the lungs. Through the walls of these tiny vessels, or capillaries, there is an interchange of gases betwcen the hlood and the air in the aircells of the lungs, carhonic acid gas passing out and oxygen passing in.

The purified blood is collected into the pulmonary veins and carried to the left upper chamber of the heart (left auricle). Here, again, at the start of the heart beat, the blood passes through another valve, flowing into the left lower chamiler or left ventricle of the heart. The walls of this chamber are very thick, and when they contract the blood is forced into the main distributing artery, the aorta, and reaches every portion of the body. The farther it goes from the heart the smaller become the branches of thic arteries through which the blood passes, until finally it enters into the minute capillaries. The blood is then collected into veins which constantly increase in size and finally empty their contents into the right upper chainber of the heart.

The main bulk of the blood of the body is thus constantly moving through the circle. The blood of the walls of the intestines, however, after it has absorlied certain of the products of digestion, nutriment, etc., is carried by the portal vein to the liver. Here it passes again through capillaries, giving up certain oif its constituents, and being collected again into a large vein, which in turn carries it to the right auricle or upper chamber in order to begin a new cyole.

Impairment of the circulation may be general, and may be due to heart; lung, or kidney disease, or to anaemia amongst other conditions; or it may be local, as in piles, or chilblains, or Raynaud's disease The person who always complains of cold hands and feet should keep his bowels ireely regular, and take plenty of plain food, including fats. He should take open-air exercise. and should massage the affected parts. A sufficiency of woollen clothing should be worn. See Heart.: Lung.

CRRCUMCISION. Wherever in infancy the foreskin is notably long, and cannot be retracted easily and thoroughly, circumcision should be periorined. The operation is a minor one, and can be performed by the doctor in the baby's home. If this is not done, the secretions of the glands become dried and foul, causing local irritation, which may lead to other troubles

CIRRHOSIS. Whenever the special tissues of an organ, such as the liver, kidney, or lung, are, as a result of disease, replaced by ordinary fibrous tissue, the condition is described at cirrhosis. Cirrhosis of the kidneys is the condition present in the small red kidney of Bright's disease (q.v.). Cirrhosis of the liver is a common result of prolonger over-indulgence in alcohol, or may be due to infectiçus diseases.

Nausea in the mornings, diminished a ppetite, a sour taste in the mouth, and a pallor of the skin, together with a gradual loss of energy and perhaps loss of weight, are the syniptoms usually lirst noted in cirrhosis of the liver. The veins over the abdomen become engorged with blood and show through the skin as noticeable blue lines. Fluid eacapes from the overcharged veins and collects in the abdomen, setting up dropay. The patient has difficulty in breathing, through the pressure of the fluid in the abdomen pressing upwards against the diaphragm.

No treatment will bring a cirrhosed liver back to its norinal healthy state, but much can be done to retard the advance of the disease. The first step is to give up alcohol in any shape or form. The diet must be reduced to the simplest and most easily digestible form. Milk diluted with alkaline waters, vegetables, custards, etc., should be prominent in the diet, while heavy meats and all rioh, highly spiced foods should be avoided. Plenty of plain water or inineral water may be drunk bet ween meals, so long as there is no evidence of Huid in the abrlomen. Constipation must be avoided.
Diarrhoen is often troublesome; but as much of the surplus Huid in the system is in this way got rid of, it should not be checked unleas excessive, and not without advice. The following mixture is useful for the purpose

## Carbomate of calcinn <br> Dhosphate of calcinn Carlonate of blsmuth

Mix thoroughly and inkc one teagnogit every three hourn, until the diarrhoea is checiked. See Constipation; Diarrhoea.
CISTERN : In the House. As receptacles for water, cisterns arc generally of galvanised iron, rectangular in form and open on the top. Usual stock sizes vary from 2 ft. in length, 16 in. wide and 15 in . deep, having a capacity of 20 gallons, to the 1,000 gallon tanks measuring some 9 ft . by 5 ft . by 3 ft 6 in . A durable cistern should be made of 16 gauge or 14 gauge steel plate, with closely riveted corners, and have strengthening angles at all corners and edges

When fitting up a cistern it is vell to bear in inind the very considerable weight of the water and to provide ample support. The cistern should always be placed as near to a wall as possible, if resting on the ceiling joists, and, further to distribute the load, should rest ujon stout bearers of wood at least 4 in . by

2 in and extending lor 18 in or so on each side of the cistern See Ball Cock; Bath; Centra' Heating: Water Supply

Cistus. Thia is a name of hardy and halfliardy peicnnial shrubs also known as rock roses See Rock Rose.

CITRATE OF MAGNESIA. Eitcr. vescent citrate of magnesia is a pleasant laxative and cooling medicine in doses of 1 to 3 drams. A solution of manesium citrate, with the saine properties, can also he obtained, the dose being $5 \cdot 10$ fluid oz. See Aperient.

CITRIC ACID. Obtnined from the juices of fruits such as the lemon, citric acid in the proportion of about $\frac{1}{2}$ teaspoonful to 2 tablespoonfuls of water makics a solution about as atrong as lemon juice. The dose of citric acid is 5 to 20 grains A wenk solution increases the llow of saliva, and so is often useful in allaying thirst in fever cases. Sodium citrate is frequently added to the cow's milk given to hand fed infants, in the proportion of 1 grain to the oz. Tablets containing 5 or 10 grains miay be obtained for the purpose.

Effervescing drinks are made with citrio ncid, such as the following. In half tumbler of water dissolve 20 grains citric acid; in another tumbier half full of water dissolve 30 grains hicarlonate of potash. Pour the two half tumblers of liquid into one large tumbler and stir

A good home-made heverage may be prepared hy boiling the peel of a lemon in a saucepan containing $\}$ pint water and $\$$ ib sugar. When these have hoiled for 4 or 5 min , pour on $\frac{1}{\mathrm{oz}}$. citric acid, adding the juice of a lemon when the drink is almost cold. Pour a tableaponnful in a tumbler and till up with plain water or soda water.

CITRON: The Fruit. The fruit of the citron trec resembles a large lemon, with much the same flavour and medicinal qualities. Ser Candied Peel: lemon.

Citron: The Wood. This is sometimes used by cabinct makers, and is that of the sandarac tree. See Wood.
Clamp. The word is largely used to describe the various forms of cramps used in many trades. See Cramp.
CLAP BOARD. This name is frequently applied to a featheredged board used ns a westher boarding It is also given to an inferior quality of onk inuported from Norway. white coloured streaks distinguishing it from wainsent oak. Both materials are inexpen. sive. See Board; Wood.

CLAPPED BREAD. Also called clapbread. this is much made in Lancashire and Cheshire. Two wooden sponus and a girdle, or griddle, are the utensils required, and if a girdle is unobtainable a thick baling sheet must be suhstituted.
To make it, put about six tablespoonfuls of oatmeal in a basin with a small teaspoonful of salt. Nix these well, and add suflicient cold water to make a stiff paste, but it should not he dry enough to crumble. Shake a little ontmeal on the board, turn the paste on to it and oat it out with the two wooden spoons as thinly as possible. It is this patting or clap)ping that gives the bread its name, also its characteristic shortness. Dredge the paste with more meal if it sticks, and put the girdle on the fire to heat whilst the making is in pragress The cakes should be about the size of a breakfast plate.

When ready, dust the girdles thinly with oatmeal and carefully slip on a cake, one or nore according to the size of the girdle. Bake them on the top of the fire until they are erisp, turning them nccasionally. They may be served hot and buttered, or cold. They keep in dry tins, but need to he reheated. At first it is wise to mix only sufficient for one cake, ns the meal dries so rapidly.

CLARET. A great proportion of the wine drunk as clarct is but vin ordinaire, or the secondary winc of the country, for the prime growths fall far short of the demand. All clarets need a full six months in hottle hefore they are lit to drink Fine clarcts will mature in bottle for 30 or 40 years. When maturing. the wine should be kept at an even temperature of (i) ${ }^{\circ} \mathrm{F}$., and not exposed to sunlight. Claret will not keep sound for more than 6 or 8 hours after heing opened It should bedrunk at the temperature of a comfortably warmed room $\left(65^{\circ}\right.$ to $70^{\circ}$ ). The best way is to $\mu$ ince the wine on the dining room siclehoard or mantelpicce for an hour hefore meals, and then decant. At n formal dinner-party, where several wines are given, claret is served with the entrées or roast See Wine.
Claret Cup. The following is a recipe for claret cup. Take a bottle of claret, a tumbler of sherry, a hottle of soda or seltzer water, the peel of a lemon, a slice of cucumber, and sugar toraste. These should be mixed tngether, and served iced in a glass jug or bowl.
CLARIFYING. Any pieces of fat left over from ment or hacon, or the fat that is skimmed from the surface of stock, can be clarified and utilised in various ways. Pieces of fat should be cut small and placed in an iron or steel saucepan with suflicient cold water to cover them. slowly brought to the boil, and simmered until they look dry and shrivelled. The liquid is then strained into a jar or basin, and when cold will be a firm white cakc of fat.
The fat skimmed from the stock-pot should be covered with boiling water and left to cool. Any impuritios can he scraped away from the underneath of the fat when it has solidified Cold water should bo poured over dripping left in the tin in which meat has heen haked: when the fat has set it should be lifted and the water poured away. Fat that has been used several times for deep frying can be clarified by being poured while hot into a basin containing cold water, well stirred and left tos solidify. Cooked or uncooked fats may he clarified and are best kept asparate.

Clarinet on Barnew sysum

CLARINET. Generally made of coculs wood. the c:larinet comprises live paits : the mouthpicec, the socket, the upper joint (lingered by the left hand), the lower joint (fingered by the right hand). and the bell. The twhe is pierced with holes stopped by the fingers, and is litted with keys which alfect other holcs The number of the keys varies; it is usually 13, but with the Boehm system this is considerably.increascd. The compass is over three octaves, and is divided into three registers, ench completely chromatic.
The reed should be of medium strength; if too Hexible or too stiff, the tonc will be either weak or harsh. Fix it carefully on the flat side of the mouthpiece of the lignture. Place the two joints together, with the fingerholes in a straight line, and add successively the socket, the mouthpicce, and the bell. Behind the lower joint is a projecting rest, under which the right thumb is placed, so its to support the instrument.
The following is the basic fingering of the clarinet, and it should be committed to memory before trying to produce a sound.

Right hand. Iat finger works keys 9 and 12 and atops hole 4; 2nd fluger ftops hole b; 3rid llnger works key b, and stops hole 6 ; 4th finger works keys 3 and 4 .
Leit hand. 1at finker works key 11 and atops hole 1: Und fluger works key 10 and atops hole 2: 3 ril finger works key 8 and stops hole 3 ; th finger warks keys 7 , 1 and 2: thumb stope the liole at the back of the upper joint.

To play, draw the lower lip over the tecth so as to obviate their contact with the reed, put a hout half of the mouthpiece in the mouth, the reed gently touching the lower lip, and then draw the upper lip round the mouthpiece, in order that no breath may escape. Take the breath through the nostrils or through the sidns of the mouth, but on no account through the instrument. Press the tongue against the upper teeth and pronounce the word "too." which will cause the breath to pass hetween the red and the mouthpiece Keep the pressure of hicath stendy. To get different sounds, sturly the table of fingering given in your instruction book, where also will be found excreises for the production of tone.
An inherent defoct in the instrument is that
many notes

Clarkia. Single mauve variety
of this showy bardy annual are diflicult to get in t.unc. Correct intonation can only be acquired by steady, welí. directed practice in controlling the lireath. After use, with a soft duster re. move from the interior any moisture caused by the condensation of the brenth. See Bassoon.
CLARKIA. A showy liardy annual of which seeds are sown out of doors in MarchApril where the planta are to bloom from July onwards. There are two types: elegans, which grows 2 feet high and prodinces charming decorative flower aprays, and pulchella, whioh is ahorter and more graceful. Each type is represented hy varicties of rose, purple, salmon and other colours.

CLARY. The leaves of this aromatic plant of the aage family are sometimes used for flavouring soups and for seasoning, and the llowers for llavouring fermented drinks. The lower leaves are laige, rough, erimped, toothed, and grey-green in colour. The claumy, quadrangular flower-stem rises abouk 2 f1. high, and bears pale blue or lilac flowers in small clusters. The plant is jerennial by nature, but is best treated as $\pi$ biennial. The seed ahould be sown thinly in spring, and the plants set out about 18 in. apart when $3-4$ in high. The first leaves will be ready for picking late in summer. Its use has alinost vanishet, hut in oldworld or historical plant collections it cannot be ignored.

CLASP NAIL. Used for general woodwork, the clasp nail is of cut steel from 1 in . to $(\mathbf{i} \mathrm{in}$. long. Its shape is shown in the illustration. A smaller type, the wrought clasp nail, with the head and ear's in the form of a harb, has considerable drawing power, holds firmly, nud is difficult to withdraw. Clasp naila should be driven in with the wide part of the nail the same way as tlie grain of the wood.

CLAUSTROPHOBIA. A condition of uneasiness and apprehension is experiensed by certain people when they are in closed spaces Known as claustropliobin, it is one of the effects of neurasthenia (q.v.), and may be contrasted with agoraphobia, the term used for fear of open spaces

Clavicle. Sce Collarbone.
CLAW AND BALL. In furniture this term is used for the terminations found in many chair and table legs of the early part of the 1811, contury. The way in which the claw grips the ball varies, and much of the intorest and value of the pieces lies in the skill with which the nondelling is executod. It is gener ally associated with the introduction of mahogany into the cabinct making trade, and is almost always found in this wood. See Cahriole leg: Chair; Chippendale; 'Table.

CLAWFOOT. This is $n$ deformity of the foot in which there is a minrked increaso in the hollow of the sole. The tries are also hent backwards towards the instep, nnd as a result of those changes the foot is inuch shortened. The condition often begins in early life, and should be thought of where a child is awkivard on its feet and tonds to stumble.

The trentment recommended is persever

Claw Hammer. Illustration showing method of holding when
ingly to bend up the foot several times on three or fourocensions ench day, till the angle in front of the ankle is less than a right angle Care should betasen that alongenough boot is pro vided, and this should have a bar nbout $\frac{1}{2}$ in thick placed boneath the tread, to hrow tho front of the ont up. See Font.
CLAW HAMMER. This is $n$ hammer with a claw-shaped tail for extracting nails. 'Tho ordinary cheap kind has a malleable cast head, and is only adapted for very light work. The Kent or Canterbury is of solid steel, with forged sirle straps; a medium size weighing 1 lb . is suitable for household use.

CLAY: As a Soil. Clay soil is difficult to cultivate because in continued wet weather it becomes sudden and in prolonged dry weather it cracks. Yet most trees, shrubs and hardy plants llourish in well tilled clay soil

The best way to lighten clay and render it friahle is to dig it deeply in the lato autumn, and leive the surface rough so that the winter frusts and moisture can percolate and disintograte it. Clay land is greatly improved by adding hurnt soil, lime, leaf-mould, sand, sifted coal ashes, wood ashos, mad grit, old potting soil and strawy inamure.

Clay is sometimes considered as heing dangerous to build upon ; but except on unsuitable or improperly drained sitos a clity soil is quite satisfactory if the foundations are taken deep enough to he beyond atmospheric action. The whole area beneath the house should be covered with six inches of coment concrete. The great thing to avoid on a clay soil is waterlogged ground.

CLAYTONIA. These pretty little plants of the Puralane family are low in habit and suitable for the rock garden. Sibirica, rose.
and virginica, white. are readily grown from vear's growth Varieties when need this
seed sown in spring. Thcy thrive in shado in kind of pruning are seed sown in spring. They thrive in shado in ordinary soil, if not stiff, but loans and leaf. mould suit them well Othar species are camliniana and perfoliata, the latter an annual. Claytonia is sometimes described variously as the Cuban spinach and the Chinese chickweed, though it is related to neither

CLEAR COLE. Before distempering wood or plaster the pores are first filled with a conting of medium strength size to which a litule whiting has been added. This is called clear cole. See Distemper; Plastering.

CLEAT : For Fastening. A cleat is used for securing $a$ cord or line by twisting it nbout its projecting horns. It is uscful for many purposes in the hoine. such ins holding a fanlight or greenhouse skiylight cord Cleats measuro from $2 \frac{2}{2}$ to 6 in. long, and are simply screwad in prosition They are made of cast irnn, superio varietics in malleable iron. the best are of cust briass, burnished and lacquered or olcctro-plated.
CLEFT PALATE. This is a congenilal deformity in which the mof of the month shows a cleft down the centre. It may be associnted with hare-lip. The only treatment is an operation, which may he perfurmed between the third and sixth months after birth, though some surgeons prefer to wait till between the second and third years
CLEMATIS. One of the Inveliest of hardy climbing plants, represented in gardens by many species and varictios. If a carcful selection is made, one or another will provide bloom from May until September.

The successful inanagoment of clematis depends chiefly on correct preparation of the soil and pruning. As clemntis is long-lived, it is worth while naking a hole 2 ft "ide and 18 in. deep for esch plant: woll decayed manure and a f́ree scattering of nortar rubble should be mixed with the excavated soil before it is returned to fill the hole. Clematis is grown in pots by nurserymen and may be planted at any time of tho yoar, though early autumn and spring are the best seasons. If the roots are inatted together they should be soaked in water to remove the soil: the roots can then he disentingled to some oxtont and spread cut at planting time. Although the clematis loves the sunshine, the base of the plant should be placed among other low. growing planta.

There are several types ur groups of clematis, and they need different pruning. Those varieties belonging to tho Jackınanni and viticella g oups should be cut down in Fehruary to within ahout 10 in . of the base of the previous summer's growth; they bloom from July onwards on fresh shoots of the current

Clematis. Flowers of this very decorative

Ascotilensia, lavender blue: Comitesse de Buuchand, old rose, very beautlful: Gipsy Quen purple: Jackinanii, purple (and nil othire Jackmanli variepurnic Mme E. Andrish; Lady. Betty Balfour reddialh vinlet. Mra. Cholmonilcley, llatit bluc: redar viniet Mra. Chomnnicley. Noht blue Ville de Lyon. carmine red
Large flowered varieties of the other groups, which hloom in May and Junc. need quite different proning. It is sufficient to look over the plants in Fobruaiy and to cut oul weak, useless shonts to give more runm to the others, especially those of the previous year's growth. Jong, straggling shoots should be shoriened, but there must be no severe cutting back, or they will blomin sparsoly. Some of the chict varietios needing this trealment are
Beanty of Worcester, violet Wue: Crinison Klng, crimson; double; Fairy Queen, pale ficali nink: Henryi, cream white. Edvard V1I vlolet: Iady Nevill. lavender Rrey': Indy Nortliclifie. Invender blue: Luxuaturn. purple blue : Marcel Moser, Hauve shade; Nolly Moser, male mave : Tlic Queen lavender.
There are some vigomus and beautiful linds of smallflowored clematis All are rampant. and sonn cover a large anca It is impossible to prune them systematically. but they ought to be thinned out occasionally after llowering to get rid of old. worn-out and weakly shnots. Clematis montana brars white flowers in May: flammula, which is ill full beanty in August, has sweet acented Ilowers; vitalha. Traveller's Joy or Old Man's Beard, exceptionally ranipant, bears white flowers in summer followed by decorative fruits in nutumn

Clematis tangutica bears sinall yellow llowors in September: indivisa, white flowers in spring, is tender and suitable only for the greenhouse; recta is a bush clematis which bears white thowors in summer: heracleafolia is of somowhat shrubby grow'th and bears small blue towers in suminer

The casiest way to increase clematio is by layering the shoots in July Cuttings may be inserted in sandy soil in a frame in Septem her. Most of the planta sold by nurserymen are grafted on clematis vitalba

A disease which causes the surlden collapse of the plant sometimes attacks clematis. If all the stcms arc cut down, fresl) growth may spring up from the hase . it it dies not. nothing further can be done See Climbing Plant.

CLERGYMAN'S THROAT. Chronic in. Hammation of the tissues at the back of the throat, and perhaps of the vocal chords, is commonly caused by over use or improper use of tho voice In this condition, whish is termed clergyman's 'hroat. the lining at the back is covored with little elevations varying in size from a pin head to a peat, or even larger in some cases. The irritation is aggravated by a dry cuugh, and the voice gradually becomes woak and husky.
In treatment, any defect of the general health should be remodied. If the granules at the hack of the thruat are prominent thoy should be destroyod by galvano-cautery. Tho voice must be rested. The following gargle maly be usod four or five timos a day.

> Tincture of krameria
> Tincture of myrrh
> Compound tincture of lavender
> Water to make

ETLE. Several species of click beetle are found in gardens, and, though as beetles they are harmless, the femnles Iny eggs from which are hatched the garden pests known as wireworms (q.v.).

CLIMBING PLANT or Climber. The raised from seeds sown in March, and potted in uses of climbing, trailing, and rambling plants a inixture of loam and sand, with some well in the garden and greenhouse are manifold. rotted manure. The roots can be divided In the open air they are loved by the gardener, after flowering. A winter temperature of $45^{\circ}$ though not by tho architect, and their vogue increases as new houses are built everywhere.

Among the scveral self-clinging climbing plants the best are Ampelopsis Veitchii, with small leaves which colour brilliantly in winter, Hydrangea petiolaris, and the ivy, of which there are many varieties with green or variegated leaves. Rose, clematis, honeysuckle, jasmine wistaria, ornamental vine, prasion flower (for sunny walls), Cotoneaster horizontalis, Ceanothus veitchianus and the firethorn

Climbing Plant. Fig. 1. Trainers made of scantling

Diagrams for making tralners
 (pyracantha)
are some of the are some of the
chief hardy climbing plants and shrubs.

Before planting, it is necessary to prepare the site thoroughly by making a large hole and filling it with manured soil: climbing plants on a "all must be watered freely in very sunny weather. Certain annuals make food climbing plants for trellises. Chief among

50 in . naterial. The shaw las or material is merely doubled across to bring the two edges together, and one set of selvedges are caught together at a point about a foot from the fold to form a hood, which hangs down the back, and shapes the neck sufficiently to make the cloak sit on the shoulders. The top front corners are turned back to form revers, and each point, as well as the hood, can be finished with a tassel. The fronts of the garment inay be fastened with a clasp, or, in the case of a shawl with a surplus of material, the fronts are draped across and held in place by the hand.
them are canary creeper, climbing nasturtium, ornamental gourd, Japanese hop and sweet peas. Secds are sown under glass in March, the seedlings being planted out in May, or seeds may be sown out of doors in April.

Favourite climbing plants for the greenhouse are abutilon, fuchaia, heliotrope, Clematis indivisa, the scarlet trumpet honeysuckle (Lonicera sempervirens), roses, lapageria, Cobaea scandens, hougainvillea and Cassia corymbosa. See Arch; Clematis; Fuchsia; Pergola; Trellis.

Clinical Thermometer. See Temperaturc; Thernometer.

CLINKER: Its Uses. A hard, rocklike residuum is obtained under the name of clinker from gasworks, briokyards, and other places where furnaces arc in operation. It is cheap, and has many applications, especially for making garden paths and for inferior grades of concrete.

In large lumps clinker may be used for rock gardens; its black colour can be altered to some extent by coating it with cement wash. The finer grades, when sifted through a sieve, make a good aggregate for cement partitioning blocks intended for subsequent facing.

The clinker from brickiyards being very thoroughly burnt is generally fine, and makes "good path for a garden when laid to a depth of 3 in . to 4 in . and thoroughly consolidated with water and a heavy garden roller. A heavy clay soil can be lightened considerably by an admixture of fine clinker, but it must be used sparingly. A shovelful per square yard is sufficient. See Brick; Cement; Concrete.

CLIVIA : A Greenhouse Plant. Belong. ing to the amaryllis order, clivia is an evergreen, Howering plant, with reddish-yellow blooms in the spring. It is a greenhouse plant, and is than 30 hours. It was common for such clocks to have an hour hand only. These clocks werc of brass and the earlier ones had thickly gilt dials. I decorative feature wns the fretted ornament surrounding the clock above the dial, often contuining a conventional rendering of the orest of the owner, and at the botton the maker's naine. One of the earliest makers was Willian Bowyer, who in 1642 presented a great chamber clock to the Clocknakers' Company.

An ider of the size of these early English clocks may le gathered from the diameter of the dial. which was from 3 in to 5 in ., though larger examples are known, up to $7 \frac{1}{2}$ in. The bigger dials often projected each

A wide circular cloak, out without a join and known as a cavalier cloak, is attached to each shoulder with a buckle of elaborate ornament It has much fullness, which may be drawn across the front and over the left shoulder, and allowed to hang in folds down the hack.

CLOCHE : In the Garden. Cloches are domed covers of thick glass, very useful in the garden, especially in French gardening, where they arc used to cover lettuces, cauliflowers, and other plants which are grown under the system of intensive culturc. See Bell Glass.

## Clocks: For Use and Ornament

Choosing Them and Keeping Them in Good Order

## Subsidiary articles to the one below deal with Alarm Clock; Cuckoo Clock; Grandfather

 Clock. See also Watch
## Chamber clocks, as the early 17th century side of the frame or structural body of the

 examples were called when clocks first began to clocks. Thesc lantern clocks continued to appear in English houses, were often referred be made for quite 100 years. A wooden to as lantern or bird-cage clocks. They had hood was commonly used over the bell to no prendulum, as it was not introduced until protect the works from dust.about 1658 . A bell on the top was struck with
a hammer ns the hours progressed, and, after Clocks by Thomas Tompion (1638-1713) are , after the most desirable acquisitions, from the

Adam style clock, with carved firure of Time with bis scythe and surmounted by a vase painted with classical subjecta hop, with a sign of the Dial and Thipec Crowns, was in Fleet Street at the west top corner of what is now Whitefriars Street.

Toinpion was the chief watch and clockmaker of the time of Charles 11. Fine examples of his clocks are to he scen in the Pump Room, Bath. the British Muscum, and Windsor Castle. His name and date are usually on the dials of the clocks hemade. Two other great clockmakers of the Tompion period are Daniel Quare and Joseph Knibb. During the reigns of William and Mary and Quecn Anne, when walnut succeeded oak for clock cases, twisted or corkscrew columns were often seen at the corners each aide of the dial, supporting a horizontal moulding,
sometimes finished with a pediment. When mahogany became comparatively common in the first quarter of the 18th century, it was employed largely and walnut discarded.
Clock cases were made during the reign of George III in rosewood, chestnut, kingwood, pear, and other woods, while ebony, tulip, amboyna, and satinwood werc used effectively for inlaying. Bracket or pedestal clocks ware simply ohamber clocks with enriched wooden cases. French clocks of this period were heautifully decorated often in the Buhl style with delicate inlays of metal and tortoiseshell.
The imposition of a tax upon users of clocks and watches in 1797 resulted in the making of what are known as Act of Parliament clocks. They were used by inn-keepers, who, anticipating the probability of their customers being without watches, put up such clocks in their public rooms. They were, for the most part, very plain, and had a large dial of wood, painted hlack, with gilt figures, the face covered by a glass. They were hung on the wall, and had an extension below to give cufficient room for the movement of a seconds pendulum. The Act was so obnoxious that it was repealed in April, 1798.
The 18th century bracket clocks, with improvements in mechanism, are reproduced freely. Now that mantelshelves are often absent or so narrow that they do not admit of a large clock, the brackets solve the problem of accommodation. The cumbrous 19th century models in marble have given place to small lacquer-framed clocks with clearly marked dials and strut supports at back, or glass framed clocks.

## Mechanism. Figs. I

 and 2 illustrate n type of English clock which is known as a fuzec and chain pendulum timepiece This varicty is the most generally used where a timekecper pure and simple is required. The plates or frames, A, Fig. 1, usually made of brass, are held to gether by four brass pillars, pivoted between which is the barrel, B, Figs. 1 and 2. Inside of this is coiled the mainspring, the outer end of which is hooked on to the rim of the barrel, and the inner hooked to the arbor, C Figs. 1 and 2. This is pivoted betwcen the two caps of the barrel so that the barrel is free to turn; the arhor is also pivoted between the frames, with one end coming through. This end is squared, and fitted on the square is a ratchet wheel, D, Fig. 1, into which fits a click, E, Fig. 1, to prevent it running back. Round the barrel is wound the chain, F, Figs. 1 and 2 , one end hooked to the rim of the barrel and the other to the largest end of the fuzee, G, Fig. 1.

The winding is done from the fuzee, which is which when the fuzec is wound full ol chain is pivoted through and kcycd on to the main- drawn into action and catches the hook at wheel, H, Fig 1, but can only turn one way, the end of the furee, thus preventing its being as between the fuzee and the mainwheel there wound any farther.
is a click and ratchet. The arbor which
The motive power is transmitted from the carries the fuzee extends through the p!ates, mainwhec to the centre pinion, JJ Fig. 1, and the end is squared to fit the key or winder When it is wound, the flizee is turned, and the chain begins to wind round the spira grooves. The other end of the chain, being hooked to the barrel, will pull the harrel round, incidentally coiling up the mainspring which then has a natura! tendency to uncoil itself Thus it pulls the barrel hack again and with it the chain. Since the fuzee is held by the ratchet, it cannot go hack. It therefore puls the mainwheel with it. and thus arises the motive power that keeps the clocl: going.
The fuzee is a spirally groved pulley of varying diameter. Its object is to convert the varying force of the mainspring into a constant pressure on the train of wheels. Working on the small end of the fuzec is what is known as the stopwork, J, Fig 2.
 which carries the hands. Fixed to the centre pinion is the centre wheel. K, Fig 1: which in turn gears into the third pinion $L_{\text {, }}$ Fig. 1. Fixed to this is another wheel, the third wheel, M, Fig 2, which again gears into the escapc pinion, N, Figs. 1 and 2, to which is attached the cscapo wheel, O. Fige 1 and 2. From here the power is transmitted through the pallets, $P$, Figs. I and 2, by the way of the crutch. R, Fig. 2, to the pendulum. S. Figs. 1 and 2.

The pendulum controls the timekecping. If it is raised from the point where it is at rest and then released it will, by the force of gravity, fall back to that point, and the momentum it gains in descen' will carry it as far up the other side. If it were not for other factors, viz, the resistance of the air and the friction of the suspending spring a pendulum would go on vibrating indefinitely. The motive power supplied by the clock should only be sufficient to make up to the pendulum what it loses through this cause.

The escapement is the point where onergy stored up by the mainspring escapes at regular intervals. The stcel pallets swing with the pendulum and alternately release and catch a tooth of the escape wheel. They are sc shaped that the forward movement of the escape wheel imparts to the pendulum by way of the crutch the amount of energy required to keep it vibrating
The length of the pendulum used govern. the ratio of the wheels and pinions necessary to show true time. The centre pinion carrie the wheel to which the minute hand is attached by means of a sleeve over the extending part of the contre pinion, pinned down friction tight by means of a spring behind the wheel to allow the hands to he moved forward or backwarl This is the minute pipe (T, Fig 1). Geared into this is another wheel of the same size and number, U, Fig. 1, which in turn is geared into the hour wheel, V, lig. 1 , at a ratio of 12 to 1. To the hour wheel socket, W, Fig. 1, is attached the hour hand; thus the minute hand travels round 12 times while the hour hand travels once. Thus the clock mechanism by way of the dial and hands indicates the number of vibrations the pendu lum makes, and so, by the length of the penduluin and the ratio of the wheels the hands are made to register the time.
Striking Clocks. The fuzee and chain striking clock, as far as the timekeeping mechanism is concerned, is exactly the sume as the timepiece. For the striking train it will be seen that an additional barrel and fuzee and train of wheels are used : the work. ing of the barrel and fuzee has already been explained. The mainwheel in this casc, $A$, Fig. 3, gears into a pinion, B, Fig. 3, carrying a wheel which is called the pinwheel, C. Fig. 3 : driven into the web, and at right angles to the wheel are eight pins set at equal distances : it is these pins which raise the hammer, D, Fig. 3, to strike. This wheel gears again into the pallet pinion. E. Fig. 3, at a ratio o
eight to one: thus for each blow of the hammer this pinion turns once.

Attached to this pinion is another wheel, Fi, Fig. 3, which in turn gears into the warning pinion, $G$, Fig. 3, at a ratio of 7,8 . nr $?$ to 1 , according to the speed the clock has to strike. On this pinion is fixed the warn. ing wheel, H , Fig. 3, which in turn works into the pinion

hour. This is a double arm lever which. when lifted by the pin in the minute "heel, in turn lifts the rack hook, 0 , Figs. 3 and 4. hy means of a pin on the end. Attacherl to the extending portion of the pallet pinion which comes through the plate is the gathering pallet, P, Figs. 3 and 4, which is usually squared on and pinned across. When the striking train is at rest it tocks on a pin in the rack, R, Figs. 3 and 4.
As the hour or half-hour approaches the pin in the minute wheel gradually lifts thic lever, N, Figs. is and 4, which in turn lifts the rack hook. In doing this the rack is now. free to fall. aided by a spring, S, Figs. 3 and 4, working on a smiall exten. sion of the rack. In falling. the rack arm pin falls on to one of the steps of the snail. When the rack has fallen, the gathering pallet, and with it the train, would be free to turn, but the train is held in cheok by what is known as the warning, that is, an extension of the lifting piecc passing through a slot in the plate, $T$, l'ig. 4, and catching a pin in the rim of the warning wheel, H, Fig. 3. When the clock reaches the hour or half-hour the pin in the minuto wheel reaches the end of the lifting piece, which then falls into its original position and clear of the warning pin and the rack hook.
Now the train is free to move the gathering pallet, turning once to every blow struck. On the gathoring pallet is a smiall nib which as it turns gathers up one tooth of the rack, the rack hook by reason of its shape and position riding out and falling again behind the succeeding tooth. This is repeated until all the teetil are gathered up, whon the gathering pallet will come to rest on the pin, $R$, thus again iocking the train. So the number of blows struck depends on the step in the snail on to which the rack arm falls. At the halfhour only one blow is struck. This is done by means of the first tooth in the rack being out shorter than the rest and the pin in the minute wheel for lifting for the half. hour being placed nearer the centre of the wheel. When it lifts it is only far enough to let go the first tooth of the rack, and therefore the clock will only strike
 forward or backward turns a wheel and moves up or down a small alide which lengthens or shortens the pendulum.

Pendulum Clocks. When a pendulum clock atops, and. although it has been wound up and restarted, stops again almost immediately, the trouble is nearly alunys due to unsym. inetry of beat. This is easily detected: if the beat is unsym. metrical the intervals between the sounds of successive ticks are alternately a longer and shorter time, instead of being all equal. The simplest remedy is to place a small parl of paper or the point of a wedge under the right

French Strikiag Clocks. Theso are choaper than the English fuzce clocks, and on account of their small compass they can be ohered in a large variety of cases. Here the fuzee and chain are not used, the mainwhed and spring harrel being all in one, A, Figs. i)

Fig. 3. Sicie and front viem al English striking clock

1. W. Benson, L/d
and 6. and the winding is done from the barrel arbor. This necessitates an extra wheel and pinion between the mainwheel and centre pinion on one sido and between the mainwheel and pinion on the other, B, Fig. 5. The working of the other parts is fundamentally the same, except that the striking work is locked in a different manner. The gathering pallet in this case has no tail to it, the locking of the train being done by the rack hook, which is fixed to $H$ dotent, C. Figs. 5 and 6, pivoted betwoen the plates with an extending arm which catches on a pin in the pallet wheel, D, Fig. 6.

This kind of clock is also fitted with what is known as a Brocot regulation. that is, a shaft kinown as a Brocot regulation. that is, a shaft
passed from the front of the dial to the $13 r$
Clock. Figs. 1 and 2. Front Clock. Figs. 1 and 2 . Front and back Fiews of the works timeplece
carrying the Hy, J, Fig. 3. The fly acts as a sort of governor when the striking train is in motion. It will be seen that while the striking train is in motion it will keep lifting and dropping tho hammer, which in its fall strike the gong or bell. The mechan
Screwed to the hour socket is a disk with 12 steps, called a snail, J.J, Figs. 3 and 4, each succeeding step being nearer the centre ; this is what regulates the number of blows to be struck. Close by this and working on a stud is the rack, K, Fig. 4, on the outer edge of which is cut a series of inverted ratchet teeih. The distance of these apart in proportion to the distance from the centres tending from the working centre of the rack is a lever called the rack arm, L, Figs. 3 and 4. In the end of this and at right angles is a pin; when the rack comes into action it falls on to the snail, and accoryling to the step it falls on, it allows a corresponding number of the rack teeth to come into operation.
To set the striking clock in motion the minute wheel, M, ligs. 3 and 4, has two pins; as this wheel turns once an hour,
one of these pins will come into contact with the lifting picce, N, Figs. 3 and 4. every half-
or werlge han been put under tho wrong aide o the clock case; it should he put. under the other side and the procedure repeated.

In some kinds of clocks the works are en closed in a drum-shaped metal case of the same diameter as the clock face, this metal case heing s tight fit in the outer ornamental case but not being fixed immorably therein In clocks of this type the beat may be adjusted by turning the inner case in the outer case by small smount.

In the case of a clock not provided with the special facility described, it is still possible to avoid tho unsightly appearance of the wedge, but the process is one of some delicacy. In many good class clocks the crutch or part which is alotted to receive the pendulum rod is a tight fit on the pallet spindle but is not fixed immornbly. Consequently the crutch can be rotated by a minuto amount

Fir. 5. Front and side viek of a French striking clock
relative to the pallets about the common axis. The procedure is similar to that used in the wedgo method. A small adjustinent is tried, and the clock re-started; if there is improvement but not yet equality of bent, more adjustment is required in the same direction, while if the first adjustment has made things worse, then the second adjustment should be made in the opposite direction.

In other clocks the crutch may be $n$ wire which is firmly fixed to the pallet axis; in such $\Omega$ caso the crutch can bo slightly bent with the pliers to one side or the other till the clock is in " beat." It is not genernlly advisable for the amateur to attempt the curo of other troubles in pendulum clooks, or of any trouble arising in bolance-wheel clocks; these are rnthor mattors for the expert.

Regulating a Clock. In the ense of a pendulum clock, the pendulum hob is usually held in its place on the pendulum rod by a nut underneath the bob. To make the clock run faster, the nut is screwed up a littlo, so that the bob is a little higher up the rod. Some pendulum clocks have a small square peg at the top of the clock face, with the letters $S$ and $F$ on either side of it. Such a clock can be regulated without stopping it, the procedure for making it run fuster being to turn the peg with a key towards the letter $F$, and vice rersa.

The regulator of a balance-wheel clock is a sinall pointer at the back of the clock, which can be moved by hand over a graduated are towards $F$ to make the clock go faster or towards $S$ to make it go slower. In clocks of French manufacture the letters $\mathbf{S}$ and $F$ anc repliced by R and A respectively. The balance is $\Omega$ small wheel with a bar across the centre connecting opposite sides of the rim. It is very delicately adjusted and is pivoted in plain
conical boarings
forwards by the the action of a fine-spring, called winds spring in one movement the whee the spring; the second movensent is caused by the impulse of the spring to regain its normal tension. The regulation of the bal. ance requires great care and the pin should be moved very graslually.
When setting a clook, if the clock either strikea or has an alarm, the hands must not he moved backivards, but instend must be inoved forwards neaily 12 linurs. Moving the hands backwarls is permissible for other clasaes of clocks. The case of a clock should nevor be left open nny longer than is absolutely nocrrsary for winding, etc., or elso dust will get into the worlis. If a pendulum clock is moved otherwise than with the grentest care it will to stopped, and may dovelop an unsymmetrical beat. All members of a household should thorefore avoid accidentally moving such a clock, and intentional moving in order to dust behind it should be forbidden.

CLOCK GOLF. The game of clock golf can be played in any garden when there is room to chalk out a circle of $\mathbf{4}$ to $\mathbf{6} \mathbf{y d}$. dinmeter. which is then marked with figures placed exactly as on the face
 striking clock
shown in the diagram, not in the contre, but nearer to some of the figures than to others.

If there are only four players, the game can be one pair ugainst the other; if mone, each person scores for himself or herself. A golf ball is placed on the figure $I$, and the first player, armed with a putter or any other golf club, endeavours to get the ball into the hole in as few strokes as possible. When he has succeeded, the next player takes his turn, and so on until all have played. The player who succeeds in the fowest stmkes wins the hole. The ball is then moved to the figure II, and the game proceeda as before. When all the playera have played from each figure on the clock face, tho game is scored by holes as in ordinary golf

CLOG. Footwear with wooden soles and leather or fabric uppers, known as clogs, is used for a variety of purposes and in many industries. The Eng lish clog should not be confused with the continental sabot, for whereas the former is a wooden.

Clock Golf. How the numbers may be marked on the grass to be at unequal
soled bont or shoe. the latter is merely a block of wood, shaped and hollowed to admit the inot. The wood for the soles of a clog is usually cither beech, ash, or alder. The first. being a closc-grained wood, is less liable to swell and split when sonked: it is therefore invariably used in occupations which entail much standing about in wet piaces.
Clogs are more comfortable for garden work and on the allotment than boots. The ironshod soles never wear out, and when in course of time the uppers become perished and craclied, they can be renewed nt home. Ner clog uppers can be obtained at most leather and grindery shops. The clog upper is nailed round the outer edge of the sole in a rebate of about $\frac{1}{5}$ in. To affix $n$ new upper, first rernove the welting or thin strip of leather which is used to hide the join betwcen the sole and upper. If this is done with care, the welting may be fit to use again. After all the naile aro removed the new upper should be light! $y$ attached with a fow tacis, nnd the old welting or a new strip cut to the same size, put intc place and freely nailed See Boot Repairing.

CLOSET. Originally the name given the a small private room, the idea of privacy has been retained in the present use of the word for an earth oloset, chemical closet, or water closet. The portable chemical closet is convenient for indoor use where a water closet is not available, and is specially adapted for the onravan, bont or temporary building. See Earth Closet : Sanitation: Water Closet

CLOT : Of Blood. The solidified state of the blood when it coagulates constitutes it clot. This is composed of a network of fine atrands of fibrin. in which the blond corpuscles are enmeshed, the red blood corpuscles giving it a red colour. At first the clot includes the whole blood, but the serum is gradually squeezed out and the olot contracts.

When .bleeding occurs inwardly the clot softens and disappears; if not, its place is taken by new fibrous or scar tissue. When a clot forms in the heart or blood vessels during life it is called $n$ thrombus, and the process thrombosis. A clot of blood on the brain may mean that thrombosis has taken place. See Coagulation; Embolism: Thrombosis.

CLOTH. In all woven cloths two sets of thread, crossing at right anglos are interlaced with eisch other. Compound oloths can be woven with more than two sets, but not with less. Knitted cinths are madc by forming a thrend or threads into a succession of loops joinod to one another. Animal, vegetable, and mineral materials are employed. Wool, hair, and silk appear in the first group; cotton. linen, jutc, hemp, ramie, and artificial silk in the second; cloths woren from asbestos, spun glass, and metal wire come into the third.

Widths are limited only by the widths of the machines. Velvets are made as narrow as 16 or 18 in . : trouserings and handwoven tweeds are 27-28 in.; most cretonnes and many linings are 31 in . : dress serges are often 40 to 44 in. : inrious upholstery cloths are made in [0 in:, and the nominal width of many wool cloths is 54 in

Added width sn oftell masns a saving of length in cutting-out that a large proportion of goods are inado in broader sizes. Narrow width is an ambiguous term usually implying 27-29 in. and double width 50-58 in. It is much better to specify the breadth in inches for clearness.

Cloth for Govornment service use is tested by specia: machinery, which applies tension, note being takell to the pound pressure at
which breakage occurs. The ordinary test for wearing power is by the thumbs; when a cloth is so strong that the thumbs cannot be pressed through it, though tightly held and strength exerted, it is considerer satisfactory.
Yarns and Weaves. Worsted can be distinguished from woollen by noting whether the yarn fibres are parallel or bunched criss. cross. Combed cotton may be told from carded cotton by the evenness in the length of the fibro recovered. Linen differs from cotton in the much greater length of the individual fibres. Spun silk can be told from raw or thrown silk by the fact that the one is made like worsted, from a large number of detached fibres, where the other is made by twisting more or less tightly together a few fibres of virtually endless length. This process does not afford final proof, but is informative so far as it goes.

Another point to be noted in examining detached threads is whet her the yarn is tightly or loosely twisted. Tight twisting is favourable to wear, but makes the cloth harder and may militate against its graceful draping or the brightness of its appearance. Tight twisting is sometimes resorted to because the fibro is too short and poor for use otherwise. Hence it follows that cloths which feel very hard and substantial do not always wear well.
Double or two-fold threads are preferred to single for wear. and from a length of the yarn it is easy to tell by rolling one end between the fingers, while holding the other end, whether the thread is single or not. Singlestrand yarn disintegrates forthwith into fibre, whereas two-fold splits into two individual threads.
Woven cloth, being composed of two sets of thread, is firmer and stronger the more efficiently these two are bound together. They are never more securely interlaced than in the plain weave seen in handkerchiefs. Cloths are made to feel thicker for being woven in twill or step formation. Their surface is made smootherand more lustrous bysatin weaving, in which the thread, after passing under one of the opposing set of threads once, passes over the next five, six, or more. Under given conditions firm and good-wearing cloths can be made in these and in more fancy weaves, but it is not an advantage to the wear that there should be long unbound floats of thread lying on the surface. Woven cloth, on account of its structure, is firmer and less liable to stretch than knitted cloth. Knitted fabrics arc used where elasticity is specially required. Cloths are knitted also when stockinette or jersey is in fashionable demand. See Braid: Sergo ; Tapestry ; Tweed; Weaving.

CLOTR BALL. This is a compressed tablet. chiefly composed of precipitated chalk and magnesia, used for cleaning white and coloured fabrics, sucde shoes, handbags, gloves, hats, etc. It can be obtained in white and in many different tints.

The white cloth ball is particularly useful in cloaning white furs, white satin shoes, and so on. The coloured balls are used for cleaning coloured nap cloths, coloured shnes, velours, hats, and velvet fabrics, pile carpots and rugs.

The methods for cleaning white and coloured fabrics is as follows. Brush well with a stiff clothes-brush, and free from dust as much as possible. The cloth ball is then rubbed vigorously into the nap or pile. Care should be taken that a good deposit of the cloth ball is rubbed into every part of the article, as noglected parts will spoil the effect of the cleaning. Fabrics should be fulded carefully with the treated surface on the inside, and put 'sway in a dry, warm place for at least 24 hours.

Shoes and other articles that cannot be folded should be covered to keep free from dust, and put into a warm place for a similar period. At the end of this tinue the cloth ball
powder should be shaken and brushed out. and the article will be found to be almost completely restored to its original freshness and colour. In the case of articles that have been allowed to become very much soiled, a second application of the cloth ball may be necessary.

In suide shoes and suèdc goods generally, the nap in wear has a tendency to be rubbed down, and the article presents a shiny surface.

This is particularly noticeable in shoes and handbags, the rubbed parts presenting a greasy, black appearance. If such is the case. procure a piece of fine sandpaper and gently rub against the nap until the surface is restored. Then apply the cloth ball in the manner alneady described. To avoid an uneven appearance, the sandpaper should be applied to the whole of the shoe upper, extra attention being paid to the soiled parts. See Fur ; Suede.

## Clothes and Their Treatment

## Care that Makes for Economy and Good Appearance

This artice'e tells how both men and women can keep their clothes in good condition. See also entries on Darning Mending; Pressing, and articles on Boot; Hat, etc.

It is not always realized that a sma!! income does not preclude anyone from leing turned out well groomed, since appearance depends less upon the extent of the wardrobe than the care taken of it. The chief enemies of woollen garments being clust, damp, and moth, it fol lows that no clothing should be put away for any considerable period without a thorough airing. If clothes are brushed thoroughly once a weok, there is no fear that they wil become a prey to moth. If it is necessary to pack clothes up for a lengthy period, either in a wardrobe or a trunk or other receptacle, there is nothing more suitable as a wrapper than a newspaper, the smell of which is particu larly obnoxious to the moths that infest clothes.

Cloth is highly susceptible to the effects of heat and damp. When a man has worn a suit of clothes all day, and particularly if covered by an overcoat, it cannot fail to be somewhat creased, especially in the arms of the coat and the legs of the trousers. If these garmenta are carelessly thrown on a chair, they will assume permanent wrinkles instead of temporary ones. The chief damage is done during the first few hours after removal, so it should be a rule always to place the coat on a suithanger with a lower rail over which to place the trousers neatly folded. A trouser-press is a help, as by its aid trousers can be kept in good condition and their life prolonged.

When clothes become soiled they should be sent to a good cleaner, who will tailor-press them before sending them home.

## Renovations by the Tailor

Early attention should be paid to any sign of wear at vulnerable points, e.g. bottoms of trousers and cuffs of sleeves. If the damage is severe, take the garment at once to a tailor, who will present a new wearing surface by shortening the sleeve or trouser leg by a fraction of an inch.
Hats should be kept well brushed. Nothing is so damaging to them as dust, which eats its way into the felt, and speedily renders the hat too shabby to wear.

Neckties need careful treatment. Silk is a material which gives the greatest resistance to creasing, but silk ties are not composed entirely of that fabric. There is an interlining of swansdown, horsehair, wool, canvas, or some uther material, and this interlining either becomes displaced or distorted through being re-tied day after day in exactly the same position. The only remedy is to have several ties in use. and to wear them in succession placing them for a rest in a tie press or smooth. ing them out as much as possible after a period of wear.

Underwear should be changed frequently for airing, but not necessarily washed so fre quently. These remarks inny also be applied to socks and stockings-and it may perhaps be added that keeping the twe nails cut short prevents frequent darning. The practice of carrying loose change in the trouser pocket, or a heavy bunch of keys, speedily wears a hole in the under-garment. The stuffing of all sorts of articles in the pockets of the outer
garments should also be avoidel, as nothing contributes more to loss of shape. Boots and shoes, innmediately they are taken off, should be put on boot trees. Here also the rule of having more than one pair in wear is highly to be commended. Where the heels have a tendency to wear on one side more than the other, the addition of a rubber tip will be effective. If a man follows the policy of constantly changing all the articles ne wears, of keeping his garments well brushed, and of placing them in the best position after wear to recover the shape, he should save many pounds a year, and present a better appearance.

Hints for Women. A woman who cultivates neatness generally manages to look welldressed, however little time or money she may have to spend.

Directly an outdoor costume is taken off it should be brushed, unless wet or muddy, and hung on a coat or suit-hanger. Wet mud stains must first be allowed to dry, and a solution of soap bark from the chemist may be used to sponge any stain that the brush fails to remove. Damp clothing must be carefully hung up to dry, otherwise it will present a hopeless mass of creases next day. It may be necessary after being caught in a very heavy rain to send the garment to a tailor to be properly pressed.

Fragile dresses inay be covered by a muslin bag when hung in the wardrobe on a silk covered hanger. For long dresses a useful hanger is made from an ondinary coat-hanger, the metal hook being removed, the hanger slightly padded, covered with ruched ribbon inverted and suspended at either end by a cord. The dress is simply laid over the concave padded rail.

At the end of a season washable frocks and underskirts may be rough dried to free thein from starch before being folded and put away. Most housewives provide themselves with overalls, which protect the dress when attending to household duties.
Hats should be brushed each time they are taken off. and if kept on the shelves of the cupboard or wardrobe, ought to be covered with tissue paper. Boots and shoes retain their shape better if kept on trees when not in use, or they can be stuffed with paper. A cupboard is the best place to keep footwear, or, failing that, a small packing case can be improvised with a shelf and a cretonne curtain covering. An umbrella will last longer if when wet it is left open and laid down, resting on the handle; if the moisture is well shaken out it will soon dry.

Underelothing should be kept in a drawer and covered with blue tissue paper or muslin. All clothing should be periodically overhauled and mended neatly when necessary.

Small Renovations. In spite of proper care wear and tear are bound to have their effect eventually, and there comes a time when some form of renovation is necessary. Coats grow shiny; collars begin to look greasy and stained, and garments require pressing.
To remove shine from a black coat rub the latter gently with some fine sandpaper, after-
wards sponging it with a solution of common washing blue and water. Press the coat while it is still clamp, but if it requires freshening, first brush it and clean it with benzine. afterwards sponging it with a quart of water containing a table spmonful of aminonia. Coat collars are best renovated with a mixture comprising 1 pint benzine, $\underset{t}{t}$ dram chloroform, and 1 dram alcohol. Apply this with a soft rag, or, as an alternative, rub the collar with a cloth dipped in ammonia.
A common thing which ruins the look of a pair of trousers is bag. giness at the knees. This is caused, to a large extent, by sitting, and ordinary pressing will not remove it. It is possible to remedy it in the following simple manner.

Place the trousers flat on a rable (in the same way as indicated in Fig. 2 of illustrations of how to fold a lounge suit) and danip the knces alightly with a moist cloth. Then place the left hand tirmly just above the knee so as to hold it in position, and with the right hand take hold of the back of the trouser leg. about midway hetween the knee and the hottom of the leg, and pull haid towarda the bottom. Transfer the right hand to a similar grip in the font of the leg, and again pull downward. It will be found that this entirely remores the bagginess frmm the knee. Each trouser leg should be treated separately The trousers can then be pressed in the usual way, if desired.

Never use a light-coloured cloth in pressing dark clothes, since the white lint invariably leaves an inipression which is difficult to remove. Do not rub, as in imning, but lay the iron on gently and nove it alowly over the garment. When clothing has hecome nildewerl, put the affected part in a bowl of buttermilk and it will come out like new. In the case of a fabric on which there are acid stains, it is best to apply ammonia. If this is done without delay the effect of the acid will bo neutralised, the material prevented from rotting, and the colour saverl.

Clothos which are made of light materials can be cleaned with a cloth ball (q.v.). Perspiration stains should be treated as early as possible by soaking the affeoted part in cold water for 15 min ., then aprinkling it with lemon juice and leaving it for a few minutes hefore rinaing it in clean water. If the firat treatment is not successful, repeat the process, taking care not to leave the lemon juice on too long, as this might affect the dye in coloured materials

CLOTHES BRUSH. In the best sorts the fine. springy quality of the bristle is easily noticeable. In a common brush the bristle will either be aoft or cut short to produce greater atifincss. If preferred, a brush can be obtained with the end portion of the back set with short, stiff knots of bristle which are useful in removing hard deposits of mud.

In a hat brush atifiness is not an essential. A clothes brush and a hat brush of the squareback shape, with screw eyes to liang on $n$ polished board, make a hall set, and are leas obtrusive than the more elaborate ones with hevelled mirror, hosider the fact that fibre, which is extensively used with bristle in making common clothes brushes, is often found to be a component part of such hall sets. Pibre is detrimental to good cloth, and the knota of this mixture are usually punched into

How to Fold a Lounge Suit. 1. Fold tronsers, button to button at top and seam to aeam in leg. 2. Place fiat on table. 3. Fold vest, with lining inside and fronts ontside. 4. Place vest on top of trousers. 5. Fold jacket, nushing out tops of aleeves. 6. Place on table, with sleeves straight, and fold over untre 8 Foid rrousers over as far as porsible and are crease in lezs. 9. Turn tod of coat over as far as bottom of tronsers will allow Courlestl of My Valet. Lid
the holes: this can be detected by the absence of a separate glued and screved veneer back. The fibre mixture will not last in wear: the bristle is poor, the fibre soon wears off, and the polish on the back quickly dulls, so that this brush is soon rendered almost useless.

A good brush should have stiff hriatle of fair length, a well-filled stock and a separato back. The back should be secured by brass scresw and finished by polishing. See Brush.

CLOTHES HORSE. A clothes horse is usually made with two folds of equal size, but sometimes with three or four, thic latter being cumberanme to handle. A more compuct form is to make it in three folds, the centic one wide and each of the wing folds half the width of the centre fold, so that the whole closes that into two widths only. The uprights should finish $1 \frac{1}{2}$ in. by $1 \frac{1}{8}$ in. each, to be mortised right through for the spaced rails to enter. These can be tenoned to enter right through and be double wedged. When fitted up they can be well anndpapered and left with the natural surface, the rails heing slightly rounded on top odges. The folds are hinged together with strong webbing, with two hinges above and two below to each pair of meeting uprights.
The dimonsions may vary according to requirements. A size of 3 ft .6 in. high may bc 2 ft .3 in . wide, each fold being, thercfore,

$16 \frac{1}{2}$ in. A 4 ft . size can be 3 ft . wide when closed, and a 4 ft . 6 in . size 3 ft .4 in . wide, all with three rails to the fold. Larger sizes of the article may have four or more rails. See Airer.
CLOTHES LINE. When clothes are hung up to dry they are suspended from lines which may be made of hemp, jute, or galvanised iron stranded wire. The hemp lincs are generally put up in 18 to 20 yd. lengths with a ring at each end. Galvanised wire lines aro made in two thicknessos, the No. 11 gauge and a much stouter line, known as No. 8 gauge, and generally in 50 or 100 ft . coils
Tho lines are supported by wooden posts. $2 \frac{1}{2}$ to 3 in. square and 8 ft . long. The upper end has wooden pegs for attaching the lines on all four faces; tho lower end has a fillct $A$ to support the post as it rests in the wooden socket 13 (Fig. 1.). The latter should be tarred and buried in the ground, preferably in a lump of concrete built mund it as a foundation. With this arrangement the posta can readily be lifted out of the sockets and stored away when not in use.

The rocket rhown in Fig. 2 is made of cast imn; it is sunk into the ground and hedded in concrete. The posts used for this socket should have tapered ends to fit tightly into the hole in the socket. However carefully the rockets are fixed, the post is seldom rigid: it is a good plan to provide a hook low down on an adjacent wall, or screwed into a wooden post driven into the gmund, and to attach one end of the line to this hook, then twisting it around the post. The line thus acts as a guy or stay and keeps the post rigid. (See Fig. 3.)

When a wall or the side of the housc is available it is beat to fix a hook or an eye-bolt
securely into the brickwork and to provide a pulley for the line. A clothes line should always be brought indoors when not in use. It is unsightly, and exposure to wet rots the rope. Frequently in towns, and occasionally even in the country, the line should be clesnsed in hot anda and water, otherwise it will colloct smuts and leave dirty marks on the clean linen. Fine, light clothes lines, which fold up very small and are easily set up in an ordinary room, with small pegs to suit, are sold for travellers and women who live in bachelor flats, and are a help in the laundering of light articlos. See Airer: Cord.
CLOTERSS MOTR. This tiny winged insect of the moth family is most injurious to clothos, particularly furs and woollens. Before dying in early autumn it lays its minute flat eggas in such materials, on which the larvee foed when they omerge in the spring. The chief times for the housewife's vigilance are August and September, when the eggs are laid, and the spring, when they hatch. The spring and autumn household cleanings, with their attendant turning out of every drawor and cupboard, protect against moth as well as clearing away dirt and lumber. Thore is little risk of moths attacking clothes which are in constant use. The things that need watching are woollen cloths, curtains, blankets, eiderdowns, and furs which, not being in usc, are stored away during the summer months.
Preventlves and Remedles. The contents of all drawers and wardrobes should be turned out periodically, and every item oxamined for moth marks. All should be well shaken in the open air, and if possible hung out of doors for \& few hours Furs should be hung over the line and well beaten with a light cane before being paoked away.
Pockets in overcoats and wintor wraps not in use should be turned inside out and brushed froe from fluff, and then filled with small broken pieces of a cigar box or cedar chips : moths object to the smell of cedar. Clothing stored in newspapers, linen and other materials with a cold surface is seldom harmed, since moths avoid all substances of a chilly nature, because they are unfit for hatching. The only precaution needed is that the edges of the paper must be pasted together, and the linen sewn so that no moth can enter.
Apart from their dislike of cold substances, moths have a distinct aversion to certain odours, such as tohacco, Russian leather,

Clothes Pog. Types in commor ase: top, Amencan: centro, spring-grip: and sandal-wood. Two other odours which is undoubtedly supe score the American type keep away moths ane those of naphthe and lavender, and both should be ineely used among stored things. Naphtha balls can be bought by the pound and placed one or two in drawer corners and in the folds of blankets, etc. Clothes stored on hangers in a cupboard should have a little muslin bag containing either lavender or a couple of naphtha balls suspended from each hanger.
When it is suspected that moths are in an article of clothing that will lond itself to steam treatment, wrap it in a clean damp towel, put it in the oven with the gas turned low, and steam out the grubs. If the garment is too large for the oven, place it under a damp towel, and press it with a rather hot iron.

When moths have actually been detected in furs or clothes, brush the latter with a whisk broom saturated with formaldehyde solution. 'Trunks should also be treated with this

Clothes Line. Pis. 1. Post with four wooden Dege and aill, $A$, for insorting into the 800 ket athown at B. Fig. 2 Oant lion sooket bedded in concrete. Fig. 8. Method of keeping post rigid
Fig. 1
solution, and afterwards left in the fresh air for a few hours A good substitcto for formaldehyde oonsists of 3 tablespoonfuls of turpentine added to 3 quarts of cold water. This may also bo used for rubbing on floors under carpets and rugs whioh have been attacked by moths.
CLOTEISS PEG. Probably the best is the American, turned from a piece of beech or other hardwood, and the V-shaped slot or jaws, formed by sawing away the material to the shape substantially as shown in the illustration. Thoy are readily produced from dowel-rod, turned to shape with chisel and gouge. A two-part block, hollowed in the centre to reoeive the peg, is used to support it in a vioc while sawing out the slot.

Another type of clothes leg, known as the gipsy, is made from odd bits of wood whittled with a l:nife and the two pioces secured with a narrow band of tinplate. The patent pegs furnished with spring grip aro small in size but scarcely so durable as the American type; they are more suited for indoor use. Clothes pegs should hold tightly, and never get rusty, or otherwise they are liable to damage the clothes. On this score the American type to rust, no joints to give way, and the long tapering slot, together with the natural springiness of the material, gives it a secure and powerful grip.

CLOTTED CREAM. In the preparation of clotted cream it is desirable to use rich milk, but this is not essential. Whole milk, warm from the cow, is strained into setting pans. The pans most suitable for the purpose hold abcut 6 to 8 quarts of milk, and measure 15 in . across the top, 7 in . in depth, and 11 in . across the bottom, being somewhat deaper than the usual. The pans of milk are left undisturbed in a cool dairy for the cream to rise. In summer 12 hours or less is the time allowed, but in winter 24 hours is usual.

Scalding is then carried out by placing the pans on a hot-water stove, and allowing steam to play under them until they have attained a temperature of $175^{\circ}$ to $185^{\circ} \mathrm{F}$. in not less than

20 min ., when they are removed, and allowed to cool naturally in a cellar or other cold position. The scalding should not bo done too quickly, or the cream is rendered greasy. The heating may be carried out by placing the pans on a kitchen range or hob, but the hot-water method is preferable.

When the scalded milk and cream are coldin warm weather the cooling should bo donc quickly-the cream may be taken off in a thick clotted condition, and is ready for use. The cream is generally sold by the lb., and 1 IL of cream may be obtained from $1 \frac{1}{2}$ gal. or less of Jersey milk; nearly 2 gal. of Shorthorn milk may be required to produce the same quantity. See Cream; Milk.

CLOUD GRASS. The popular name of cloud grass is given to a hardy annual group ol grasses callod Agrostis, which are very uscful, when dried, for the purpose of room decoration.

CLOUT NAIL. Having a broad liead, relatively large in diameter to the shank, the clout nail is useful for fixing such material as zinc shects, roofing felt, or for any purpose where the material to be fastened is comparatively thin or fragile. Various patterns are illustrated. Blue-wire clout nails are made from $\frac{1}{2} \mathrm{in}$. to $1 \frac{1}{2}$ in. long: wrought clout nails, fine (that is, thin) or strong (stout), are from $\frac{1}{2}$ in. to lo in. in ength. See Nail.

CLOVE. The dried buds of an

Fiastern plant are

Clout or Broad-headed Nail. Let to right ane wrought ; ctrons wrought; counter-annk: blue-wire videly used both in mcdicine and in cookery under the name of cloves Their most valuable constituent is oil of cloves, of which the dose given by doctors varies from $\frac{1}{2}$ to 3 minims. Applied outwardly it has a stimulant effect on the skin, producing heat and redness. When applied to a cavity in a decayed toot/h il ofton relieves tho pain of toothache.

Taken internally, oil of cloves causes an increased flow of saliva in the mouth. In the stomach the normal movements are stimu. lated, and there is an increased flow of gastric juice. Oil of cloves increases the appetite and improves the digestion ; it is often prescribed in cases of indigestion with flatulency.

For culinary purposes cloves form a valuable spice, sold whole or in powder form ; they have a strong aromatic odour, and a hot, spicc-like Havour. A clove should not float horizontally

Clove Eitoh. Diagram illustrating turns of rope round a beam when placed in water: if it does it shows that the cssen. tial oil has been extracted.

Two or three cloves added to apple while it is stewing or put into an apple pie will improve the flavour. Tinc. ture of cloves is used for flavouring mulled wine. It can be prepared at home by dissolving $\frac{1}{\frac{1}{2}} \mathrm{oz}$. fresh oil of cloves in $\frac{1}{2}$ pint rectified spirits of wine.

CLOVE BITCE. This is a simple method of attaching a rope to an object without the use of a knot. The illustration shows how the fastening is made, the two turns being brought
close together after they are formed. The security of this bitch depends Inrgely on the fact thint the ropo bends over itself.

CLOVER. The name is applied to various grases belonging to the genus trifolium, of which the red clover, cow grass, zigzag clover, and woorland clover are the best sorts for pasturage. The different clover grasses are usually inc!uded in any mixture of seed for lawns, or ot her turfy stretches for the purposes of tennis, croquet, or bowls. The shamrock is commonly said to be one of the clovers, trifolium minus

CLUB FOOT. Paralysis and the contrac. tion of scar tissuc after an injury are the commonest causes of club foot, which is a permanent malformation of the foot or ankle. The deformity miny be present at birth or it may be the result of accident or disense, and there are four varieties. In the first of these, Talipes equinus, the heel does not reach to the ground, the patient's weight falling on the ball of the foot. The opposite condition in found in the second kind, Talipes calcaneus, the heel alone touching the ground, while the toes and the front part of the font are lifted up. In Talipen valgus and Talipes varus the outer and inner sides respectively of the foot are turned upwards so that the patient walks on the inner or outer side. Sec Foot

CLUB ROOT. In enbbages and other greens this is a most troublesome disenso. It causes great loss and infects the soil, attacks the mots and canses the plants to rot. It attacks other members of the snme family (crucifcrae), e.g. turnip, wallflower, charlook and the shephord's purse weed. The best treatment is to lime the land heavily and not to grow susceptible crops on infested land for three years. Anbury and finger and toe are other names for this disease.

CLUMBER SPANIEL. Bnth in disposition and appearance the Clumber differs materially from the rest of the npaniel family He is heavily built, weighing from 55 to 6.5 lb ., slow but an excellent game-finder ; not being beadstrong, he is easily broken. His white coat is relieved with lemon markings, and his square, massire head and deep flew's give him

Clumber Spaniel, a henvily built breed of sporting dog a dignified look. The stout legs are, of coursc, short, and his back is pow. erful. T'be breed originated at Clumber Housc, near Work: sop, Notting hamshire, the seat of the dukes of Newcastle. See Dog.

CLUMPS. For a large party of people clumps is a good ganie, but it should not be attempted with less than 10 . The players divide into two parties, which occupy opposite ends of the room. Each camp ohooses a representative from the other, and the two representatives go out of the room together and decide upon some object-no matter how obscure-which is to be guessed by the others. They might, for example, choose the largest diamond found in the Kimberley onines in a given year. On their return each representative goes to the hostile camp: the one chosen from enmp A goes to camp B and vice versa.

It is then the business of the respective camps to find out by close questioning what object has been chosen. To these questions only "Yes" or "No" may be given as answers. The camp which first arrives at the correct solution wins the round and retains the representative, as well as its oun member, who returis from the losing camp Nec Children's Party: Evening Paity

## The Clutch on Motor Vehicles

## Its Working Principles Described and Illustrated

This is one of the articles in this work that deal with the mechanlsm of motor vehicles, others including Brake and Gear. See also Motor Car; Motor Cycle

The clutch is employed as a friction-gripping device by which the engine is enabled gradually to take up the drive through the gear box to the back axle. It is necessary to disengage the engine from the transmission before making any change of gear; as well to enable $a$ vehiole to come to rest without having to stop the engine; also to allow the engine to run before the vehicle gets under wny.

The importance of the part played by the clutch and tho need of keeping it in good order cannot bo over-estimated. Should the clutch get dirty and stick up, it will be impos. siblo to engage the low gear without consider. able noise and consequent damage to the gear teeth when starting away from rest. The clutch may fail to engage properly, or it may suddenly take up the drive, thereby throwing severe strains upon the transmission. As a result, gear wheels may bo stripped, tho cardan ahaft twisted, universal joints broken, or the differential gear damaged.

Single-plate Clutch. This clutch, which has largely taken the place of the cono typc, is ype, is tapered end of the crankshaft. B. and the
 in upkeep, and has the great advantage that its speed quickly falls when rlisconnecterl. The principal parts are shown extended in Fig. 1. The plate G, which is bolted to the flywheel rim A, carries all the clutch elements. The parta are thus enclosed in but do not touch the Hywheel recess. The driving memher is a plate, I), having a number of radial saw cuts which afforl Hexibility ; the
splined centre engages the end of the clutch shaft, E, on which it may slide slightly end wise. The plate $D$ is held between a fabric disk, $J$, riveted to the pressure plate. $K$, and a similar disk on the plate $G$ (not shown).
Studs, L, screwed into the pressure plate project through holes in the fixed plate, G. and pressure is applied by means of springs, $\mathbf{H}$. fitted on the studs outside plate $G$ and held fast by the nuts $M$, which permit of adjustment. The parts are normally held together by the springs. When the clutch pedal is depressed the inner ends of the three levers. N , are forced towarls the flywheel by means of the ball thrust race, $O$, the rear end of which is engaged by the clutch fork. The adjustable screws $T$, in the outer ends of the levers $N$, engage the pins $P$, and thus forec the pressure plate away from the fixed plate ${ }_{2}$ leaving tho driven member, $D$, free.

Fig. 2 shows a Clyno single-plate clutch in section. It is enclosed in a casing formed between extensions of the gear box and engine casings. The flywhecl is keved on to the
driven member is mountal on the forward splined end of the clutch shaft. The rea end of the latter extends into the gear box and carries the firat driving gear-wheel. C. Pressure is applied by means of the six helical springs $H$, mounted on the ends of tension bolts. When declutching. the ball thrust race is moved towards the flywheel by $n$
clutch fork mounted on the clutch operating spind le, R.
The adjustable screws, T, and the adjustable collars which retain the clutch springs $H$, should be left as set by the makers. If some alteration should hecome necessary, it is essential that the same number of turns be given to each end, so that even pressure is maintained over the whole face of the olutch In the case of the screws, T, a clearance of at least inch must be left between the shoulder on the front cover of the gear box and the rear end of the sliding member which houses the ball thrust. This is to ensure that the full pressure of the springs is utilised, and that the pressure plate, $G$, is not held off by the thrust race abutting ngainst the gear box cover.

Multiple-disk Clutch. In this typea number of disks are connected alternately to driving and driven members, and aro forced together by springs. In this way high powers can bo transmitted through a clutch of relatively small overall dimensions.

Fig. 3 is a section through a Buick clutch. Five thin metal driving plates, $D$, have rings of friction inaterial riveted to them on each side, these rings engaging five alternate metal. driven disks, E. When the clutch pedal is depressed the plates separate, and there is no driving connexion between crankshaft, ${ }^{\text {B }}$, and clutch shaft. $F$. When the perdal is released the plates are bmught together by the clutch spring, $G$, and the resulting friction between alternating plates causes the clutch to rotate as a whole, transmitting the tomue.
On the outer edges of the driving clutch plates, $D$, are teet $h$ which engage corresponding tecth in a recess in the rear side of the llywhecl, A. There is sufficient fresdom of movoment to allow the disks to move endwise sufficiently to free them from contact with the alternate driven disks. The inner edges of the driven disks have similar serrations which engage corresponding teeth on $n$ driven member, J, connected by splines to the clutch shaft, $F$. The forward end of the clutch shaft is spigoted in the rear end of the crankshaft. B, by means of a small hall bearing.

At its rear enll the cavity in the flywhed is closed by a plate, $H$, bolted to the flywheel. The central dished part of this plate forms an abutment for the spring $G$. The other end of the spring forces the rear clutch release plate, K, awny from the flywhecl. This plate is connected by lolts, M, to the front release plate, $\mathbf{N}$. When the clutch pelal is depressed the two release plates are moved towards the Hywhecl, the pressure heing applied through a thrust bearing. The clutch plates then separate, and thus there is no driving connexion between crankshaft and gear box primary shaft.
The clutch will not wark properly unless the connexion to the pedal is correctly ad. justed If the pedal when the clutch is released strikes the fontboard before the clutch is fully engaged, an adjustment must he made to ensure a clearance of $\frac{t}{d}$ inch.
The Morris olutch (Fig. 4) is n multiple-disk olutch running in oil. There are four driving surfaces, comprising the rear foce of the flywhecl, A, bnth faces of a flonting disk, C, and the forionrl face of the pressure plate, $N$. 'Three driving pins, $P$, pass through flywheel, foating plate, and pressure plate, which all motate with the engine. The driving pressure for the clutch conies from springs mounted on the driving pins outside the pressure plate. The driven surfaces are a double line of cork insets in two stcel plates, one of which is shown separately in the diagram. The plates ara mounted on a tonthed driving hub keyed on the clutch shaft or the primary diving shaft. F, of the gear box.

Clutoh. Two examples of clutches used on motor cycles. Fig. 5. Sturmey-Aroher countershaft clatch.
Fig. 6 (right). Type with cork insets in the driving digks

The clutch is disengagerl by the tork (not shown) moving the thrust bearing, $E$, and pressum plate, $N$, away from the flywbeel, thus compressing the aprings and relioving the pressure on the cork insets.
The steel driven plates move slightly endwise on the tonthed hub. Wear on the tecth of the huh will interfere with this novement. and it may be difficult to release the clutch; if this occurs the toothed hub should he replaced. The cork consolidates a good deal under pressure during the first few thousand miles running of a new car, but subsequently little further yield may be expected. The yielding allows the pressure plate to move nearer the lywheel, with a corresponding movement in the clutch pedal casing, which will come nearer the foothoard when the clutch is disengaged. If the pedal touches the footboard the full pressure of the springs is not available, and the olutch may slip. Adjustment should be made to allow at least $\frac{1}{2}$ inch clearance between pedal and footlmard when the clutch is engaged.
Motor Cycle Clutches. The clutch on a motor cycle is usually combined with the chain sprocket wheel driven by a chain from the ongine, and also with the sprocket pinion, which is connected to the road wheel. In the multiple disk Sturmoy-Archer counterahaft clutch (Fig. 5), the chain wheel. A, geared to the engine drives the first motion shaft. B, of the gear box through a pack of driving and driven disks with interposed fibre rings: the main driven member, C, which is keyed to the end of the shaft, B, carrios the three driven disks, D ; several coilcd springs supported on pins, $E$, clamp the disks between the driven meinber, C , nnd the outer driven disk, $D$.
Another type (Fig. 6) employs cork insets $(G)$ in the driving disks, which rotate with the chain wheel, $A$. The driven disks rotato with a driven member. H , having a splined connexion with the shaft, J. The coiled spring, K, forces the disks into engagement.
CLYDESDALE TERRIER, Of the several brceds of Scotlish terriers the smallest is the Clydesdale. Its coat is long, fine and silky, with a high gloss, and there is no undercoat. A parting runs along the middle of the back and head, and from this the coat falls in two perfectly straight and even curtains to the ground, hiding the short legs and the dark, sharp eyes. The small ears stand erect almost on the top of the head, their lang fringes covering the sides of the head. The geneml colour is an unmixed briglit steel blue; but head, legs. and paws are a clear golden tan, and the tail is dark blue or black. The weight is a bout 18 lb . Sce Vog ; Terricr.

COACHMAN. A coachman is a man who drives horses for an employer, the word being usually restricted to one engaged by a private employer. Boing $n$ male servant, his employer must takic out a licence for him; this costs in Grent 13ritain 15s. a year. Coachmen usually woar some lind of livery, those in the employ of persons of rank wearing the livery with armorial bearings of the family. See Chaufteur . Driving: Horse; Insurance.

COAGULATION. The change from a fluid to a more or less solicl state, as seen in the olotting of blond, the curdling of milk, and the hardening of white of cgg by heat, is termed congulation. Blood congulates when it is shed, and whon it is received in a vessel the following sequence of events is ensily obsersed. The process begins on the surface of the blood, which in about 2 or 3 minutes begins to stiffen and hocome jelly-like. This takes place throughout all the blood, and is complete in from 10 to 15 minutes. Then a pale straw coloured fluid oozes out from the clot, until in an hour or two the clot, which has become smaller and harler, is Hoating in the fluid.

Clotting is due to the formation of is substance known as fibrin ferment by the injured cells and the leucocytes. In the presence of salts of lime this ferment throws the solid substance of the clot out of solution. If blood when it comes from an opened blond ressel did not undergo this change, which plugs the npening, we should be in danger of bleeding to denth from the slightest wound, as is the case in haemophilia, where the process is delayed beyond the normal time.
In addition to heemophilia the blood is long in clotting in haemorrhagio purpurn, pernicious anammia, and jaundice. In these conditions slight bruises may produce considorable bleoding under the skin, and bleeding occurs in nlarming quantity from wounds or mucous membranes. See Clot ; Milk.
COAL. Conl is made up of a combustible portion, which is chiclly carbon, and an incombustible portion, which is mineral matter and constitutes the ash. Of all kinds of coal the richest in carbon is antliracite, which contains !o) per cent. Harcler and heavier than ordinary coal, it burns with practically no flame nor amoke, giving out an intense heat and leaving little ash. It is not very suitable for ordinary grates and should be burnt in specially constructed stoves. An anthracite stove is very uscful in a hall or library, and once it is started it nceds practically no attention beyond being replenished every 12 hours or so.
Soft or bituminous conl is sold under such names as W'allsend, silkstone, selected, Derby or Nottingham brights, household and kitehen. A coal that gives excellent rosults in the kitchen range may not be good for the drawing room, and on that account two varicties of coal may be used in larger homes.
Cobbles and nuts are intended mainly for kitchen use. The terms refer to size rather than to quality, cobbles representing pieces between 6 in and 4 in . and nuts between 4 in . and 2 in. If a separate coal fired boiler is used in connexion with a central heating installation. hard steam conl is to be preferred to $\boldsymbol{n}$ soft one.

Clydesdale. Specimen of the small Scottish terriep

Dross or coal dust in a bugbear to the house holder, and cvery effort should be made to prevent its accumulation in the cellar. When is big lump of coal has to be broken it should be placed on the Hoor of the coal cellar and not allowed to rest upon the other coal; in this way a clean break can be made.

When a fresh supply is got in it should not be dumped on top of any sinall coal and dust remaining. This should be scraped to one side, and it should be a rule to use some of it cvery day along with the larger lumps. A good fire can often be kept burning for a long time without attention if banked up with small stuff.

The dust can also be formed into solid blocks or briquettes with the aid of a little Portland ceinent and water, a vessel such as a flower-pot being used as a mould. The briquettes and oroids (egg-shaped cakes) obtrinable at the shops are inade of small coal compressed with pitch as a binding material. See Anthracito; Cooker ; Range.

COAL BOX. For a drawing room the helmet-shaped box in brass, or a circular box of pierced steel or brass-the selection of metal being dependent on the other accessories of the hearth-with an iron lining and supported on fect, is always suitable. The latter with a lid is often vase-shaped in the Adam style of decoration, but is also seen in rather a heavier typo

Coal Boz. An attractive and useful example which can be tilted forward when used Courtesy of Waring and Clllow, Lid
of box without a lid. The iron cauldron and the wooden tub, strongthened with bands of copper and a separate lining, both look well with a brick hearth. Wooden hoxes of the oldfashioned type with hinged and sloping lids are best in plain designs. Square-toppled coal cabinets with drop fronts and removable liners, which tilt forwaid when the front is opened, are sometimes liked, as the top forms a convenient small table surface.

For a dignified fircplace, or with an aakpanelled chimney piece, nothing could be more suitable than the metal hox illustrated. See Chimney.

COALBROOKDALE. Old chinn bearing this name was produced at the Shropshire vil. lage of Coalport in Conlbrookidale. Those pieces which are marked CI), CBD, CDale, or the full word, are called Coalhrookdale, to distinguish them from those bearing the later Coalport marks. One of the characteristics of the dalesmen potters was to produce carcful copies of Sevres, Chelses and other wares. These were either unstamped or bore copied marks: when such pieces are traced to their real makers, they rank as Coalbrookdale. See China; Coalport.

COAL BUNKER. In llats and small houses a coal bunker is frequently built into some odd corner. It must be made strong enough to withstand the frequent introduction

and removal of the coal. For this purpose hoards are fitted into grooves or a channel at the front of the bunker (A, B, Fig. 4). These are removed one by one as the coal is consumed

In modern flats wherc the coal cellar is often simply a cupbnard beneath the stairs, it is the cause of much grit and dirt getting scattered about. This can be remedied to some extent by building a rough partition with stout hoards about a foot away from the door, as in Fig. 1. In front of this place a wire grid or woven wire mat, so that when handling the coal most of the dust will fall on to this grid, pass, through it, and be kept from littering the house.
Where circumstances permit, a gond plan is to construct a hopper, as illustrated in Fig. 2, provided with an exterior door sliding in strong gmoves, shown in section, Fig. 3.
The upper part of the front of the bunker may be provided with a hinged Hap or with removable boards having runners similar to those at the bottom. This provides for the introduction of the coal, which can be withdrawn liy opening the door at the hottom and allowing the coal to fall out directly into the coal scuttle. A stout poker will be found convenient for raking the coal should it show any tendency to jain in the hole.

COAL CELLAR. A coal cellar in small houses is often an excavation beneath the floor, approached by $\Omega$ flight of steps; the coal is delivered through a shoot covered by a circular iron plate, protected against intruders hy a chain or bar. Such cellars are liable to be flooded during heavy rain or liy the overHowing of a gully or drain. This can be dealt with by raising the height of the curb and providing more suitable channels for the overHow water to drain away.

A cellar that is not wanted as a store for coal can be converted into a useful room, provided that it is dry and there is sullicient height to move about. The walls may bo covered with old or cheap linolemm, with the back of it facing the room, as it is damp-proof and durable. Nail this to the walls and decorate it by panelling with narrow wooden strips. The ceiling is covered with beaver boards nailed to the joists, and panelled in any way desired. The lino can be painted. rose Du Barri, turquoise and

Coal Cellar. Method of converting a coal cellar Into a useful room

Coalport Chins. Modern plate reproducing an old deslgn Courtesy of Coalport China Co. I I.f1 apple-green grounds were especially rich, and the landscape panels neatly done. The Chinesc willow pattern, which was first imitated at Caughley, was continued at Conlport. Old Conlport was undated, and much of it un marked. See Chinn.

Coal Scuttle. See Cauldron; Coal Box.

COAL TAR. Coal tar is a black viscous liquid which is obtained after coal has bcen heated in the production of illuminating gas It contains valuable chemicals used in the manufacture of dyes, drugs, and disinfectants, and after these have been extracted it is used to protect wood, brickwork, stone and
iron, for which purpose it is mercly painted on and a!lowed to dry.

As a protective material it is videly employed in laying wood pavements and in preventing dust on roads. It would be of value in treat ing dusty spaces around the house, being sprayed or painted on the surface and then covered with sand or gravel, but it must be remembered that it has a poisonous effect on vegetation.

Coal tar soap consists of soap impregnated with a certain proportion of coal tar disinfectants, and is used for the same purposes as carboljc soap. Disinfectants inade from cơal tar are amongst the most effective that science has produced. See Disinfectant; Soap.
COARSE STUFF, A mixture of lime, sand, and hair is used in plastering under the name of coarse stuff, generally for tho first and second coats on internal surfaces. The proportions are 1 nart of lime to 3 parts clean, coarse, sharp sard, gauged by measure, not by weight. To this is added about 1 ll , by weight of long, clean ox hair to every 3 cubic ft . of the coarse stuff or, say, 3 oz. of hair to a pailful of mixture. See Ceiling; Cement; Lime ; Plaster
CUASTER HUB; The design of this hul provides a frec whdel, as well as a powerful lurake having a very sweet action: the brake

in a backward direction. This will further unserew A off B. Therefore, A will be forced tightly into the brake clutch cone F , and a further backward direction of the pedals will cause the pin $\mathbb{F}$ to operate the cam lever $\mathbf{G}$ hy means of the slot H , into which it fits, thus expanding the lorake band K against the brake drum that is a part of the hub sheli. The pin F is machined integral with the cone $E$. and is held in a stationary position by the slot H
The brake band with operating cam lever $G$ is held in position by the corer plate M, the arm of which is secured to the bottom chain stay of the bicycle by the clip $\mathbf{N}$ The brake shoe is returned to rest by the natural spring of the brake band itself. This band is formed of two metals; the outer band, which takes the wedr, is of phosphor bronze, and the inner band, which acts as the brake releaso spring, is of spring steel. The brake is immediately released by a forward movement of the pedals, which action by means of the quick pitch screw D iminediately draws the cone $A$ from the brake cone $E$. The spindle which passes through the centre of the unit carries the cone $R$, lor the ball race $P$, which is provided to take the thrust of the cone $A$ during brake application, and is adjusted in the usual way. When fitting the hub to the machinc it should be noted that this adjustment also controls the main bearings.

The proper functioning of the hub depends almost sole ly upon freedom of movement bet ween the quick pitoh screw on A andi 1 . Therefore; wash out with paraffin occasionally and lubri. cate at regular intervals, as specified by the makers. A point to remember with practically all forms of coaster hubs
Coaster Hab. Diagram showing the brinciple on which the hab is constructed is applied by back-pedalling, while the free is that the brake will be gradually wearing away wheel or coasting action is obtained by kecping the feet stationary.
To take the driving and frec wheel action first, it will be seen from A that there is no part of the mechanisin that can be said to have any resemblance to the frec wheel as commonly understood. Its mode of operation is as follows: $A$ and $B$ are the driving meenbers, and rotato as one with the chain ring; $B$ is machined integral with the chain ring seating. On $\mathbf{A}$ is secured the friction spring $\mathrm{C}_{\text {, }}$ which bears against the inside of the hub shell It follows that if $B$ is rotated in a forward direction faster than the hub shell is moving, then A , the rotation of which is being hampered by the frictional contact of the spring C , will be made to screw itself on to $B$ through the medium of the quick pitch screw $D$. The drive to the hub is taken up by the tecth shown on the face of B meshing with the corresponding teeth on the inner face of the hub shell, marked X. The harder the pedalling, the firmer will become the grip of these teeth, so ensuring there being no nossibility of slip.
The free whecl, or conster action, is practically a reversal of the foregoing, and is obtained in this way. Stop pedalling and the hub, which is still being rotated by the momentum of the licycle, will now be rotating faster than $B$. The result is that, through the medium of the spring $C$, the conc $A$ will unscrew itself along B , thereby becoming disengaged from the hub. Thus the hub is left to rotate free, whilst the cone A is left stationary with B, ultimately making a very light contact with the brake operating cone clutch F .
Operating the Brake. To operate the bratic it is only noccssary to move the predals
its frictional faces during the whole of its life ; which means that the day will come when the hub as a brake will fail to operate. To forestall this contingency, make a point of noting how far the pedals have to be reversed before tho brake operates. When this distance becomes excessive it is time to renew worn parts.
Other types of coaster show a certain amount of similarity in their design to the hub already described, i.e. the brake is applied through the medium of friction plates or by an expanding split sleeve operated by backpedalling. The coaster hub is frequently combined with a change-speed gear and a diagram of a typical huh is given in the article on thrce-speed gears. See Bicycle; Brake; Gear.

COATING : For Clothing The wool cloths used in men's suits are called in general coatings, and their variety is great. Coatings are ordinarily about 54 in . wide, and thus more economical to cut up into suits and costumes than the narrower and lighter dress stuffs. Their weights run from about 8 to 22 oz . per yard. Wool cloths materially heavier than 22 oz are over-coatings or mantlings. In single (i.e. 27 in .) width the goode are called trouserings or restings.
Coating scrges, most often plain black or hlue, are the ehief typo of plain coating; fancy coatings have check, stripe, or other patterns, usually in coloured threads. Coating is best for classical tailored suits for women. Warmer in wear than wool stuffs, coatings are also more expensive. Botany coatings are smouthest to the touch, and cost more than Cheriot or cressbred cloths. In buying
coating serges it is advisable to see that they are warranted fast dye and fully shrunk.

## See Cloth ; Serge.

COBAEA. I quicligrowing climbing plant popularly known as cups and sancers, owing to the shape of the flower. It is raised from seeds under glass in spring and is usually groim in the greenhouse. Pron. Co-bé-a.

COBBLER : The Drink. This long drink is made with almost any kind of wine or with brandy, whisky or gin. One of the best is sherry cobliler, which can the made from about $\$$ pint sherry and a teaspoonful each of sugar syrup and pineapple syrup or curaça. Ice well, and stir up. Strain into a tumbler which has been filled with broken ice and serve with straws: Champagne or moselle cobbler is made with one glass of champagne or moselle in a large tumbler, a spot of old brandy, a slice of lemoll, and sugar if desired. Finally fill up the tumbler with crushed ice.

COBBLE STONE. Round coblle stones are used for paths and roadwaps, especially in the Midlands and the north of England and in Scotland. Walls of buildings are sometinies constructed with them in districts where this niaterial abounds. They make cheap and durable garden paths, as they present a dry surface under most conditions.

Cobbles are laid by first excavating the top soil and ramining until a firm base is obtnined. The stones are then set in sand or fine earth and beatan down to a tiniform surface with a beetle or ruallet. Considerable skill is needed in choosing and setting the stones and to secure a bond or stable condition by properly placing them one with the other, so that no stone lies unsupporterl. They can further be secured with a grouting of cement mortar.

COB LOAF. A white loaf of bread, shaped into a roundish form, and baked on the bottom of the oven and not in a tin, is in certain locainties called a cob loaf. See Bread.
COB NUT. A variety of the hazel-nut, cob nuts are frequently cultivated. Kentish cobs are considered specially good, leing large and well-fla voured. They should be gathered when fully ripe, but before the lightest touch causes them to drop from the bushes, and dried well in the sun. After that, in order to keep them, put them in a cool, dry place, or pack them in layers with salt in dry jars. The cob is a good dessert nut, the kernel being sweet and timm. It is larger than the hazel or Barcelona, and is rounder than the lilbert. See Filbert; Hazel Nut; Nut.

COBURG CAKE. To malie thesc little cakes, cream together 3 oz . sugar and 4 oz . butter, and add iwo beaten eggs and 1 teaspoonful golden syrup. Beat well, and then mix in 0 or. Hour, 1 small teaspmoniul haking. powder, I teaspoonful ginger, the same quantity of cinnamon, $\ddagger$ teaspoonful mixed spice, and a little milk to bind. Half fill some greascd patty tins with the mixture; bake for about 00 nin. in a moderate oven.
COCANNE : Its Uses. An alkaloid that is obtained from coca leaves, cocaine is used in medicine chiefly as a local anacsthetic. Thus it is useful in eyo work and in operations on the nose and throat and elsew here; it is of great service in dentistry. For most of these purposes it is combined with suprarenal extract. It is also used sometimes in cases of pruritua. Among other conditions which may be benefited are sea-sickness and the vomiting of pregnancy and asthma.

But its employment should be limited as far as possible to single occasions, as a craving for the drug is very casily established, and the moral and physical degradation this produced is a price which no person can afford or should be allowed to pay for the relief of any pain or discomfort whatsoever. Cocaine can only he pmenred by a patient on a doctor's
prescription, and a fresh prescription must be procured for each occasion.
In poisoning, among other symptoms there may be difficulty in hreathing and convulsions Pending the arrival of the doctor sal volatile may be given or strong coffee by the mouth. or, if necessary, by an enema

COCCIDIOSIS : The Disease. This is a discase of various animals caused by the multiplication of a very small protozoan parasite in the tissues of the intestine and liver. Animals most frequently affected are rabbits, poultry, feathered game, sheep, goats and cattle.

In the rabbit, coccidiosis may affect either the liver or the intestinal wall. The disease may take an acute or a chronic course. As a rule the acute type is seen only in young animals, which appear sleepy and dull. In the early stages of the disease they may eat and drink ravenously when roused Later they refuse food and rapidly become emaciated Not infrequently there is a profuse discharge of saliva from the mouth. Diarrhoea scts in and the animals die within a short time of the onsct of the first symptoms. Where young rabbits are dying in large numbers and the deatha are usually preceded by diarrhoea, the owner should always suspect coccidiosis as the cause and send material for micro. scopical examina. tion to the Ministry of Agriculture, from whose Leaflet No. 364, these particulars are taken In older animals the disease takes a more chronic course, and the mortality is not nearly so high.

Amongst poultry the symptoms of the disease are similar and the acute type is essentially a disease of young birds. It is commonly classed by poultry breeders as white diarrhoea, or white acour of young chickens, but not all these are due to coccidia It must be understood that coccidiosis is only one of several diseases, the most prominent symptom of which is diarrhoea

Certain workers have reported satisfactory results from the use of crude catechu. The eatechu is powdered and mixed with water in the proportions of from 10 to 15 grains to one gallon of water, and this is given to a badly infected flock in place of drinking water. In the chronic type, where catarrh is a prominent symptom, washing of the nostrils and eyes with antiseptic solutions may be of some value.

Cardinal mules to be observed if prevention of outbreaks amongst young animala is desired may be stated: (a) Use high, well drained land for young atock and take care that the land chosen is clean, that is, that it has not been soiled during the last twelve months by the faeces of animals suffering from the disease or even by any adult animals. (b) Avoid overcrowding. (c) Keep the young separate from the older stock until they are past the age of two months. (d) Kcep the foster-mothers, pens, or hutches clean. Where these are of the floorless type move them frequently. (e) See that a good supply of fresh drinking water is available, and use a type of drinking trough not likely to be sniled by faeces.

Once diagnosis has been made by means of microscopical examination, all sick animals should be segregated and their droppings hurnt. Carcasses of any animals that die must also be burnt. The pens or hutches

Cochin Fowl. Cock and ben of the partridge variety
containing the healthy animals should be disinfected thoroughly with hot water and strong cresol, or 3 per cent. aulphuric acid, every other day lime washing of the pens wite serve as woll. Where pens of the remorable type without hoors are used, they should be noved to freah ground and cleaned out cvery other day. The object of fixing this 4 S hour interval is to ensure that any parasites passed out with the facces shall not have sufficient time to enable them to reach the infective stage before the animals are again moved or the pens thoroughly disinfected. Infected pastures may be given a top dressing of quick lime, say, 6 cut. to the acre See Poultiy Rabbit. Pion. Coc-cid'-i-osis.

COCHINEAL. The red colouring mattor obtained from the cochineal insect is most valuable in the kitchen, being perfectly harm less and devoid of taste, while by its use the appearance of many fuods, such as blancmanges, stewed pears etc, can be greatly improved

COCHIN FOWL. This is one of the breeds of poultry that has come much to the fore from an exhibition standpoint but in sor doing has suffered from a utility standjoint. It is a massive bird with heavy feathering. There are several varieties, buff, partridge, black and white being the most popular. The cochin is considered by
some a gond winter layer, but its merits as a table fowl are small Sec Poultry.

Cochlioda. The name of a family of orchids with showy flowers. They need the same treatment as does the odontoglossum (q.v.).
COCK - A - LEERIE. This highly nutritious soup has its foundation in chicken stock and leeks A cheap way of making the stock is by simmering the neck, gizzard, fect and boncs of a fowl for one or two hours in salted water. To one quart of stock, which should be skimmed of all fat and strained, four leeks ahould be allowed. These are cleaned, trinmed, and cut into inch-long strips, and put into the atock, with a amall onion, carrot and turnip, grated finely. Then bring the vhole to the boil and simmer for about half an hour. Salt and pepper should be added, and if the soup is not considered thick enough, a white roux may be added. The roux is made by melting a tablesponful of margarine in a saucepan and atirring in the same quantity of flour until a smooth paste results. A little of the soup should be poured into the roux in the pan and stirred round until it is liquid, and the liquid then added to the soup-which should be brought to the boil again.

COCKATOO. A member of the parrot family, the cqckatoo is distinguished by its crest of feathers. Compared with the parrot, though equally docile and affectionate, it is an indif. ferent talker. The two species most commonly kept as pets are the great white-crested and

Cockatoo. Specimen of the sulphur
crested specles, with crest erect
the lesser, or sulphur-crested. Like the patiot, the cochatoo may be kept in a large bell cage. or it may be chained to a stand See Parrot.

COCKCHAFER GRUB. The grub of the great hrown May fly is the cockchafer grub, which is quite capable of eating through thick roots, but fortunately is rarely seen in large numbers. It is not uncommon to turn one up when forking among trees, shrubs, and herliaceous plants.

When the gruh is present in such numbers as are likely to become a danger or nuisance, it is well to dose the roots of suspected trees or shrubs with a strong solution of salt As the grubs talie three years to come to maturity, and can do quite a lot of damage during that perind, it is well to destroy them while they are young.

Cocker Spaniel. A popular animat noted for ita lively nature, and used as a sporting dos

COCKER SPANTEL. The smallest and merrient of all spaniels, this dog weighs from 20 to 25 lb . His cheery nature and bustling ways make him a universal \{avourite, either for work or as a companion. Fairly short in back, and moderately high on the legs, he is as active as could he wished. His head is cleanly chiselled, of moderate size, ears lobular long, and set on low, clothed with long, silky hair; the eyes are hazel or brown in colour, harnonising with the coat, which may be all black, black and white, or roan, brown, livet and tan, black white and tan, etc. The tail, which is said to be indicative of bluc blood, although set on low, should be carriesl in a line with the back, and when the dog is in action it will be waved incessantly to and fro. The coat of the cocker spaniel should he Hat and silky, never waved or harsh. See Dog

COCKLE. The small shell fish known re cockles are found in great abundance on many parts of the 13 ritish coasts The double shells are rounded and deeply ribled, moro like scallop than oyater shells; the fish when cooked and removed from the shells are marked yollow and red. All cockles need to be thoroughly cleaned, otherwise they are exceedingly gritty. The best way is to wash well the shells till they are free from sand; then lay the fish in cold water to cover them, and a handful of salt and oatmeal, and leave them till the next day to rid theinselves of any sand they may contain.
To open cockles, put them ill a basin and pour on to them fast-boiling water to which a little salt has been added. Repeat this if the sliells do not open easily with the point of a knife. When open talie out the fish and cook
them as desired. Cockles can be used in most ventures out of doors in the hotteat weather for recipes suitable for oysters They make excellent patties or sauce. See Oyster.
COCKROACH. Known as the black beetle, although its colour is really brown, the cockroach cannot claim any c hard-shelled beetle tribe.

Cockroaches are members of the straight-winged ( Or thoptera) order of insects. They are much flattened from above and below, which enables them to hide in crevices during the day, and the upper pair of wings are merely leathery, instead of being loorny, as in beetles In the female of the common cockroach the wings do not develon, and are represented by mere scales, and those of the male cover only half of the body. The front part of the fore body is developed into a broad shield under which the inscct hides its head. The mouth is furvery long, flexible antennac, and the Iong Deatruction.
logs are covered with strong hristles.
A nocturnal insect, $a$ house that swarms with cockroaches might appear in the daytime to he free from them but for the unpleasant odour characteristic of them. The eggs are contained in little horny purses, which are deposited in crannies; each receptacle contains 16 eggs. The conmon cock roach is an alien which came from the East There are three native species, quite small creatures which never come into houses, but the alien, used to warmer conditions, only

Cockscomb. The carious head of the cockscomb, Celosia cristata
the purpose of establishing itself in neighbour ing houses. There is a amaller and paler sprecies, known as the Croton bug (Blatella germanica), which emanates from Central Europe, and in ome places is exceedingly a hundant.

A good remedy against the cockroach is to strew its noclurnal haunts with freah alices of cucumber, which, being consumed, renders them helpless. Beetle traps which entice them to fall into beer and get drowned may also be used with success in reducing numbers; but a more deadly device is the spreading of phosphor paste on thin bread or mixing it with honey and laying it in their way. Arsenic added to potato boiled and mashed or mixed with the pulp of a roasted apple, is a certain remedy. Great caution must he observed in the use of these poisons, or food

COCKSCOMB. This is the popular name of Celosia cristata, a half-hardy annual which bears cockscomb-like hends of bloom in crimson, yellow, and other colours. It is nsually grown for the summer decoration of the greenlonuse, but may be used to fill summer flower beds. Seeds are sown in Feb ruary-March in a temperature of $50-55$ degrees, and the plants are potted finally in 5 -in. or 6 -in. pots in a rich compost. Celosia plumosa, which bears feathery heads of blonm in red and yellow. needs similar treatment.

## Cocktails and Cocktail Parties

## How to Mix Cocktails and What to Serve with Them

This is one of various articles containing suggestions for the hostess. Other entries of related interest are Bridge Party; Dinner; Luncheon. See also Hors d'Ocuvre; Sandwich

A cocktail party may be an informal gathering before dinner, usually from $6 \mathrm{p} . \mathrm{m}$ to 7 or 7.30 p.m., or sometimes such a party is given later in the evening, when varieties of refreshments accompany the cocktail tray. These may take the form of hot toast sand wiches, containing a mixture of grilled kipper and bloater (freed from bones and skin and sharpened with a squeeze of lemon juice and a little cayenne), or a slice of grilled bacon. Tiny squares of hot buttered tonst may have a apoonful of caviare or a curled anchovy placed on them ; dishes of crisp potatoes are also liked, and may be eaten with the fingers at a cocktail party Other refreshments suitable to be served on any such occasion are finger-strip sandwiches with appetising fillings such as smoked salmon or bloater creani, stuffed olives, plain biseuits buttered and spread with Gentleman's Relish, salted almonds and cheese straws. A big dish of fruit is decorative, and useful with dainty cakes, fruit punch and pineappleade to offer any guests who do not take alcoholic drinks.
Cocktail Appetisers. Although a cocktail is usually a mixed drink there are certain appetisers known under that name which may be served either at a cocktail party, or may replace hors d'oeuvre at a dinner or luncheon An oyster cocktail, which inay be put into stemıned glasses and acconıpanied by biscuits, is made with shelled oysters, and a table. spoonful of the following sauce to each glass Nix one tablespoonful lemon juice, two table. spoonfuls tomato ketchup, $n$ dash of tobasco sauce, a teaspoonful of vinegar and salt and pepper to taste. Clam cocktail can be made in in similar way, using six of the smallest clams and their liquor.

Tomato cochtails are made by placing the pulp of fresh tomatoes in a glass, flavouring with tomato sance and garnishing with chopped olives. These appetisers should be placed on ice before serving.

A piek-me-up cocktail is the prairie oyster For this two teaspoonfuls each of Worcester sauce and brandy, one teasponnful of vinegar and one of tomato ketchupare mixed together, the yolk of a fresh egg is dropped in, and a dash of red pepper added.

Many cocktails can be made easily at home A shaker, a pair of nickel receptacles. is required to mix the ingredients properly and ensure the cocktail being cold Crushed ice is required for most cocktails For an almost complete outfit the mixer needs a bottle each of dry gin, whisky. brandy, pale sherry, French and Italian vermouth, Angostura bitters, orange bitters, plain sugar syrup, orange syrup, grenadine or raspberry syrup and such ingredients as oranges, lemons egga, tinned pineapples and soda-water When scrving a dry cocktail put an olive in the glass, with a sweeter one a cherry

The following recipes are for some of the better-known cocktails: Bronx is made by tilling the shaker half-full of broken ice Add the juice of $\frac{1}{3}$ orange, $\$$ gill of dry gin, $\frac{1}{}$ gill of French vermouth and $\frac{1}{6}$ gill of Italian vermouth and mix all well together. Brandy cocktail needs threc dashes of maraschino two dashes of Angostura bitters, one dash of orange bitters and one portion of brandy. Fill up with ice and mix and strain into a cocktail glass. Gin cocktail requires three dashes of Angostura bitters, one small lunp of sugar, and one portion of gin

Favourite Recipes. For Manhattan take ] or 2 dashes of Angostura bitters, $\ddagger$ gill of whisky, $\ddagger$ gill of Italian vermouth and 2 or 3 dashes of syrup. Fill up with ice, strain into a cocktail glass and squeeze lemon pect on the top. If it is required dry, leave out the syrup and use French instead of Italian ver mouth. Martini, one of the most famous of cocktails, is best made with one dash of orange bitters, $A$ gill of vermouth and $\frac{1}{3}$ gill of dry gin. Stir it up and strain it into a cocktail glass, squeezing lemon-peel on the top.

Vermouth cocktail is made with a smal glass of French or Italian vermouth to which is added a dash or two of hitters and a piece of lemon peel Whisky sour is a wineglassful of whisky, 2 or 3 dashes of lemon juice. $\frac{f}{2}$ tablesjoonful of sugar, and a squirt of soda water or seltzer. Fill the glass with ice and strain it after stirring well.

Cocktail Party. Appetising light refreshments arranged to accompany cocktails at an evening party Courtesy of Lavteys

Cocktall. The ingredients mized in the shaker ready for vigorous shaking
Courlesy of Lauteys
Of many other cocktails the following are examples. Ale cocktail or sangaree is made by dissolving a tablesponnful of sugar in a wineglassful of water Pour this into a large tumbler and fill it up, with ale, adding a little grated nutmeg. Turf cochitail needs 2 dashes of orange bitters, 2 dashes of maraschino, 2 dashes of absinthe, $\frac{1}{4}$ gill of gin and the same quantity of French vermouth. Stir it up well in n glass half full of broken ice. Star cocktail requires 3 dashes of orange bitters, $\frac{1}{2}$ gill of apple brancly and $\underset{\&}{\&}$ gill of French vermouth, "ith 2 dashes of orange curaçao. Squeeze some lemon juice into it and add an olive.

Harvard cocktail is made from \& gill brandy and the same amount of Italian vermouth, with 2 dashes of Angostura bitters and one dash of gum syrup. It should be stirred up well in a glass half full of broken ice.

Valencia cocktail needs equal quantities of tangerine juice, apricot brandy, and dry gin, to be well sliaken and chilled.

COCOA: How to Make. Cocon is prepared from the sceds of a tropical tree. It is sold either as nibs, llake, or soluble cocon. In many so-called soluble cocons a small proportion only of cocoa is present, the remainder being made up of added sugar and starch. These ingredients, though fiarmless, necessitate boiling the mixture in order to cook the atarch and render it digestible

When making cocon allow a heaped teaspoonful of the prepared variety to $\frac{1}{2}$ pint milk or milk and water in equal proportions. Mix the cucoa with sugar to taste and a little of the milk to a smooth paste ; heat the milk and water together, and when they hoil pour them over the cocon, stirring all the time. Return the whole to the pan, boil it up, and serve it immediately. See Chocolate.

COCOA BUTTER. This is a yellowish. white fat extracted from the cocon nibs. It is somewhat hard, and has a distinct odour of chocolate. It is chiefly used for medicinal purposes or the making of chocolate.

COCOA PUDDING. To make this light sweet, sieve together 4 oz. flour, 2 tablespoonfuls cocoa, and 1 teaspoonful haking. powder, and cream together $20 \%$ each of butter and sugar. Whisk into these one wellbeaten egg and lightly fold in the flour, etc., and a little more than a gill of milk. Put the misturc into a thickly greased basin, twist a piece of greased paper over the top, and
steam it for 2 hours. To test if the pudding is conked, push a clean, warmed skewer through the centre. If on withdrawal it is as clean and bright as at first, turn the pudding out and scrve it with oustard sauce.

COCONUT. The fruit of the ooco palm is of great value looth in and out of the kitchen. The fresh nut, when opened, is used as a fond by scraping out the nutty pulp and eating it plain or with sugar and lemon juice or a sprinkling of sherry. The juice or milk is used in the preparation of curries The kernel of the nut, dried or desiccated, keeps for years in a dry place, and is used for cakes, puddings, and confectionery.

COCONUT BISCUIT. Prepare these by mixing 4 oz. desiccated coconut, 2 oz. Hour. 3 oz . granulated or castor sugar, and 1 oz . cornflour. Bent up an egg, mix it with these ingredients, and then prour in sufficient milk to form the whole into a dry paste. Turn the mixture on to a slightly floured hoard, roll it out till it is about $\ddagger \mathrm{in}$. thick, dust it with sugar, and then cut it into rounds the size of ordinary biscuits. Place these on a greased haking-sheet and bake them in a hot oven for 10 or 15 min . These biscuits are better if baked the day after they are prepared.

COCONUT CAKE. From the recipe here givén a light coconut cake may be mads. porvided always that the ingredients are thoroughly beaten. Sieve ? lb. flour with " level teaspoonfuls baking-powder. Put 6 oz. cach butter and eastor sugar into a warmed basin, beat with a wooden spoon to a soft white cream, and work in 3 or 4 eggs, whisked to a froth. Now add the flour lightly, folding rather than stirring it in. Now mix in a teacupful of desiccated cuconut and $\mathbf{t}$ tablespoonfuls of milk. Pour the mixture into a paper-lined tin and bake the cake in a moderately hot oven for about $1 \frac{1}{2}$ hours. A pretty finish is given by coating the top of the catie when cold with a little glacé icing and sprinkling coconut and ohopped pistrachio nuts on the top.

Small coconut cakes are made by creaming together 3 oz. margarine and $\& \mathrm{Ib}$. granulated sugar and heating in an egg. In a separate basin sieve ! lly. llour and I teaspoonful baking-powder, add $\ddagger \mathrm{lh}$. desiccated coconut, and then stir these into the sugar, eto., together with $\frac{1}{2}$ gill or more of milk and a few Irops of vanilla llavouring. Put the mixture into small greased cake-tins and bake them in a hot oven for about 20 min .

COCONUT CREAM. To prepare mix 3 oz . ground rice to a smonth paste with $\frac{1}{2}$ gill milk. Put what remains from 2 pints of mill:

Coconut Cream. Party sweet favoured with coconut and ornamented with glace cherries
into a aaucepan, together with $1 \frac{1}{2}$ oz. margarine or butter and 2 oz. white sugar, and when these are boiling pour them on to the rice paste. Return it to the saucepan and bring it again to the boil, keeping it well stirred Then add 2 oz. desiccated coconut, cook the whole slowly for 8 or 10 min ., and draw it away from the fire before adding a little almond or vanilla Havouring, $\frac{1}{2}$ gill cream, and 1 oz. quartered glace cherries. Mix all these ingredienta together, then pour them into a glass dish and leave them to cool. Before serving decorate the top with some more glacé cherries.

COCONUT DROP. These cakes are prepared from d lb desiccated coconut, 6 oz . castor sugar, 3 eggs, and a little almond flavouring. Whisk the sugar and eggs togetimer for about 12 min . or until the mixture becomes thick and free from streaks; then sprinkle in the coconut and heat the whole thoroughly for a few ininutes heforc adding the flavouring. Grease a baking-tin, take a deseertspoonful of the inixture at a time and drop it on to the tin. Cook the drops in a moderately hot oven for about 10 to 15 min ., cool them on a sieve, and sprinkle with castor sugar.

COCONUT FIBRE. Made from the coans fibrons covering of the nut or fruit of the coco palm, coconut fibrc has niany uses in the home. It is employed in horticulture, and occasionally as a packing material, sometimes as the fibrous constituent of plaster ormaments. Its principal domestic applications are in the form of matting, rugs and carpets. The material is made in different widths and obtainable in many colours, patterned and plain.

Coconut Biscuit. Small, round biscuits. very attractive for afternoon tea

For hard wear on rough or uneven surfaces it has many advantages. It conforms readily to unequal surfaces, and is not seriously affected by damp. A tendenoy to roll up at the corners is checked by a drugget pin if on a wooden floor, or by a screw driven into a rawlplug in a solid tloor. A counteraunk brass screw and washer to suit is the best arrangenient under these conditions.

Periodical shaking and beating are essential, hut in addition the matting can be washed and scrubbed to remove dirt and stains.

The fibre of the coconut is a useful medium in which to grow such bulbs as lyacinths, tulips, narcissus, snowdrops and crocuses in howls. When making up a fibre bowl, a layer of charcoal should always he placed at the louttom of the receptacle, and the fibre muat not be knotted or luınpy. See lBegonia; Bulb; Hyacinth; Mat.

COCONUT OIL. The oil obtained from coconut, which in appearanco resembles a white solidified fat, melts at a comparatively low temperature. Coconut oil is used in the manufacture of margarine, for whioh purpose it undergoes a process that deprives it of its taste. Large quantities are used in the manufacture of sonp, $n$ variety known as marine soap giving a lather with sea water: the soap is the basis of a shampoo for the hair. See Hair ; Shampoo.

COCONUT PUDDING. Pieces of stale hread may be used in the making of a gand baked coconut pudding. P'repare it by cooking 3 gills mills and ! Ib. desiccated cocomut in a saucepan over the lire for a few minutea When the milk looils sprinkle intu it 2 or. lireaderumbs, and add also $1 \frac{1}{2}$ oz. margarine and 3 oz. white sugar. Mix all together thoroughly, then draw the pan to the side of the grate. Separate the yolk from the whito of an egg and stir the former into the mille, etc. ; acid a few drops of ratalia llavouring and then fold in the white of egg, previous! y whisked 10 a still froth. Tum the whole into
a grcased pie-dish and bake in a moderately hot oven for a bout 3 s min , or until the pudding is golden brown. It should be served in the dish in which it is cooked.

COCONUT PYRAMID. When possible, these cakes should be mired the day before they are baked Prepare them by mixing $\frac{1}{2}$ th

Coconut Pgramid. Cone-shaped cakes made with
desiccated coconnt. very popular with children
deaiccated coconut with $\ddagger \mathrm{lb}$ granulated sugar, adding a benten egg, a little vanilla flavouring, and enough water to make the coconut and sugar adhere when pressed together. Form tablespoonfuls of this mixture into pyramids, place them on rice paper in a baking-tin, and bake them in a copl oven until they are firm and lightly browned. A few drops of cochineal may be added to the mixture.
C.O.D. Recognized abbreviation for cash on delivery, a method by which the Post Office collects money for gonds acnt through the post The amount collected must not exceed $\mathbf{1 4 0}$. The charge is 4 d for parcels worth 10s. and under, then it rises to 3d. for those up to $£ 1$, to 8 d . for those up to $£ 2$, and to 10 d for those up to $£ 5$. Beyond this there is an additional 2 d . for each Ej or less. If the parcel is sent by rail the charge is $\mathbf{3 d}$. more.
An incoming cash on delivery parcel is delivered by the postman in the ordinary way (except that. if the trade charge exceeds $£ 5$, the parcel is kept at the Post Office to be called for, notice of its arrival being sent to the addressee). The postman is striotly forbidden to give up a casli on delivery parcel, or to open it at the request of the addressee, or to allow the addreasee to open it until the trade charge and any other charges due have heen paid A delivery fee of 4 d ., in addition to the anount of the trade charge, is collected from the addressee of a cash on delivery parcel received from a place abroad. The amount of the trade charge collected is remitted to the sender of the parcel without deduction. No receipt is given for a trade charge. When the trade charge has been collected, the Post Office undertakes the responsihility for the due remittance of the amount to the sender of the parcel ; and a trade charge, once collected, is in no circumatances refunded to the addressee.
This service does not apply to the Irish Frce State. There is, however, a reciprocal service betwcen Great Britain and various parts of the British Empire and certain loreign countries.

COD: How to Cook. A highly nutritious fish, cod is at its best from November to March. The liver contains valuable products, and can be cooked separately from the fish; from it is obtained the well-known oil. Cod's roo is also made into a separate dish. The liead and shoulder of cod are the parts most in demand, but from the thin tail end suitably sized steaks for frying are obtained.
To boil cod, the fish is washed and placed in a deep fish kettle containing warm salted water, with a tablespoonful of vinegar added. It is then brought to the boil and allowed to simmer gently for about 30 min . The fish is served with parsley, egg, anchory or caper
sauce, or melted butter, and garnished with slices of lemon
A method of baking a cod steak is the following: Wash and dry the fish, trim off the fins, and tie the steak in shape. Dip it in Hour, brush it over with beaten egg, cover it with breadcrumbs, and then put it in a greased firepronf dish. Mix together 2 tablespoonfuls breadcrumbs, 2 oz . chopped suet, 1 dessertspoonful ohopped parsley, and a teaspoonful ohopped herbs. Season this mixture, heap it on the stoak, lay a piece of greased paper over the top, and bake it from 15 to 20 min Serve it in the lint dish with anchovy or other fish sance poured round.
To fry cod steaks, wash and dry the fish, coat it on both sides with Hour that has been scasoned with salt and pepper. Fry it in hot fat until it is light brown in colour, then turn and fry it on the other aide. Cod sleaks can also be dipped in batter or coated with egg and breadcrumbs before being fricd. The steaks should be garnished with slices of lemon and served with parsley, egg, or anchovy sauce.
Cod Recipes. Cod can alan be stuffed and haked. Make a veal stuffing and press somc into the middle of the fish through an incision Close the incision with skewers, and place the fish in a casserole with 2 tablcspoonfuls of dripping and the same quantity of stock or water. Baste it frequently and bake it in a morlcrate oven for about an hour. Serve it with parslcy, egg, anchovy, or tomato sauce.
Creaniod cod is another way of cooking this fish. To prepare it, the cod should be placed in warm water and slowly brought to the

Devilled cod cutlets, an appetising way of preparing the fish with 1 oz. margarine cut into small pieces on the top, and bake them in a moderately hot oven for about 15 min .
Salt Cod. If possible, leare salt cod to anak overnight in tepid water and change the latter two or threc times. To boil it, put it into a saucepan containing enough warm milk and water-mixed in any quantities-to cover it. Boil up slowly, and once it has reached boiling point, let it simmer for $\frac{z}{}$ hour or more. When thornughly cooked, drain the fish, and then flake it on a prepared dish, pouring over it about $\frac{1}{2}$ pint of parsloy sauce.
Salt cod is excellent for breakfast if shinned. cut into convenient-sized pieccs, and then fried in bacon fat to which a little butter has heen added. If liked, a few slices of bacon may be served with it (See Fish Pie.)
Cod's Roe. To cook a hard ree, wash it, tie it' in a piece of butter muslin, drop it into a saucepan of warm salted water, and cook it for about $\}$ hour. Then let it get cold, cut it into slices about 1 in . thick and fry them a golden brown in hot fat. If preferred, the slices could first be dipped in frying batter or coated with egg and breadcrumbs. In either case it should be served very hot. A soft roe could be fried in the same way, but would not neod the preliminary boiling.

To serve cod's roe on tonst as a breakfast dish, cut up $\$ \mathrm{lb}$., either hard or soft, into small pieces Put them in a saucepan with 2 oz. butter, 3 to 4 tablespoonfuls milk, a well-beaten egg, seasoning; add a little chopped parsley, and stir the whole over the fire till it thickens. Then add a fow drops of lomon juice. Spread the roe snuce over buttercd toast. See Dunning.
CODICIL. A will may be altered by 8 short additional docu ment, called a codicil. It should begin: "Thin is a codicil to my will dated (here give dute of will)," and should then brielly set out alteration or addition boil, when the atock should be strained off and requirol; thus: "In place of the sum of $£ 100$ reserved. Arld about 1 oz butter to the fish, bequeathed in my will to George Robinson, together with a pint of milk or fish stock, and bring all to the hoil. The corl is then taken out, the honce removed, and the Haked fish put into the saucepan The sauce should then be thickened by the addition of 2 tableapoonfuls of Hour made into a paste with cold milk. The contenta of the pan are stirred over gentle heat while the thickening is being added and until the inixturo is thick and creamy. Pepper, salt, and a tableaponnful of chopperl parsley should then be added, and a few minutes before serving the pan should be drawn to the side of the stove and one or two well-beaten eggs thoroughly stirred in.

Devillod cod is prepared by washing 3 large cod cutlets and drying them in a cloth. Put i small teacupful of cold whito sauce into a basin, whisk it until it is smooth, and then stir into it half a teasponful anchovy ossence, 1 tcespoonful mixed inustard, and 1 level tablesponnful chutney, seasoning the whole with salt and cayenne. Melt loz. margarine and brush it over the cutleta; then spread the sauce mixture thiokly on both sides, and finally coat with ? large tableapoonfula bruwn breadcrumbs. Put the cutlets on a greasod tin

Codling Math. 1. Periect insect, magaifled to show markings. 2. Caterpilling and two nupa skins, magnifled
give him $£ 150$." or as the case may be. The codicil must be signed by the testator and witnossed by two witnesses, just the same as the will was, who take no interest either under will or codicil. If there is anything but the very simplast of alterations to be made. it is better to call in a solicitor. See Executor Legacy; Will.

CODLING MOTH. Of all apple pests the codling moth is prohably the most notorious and ita attacks are not confined to the apple for pears at times suffor mither severely and the fruits of the quince and walnut inay also be damaged.
According to Leatlet No. 30, issued by the Ministry of Agriculture, the hest methods of dealing with the moth are as follow: In orchards where spraying can be practised, the trees covered with moss and loose bark should be cleaned by means of a tar-oil winter wash Tho trens should be sprayed with lead arsenate just after the petals havefallen. It will be found that there is a period of from 7-14 days during Which the calyx cup, subsequently the eye of the apple, is open, while later it closes.
The object in spraying is to force the arsenate into the calys oup, where it is retained
after the calyx closes, with the result that any codling larva which attempts to burrow through the eye of the apple is poisoned. It is useless, therefore, to spray too late, when the calyx cup is closed; but it is also necessary to wait until the blossom has completely fallen, or there is danger of poisoning the bees. One pound of lend arsennte paste should be allowed to every $20-25$ gallons of water.

In orchards where spraying is impossible the trees may be banded in June with old frayed sacking, folded paper or ropes of hay. If possible, two bands 4-6 in. Wide should be used on each tree, one just below the junction of the branches with the trunk and the other a few inches from the surface of the ground The larvac on leaving the fruit are likely to nake their cocoons in the folds of the sacking or in the hay, and the bands must therefore be burnt in the autumn.

Ill fallen fruit should be picked up and disposed of in such a way as to kill any larvae inside. All rubbish near the trees sliould be cleared away and burnt. See Apple; Pear.

COD LIVER OIL. Whether in its natural purified state or in the form of an emulsion, the oil extracted from the liver of the codfish provides a valuable nutritive tonic for invalids and particularly for consumptives and rickety children. It is a useful addition to the diet when one is working at high pressure; and persons suffering from chronic bronchitis will derive benefit from it. It is rich in the fat soluble vitamin $A$, which is so important in uutritional efficiency, its absence from a diet leading to the development of rickets and other conditions.
Cod liver oil is often prescribed with iron, as in the following tonic mixture, for a rundown thin child and for children developing tubercular glands in the neck. The dose is 1 to 2 teaspoonfuls three times a day after meals.

Mixtures of cod liver oil, malt, and iron such as the following are also useful tonics to be taken during the convalescence after any severe and lowering illness: The dose for n child of 6 to 10 year's is $\ddagger$ to 1 teaspoonful three times a day after meals.
$\begin{array}{lllllllll}\text { Codd liver oll } & .: & . & . . & . . & .- & . . & 1 & 07 . \\ \text { Extract of malt }\end{array}$

COELOGYNE. This has been described as the amateur's orchid, for it is one of the easiest to grow. The imported plants should be placed in a warm bed of moss and sprinkled with tepid wrater in the greenhouse, until the pseudo-bulbs have swollen to their normal size. They should then be placed in welldrained pans containing a mixture of loam and peat, with a little crushed charcoal, and treated as ordinary heated greenhouse subjects for winter flowering. C. cristata and its varieties propagate readily by division of roots. The Howers of C. cristata are white with yellow crest on the lip. Those of C. pandurata are green and black, a striking combination. There are other species and varieties. See Orchid. Pron. Coe-log'y-ne.

COFFEE. Coffee is a general stimulant and promotes the activity of the brain and the beart. It is refreshing when one is fatigued, and, like tea, its beneficial effects are more lasting than those of alcohol. In cases of heart discase and in prolonged depressing febrile diseases, e.g. pneumonia and enteric, coffee, either black or with milk, is a useful addition to the dietary.

How to Roast. In making coffee, if the best results are to be obtained, the berries should be freshly roasted nnd gmund. If a coffee roaster is not available use an ordinary
enamelled frying-pan. Melt just enough butter in the pan to moisten the berries, and turn them frequently over n smokeless fire or moderate gas stove until they become rich hrown in colour. It is a good plan to roast them in relays, passing them to the coffec mill at once, and making the coffee as soon nfterwards as possible. If any of the berries turn black during the roasting process, take them out of the pan without delay. One of the strongest and most serviceable kinds of coffice mill is made of cast iron, and fitted with a funnel-shaped top, into which the beans are poured. The grinding action is controlled by means of an iron handle, which, when turned, causes the ground coffee to fall into a tin or basin placed immediately beneath the mill.

When using a coffee mill, make certain that the coffee is being finely ground, otherwise its full strength will not be extracted. If the coffee a ppears conrse, it is generally a sign that the mill requires readjusting.

A French method of coffec-making consists of allowing 1 tablespoonful of coffee to $\frac{1}{2}$ pint of water, pressing the coffee down in the percolator or cafetiere ; pouring on $\frac{8}{4}$ pint of boiling water and slowly adding as many coffee-cups of watcr as are required. Should the coffee-pot be made of silver, scald it out twice before pouring in the coffee, and if the latter has to stand for some little time before being used, keep the pot in a bowl of boiling water.

Flavour can be improved if the amount to be used is put in a cup, covered by a saucer, and placed in the oven for a few moments to warm; also by adding a pinch of salt to the made coffee. Reheated coffee loses its flavour. To make the grounds settle in the pot a little coffee should be poured into a cup and then poured back in the pot. This should be done several times.

Coffee is drunk either white or black-that is, with or without milk. Black coffec should be strong and may le served only with sugar after dinner. Never use cold milk for white coffee.
Iced Coffee. A method of making iced coffee consists of putting 4 heaped tablespoonfuls coffee into a quart of boiling water, boiling them in a pan over the fire, then removing the pan for a few seconds, replacing it again and reboiling the whole. Repent this process 2 or 3 times, then let the coffee stand for 5 or 10 min . before straining it. Put 4 oz. castor sugar and $\frac{1}{2}$ pint milk into a pan over the fire, stir these until the sugar has dissolved, and then bring them almost to the boil. Add these to the coffec, and leave the mix. ture to cool. When it is quite cold, add $\frac{1}{2}$ pint cream and a few drops of vanilla essence, putting the jug in an ice cave or in a vessel which is well packed round with ice.

Coffee-making Machines. There are many varieties of coffee-making machines in most of which the same principle is employed of straining the freshly ground coffee through boiling water. In a cafetidre the necesmary quantity of coffee is placed in an upper part which
forms a strainer. Boiling water is then poured in, which passey through and is impregnated by the coffee, and percolates through the strainer into the lower part.
In some of these coffee-making machincs there are two vessels, an upper and a lower, on the same principle. In others the upper vessel is of glass and the container is made of hrass with a small spout: when the coffee has passed into the container the latter can be removed for use as a coffee-pot.

In another class of machine a glass globe is used, and in this the filtered coffer is hea ted by means of a small spirit lamp. The coffec is placed in an upper glass vessel and peroolater into n hoiler or lower glass vessel, circulation being effected by a central connecting pipe These machines are generally arranged so that When the coffec is ready for service the upper vesse! is removed, and the lower glass globe, complete with the stand and handle, acts as a cotfee-pot.

Figs. 2 and 3 show a cafetière with its com ponent parts. As the materinl of which these are made is fireproof, they can be left to simmer over a gentle heat and thus extract the best of the flavour from the coffee.

Coffee Service. In silver or plate the 18th century designs for the three-piece coffee services have not been improved upon. Benutiful among those are the octagonal stylo with ebony, fine wicker, or stained green ivory hnndles to coffee port and jug, and monlded bases; the penr-shaped, plainbodiod pattern with ornamentation round the edge of lid and foot with round sugar basin and the vase-shapes copied from old Shefficld plate examples in Adam styles.

For after-dinner use coffec cups in one of the many old English designs look best with this description of service, while the conventional patterns, the plain coloured chins rimmod with hack, the all-black except for gold or coloured

Coffee-making Machine. 1. Cona coffee-making machine. 2. Caletidere in Arenfool ware, and, 3 , its component parts 1. Courtesy Cona Colled Machine Co.. Hidd
be used. In earthenware, coffee pots and milk jugs are sold to match most of the good stock patterns, and are made in various sizes suitable for breakfast use Sce Breakfast.
COffee Cream sandwich. Mako this in a mund, shallow, हुeased cake-tin lined with greased paper. Whisk the yolks of 3 eggs with $\ddagger \mathrm{lb}$. castor sugar for 15 min Mix together f b. Hour and 1 level teaspnonful of baking-powder. then sieve and add them to the yolks and sugar. Whisk the whites to a stiff froth, fold them lightly into the othor ingredients, and add milk if required. Put the mixture into tho prepared tin and bake it in a bot oven for about 20 min . When cold split

Coflee Cream Sandwicb, a dainty and delicious cake lor afternoon tea
the cake in half, and prepare some ioing with $\ddagger \mathrm{lb}$ butter, 1 oz. chopped walnuts, 9 oz icing sugar, and 2 dessertspoonfuls coffcc essence (obtainable at any gmecery store) Beat the butter and sugar to a cream, add the flavouring, and then put $i$ of the icing aside. To the remaining $\$$ add the chopped walnuts, then spread this on top of the lower half of the cake, replace the top half, and leave it to get firm. Spread the outside of tho cake with 3 tablespoonfuls of apricot jam, and aprinklo over this 3 oz of chopped walnuts. Decorate the top with the remainder of the icing, forced through an icing tube into a docorative pattern.
COFFEE ECLAIR. These finger-shaped cakes are marle in the anme way as chocolate eclairs, except that they are coated with coffee icing. See Chocolate Eclair.

COFFEE ICING. To prepare coffee icing, put 2 oz . fresh butter into $\Omega$ basin and beat it to a soft cream with $\pi$ wooden spoon. Then add $\ddagger \mathrm{lb}$ sieved icing sugar and heat the two ingredients together until the mixture looks like whipped cream. Gradually add about l dessertapoonful of coffec essence. A forcing-hag and pipe should be employed to apply the icing on cakes.

An excellent coffee glacé icing whioh must, however, bo used immediately after making. can be prepared from ${ }^{3} \mathrm{lb}$ icing augar, $1 f$ tablespoonfuls strong coffice and the same quantity of hot water. Mix all these ingredients well together, and warm the whole.

COFFEE MÉLANGE. Cut a pint packet of vanilla jelly into amall pieces and pour over them a pint of hot-not boiling-milk Stir the mixture occasionally until the jelly is thoroughly dissolverl. Let it become almost cold, then add 2 large tablesponnfuls of coffee essence. If the jelly is not sufficiently sweetened, add extra sugar dissolved in a little hot milk. Pour the whole into a wetted mould. and when it begins to thicken atir in a thinly sliced banana and a fow slices of tinned apricots, peaches, or pears. When the inould is set, turn it out on to a glass dish, and serve it with whipped creans.

Cognac. The French brandy known as cognac is distilled from the vines of the Charentes. See Brandy.

## Coins: Their Collection and Arrangement

## With Instructions on Making a Display Cabinet for the Specimens

Other collecting hobbies described in this Encyclopedia include Birds' Eggs; Butterfly; China ; Stamps. Sec also Brass; Pewter; and Amateur Carpentry

The enrliest known coins are those of Greece. with only an obverse design, the reverse showing the impress of the punch or vice which held the ingot steady for the coiner's hammer. These date back 700 years b.c., and are supposed to have been struck in the Greck colonies in Asia Minor, which were more or less under tribute to Lydia No earlier coins are extant of ancient Egypt, Babylon, or Assyrim, and the original Jewish shokel was only a weight. So the Greek coinages. from the period stated to about the 3rd century A.D., form the first division in numismatics

The next important division is that of tho Roman coinages, starting nearly 400 years B.C., with large coins cast in bronze, and ending with the fall of Rome in the 5th century ad., although the Jatin language on Byzantine coins was continued unlil the llth century, when it was finally diaplaced by Greek. A third division of numismatics is concerned with Oriental coinages distinguished by Eastern languages on the specimens and comprehending Persian, Arabian, Afghan. Indian, Chinesc, and Japancse coins
The later coinages of the Western world, can be divided into two periods: (1) from the three sections is a magnificently varied range Carlovingian coinage in the 8th century, when for specimens. A complete series of types of
 2. Roman, brass cain, Vespasian. A.D. 70-79. 3. Isle of man, copper penny, 1758. 4. Spanish, silver 7. Bengal, copper balf anna, 1835. In each case the obverse of the coin is shown either above or to
the Roman denarius became a denier or penny to the rise of the U.S.A. ; (2) the ultra-modern coinages of the democratic era down to the present day
Among foreign coins of the former period is the silver thaler, daler, or dollar, coined in Germany about the time when Spain was under (ierman domination. This coin was subsequently introduced by the Spaniards into the Indies and Americar as a piece-of-cight. the Spanish sixpence, or royal, or real, beino then equal to one-eighth of a Spanish dollar The modern American silver dollar is thus the lineal descendant of the piece-of-oight.
British Coins, As regards British coins, the custons lins been adopted of placing the head of each sovereign in a direction opposite to that of the previous one. Thus the head of George $V$ faces the reverse way from that of Edward VII, as can be scen from a glance at any of the coins issued during their reigns.
British coins may be divided into three sections: (a) coins issued in Great Britain by regal authority, (b) tokens issued in Great Britain by private authority, (c) coins and tokens of Britain Overscas. In these
 the leit of the reverse

Engliah pennies, in bronze and copmer, is First make the quite a fascinating start for a small collection coin trays thembefore developing a larger one. Begin with selves. This can be the bronze penny of King George $V$, already done by obtaining lescribed. The penny of Edward VII has from any masterDE $S$ for the designer's initials, meaning de Saulles, and the legend on the obverse whows, for the first time, the monarchical title BRITT: OMN: REX-King of All the Britains.

There are two types of Qucen Victoria's pennies in bronze and onc in copper. The later bronze, which wis coined from 1895 to the end of the reign, depicts the crowned queen in her widowhood, with IND : IMP : (Empress of India), added to the royal title. The carlier bronze type, 1860 to 1894, pictures a younger queen, and the crown is not expressed, while on the reverse a lighthouse and a ship are in the device.

Penny Coinage. Preceding the bronze coinage was the larger Victorian penny in copper, from 1839 to 1860 , with the date on the obverse, under the head of the queen as she appeared in her girlhood, and the exergue on the reverse bears the rose, shamrock. and thistle. The 1860 penny is very rare

The copper pennies of Willians IV and George IV differ very little in style from those of the queen's first issue. Prior to them was the George III penny of 1806 and 1807. And when the George III penny of 1797, with its raised rims for the legends and with the date on the reverse, is reached, one has got to the first copper penny issued by royal authority in England. The copper pennies circulated in England during the token period were mostly those issued by private authority, and a collector needs grat judgement in selecting specimens Between the years 1811 and 1815 these pennies were coined in at least 70 different types all over England and Wales. Each of the genuine specimens usually indicates clearly the name and locality of the issuer.

The beautiful Anglesey pennies were issued by the Parys Mines Company in 1787-91; but most of the other socalled pennies dated in the latter part of the 18th century are either private medals made by collectors, or imitation tokens place of coing during the 18th centary

Coin Collecting. Obverse and reverse of the Anglesey Penny, one of the best designed copper tokens issued in the tray. The pivot
 of tho bit must go right through the tray, but on Cabinet Making, which will be found on when the circle has been sunk ahout $\frac{1}{\frac{1}{2}}$ in., it pages 172-3.

COIN TRICKS. One of the simplest of coin tricks is to offer to apin a penny on a coin tricks is to offer to apin a penny on a
smooth table, from which the cloth has been removed, and to tell, when blindfolded, whether it has come down head or tail. The secret is a very simple onc. On the extreme edge of the penny a smail notch is made with n penknife, so that a tiny piece of the metal projects. This projection is so small as not to be noticed. When the coin is spun it will settle on the unnotched side with the usiral long, steady, even whirr.

If it settles on the notelicd side, however, the time of settling is only about half the other, and the sound, instead of gradually becoming fainter until it ceases, ends suddenly. The difference in the two sounds is rarely detected by those who do not know the trick
The simpler the principle of a trick the more made by dealers for sale to collectors. The at each end of the trav, thus leaving a difficult often is its detection. The following rare book of plates by Pye, of Birmingham, projection which runs in a groove formed in published in 1801, is a good guide to the genuine tokens of the time.
There are copper pennies issued earlier still, in the 17th century-such as Prockter's Lancaster penny of 1671 , with the Stanley crest of an eagle and a child; Sytton's Blackfriars penny of the same ycar, with the figure of a friar ; and Taylor's penny, issued at Settle in Yorkshire in 1668. When onc has included all these with the other types sketched a fairly complete collection of English copper and bronze pennies will have been obtained. Then the halfpennies in copper and bronze can be tackled and the farthings, and the silver pennies that reach from Charles II right away back to the time of Offa of Mercia. The rest can follow later.
Clean dirty coins with oil of turpentine and a badger-hair brush, but do not rub them so as to takc off the tarnish of age.

Making a Coin Cabinet. The simple cabinet shown in Figs. 1-5 is quite easy to construct, and the home worker will find nany helpful lints in the article on Birds' Egg Cabinet, which will be found on pages 102-103.
the end wall of the cabinet
(Fig. 5). The completed tray is shown in Fig. 4.
The cabinet itself may be made to the dimensions required, the number of trays being suited to the collector's present or future needs. The cabinet illus. trated accommodates fourtecn trays; a larger one might have the trays arranged in two tiers on the lines of the Birds' Egg Cabinet. The Methods of construction may be gleaned from the last named article, and from the one
 Announce to the audience any member can take a handful of coins and that you will say whether the number is odd or even

Asl: himito place lis coins in a hat. and announce that you will, even when hbindfolded, add a handful of coins from your own pocket so that the total will be odd if the number of his coins is even, and even if the number of coins is odd. When you have dropped in your coins ask him whether the numlier ho chose was odd or even, and it will be found that the total in the bat is always the reverse. The trick depends simply upon the pe:former dropping into the hal
nn odd number of coins. The principle in voived in this coin trick is the simple one that the sum of an even and an odd number is odd and of two odd numbers even.

The following which will keep guessing for a
trick is one an audience very long
and maslied Cold remains of potatocs and cabbages fricd together are in some places called hy the same name.

## COLCHICUM. Another name for meadow

 saffron or autumn crocus See Mendow SaffronIn medicine colchicum, a drug obtained from its sceds and crowns, is used to relieve the pains of gout. The wine of colchicum is the preparation commonly chosen, and is combincd as a rule with an alkali and with Epsom salts. The dose is $10-30$ minims. The active principle colchicine is sometimes used instead. Colchicum shanded only be used by the orders of a doctor.

COLD: Prevention and Cure. This is an acute infection producing sore throat, a "stuffed" head, and Inter a f́ree discharge from the nose, headache, signs of feverishness. and possibly bronchitis. Close contact with $n$ person sulfering from a cold, as in a room, a railway compartment or the inside of a bus, is almost certain to produce infection. In addi tion, sources of irritation may be present in the nose or a chronic irritated condition of the throat and the hack of the nasal passages may be kept up by constipation, dyspepsia, pyrrhoca, the ahuse of alcohol or tolincco. If the colds are frequent and there is no evident cause of irritation, advice should be taken ahout vaccine treatment.

The tendency to cold may be lessened by hardening oneself against the chilling effects of changes of 1 cm . perature. This can be done by exercise in the open air and by keeping rooms thoroughly ventilated. The windows of thic bedroom should be widely open at night The morning tul is very useful, but if it is not taken a good substitute is to douche thoroughly the neck and shou!. ders with cold water and a sponge. The underclothing should be of wool or, for those who can afford it, silk.

Treatment. In treatment of the condition it is wise to consider whet her the cold is not the lreginning of such or inlluenza, as in such a cose the patient should keep to bed, as also be should do if he is particularly feverish even from a common cold. In any case a hot mustard foot hath at night is a good thing, with some hot whisky and lemon, and perhaps 5 grains of Dover's pouder. Headache nay be relieved by 10 grains of aspirin. If the patient pershould be caieful about exposure on the following day, should the go out.

Ammoniated tinc. ture of quinine is often taken at this time in tablets or a mixture, such as this: ammoniated
tincture of quinine, 6 drains; tincture of orange, 3 drains; glycerin, 4 drans; chloroform water to 6 oz . Take a table. spoonful in water four times daily Cinnamon essence and spirit of camphor nre also used, about 15 drops of either on sugar. Carbolised smelling salts may be inlialed, or pinol, elicalyptus, or menthol. The oils may be inhaled from the bottle, dropped on $n$ handkerchief, or from stenming water. If the thront is sore a gargle of stecl drops, 20 minims to 1 oz . water, or a weak antiseptic solution, e.g. permanganate of potash, should be used.

The diet sliould be light and rasity digested. If the bowels are constipated give 2 grains of calomel, followed by 2 drams of Epsom salts in the morning. When the cold has passed off, Eanton's syrup in $\frac{1}{2}$ dram doses, or the compound syrup of hypophosphites in dram doses, could le taken for a weck or two. See Catarrlı; Cod Liver Oil; Cough! Friar's Balsam, etc.

COLD CHISEL. The name cold chisel is applied to all kinds of metal cutting and chipping chisels, which are used for cutting cold metal, but have other applications in the house. The cheapest and commonest type is a round steel bar llattened and sharpened at one ond Such a tool is only fit for use as a case opener, or for breaking down old brickwork.

Those which are of real use to the home worker are the flat chipping chisels, in three sizes, 6 in. long by 3 in. wide, 8 in. long by 3 in. wide, and 18 in . long by 1 in wide The lirst are for small work in brass, copper, or thin slieet-iron. The intermediate sizo is for such jols as cutting sheet-iron and chipping olf the projecting ends of bolts The large size is for cutting ratickivork and all kinds of demolition work A (i) in. cross cut, a 5 in. diamond point, and $\pi 4 \mathrm{in}$. half-1ound will all be found worth their trifling cost.

The chisels must lse kept sharp by or smokelcss fuels, such as coalite, are made at a much lower temperature than gasworks coke, and therefore contain a larger percentage of the volatile matter of the original coal. The result is that they ignite more easily than ordinary coke and produce a more checrful fire, while giving off little or no amoke. Sec Brecze Block; Conl.

COLANDER . One of the most useful articles in the kitchen equipment, the colander is a perforated Lowl through which vegetables arc drained so that they will be frec of moisture when dished up. See Baking.

COLCANNON This consists of potatoes and cabbage boiled together

Colander made of aluminlum, with perforated presser Staines Kitchen Equipment Co., Lid.

Cold Chisel. 1. Rannd-ended chisel for cutting corrugated fron 2. Ordinary type of cold chisel ; and, 3 , grinding the cutting edges. For very finc work they can be sharpened on an oilstone in the same way as carpenters chiscls. Bricklayers' chisels are ground rather finer and thinner than those for metal cutting. A round-ended chisel is handy for cutting corrugated iron. The diamondpoint chisels are useful for chipping lines on metal and squaring up comers, and the halfround for chipping out screws or bolts that have broken off in their holes, and for shaping curved surfaces. A wise precantion is to giind off the ragged ends that form on the head of the chisel after use. See Chisel.

COLD CREAM. As a toilet requisite cold cream is used for softening and cooling the skin after sunburn, as a cleansing cream, to relieve harshness of the skin, etc. It may be obtained by asking a chemist for the official ointment of rose water The usual foundations for cold cream are either white vaseline, benzoated lard or white wax. See Beanty Culture : Skin.

COLD FRAME. Frames as used by gardeners for the growth and protection of certain plants and fruits are known as liot or cold, according to whether they arc heated or not. See Cucumber; Frame
COLD MEAT: Useful Hints. The re mains of different kinds of meat can sometimes advantageously be made up together. For instance, veal is improved if conmbined for a made-up dish with a little cold ham or bacon mutton and rabbit comhine well, and poultry combines with ham or veal. An underdone joint can be rebeated and served in the same way as a freshly baked joint if it is covered with mashed potatoes and placed for hall an hour in a quick oven Beef stands being recooked better than any ot her meat, and veal can be made into gooil entrée dishes Boiled rice is served with mince and curries, and sippets of toast are arranged round dishes of hashed meat

A joint of meat can be used down to the last The bones should he scraped of all the meat that remains, and this should be minced. Soak some slices of bread in cold inilk and let then stand for an hour. Whisk the bread and add the mince and scason well. This misture can be used to stulf tomatoes, to fill scooped-out haked potatoes, to add to omelettes and serambled eggs. The hones should then be put in the stock-pot and used for soup. The bones of poultry or game can be devilled
Savoury Puddings. Cold beef or mutton can be utilised for savoury meat puddings A liatter is made from potatoes, boiled, then rubbed through a colander, and beaten well with two eggs, a dessertspoonful of butter, and aufficient nilk to make them into a batter consistency This jotato batter should be spread on a baking-dish and a ices of meat placed over. These are covered with a !aver of batter and the dish is baked for about an hour
A steamed pudding is made in the following way. Soak pieces of stale bread in milk and strain from the liquid. Beat up the bread with an egg and a dessertapoonful of butter and stir over gentle heat until the mixture stiffens. Allow it to cool. Add seasoning, a sprinkling of mixed herbs, and a spoonful each of tomato ketchup and mushroom ketchup. Add the meat, ininced finely, and mix we! Turn into a buttered hasin and stean for about two hours. Serve with thick, broun gravy.

A pie is made from cold meat, macaroni, and pastry. A pie-dish should be lined ivith pastry and filled with a mixture of minced meat, cooked macaroni, and seasoning. Pour over a little white sauce and cover with pastry. Bake in a moderate oven for 45 min

Another form of savoury pie is made by mincing the meat, sensoning it well, and placing it in a pie-dish with gravy or stock Fry one or two onions and ahout four tomatoes, and cover the mince with alternate layers of onions and tomatoes. Cover the dish with mashed potatoes roughed up with a fork. Bake until the potatoes are nicely browned. See Casserole ; Cornish Pasty; Rissole; Stew.

COLD PACK. Cover the bed with a waterproof sheet and over this lay one or two blankets. Wring a sheet out of cold water and spread it on the bed. Lay the patient atripped on this, and wrap it round him, quickly folding it around each leg separately and leaving the arms free. Then cover the patient with a couple of hlankets and tuck them in about him. The pack may last 15 inin. to an hour, and may be repeated several times a day. It is used in cases where the temperature remains obstinately high.

## Cold Storage. See Refrigerator.

COLE. The local name of cole is applied to several members of the brassica or cabbage family, including kale, cottager's-kale, curly kale, horecole, kohl-rahi, and other greenstuffe. Sce Cabbage ; Curly Kale, etc

COLEUS. This gicenlouse plant is grown or the sake of its brightly coloured leaves in the greenhouse in summer. It is usually

Coleus. Briphtly coloured foliage of one of the varieties of the handsome rreenhouse plant
treated as a half-haidy annual and raised fresh each year from seeds sown in warmth in February. Coleus can also be increased by cuttings taken from the old plants in spring or summer. Coleus thyrsoideus, which bears hlue flowers in winter, is increased by cuttings inserted in a propagating case in early apring.

COLEWORT. This useful little autumn cabhage is raised from secds sown out of doors in May; the seedlings should be $t$ hinned to 10 in . apart, not transplanted. The rosette colewort and hardy green varietie are groun: the former is the favourite

Colewort. Specimen of the rosette colewort, an excellent little autumn cabbare

COLIC : Its Causes and Cure. The prominent symptoms of colic are scvere griping pains over the centre of the abdomen, with Hatulence, distension of the ahdomen, and either constipation or diarrioea. Fating overripe or unripe fruit, n chill, or neglect to keep the bowels regular, are the clief causes of the ailment. Acute indigestion from any source inay be accompanied by the pains.
Where indigestible food is known to have been taken, from one to two tablespoonfuls of castor oil should be given to clear out the intestine. To check the pain, 10 to 15 drops of tincture of opium may be mixed with the oil. Locally, a hot-water bottle applied to the
abdomen while the patient lies on his side in lied is helpful in getting rid of the Hatulence and relieves the pain. The diet should be entirely milky until the attack lias subsided, and afterwards for a time the total'ainount of food taken should he reduced, and all indigestible articles as woll as coarse vegetables should be forbidden. When flatulence is ar prominent symptom, this misture is useful, taking the $\frac{1}{6}$ part threc times a day

> Tincture of kinger
> Aromatic apirits of ammonia
> Spirit of chloroform
> cinuawon-water
> 1 dram
2 drams

When the cause of the colic is not clear, or if there is vomiting or the patient looks ill, opening medicine should not be given without medical advice. An enema will be safer.

With infants and children severe colic may bo brought on by such widely differing causes as improper feeding, want of cleanliness in the feeding bottles, sudden changes in the temperature, or exposure to chill. The patient should be kept thoroughly warm by being wrapped in blankets with a protected hot-water bag at the feet. A turpentine stupe, made by spinkling a cloth wrung out in very hot water with a few drops of turpentine and placed over the abdomen, usually cases the pain. Tenspoonfuls of hot water may be given.
Colic in an infant may be taken as a surc sign that something is wrong with its fecding mixtures. The milk may be too rich. and when diluted with whey or harley water all tendency to colic may pass off

COLITIS : Its Treatment. Inflammation of the colon, the large intestine, is termed colitis, and is of three chief types, namely. simple, mucous, and ulcerative.

The first of these comes on suddenly with severe pain in the abdomen, diarrhoen, perhaps vomiting, cramp in the calves, sometinies slight fever, and considerable mental and physical depression. Generally the attack is comparatively mild, but occasionally the diarrhoea is severc and exhausting. The treatment is to put the patient to bed hetween hot blankets and apply hot-water bottles or hot poultices to the abdomen. The patient should he kepit on a milk diet chiefly while the attack lasta. The milk is lest taken cold and should be sipped. Whey, milk, and isinglass, or white of egg beaten up, may also be given. To check the diarrhoca, give three minimi doses of strong spirit of camphor every 10 min . for an hour. In mucous or membranous colitis, large shreds or pieces of membrane may be passed by the bowel, and there may he much pain, with symptoms of indigestion and constipation with flatulence. The disease is a very chmonic onc, and associated with hysteria or neurasthenia, but there may be a tumour or other condition obstructing the bowel. It is therefore desirable that the patient should be overhanled by a physician at the start.
Ulcerative colitis is inflammation of the bowel combined with the presence of ulcers, some of these cascs being really dysentery. The symptoms are first collicky pains in thic abdomen, with attacks of severe diarrhoca often alternating with periods of constipation. Blood and some mucus are commonly passed. Vomiting is often very severe. Keep the patient in bed, apply cloths wrung out of hot water to the alidomen, and send immediately for the doctor. See Dysentery.

COLLAR : How to Stitch. Collars, unless of lace or net, are mostly cut in doulile material, and if made in heavy material for outdoor garments should be interlined with canyas.

In the case of a roll-over collar, the outer or under section is slightly smaller than the inner section, and in any collar the canvas interlining should be slighitly smaller than the material outer section.
To make a collar of this heavier type, tack the canvas to the wrong side of the outer
wection and catoh the material edges over to the canvas; then hem the collar over the neck of the coat, unless it is one of the long roll shape. In this case the neck edge of the collar is left unneatened, and the neck odge of the coat hemmed over it. Finally the linen is covered with the inner section of material. or with satin, velvet, etc.

Soft collars are more simply made. They may be atrengthened by an interlining, if necessary. To malje one, join the edges on the wrong side, leaving the neck edge, turn over, and, if the collar is detachable, sew a narrow binding along the side left ojren. See Crochet; Linen, etc

COLLARBONE or Clavicle. The collarbone mans from the shoulder to the top of the breastbone. It is frequently fractured,

Collarbone. Dingram showing a Iracture of the clavicle in children as well as adults, and this is unually due to a fall on the shoulder or the out. Atretched hand. It may also be dis. located at either extre. mity, inore commonly at the shouifler In fracture the whole shonlder ap. pears flat. tened, the arm is held close to the side, and the patient usually supports the ellow of the injured arm in the palni of his other hand. In order to relicve the tension the sufferer frequently hends his head towards the injured side.
linat aid consists in placing a considerable pad in the armpit on the injured side, and then supporting the limb with $n$ greater arm sling, except that bere the lower end, instead of being laid over the injured 3houlder, is passed through the armpit below the pad, and the two ende are knotted be. hind. The elbow is drawn well forward, and is held there by the point of the bandage, which is brought round it and pinned off. A narrow fold bandage is then tied round the hody and the affected arm just alove the elbow, with the object of levering the shonlder outward. Apart from aps. paratus, the patient may be kept Hat on his back on a hard mattress without a pillow, till seen by the doctor. Some deformity usually remains after mont frac. tures of the collarbone. See Bund. age; Finat Aid.

COLLAR BOX. Collar boxes, which may be obtained or made in a variety of shapes,

Collar. Diarram showing bow Collar. Diarram showing how and revers of a coat rectangular, square or circular, are made of leather, or some kind of wood. A suit. able size for a rectangular box is Ift 6 in. by $10 \frac{1}{2}$ in. by 41 in., but these nersure. ments may be

For a really nice article hardwood bhould be selected. Mahogany, if chosen, will look well all plain with a full polish, or may be inlaid with satinwood banding, hox, holly, and ebony lines, or a little coloured inlay in centre only. Walnut takes a waxed finish well, and may have inlaid ebony lines, or a little grey. wood with ebony lines may be introduced in tahlet form. Oak may be either fumigated or full-polished after staining to a nut-brown colour, if to be kept plain. Rosewood may carry mahogany, satin wood, and eloony inlay.

Making a stait with the hox frame, this will take two pieces 1 ft .4 in . by 3 in ., and two pieces $9 \frac{1}{\mathrm{f}} \mathrm{in}$. lyy $3_{4}^{3} \mathrm{in}$., the material used finishing If in thick. In best style they can $^{\text {in }}$ be secret-dovetailed together, or may be lap. dovetailed together. In a simpler way the sides inay be housed into front and back
(Fig 3), or, again, they may be mitre-halved together and stiffened by the neatest possible rounderl and glued slip in the angle. The botton may le $\{\mathrm{in}$. thickness, cut to a size to project $t$ in. all round, this portion being rounded and the bottom screwed up to under edge of sides with small brass screws. For the moulded effects shown at Fig. 2, a ${ }^{3}$ in. section can be mitred round a flush-finished botton. If the inoulded front of box is preferred, a $\frac{3}{B}$ in. section kept as flat as possible can be mitred round, glued, and panel-pinned on. The lower length of mould beading upon the bottom will be cut sufficiently wide to finish flush.
The lid, if to be jointed up, may be tongued together to finish 1 ft .6 in . by $10 \frac{1}{2}$ in by $\frac{3}{8}$ in thick. As shown at Fig. 1, it is in two parts, opening out left and right, the projection being a little more over sides than at front or back. The edges may br kept square, but will he intproved by thumb moulding, or to an ovolo or ogee section. The lids are hinged on with brass butts (Fig. 2). The face treatment of lid in Fig. 1 may be either an inlaid line or banding ; but if something better is preferred, Fig. 5 may serve as a suggestion, showing an inlaid line round, with broken key comers, and a central wreath inlaid equal!. each side of the meeting edges of lids. Such a wreath could have the stem in brown and leaves in green, with berries in red, and the knotted riblion in blue.

The inlaid front (Fig. 1) might also be made in colours to match the wreath. Ar, alternative treatment for the front is seen at Fig. 2. and on a birch or satinwood ground such detail could the painted in oil colour, mixed with gold size, which is quick drying in its action and useful to those who are clever with the brush. The interior fitting of Fig. 2, with three long and three square divisions, will be handy for gloves, ties, handkerchiefs, mufflers, etc., hut does not provide for collars, and is for a smaller-sized box, which might then be made 6 in . deep and fitted with a lift-out tray.
The arrangement indicated at Fig. 4 works out very usefully, and is comprehensive The lining can be of $\frac{1}{8} \mathrm{in}$. thickness, cleaned up and V-grooved together and polished. The circular portion can be of knifeout veneer steumed or soaked in hot water and carefully bent and glued round a cone of at least 6 in. diameter, suchas a straight. sided llower-pot, or even the do inestic cake tin. This part could also be made of stout bendable cardboard (t и o layers of $\frac{1}{10}$ in. thick will do), glued together and covered with thin silk, the remainder of the interior leing finished to match.

In a smaller box a single lid only may be desired, and, in an endeavour to make it look as well as possible, treat. ment may follow the method sug. gested at Fig. 6. This shows
quadrant comers to a cross-banded surround, and the panel quartered up in oak, walnut, mahogany, or satinwood. The central device, neatly lined in, also affords a chance for careful quartered filling. All four sides can be finished as at Fig. 7 The amall brass ball feet can be screwed into blocks glued under the bottom, and will add lightness to the general effect.

COLLECTING. The collecting of articles which are rare or noteworthy for their age or beauty, or both, is a hobby which is greatly increasing in popularity. Many make collections of china or furniture, while other articles collected include books, brass ware, coins, etchings, glass, miniatures, and silver Another class of collectors go to nature and make collections of beetles or birds' eggs or butterflies. Some of the collections, e.g china and birds' eggs, are often kept in special cabinets See Antiques; Birds' Eggs; Brass; Butterfly; Cabinet; Chair; Coins; Glass, etc.

COLLEGE CREAM. Make some cheese pastry, a few hours before it is required, using 2 oz each of Hour and butter, 1 oz. cheese, the yolk of an egg, and a little salt and cayenne Mix the cheese and flour, then lightly rub in the butter; season the mixture well, and add the beaten yolk of egg and enough water to inake a stiff paste. Roll it out $\frac{1}{2}$ in. thick and stamp it into rounds with a sherry glass. Bake these carefully for ahout 8 to 10 min in a moderate oven, and let them cool Whip onc gill of cream till it just hangs on the whisk, acld 2 table spoonfuls grated Parmesan cheese, and scason the mixture with salt and cayenne. Then heap it up on the cold cheese biscuits.

COLLEGE PUDDING. Mix $\frac{1}{2} \mathrm{lb}$. fresh white breadcrumbs with 3 oz sugar, 3 oz . chopped suet, 3 oz. sultanas, or currants and sultanas mixed, $\frac{1}{2}$ oz. chopped pecl, a good dust of powdercd spice, and a small saltspronful of salt. Beat an egg to a froth, add it to 1 gill of milk, and stir it well into all the other ingredients Turn the mixture into a thickly greased pudding basin, twist a piece of greased paper over the top, and steam the pudding for $3 \frac{1}{2}$ hours. Then turn it out and serve it with sweet melted butter sauce If liked, chopped raisins, dates or

Colles Fracture. Diagram showing the displacement of the broken portion of the radius immediately above the wrist
sometimes too, in establishments that are ton small to set off his fine proportions

The collie is 22 in to 24 in high at the shoulders, with a weight between 45 lb and 65 lb . The head is flat, wide between the small, semi-erect ears, tapering to the eyes and thence to the always black nose. The long, dense coat is harsh to the touch, but beneath it is a soft, furry undercoat. The conspicuous feature of the collie is the heavy mane, continued as a frill over the shoulders. The muscular legs are all well feathered, as is the long tuil, usually carried low. See Dog.

COLLINSIA. This is a pretty, easily grown hardy annual, 10 inches high Seeds arc sown out of doors in March-April, where the plants are to bloom in summer. Favourite sorta are bicolor, lilac rose and white, and candidissima, white

COLLODION. When it is wished to apread a protective film over an injured skin surface collodion is often used by doctors. When it is applied the contained ether rapidly evaporates, leaving a smooth, glistening, hard, transparent surface, which prevents germs and other substances from reaching the wound Collodion should not be used to cover a dirty or a dis charging wound New skin can be used in the same way as collodion. Collodium callosum is a preparation which may be used for dissolving warts or corns, and salicylic collodion can be used for the same purpose

COLLOMIA. This showy hardy annual, about 10 inches high, is grown from seeds sown out of doors in spring where the plants will bloom in summer Collomia coccinea is chiefly grown: it bears red llowers

COLLOPS: How to Cook. Take 1 ll . raw lean topside of beef, or good steak, and mince it finely by hand, as a mincing-machine cuts it too small. Remove any fat or skin, replacing some of the former after chopping it finely Melt about $1 \frac{1}{2} \mathrm{oz}$ good becf dripping or butter in a saucepan, and fry in it 3 teaspoonfuls of very finely. olopped onion. Stir in $\frac{1}{2}$ oz. Hour and then the beef
Stir it over a moderately sharp heat till the leeef changes from red to a brownish tint, then pour in $\underset{d}{d}$ pint stock Stir over a gentle heat until tho figa can be used instead of the fruit named. gravy thickens, then add $\Omega$ dust of seasoning COLLES FRACTURE. This is a fracture and simmer it all till the meat is tenderof the lower end of the radius just above the probably for about 30 min . If it hoils the wrist It is onc of the commonest fractures, especially among clderly women, and is usually caused by falling on the hand with the arm outstretched Unless properly treated it may cause permanent deformity of the wrist and some loss of movement in the joint.

First aid consists in taking two splints reaching from the elbow to the finger-tips and padding them. The forearm is bent to a right angle at the elbow with the thumb pointing upwards, and the splints are applied on the back and front of the forearm. A narrowfold triangular bandage or a handkerchief is used to fix the splints just in front of the elbow and another to fix them at the wrist In applying the latter the middle is placed over the outer splint just above the thumb, the ends are crossed over the inner splint, brought forward below the thumb, and tied over the outer splint. The forearm is then supported by a greater arm sling Probably some degree of shock will be present, and should be treated. See Bandage : Fracture.

COLLIE. Though the collie belongs chiefly to the farm, he is not infrequently compelled to put up with a more domestic existence;
meat will be leathery and tasteless. Add 2 oz.

Collie. Champion rougl collie, a splendid example of the breed

Collingia Lilac and white flowers of Collinsia bicolor, a hardy annual
breadcrumbs a few minutes before serving, to absorb the grease Serve the collops with a border of sippets of toast, or croûtons.

Mutton collops nay be made with about 1 ib cooked mutton Cut it into rounds, about $\frac{1}{8}$ in thick and 2 in in diameter. Chop, one small onion and inix with it $\frac{1}{2}$ teaspoonful powdered herbs, a pinch of powdered mace and salt and pepper. Spread this mixture on one side of each collop and let them stand for about an hour, in order to flavour them. After that time fry them quickly in a sancepan in about 2 oz . of clean dripping, turning them with the savoury mixture downward.
Then take them out of the saucepan and into it stir 2 teaspoonfuls of flour, browning this carefully Any fat not absorbed by the Hour should be poured off. Stir in $\frac{1}{2}$ pint of good stock and allow it to boil. Simmer the sauce for 10 min ., attending to the skimming and seasoning, and strain it round the collops after arranging them neatly on a hot dish. This is sufficient for three or four persons.

COLLYRIUM. An eye lotion which is termed a collyrium may consist of solutions of boracic acid, zine sulphate, permanganatc of potash, and other antiseptics. The solution should be warm and may be applied by a swab of cotton wool or an eye-bath; or a few dropis may be put into the eye. The following would serve if mixed with an equal quantity of warm water : Boracic acid, 20 giains, and dis. tilled water, 1 oz ; or boracic acid, 15 grains, zinc sulphate, 1 grain, distilled water 1 oz

COLOCYNTH. Colocynth is a fruit also known as bitter apple. It is a drastic cathartic, but in small doses it is fre'quently given in aperient pills. It may bo used as colocynth pill or the colocynth and hyoscyamus pil!, the dose of each heing 4 to 8 grains Hamilton's pill resembles the latter. in its medicinal action.

## How to Achieve Pleasing Effects in the Various Rooms

Other articles in this Encyclopedia dealing with this sublece Include Decoration; Drawing Room; Nurscry; etc. Secalso Carpet; Curtain; Cushion

The primary colours are red, yellow, and blue, whioh in combination give black, if they are exactly balanced The secondary colours ennsigt of a mixture of two primary colours, varying according to the proportion of each. A mixture of red and yellow gives orange Yellow and blue give green; blue and red purple.
There are innumerable tones in these colours, according to the proportion in which the two primary colours are mixed. The purples will vary from the red purple of the Orleans plum, through amethyst to the mauve of wistaria Similarly with orange and with green. Tertiary coloura are compounded of two secondary colours.
Complementary colours are those which complete one another, i.e. the pigments when mixed with one another make black. Thus red is the complement of green, yellow is the enmplement of purple. and blue the comple. ment of orange. The various shades of grey are, if the grey is pure, broken down from black by the addition of white. Mixtures of the various secondary colours give a range of greys.

Harmonious Effects. Where moms open out of the same hall it is well to remember that the hall should form a kind of bridge between them. A grey hall, with rooms opening out of it, in which a range of colours from pinks (pink is only insipid when badly selected), reddish purples and blues are well blended and contrasted, makea a charming interior for those who have old china and Persian rugs for purposes of decoration and relief. A hall with black and white tiled floor, black paint and grey walls, will allow of vivid touches of colour in curtains, etc., which notes of colour are re. peated in the rooms opening off it Another device is to choose the same colour for the carpets or flooring throughout-brown, for example, and to build up harmonious colour schemes on that.

Each room will then have $n$ dominant colour. The dominant colour is the one which drawsimmediate attention, and not necessarily that which covers the largest surface. In a lounge, for instance, the carpet of which was a bmwn pile, the upholatery brown and fawn velvet and walls primrose yellow, the dominant note was atruck by a book table in vermilion and gold lacquer, the same note of red being picked up in the appliqué design on the curtains, the frame of a large mirror, and one cushion. In a small room the dominant colour note may be provided by a painting or the tiles of the fireplace.

## Psycholorical Elfect of Colours

In selecting harmonious schemes it should alan be borne in mind that blues, purples, and greys are soothing, orange and red stimulating, light warm pinks and also yellows give an effert of sunshine in dark rooms. Green should only be employed in sunny nooms, as it absorbs instead of reflecting the light. These remarks apply to large surfaces treated with these colours, as practically any colour can be utilised merely as colour accents in right rela. tion to various achemes; a cool scheme requiring certain warmer notes to prevent it from being depressing, a warm scheme requiring to be toned down by a neutral shade to prevent it from being either garish or irritating. It may also be noted that no colour is successfully uset unless the right materials are selected for its expression. Thus certain shades are beautiful in glossy surfaced fabric, which are oppressive or dull in a mat surfaced one : while in every colour the range of shades make it possible for certain combinations-
say green and purple-to be either harmonious or crude and unplensant.

Colour Details. Blue is an instance of a colour the use of which is sometimes misunderstond. Wedgwood is a beautiful shade to combine with purples and also with pinks which have a tinge of mauve in their composition. In pale shades Wergwond blue can be used in a sunny room for the walls and also for the ceiling. It is charming with ivory paint or with grey woodwork picked out with lines of metallio silver paint. The tulip colourings (except red) are exquisite against this shade of blue as a background. Greenish blues are useful as sharply defined decorative notes. Turquoise blue tiles or kingfisher blue for cushions may be heautiful points of interest in a neutral scheme.

Grey is a dignified colour for walls, but is depressing if carried over the ceiling. For a bedroom, grey, black and coral pinks are a good choice. In a sunny room the walls could be grey, paint black, and the furnishing fabrics could introduce the pinks with discretion, avoiding too much warmth: or for a mom with a north aspect, walls and ceiling could be distempered a yellowish pink, which gives a beautiful sunny effect, and the grey introduced into the furnishing details with a patterncd cretonne in grey, deeper pink, yellow and black. For this scheme the woodwork could be painted grey with akirting board, window frame and architrave of the door in black or a deeper shade of grey.

Backgrounds lor Oak and Walnut
Yellowish pink is also excellent with browns, and may be most successfully used for a ceiling in a scheme in which brown panelling and oak parquet Hooring are employed. Rose pink is good with dainty furniture, especially with panel mouldings and woodwork in ivory paint. Pinks are auccessful in distempers, and the gradations of colourings are excellent in this medium.

Light apple green is right for walls in a room with walnut furniture in the style of Queen Anne, the woodwork and mouldings picked out in gold and the ceiling enriched with a dull gold paper. Pinky-mauve and plum colour are the notes to emphasise in colour accessories with such a green. Malachite green is a good choice for woodwork with apricot tinted walla, and mauve shades introduced into loose covers or curtains.

Red definitely needs most careful treatment. In a sunny room indiscreet use would be most irritating : even in a room with a cold aspect bright red is only right for a colour note. A claret ahade may be beautiful in rich materials for upholatery, especially for winter use in a room with stone coloured walls.

Orange and brown are a good combination with cream or golden yellows. Such a scheme will pmbably require cooling with the judicious use of green or blue. A yellowish orange is best with lighter browns, and a reddish orange with very dark browns. Mahogany has so much red in it that it is better with a yellowish orange-suggesting the colour seen in Sheraton inlaid furniture. Black is too violent a contrast to be used in a mass with orange, but is valuable as a colour accent, as for example in a cretonne or other patterned fabric into which yellowish-pink, soft blues and mauve may also be well introduced.

Uses of Colour. Defects in the shapes of rooms can be to some extent correcterd by the proper use of colour. The ceiling may be washed in a paler shade toning into the walls
if the room is a low one. Pale grey on walls and a cloudy blue for a ceiling also give height. A box-like room, too high for its breadth, can be made to appear lower by having the ceiling painted with a design in colours or by being trented with a colour darker in tone than the walls or carpet of the room. With ivory panelled walla, cobalt blue is a fine ceiling colour, used either plain, slatted with ivory lincrusta or wood, or painted with an effect of clouds or stars

Glowing sunshine can be simulated in a dark mom by a wall paper which graduates upwards from deep orange-yellow to palest primrose, with paintwork in umber scumbled over a gold undercoat and then varnished. Happy schemes-particularly for bedroomsmay be evolved by taking a flower as a pattern for each room. A bronze chrysanthemum, anemones in varying shades, or a delicately tinted iris would help to build up beautiful colourings for which it would be possible to select patterned chintzes, cretonnes, or linens in the respective floral designs. Sometimes when walls and carpets are treated in neutral shades, such as biscuit, grey or stone, more variations are possible in the colour schemes of the various rooms by having a winter set of curtains and covers in strong contrast to those in use in the summer.

Aids to Selection. Before deciding on colours for a decorative acheme a good iden is to lay out on a table a number of small samples of shades of paints, distempers, etc., and also of colours approximating the ideas for furnishing fabrics. Bearing in mind the exigencies of existing carpets and furniture, place the colours fancied next to each other, altering the various shades until the harmonious effect required is obtained. Then paste those decided upon for each room, grouped together on a piece of white paper and a workable guide is evolved. Such a method has been used for the schemes illustrated in our colour plate, which serve as examples of combinations of colour and may suggest many variations of treatment

The Dining Room. A pleasing effect is given to this room by the use of harmonious and varying shades of browns enriched by the beautiful wine colour of the damask curtains and brightened by a golden paper, the golden note repeated in the silk net of the glasy curtains. The ceiling and frieze could be washed a deep oream colour. This scheme would be equally good with mahogany, walnut, or oak furniture. Colour accents for flowers, cushions for the settee (upholstered in brown velvet) and china would be yellows, soft pinks and mauves. Lampshades could be amber silk lined with pink. The chairs are upholstered in brown leather to tone with the wood selected. The foundation of this scheme was a Persian patterned carpet combining the wine, golden and brown colours repeated in the furniture and decoration.
The Lounge Hall. Brown is the connecting link between the lounge hall and the dining room. Imitation brown leather paper is selected for the wall treatment with a studded beading in brown and gold. A wide frieze could lighten this treatment in a pale sharde of pinkish stone, which colour would be also used for the ceiling. The brown and gold striped velvet curtains give a rich effect. and blue is introduced into the artificial silk tapestry with black and gold, making a beautiful colour contrast to the burnt orange of the carpet with it a parquet surround. The blue would be accented again in pottery, while the carpet would blend with the colours of a brick fireplace.

The Sitting Room. In this bright sitting. room black, brown, and a suggestion of orange carry on the harmonious scheme from the lounge hall. Walls and ceiling are a clear yellow, not too intense to contrast happily

with the malachite green of the moire cur. tains These are enhanced by hlack satin borders and appliqued on pelinet and curtains. The loose covers are in printed linen, introducing orange, mauve, green and black and pijed with black, while a camel coloured pile carpet on the liglit toned parquet surround binds the scheme pleasantly together: The malachite green note could be einphasised again in an enamelled book table, or in a settee upholstered in damaski of that colour and without a lonse cover, or in the woodwork of a floor atandard lamp.

The Bedroom. The scheme suggested for a bedroom utilises grey for the woodwork of walls and furniture. The carpet has a blue ground patterned with rose and touches of vellow, while the curtains are of soft rose taffeta. The upholatery and hedspread are in shot slub rep and artificial silk respectively, blending the tones of blue, grey and rose. The walls would be a paler shade of grey than the woodwork, and the ceiling washed with a faint rose pink. Any cretonne covers or accessorics, such as china or shades, would emphasise the rose pinks with touches of clear yellow and blue.

Colour achemes for the nursery will be found under that beading, where various methods of suitable treatment will be discussed hoth for day and night nurseries

COLOUR BLINDNESS. The commonest variety of colour blindness is that in which the person is unable to distinguish red and green. He confuses these colours with grey, yellow, and blue. This form of colour blindness is very important, as it disqualifies n man from service on the sea or on a railway, when duties involve the recognition of these culours. People who arc blind to vio!et confuse purple, red, and orange. The test may be performed by placing skeins of wool of varying shades of different colours before the person being examined, and asking him to match samples, usually light green, pink, and red.

Acquired colour blindness may be due to poisoning by alcoliol or tobacco, or both, or to atrophy of the optic nerve. A rough test of the tobacco form used to be to ask the patient to distinguish between a half-sovereign and a sixpence, which he had difficulty in doing from the colour. There is no cure for the congenital complaint, but sometling may be done for the acquired form. Treatment of the poisoning cases must include, of course, the giving up of the drugs a bsolutely.
Colour blindness may vary from a slight difficulty about one colour combination up to inability to see anything but shades of black and white, but this latter condition is rare. The abnormality is commonest among men, and is usually congenital.

## Colour Photography for the Amateur

## How to Obtain Naturalistic Results on Transparencies

## Other articles in this work for the amateur photographer include Camera; Dark Room; Developing;

Exposure, as well as the main article on Photography
Consiclerable progress has been made the plate, the focussing screen of the camera recently in processes for producing photographs (prints on paper) in natural colours, but these methods are still much too compli cated for the average amateur, since they involve the preparation of three separate prints (red, yellow and blue) and the combination of these three in exact register There ane, however, several processes which are almost as easy as ordinary photography: The results differ from those of the latter in being transparencies on glass which are vieved by holding them up to the light, or may be shown on a screen by means of an optical lantem.

In these processes a special kind of plate is used, viz. one having a coating of cxtremely small transparent dots, red, blue and green in colour, made so that the mixture does not show any colour at all. On this coating is a sensitive emulsion similar to that used for ordinary photography, and when the photograph is taken on this latter (through the coating of coloured dots), the result of special treatment is a picture in all the colours of the subject photographed.

Two makes of plate are sold for this process, vi7. Autochrome (French) and Agla (German). Exoept that the solutions for development, etc., are different the manipulation is the same in each case. These special plates are not rapid enough as a rule for use with the caniera held in the hand. The camera must be used on a tripod, and the lens must lse fitted with a vellow filter. adapted to the particular plate Unless this filter is employed the pictures will be almost entirely blue Also. the plate must be exposed in the camers with its glass side facing the lens and with the coated or enulsion side backed up with a piece of black card to protect it from damage. For this reason it is necessary to use the wooden book-form pattern of plate-holder, each taking two plates; the single metal plate holders supplied for many folding plate cameras are not suitable, because there is not room in them for the backing card. and also the sensitive surface is liable to be scratched One other alteration is needed. In order to allow for the reversed position of
must be removed from its frame and replaced with the plain or unground side facing the lens
The special colour plates differ from others in being sensitive to all colours, including red They must not he handled by the usual red dark-room light, but by one of deep green (screens are supplied by the respective makers), or by touch in complete darkness, as can easily he done with a little practice.

The subjects which are best suited for colour transparencies are those fairly near to the camera, e.g. portrnits and figure studies, garden and woodland scenes : open views, in which the colours are subdued by distance, are less satisfactory. In bright sunlight the exposure ranges from $\frac{1}{1}$ to 1 sec when using a lens stop marked 18 . By using a lens aperture of f4.5 the exposure may be as short as $1 / 8$ or $1 / 10$ of a second, or even $1 / 30$ sec. in specially good light as on sen heaches. The hest results as regards brilliancy and purity of colours are always obtained by using the larger apertures of lens such as 44.5 to $\mathrm{f6}$; with apertures of fll and smaller there is a tendency towards dullness of the colours.

Special Development. The development of a colour plate is nltogether different from that in ordinary black-and-white photography. The pioture is first developed as a negative, which is then dissolved away in a "reversing" bath. This leaves an invisible positive image, which is brought to full dopth by a second application of the developer. The wholc process takes less than 10 minutes, and it is best to finish off each plate hefore starting to develop the next. The special developing solutions are supplied by makers of the respective plates.

When developing the plate in the darkroom, it should be placed in the dish, and the developer poured over it, as far as possible from the dim green light. \fter about 10 sece. it may be brought near to the light for an instant to note the progress of development. O" the average, development will be complete in ahout three minutes. The solution is then poured off, and n gentle stream of water from the tap allowed to run over the plate for not longer than a minute. The water is drained off,
and the plate well covered with revarsing solution consisting o! about 4.5 gr . of potassium bichromate dissolved in $200 \%$ of water with addition of if drams of strong sulphuric acid After about 1 ininute the white light can be turned on, and the back of the plate examined every now and then for disappearance of the black negative image When this has taken place-in about. (wo minutes-the colours will be visible though somewhat frebly The plate is now rinsed in water as before for half a minute and in full daylight is placed in the same developer as first used. This brings up the colour picture in full vigour and brilliance, and it only remains to give a final rinse in water for about two minutes and to put the plate aside to dry.

The surface of a colour transparency, either Agfa or Autochrome, is exceedingly delicato when wet. The plate should on no account be touched with the fingers during manipulation : it should be kept in the dish throughout the process and the solutions and wash water poured off and on. Even when dry, the surlace is easily damaged, and it is well to vanvish it, but only with the varnish sold for the purpose. It is then hound up with a plain piece of glass by means of gumined atrips of paper For viewing, it is best kept in one of the folding frames, sold for the purpose. which give an enhanced effect due to the reflection of the picture in a mirror.

A variation of the colour plates described above has recently been re-introduced ns the Finlay. In this process a separate laking screen of minute red, green and hlue elements is used close against the sensitive plate when photographing the zuliject. The negative is developed in the ordinary way and from $t$ is printed a positive on glass, which is hound un with a similar colour screen al the colours of the subject being thus reproduced Tho advantages of this system are that shorter camera exposures can be given and that as many colour transparencies as desired may be madc from the original negntive.

COLTSFOOT. The variegated form of coltsfoot, Tussilago farfara, is useful as an edging in shady positions or ningled with clumps of ferns, and is not objectionable if kept well in hand: but other forms are treated as weeds. Tussilagn fragrans (Petasites fragrans), which is the winter holiot rope, grows 12 inches high and bears fragrant purplish

## Howera in winter.

COLUMBINE. This is the popular name of nquilegia, one of the loveliest of hardy garden flowers. The new long-spurred varieties in many charming colours are far superior to the old short-spurred ones. Columbines thrive in ordinary soil, in sunshine or partial shade : they are grown from seeds sown in a box of soil in a frame in March-April, the scedlings being

Columbine. Flowers of the long-spurred columbine.
beautiful bardy garden bower
Plioto. Sulton \& Sons
planted out of doors in summer, preferably where they are to remain. The final planting may, however, he donc in October. After two, or possibly three, years the plants generally lose vigour and a fresh lot should be raised from seed Several columhines are suitable for well drained loamy soil in the rock garden, e.g. alpina, blue, coerulea, blue and white, and glandulosa, hlue and white.

COLZA OIL. Colza, or rapeseed, oil is the commercial name for oil obtained from brassica seeds Its chief use is for illumination
Them are many qualities of colza oil. and colour is the best indication of value. the more highly refined oils being of a very pale golden shade. as distinct from the dark brown colour of the crude pro duct. The illumin ating power of colza is not so greant as that of paraflin or petroleum, but in practice it is found more economical, being slower in burning.

Care sliould he taken to keep the oil in a clean vessel. as even amall par ticles of foreign matter will cnuse the wick of the lamp to hecome clogged, and when this occury the wick should be removed and cleansed, and a small lump of common salt put into the reservoir of the hamp. This will attract and hold foreign particles and prevent them reaching the wick. Should water become mixed with the oil it is removed by placing strips of gelatine to absorb it. The gelatine is not solvent in oil, and may be taken out. dried, and used again for a similar purpose.

COMA. Deep unconsciousness from which the patient cannot be aroused nccurs in cases of severe head injuries, in apoplexy and heat stroke, in uraemia and diabetes, from poisons circulating in the blood, in narcotic poisoning. as from opium, alcohol, coal-gas. etc., after epileptic fits, and in many other conditions. Coma vigil is the name given to a condition which sometimes occurs in typhoid and typhus fevers. and in the typhoid state when the patient lies with his eyes half open and keeps on muttering to himself hut is unconscious.

First-aid for persons found comatuse is to send for the doctor, loosen tight clothing, place the patient's head in the position in which his breathing appears to be easiest, take careful charge of any hottle or other receptacle which may have contained poison, and keep the patient warm. In heat atmke he should be moved to a cool. shady spot and douched with cold water. See Delirium: Sunstroke

COMB : For the Hair. Dressing combs should not be too cheap, or the teeth will break readily : also roughness in finish irritates the scalp. The teeth should lee of two different sizes. coarse at one end and fine at the other, and the comb should be discarded as sonn as it becomes damaged. Many people who wash their brushes regularly are careless about their combs, which nced periodical attention just as much. Special comb cleansers, consisting of an arrangement of threads which enter between the teeth and clear out the dirt collected at the roots of them, can be bought.

Real tortoiseshell combs, though most pleasant to use on account of their superior finish and smootliness, arc expensive and need careful handling as they are easily broken

Tooth combs, which have very fine teeth set close together, are useful for cleansing the scalps of children. and must he kept serupuhously clean.

COMFORTER: For the Baby. The chicl danger of the comforter is that it is linhle to be asiled, and so infected with microbes, which produce indigestion and sometimes diarrhoen, intiammation of the mouth, and other diseases Also, the comiforter tends to spoil the shinpe of the mouth, and very ofton deforms the palate. with the result that the air passages of the nose are narrowed and the child becomes n mouth hreather A mother who gives a comforter to her baby (q.v.) may quiet the child for the time lreing, but the baby too often has to pay heavy pemalties.
COMMODE. This word is used for a small sideboard. In another कのnse it means a box used for holding a chamber utensil and ilso $a$ seating arrangement of that kind suitable for invalids. Of the sideboard known as the commode there exist very beautiful oxamples, some being associated with the name and work of Buhl. The finest were made towards the end of the 17 th century in mahogany and in pine, often with inarquetry of hrass, ehony. mother-of-pearl, ctc. In England commodes were made by the Adam brothers and their successors. Some of them are of satinwood, semicircular in shope, and are beautifully ornamented with medallions painted by ltalian artists. See Buhl: Sidebonrd.
all alternating into $\Omega$ continuous current. Commutators are found on any continuous current or direct current generator, or on any motor intended for use on a continuous curient. See l)ynamo: Motor.

COMPASSES. These are mathematical instruments used for drawing circles, or arcs of circles. Varintions of this instrument arc the chalk compasses used by teachers in achools and by scene painters and others, also the wing comprases employed in carpentry and for metal work The Lancashire wing compasses, shown in Fig. 1, are provided with a quadrant or wing, and a thumb-screw which is tightened up to hold the legs rigid.
The compasses used in mechanical drawing are made in numerous patterns, priced from a few pence upwards. The amateur drauglitsman will be wise to purchase a good quality instrument of moderate cost. Compasses with solid points should he rejected in favour of those with needle points. These have needles held in a clamp, and make only a very small hole in the diawing paper; if damaged the needles are easily replaced.

Essential features are rigidity, freedom of action at the joint, and all detachable parts secured with is clamping screw acting between t wo jaws and holding the removable part as in a vice. Other requirements are a knee joint above the pen or pencil point, Fig. 4, and some means of adjusting the needle, as in all grod drawing work the needle and the pen or pencil point must he vertical when drawing the lines. These characteristics are shown in the 6 in . compass illustrated in Fig. 2, with pen and pencil and divider points. Spring bow compasses, as shown in Fig. 3, are excellent for small work and to be preferred for cireles up to $1 \ddagger \mathrm{in}$ diameter.

Beam comprases are used for drawing large radius circles, such as occur in surveyor's work or in laying out a garden plan. A typical set, pictured in Fig. 5, consists of a jointerl metal heam 24 in. long in four sections, with pen and pencil pointa, two steel points, and $\pi$ shouldered necdle point. See Dividers: Dıawing.

## COMMUTATOR.

The device known as a commutator forms part of an electric generator or motor, and is designed to convert

Compasses. Fig. 1. Lancashire wing compasses in use. Fig. 2. Six-in. compasses with pencil point. Fig. 3. Spring bow compasses with pen point ; below, divider point. Fig. 4. How compasses should be beld, with needle-point and pencil both upright. Fig. 5. Beam compass, used for circle; of large radius

COMPASS SAW. For curved shapes the compass saw is invaluable. It is stronger than the keyhole saw, but can often be used when lock fitting or on any internal sawing where the curves are not too sharp.

When sawing a curved shape always take

Compass Saw, a tool used for cutting curved shapes, and on internal sawing
care to keep the saw blade at right angles $t$ (" the face of the work, unless a bevelled edge is the objective. Work with a steady snwing stroke, avoiding heavy pressure on the teeth. or the saw will wander away from the line.

COMPENSATION : In Law. This term is sometinies used by laymen as synonymous with damages. but in fact the two nie generally different. The word compensation is rightly applied to the money payable by an employer to a servant who has been injured by an accident arising out of and in the course of the employment It is also used in its proper sense to describe the amount that must be paid to anyone whose land or building is compulsorily acquired by a public authority, with powers conferred by Act of Parliament to take property. See Accidents; Employer's Liability.
COMPLEXION - Its Care. This depends primnrily on the state of the health. Some women naturally have a white, clear skin of a soft and delicate texture. Those who have not should pay attention first to digestion, for a sallow skin is often due to dyspepsin. An unnatural pallor inay be due to anacmin or a poor circulation.
Those whose complexions are muddy or of too high a colour should carefully consider their diet, avoiding rich and highly seasoned dishes. Over-feeding is one of the commonest causes of skin blemishes and greasiness. Women with greasy skins have need of a goud cleansing cream and a lotion which will stimulate the circulation, remove the grease from the surface of the sebaccous glands and leave the pores frec.
Women with sensitive akins often find their complexions affected by sudden changes of temperature. Such skins are usually of the dry type, and require very pure emollients. and only mild astringents. The use of ice or $\Omega$ strong astringent to close the pores after washing is dangerous for this type of complexion, as such drastic trentment of ten results in amall broken veins.
When washing the face, suft, warm water is necessary. If suap is used it must be of a pure superfatted variety and should be thoroughly sponged off befone drying. The final sponge should be with cold water. Soap should only be used once a day, at bedtime; nfter drying, the complexion will be improved by the use of a good massage cream, in order to maintain the skin in a healthy condition and keep its transparent look. See Beauty Culture: Face; Powder; Skin: Soap-

COMPO : For Building. This is a mortar composed of Portland cement and sand, or a mortar containing a proportion of Portland cement in addition to the usual mixture of lime and sand. A sound compo mortar for general house building purposes should contain : one part by mensure of grey lime (measured before being slaked) and one part by measure of Portland cement to seven phrts by measure of clean sharp sand.
Owing to the extreme difference in the time taken by lime and cement in setting, specia precautions have to be used in the mixing and using of compo. The lime and sand should be nixod and made up as mortar in
advanen in order tu onsure thiat no hot ie. innslikiad, particles of lime remain to expan:l in the linishod work

The propurtion of coment is only adrled just before tha compo mortar is required for use Thres pailfuly of lime mortar nre takenf from the heap and to them one pailful of cement is added nnd well worked into, the mass with a shovel if necessnry a little water is added. The compo mortar muat be naed immediately alter mixing
A wall laid in oompo mortar hardens and dries quickly and attains a grent proportion of its final strength very much somer than n wall built with lime mortar The shrinkage of the joints is not so grent as with lime mortar alune. See Brick: Cement; Mortar; Plaster.

COMPOST: For Plants. This is the term applied to mixtures of soils used in the gardon, or for potting purposes in frames or hot-houses Compost may consist of two, three, or more of various ingredients neceasary for the successful culture of the plants which are to derive their nourishment from it Loam (pieces of old turf) forms the basis of nearly all potting composts. Other ingrodients. such as leaf-mould, peat, and sand are added in proportions varying according to the needs of the plants.

COMPÓTE : In Cookery. This word is usually underatood to mean a carcfully prepared dish of fruits stewed with syrup. but in a few instancos it is applied to a rich variety of stew, such as a compote of pigeons or of plovers

The secret of making good compotes lies in stewing such fruits as gooseberries, cherries, and currants in a casserole in the oven lefore using them. Dried fruits can he used if, after washing, they are soaked overnight and then stewed in the water in which they were soaked.
An excellent compote syrup is made with $\frac{1}{2}$ pint water and $\frac{1}{2} \mathrm{lb}$. good white sugar Put these in a saucepan, let the sugar dissolve by the side of the fire, then boil it without a lid for about 10 inin., skimming it well, or until it forms a good thread when is little of it is taken hetween the thuinb and firat finger. To this syrup add any llavouring wished, such as lemon-juice or grated lemon-rind. If a glass of some liqueur-kirsch. inaraschino, etc., or vanilla or n!mond essence. Pour the syrup over the fruit, and allow it to cool

COMPRESS. Folded lint or other inaterial applied firmly as a pard to prevent hleedirg or inllamma tion is termed a compress, and may be applied either wet or dry. For open wounds boracic lint should be used or the lint should be wrung out of anti septic solutions.

For a black eye the compress may be cold. preferably iced. A spirit compress is made by lightly wringing the lint out of a lution consisting of methy lated spirit 3 parts, and water 2 parts, and may be applied to a bruise. It should be
 ore general cultivation. for the sake of its sweet tone, its casy mnnipulation, and its portability; but unfortunately iss reputation sulfers by reason of the chenp German variety, which is a much inferior instrument, both in tone and range. playing only in the key in which it is set, and possessing a very simple modulation. In this colleertina the lieys produce different sunds. according as the bellows are presesad in or drawn out. See Accordion.

Concertina. Tbree principal parts of tue iostrument: left to right, reeds: bellows : keyboard. TOD left, interior view of keyboard

## Concrete and its Preparation

How it is Applied to Structural and Ornamental Work
Other articles which describe building materials and processes include Brick: Bungalow ; Cement Cottage; House; Lime; Mortar; Wall

The material called concrete is a mixture tions, the aggregate may pass through a 2 in of lime or Portland cement, called the matrix, mesh sievo: for floors, the largeat pieces with small pieces of stone, broken brick, gravel or other hand suhstances, known as the aggregate. together with sufficient clean sand to fill in the interstices between the aggregate. the whole moistened and consalidated with water. It can readily be prepared by an annateur, and used for foundations, Hoors. walls and other parts of buildings.

When cast to shape in a wooden mould it makes almirable ornsmental figures, garien scats, steps, imitation crazy or stone pavings, and numerous other items. The difference between lime soncrete and cement concreto is that lime forms the malrix in the former case, and Portland cement in the latter. The emateur will generally find it beat to use Portland cement, and the following hints are hased on that assumption.
Good concrete must be homngenoous, dense, fire-rcsisting and strong, qualities attained ty using suitahle aggregates. For density, the cement must entirely surround every particle of aggregate and sand, and till the spaces between them to form a solid mass. This can be ensured by proper mixing, and by ramming and tamping the mixture when it has bcen placed in position. This ramming consolidates the concrete, and should on no account be omitted for foundation work or where greatest strength is nceded
Suitahle proportions of aggregate and cement for building uses are ne follows

## Cement

Clenn sharp sand
Foundations
River ballast or gravel
Flmors
roment
an
bruñeu brick

## Cement <br> sand

Brokeu brick furnace cllnker of braken atone
'Ihis is for walls when cast between ein:tifitiing or boards so erected as to form a cavity, which is then filled with concrete
partition Slams
Cement
Coke breeze
or
Sement
Brokeu cunker or grailte
This is for partition slabs mardo in moulds. All proportions are by bulk, or measured with a pail and not by weight.

Theso materials will be mixed as follows. Place a large boand or boards on the ground to form a solid platform. At one end of this place the aggregate. then add the sand, and put the cement on the top, making the heap conical in shape. Turn it over with a shovel to the other end, making another conical heap, and then back again. Then add water from a watercan with a rose head, and turn the material over again twice, in a moist condition. Remove it in a wheelbnrrow to the place where it is wanted, and gently tip the mass into the trench or mould, doing this carefully to avoid separating the large from the small pieces. Then ram and consolidate the conorete and work it 10 as level a surface as possible. This causes a considerable shrinkrge in the bulk, and suffi. cient extra material must be mixed in the dry state to compensate for this, at least 30 per cent. more dry material being needed to fill a given space with well consolidated wet concrete.
The size of the pieces composing the aggregate varies according to the work; for founda.
should pass is $\}$ in mesh For tine castings the aggregate should pass a $\frac{d}{} \mathrm{in}$. mesh. Coke breeze and fine clinker used for partition slabs should pass a in. mesh. Granolithic concrote for the surface of floors and liearths, etc. should be composed of 2 parts cement. with 5 parts of fine granite chippingg or tine lime. stone chippinga. The amaleur will find that colie breeze, gravel (generally culled "ballast "), or bioken brick are the beat aggregates to use. but on no account must garden mould or any other soft material he employed.

Conorete blacks for building walls and partitions are often made in machinos built for the purpose, and when any considernble number of blocks are needed it is an cconomy to purchase or hire such a machine: but an efficient substitute consists simply of four stout pieces of hoard of correct height. supported by pegs driven into the ground. These sides should rest upon a woorlen bnas (Fig. 1). The concrele is shovelled in. rainmed, and
levellod off with i trowel, and left to sot for a quarter of an hour. By uaing four such moulds the work of block-making may proceed unintermptedly. The woolen sides are removed and the block lifted by the hottom board and set on one side to dry off. Stack the blocks so that the air can circulate between them, and to avoid their adliering to one another place pieces of newspaper between them. This class of block should be allowed to dry off thomughly before it is used. and will he improved by storing for $\Omega$ month or so. The concrete should only be made sinfliciently wet to hold together: too much water is detrimental as it brings the cement to the surface. A better mould for making a breezo block is shown in Higa. 2 and 3
Concrete lintels, door pusts, window-sills, fencing pusts, and similar details are generally cast in a wooden box or mould, and should have a stout iron bar embedded in the centre. The sides of the box are screwed or bolted to the enda to facilitate their removal. The same principles nre applied to the constmetion of plinths and cornices, the strength of concrete heing greatly increased by embolding ion rods, expanded metal, or even stout chicken-run wire, an elementary type of ferroconcrete construction.
The construction of $n$ simple building, such as n garage or atorehouse, is well within the

Concrete. Fig. 1. Simple mould for breeze block. Fig. 2. Breeze in a mould. Fig. 3. Mould knocked Fig. 5. Casting a qualn block. Fig. 6. Partition wall of breeze blocks; gooln block used for bonding
capacity of an amatcur. The procedure will be governed by local conditions and personal requirements, but any one of the following methoda can he applied. The ground is marked out, excavaterl. and the trenches filled with

walls can then be enceted, with coke brecze or ballast ne the aggregate used for making the conerete hlocks, the work being
carried out as il using bricks. except that cross bonding is effected with galvanised iron wall-ties built in as the work proceeds.
Another method is to use hollow block cast in a mould made for the purpose, as in lig. \& The construction of these moulds is quite simple, and all dimensinns can be taken from the diagram, Fig. 7. W'ith this class of hlock wall-ties are not needed. Partition walls can he built in by using quoin blocks cast for that purpose, as shown at $A$ in Fig. 5, using the same mould box, $C$, with the core. $B$. The former or core is shown in Fig. 7, at the top left hand corner. These blocks can also be used in conjunction with the llat coke breeze blocks and the quoin blocks The mothod of bonding a wall made of coke lreeze blocks is shown in Fig. i, which also indicates the use of guoin blocks in making a return wall.
Still another method is to erect shuttering composed of stout wood boards with battens nailed to the back. These are held upright by simple struts. The gap left between the two sets of shuttering determines tho thickness of the wall, and is filled in by shovelling in the moist concrote and ramming it down hard and sulid. When the concretc has set the shuttering is removed and re-erected finther along for the wall. Frequent use of the plumb rule and the line will ensure the wall being straight.

The following are essentinls to all satisfac tory concrete building work. Use only the hest cemont; see that clean sand is used-it must be free from clay or earthy material ; if it is not it must bo washed by putting the sand in a trough and, while gently stirring tho materia!, letting water run through it. This will overtlow at one end and carry away the particlos of dirt. The sand used nust be coarse and gradod-that is, soine coarse and some fine. The aggregate minst be clean and graded, some to be larger and some smaller. generally ranging from $\frac{8}{3}$ in downwards for amall work, walla, and floors. Concrete must not be applied to existing dry work, as in the form of dry foundations. The latter must always be saturated with water before the concrete is laid.

## Concussion. See Brain.

CONDENSED MILK. Sold in tins, either sweetened or unsweetened, condensed milk will keep for any length of time, and can be used, diluted with water, for all purposes for which milk is required. It is made by fresh milk being boiled and evaporated until almost all the water has been drawn out. Sugar is added as a preservative, and, in the best makes, no chemical preservatives are used. When required for use as fresh milk it should be diluted with water in the proportion of 4 or 5 parts of water to one part of condensed milk.

Condensed milk that is frce from chemicals to powiler. See Allspice: Curry: Ginger is considered to he a valuable food for infants and a good substitute for mother's milk, being used in proportions that vary with the constitution nnd age of the child. As little as $\ddagger$ teaspoonful to 1 tableapoonful of water is recommended for a newly-born infant. The proportion is inoreased as the child grows older For infants' food the water must le ; Peplarder : Salt, ctc
CONDUIT : For Electricity. An electrical conduit is an outer casing or covering in which the insulated conductor or wiro is inserted in order to protect it from injury. and alao to ald to the electrical efficiency.
Stcel conduit is made from welded steel pipe of various sizes, enamelled inside and out.

Connexions are made by screwing the pipe on to sockets or other littings in much the same way as gas pipity. In other systems the pipes push into aockets formed in the littings, and arc sometimes secured by means of a clip. Standard fittings for use with this material include bends and angles for turning corners, junction boxes for conncxions and liranches, inspect ion hoxes with removable lids for access to interior. The system is the only one that can safely he embedded in plaster or out of way locations.
When installing such $\Omega$ conduit system the whole of the pipes, complete with junction boxes, bends, and so forth, are fixcd up in place, and then the electric conductors or wires are drawn into the tubes, using a thin steel wirc pushed through the tubes froin a junction hox or inspection hos, and attached to the wires to be pulled in. All wires that have to go through a particular acction of conduit must be pulled through logether. The conduit must le clectrically continuous, and properly earthed to a !arge copier platc huried in the ground, or by a wire connecting the conduit to the water-supply pipes, hut never to gas pipes. See Electricity

CONEFLOWER. This is the populur name of rudbeckia, a vigorous linrdy perennial which bears yellow flowers in late summer and autumn. It thrives in ordinary soil, inay be planted in autumin or spring, and is easily increased ly division of the clumps in March. The best are : californicn, 6 ft., Golden Glow, double, $6-7$ ft., and speciosa (Newmanni), $\boldsymbol{\geq}$ ft. Rudbeckia (echinacea) purpurea, grows 3 ft . high and heurs reddish flowers

CONFECTIONERY. This word is used for sweetmeats, and for cakes, rolls, tarts, and fancy pastry generally. See Cake; Chocolate : Pastry ; Sweets, etc.
CONFETTI. Thesc are tiny circles of coloured paper. They are used at fancy dress balls and camivals, and at weddings, being thrown in handfuls at the bride and bridegroom as they emerge from church or set out for the honeymoon. For this purpose it is more suitable than rice.

Confetti can be purchased so cheaply that not many people will trouble to inake it for thenselves, though it can be done simply enough by folding sheets of thin coloured paper across several times, and cutting half. circles out of the folded edges.

CONFIRMATION. In tho Church of England and the Roman Catholic Church confirmation is the ceremony by which a person becomes a full member of the church, and is allowed to partake of communion. The person then for himself or herself confirms the promises made by the godparents when he or she was baptized. The Church of Rome regards confirmation as a sacrament, but the Church of England does not It can only he administered by a bishop, and candidates are usually lect ween 14 and 18 yenrs of age.

Those wishing to bo conlirmed should apply to a clergyman or priest. Confirmations usually take place early in the year, in order that the conlirmed can partake of the sacrament for the first time on Easter Day. In most parishes classes for young men and classes for young women are arranged, and therein instruction is given hy the clergy in the principles of the church. Special arrangements are made for older penple, the main point being that the person prescinted to the bishop must have
satisfied a clergyman that he or she is fit to receive the rite. The publio schools usually make their own arrangements for confirmation, boys being confirmed in the sohool chapel.

Confirmation services are held at stated times. A centre is ohosen by the bishop, and at that church the candidates from the neighbouring parishes are required to present themselves. It is usual for girls to be dressed in white. At the service the bishop places his hand upon the head of each candidate as he or she kneels before him, and says over each a short prayer.
The Confirmation Cap. To make a confirma tion cap, t of a yard of material 27 or more inches wide is required, and the edges should be hemstitched. Three narrow tucks are placed at one end, and two short ends of ribbon lastened to the ends of the tucks on the wrong side of the cap. These tie in the nape of the neck, holding the cap tightly over the brows.

CONGER EEL : How to Cook. This fish is at its best for eating in September and November. The flesh, being coarse, requires thorough cooking, but is highly nutritious When small, it may be cooked in the same way as a fresh-water eel, but if large it is best cooked like cod. Conger eel can be boiled in a fish kettle in enough hot water to cover it. and a teaspoonful of vinegar. After being brought to the boil it is allowed to simmer until the flesh falls away from the bone. It is served with parsley sauce To fry conger eel, it should be dried, cut in slices, and sprinkled with flour. It is then dipped in beaten egg rolled in breadcrumbs, and fried in hot fat. It oan be served with any fish sauce.
Another way of preparing conger eel is to let it stand for over an hour in a dish contain. ing 3 tablespoonfuls of vinepar, $\frac{1}{2}$ tablespoonful of chopped onion and a sprinkling of pepper and salt. Then stuff it with veal forcemeat, bind it up with a piece of tape, and bake it for about 1 hour on a wellgreased tin, basting it frequently. When it is ready, remove the tape, and serve the fish on a hot dish, with anchovy or other sauce strained round. See Eel.
CONGESTION : How to Avoid. This means an abnormal filling of the bloodvessels with blood. Active congestion occurs when such filling is a result of the dilatation of the arteries. This form of congestion is the first stage of inflammation, but it can be deliberately produced in the superficial parts in order to draw off the excess of blood from a congested, deeper organ.

Acute congestion of the lungs may arise from breathing irritating vapours, e.g. poison gas, or from bathing when overheated or drinking large quantitiea of cold liquid. (See Lung.)

Passive congestion occurs when the blood lingers overlong in the vessels. The blood in this case is dark or venous in character. In efficient pumping by a diseased or exhausted heart is a commion cause. It inay also be due to obstruction of veins, e.g. in pregnancy or from wearing tight garters or to the veins becoming varicose. Dropsy occurs and the legs swell. Relief is afforded by reclining at intervals with the legs somewhat elevated; in pregnancy a properly fitted abelominal belt, and in varicose veins elastic bandages, will reduce the tendency to passive congestion when one has to be up and about.

CONJUGAL RIGETS. By English law when one spouse has left the ot her and refuses to return to matrimonial life without lawful excuse, the other may bring a suit in the divorce court for restitution of conjugal rights. The one who sues must be ready and willing to resume cohabitation, and thus it is usual for him or her (generally it is the wife) to write a letter inviting the other to return.

There are very few excuses that are lawful excuses for not returning; but a wifo may
refuse to return to a husband who has treated her cruelly; and a husband may refuse to return to wife who has made unfounded charges of horrible oonduct against him. A good excuse would be that the other spouse was suffering from a certain disease, or that it was otherwise dangerous to cohabit with him (or her). Matrimonial infidelity is a good excuse If the respondent disobeys the order. he (or she) cannot after the time allowed is up come along and say "I anm now willing to come back." Disobedience to the order is equivalent to legal desertion, and the petitioner is entitled to alimony. See Desertion: Husband; Separation.
CONJUNCTIVITIS. This complaint is an inflammation of the delicate membrane which covers the white of the eye and lines the eyelids. It may result from a blow, a speck of dust, or the action of microbes. As most cases of conjunctivitis are very catching, the greatest care should be taken that the patient's sponges, towels or bed-linen are not used by anyone else.

In the acute catarrhal form of conjunctivitis the whole eye is bloodshot. There may be swelling with burning, itching, and a sensation of sand or grit in the eye. There is a sticky discharge, and the patient generally complains that his eyelids are stuck together in the morning. Pain and inability to look at a bright light may become markel and the discharge may become mattery. The eye should be bathed every half-hour with
a 10 grain to the ounce solution of warm boracic lotion.

There is also the chronic catarrhal form Here the white of the eye is constantly more or less bloodshot, and there may be inflammation of the edges of the lids and a slight amount of discharge collecting in crusts in the inner corner of the eye It ought to be determined at once whether or not the patient requires glasses. If he does, and his vision is corrected. a long step may be taken towards curing the condition. A lotion that often gives excellent results consists of boracic acid 5 gr ., zinc sulphate 1 gr ., distilled water 1 oz .

Infection with the micro-organism of gonorrhoea results in a form of conjunctivitis known in infants as ophthalmia neonatorum, and said to be responsible for 30 per cent. of the cases of blindness in Great Britain. A contagious form is trachoma or granular lids. chiefly affecting the lining of the upper eyelid. Membranous conjunctivitis is frequently a symptom of diphtheria. Medical advice should be obtained at once.

Spring catarrh is a condition which affects chiefly boys and young men, giving them a pale, sleepy look. Reddish grey elevations form on either side of the cornea or clear part of the eye, and granulations on the under surfaces of the lids which have a pavement appearance. Signs of irritation, itching, intolerance of light and glueing of the lids in the morning are the result. Recourse may be had to radium therapy. See Eyc.

## CONJURING: SOME SIMPLE TRICKS

## Useful Information for the Amateur Entertainer

## See also Card Tricks; Children's Party ; and the many entries on Indonr and outdoor games that form the recreation section of this work

The conjurer should never tell an audience what is going to be done. For example, if a coin is to disappear magically, call attention to it by holding it up, and after the disappearance has been accomplished, it can be safely stated that a touch of the magic wand on the hand which apparently holds the coin will cause it to disappear.

A great many of the most puzzling effects are produced by simple means. If a trick has been well received, resist all requests to repeat it before the same audience, unless the performer has the knowledge whioh will enable him to bring about the same result by a different method. Never perform any trick in public until it has been thoroughly rehearsed. In practising sleights do so before a mirror, and endeavour to deceive yourself.

One of the most difficult branches of conjuring to acquire is the patter, or description of the problem to be presented. If a humorous style suits the personality of the performer, adopt it, but be careful that the jokes are really witty and appropriate. A story is sometimes useful to illustrate the trick. Others inay find a mysterious atylo more suitable Whatever is chosen, it nust be rehearsed

The Pasi. 1. Little finger of left hand is inserted betwoen halves of paok remaning angers resting on top,
then presiod into fort of boft tham, top half being tifted by loft yitto finger
continually until the performer is capable of exhibiting the trick without hesitating in his patter. It is not easy to do one thing while talking about something else.

The Magic Wand. The conjurer should provide himself with a magic wand. This is essential, as it is quite possible to have a small ball, a coin, or other article concealed in the hand if a magic wand is also held in the same hand. A small table is also a very uscful accessory, especially if a servante is included. This latter is a shelf hidden behind the table which will receive any small article dropped on it.

Palming a Coin. In order to palm a coin, take a half-cown, or, if the hand is small, a two shilling piece, and place it on the tips of the second and thind fingers of the right hand. Hold the left hand open, palm upwards, and pretend to place the coin into the left hand. As the right hand approaches the left. bend the fingers, pressing the coin into the palm of the right hand, slightly coutract the hand, and if the coin has been placed in the correct position the fleshy portion of the paln will hold it firmly. A few experiments will readily show the best position suited to the individual performer.
As the right hand reaches the left. closo the latter as if it contained the coil. During these moves the ejes of the performer must follow the supposed position of the coin, and on no * account must a glance be directed towarda the right hand. If the wand is used. it can now be picked up in the right hand,
which will help to conceal the fact that the coin is therc.

As the disappearance of the coin is now an accomplished fact, state openly that by the aid of the magic wand it is possible to make the coin disappear Suiting the action to the worl, touch the back of the left hand with the wand, or wave the wand round the hand. and demonstrate that the coin has magically flown by slowly opening the hand When palming a coin, endenvour to hold the hand naturally, so that it looks to the audience as if it concenled nothing. Practise this sleight in finnt of a mirror, and before attempting to palm the coin actually place it in the left hand and study corefully the movements, especinlly the position of the empty right hand, then endeavour to imitiate these novements when palming the coin.

Tricks with Cards. Curd tricks may be described as a special branch of onnjuring The essential sleights which must be learnt are the force, the top and bottom change, and the pass, and until these are mastered no really effective card tricks ane possible.

The sleight called the force only becomes successful by experience and practice. It is used when it is desired that a certain card shall be selected. Hive the card at the bottom of the pack. Insert the little finger half way down the pack so that the pass may be made. As the performer approaches the onc on whom he wishes to force the card, the pass is made which brings the lower half of the pack to the top, with the selected card at the bottom of this position. Fan out the cards as they are offered and keep them moving towards the right, and just as the person puts out his hand to talie a card, the fingers of the performer's right hand push forward the desired card

Conjuring. Forcing a card. The card to be forced A. is pusbed slightly out of the fanned-out pack

There are two chicf changes, one where a card held in the right hand tatica the place of the top card of the pack, which is held in the left hand. This is known as the top change. The second, designated the hottom change, is effected by changing a card held in the right hand for one on the top of the pack, but instead of the card taking its place on the top of the pack it is put at the bottom. To make the firat change, hold the pack in the left hand with the thumb across the pack and the fingers underneath.
The card which is to be changed held between the thumb and first finger of the right hand While attontion is drawn to this card the thumb of the left hand pushes the ton card forward to the right nbout $\frac{1}{2}$ in. Making a smart half-turn to the left, the right hand meets the left, which is adranced, and the top carl is recured with the first and second fingers of the right hand, and at the eame time the thunb of the right hand pushes the card that is to be changed on to the top of the pack.
In the recond method, the card in the right hand is held by the first and second finger's only. As the liands rench each other, the
fingers of the left hand are opened to receivc the card and at the same time the top anrd is pushed forward nind secured by the first finger and thumb of the right.

The piass is one of the most important moves in card conjuring, and consists of a sleight which trans. poses the top and bottom halves of a pack Making the pasa can be accomplished with one hand only. but for all practical purposes the double. handed pass is prefer. able

The pack is hold in the left hand in the position usual for deal. ing, the thomb being on top and the four fingers at the opposite side. Lift half the pack, and iusert the little finger of the left hand at the break so made. The other three ing the ball on the back of the right hand, the
fingers should now rest on the top, of the palm being towards the audience. pack so that if the little finger is straightened out the upper half of the pack will be lifted to a vertical position

The right hand now grasps the lower half of the pack by the edges of the carrls, the thumb heing at the lower end of the pack and the first three fingers at the top end. Pressing the lower half pack into the fork of the left thumb, it is pivoted upwards, and at the aame time the little finger of the left hand raises the top half. As soon as the lower half can pass the top half, the pack is closed up and the pass is completed. When making the pass it is best to make a backward move of the hand, which will cover to a certain extent the various moves.

Handkerchief Tricks. Therc arc many pretty illusions with silli handkerchiefs which are always popular. A simple production and disappearance of a liandlkerchief can be brought about as follows. A small hollow rubber ball about $1 \frac{1}{2} \mathrm{in}$. in dianeter is necessary, which is piopared in the following manner : A hole about $\frac{1}{2} \mathrm{in}$. in dinmeter is cut in the ball and the piece removed. Opposite the hole two small holes are bored, through which a piece of thin catgut or Hesh-colour silk is tied. The loop formed should be long enough to allow the ball to rest on the back of the hand when suspended from the thumb. To produce a handlicrchief with this simple apparatus, it is only necessary to push a thin silk handkerchief into the rubber ball, suspend.

Showing the left hand also empty, make a half-turn to the right and bring both hands together, and under cover of the fingers of the left hand get the ball between the palms. A turn to the left is now taken, and with an up-and-down motion of the hands the handkerchief is slowly produced at the tips of the fingers. The handkerchicf is now held in the left hand and the ball, which up to the present has been suspended from the thumb, is disposed of on the servante. To malie the handkerchicf disappear the several actions mentioned above are reversed

CONSEQUENCES: An Indoor Game. This can be played indnors by any number of people. Each is given a slip of paper and is pencil, and is asked to write down an adjective applicable to a man This done, cach slip of paper is folded over, conccaling the writing, and is handed to the player on the left. Next comes a man's name, and the slips are once more passed on These are followed by another adjective, this time applicable to a woman, and a woman's name : the name of some place or public building : a remark made by the man: and a remark made by the woman: what the consequence was, and what the world said

As most plavers will follow out their own train of thouglit in writing these answers, and ns each answer will conic on a different slip of prper, the results when read out at the end are often both amusing and surprising

## The CONSERVATORY AND ITS CONTENTS

## The Gardener's Duties Simply Ezplained

Throughout this work articles on the flowers cultivated in the conservatory will he found, e.g. Begonia: Geranium : Orchid Sec also Greenhouse and th: constructional articles, e.g. Brick
For the house of small propmertions there is decorntion are grown in tlower pots, but if no more delightful adjunet than is well-planned there is room for a border of anil certain conservatory, opening, perhaps, from the drawing room by glass doors. Position is a matter of importance, and a conser vatory with a southern or south-western aspect is more favourably placed than onc huilt to the north or east side of the house: but whatever the position, many advantages will be ohtained by artificial heating during winter.
A conservatory may be deseribed as a glasshouse in which plants in Hower, previously grown in a groenhouse, are arranged for effect. Must of the plants used in conservatory
kinds, e.g camellia, acacin, abutilon, fuchsia and heliotrope may be planted there

By cultivating a suitable selcetion of plants, in pots and planted out in the borders, it is possible to keep, the conservatory attiactive the whole year tound, providing it is heated sufficiently to maintain a minimum winter teinporature of 50-5: degrees

Usually there is a bed of soil in the centre. where the vigorous plants and shrubs are grown, and staging for pot plauts at cach sule It is an advantage to have the piths paved or
tiled, for they can be kept clean with the minimum of labour. Certain plants may be grown even beneath the staging: the most popular for this purpose are the green-leaved and variegated-leaved tradescantia, a creeping plant. and Begonia rex.

Certain plants grown in baskets suspended from the roof are most decorative, and add to the attractiveness of the display. Some of the chief sorts are:
Drooping varleties of tuberous begonla, asparagus sprengerl, begonla gloire de Lorralne, campanula sophylla, blue and its white variety alha. the rat (lachenalla), fuchsia, lobella tenuoir, oxalis tlor bunda, ivy loaved pelargonlum, tradescantia, tho variegated stonecrop) (sedum sarmentosum varie gatium) and sonic of the ferns-nephrolepis, davallia and asplenium bulbiferum.

The Management. With regard to the management of a conservatory, the following suggestions will be found useful. When the temperature by day, as a general rule, exceeds 65 deg., ventilation must be given. During cold or frosty periods of weather the temperature should be kept at about 55 deg., this being done by the aid of artificial heat. During the winter months the ventilators should be closed about $2 p . \mathrm{m}$. during the summer they should remain open till about. 5 p.m.

Shading from hot sunshine is most essential, and this may be accomplished liy one of the

An attractive edging to the staging for pot plants adds considerably to the charm of the conservatory. Two favourite plants for this purpose are isolepis gracilis, which is of droop. ing grasslike growth, and panicum variegatum, with narrow green-and-white leaves. These may either be grown in pots or plańted in a narrow border of soil contained in a zinc trough alongside the edge of the staging. Herniaria glabra, a creeping plant, with tiny green leaves, also makes a neat edging.

Climbing plants improve the appearance of a conservatory, and a careful selection will provide flowers throughout many months of the year. It is a mistake to train vigorous sorts on a trellis fixed beneath the glass roof, for they cast too much shade on the plants on the staging beneath The less vigorous kinds are to be preferred for this purpose, for instance, roses in variety, abutilon, fuchsia, and the blue plumbago capensis, all of which lose their leaves in autumn. The conservatory pillars ought to be covered with climbing plants; a choice may be made from hibbertia dentata, yellow, cestrum elegans, rose, asparagus plumosus, smilax, heliotrope, ivyleaved geranium, the yellow acacia baileyana, the yellow jasminum primulinum, the scarlet honeysuckle (lonicera sempervirens), the blue and white passion flowers, and the gorgeous orange and red streptosolen Jamesoni.
Vigorous climbing plants suitable only for training beneath the roof-glass of a large conservatory are the white clematis, indivisa, cobaea scandens, solanum jasminoides (which has white flowers), the rosy mauve bougainvillea glabra, and the yellow cassia corymbosa.
The lapageria, with rose or white blooms, is a charming climbing plant for the shady side of a greenhouse, and the night-flowering cactus (cereus triangularis) is worth growing, but it must have a sunny place.

Plants grown for the sake of their orna. mental leaves are invaluable in the conserva. tory. Chief among them arc :

Coleus, dracaena. green-leaved and variegated Indla rubber plant (ficus elastica), grevillea robusta, palins (cocos weddellana, geonoma gracllis, kentlia palims (cocos weddeliana, geenoma graclis, kentia
belmmreana), araucarla excelsa, ferna, asparagus Bprengerl and plumosus, sinilaz, aspidlistra, cyperus sprengerl and plumosus, sinilaz aspidistra, cyperus
alternuollus, eucalyptus and ophiopogoii varlegntum, with green and yellow leaves.

Conservatory with semi-octagonal ond oxporing a large aurface to the sun. Top, left, conservatory poreh outride a Freach window Courtesy of Boulion \& Paul. Lid.
summer-cloud preparations sold by seedsmen, or preferably by movable roller blinds. Watering is another important item, and each morning sufficient should be given to inoisten the soil, using water of the same temperature as the air inside the house. In addition, it may be noted that clcanliness and method are as essential in the conservatory as in the greenhouse.
During hot summer days it may be found necessary to give water both morning and evening, but in the event of a plant drooping by reason of dry roots, do not water in the usual way, but stand the pot in a vessel for 10 min . to ensurc equal moisture of the whole of the soil. During winter sponge foliage plants with milk and water. Keep all dead blomns and foliage removed, and fumigate occasionally to destroy pests. If stimulants are necessary, use one of the excellent chemical manures on the market, strictly according to the maker's instructions.

When properly conducted, a conservatory should be a source of interest and charm all the ycar round, and its possibilities, in conjunction with garden and greenhouse will be apparent froun the following hints, which describe the

Fig. 8

Coneervatory. Piga. 1-5. Diagrams showing
seotions of mouldod and propared timbers naed in bailding a conserratory is buimas a comservatory

plants which are most suitable for the con. servatory in the various months of the year.

For January, early tulips, Dutch and Roman hyacinths, daffodils, freesias, winter flowering begonias, cyclamens and azaleas are suitable, as also are cinerarias and Chinese primulas. The same flowers are suitable for February. For March a succession of most of those mentioned for January will be found best, together with spiraeas, primulas, heaths, clivias and carnations. The same remarks apply to the succeeding month, April.

In May the showy herbaceous calceolarias are in full beauty together with amaryllis, Dutch and Spanish irises and annuals raised from seeds sown in September. Throughout the summer months there will be bloom from tuberous begonia, gloxinia, achimenes, geranium, heliotrope, fuchsia and many others. In autumn reliance must be placed chiefly on chrysanthemum, Scarborough lily, nerine, lilium auratum and other lilies. These will be followed by early bulbs, Chinese primulas and cyclamen, uinter cherry, winter begonias and carnations.

Bullding a Conservatory. W'hatever the dimensions of a conservatory, it should be free from any suggestion of heavincss. It generally has means for heating, for regulating temperature, and controlling the annount of light. A water supply is desirable, and for the benefit of the plants a conservatory should be built facing the south.

The usual construction comprises a brick or tiled floor, set in cement mortar, with a fall to one corner where a trapped gully communicating with an adjacent drain enables any surface water to be disposed of. The surrounding walls are made of brickwork to a height of about 18 in . The walls and roof are composed chiefly of glass, carried in wood or metal framing. The latter is more durable, but requires frequent painting owing to the dampness of the atmosphere in the conservatory. The roof should be constructed with throated or channelled bars to act as gutters. This to a large extent overcomes the objectionable effect of a dripping roof. Fig. 5 shows a standard form of machine-moulded wood bar made for conservatory and greenhouse purposes.
Elaborate conservatories are frequently made with large panes of glass, cut to ornamental slapes and framed accorclingly. The amateur would do well to obtain horticultural glass, which is sold by the 100 sq. ft., in widths and lengths such as 10 in . by 8 in ., 100 sq. ft. being quite sufficient glass nominally to cover an area equal to 10 ft . long by 10 ft . high.
The framing is readily constructed by using greenhouse bars for the windows A section is shown in Fig. 4, and this wood can be obtained in various widths and thicknesses. Windows to open will be framed up and provided with a strong framework to which
they may be hung, generally from the top. A top and bottom framing should then be constructed, supported by upright corner posts ahout 3 in. square. The most convenient method is to make up the sides and ends in sections and bolt them together, then erect a ridge hoard and fix the glazing hars to it. A proper wooden ridging is made for this purpose, and a section of it is given in Fig. 1; other figures illustrate the regulation sills and end plates, all of which are obtainable from any timber yard.
A water supply is generally ohtainable either by means of a rublier hose pipe that can be connected when required to the nearest water taj, or preferably by rumning a $\frac{3}{3} \mathrm{in}$. iron pipe to the water main or of her adjacent water-supply pipe. In some districts the water company may charge an extra rate if this is done.
Means for heating may le a simple oil lamp and some hot-air pipes. I similar arrangement with hot-water pipes, or a regular hotwater circulating system, can be installed with a separate greenhouse type of hoiler. A gas heater circulator with electric or thermostatic controls is a boon in changeable weather. It can be left burning all night, and any sudden drop in temperature will cause the controls to operate and so turn up the gas supply, and lieep it up until the desired temperature has been attained
Console. A console is a projection resembling a bracket (q.v.) used to support a cornice, or to hold busts, vases or figures.

CONSOLE TABLE. A console table is a table supported by brackets, or upon legs not unlike hrackets in form, and made to stand against a wall. Some of these tables. Which were chiefly made in France in the 17th and 18 th centuries, have the supports elaborately carved, and are beautifilly adorned with representations of fruits, flowers, scrolls, etc. Some were gilded and covered with a marble slab. The chief woods used for them were rosewood and mahogany.
Consommé. This clear soupl is made from meat, vegetable, or bone stock. See Soup.

CONSTANTIA. This district of Cape Colony is noted for the excellent quality of its red wine, the best produced in $\mathbb{S}$. Africa. Constantia as applied to wine is a territorial description like Beaunc. Most of the South African wines, with the exception of the one called Constantia, aro named after their Eumpean prototypes. See Wine

CONSTIPATION. This may be due to discase, general or local, hut apart from discase the condition is more often induced by individual habits and cuatoms. The movements of the bowels are induced by the presence of a certain amount of indigestible matcrial and of Huid. Modern methods of preparing and cooking food tend to eliminate indigestible constituents, the result being that the bowel is deprived of n normal stimulus. Then, some jeople take too little liquid, and what they drink may be tea aufficiently atrong to have an astringent effect. An active out-of-doors life has a stimulating effect on the muscles of the bowel and on the inuscles of the abdominal wall, which contribute powerfully to the emptying of the bovel. This stimulus is reduced in those of sedentary occupations and habits.

The taking of food has the effect of producing movement along the alimentary tract, and with the inajority of people this, coming on after breakfast, leads to $n$ habit of relieving the bowels then. Many men find tlint a pipe of tobaceo is a further help. But the particular time does not matter so much as the habit of soliciting an action of the bowels at the same time every day, as they can be trained to act regularly. The bowels may not move for two
or three days without apparent ill-effect, but generally there is discomfort in the abdomen and a heaviness in the head, or even headache. If the condition is not relieved, the local discomfort hecomes greater, perhaps accompanied by colicky pains, the appetite falls. the tongue is furred, and the spirits are depressed and the temper is irritable. If the constipation is chronic, the absorption of poison from the bowels may lead to a large number of bodily and mental infirmities
In addition to the importance of regular liabits stuck should be taken of the diet, and this can be made morc effective by the addition of fruit and vegetables. either cooked or raw, and by the use of wholemeal bread and oatmeal porrilge. Syrup and molasses will be found helpful, and amongst fruits marmalade and stewed prunes are especially useful. Many find that a glass of water first thing in the morning and at bedtime keeps them right. Strong tea, because of the tannic acid it contains, is bad. Milk, especially hoiled, is particularly constipating, and the same applies to red wines.

## Value of Exercise and Massase

Exercises, especially those which bring the abdominal muscles into play, are useful, and should include as inuch open-air activity as possible. Massage of the abdominal muscles may be resorted to. This may be clone by hand, hut a heavy ball, say about 5 lb . weight, rolled round the abdomen from the right groin up and across and then down to the left groin is found effective by many A useful ball may be made by filling a chamois leather bag with swati shot.
Should there be any difficulty in getting the bowels to move, a small eneina, $\frac{1}{2}$ pint of cold or warm water or 2 drams of glycerin injected into the bowel, or a glycerin or soap suppository, should be employed. It may be necessary, however, to resort to drugs. Under the beading Aperient a list is given of a number of common preparations, with the dose prescribed.
During the first year of life the bowels usually move two or three times a day; in the next year twice, and thereafter once. Infants at the breast should be restricted to their regular times of feeding, and should not be put to the breast, merely to pacify them, outaide thesc times Constipation may be due to a lack of fat or sugar in the diet, however the infant is fed, and an increase of these should he tried, fat in the form of fresh crean, a teaspoonful once or twice a day, bcing given. If the constipation is urgent an injection into the rectum of a few ounces of warn water to which a little soap has been added, or a teaspoonful of glycerin, will be the quickest way to give relief.
To train the bou'els into normal regularity when once constipation has become the habit, nothing gives better results in infants and young children than cascain. To a halfteaspoonful of sugar and water add 5 to 10 drops of the liquid extract of cascara, and give it to the child last thing at night; or t wice this dose of the aromatic syrilp of cascara may be given. The dose may be decreased or increased if necessary. When the requisite amount has been determined by experience, let the child have this dose nightly for two or three weeks, and then gradually reduco the amount, finally withholding it altogether. See Aperient ; Cascara.

CONSUMPTION. This is the conmon name for tubercular disense of the lungs (pulmonary phthisis) or of the bowels. The word denotes the wasting of the body in tuberculosis. The cause of the disease is always the tubercle bacillus that was discovered by Koch. This minute organism may enter the system and settle in the lungs through a person partaking of meat that is
tuberculeus, or milk, or even through a wound in the skin. The coinmoncst source of infection is from breathing germs floating in the air. The expectoration of a consumptive may be laden with millions of such germs, and when it dries on the ground or the Hoor the gerins may live for months. Clinging to dust particles, they are carried about the atmosohere, and can infect other people. Sunlight, however, possesses a powerful effect in destroying their activities.
'Tuberculosis is still one of our commonest and most deadly disenses. Since 1913 it has been notifinble. It is estimated that about one-screnth of the human race dies from tuberculosis in one form or another. It is possible that the infection takes place chiefly in childhood, when unheaithy tonsils and adenoids are rife, and when the resistance to the passage of bacilli in milk through the intestines is relatively low. Some children are born with a low resistance to tuberculosis; but a large number of cases in which the dis. ease appears to be inherited are really instances of direct infection from an affected parent.

When the tubercle bacillus invades and devclops in the lung there is a new growth of cells which solidifies the part of the lung nfiected. These masses of cells, known as tubercles, may be sufficiently numerous this to solidify a considerable area and destroy the lung tissuc there. The cells comimonly become converted into checsy matter, which softens and is coughed up. A cavity is left with ulcerated walls, and blood vessels are opencd up or burst causing haemorrhages. which may be large. These cavities are liable to become infected with the microbes of putrefaction, and this adds greatly to the poisoning which is already being caused by the tubercular microbes and is the cnuse of the foul sputum brought up. The disease tends to spread and destroy the adjoining healthy long. In some cases, however, repair processes come into operation, new fibrous tissue forms, the discase is walled off, and a cure resulte, with a sear in the lung.

Tuberculosis of the lungs may show many variations of forin. It may occur as a part of a general hlood poisoning by tubercle bacilli, in which symptoms indicative of the in volvement of other organs besides the lungs are present, e.g. meningitis. This occurs most frequently in children, and is usually rapidly fatal. There is also tho acute infection of tho lungs, known as galloping consumption, in which the condition may resentble pneumonia (q.v.) or broncho-pneumonia. The latter is common in infancy, and may follow measles, whonping cough or simple bronchitis. These forms may prove fatal in $\Omega$ few weeks or may pass into chronic tuberculosis of the lungs. This is the commonest form of the diseasc. and usually comes on insidiously.

## Sirnificance of a Persistent Coush

Persistent slight cough with no expectoration at all at the start may be the earliest sign. later there may be streaks of blond in the expectoration. A doctor should then be consulted. Ready fatigue, $\Omega$ tendency to sweat at night in bed, and a slight afternoon rise in temperature aro other early symptoms

The spread of consumption is faroured by herding people together in amall houses and in workshops, and by insufficient or improper food. But even if accommodation is restricted the clanger can be minimised by Hooding the premises with air and light With regard to food, it has been pointed out that the decline in consumption during tl:e last 50 vears coincides with the importation of foreign meat into this country, with an increase and cheapening of protein food. It is of great importance that patients, and especially children, recovering from acute
diseases, particularly measles, whooping cough. and broncho-pneumonia, should be closely watohed throughout their convalescence, as the seeds of consumption are often sown then. It is obvious that grave dnnger lies in allowing people to spit on the strects. in public places or vehicles, or elsewhere. at large

Every lime an advanced consumptive speaks, coughs, or sneezes, he exposes those about him to the possibility of infection.
Persons who suffer from tuberculosis should carry a sputum flask or cup, which can be obtained from any chemist or hospital that treats lung diseases. A few drops of some disinfectant are carried in thesc Hasks, and in using them care should be taken that nll the sputum goes inside. If any is left on the orifice it dries and is scattered as dust, and this is the danger that lies in using a handkerchief.
To protect the rest of his household the consumptive should have his own table cutlery, plates, serviettes, etc., and no one else ought ever to use his towels or slecp in the same room with him. The habit of washing the hands before touching food should be inculcated and practised. The consumptive's handkerchiefs, pillow slips, etc., should be soaked for some hours in a solution of carbolic acid ( 1 part of carbolic to 20 parts of water) or some other disinfectant before being sent to the wash. The person who has to look after the rooms of a consumptive should always wear a light muffler covering the nose and mouth when sweeping, and utilise wet tea lenves to prevent dust. Instend of sweeping or dusting, cleaning should bc done when possible with a damp cloth, which can be wrung out from time to time in a disinfecting solution

Treatment. The treatment depends on thic stage of the disense. Broadly speaking, if the patient has an evening temperature above $100^{\circ}$, he should be kept in bed. On the other hand, he may be put to exercises or graduated work, particularly when the disease tends to become quicscent. The treatment must be closely supervised by the doctor at all stages, but the intelligent cooperation of the patient and his friends is neccssary. Essential constituenta of the diet are raw meat and eggs. Smoking is likely to be harmful. Alcohol, with the exception of beer or light red wine, should not be taken except under a doctor's orders.
The minximum of fresh air, both day and night, is required at all stages. If a shelter with a well-boarded damp-proof floor can be arrnnged in the gnrden, the patient should begin by sleeping out of doors on fine nights. Alter a few nights he will find that he is perfectly comfortable, even when the warthcr gets colder. The effects of fresh air arc often very noticeable. The hectic Hush, the pallor, the irritating cough, and the tendency to night sweats often immediately pass off. If the patient cannot slcep in the open, his bedrnom should be as simple and bare as possible. The bed should be placed near the open window: Draughts will be avoided by having the window widely open night and day.
The most useful of all medicines in consumption is cod liver oil (q.v.). Other drugs frequently used are creosote, guaiacol oarbonate, and arsenic. Treatment by injections of preparations of gold have given good results. Preventive measures include the ndministration of Calmette's tuberculin during the first week of life.
Intestinal Consumption. Consumption of the bowels is common in young children, and the tubercle bacillus may cause ulceration of the bowels, and may settle in the glands renning along the spinal column at the back of the abdomen. This a bdominal tuberculosis is verv frequently associated with the disease
on the lungs or elscwhere. In the great majority of oases it is due to the infection by the type of tubercle bacillus found in cattle and conveyed in unboiled cow's milk. Fresh air and sunlight are essential. If possible the child should be taken to the country or the seaside. Complete rest is necessary, but when the child's condition warrants it, this should be on a bed out of doors, or in a long pernmbulator or invalid carriage. With regard to diet, here also raw meat and eggs arc indispensable. Cod liver oil will be useful. One way to give it is to rub it gently into the abdominal wall, or apply it there and cover over with : Hannel binder, when the movements of the child will rub it in.

CONTAGION: How to Avoid. In. fectious diseases may be acquired by direct contact with a person suffering from such a disease, from liandling cluthing or other articles which have been in contact with him, from infected air, water or milk, or other food, or in some cases, the diseaso may be through the agency of insects.

In public places of refreshment, during a rush of business, the glasses, cups and other dishes would appear often to be wa.shed in a perfunctory manner, and it may be wiser to go thirsty than drink out of a glass which has possibly just been used by one whose month is in an infectious state. The use of a hairbrush which is at the disposal of all and sundry involves a risk, at the least, of dandruff, and possibly of ringworm. The same applies to laying onc's head on the cushions of a public conveyance. Anthrax has been acquired from shaving brushes implorted from abroad and when a new one is purchased it should he soaked in a disinfecting solution. Various disorders are propagated by air ; for example, a common cold, influenza, measles, tuberculosis, ctc. In such diserses as consumption where there is much expectoration a sputum Hask should be rigorously employed.

There is always a risk of infection through unprotected cuts or sores on the hands. When one has come into contact with a possibly infected person in any way a free usc of soap and water, and preferably also of an antiseptic solution, such as permanganate of potash, should never be neglected. A neasure of protection more or less effectual is afforded by vaccination against smallpox, by inoculation against enteric fever, ett., and by vaccines against colds, influenza, and other disenses. See Disinfection: Fover: Fly, etc.
CONTAGIOUS DISEASE. Disease that is passed from one person to another by contuct is termed contagious disense. The person passing the diseasc inay be one actually suffering fmom it or he may be a carrier : that is to say, that although he maly be quite well in himself he carries disease-producing miorobes about his body. This may be because he has at one time had the disease, hut not necessarily, as pcople are found with the microbes of such diseases as diphtheria and cerebro-spinnl fever in an active form, although they might not have shown the aymptoms of the disease or, at any ratc, have att racted any attention.
The contact may be of an intimatc character, ns in ringworm and other diseases; but, on the other hand, clothing which has been worn by infected persons, e.g. smallpox or scarlet feyer, may be conveyed hundreds of miles away and infect other people.
In Great Britain the law requires the notifieation of certain of these diseases, smallpox, scnrlet fever, diphtheria, enteris fever, etc., to the medical officer of health, and, if necessity arises, other diseases, such as measles and whooping cough, may be added to the list. In addition to others, pneumonia, malaria, tuberculosis, dysentery, spotted fever, and Encephalitis lethargica a re notifiable.

The advantage of notification is that means can be talien at once to isolnte patients and those who have been in contact with them. See Disinfection; Fly; Notification: Quarantine; Vaccine, etc.

CONTRACT: The Legal Sense. I contract is an agreement enforceable at law It requires an offer and acceptance of that offer ; valuable consideration; and an inten. tion that the agreement shinll be a legal onc ; thus, if one offers to receive a man to dinner in a friendly way, and he agrees to come, it is not a contract. Offer and acceptance may be by word or conduct. An acceptance of an offer is not an acceptance unless it ís unconditional. Thus, if one man offers to sell another something for $£: 0$, and the other replies that he will take it subject to 5 per cent. discount for cash, he has not accepted the offer and there is no contract. A contract by post is complete and binding on both parties the moment a letter accepting ye offer is posted.
In offer can be cancelled at any time before it is accepted, unless something has been paid for it to be kept open. Thus, if a man asks a tradesman to kieep open till Monday at 12 noon an offer to sell him a dress at a certain pricc, and the tradesman agrees, he can nevertheless cancel his offier before 12 on Monday. But if even a penny has been paid to keep the offer open till that time the tradesman must keep it open. An offer is open for a reasomabise time, unless a definite time is specified; and after a reasonable time has elapsed it is automatically cancelled without further notico.
Acceptance must be expressed whether in words or by an act. Thus, a letter says, "You can have the sealskin coat you saw for £.50, and if I do not hear from youl I shall send it to your." The person to whom such an offer is made is not bound to answer ; and if he does not, and the coat is sent, he is not bound to takc it. Of course, if he keeps it, he must pay the $£ 50$.
A few contracts require to be evidenced by writing. The writing may be signed at the time, or may be contained in subsequent correspondence so long ns all the terms of the contract are shown. The following arc contracts that must be in writing :
Contracts for the anle of land or any interest thercin. within a yeur from the day they are made, e.R.a contract to nongage a governes for o year, tlic servico to hegin two days lience.
Contracts in consideratlon of inarringe- Dot a promise to marry ; but such a contract as this, " If youl will marry me, (or my son or my daubliter), will give you $\varepsilon 1001$."
Contracts of glinrantec.
(Contracts for the sale of pooils at a price of $£ 10$ or over. But If anything has been paid for or Ons goods or part of them or bind the bargain, or the accepted by the buyer, there is no need for writing.

Although in other cases writing is not necessary, it is always bettor to have the terms of a contract of any importance in writing. One should sit down and write a letter, "Confirming our conversation of to-day's date," and set out all the terms agreed on as clearly as one can.
The consideration for a contract required by English (but not Scots) law may be a payment or a promise to pay ; doing something or promising to do something. And the payment or the act done need not be for the benelit of the person who makes the coatract. Thus, if A chooses to say to B, "If you will give Jones a job as your gardener, I will give you a ton of coal," and B gives Jones the job, A must give B the coal or pay him the value thereof. See Agreements.

CONTRACT BRIDGE. This form of the game of bridge differs in one or two ways from auction bridge. The chief difference is that when a side has won a game it is vulnerable,
and its bonuses and penalticy arc increased Another difference is that players score be low the line, or towards a gaine, only for tricks which they have contracted for and made Points for excess tricks are scored above the line. Likewise the score for a slam oan only be made if it has been bid for.
In contract bridge the values of the different suits are as follows:

The players begin by bidding for the lear $\hat{a}^{g}$ in auction bridge and they play out the Cards with the leader's partner, or thiri hand, laying his cands down on the table and taking no further part in the game. Onc hundred points acorcd below the line make a game. All other points are scored above the line and therefore do not count towards game. Calla can be doubled and redoubled as at auction bridge.
Above the line the score is made by honours, slans and bonuses of several kinds. Honours are only declared when four or five are in one hand. Four honours in one hand is 100 pointa : five in one hand is 150 points. With a call of no trumps four aces in one hand count 150 points. Small slam counts 500 points and great slam 1,000 points. A rubber won in two games counts 700 points; if it takes three games 500 points. For tricks taken in excess of the number bid 50 point per trick are scored. In case the contract is not fulfilled the opponents of the bidding side count 50 points per trick. If a call is doubled and the bidding side wins they count $j 0$ points for fulfilling the contract. If it is redoubled they count 100 points.
Vulnerablity. The above pointa arc made during the first game. After that one side, having won a game, becomes vulnerable, and for it, but not for its opponents, some of the penalties and bonuses are increased. For exainple, the vulnerable side counts 780 points for small slam and 1,500 points for grand slam. If a call is doubled the vulnerable side obtains 100 points for fulfilling its contract and 200 points if the oall is redoubled. Alsn if doubled the vulnerable side receives 200 points per trick and 400 points if redoubled. for all tricks made in excess of the contract.
The vulnerable side's penalties are corre spondingly increased. If a call is undoubled it loses 100 points for the first trick contracted for but lost and 200 for each subsequent trick. If the call is doubled the vulnerable side will Inse 200 points for the first trick, and 400 for each other trick lost.
Revoking. Tho penalties for revoking at contract bridge are two tricks for the first revoke. Thesc are taken at the end of the play from the score of the revoking side and addel to the tricks of the other side. They arc figured as if actually won in play. Sub sequent revokes in the same hands are penalised 100 points carh and scored in the honours column. See Bridge.

CONTUSION. Any injury inflicted on the tissues by a blow from a blunt body or instrument which does not break the skin is termed a contusion. The soft tissue below the skin is torn, and bleeding takes place from its vessels. The prit is swollen, hot, and painful, and discoloration usually follows. The treatment consists of reat and the appli cation of cold cloths. See Bruisc.

CONVALESCENCE. The period follow. ing recovery from a disease, but before the restoration of normal health, is known as convalescence. In acute febrile disorders this usually dates from the final drop in the temperature, but the patient is left with debilitated tissues and organs. This condition is the effect of the fever and the poisons in the blood which were responsible for its production

In the casc of discases, the brunt of which falls on particular organs, there arc gross lesions to le recovered from, e.g. ulcers in the bowel in cnteric fever and more or less consolidated lung in pneumonia. The patient's digestive powers and his capacity for exertion are therefore reduced, perhaps very much reduced. He may himself be conscious of this and amenable to necessary restrictions imposed by the dootor, but sometimes he may be impatient, thinking that he is better than he really is. The doctor's instructions must nevertheless le carried out, and on the part of the uurse firmoness and tact will be called for

In changing from slop; to ordinary diet there should be a progressive introduction of articles of fund which nake greater demands on the digestion, and to begin with there should be a number of smull meals, given at regular times. Variety should be ained at, and the cooking and serving sliould be as attractive as possible. The nurse and not the pationt should decide what food is suitable.
Food for Convalescents. To facilitate the composition of the daily menn the follow. ing suitable foods may be named, it being understonl that those first mentioned are intended to be the sole diet in the first days of convalcacence, though they may be continued throughout; but those in the latter part of the list are not sclected until after fou or five days of uninterrupted progress. All pastries should be avoided.
Mlik, alone or with soda or potash water, Benger's foni, Allenbury' Diet No. 3, beef tea, atrong hock soup, eqR illp, thin armowroot made with milk, te: Culf's-foo
chicken eot jelly, chicken jelly, mutton broth chickult, plain sponge cakes, mallk jelly, junket.
Ont flour porridge revalenta, good milk pudding and custards, egag ponched or noft boiled, atcamed flish (whiting, sole. plaice or haddock) with milk sance.

Camlinower with white rauce, spinach, fripe or sweetbreals, chickell or rablit, bmked apple witli cream, a little freslı fruit.
Ronst mutton or the eyc of $n$ tender mutton chop, boiled mealy potato.
In convalesoenco from enteric fever the craving for solid food may be very attong, hut should be resisted until the doctor gives his permission, as rupture of the bowel through a partially healed ulecr has been a not infrequent sequal to an evasion of his orders. At the same time it must be ever present in the minds of patient, nurse, and friends that while the pace must be regulated, steady progress towards recovery is expected.

CONVOLVULUS. Alternative name for bindweed. There are perennial and annual bindwreeds : two of them, Convolvulus arvensis and sepium, are most troublesome weeds. Creorum is a clarming rock garden plant

Convolvalus. The climbing annual convolvulus, a bowy summer flower
with grey leaves and pink flowers, it nceds well-drained soil and a sunny place, and is hardy only in mild districts. Among the annual forms of convolvulus are several showy half. hardy plants. They are raised from sceds sown under glase in March, the seedlings being planted out of doors in May. Seeds may also be sown out of doors in April Convolvulus major, a climbing plant, and minor, of low growth, have flowers in many showy colours-pale blue, crimson, purple and rose. Other llowers often called convolvulus are known botanically as ipomoea. The loveliest of these is Ipomoen rubro-cocrules which bears large bluc Howers and is best grown in the greenhouse from seeds sown in spring. Coccines has bright red flowels.
CONVULSIONS: Cause and Cure. In infants and young children convulsions arc most often duc to teething, indigestion, worms, rickets, or the onsct of acute fevers. In grown people the commonest causes are epilepsy, hysteria, uraemia, poisoning, chronic alcohol sm, pregnancy, and brain tmmour or injury. The rolling of the eycs, jerliy movements of the limbs and head, with twitching of the muscles and grinding of the teeth cannot be mistaken Consciousness is lost, except in strychnine poisoning, where the mind remains clear, and in hysteria unconsciolsness is more apparent than real

If an infant is attacked the doctor should at once be sent for The infant must be placed in a warm bath, and a succession of cold cloths applied to the head. The duration of the bath will be 5 to 10 min . In adults the convulsion will probably come on suddenly, and the patient falls down if he is on bis fcet at the time. No attempt should be madc forcibly to prevent the movements, but these may bo controlled sufficiently to prevent the patient from injuring himself, and if necessary ho should he moved out of the way of danger A pillow of a folded cont should be placed below the head and shoulders, and any tight clothing about the neck or waist should be lonsened To protect the tongue, which is often bitten, cork or a piece of wood, or the handle of a pocketknife well guarded by wrapping a handker. chief round it, should be thrust between the back teeth.

CONY. The old name of the rabbit is now used chiefly for its fur when employed for wearing purposes. Ordinary cony skins come in vast numbers from Australia, and white rabbit pelta either from Normandy and other parts of France or from China

Cony is usually treated to imitate one of the more costly furs. Thus white rabbit figures as ermine, and when dyed as chinchilla, beaver or electric sealskin. White rabbit furs, if first stripped of their linings and wadding, will wash beautifully in a lather of warm soapy water They should be shaken out well and hung in the open air to dry. See Fur.
COOK. Except where there is a housekeeper the cook is the head woman servant She is responsiblc for the cleanliness of the kitchen premises, though in larger households ahe takes no actual share in the work of cleaning. The dining room meals are her chief concern. She is often expected to arrange $\pi 4$ well as cook then, and probably has a kitcheh maid to do the rough work and help with the preparation of the food.
In smaller households where there is neither kitchen maid nor scullery maid, she is usually expected to do a certain amount of cleaning and housework as well; she is then responsib!e for the kitchen premises herself, and may occasionally be expected to look after the hall and dining room in the early morning. If this is to be included in her work it should be mentioned when she is engaged. A cook can command higher wages than any other maid. mervant. See Chef ; Servant,

## Cookers: GAS, Electric and OIl

## The Best Examples of the Three Types Described and Ilustrated

For further information sec Boiler; Kitelen; Oven; Range. The entries Electricity; Gas may also be consulted with advaniage

Apart from the ordinary kitchen range, to he used for the former purpose a separate which may he maic to burn coal, coke, woorl or houschold rubbish, cookers are constructed to consume three main types of fuel: gas, electricity and oil. For this reason they are dealt with here unier these threc headinge. It should be remembered, however. that the liitchen range usually performs four separate and distinct functions. The first of these is cooking, twasting, heating Hat-irons. It heats the litelien and heats water, usually by means of a boiler situated at the back of the tire-box, for usc either in the scullery, lavatory or linthroom, or for warming the house by means of hot water or stean radiators. It also consumes household rubbish.

When the three types of fuel are used, these functions are performed separately, and it may he necessary when replacing a kitchener to divide up these four functions among the various fuels available. For instance, if gas, coke and electricity are available, a good method is to cook by means of gas or electricity, and to central-heat with coke. The choice is influenced by the two main factore of labour-saving and convenience, as opposed to the cost of installing and running the various systems.

Wherc clectricity is already installed, gas is generally available. Most gas or electricity companies will, if desired, hire out a cooker, and some companics supply cookers on hirepurchase terms, payments for these being made over one or three years.

In considering cost, it may be taken that where the cost per unit of electricity is not more than one-tenth that of the gas therm (e.g. Id. per unit and 10 d . per therm), electric cooking is as cheap as gas cooking. An addvantage in the usc of electricity is that the heat can be produced in the exact apot where it is required. In a saucepan or kettle the heating coil can he placed in the middle of the liquid. A cheaper ratc is allowed for electricity for cooking and heating than for lighting, and where clectricity is

Cooker. Fig. 1. Enamelled gas cooker with back plate and rack for dishes, etc. Fig. 2. Gas cooker for a larger establishment. The oven, thermostatically controlled, is e!evated. and bas a plate-warming compartment beneath it

Fig. 3 shows another type of elevated cooker, in which the plate-warming chamber is above the oven. The ventilating canopy in this case is inade of wired glass in a framework of stainless steel. The flue from the oven has an outlct under the houd, this being the lawer of the two gratings shown, the stcam and all vapour from the oven passing away into the chimney through the upper grating. If the oven llue were taken direct into the chimney there might be a risk of down draught which would interfere with the proper working of the oven.

Sinaller types of cookers also are obtainable with ovens litted with thermostatic contiol.

Cooker. Fig. 3. Elevated gas cooker with platewarming compartment above the oven

If the oven hecomes too hot, the gas antomatically goes down: should the heat begin to cool off helow the desired temperature, the gas goes up again to keep the heat just right. A chart is supplied with the cooker, hy which the oven is regulated. The buttom of the oven is closed in by a hase-plate upon which low. temperature cooking-milk puddings, casseroles, etc.-may bc carricd on while the other items of the moal are cooking above. Gas is economised by having only onc bumer in the oven instead of two, and by the fact that the Hue outlet is at the lottom instead of at the top of the oven, by which arrangement the heat is retained for a songer time.
In some makes of cuokers the boiling burners are so designed that they do not bccome clogged, neither will flames he extinguished lyy liquids boiling over. Each burner is fitted with regulators to ensure an even heat spreading over the bottom of the cooling utensil. There are also metal disks to provide a firm rest for small sauccpans on the hot-plate.

Hints on Cleaning. Little and often should be the motto for cleaning all gas cookers. The oven, plate-rack, stand, trays, etc, should be all washed every day if possible. but at least once a week. The burners, in particular, cannot lie expected to give their highest efticiency and economy unless they are kept scrupulously clean. Hor this reason, all burners and

required for baking, roasting, etc. It is liest to get the oven up to the required tem.

Cooker : how to keep a gas cooker clean. Fig. 4. Grids and burners being scoured with hot water and soda. Fir. 5. Removing grease with a special praparation

Unless of rustless steel, the hright asteel parts should be cleaned every day with finc emery cloth, and the hot-plate grids with a rag moistened with turpentine and then wiped with a dry cloth.

Unless the unpolished parts of the outside of the cooker aro enamelled, they should be eleanel with blacklead daily. If the stove is not going to be used for some time. these parts should be thoroughly washed and dried, then coverel with grease. Before using the cooker the grease must be whahed off again with hot water and soda. When using a gas cooker always turn out the gas immediately it is no longer needed, and never allow Hames to llare up the sides of pots.

HInts on Using. The proper way to heat up a gas oven is to turn the gav half on, light it. and leave the door closed for two or three minutes. Then turn the gas full on for about 10 min , after which the oven will have attained its full heat, and the door should be left open for a ininute or two to allow all the stean formed to eacape. The oven will then be ready to givo out the steady. Wry hent

Cooker. Fig. 8. Small electric cooker which may be stood upon a table or special stand

Courlesy of Belliny \& $C o$
perature to start with, and then lower the gas to maintain this. Never turn on the oven gas without first opening the oven door Always have a lighted minteh ready hefore turning on the gas. especially for the oven burncr. Don't heal the oven up specially for one or two smail dishes: make good use of it on baking days. As soon as cooking is completed. the oven should be wiped out with a damp oloth. A bowl full of water placed in the ovenimmediately after cooking is linisherl and the gas has lieen turned out will provide hot water for washing up with. out extra cost.
Never uso a solid shelf in the oven, ex cepting as a deflector to throw down the heat on to the top of the forl being cooked (for browning purposes), ns a solid shelf effec. tively prevents the heat from rising to the food on the shelf above. With all ordinary gas cookers

Fig. 8. Horizontal electric cooker, with an extra plate-warming compartment above the oven Courtesy of Belling \& Co
control as the thermostatic for gas cookers is obtainable in the more expenaive electric models, by means of an automatically operating time switch. Electric cookers arn casily movable, so that they can be placeal where required, and are made in various sizes to suit the reguirements of the household.
For the very sinall kitchen, or the hachelor flat, there is a little cooker specially designed, which may either be stood on a table, as in our illustration, Fig. 6, or on a stand available at a small extra cost. It has an all-metal enclosed boiler-griller plate (3.hent) which the hottest portion of the oven is at the hottom. Stenmers with several compartments over one
burner, instead of several pans, each on a dif. ferent burner. should loe employed for this work.

## Electric Cookers

 It may be as well to state that with a properly installed electrio cooker there is no danger whatever of shock. Elec tricity, properly used, is such a con. venient form of providing heat, without fumes. smoke or smell that it mesns cooking under ideal conditions. The heat is always constant and there is saving in weight and value of the foorls cooked by this method.Generally speat ing there is a cheap rate available of about Id. per unit for cooking purposes, plus a small atanding charge based on the rates of tho house or whatever the system of the town may happen to be. Most supply companics will install a cooker on simplo hire terms, the hire including cost of wiring and fixing.
The heat can be perfectly regulated and controlled in a satisfactory electric cooker. Each part, oven, grill, or hoiling plate, is in four burners. Fig. 9 shows an efficient type of the larger models independently switchel. cooker for family use with three hurners, one T'emperature indicators ensure scientifically being a giant burner for rapid boiling. There is accurate results. Somewhat similar oven a wick adjusting apparatus, and a giass door to

Cooker. Fig. 9. Oil cooker with three burners and having a glass door to the oven Courtesy of Anylo-American Oll Co., Led.
the oven which obviates the necessity of opening the door to see how haking progresses. 'The cabinet top posserses a plate rack. The double walled chimneys concentrate the heat where it is required. The wicks should be thoroughly cleaned nt least once a week by raising them even with the top of wiok tubes and seraping the carbon from the top of the wick with a cleaning tool provided with tho stove. Tho wick is then turned down and the screv top removed and any dirt cleansed from the inner wick tube, the screw top then being replaced. It requircs from three to five ninutes for the flame to reach full height after lighting. The flame should be a clear blue colour and extend above the top of the grate.
The pressure type of oil stove (lig. 10) burns paraffin without a wick. This type of burner first vaporises the oil by ejecting it under pressure thmugh a small heated nozzle, then mixes it with air, and finally burns it in n rose. not unlike a modern high efticiency gan burnor. This type of stove is suitable for camping

Cooker. Fig. 10. Pressure type of oil cooking stove. hicb burns paraffin withoot a wick
or for use where baking is not required. It can be furnished with accessories for toasting, etc. A similar stove may be obtained with only one burner. A small oven on legs might be arlded.
A comparison of the working costs can be made by assuming that each burnef, when full on, will use from a quarter to half a pint of paraffin per hour. The pressure type of burner is undoubtedly very economical, but has two main disadvantages. One is the neccesity of heating up the burner with methylated spirits for a few minutes before lighting the stove, and the other is that of having to pump up the pressure from time to time while the stove is working.
The chief cause of all working troubles with oil corkers is dirt. Dirt cnuses smell, smoke, clogging, and many other ills which accom-
pany such slight details as allowing carbon deposits to form on nozzles, etc.

A good wrinkle with a pressure cooker is from time to time to open the valvo after the pressure has been pumped up, but before the burner has been heated. This will force n thin stream of oil through the nozzlo and air injector, and carry noway any small particlea of dirt or carbon deposit.

COOKIE. These caker are prepared by creaming 5 oz of butter and $B \mathrm{oz}$ of sugar. Into these bent an egg, then stir in 3 gill milk, finally sicving in $\$ 1 \mathrm{l}$. flour and 1 teaspoonful baking-powder. Roll out the mixture thinly, adding nore flour if necessary, and then form it into rounds. Bake the cookies in a fairly hot oven until they are golden brown

COOKING BOX. When long and gentle cooking is required a cooking box will be found useful, the fond being brought to the boil before being placed in the box. To make $n$ cooking box, line a packing-case or angar box with tivo or three thicknesses of newspaper, covering the latter witl flannel or the type of felting used under atair carpets. Nail this on neatly, and line the lid in the same manner. Make some balls of newapaper, pack then tightly into the bottom of the box to a depth of 3 in ., and place the saucepan or casserole on top of then, packing it round with more newspaper halls so that, when it is lifted out, a nest is formed. Should there be mons for two sauce. pans, stand both on the layer of paper, but put a thick padding of paper balls between the two. The cushion or cushions placed over the top can be made of Hannel or felting stuffed with paper tom into amall slireds. See Haybox.

COOLING : OF Rooms. In temperate climates n few simple precautions sullice to keep a room cool on the hotteat day. Most important of all is the outside blind, which need not necessarily be a sunblind on nn iron frame, though that is the most convenient. Any dark blind which comes outside the window pane answers the purpose by preventing the radiation of the aun on the glass.

Windows should be shut during the heat of the day and the outside hlind pulled down. They may lie opened agnin when the heat of the sun has abated, the blinda being then pulled up, provided that the sun no longer shines on that particular window. Where a window may safely be left open all night this should le done, par ticularly passage and landing win. dows, which ensure a current of air through the entire house.

Electric fans are of assistance in oirculating air and so keeping rooms and passages cool. In rooms with tiled or stone floors, such ns sculleries, dairies, and old-fashioned kitchens, a little water may be sprinkled on the

floor with a "atering.can to cool the air by evaporation. Hyposulphite of sodn has a cooling effect when it is dissolving, and some crystals moistened in a dish may be placed on the window ledge and the window pushed up a few inches See Ventilation.

COOP. A coop is a wooden structure, with hars in front, and is used to house a hen and her hrood until the latter are weaned. The bars are so arranged that the chickens can have free ingress and egress to an attached run without the hen. The main cssentials in a good coop are durability, security against inclement weather and rats, etc., together with ample ventilation without draughts. When rats are troublesone, a floor is necessary : but, when.

Coop. Uselal and elfective type of ben coop instractons for making which nre given in the text
ever possible, n coop should be located on short grass and inoved to fresly ground from time to time.
A coop is quite easily made at home, and the design here given has proved satisfactorv either as a sitting coop or as the first home for
the hen and ohicks: it has been devised for use in conjunction with a small portable chicken run
Made in sections to bolt togetlier, it can be diamnntled and packed away during the winter months. The dimensions are given in the accompanying drawings
The lirst thing to do is to make up the front (Fig. 1) and back (Fig. 2) frames from deal $1 \frac{1}{2}$ in. square, the comers being mortised and tenoned and well serewed Five of in. diameter holes are drilled through the front frame and the iron hars driven through the four outer holes. The central hole is used for a movable rod, which prevents the hen escaping, but gives complete freedon for the young chicks.
The door or cover (Fig. 3) is made from $\frac{5}{1}$ in. tongued and grooved matchboard, has a batten across the centre, and three 1 in . diameter holes at the top for ventilation. This fits into the front framework, and is kept in place by two turn buttons. The back frame is covered on the outside with in. T. and G. matchboard. The two sides (Fig. 5) are made up from sinilar material nailed to battens 2 in wide and $\{$ in. thick at top and bottom. These must be made up in pairs so that the battens are on the outside. The roof (Fig 4) consists of four lengthis of weather-board, preferably moulded and rebsited as shown. It is nailed to the $1 f$ in. by 1 in . battens, which are at auch a diatance apart as will just olasp the sides.

The coop is assembled by drilling $\ddagger$ in diameter holes in the tivo side pieces, near the front and hack at $\bar{i} \mathrm{in}$. frotn the edges, corresponding holes being made through the framework of the front and back. The-front and back are then bolted in place, and the ronf put on top and sccured to the sides with two stout brass acrews on each side, passing through the roof hattens and those on the side pieces. A hole is dilled through the roof to permit the passage of the novahle rod. The resulting coop is shown in the photograph. The best finish is a coating of creosote inside and out ; this is a good preservative and an efficient insecticide. See Chicken; Poultry.

COPAIBA. An oily resin obtained from the bark of a S. American tree contains n medicinal oil which has been extensively em. ployed in the treatinent of gonorrhoea. It has also been found helpful in chronic bronchitis. The dose of copaiba is $\frac{1}{2}$ to 1 Huid dram, and that of the oil is 5 to 20 minims. The oil may be taken in capsules or in mucilage of acacia, prescription consisting of copaiba 2 drams, mucilage of acacia 2 oz , pepper-mint-water 8 oz . The dose is $\geq$ tablespoonfuls 3 times daily after food. Pron. Co-pā'ba.

COPAL VARNISH. This hard clear varnish is usually employed in finishing carriage hodies, and hecause of its durability and brilliance is suitable for all outdoor work, or for indoor work subject to lined wear. Varnish made from the darker tinted copal is in no way inferior to the lighter grades, but it fetches a lower price because its usefulness is more restricted. Colourless varnish can be used for covering very delicate colours, hut the deeper coloured variety is only suitable for such pur. poses as vamishing wall-paper or for dark woodwork where the yellow tinge will not mar the body colour.

Oil should on no account be added to varnish, or it will be found almost inpossible to get it to dry. Thinning should be aocomplished with turpentinc. The varnish should be stored in dry airtight vessels. See Varnish.

COPENEAGEN WARE. The hard porcelain produced at the Royal Copenhagen factory stands in the front rank of technical precision and decorative excellencc. Employing a high percentage of pure Swedish crystal. lised felspar, combined with fine china clay which is obtained from Cornwall and elsewhere, it yields a singularly limpid white ware.

Copenhagen ware dates back to 1772 . Its a plain Inthe is available shect copper can be most characteristic designs, in cool, underglaze blues, greys and greens, are sometimes based upon the virilc motives of Scandinavian art, sonetimes suffused with Japanase fecling. and these are imitated by Japanese potters themselves. Besides dinner and tea services, there are charming figures of birds, fishes, and the like, both in white biscuit and in sublued tints, together with reproductions of 'Thorwaldsen figures and reliefs. The mark is a triple wavy line in under. glaze bluc. See China
COPPER: The Metal. Although displaced to a great extent by aluminium for cooking utensils, copper is still used for preserving pans, kettles and moulds, while for other household purposes, such as accessorica for the fireplace, and for appliances such as geysers, boilers and clectric fittings, it is n satisfactory metal. Extremely ductile, malleable and tenacious, it is the best known conductor of heat and electricity. It possesses a heautiful oolour, and if suitably chosen for decorative objects may enhance a room.

For culinary purposes the drawhack to its use, besides thi initial expense of copper articles, is that acids on its surface form poisonous salts. To obviate this, cooking vessels should be tinned on the inside, as tin does not form salts, nor is it acted upon by weak acids or other substances met with in articles of food. Utensils such as kettles and coffec percolators aro satisfactory in copper ; they rarely need retinning, as there is nothing in their ordinary uae to wear the lining. It is an economy to have a tinned iron kettle with a copper bottom.

If kept scrupulously clean and well dried after washing there is no danger in using unlined copper preserving pans and moulds. If allowed to remain dirty or moist the two chief poisonous anlts which might form are verdigris and copper carbonate. The first is formed by the nction of vinegar on this metal, the second on wet copper ly the action of carhon dioxide, always present to some extent in the air.

Cleaning Methods. Decorative articles or those partly decorative and partly utilitarian. like fireirons, knockers, coal scuttles, etc., are usually covered with a lacquer when new, chielly composed of shellac, coloured, and dissolved in alcohol. This solution is painted on to the article and preventa tarnishing and oxidisation. As long as the lacquer remaina, no cleaning is necessary. Any good metol polish that does not corrode can be used for articles not employed for culinary purposes, e.g. hot pipes and geysers.
Cooking utensils require special care in cleaning. Scouring with silver aand and soap is an excellent method. When the copper has been well rinsed and dried, a brilliant polish can be obtained by rubhing over a little paste made of whitening and water. Bath brick moistened with water and soap or any other gritty cleaning powder can also be used for cleaning.

The Manlpulation of Copper. One or two practical hints may be serviceable to the amateur craftsman who desires to undertako work in copper, for it has peculiarities that render it easy to work in some ways and more difficult in others. It is ensily bent, curved, or beaten to any desired shape or bent to acute angles without fear of cracking. For ornamental purposes it is embossed and worked up into plaques and decorative pancls. When

Copenharen Ware. Vase with Dattern
spun into circular forms, such ns Hower-bowls. But the metal is difficult to machine, is it is liable to tear: drilling and sawing are more troublesome than with brass Copper atheres to and clogs the cutting edges of tools, and it is therefore necessary to use a lubricant, either milk or tallow or a mixture of lard, oil, and turpentine. To file coppor without tearing the surface French chalk should be employed is a lubricant.
Do not use copper for bearings or on working surlaces, as it is difficult to kcep it from scizing, and it would speedily wear away. Copper wire is useful for binding metal fittings to hose pipes, for the fistening of rods and cance, and any purpose where a secure joint is needed more durable than one made with string. A difficulty sometimes is the selcction of a suitable gauge of metal for a particular jol. In general copper pipes are artisfactory in Nos 18 or 16 gauge ; shect copper for spinning in No. 22 gauge: for benten inelal work about No. 24 to No. 20 gauges will be found to answer very well.

Copper nails and rooves are used for making joints between the planks of small boats. and call be used for other purposes where an imn or steel nail would be objectionable on account of rusting, th for lead flushings or gutters. Small oopper rivets and washers, or burrs, are invaluable for making riveter joints in sheet metal, and are avnilable in convenient sizes at most ironmongers. Thin sheets of copper can he pierced by sawing with n fine metal. outting fret-saw, by punching, or by cutting with very keen cold chisels.

Sometimes the amateur is confronted with a danaged piece of copper, such as a cracked pipe. In general the best method of repair is by silver soldering or brazing. To solder copper with ondinary soft solder, it is firat necessary to tin the surfaces to lhe united When hard or silver solder is used the burax is generally applied to the joint, and the silver soliler melterl by means of n blow pipe (q.v.), heat being applied until the solder has Howed properly ints, the joint. The brazing of copper requires care, as the melting-points of the copper and the spelter are very nearly alike. lior all ordinary small pipe joints, auch ns those found in motor velicles or in hotwater inslallations, silver soldering is prefernble to bra\%ing.

How to Bend Copper Pipes
The bending of small copper pipes can often be satisfactorily carried out with the hands alonc, eapecially if the copper be soft or well annealed. If the bends are very sharp it will be desirable to grasp the pipe between two pieces of wood held in the vice, and tight enough to hold the pipe, but not so tight as to crush it. The object is to prevent the tube from buckling or fiattening. The pipe can then be pullerl into shape by slipping a larger-size pific over the outside where it is desired to keep it straight. This localises the pressure and whereabouts of the bend. Pipes about $\underline{d}$ in. diameter and upwaids are gencrally bent in a pipe-bending inachine, or are filled with sand, which must be rammed hard and the ends securely plugged

Tho annealing of copper for amateur use is a very simple matter ; merely lieat the copper to $\Omega$ uniform dull red heat and immediately plunge it into cold water, and leave it to cool. If any hollow work has to be anncaled, take special care to avoid the escaping steam.

COPPER: The Boiler. A washliouse or larger camera with a good lens and a ground boiler, generally made of galvanised iron, is known as the copper, and the best sorts are in fact made of copper. There are two types: found generally in older housos: the other. prints from larger negatives. Roll film the portable type, con. sista of a metal exterior that supports the inner pan or copper. The hottom part is adapted to receive a gas burner, n high-pressure oil hurner, or an ordinary conl or wood fire. Some patterns have removable pans, a draw-off tap and n steam escape pipe connected to the flue pipe
'fo instal a portable copper the only fitting necessary is to provide a good, solid, fireproof base, and to see that no part of the copper is near any woodwork or inflammable material. The smoke box terminates in a socket, into which is fitted the castron or sheet-iron stove pipe, which is preferably taken directly out to the air by breaking through the brickworls of the wall, and then fitting a canister elbow with an inspection door in it, and carrying the stove pipe upwards to above the level of the ronf and terminat in $n$ cone cow
The inside of a copper should be thoroughly washed and dried, and any signs of rust carefully guarded against. If greasy, it can be cleancd with parafin and soft soap, then acoured, and af terwards rinsed with hot water. Coppers should be filled hefore the fire is lighted, and emptied after the latter has been put out. Coke and cinders, being cheaper than conl, we frequently used as substitutes for the latter in copper fires. See Laundry

COPPER NUCLEINATE. The organic preparation of copper known as copper nncleinate is made by combining its oxide with nuoleol, $n$ substance obtained from veral. It is $n$ fine powder and 5 to 10 per cent solutions have been found useful in various forms of oonjunctivitis (q.v.), for example, trachoma or granular ophthalmia This preparation is known also as cuprol

COPPER SULPHATE. In medicine copper sulphate is sometimes used externally as a caustic or internally as an astringent or is an emetic. As an astringent the dose is 1 to 2 gr . and 5 to 10 gr . as an emetic. It is a uscful emetic in narcotic poisoning and in acule phosphorus poisoning. As blue stone it is used in reducing "proud flesh." In styes, after pulling out the affected eyelashes the parts may be bathed with a 1 per cent solution every hour or oftener. The hathes will grow again in the course of time.

Poisoning by copper suljhate produces vomiting, abdominal pain and more or less shock. The doctor should be sent for. The vomiting should be encouraged by copious draughts of tepid water. White of egg or rich milk should be given after the stomach has heen thoroughly emplied. Rest in hed, with warmth to the feet, and stimulation by table. spoonfuls of hot strong coffee comprise the rest.

COPYING: In Photography. In copy ing pictures, photographs, engravings, nad printed matter, it is necessary to uso $n \frac{1}{2}$-plate

rgements from the negative, which will and the best results will be obtained with backed plates.

Very short focus lenses arc unsatisfactory for this work; but the longer the focus of the lens the greater must be the extension of the camera bellows

The print to be copied must be fixed in ni ahsolutely vertical position and the camern pointed squarely at it. therwise some portion of it will not he sharply in focus. The original may be pinned to a door or wall. A good work. ing arrangement is illus. trated in Fig. 1.

The best arrangement or regular work is to liave the camera in a lixed position, square to the easel, the easel itself heing supported on runners so that it may be moved backward and forward in line with the camera, according to the size of the original to be ocussing is then done opied. The rina

The lighting is of the greatest importance. Light must be evenly distributed over the whole subject. Perhaps the best is obtained out of doors on a north wall (not in the sunlight). Indoors, $\Omega$ room with a good north window will serve if care be taken that the camera itself cuts no light from the object.

Artificial light is sntisfactory if properly arranged and controlled. Two lights of equal strength, placed on either side of the copying hoard and shielded from the camera lens (Fig. :2, 4 and 13), or one strong light immediately above the centre of the camera (Fig. ㄴ, C) may be used. Electric light is easily arranged with sufficient flex. Mag. nesium ribhon is one of the best artiticial illuminants. Two pieces can be burnt simul. (aneously, as at I) and E (Fig. 2), or one, centrally, as at F (Fig. 2).

An excellent way of using magnesium is 1.0 erect a screen of tissue paper, with the camera lens projecting through, and burn about a foot of ribbon behind it, moving it about during the exposure.

Jo test evenness of illumination when two lights ate used, place a pencil in front of each light. The shadows ouglit to be of equal depth. If on looking at the original through the focussing screen or over the top of the
 the object being copied
camera any reflection of the light from the surface of the original is seen, the light must be diffused by mean: of tissuc paper, or a thin handkerchief held in front of each light. Altering the position of the lights will also reduce the trouble.
Panchromatic Plates. If the picture to lie copied contains much colour (especially reds, browns, yellows, or greens), colour sensitive or panchromatic plates must be used in conjunction with a light filter in front of the lens. Similarly, if an old print has brown stains (foxing), or an old photograph is yellow and faded, much the best results will be obtained by using panchromatic plates and a light filter. An old photograph should first be cleaned by rubbing with cotton-wool, part of the aged appearance being due to dirt. Exposure in copying is largely a matter of trial and error, but, in general, there is little risk of over-exposure. Out of doors an exposure meter can be used. Indoors, near a good north-lighted window, at mid-day in bright weather, using $\Omega$ stop of $\mathbf{f} \mathbf{l 6}$, ordinary medium speed plates, from $\frac{1}{2}$ to 1 min . would probably be sufficient.

With artificial light from 2 min . to 2 hours may be required. It is best to waste a plate at first on a trial exposure. Drawing out the slide about $f$, a minimum estimated exposure of, say, 5 min . with a strong light may be given. Exposing each successive $\ddagger$ of the plate for double time, i.e. starting with 5 min . and then giving 10,20 and 40 , the correct exposure can be judged after the plate is developed and printed. Therenfter, if the same lights and the same plates are used and the same distance kept between camern and copying hoard, no difficulty will arise. If it is necessary to make copies in different sizes, reference should be made to tables of relative exposures in a photographic text-book. It is particularly desirable to keep to the use of one kind of plate in copying work to olstain uniform resulta. See Blue Print; Panchromatic; Photography.

COPYING INK. A special ink is used to copy lettera by pressing them upon damp tissue paper. This copying ink is best made by evaporating 10 volumes of ink until reduced to 6 , and adding 4 volumes of glycerin. Sugar cancly dissolved in the ink may be used in place of glycerin. Ink for copying pads or heclographs is made by dissolving methylviolet aniline dye $10 \%$., in a mixture of water: 7 oz ., and methylated spirit 1 oz . See Ink.

CORAL: For Wearing. The value of coral, which is fashioned into many pretty articles of jewelry, depends upon its colour and upon the high polish which its close, hard texture permits it to takc. It varies from a deep red to a delicate rose or tlesh tint, and sometimes a milk-white variety is obtainable Coral is essentially suited for children's orna. ments. A string of pink coral beads is a favourite olpistening gift from gorlparents to a baby girl.

CORAL SPOT.
No fungus is more plentiful on cleadtwigs and dead branches and more familiar to every gardener than the
coral spot It is abundant and conspicuous in damp weather on dead branches of elm, lime, poplar, sycamore and many other trees, and is always to be noted plentifully on old pea-sticks, particularly hazel, in autumn and winter. The coral spot fungus may be recog. nized by the small pink or flesh-coloured warts which are thickly scattered over the surface of the dead and dying branches. The warts are spore-pustules, which consist of fungus filaments bearing masses of spores.
On fruit trees coral spot is particularly common on red and black currant and goose leerry, but it also attacks apples and pears. The fungus gains entrance in two ways, viz., through dead branches and through wounds All dead shoots and branches should therefore be removed during pruning and care taken that no snags which will die back are left. Injury to bushes should also be avoided, whether in pruning or in cultivation with the hoe. Wounded surfaces should be protected by tar. Discased branches should be cut clean out, taking care to cut back to healthy wood and to protect the wound.
Accumulations of dead wood and sticks should never be allowed in an nichard. On such débris fungi of all sorts flourish, and millions of spores are liberated and blown amongst the trees. The better the sanitary condition of the orchard, the less the chances of infection by fungus parasites. This information is taken from Leaflet 115, issucd by the Ministry of Agriculture. See Apple; Black Currant: Gooseberry: Peas: Red Currant, etc.

CORBEL: In Architecture. This term is now used of any masonry built in tiers outwards from the piane. Even the upper storey of a house that overhangs a lower storey may be said to be corbelled. In modern building, however, the term is chietly employed in connexion with purely omamental features, generally stonework, but sometimes timber, on the exterior of a house, and is rarely seen except on structures of some pretensions. In the latter a corbel support for an oriel window sometimes affords effective relief to the façade of a house.
In brickwork corbelling is a method of laying bricks where onc or more courses project above the others. Corbelling reduces the stability of the wall, unless compensated by a leam or floor joist, spanning the space between two walls. See Brick.

CORD : How to Purchase. Wholesaie, the cheapest way to buy cord is in a 50 yd . hank. The poorer quality cord is used for clothes lines, which should to well washed heiore use, to prevent the clothes from getting soiled. The better quality cords are used as sash cords, blind cords, for hanging pictures and binding cushions. Thich cord is necessary for window sashes, and for this purpose a speetial kind is sold. Linen blind cord has two qualities. It can be purchased in white, green, crimson and brown. Upholstery and cushion cord is sold by the yard in any colour. Fancy cords of twisted silk and silk mixtures are used in fancywork and upholstery. Piping cord is used in gauging cushions and to cover seams in dresses, etc See lirer; Blinds; Clothes Line; Picture; String.

CORDON : For Fruit Trees. These are invaluable for small gardens, for they take up little room and produce first-clas fruits There are both upright and horizontal cordons. The single-stemmed upright cordon is chietly grown, though each tree may be trained with two or three stems. The horizontal cordon, which is very useful for planting alongside a garden path, has a stem about $12 \mathrm{in}$. one long branch, trained horizontally, on cach side. Single-stemmed upright cordons may be planted at 18 in . apart, those with two or three branches must obviously be placed farther
from each other. Instead of being perpendicular, the branches are often trained at an angle of 50 degrees to prevent the growth becoming vigorous at the top and weak at the base

Apples and pears are chietly grown as cordons. Plums do not riourish in this form. Gooseberries and red and white currants do well as cordons. The trees niay be trainerl against a trellis in the open border or on a wall. Cordons must be hard pruned or they will soon cease to be cordons. The side shoots which grow in summer are pruned to within about six leaves of the hase in late July, and these shoots are again shortened in winter, lea ving only two or three buds. As the trees age the fruit spurs will becone large, and a few of them ought to be cut back every year. Summer growth at the top of the cordon is pruncd by about two-thirds every winter until the tree has reached the desired height. It must then be treated in the same way as the side shoots. Vigorous varietics of apple and pear are not so suitable to grow as cordons as those of inoderate vigour. See Apple.

COREOPSIS. The annual and perennial coreopsis are very free-flowering hardy plants ; they yield a wealth of long-stemmed ilowers in summer. The best of the perennials are grandiflora and auriculata superba, botlı having yellow flowers: they are, however, not long-lived, and it is usual to treat them as biennials and raise a fresh lot of plants each year. Seeds are sown out of doors in June to provide plants that will flower the following year. The seedlings aro set in their final position in October. The annual forms of

Corespsis. Golden-
$\mathrm{y} 0110 \%$ flowers or Coreopsis grandillora
coreopsis are sown out of doors in March-April, where they will bloom from July onwards: tinctoria, yellow, atrosanguinea, dark red, and Drummondii, yellow, are some of the best.

## Corer. See Apple Corer.

CORIANDER. Flourishing in light, warm, sandy soil, coriander is a hardy annual which produces white flowers on stems $1 \frac{1}{2}$ to 2 ft . ligh in June. As it soon runs to sced, those who want a continuous supply should sow at intervals from March onwards, and thin to about 9 in. apart. Coriander is almost exclu. sively grown for the sceds, which are used in the manufacture of liqueurs such as kümmel.

It is also used in medicine, the dried ripe fruit being an aromatic and carminative. It yields an oil, of which the dose is $\frac{1}{2}$ to 3 minims. This is used in some of the preparations of rhubarb and senna to prevent griping

Coriander is also used for flavouring confectionery, and forms one of the chief ingredients in the making of curry powder. The leaves may be used in salads.

CORK : For the Home. The light, porous bark of the cork-oak has numerous applications in industry, and is chiefly found in the domestic sphere in the form of stoppers for bottles, floats for fishing-lines, and cork mats For the latter purpose it is prepared as a composition. Cork linoleum is an instance of its use in industry. The amateur can repair cracks and bad places in cork linolcum by using a pasto composed of finely powidered cork and shicllac varnish or hot beeswax This is pressed into the cracks and smoothed off with an iron bar, warmed to prevent the shellac chilling too quickly Colouring pigments may be added
A cork that is a little too large for the bottle may be made to fit by rolling the cork on the floor and pressing upon it with the sole of the boot. When a cork lecomes lodged in the neck of a bottle an effective way of loosening it is to hold the neck before a fire, or to wrap it up tightly in a thick piece of cloth which has been previously heated. This will have the effect of expanding the glass slightly, and the cork will then come out readily.
Cleaning Hints. Instead of throwing away old corks it is worth while to colleot them in a box, because of their practical value as cleaning agents. A cork dipped in paraftin is effective in removing rust from metal and stains from lamp-glasses and hearth-tiles, while disfiguring marks on polished wood and also on wall paper and window-panes will often yield to treatment with a dry cork. Stains on aluminium and enamelled saucepans can be removed by means of a cork dipped in salt, and kitchen knives, together with any cutlery not made of stainless steel, are best treated wit $h$ a moistened cork rubhod along a bar of houschold soap. Burnt marks on plates can be removed by means of a cork dipped in a little dainp saii ; spots on linoleum disappear when mbbed with a cork repeatedly dipped in benzine or petrol See Bottle ; Bung ; Cramp ; Linoleum ; Mat.
CORKSCREW. The ordinary corkscrew made with a wooden handle and a twisted wire worm or screw docs not always get a suflciently powerful grip on the cork, and sometimes pulls out, lenving the cork in the bottle Another type of all-metal corkscrew has n cast inetal handle with ears at the side to provide a powerful hold.
Many kinds of selfextracting corkscrews have been evolved. In one characteristic type the worm is driven into the cork by turning the handle at the top. This drives the care down until it engages with the top of the bottle. Further rotation of the handle draws the cork out of the bottle, this being accomplished by the screwed shank of the worm itself, which winds its way up the cage, bringing the cork with it.

In the absence of a proper corkserew a cork can often be drawn ly screwing a stout wond
screw into it and grasping the head with a pair baking powder, 1 well-beaten egg, and 1 tableof pincers. Another method is to insert two knife blades between the cork and the neck of the bottle and on opposite sides of the cork By grasping both knife handles with a cloth the cork may be removed with a screwing motion. See Bottla.

CORE SOLE. These inner soles are usually inade of compressed granulated cork, covered with felt, and are used either to secure increased warmth for the feet in cold weather or to fill footwear which is slightly larger than required. The comfort attendant upon wearing cork soles can be increased by fixing them to the soles of the boots with dextrine paste.

Cork soles can be manipulated to afford soine relicf from the tortures of an enlarged toe joint or a callus on the sole of the foot. Remove the stocking and moisten the affected joint or the hardened skin so that when placed upon the cork sole their exact position will be clearly indicated. With a sharp pocket-knife cut away the part o' the sock inarked, slanting the knife so that the edge of the cut will slope outwards. Sockets will thus be formed that will relieve all pressure upon the affected parts.

A common fault in walking, namely, treading over the heel, can be cured by a cork half sole cut as follows. Procure a piece of cork it to $\frac{1}{} \mathrm{in}$. thick, as long as from the heel to the ball of the foot and half as wide as the tread With a sharp, knife cut this on one cdge to the sliape of the foot. This should be pasted into the boot with dextrine on the sids which is usually trodden down. See Boot.

CORN : Elow to Remove. Pressure or prolonged rubbing on the toes or soles of the feet causes thickening of the skin into painful circular swellings with a core or oye in the centro. These are hard corns, but where the feet perspire frecly soft corns may develop. Tight boots are a common cause of trouble, and beforo anything can be done thicy must be exchanged for boots that fit casily and so relieve the pressure. Ridges, creases, or lumps inside boots may be responsible for corns, and in such cases the boots should be sent to the shoemaker for attention. Often a pair of cork soles is of assistance.

Corns are removed either by cutting or by applying a plaster or solvent of which salicylic acid is generally the base. It may he used in the form of salicylic collodion, collodium callosum, or salicylic plaster $10-40^{\circ}$ per cent. The collodions are painted on and allowed to dry. If the plaster is used, a piece sufficient to cover the com is applied and kept in position by a strip of adhesive plaster. These preparations may be left on for 4 or 5 days, when the softened skin is peeled off, and another application made if required. If necessary, the foot may be soaked in hot water to get the dressing off.
The removal of corns with a razor or knife requires some skill and care. If bleeding occurs an antiseptic dressing should be applied to prevent poisoning of the wound. For soft corns socks with separate compartments for each toe, similar to gloves, may be worn or pads of cotton-wool may be placed between the toes during the day. The thickened skin should be removed by applying a salicylic plaster, or a little piece of felt with a central hole to fit over the corn may be used to separate the toes, the hole in the centre being filled with powdered salicylic acid, The skin between the toes should be frequently washed and carefully dried and painted once a day with spirit of camphor. A zinc powder may then be clusted on. See Bunion; Chiropody; Foot.

CORNCARE . These cakes are of American origin and are made of the best yellow maize meal. Mix together 1 breakfastcupful each of maize meal and milk, quarter of a cupful sugar, half a teaspoonful salt, 3 level teaspoonfuls
baking powder, 1 well-beaten egg, and 1 table-
spoonful warmed butter. Blend all these very thoroughly and spread the mixture in greased tins until they are lalf full. baking them in a liot oven.

CORN COB. These green cobs should be cooked quickly after they are cut, as they soon deteriorate. Remove the husks and strip off every thread of the silky fibre. Take some of the cleanest of the liusks, wrap thesc round the cobs, and tie them in place. Lay the cobs in boiling, slightly salted water to cover them, and cook them quickly for about 10 min . after the water reboils. When nearly cooked, try one of the kernels to see if the raw taste is destroyed; if so, drain them at once from the water, or the kernels harden and lose Havour Then remove all the outer husks and serve the cobs on a hot dish with oiled butter, seasoned with cayenne and salt. When eating the corn, score each row of kernels through with the point of a sharp knife, pressing out the centre of the grains with the teeth or the knife, and leaving only the indigestible hulls on the cob.

Another way to prepare the green cob is to make it into fritters or rissoles Grate or chop the grain finely, allowing to every breakfastcupful $2 \mathrm{eggs}, 1$ dessertspoonful of melted butter, twice that amount of milk, and about a tablespoonful of flour. Beat the eggs well, and while still beating them slowly drop in the grated corn. Season the mixture, then add the inelted butter and the milk, and bind the whole with the flour. Form it into round flat cakes, and fry them in hot fat. This dish should be served very hot. The unripe grains of the corn cob are roasted to make pop-corn, while hominy, maize meal and cornflour are all products of the ripened ear. See Cornflour ; Hominy ; Maize.

CORNED BEBFP. A round of beef is required, and this must be pickled and then slowly simmered. To pickle the beef, 2 quarts water to $\frac{1}{2} \mathrm{lb}$. coinmon salt, 3 oz brown sugar, and $\frac{1}{2}$ oz saltpetre must be used. These ingredients should be boiled together for 10 min . and then skimmed and strained. When the liquor is cold the meat should be immersed in it and allowed to remain for about 10 daya. The use of an earthenware vessel is advisable for this process. After the 10 days' iminersion, the beef should be boiled up with sufficient warm water to cover it, simmered gently for $2-3$ hours, and lifted out when cooked. See Beef.

CORNER CUPBOARD. The comer cupboard is a cupboard made to fit in the comer of a room. It originated in the 18 th century, and soon became a decorative piece of furniture. It was made of oak and mahogany, and some had a glass and some a solid front. Ma yy were inlaid with ebony, box and satin.
wood. Instructions for making a hanging corner cupboard in the Chippendale style are given in the article cupboard (q.v.).

A corner cupboard as shown in Fig. 1 is of service in utilising space that would otherwise be lost. and often furnishes an awkward blank. It can be tastefully handled without elaborate construction, and whether finished with a straight or bow front, should not set up) undue difficulties. The height from ground to table top is 3 ft . and depth on angle back to front is put at 1 ft . 6 in ., which will give a width over front of 2 ft . 1 in . These sizes can. of course, be altered slightly to meet individual requirements.

The style of the cupboard would agree with Chippendale furniture Bow-fronted oupboaid of the earlier period, and either wainut or
mahogany would be a suitable wood to use. Uak, stained to a nut-brown colour and with panels bevelled, would achiere a good result. The cupboard can also be made of birch, Amcrican whitewood or pine, painted to a green, vermilion or blue-black colour and decorated with a Chinese design in gold lacquer work. The cupboard can, of course, be constructed to size in several slightly varying ways, and it is rather with the lighter and cheaper method that these details and notes are offered, the enlarged sketch of cabinet front (Fig. 2) giving an alternative finish to Fig. 1.

The top (A, Fig. 3)

Fig. 2 Alernative deriga for the bowtroated oupboar 1
can be of $\frac{1}{8}$ in. thickness (or oven $\not t$ in hardwood if of picked wood, sound and dry) glued up of narrow boards with the grain reversed, to cut 1 ft . $7 \frac{1}{2} \mathrm{in}$. by 1 ft . $7 \frac{1}{\frac{2}{2}} \mathrm{in}$. on the angle. The frame front (B) is finished hollow mould, as indicated, to a curved line showing 3 in . to 4 in . projection in centre, and the top (A) will follow this line with $t \mathrm{in}$. projection beyond it. The piece will be finished $\frac{2}{8}$ in. thick, making (with the top) $1 \frac{1}{8}$ in. thick. It has a mortise cut in

Carnar Capboard. Fige 8-12. Diagrams ahowing how to make the coruer cupboard illustrated alote
by $\frac{3}{3}$ in net will allow for paring to shape. The angle battens ( C ) are rebated into each other in the corner at back and halved into $B$ at front, the mortise being cut through hoth. Pieces 1 ft .6 in by 3 in. by $\frac{7}{6} \mathrm{in}$. net will answer for these; they are set in $\frac{1}{} \mathrm{in}$. from angle edges of top (A). The inner lining of top (D) can be of $\frac{3}{8}$ or $\ddagger$ in. thickness, cut to finish flush with angle edges of $C$, but set in sufficiently under B to serve as a stop for the doors to close against when hinged. The bottom frame ( E ) can be put together in a similar manner of material about $1 \frac{1}{2}$ in. thick, the bottom ( $F$ ) being glued and panel pinned down to serve as a stop for doors in line with D above. The upright ( $G$ ) tinishes 23 in . by $\bar{k}$ in., or in pine had best be made up to $1 \frac{1}{8} \mathrm{in}$. thickness, with $f$ in. hardwood facing. A length of 3 ft will include joints and paring.

The angle sides ( H ) of $\frac{3}{5}$ in. or $£$ in. thickness, tongued or butted together, can be nailed into rebate top and bottom or can be grooved in. The part plan (Fig. 5) refers to the above and indicates, in the wall angle, an upright (J) tenoned top and bottom in similar fashion to $G$, of material $1 \frac{1}{2}$ in. by $1 \frac{1}{2} \mathrm{in}$. or so.

The doors, as lig. 2, with llush fronts to finish in line with uprights ( $G$ ), are made up on a framing in the manner indicated by Fig. 11 Two uprights $1 \frac{1}{8} \mathrm{in}$. wide, and three rails, say, 2 in . wide, are halved and acrewed together. The rails can be cut to shape from the solid, or laminated on a template to finish $\frac{8}{8}$ in. thick in oak or other hardwood, and ? in in pine. They are then faced with stout three ply or $\ddagger$ in hardwood boards, which require to have the meeting edges alightly bevelled to olitain a good joint.

## Details of Door Construction

The material used should be thoroughly well seasoned, and the surface of door can be veneered. The angle of bevelling is easily ascertained from the working drawing by a pencilled line connceting the set-out of meeting edges with the centre from which the front curve is struck. The doors are hung on uprights with fancy plate hinges of the Queen Anne type, or a form of strap hinge could be adopted. In the design illustrated at Fig. 1, $\Omega$ three-beaded fillet, to finish with $\frac{1}{k}$ in. projection beyond face of doors, is fitted to the meeting elges in centre, size being $\frac{3}{8}$ in. by \# in thick. (See detail in Fig. 12.)

A more substantial method of construction is indicated by the part plan (Fig. 4). In this way the angle sides are framed up by mortise and tenon and grooved for panels to finish llush inside, the whole being tongued into tho "prights (G) and rebated together in the wall angle. Both bottom and top are then rebated and dovetailed flush into the frames and pil. asters and afterwards screwed. A little relief, in a simple way, can be given to the uprights (G) by mounting a length of moulded flat after the manner indicated at M, Fig. 9. This also indicates the calinet as finished with a straight, instead of a shaped front, the doors being of the nsual mortise and tenon type, with panels rebated in and beaded from the back. In this case a $\frac{1}{i n}$. ovolo mould worked round the pancl opening has a neat offect. Stiles can be $1 \frac{1}{2}$ in. wide and rails 5 in. wide by $\frac{7}{z}$ in. thiok. Ball feet of the bun pattern can be fitted, cut and shaped from blocks 3 in . by 3 in. by 13 in., and screwed on.

The interior fittings consist of three shelves supported on $1 \frac{1}{2} \mathrm{in}$. by $\frac{3}{3} \mathrm{in}$. fillets, screwed and glued to the angle sides, or toothed into the uprights. The front edges of the shelves may be made to heighten the effect of the cupboard when opened by shaping them to either of the alternative lines indicated at Fig. 6. A section of upright ( $G$ ) entering top is scen at Fig. 7, and a section for built-up top with door closed at Fig. $8 . \quad$ Fig. 10 is an alternative mould for the front of the cupboard. See Cupboard; Lacquer.

CORNER DRESSER. The corner dresser shown in Fig. 1 is made in oal;, and embodies in-its detail many Jacobean features. Nearly all the joints of the under part are of the mortise and tenon type, the only awkward
 part being the juncture of the sides into the front legs (Fig. 4), for since the legs arc turned it will be obvious that the square portion at the top must not be cut away at a greater depth than the top nember of the turning.
This difficulty can be obviated by setting the job out full size, as in Fig. 3. Fig. 4 shows just how much to cut away and how the side of the leg is cut in to take the side rail. The back and the front legs are from 2 in.
under the top is glued to the carcass only, so that the screws hold the top.

The upper fortion mensures 4 it 6 in in height. No back is shown in the illustration, though this may be added if desired In that caso the ends would be rebated and the shelves recessed in a line with the rebato to take the back. The ends and the corner picces are inade from 1 in. stuff and are grooved to take the sholves, the tops heing rebated for the top. Next cut out the top. and upon this mark out the shelves to ensure their fitting accurately with the top. These shelves are tongued and grooved together at the angle, (Fig. 2), and are grooved into the corner pieces in a similar way to the ends. They also have a bovelled groove run along the top near the back, in which the plates stand.

A rail 2 in . wide is tenoned at each side at the bottom into the ends and corner pieces. When glueing together, fasten all the shelves into one end first : next into the other end. the top being put on last. The cornice moulding is glued and pinned round the top and the shaped heading fixed, as in Fig. 5, by cutting away the ends and nailing, and by screwing to the back of the moulding. The complete upper portion is not permanently fixed to the lower, but rests upon the top, secured by dowels. See Dresser.

CORNER SEAT. As a rule, a corner seat will look best with the woodwork finished to inatch the woodwork of the ronm. Thus, in some rooms it will be painted or chamelled in ivory or any colour used for the skirting and door, etc., in others it will be stained a dark brown colourand finished by wax polishing. An

squares, and the two side logs 2 in. by 1 in. These should betirst prepared toshope (the front legs being turned) and mortised and all rails cut out. The tenons of the side rails should be run right through the side legs and be wedged from the bick. When glueing together, it is advisable to glue the front first and allow it to set: then phue the two back framings and finally the siiles. It is necessary slighty to strain the rails outwards when doing this.
When dry, the drawer runners are fixed. It is impesssible to allow the drawer to take up the full width of the front, as this would mean that the drawer would have little or no depth. The difliculty is surmounted by recessing the drawer sides from the onds, as in Fig. 3, and fixing tho runners accordingly. These are dovetailed into the front rnils and sunk into the back rails and nniled or screwed. The drawer sides are duvetailed into the back in the usual way, and a doveluil is cut right across the drawer front for the front joint. After this is inade, it should be put into position and guides fixed to the lower rumners at each side. The top overhangs at the back 1 in., that it may come llush with the wall (the skirting prevents the legs from reaching the wall) and is pocket screwed from underneath. The mitred mouldings on the drawer front and those round the framework com plete the under part. Note that the moulding
impression of the finished job is given in Fig. 1. and details of construction in other diagrams. The size may be modified to suit requirements. the dimensions given being appropriate to ronms measuring about 15 by 20 ft .

The simplest way in which the amateur can make such a corner seat is by using the ordinary commercial building deal, selecting pieces that are as dry and as free from knots as possible. For the corner posts use ordinary 2 in . by 2 in . and plane it up nicely to 18 in . square, cut to length ( 4 ft .), and shape the tols by careful paring with a paring chisel. Mark out and cut the mortises for the back ratil. This can be inale from if in. $T$. and $G$. prepared tlooring 6 in. wide. When planed up it will measure ahout $1 \frac{1}{8}$ in. thick, and he

Corner Seat. Fig. 1 Old-fashioned seltee which cin be made by the hame woodwarker

The tongue must be planed off, and the edge rounded: the groove can be widened with a plough plane or chisel to accommodate the 会 in. seat back, as shown in the detail, Fig. 4.

When the two back rails have been fitted to the mortises in all the corner posts, they may be put aside and the two sides prepared from lt in. T. and G. flooring. Five pieces of $G$ in. flooring will be needed to form the end, and should be glued together, well cramped up and allowed to set. Then glue and screw on the $1 /$ in. square battens (Fig. 4).

Afterwards cut the boards to the shape required and finish off the edges by rounding thein with a spokeshave. Take care to have the projecting tongue on the wall side, as this has now to be fitted to the two outside corner posts by ploughing a groove along the face to take the tongue, as shown in Fig. 3. Glue the tongue and seeure to the comer post by long, thin screws put in from the back.

Prepare two brackets from $1 \frac{1}{f}$ in. wood, to the sizes in Figs 2 and 5, and a similar one but 15 in. long for the angle comer. Next fit a 3 in . by 1 in . bearer, by notching into the angle corner post as in Fig. (i. Mortise the bracket into it, and cut a flat on the angle face of the post to allow the bracket to seat home upon it. Take carc also to set this bearer and bracket at the same angle as the battens on the end jicces. Ilue and screw the bearer and bracket in place, and fix the top rails to the corner posts, standing the whole structure on a level surface and securing the bottom with a temporary strut. T'est the corners and sides to see that all is square, and then cut the pieces for the seat, initrcing them carcfully at the anglecorner. Glue and screw the first boards in place, then cut and fit the remainder, cramping them tightly together, after glueing the joints, and making them secure.

The seat is best made from $1 \frac{1}{}$ in. T. and $G$. Hooring, arranging the tongues to the front. If a circular corner is wanted cut and fit the pieces to make up, g'ue them in place and finish off by the spokeshave while in their proper jlace, also shave off the tongue and round the edge of the seat. The seat can be sccured with $2 \frac{1}{2} \mathrm{in}$. oval brads punched well below the surface.

Drill the dowel looles and glue the brackets in place. Then cut the back pieces from 8 in. boards or from sin. T. and G. inatchboard, and prepare the top so that it fits snugly into the groove cut in the back rails. Glue and screw the $1 \frac{1}{i n}$. square fillet to the seat and glue and jin the back boards with 1 in. oval brads.
A channel must be cut across the corner josts at the outer ends where the scat back slants across. This can best be done by marking the exact position from one of the seat back boards and then sawing and chiselling away the unwanted parts. A little detail
fitting is called for at the angle comer, as the two end boards will hasc to be cut tapering somewhat, and the edges mitred.
In order to make the corner firin they can be blocked up with wooden blocks glued in place from the back and inserted letween the post and the reat back.

CORNJR WARDROBE. The corner wardrobe as shown at Fig. 1 is enclosed with curtains and is suitable for fitting in the hall, on a landing or in a bedroom.

The fitting is shown complete at Fig. 2, and a plan with a suggested dimension at Fig. 3. The boards forming the top could be 1 in. thick, with grooved and tongued edges, cut to fit the comer. The top is nailed to the sides, which are 3 in. deep by $\frac{1}{y}$ in. thick section, rebated and nailed together at the back as at Fig. 4. The front corners of the sides are rounded, and finish abont $t$ in. in from the edge of the top. The pediment is 4 in . high by $A$ in. section, glued and nailed above the top. A piece of 1 in. moulding should be fitted along the edge, and a few glue blocks fitted between the jediment and top, as indicated in Fig. 5.

Three or four coat hooks should be fitted at each side, and a swivel hook in the middle

Pig. 1
Corner Wardrobe. Fig. 1. Useful fiment consisting of a wooden top and curtains.
of the top, as illustrated at Fig. 2. The fitting may be fixed to the wall with hanging plates, or nails may be driven through the sides into the wall, a suitable height being about 6 ft . from the ground. A pair of curtains is generally
more convenient than one, and they may be easily suspended from a wood or metal rod fitted to the edge of the top with a screw eye at one end and a hook at the other, 28 shown in Fig. 6. Brass rings sewn to the curtains a little from the top should be used. Sce Bcdroom; Wardrobe.

CORNFT : How to Play. The player holds the instrument with his left hand. fingers around the valves, while his right thumb is placed under the main tube between the first and second valves, so that he can easilv press the pistons with the first, second, and third fingers. The finger action from the knuckle-joint must be firm yet agile, and care must be taken to allow the piston to return to its norinal position, by raising the finger very slightly above its surface. Put the mouthpiece to tho centre of the mouth, the lower lip occupying two-thirds of the cup. The sound is produced by forcing breath between the tense lips, the air in the tube being thus made to vibrate. Increased pressure results in higher pitch. Breathe through the nostrils or the sides of the mouth, but not through the instrument.

It is advisable to use a plated cornet for the reason that it looks nicer, while so far as the cup is concerned, plating may obviate any trouble arising from sore lips coming into contact with brass. Should the valves work stiffly, the remedy is to unscrew the cap, take out the piston, wash it, dry it witl a soft silk handkerchief, slightly moisten it, and replace. It should never be oiled. Should grease get upon it, the lest plan is to wash it in hot water, dust it with French chalk, replace it. and work it until it moves freely. It should then be washed again in order to get rid of the chalk. A little water is the best lubricant for this purpose.

CORNFTOUR. Comflour, which is obtained from finely ground Indian corn, is used much in the same way as ordinary flour, but is better adapted for thickening sauces, sravies, and soups, as its flavour is more delicate. It is specially valuable in making blancmanges, puddings, and cakes. It should always be moistened with a little cold milk or water before being used for thickening. See Arrow. root; Blancinange.

CORNJLOUR CARE. To make these takc

fis 3 Figs. 2-6. Diagrams showing how curtains are hang and method of fixing hools o7. mar garine, 3 eggs, and a teasjoon. ful of baking powder. Beat the margarine and sugar to a creamy consis. tency. Then add the cggs, one at a time, beating each in well. Mix the flour, comflour, baking powder, and a pinch of salt together before stirring them lightly into the mar. garine, eggs, and sugar. Beat the whole light. ly but well, turn it into patty tins, and lake the cakes in a moderate oven until they are done.

CORNFLOUR MOULD. A fancy mould is used for this sweet. To prepare it, mix $1 \rho 2$ cornflour to a smooth parte with a little milk, putting what remains from a pint into a sauce-
fire, then pour it on to the cornflour; return the whole to the saucepan and bring it to the hoil. Let it simmer for 6 min , keeping it well stirred, add 2 dessertspoonfuls castor sugar, and draw the pan from the firc to cool the mixture slightly.
Beat up the yolks of 2 egga and stir them quickly into the cornflour. Cook the whole slowly at the side of the fire for $\boldsymbol{n}$ few minutes, hut do not let it boil Cool it again slightly, then add the stiflly whisked whites of egga and a few drops of vanilla. Finally, stir in $\ddagger$ oz. leaf gelatine dissolved in $\frac{t}{2}$ gill of hot water, and pour the whole into a wet mould. Turn it out when set.

CORNFLOUR PUDDING. Blend 2 oz cornflour, 1 tablespuonful custard powder. and $a$ pinch of salt, with a little cold milk. Put what remains from a quart of milk into a saucepan with $\Omega$ thin strip of lemon peel and bring it to the bmil. Pour this on to the cornfiour mixture, stirring the whole well ; return all to the saucepan, and boil it for 8 min ., stirring all the time. If the mixture is too thick, add a little nore milk or water. Then put in 1 oz . sugar and n few drops of any Havouring essence, and pour the whole into two soup plates previously rinsed in cold water. When the mixture is cold and set, warm a little jam, put the contents of one soup plate on to a glass dish, spread the jam over, and then put the other portion of the pudding on top. Sprinkic ohopped nuts over it when dished.

CORNFLOWER (Centauren cyanus). This favourite hardy annual bears blue, white or rose-coloured flowers. The best results are

Cornthower. Fiowers of Centaurea montana, popularly called the perennial cornflower
obtained by sowing seeds out of doors in early Neptember. The final thinning of the seedlings should be done in spring; the plants left to hoom ought to be $10-12 \mathrm{in}$. apart. Seeds may also be sown out of dours in spring to provide Howers from July onwards. Centaurea mon fana, sometimes called the perennial corn Hower, grows 2 feet high and hears summer tlowers of various colours. It lives on from vear to year and is increased by division in nuturnn or spring

CORNICE : Of the House. A cornice is an ornamental moulding applied to the upper purts of the walls. Modern cornices are frequently used as decoration without practical significance, and may be minde in several different materials, such as stone, brick, stucco, Portland and other artificial cements. In
cabinet and other work, the moulded top, as of a wardrobe, is also known as a cornice.

Cornices for the ceilinge of ronms are com posed of plaster and cement. They are sometimes produced by casting in moulds and screwed to wood grounds fixed in the building. Plaster cornices are, however, usually run on the work itself. The backing for the cornice is first built in briok or stone roughly haclied to the shape of the moulding, or is constructed in wood with rough brackets, lathed ns if for a ceiling

In fire-resisting construction, steel lathing is used, and is secured to bars bent to the required shape. The pricking-up or rendering coat is trowelled on as in ordinary plastering. The second coat is applied thickly, and the mouldings are formed by dragging a template cut out of zinc on wooden guides already nailed in position. The final coat in internal work is generally inade of gauged stuff. composed of one part of fine stuff, lime putty, and washed sand in equal proportions, to one part of plaster of Paris. This is a quiok setting mixture, and the plasterer only applies as much as he can finish at one operation

The guide rails of the template ensure a good joint at the commencement of the next length of run. Plaster of Paris is soluble in excess of water, and where used in external work must be protected by several good conts of oil paint. Where backings of cornices are built of brick, the greatest care must be taken to ensure that their connexion with the wall is thoroughly sound in every way.

Where two walls meet at cither an external or internal angle the cornice on these walls meets in a mitre line. A mitre mould is sometimes employed, but the angles are, as a rule, made by hand, and are mainly worked with the joint rulc, the smaller members and those at the top and bottom being first worked, and the larger nembers rulerl in afterwards. See Adam Style; Cappinga : Ceiling ; Moulding ; Picture ; Plastering.

CORNISH HEATH. This is a benutiful Hpecies of English heather, found wild in Cornwall. Its botanical name is Erica vagans. The small pinkish mause flowers come out in August and September. The plant forins very neat close clumps, from 6-12 in. high, and is extremely useful for edgings to Hower gardens. See Heather:

CORNISH PASTY. A plain short-pastry is needed, and the meat is best when uncooked; but cold cooked meats can also be used up in this way To two amall potntocs and half an onion 8 oz. meat are allowed, all cut small, mixed together with seasoning, a sprinkling of mixed herbs, and a tablespoonful of gravy When the paste is made, it should be rolled out and cut into rounds. A portion of meat and vegetables is laid in the centre of one half of the mund of pastry, and the other half is foldel over, the edges being moistened and pressed together. The top of the scallop must be pricked twice with $n$ fork to let the stenm escape. The pastios are then baked in a moderate oven for about half hour.

A sweet Cornish pasty can be made by placing a large spooaful of jam on the pastry instead of meat. Slit the top covering once or twice with the blade of $\Omega$ knife. In this way the jam escapes when it boils up in the baking. without spoiling the appearance of the pasty. In Cornwall the custom is to pour the cream through the slits in the pasty cover as soon as the pasties are cold

Cornish Pasty, Dish of light pastry turnovers which can be made with meat of jam

CORNISH SPLITS. Sieve $\frac{1}{2} \mathrm{lb}$. flour, and rub well into it $1 \frac{1}{2}$ a\%. Inrd. Then ridd a teaspoonful cream of tartar, a level dessert. spoonful sugar, a pinch of salt. and mix well together. Disanolve half a teaspuonful hicarhonate of surla in $\ddagger$ pt. milk, or sour mills if is is arnilable. Pour this over the other ingredients and mix quickly to a dough. Turn it on to a floured board and roll it very lightly and quickly to $n$ thickness of abont 1 in Cut it into rounds with a pastry cutter about the size of the top of a tumbler. put them on n floured baking sheet, and hake in a moderate oven until browncd. When these little acones are cold, split then in halves. Spreal cach half thickly with jam, and put on the tup of each a large diab of clotted cream

CORONILLA. These herbacenus perennials and shrubs, which bear pea-shaped flowers in summer, need well drained soil and $n$

Coronilla. The pink-flowered Coronilla varia
place in the sunshine. The chief favourite is Coronilla glauca, which has yellow flowery; it is commonly grown as a pot plant in the greenhouse but is hardy in mild districta. Cappadocica, which is of trailing growth and bears yellow blooms in late summer, is grown in the rock garden. Emerus is a leaf-losing shrub, 4 fect high. with yellow Howers in spring ; varia has pinkish blooms in summer nad grows 2 feet high. 'The shrubby coronillas are increased by cuttings placed in sandy soil in a frame in August, the others by seeds sown under glass in sprilig.

Corpulence. See Obesity.
Corridor. Sce Hall ; Landing.
CORROSIVE. A pison which destroys tissues with which it comes into contret is a corrosive. Included in this class are the following: Strong mineral acids, such ins sulphuric acid (ail of vitriol), nitrio acid (aqua fortis), hydrochloric acid (spirit of salt); strong alkalies, such as caustic soda; carbolic noid and creosote; strong solutions of oxalic citric and tartarie acids; chlorides of zinc, tin, antimony, and mercury (corrosive sublimate).

When swallowed the substance will havenstrong acid, alkaline, metallic, or sweetish,
pungent taste, according to its nature, the but there are many qualities on the marke last being suggestive of carbolic acid and creosote. There is also an intense burning pain in the mouth, gullet and stomach, and shortly over the whole abdomen The patient vomits, and there is also purging. Difficulty of breathing may occur from damage to the larynx. The patient may quickly show signs of cullapse There will be signs of burning on the lips and adjoining skin, and in the mouth in the shape of white, yellow, or black patches, and signs may also be found on the clothing.
Treatment consists in giving an appropriate antidnte moderately diluted with water, warm fomentations to the abdomen for the pain and to the throat for the difficulty in breathing, and warmth for the collapse. A doctor should be summoned. See Antidote; Poisoning.

## CORROSIVE SUBLIMATE. This is

 another name for bichloride of mercury. It is used, dissolved in water, to form antiseptic lotions: 1 in 1,000 to sterilise the hands before operating or dressing a wound, 1 in $4,000-$ 8,000 for washing out wounds, 1 in 10,000 for an eye or ear lotion. Coloured tablets are sold which tint the water and prevent ite being mistaken for and drunk as plain water ; and they also make it easy to prepare lotions of any desired strength. Metal instrumente should not be put into these lotions, otherwise they are blackened and destroyed. Solutions 1 in 10,000 to 1 in 1,000 may be used for disinfecting linenThe drug is very poisonous, and if taken has a strong metallic taste, and produces a burning sensation in the throat and gullet, severe vomiting and purging, perhape difficulty of breathing, and pain, though this may be absent. The lips and tongue are white and shrivelled. In the end there may be coma or convulsions. Pending the arrival of a doctor, whites of eggs and milk may be given. The patient should be kept warm in bed, in which are placed hot-water bottles, and if breathing is difficult hot fomentations should be applied to the throst

CORRUGATHD IRON. This useful material is made from sheets of iron, by a machine which bends it into a series of parallel ridges or corrugations, thus greatly increasing the effective strength of the material. As generally used for domestic work, the iron is galvanised to render it rust-proof;

When comparing prices be certain of the gauge or thickness of the shcets: a few pence more expended at the outset will often suve pounds in the long run.
A medium gauge is known as No. 24. a light or thin sheet as No. 26, and a heavy as No. 22 gange. The sheets measure 2 ft .3 in . wicle, and are generally stocked from 4 ft . to 8 ft . in length: 9 ft . and 10 ft . lengthe are obtainable to order, although for long spans of over 8 ft . it is generally preferable to use two shorter sheets and to overlap them at the joint.
The approximate weight of a No. 26 gauge sheet is 2 lb . per foot run, a 6 ft . length thus weighing 12 lb . The 24 gauge sheets go a little under 3 lb . per foot run, a 6 ft . sheet weighing 17 lb ., an 8 ft . sheet 23 lb . In conjunction with corrugated iron, it is well to use a few sundries made for the purpose. These comprise galvanised rillge capping, to finish a span ronf at the top or ridge: galvanised nails and washers for fastening the iron sheets to the rafters; and, when required, galvanised shuting to collect the rain water. together with the ncedful stop ends, angles, brackets, and outlet pieces for use with the shuting.

Corrugated iron is admirable for outbuildings, stables, and other erections. The objections to its use for dwelling-houses include lack of durability as compared with tiles or slates, the noise it makes in a heavy rain, and a peculiarity known as sweating. It is also cold in winter and hot in summer, unless special precautions be taken when designing and building the roof. Against these objections are the advantages of cheapness, lightness, and ease of erection. Durability can be gained by repeated and regular coating with preservative paints. When the iron is laid over a boarded and felted roof, with an air gap, the objections of noise and sweating are largely eliminated. This material is satisfactory, when properly applied, as a roof covering for bungalows, etc.
When laying corrugated iron always reckon that a sheet only covers a width of 2 ft ., as the odd 3 in . has to be lapped over the top and edge of the next sheet. Always endeavour to use the iron in its stock length, as it is difficult to cut. The best way to do this is to cut it lengthways with stout tinman's shears or snips. To cut across the corrugations, use the proper kind of chisel, and cut the iron by laying it flat on a solid support, with a hollowed block of lead immediately beneath the chisel. An alternative method is to saw it across with an old hand saw, exactly as if cutting a picce of wood, using plenty of oil as lubricant.
When covering a roof, if the length of the sheet is sufficient to reach from ridge to eaves in one piece, work from the ridge downwards. If two or more sheets are needed, begin by planning out the best arrangement by placing one sheet at the eaves, with its proper projection, temporarily fix another sheet from the ridge, and fill in the gaps by overlapping equally on each sheet above and below. Then fix the sheet next above the eaves course, follow this with the next above, and so on, finishing at the ridge.

It is generally Dreta Section Fig. 2 Brackel more convenient to lay the shcets from eaves to ridge and

Corrugated Iron. Fig. 1.
shoets are fastened to joirts and bolted together. Fis. \& The ond of a building with rooing in progrese
then the next set from ridge to eaves. When three such sets have been laid, fix those on the other side of the roof, if a span roof, then fix the ridge capping. Then do the next
sets, and so on to the other end of the roof. l3y these means it is easier to get at the shects than by laying the whole caves course first. Use a line stretched taut to keep the courses level, especially at the eaves, unless the roof has been boarded, when the line is not needed.

The proper way of fixing corrugated iron is to drive the nails or screws through the ridge and not in the trough of the material, the object being to keep the nail as far as possible out of the water, which naturally runs down in the troughs or hollows. The

corydalis. Porn-like leaves and yollow howers of this hardy perennial plant. 800 below
scantlings needed to carry the iron, as well as questions of the arrangement of the roof, if it is to be boarded or felted, must be decided according to the nature of the building and the purpose for which it is required. See Galvanised Iron ; Roof.

CORUNDUM: An Abrasive. This is a natural aluminium oxide. The finely coloured transparent varieties include such stones as rubies and sapphires, while the impure and coarse forms are known as eniery. Corundunt is used as an abrasive: it is extremely hard, and fractures in such a way as to ensure sharp cutting points, hence its value and extensive use. It is chiefly found in the home in the form of emery powder or knife powder
India oil stones are made of pure corundum in three grades,-fine, medium, and coarse. They are excellent for sharpening tools and the grades are often found in combination on the same stone. See Emery Powder: Grindstone.
CORYDALIS (Fumitory). These hardy perennial plants, $10-12$ inches high, with graceful, somewhat fern-like leaves are suitable for the rock or wall garden. Most of them will flourish in the shade. They like well drained light soil. The commonest is lutea, which has a long flowering season and will thrive in any odd corner. Cheilanthifolia, nobilis, thalictrifolia and Wilsoni are ot her attractive sorts : all bear yellow flowers in summer. A distinct group of corydalis has tuberous roots: two of the best are scouleri, with rose purple blooms in May, and tubeross with purplish flowers in March and April: these may be propagated by detaching small tubers in autumin or by seeds sown in spring in a frame. The fibrous rooted kinds inentioned above are increased by dividing the old plants in autumn or by sowing seeds in spring. See illus. above.

CORYLOPSIS. These Chinese and Japanese spring- flowering slarubs are nearly related to the witch hazels. They need peaty or leafy soil. One of the best is Corylopsis pauciflora,
which bears fragrant yellow Howers in spring. These shrubs are not very hardy and the young shoots and Howers arc liable to be damaged hy frost unless in a sheltered spot.

COSMETIC. A cosmetic is a preparation used for beautifying the akin and the hair. Among them are face creams, hair oils and similar compounds. See Beanty Culture: Beeswax; Face; Hand: Skin; Soap.

## Cots and How they are Made

## Considerations Affecting the Health and Comfort of the Child

The reader may consult the articles Baby; Child; while Nursery; Pcranibulator; Ventilation are other related subjects. See also Bedstead; Coverlet

The average cot for a child measures blankets and an eiderdown complete the 4 ft . by 2 ft . 6 in ., but if spacc is no object, bedding and can lic adapted to temperature.
it is a great advantage to select one measuring 4 ft . 6 in . by 3 ft . The child can sleep in it comfortably up to the age of 5 or 6 years. The cot made of hardwood is to be recommended rather than the iron cot. If the child falls against wooden bars, the injury is stight compared to a similar fall against iron; alao wooden cots can always be obtained in a folding pattern, and can be conveniently carried from room to room, and if they have to be travelled, the charge for freight is comparatively light.

The hars should be perpendicular, and ton close together to allow the child to push its head through. The height of the sides should be sufficiently great to prevent the energetic two-year-old practising his fondness for climbing. It should be possible to let down at least one side of the cot to within 2 in . of the mattress level.

A good hair mattress is strongly advised. It is twice the price of a wool one the same size, but it never goes into lumps and hollows, and is far more sanitary, and can always he re-made and cleancd. Hair pillows are also procurable, and have the advantage of being less heating for the head; hut they are not necessities, and a well-stuffed fenther pillow in a strong case of white drill can be sufely used. Sheets should be avoided in a young child's cot. A mackintosh, an old hlanket, or a thick cotton blanket are hest for it to lie upon. One or two light but warm upper

Many of the hetter-made cots are raised upon legs from the Hoor, so that there is no back-breaking work for the mother or nurse when baby has to be lifted in and out of his bed. These cots are also procurable in a folding form, so that they have a double advantage, especially for families who are accustomed to travel. In the case of a child who sleeps out of doors throughout the summer, the cot can be mounted on rubber-tired wheel castors and fitted with an all-enveloping curtain, arranged by means of a canopy pole and support. Mosquito nets on supports can also be fitted as extra attachments.

Fig. I shows an easily-made child's cot. As indicated the cot is made up of frames. three of which are fixed and one made to lower, and thus give convenient access to the lerdding. A set of castors can be fitted to facilitate change of position; but, as the whole thing is light, it can easily be lifted from place to place. The size for a small, ordinary size cot is 4 ft . by 2 ft ., and the height 3 ft . 6 in . For an older child the next size would be 4 ft . 6 in . by 2 ft .3 in ., after which it would probably prove more economical to construct a form of cot bedstead. Beech, birch, satin walnut, American whitewond, yellow pinc, sjuruce, andred deal are all suitable woods that can be pressed into service. Finish can then lie by staining, or in white enamel.
A commencement may he made with the two ends. The posts are of material $1 \frac{1}{2} \mathrm{in}$. by $1 \frac{1}{2}$ in. spuare, planed and cleaned up to 18 hy 13, and should le
 mortised for the rails as they occur. The tops of the posts can in the aimplest manner he linished by rounding over as at Pig. 3, or, if a lathe is at hand, the upper 2 in. can he turned to a ball linish as at Figa. 1 and 2. Some working turncrs keep in stock $n$ sopply of such turned tinials, and $n$ set-with dowelscan be purchased for a small sum. In alternative method of finish, which is nlso serviceable for the fix. ing of a cot-net, is that at Fig. \&, whilst a neat tinish is afforded hy the fitting of 23 in . hy -? in hy $\frac{z}{} \mathrm{in}$ caps with the upier edges nicely romided as at Fig. 1. These are hest fixed by a short tenon on prosts, although they can
be dowelled and pancl-pinned to prevent twisting out of the squarc if preferred
The mortises for the upper rail should start 3 in from the upper end of post, and the lower end rail can be ift 4 in up from bottom The cot may be framed together on all four sides at the seat, but being intended to have one side pivoted to let down, it is mortised on one side-only to the posts ahove the seat rail The position for pivot holes in posts is about 1 ft . 6 in . ahove ground

Panels and Bars. The top end rails, which are shaped as at Fig. 2, call be finished from pieces 2 ft. by $3\{\mathrm{in}$. by 1 in . They can he tenoned or dowelled to posts, and should also be shallow-mottised on under edges to receive the hars and centre panels. The panels (Fig. 2) are $3 \frac{1}{2}$ in. wide, with a small fret-cut opening in the upper part loy way of relief. A scratch bead may also be cut $\frac{1}{8} \mathrm{in}$. from length erlges with neat effect. The hars can finish $\frac{7}{k}$ in. by $\mathrm{g}_{8} \mathrm{in}$. thick, and, inclucling joints, arc 2 ft .1 in. long. It is possible to use $\frac{3}{3}$ in dowel sticks for the bars instead of the square section. provided they are nicely cleaned up The lower end rails linish $2 \frac{1}{2}$ in wide, and are dowelled or tenoned to posts and mortised for housing the bars and pancls.
The top side rails finish $1 \frac{1}{2} \mathrm{in}$. by 1 in . net thick (two lengt hs of 4 ft ., allowing a tritle for fitting and joints, are requiled), and each rail is mortised on under edge to receive 10 bars Instead of the mortises, a groove may be ploughed the length of the rail, and slips of equal length be packed between each har in the groove The ends of the top rail intended to lower should be banded or ferruled with sheet hrass a lull 1 in wide as a prosision againat splitting. As this rail, when up, is kept in position hy a brass screweye and chain attachment, tenons are re. quired. 'Ihe nttachment con sists of a nut sunk in the rail and kept there by a brasaplate

Cot. Fir. 9. Support for canopy or mosquito netting screwed onl, the eye being tapped to fit the nut, and a length of hrass chain fastened thercto to hook on to a clip
The lower rails are also $1 \frac{1}{2} \mathrm{in}$. by 1 in . net, and are mortised for bars in the same way and, on the fixed side, have tenons cut io enter posts. The loose end, as indicated at Fig. 4, is handed and pivoted into posts, a brass screw with the head filed off answering well for the purpose. The bars can be entered into the rails to their full thickness; or, again, hardwond dowels can he employed closer together. These latter may be spaced with fretcut pianels hetwcen, a suggestion for the latter being given at Fig. 5.
The seat rails can finish $2 \frac{1}{2}$ in. wide by 1 in. or $\frac{7}{6}$ in. thick if tenoned to posts and pinned; or, as is sometimes done, dowelled and stiffenerl with hrass or iron angle brackets to be screwed to angles formed by under side of rails and posts. Wire spring mattresses on iron fraines are made specially for cots, and if one of these is used the whole structure will be rigid and comfortable for the child.
Sliding Side to Cot. As an alternative the side may be fitted to slide up and down a stcel or nickelled rod, or a length of hardwood dowel could he substituted at a pinch. Figs. 7 and 8 will make the arıangement clear. The rod (B) can either be hrazed or biveted into the cup, or may simply rest in it. The rofl is capped at top and held by eyes (C) attached
(1) pusts as indicated, both rails of side being bored for the rod to pass easily through. When up, the sides can be kept secure by the clevice indicated at $\dot{A}$. It consists of a rod with a clubbed end, and a bolt liandle in centre normally pointing towards the ground, the whole being attached to under edge of lower (seat rail of cot side by means of cyer. The clubbed end rests upon a metal box, as at Fig 8, and this bearing keeps the cot side up in position. To lower the cot side, the handle is grasped und raised outwardly, which disengages the club from the box and allows the side to slide down the rod, stopping upon the screw-eye.

In another type of fitting two catches screwed to the posts are made to engage with the lower rail of the cot side. A net of niokelled fittings for the rock garden or border edging for this may be purchased for a few shillings from a furnishing ironmonger.

A support for a mosquito netting or a canopy is often added to a child's cot. It may be made from two pieces of $1 f$ in. by $t$ in.

## CotTAges: ALTERING AND FURNISHING

## Advice on the Improvement of a Small Country Property

Other useful informatlon will be found in the articlea Architecture and House. See also the entries on Casement ; Damp; Floor; Plumbing; Sanitation; and those on Chair ; Curtain Dreaser and other furnishings

When buying a cottage with a piece of land attached, inquiry should be made into, such matters as sanitation, water supply, and rights of way. An otherwise desirable plot inay be rendered unsuitable by the existence of a footpath or right of way across it, whilo the proximity of a cowshed, with its manure heap, is likely to be an obstacle to many

If there is a well on the property the water should be analysed to be sure it is fit to drink, or if it can be made so by not too expensive filtration methods. Sanitary arrangements in most cases will probably be of a rather primitive character, which will have to be altered or replaced by the new owner either at the instance of the local authoritice or for hygienic reasons. A good earth closet should not be condemned as, under approved conditions, it may be more efficient than a water-borne system. Where water supply is inadequate chemical cloeets are also worth considering. They are approved by the medical authorities and very efficient if carefully used.
The possibilities of renovation nust be kept in mind, as very often a dwelling w th communicating rooms can be converted with little expense into a convenient home, especially when the owner is able to undertake much of the work with his own hands. Eco. nomical methods are essential, but the very nature of the building demands plain work, with simple furnishings. The essentials of satisfactory restoration or the addition of now work calls for an adherence to the local traditions of building.

Altering an Old Cottage. The first thing is to decide upon the scope of the alterations, the location of additional windows or the enlargement of those existing. The whole of the exterior should then be gone over, replacing any missing tiles, repairing a stonc mof, or renewing the thatch, as the case may be. Get up into the roof, inspect the rafters, snd if any of them show distinct signs of failure these should be relieved by fixing a flitch plato or an extra rafter, laid alongside.

Then give attention to the walls. Brick. work may need re-pointing, but do this carefully. A struck joint will probably look best, and it is not necessary to remove all vestiges of moss and lichen, as they add to the charm of the exterior. Oak timbering shoull be treated with boiled linseed oil well brushed into the surface: two or three applications may be needed to reatore the lark culour se90ciated with old work. Any inconsp

Cottage. Plans showing how a terrace cottage can be improved at a minimam of expense. The apper plan showe the ground floor before convertion ; the lower, after the improvements have been made which might be set alight by the heat from the flue-pipe. Any room not provided with a fireplace should have a ventilating air brick or other device arranged in the upper part of one wall, or a small grating over the door.

Old doors will often be found deficient at the bottom or ill-fitting in the framework. Effective remedies are to cut away the badly damaged parts, work a feather on the end, and fit a new piece. New duor stoppings make a marked difference tu the comfort of a room if they are fitted clusel. to an old door that has warped and does not shut tightly. Worn threshulds are easily restored by cutting away the worn parts and making a new oak tread, which can be secured with well countersunk brass screws. Floors may need patching or renewal. A worn brick or the floor can be greatly
mproved by taking up the old bricks or tiles, re-levelling the soil, and re-setting the bricks or tiles in cement mortar but with the worn sides downwarlls: the original under-sides of the tiles will probably be found to be in perfect condition
The Water Supply. The provision of $n$ bathroom larder, and improved facilitiea for water supply depend almost entirely upon individual requirements, but one point must be mentioned in connexion with the erection of a water-tank or cistern in the roof This must be very carefully considered and before commencing work it is necessary to make sure that the pipe lines can be laid correctly, and that the cistern is not placed in the middle of the ceiling ralters. A small tank of 50 gallons eapacity may easily weigh $t$ ton when filled, and the ceiling rafters will not support such a weight. The cistern had best be placed over a wall, or in some place where adequate support is obtainable. The great object in modernising a small dwelling should be to retain the charm of the country cottage while providing all the essential modern conveniences
How to Furnish. The necessary repairs and renovations completed, the charm of the cottage can be added to by suitahle interior decoration and furnishing The keynote should the simplicity.

The type of cottage that one may wish to furnish may vary fmm an old half-timbered one with thatched mof, inglenook, etc., to a plain brick building with sash windows and Victorian fireplace. The furnishing of the former type is comparatively easy. Every possible use is made of the special features, and care taken that the furniture should go with its surroundings.
for example, the charm of a room with oak beams would be enhanced with old dark wood cottage furniture. If this is not available, inexpensive reproductions can be obtained in oak, walnut or birch colour ; or wood may be left unstained and wax polished where there are no dark oak beams to set the decorative scheme.
The roons of most cottages are small, the doors narrow, and the ceilings lowpitched, so pieces of heavy furniture that would suit a house of moderate size would look too large and take up too much of the limited space a vailable.
Unless two cottages have been knocked into one, thus providing more accommodation, the arrangement of the rooms must be well thought out. Sometimes the living room has a dining recess, the room having been enlarged by taking in the old kitchen and converting the
scullery into a more modern kitchenette Thus a dining room and sitting room are obtained. the former sonetimes combin ing with the hall sis the fiont dour opens directly into it and the stainease may ead out of it to the first tloor. Such : plan has an informal and at the same timu decorative effect if the woodwork is of oak and an old lan tern is hung from a wall bracket to light the staircase angle. The sitting room naty contain two or three useful pieces of furni ture, a few comfort able chairs, a good table, shelves for hooks, window seat. and an upholstered settee or divan

If the window cur. tains, valances and chair covers are made of some figured fabric like chintz or cretonne, the wall should be rough surface plaster, distempered with some self-colour or papered with plain paper. An unpatterned wall surface gives $n$ greater iden of space, so is emin. ently suited to small rooms. Even moro important, the gay colours and design of furnishing fabrics show to perfection against a plain back. ground.

Occasionally cottages used for short holidays In small, low pitched rooms wall ornaments and week-ends only are furnished with un- should be used with discretion. An antique wanted picces from nother house. A cottage warining pan, a few picces of pottery, an can be made attractive under such conditions arrangement of llowers on a shelf to break the if attention is paid to colour and details. To wall line are more restful than odd pictures supplement oddments, the amateur or village or crowded effects. carpenter can make such things as inglenooks. window seats and other useful pieces.

Cottage. Plans showing how alterations can be made to improve a detachej cottage. Top plan, ground floor belore alterations. Centre, ground foor after improvement. Bottom, first floor, showing in broken lines suggested alterations

Cottage. Left, igpical English thatched cottage. Right, L-shaped living-room. The dining recess is in the amaller portion bepond the fireplace : it bolds a refectory table and sir chairs and has a serving batch. The armehair is covered in a printed linen and the curtalns are of gaily checked gingham

Left-hand photo, courlesy of Our Homes of Gardens
damp allows a certain amount of moisture to percolate thmugh it. For this reason aroid the use of tight-fitting linoleun or other covering which excludes access of fresh air Uncven surfaies, such as worn brick os flagged stone Hoors, soon cause holes and cracks to appear in the linoleum, and any dampnesa on the under surface would tend to rot the cork Coconut matting is excellent on such floors Strips can be used for pasagges, and mata and small carpets in coloured fibre can be bought very cheaply. The advantage of fibre is that air can rendily pass through it to the bricks. and any moisture that is absorbed by the matting helps to lengthen its life.

The living-room with dark beams lends itself to stone-coloured, or cream distempered, or painted walls. In nolth rooms warmer tones could he used with advantnge; buff, apricot or primruse yellow are suitable. The woodwork would probably be finished to match the timbering, though lighter colours are effective for window woodworl, unless the windows are Intticed. A suggestion for a sunny room is cream-coloured plastered walls, oak-coloured paint, short curtains with the valance fixed to a pelmet board. A window seat with upholstered cushions could be covered, and all other hangings niade from a cretonne in which blues, yellows, greys and soft reds mingle.

A preduminant nute of blue harmonises well with brick tiling on the Hoor or a brick fire. place Striped woven rugs or a small oriental carpet may be used Oak or other hardwood atairs merely require to be stripped and wax polished Those made of white wood and having painted sidea can be made attractive by having plain or bordered hnir stair-carpeting laid. Light coloured walla are essential if the stnircase should be dark or narrow
The furnishing of the bedrooms should be simple, cheap painted furniture is suitable. in the absence of better pieces. If space is limited, make a dressing table from a trinngular shelf placed across one corner. If a bathroom has been introduced during alterations it is rarely necessary to have washstands.

A cupboard with fitted drawers at the bottom answers as a wardrobe This should be placed against a dry inside wall Corner fitments with curtains are useful for hanging clothes If the lloor buards are in good condition, linoleum or cork carpet can be used with rugs, or square of fibre or hair carpet. In order that the exterior of the cottage may be as charming as the inside, the curtains of all windows that can be viewed at the same time should be of, or lined with. the same colour

Cottage Pie. This is made from cold minced meat and potatocs, and is also known as shepherd's pie (4.v.)

COTTER: A Wedge. A wedge-shaped piece of metal, known as is cotter, is adapted to draw up the joint between a shaft and a crank, or other part of a machine. A familiar application is the cotter pin in the crank of a bicycle (q.v.). Essential requirements in fitting such cotter pins are, that the pin shall fit accurately in the hole drilled in the crank, and that the Hat surface on the cotter is correctly shaped to bear on the flat formed on the shaft. Both surfaces should be in contact over as large an area as possible. It is tightened up by a nut and washer

COTTON. Not only are clothes, furnishing fabrics, and sewing materials obtained from cotton, but the seed on which the cotton fibre is found is rich in oil, and this is pressed out and used to make soap, margarine, and so on The lint adhering to the seed after the min part of the fibre has been removed forms a base for making guncotton, collodion, and nrtificial silk, and is frequently made into cheap cotton wadding. The residue of seed remaining after expressing the oil forms a cake which is videly used and highly valued as cattle food

The superior cotton fibres are silky and anft, wherens some are harah and wiry. The longer and silkier are naturally the most expensive, and from them the finest threads and most delicate cloths are made. The very best cotton spun into the finest yarn fetches a far higher price than silk
Cotton Fabrics. Tent and sailcluths are generally cottons, and so are nainsooks and cambrics. The lawns, sheetings and shirtings once universally made of linen are now generally cotton, which also replaces wool in fannnelettes and even in blankets it takes the place of silk in mercerised linings and embroideries, in velrets and umbrella cloths. Cotton reps, damasks. tapiestries, and cretonnes cover furniture, and cotton rugs and mats are used on Hoors. Lisle or hard-twisted, superior cotton thread makes stockings; and cotton fabric. with a suede finish, is used to make gloves Raincoats are often cotton, as are curtains. tape, lace, imitation leathers, bandages Much twine and cord, containers like Hour bngs, and most of the webs for braces and belts are cotton Motor tires are made upon a foundation of the very best cotton : electrical wires are insulated with cotton, and nearly all clothes are sewn together with it.

Uses and Defects. Cotton is blended with woollen materials that would otherwise be too poor for use, in order to lend strength to the whole and not necessarily for cheapness Fairly expensive cloths used in place of fannel are rendered practically unshrinknble and better wearing for being made of a blend of fine cotton and tine wool. It is now possible to dye cotton with more fastness than any minterial Cotton can be lent the apprearance of silk, as seen in the mercerised cottons employed for so many purposes By being woven in olen cellulaitexture, or bushed like Hannelette, or made with a loop surface like Turkish towelling. or with a smooth pile like velvet, it is made an efficient non-conductor of heat and thus warm to wear.

The defects of cotton vary, and in general it does not hear washing as often as linen Cutton damask table-cloths and napkins are more fluffy and less firm than linen The short fibre comes away as lint, as is seen in using cotton dusters or glasaclothas. Used as dress material, cotton shows creases more than wool or silk, for it lacks resiliency

A simple nid moderately effective process to reduce the inflammability of cotton is to steep the article in $\frac{1}{2} \mathrm{lb}$. alum, $\frac{1}{2} \mathrm{lb}$ phosphate of ammonia, dissolved in one gallon of water. As the deposit of these salts left upon the fabrio produces the Hame-proofing effect, the articles must not be wrung too heavily and should be hung to dry. Cotton gonds are easily scorched in ironing or in drying too close to a fire, and such heat enfeebles the fibre-and shortens the life of the cloth

Sewing Cotton. A fine quality of raw cotton is required, and a uniformity of thickness for the yarn from which sewing cotton is made. It is important for neat and atrong needlework to use sewing cotton of the proper thickness. No. 50 is a good average for general sewing, with 60 or even 70 for fine work such as babies' garments, 40 for strong calicoes and 30 for such johs as securing buttons on which there is considerable pull.

A convenient way of storing recls of cotton, which take up too much room in the workbox. is to string them on a long loop of string, and hang them from a hook or nail. The loop can easily be taken down nnd laid on the worktable when sewing is in progress, and every colour and thickness will then be handy. Mercerised sewing-cotton is dipped in a solution which gives it a silky appearance. It is useful for stitching mercerized and mixed cotton and silk fabrics. See Laundry ; Mending; Sewing Machine.

COTTON THISTLE (Onopordon). A very fine and vigorous growing biennial plant, the cotton thistle is suitable for shrubberies. The stems are covered with whitish hairs, and the heads of flowers are thistle-like in form and purple in colour. The hest sorts are acanthium (known as the Scotch thistle) and bracteatum, which grow 6 feet or more high.

COTTON WOOL. Cotton wool is used for affording protection from cold and injury and for absorbing discharges It can he oh tained medicated with horic acid, salicylic acid, iodoform, etc. For dressings the absorbent variety should be used

Cotton wool is sometimes used to plug the ears, e.g. in bathing and after syringing. Care should be taken to prevent the plug from slipping into the ear by making it sufficiently large and not pushing it in too far. When the ear is discharging, a plug miny be dangerous, as it may imprison the discharge : so if this is at all free it is snfer to place a prad of cotton wool over the ear hole and keep it in position by a handage. or sticking-plaster

A piece of absorbent cotton wool is a good thing to use as a sponge in dressing wounds, etc. It is soft and comfortable. and can be burnt. afterwards.

Thick pads of cotton wool nlay be used in conjunction with camphorated oil to cure colds on the chest The oil should be rubbed on the ohest just before the patient retires for the night, and a pad of cotton wool placed over it. The pad may be held in position by means of a bandage, but the Intter must not be too tight, otherwise it will interfere with the patient's breathing. The most useful form of cotton wool for this purpose is gangee tissue, which may be shaperl to form a jacket

COUCH. Originally meaning any article or spot used for resting or slecping on, a couch is now usually a synonym for a sofa See Chesterfield: Settce: Nofa

COUCH GRASS. One of the worst of garden weeds, its hotanical name is Agropyrum repens It spreads alarningly by meairs of its creeping rootatock and can be exterminated only by digging out the ronts

COUGH. A cough is nature's method of clearing the air passages of material which should be got rid of, whether it has been intro duced from without or heen formed in the lungs or air passages themselves. If anything we are swallowing goes the wrong way we at once cough and prevent its entrance into the trachea. What happens is that in response to the irritation produced by the substance on the lining of the entrance to the larynx, we take $n$ deep breath and the vocal corils are closed. We then make to breathe out strongly, the vocal cords Hy aphrt, and the air is expelled with force and suddenness, sweeping the offending material in front of it. The irritation has stimulated a centre in the medulla oblongatn, the part of the brain which is con tinuous below with the spinal cord, and this sets the expiratory muscles in motion.

Frequently the centre is stimulated by irritation, occurring it various parts, when thereis nothing to be brought away, and the cough serves no useful purpose This is spoken of as a dry cough, and it may be due to irritation from adenoids, or a long uvula, to inflammatory mischief in the air passages or-elsewhere in the organs of respirntion, to tumours of the Iarynx, and other causes. It is the cough of dry catarch which is often so troublesome in elderly people. Irritation of the Inrynx pro duces a croupy, hoarse, or brassy cough. This occurs in lary ngitis, diphtheria, aneurism of the chest, and other conditions.

A paroxysm of coughing may occur from persistent or severe irritation, but when it terminates in a crowing sound produced by a longdrawn intake of the breath it usually means
whooping-cough. Winter cough is that due to a chronic bronchitis, which improves in fine weather and grows worse or only appears when the weather becomes cold and damp. A stomach cough may occur, but it is much more uncommon than is supposed, and a persistent cough should not be accepted as merely a stomach cough without consulting a doctor, as it may he due to early consumption. Cough is merely a symptom, and its treatment should be directed to its cause. See Bronchitis: Cold Consumption Whooping Cough, etc.

Cough Lozenge. Numierous lozenges for relieving coughs can he obtained from chemists but for a siniple and slight cough a lozenge can be made at home, if desired, from syrup of horehound The syrup can be made from the atems and leaves of the horehound plant steeped for several hours in cold water. Allow $\frac{1}{2} \mathrm{oz}$ of horehound to a cupful of water. The syrup can also be obtained from a chemist

Boil up the liquid with 2 lb of demerara sugar and 2 tablespoonfuls of vinegar until the syrup sets when dropped into a cup of cold water Add $\frac{1}{2}$ a tenspionful of carbonate of soda, and boil up again until, when a little is dropped into water, it sets and is britile Pour it out on to a buttered tin to set, mark it out in squares with a knife, and, when cold, snap off as marked and wrap each piece in waxed paper Store them in an airtight tin Ordinary treacle toffee has a soothing effect

Cough Mixture. Cough is merely a symp lom of a large number of different complaints, and in the case of any particular complaint a drug which is useful at one stage may be harmful at another It is unwisc, therefore, to take medicine for a cough without knowing what the cough is due to, and to persist with a cough mixture because it has benefited some hody else's cough. In the case of a cough which comes on each year in cold, damp weather, the winter cough, the following may prove useful: Chloride of ammonium, 2 drams: compound tincture of camphor, 4 drams liguid extract of liquorice, ? diams ; spirit ol chloroforin, 2. drams; infusion of senega, to (ioz. The close is a tablespoonful thrice daily, in a little water, after food. Sep Bronchitis
COUNTERBORE. This tool consists of a central peg, or pilot, and a larger diameter eutting piart, rotated in $n$ lathe or drill press

Tue rool is fed into the work until the desired clepth has been attained. A goorl counterbore should le capable of turning out a neatly finished hole or recess having square comers, such as are required for the reception of $a$ screw head that has to be sunli below the surface of the surrounding metal, as illustrated The same result is obtained in woolwork by using an nuger bit, drilling out the larger diameter hole first and following with the smaller onc, otherwise there would be no material to guide the auger, unless the small hole be temporarily plugged for the purpose.
COUNTER IRRITANT. a counter irritant is an agent which produces redness and irritation of the skin. The idea is to bring an abundance of blood to the akin veasels, with a view to relieving congestion of deeper structures or organs. Counter-irritants include mbefacients which redden, e.g. acetic acid, solution of ammonia, liniment of camphor and ammonia, liniment of capsicum, mustard,
iodine; vesicants which blister, e.g. cantharides or Spanish fy ; and pustulants which produce pustules (hlisters containing matter). e.g. Junar caustic and croton oil.

It should be remembered that substances of the first class, if used too strong or too long, may blister, while those in the other class may be used sufficiently diluted to produce redness only. In applying counter irritation for the relief of an underlying condition, better results may be achieved if it is applied rather at a little distance than just over the seat of the pain. See Plaster.

Counterpoise. See Earth
COUNTERSHAFT. A countershaft is used in connexion with belt-driven machinery. It is a short shaft mounted in suitab e bearingr and equipped with pulleva
The counter. shaft is driven hy a belt from thie main orline shaft, and another belt transmits the drive from the countershaft to the machine. As usually arranged, a striking gear is provided to move the helt from the driving pulley on to one of equal size, situated next to it, called the loose pulley, as it is free to revolve on the countershaft itself. A typical countershaft that is suitable for an amateur's turning lathe is illustrated above See Aniateur Carpentry Gear: Lathe.

COUNTERSINK : A Brace Bit The name of countersink is applied to $n$ type of brace bit used to form a conical-shaped recesa in wood or metal, etc., whereby the head of a screw or rivet can be let in flush with the surfuce. See Bit.

COUNTESS PUDDING. A good steamed pudding is made ly greasing a mould with hutter, and arranging 2 oz quartered glacé cherries and the same quantity of quartered stoned raisins in the hottom of it. Now line the sides with some thin strips of plain madeira or almond cake. Ahout $\frac{1}{}$ Ih. cake should suffice. Mix any left over with 4 oz . crushed macaroons, 2 lightly heaten egga, and $\frac{1}{2}$ pint milk. Fill the mould with the mixture, tie a buttered paper over it, and stcan it for about $\}$ hour. Turn it out to serve.

COURSE : At Meals. For the ordinary luncheon two course's, either an egg dish, fish or meat and a sweet, are the rule, but the menu miny be supplemented by a soup, or

Counterbore. The tool used in metal work. and diakram showing counter bored recess for a bolt bead cheese course For dinner it is usual to plan a mical of four courses, stretching to five or six for special occasions. In small house holds, soup or fish, entrée or joint, swcets and savoury, are generally enough. serving melon, grape fruit or hors d'oeuvre instead of soup for a change, or including fish and onlitting the savoury.
When entertaining, a poultry or game course can be introduced after the entrée, or this can be varied by a vegetable, such as asparagus. salsify or seakale, served as a separate course It is not usual now to serve an ice as well as sweets, but the former frequently takes the place of the latter at either a luncheon or dinner party. At a small dinner dessert may be omitted, especially when some kind of fruit ce or salad forms the sweet course.
For a more ceremonious dinner party the (ull list of courses would le-melon or hors d'ocuvre, soup, lish, entréc, joint, poultry or game, siveets or ice. savoury, dessert. The entréc should be completc with nny neccssary vegetable in one dish. but potatoes and one or
two vegetables are served with the joint and salad with game or poultry On rare occasions a sorbet-a punch ice-is served bee ween joint and game, and small Russian ciguettes may be handed round with this course For H supper hot soup may be scrved, but otherwise the term usually signifies a cold meal with meats, sweets and sa vouries either on the table or sideboard, and no formal courses See Dinner ; Luncheon.

COURT PLASTER. This is a mixture of isinglass, glycerin and alcohol spread on silk. It is used to bring the edges of a cut together and to protect it.

COVER : For Furniture. Loose covers of chintz cretonne etc., afford jrotection for furniture, and are also useful for bringing

Countershaft for use with belt-driven machinery odd chairs into a harmonious colour scheme or for placing over worn chairs or settees. These should be clcansed thoroughty hefore the neiv covers are put on. An armehair should br rubled with stale bread, and il this lails to remove the marks. benzoline will probably lo successful. This is best applied out of doorn benzoline heing highly inflammable

A plain rep fabric or onc with a small pattern can be chosen for a cover because it is easily fitted, but if a distinet pattern is selected for decorative value care must be taken to sod: that it is correctly placed. Hang the fahric wrong side out over the chair, so that any pins uscd in fitting can remain until the cover is sewn. Allow at least 1 in . all round for the hem at the hottonn, and, when fitiing, tuck the material well in at the back of the seat Since the covers are not to be tight fitting, a certnin amount of fullness should he allowed at the back and front, and plenty of material used for tucking in at the sides, where if possible, all joins should lie arranged.

If necessary pieces should he let in at the Iront of the arms. Having fitted the chair, cut the materials to the required shape. remove the fabric, and the cover is ready to be sown up. In doing this lenve the necessary opening at the back, make a false hem for the buttons, and an inside flap for the buttonhole. The seams and lining edges of the furniture should be piped. Use strong cotton for the sewing, and oversew each corner firmly. Turn up the hem and thread a tape through it from end to end The tape will draw the cover neatly round the frame, and can be hidden by a flounce reaching to the floor. For a chesterfield or large settee douhle width material ahout 50 in . wide is best. See Cretonne: Dccoration.

COVERLET. This is another ward for bedspread or cot cover. A waterproof or a fabric cover of an ornamental nature for the perambulator is also called a coverlet
I cosy cot cover is worked with blue and cream double knitting wool, and besides being very warm will outwear any of the woven variety. The necessary materials are 1 lh . of douhle-knitting wool in blue for the centre, 6 oz of cream for the border, and a bonc crochet hook, No. 8 These produce a cover measuring $49 \mathrm{in}$. long by 39 in . wide, but the size can le varied.
Begin by making 134 chain, and work the first row thus: Treble in the 5 th ohain from the hook, then treble in each chain to the end of the line. Make 2 chain, turn, and in the sccond row miss the first stitch over which the 2 chain stands, as this will represent one double crochet. Then double-crochet in ench trehle to the end of the row, taking up the back loops only Make 3 chain, turn, and commence the third row by misaing the first double chain

Do one treble in each stitch to the end of the line, taking up the back loop only: the last treble will he worked in the top of the 2 chain. Make 2 chain, turn, and then repeat the second and thind rows alternately 53 more times.

For the horder, use the cream wool, and work all round thus: Do 2 treble uniler the side of the trebles on the left side of the cover, and 1 trcble in the double ornchet: then across the ends there will be 1 treble in each stitoh. At the corners put 2 treble, 2 cha in. and 2 treble right in tho cornermost stitch. In fol. lowing rows there will be 1 treble on each stitch, and 2 treble. 2 ehnin, 2 treble under the 2 chain for the corner. There are 11 border rows in the model illustrated, the order being 5 cream, 3 blue, and 3 cream.

Cot or perambulator covers mny be made in linen or wool blanket cloth. The former may be embroidered and hemstitched in a contrasting colour, the latter bound with antin ribbon and either worked in coloured wools or suitable designs appliqué. See Appliqué: Bedspread: Quilt.
COVERT COATING. This is a tailor's cloth in neutral shades, heavier than the similar-looking gabardine cloth, and the front edges of coats and raincoats made from it are less inclined to roll at the flap. Made both in worsted and woollen cloth, it shows a steep and pronounced screw twill, and the colouring is uavally mised light nnd dark in the same thrcad.

Gond covert coating wears well, hut has been imitated in light and cheap makes, although these are more usually called gabardines.

COWHEEL. Boiled cowheel is a nutritious dish. To prepare it, wash the heel thoroughly. and boil it for $1-3$ hours in sufficient milk and water to cover it. The milk and water may be mixed in any proportions. Add one large sliced onion and a little salt, and when the meat is cooked take it out and keep it hot Thicken the liquor with flour, using 1 oz to cvery pint of liquid, and mixing the flour thinly with cold milk before adding it. Stir the sauce till it boils, then ndd I tenspoonful chopped pirsley and reasoning, which should include a fow drops lemon juice and a light dust grated nutmeg. Arrange the pieces of the heel on a hot dish, pour over the sauce. and border with toast sippets.

An excellent family broth is made by divid. ing one boiled cowheel into quarters and putting it in a saucepan with 3 pinta cold water and a small teaspoonful salt. Bring to boiling point, skim it well, and add 1 oz . each of carrot, turnip, onion and celery cut into dice. Int the soup boil for about 1 hour, or until the ment alips off the bones. Then take nut the ment and bones, cut some of the best pieces into dice nnd put them back into the soup with 1 o7. rice. Boil tho broth again until the rice is thick, then season the whole carefully, adding a tablespoonful of chopped paraley and $\Omega$ dash of lemon juice. Serve the soup with toast cut into dice. If $\Omega$ cowheel which has not had the preliminary boiling is used, it will require 3 or 4 hourg' cooking before the ment leaves the bones.

COWPOX or Vaccinia. This is a mild, contagious disease of the cow in which vesicles or blisters appear on the udders and teats. The lymph obtained from these vesicles, calves being used for the purpose, is the

Coverlet for a baby's cot, made altes the pattern plven in this article
material used for vaccina tion against smallpos. It does this by producing vaccinia in the human subject There are strong grounds for believing that human smallpox and cowpox arc the same diserse, or, at any rate, that hoth diseases have had the same origin, that is, from one type of micro-orgnnism whinse progeny show differences according as their trans inission has been thmugh man or cattle See Small. pox: Vaccination.

COWSLIP. The popular name of Primula veris. This is n well-known wild tlower, common in meadows and open wondland. It does not succed well under cultiva. tion, though it is the parent of the auriculas and other spring flowering favourites.
COX'S ORANGE PIPPIN. This apple is the finest llavoured in cultivation. The fruits are at their best in November and December It is self-sterile and does not fruit well unless it is planted among other frec-blossoming varieties. e.g. Worcester Pearmain See Applo.

Cos's Orange Pipuin. a rood dessert apple
CRAB: How to Prepare. It is of the greatest importance that $a$ crab should be perfectly fresh and in good condition. It should be heavy in comparison to its size, with large claws, and the shell free from white incrustrations, these denoting that the fish is agod and probably stringy. Crabs are at their best from May to August, but. like other shellfish, with the exception of oysters, are far from being digestible, and should be eaten sparingly and never given to invalids. A crab when bought at a shop is already boiled.
To dreas a crab break off the large and small claws, remove tho underneath portion and all the flesh from the shell, also the little bag near the head. usually full of sand, and throw away all bone and the lang grevish pieces termed dead man's fingers. The tleah is of two kinds, some firm and white, the rest soft and dark. Separate the former into shreds with a fork, also the ment from the claws after cracking them. Mix the dark soft meat with about 2 tablespoonfuls each of fresh breadcrumbs and oil and vinegar, and seasoning to tasto Scason the shredded white meat, but keep separate from the remainder

Wash and dry the empty shell, chipping ofl the under portion up to the faint line which serves as a guide Fill the shell with the two mixtures, arranging them alternately. so that they nppear in dark and light stripes, herping thein higher in the middle than at the sides lecorate with lines of finely ehopped parsley. and force a little butter round the edge with a forcing bag and pipe. Place the crab on a fancy paper or on a bed of fresh aalad

For a quickly made savoury dish, prepare some rounds of crisp, neatly trimmed buttered torst, and keep them hot. Melt 3 teaspoonfula of hutter in a chafing dish, stir into it I tablespoonful of flour and then $\frac{1}{2} \mathrm{pt}$ of milk Stir these until they thicken, then add the ment from a medium-sized orah. seasoning it with cayenne, salt, chopped parsley, 2 tea. spoonfuls of Worcester saucc and l oz of grated Parmesan cheese Heap this mixture on the toast and serve hot.
Potted crab is a good fish paste Remove all meat from the shell and pound it, adding salt. cayenne, mustard. and vinegar to taste. With a wooden sponn rub it through $n$ hair sieve, and press it into sminll pots. which must be clean and dry Bake slowly for 30 min. and then leave them until cold. Pour on the top of each pat melted mutton fat, to the depth of about $\frac{1}{d}$ in., taking care not to move the pots until the fat has set and hardened

Crab Croquettes. An excellont fish course is made by pounding the flesh of a crab to a smonth paste, and adding half the quantity of fine breadcrumbs, with ennugh melted butter to bind the mixture. Season it with lemon juice, pepper and salt, and malie it into small rissoles Coat them with beaten cgg, moll them in breadcrumbs, and then fry them to a light brown.
Crab Pie. Crab pie or partan pie, as it is called in Scotland, can be made as follows: lick all the meat out of a freshly boiled crab. mixing dark and white meat together with a sessoning of salt, cayenne, oil, and rinegar. If the mixture is too soft, work in a few bread crumbs, put the whole back into the shell. strew it over with crumbs and grated chcesc, mixed in equal parts, and bake it in a quick oven until lightly hrowned. Serve the pie hot, with thin slices of brown bread-andbutter, cayenne, and sprigs of prepared

## watercress

CRAB APPLE. The common wild crab (Pyrus malus) is used as a stock on which to graft standard npple trees, and thus serves a very useful purpoise in gardens. There are many ornamental crabs valued for their hlossoms or fruits or hath The Siberian crab (Pyrus baccata) inakes a large tree which is beautiful when in bloom in spring and itsfruitsmake oxoellent jelly. 'The crabs named John Downie, Dartinouth and Transparent bear handsome Iruits of decorative value. Ругия ярес tabilis, floribunda, Schiedeckeri and Eleyi are grown for the sake of their cxquisite spring blowsoms. All four are hardy. and thrive in ordinary snil.

Crab Apple. Cluster of fruit

Crab Apple Jelly. Aiter being washed and stalked, but not pared or cored or flavour will be lost, the fruit should be out in halves with a plated knife. Put 3 lb . thus prepared. in a pan with sufficient cold water to float themprobably about 3 pints. The thinly pared rind of I lemon is added and the fruit bniled gently until soft, but not in a mash. The juice is strained through a jelly bag or tammy-cloth. the fruit being pressed gently but not aqucezed or the jelly will be cloudy.

After rinsing out the pan the juice is put hack into it, with 3 pint of gond white sugar to each pint of juice, and the jelly boiled quickly with the lid of the pan. It must be well skimmed all the time, and $\Omega$ few of the pips may be pecled and stirred in. When a small partion of the jelly sets firmly on a plate. it is ready to be poured off into clean. dry pots These should be securely covered and stored in a cool, dry place.

CRACKER : For Christmas. This lıarmless induor firework mny be a tiny honbon of ordinary sloape in a brightly coloured paper covering, or one of the ginnt variety, either bolster or fancy shaped, to be suspended from the ceiling at a Christmas party and containing all sorts of toys and trinkets. Fancy crackers are quickly trimmed with amall dolls, holly or Hower sprays, etc. Centre picces can he ensily made by using $n$ gilded or silvered basket decorated with coloured berries and tinsel ribhon and filling it with pretty crackers, or the crackers may be suspended in a toy aeroplane. By the addition of some little arnament or flower the simplest crachers can be tranaformed into decorntive ones. The tiny bonbons may be used to surround a Christmas cake, placed upright and held in position with a ribhon until the cake is cut and the crackers distributed nmong the guesta See Christmas.

CRACKLE WARE. This term js applied to Chinese and Japanese pottery whose surface is covered, partly or wholly, with a network of fine cracks. They vary in size from tiny meshes like fish-roe and pigskin up to ostrichegg effects, and the still wider fissures called ice-cracks. One form resembles trout scales.

Crackle is produced intentionally by the unequal contraction of the body, and sliould not be confused with the accidental crazing of the glaze seen in some European ware, both old and new. Black inks or red ochres, some times hoth, are rubbed in to make the lines prominent. The oldest pieces, which are Sung ware, go back nearly 1,000 years, and a good apple-green, turquoise or celadon crackle is highly prized.

CRADLE. Tho cradle is a very old piece of furniture, but the oldest existing examples probably date from the 16 th sentury. In the 18th century, following the French example, some were made in very claborate atyles, being panelled or carved and inlaid, but the ordinary type were of plain onk or other wood. In the 19th century iron cradles were introduced, but these soon gave way to wicker ones. Cane is also sometimes used, but the oradle itself has dianppeared in favour of the cot in many nurseries.

It is never wise to put much lace on a cradle. Narrow Valenciennes eased on to the muslin covering is permissible, hut the better trimming is to frill the material itself.

A usual type of oradle is ahout 2 ft . long. 14 in broad, 6 in. to 12 in . high. The oradle may have $\Omega$ hood over one end as in the bassinet type, or a canopy formed from some light and porous fabric, preferahly muslin, and lined with a darker piece of the same material; the object being to provide the requisite shade and yet allow free ventilation. When in use the oradle must be kept scrupulously clean, and free from any rough edges or projections which are likely to disturb the rest of the the infant. See Baby ; Cot.

In surgery the term cradle is given th an appliance which protects an injured limb in bed See Bed Cradle

CRAMBO : How to Play. Crambo is n goond game for ndu!ts, and is suitable for any gaines party. Ench player is given two slips of paper, distinguished from each other in some way. On one of these he writes any noun that occurs to him, and on the other a question He then folds each paper over and hands it to the person in charge. The nouns are put into one bowl and the questions are put into another. When they have been well shaken up they are handed round once more, each person taking a noun and a question. His task then is to write n verse answoring the question and including the noun.

A time limit should be ret, and when it has expired the papers on which the verses have been written should be collected and the results read aloud. Dumb Cramho (q.v.) is an entirely different game.

CRAMP. The commonest form of crainp, which is a local painful spasm of a muscle, occurs in the calf at night, when one wakes suddenly with an excruciating knife-like pain, and finds the calf like a hard ball. The pain may pass off after $\Omega$ moment or two as suddenly ns it appeared. Gouty or rheumatio tendencies, exposure to cold or damp, and over-fatigue are the commonest causes.

Cramp is not unconmon in pregnancy from pressure on the nerves supplying the legs. It is also a symptom of the neuritis produced by chronic alcoholism. There is a form of cramp which is caused amongst other things by excessive tohacco smoking. After walking a short distance cramp ncours in the calves: this passes off in a short time, hut recurs when a short distance has again been covered: so that in taking a walk it is necessary to make frequent halts.

In treating oramp, rub the part vigorously with the open hand, alternating this with masage with the fingers. When the acute spasm has passed off rub in well any household liniment, wrapping the part immediately afterwards in cotton-wool to prevent chilling. People subject to muscular oramp will find the following liniment of the greatest service:

Chloral hydrate
Menthol
Camphor
$\begin{array}{ll}1 \\ 1 & 07 . \\ 1 & =\end{array}$
The liniment should be mixed well in a mortar until of a syrupy consistence, and used externally, rubhing in well. Where the tendency to crainp at night is associated with flatulent indigestion, it will be found helpful if a teaspoonful of sal volatilo in a little water is taken nt bedtime.

Stomach cramp is a common symptom in indigestion. The pain may he the result of sudden distension of the bowel with gasce caused by ahnormal firmentation of the contained food, or the spasm may be due to irritation of the nerves supplying the stomach and intestiner Apply a hot-water bottle and give bicarhonate of sodn and carminatives See Colic: Muscle.

Cramp in Poultry. Craınp is a complaint to which both chickens and duoklings are subject. It generally nffects the legs, causing the hird to squat down helplessly, and is usually hrought on by damp surroundings. The condition is sometimes liable to be con fused with leg weakness.

The only cures for cramp are warmth and friction to restnre the circulation Rubhing the legs freely with cmbrocation, provided the bird is kept in a warm place while under treatment, will generally effect a cure. See Poultry

CRAMP: The Tool. The tool named n cramp is used for tightening the joint between two pieces of wood or other material, and it frequently forms an integral part of a small machine such as a minoing machine, which can thus be readily attached to n tnble. It is sometimes called a clamp.

Ordinary woodworkers' cramps are made in a very light pattern, comprising a light steel bar bent to shape, and onc leg acrewed and fitted with a clamping screw. A superior pattern called the G-cramp is made of solid cast metal, and wi!l last for years, especially if fitted with n clamping acrew having a squaresectioned thread. Such cramps are made to hold from 2 in . to 12 in . in width Parallel cramps are made with two hard steel jaws, which are drawn together by two hand screws. They are very useful for small metal work of all kinds, and will hold work up to $1 \frac{1}{4} \mathrm{in}$ in thickncss. Corner cramps are used to hold the two parts of a picture-frame or other mitred work while the joint is being fastened Sometimes four of these cramps are used with a tensioning bar between them, and adapted cspecially for picture-framing With all types it is desirable to interpose wood between the work and the jaws, to avoid bruising the surface.

Sash cramps or bar cramps consist of a long steel bar ahout 1$\}$ in. deep and $t$ in. thick from 24 to 48 in long. At one end is a strong upright with a square-thread oramp screw which pushes a sliding jow along the bar. A movable jaw is arranged to be fixed by menns of $n$ stcel pin to any desired position on the bar, and by this means all classes of work can readily be held, up to the capacity of the oramp. It is of grent use to the amateur who

Cramp: parious types used for special purposes. 1. G-cramp, with square thread acrew. 2. Tool makers' parallel cramp. 3. Corner cramp. 4. Bench-cramp. 5. Sash oramp
undertakes the construction of doors, cabinets, and other large work.
A bench cramp is useful to carvers and other woodworkers, as by its aid the work is held down on the bench. The tool comprises a circular bar that is inserted into a hole bored in the bench top. The cramp screw presses the long bar tightly on to the work, which is thus securely held in position. See Glue ; Picture.

CRANBERRY. Those who have a moist site with peaty soil may grow cranberries, but they are very rarely cultivated in gardens

The plant is a slender, wiry, trailing shrub, with small red acid berries. It grows wild in England and Wales and in Scotland. Its botanical name is Vaccinium oxycoccos. The whortleberry and bilberry are closely related to the cranberry See Bilberry.
How to Cook. To stew cranberries, put in a stewpan 1 lb well-picked fruit, just enough water to cover it, and at least $\frac{8}{} \mathrm{lb}$. sugar. Let it simmer slowly until soft. Stewed cranberries are best served cold with custard or junket. To relieve the acidity apples are often stewed with them in the proportion of $\frac{1}{} \mathrm{lb}$ apples to 1 lb . cranberries.

Cranberries make appetising condiments for meat and poultry dishes. A good chutney is prepared by putting 2 quarts of the pickled berries into a pan with $3 \frac{1}{2} \mathrm{lb}$. white sugar, 1 lb . stoned, coarsely chopped raisins, the thinly pared and finely chopped rinds of 2 oranges, and $\frac{1}{8} \mathrm{lb}$. chopped onions. Add $\frac{1}{2}$ pint good vinegar, the strained juice of the oranges, $\frac{1}{\frac{1}{2}} \mathrm{oz}$ mustard seed, and a level teaspoonful each of yround ginger, powdered cloves, and cinnamon, and a little salt and pepper. This is boiled until it is thick, and is then bottled.

Cranberry Jelly. Cranberries are excellent ns a jelly to vary red currant jelly with venison, roast mutton or jugged hare. Taking 3 lb . of the fruit, pick over and wash the berries, put them into the preserving pan with 3 pints cold water, and let them boil until soft and broken.

Strain off the juice through a fine hair sien. or through a jelly bag, pressing, but not rub. bing down the fruit, or the sparkling clearness of the jelly will be spoilt. Add 1 lb . loaf sugar to each pint of juice, and boil it without the lid until it jellies on being tested on a plate. It can then be poured into jars and stored. It keeps some months without deteriorating.

Cranberry Sauce. A sauce which is specially good with turkey, though it may well be used with other poultry, is simply made by simmering a pint of cranberries in a gill of water until they are soft, and adding 3 oz . of white sugar and a glass of port wine. The liquid is then re-boiled, seasoned, and strained ready to use.

CRANE FLY. The larvae or grubs of the large, awkward, long-legged ty known familiarly as Daddy Long Legs are very destructive of all kinds of garden orops. These pests are, however, chiefly found in gardens which have been recently converted from grass or waste land, or where the grass and weeds have been a bundant the previous summer. Sods of turl buried in the ground will attract them. Whern the grubs are numerous an application of semirefined naphthalene at the rate of 2 to 21 oz per sq. yd. is worth a trial. The naphthalene should be worked into the soil, after which a thorough watering is advisable. This should not be used on seed beds just about to be sown. See illus. above.

CRANE'S BILL. This is a popular name given to the hardy geranium. This is quite a distinct plant from the geranium (really. pelargonium) used in suminer flower beds. See Geranium ; Pelargonium.

CRANK. This is a bent axis in any form of machinery, and is used as a driving or driven means of transmitting power by radial motion. To name but a few common forins, therc is the pedal crank of the bicycle, the

Crane Fly or Daddy Long Loge. A. Male. B. Pemale. C. Larva. D. Papa caso. 8oe below By dermiasion of Minta. os stationery OAtice and the
starting handle of a car, the crankshaft of any engine. In fact, any form of leverage working through a radial motion by means of an off-set arm becomes a crank.
CRANECASE. In its widest sense this term relates to the cavity in which works the crankshaft. and very often the camahaft, the timing geara and the oil pump of an internal counbuation engine auch as that employed in the motor car. This cavity is included between the sump at the lower part and the casting forming the upper part of the crankcase.

In many modern motor car engines this casting is integral with the cylinders and the flywheel housing, as well as with the upper part of the crankshaft bearings. The upper part of the crankcase and the parts with which it is associated form one of the largeat and most complicated components on a car. In aome oases the crankcasc is mase of aluminium and the cylinders form an independent casting bolted thereto. This method of construction does not, however, produce such a rigid engine.

The crankcase or cavity contains, in addition to the parts mentioned above, the following: magneto driving shaft, dynamo driving shaft, oil ducta or pipes, oil filter, and in certain cases the troughs for the dippers on the big.end bearinga.

The crankcase casting is provided with seatings for the electrical units, timing gear cover, fan bracket, water circulating pump, and other minor parta. It is also formed with bearer arms by means of which it may be bolted to the car frame, or with seatinga to which such arms may be secured.

In some engines the gear box is bolted up to the flywheel housing of to an intermediate casting or clutch casing. and the Hywheeel housing oarries bearinga or attach. ments for the clutch, brake. and accelerator jedal hearings.

When the crankcase is of aluminium, studa are alwaya firmily screwed into the metal for the aftachment of other parts. Set bolts are never used, as the sorewing in and out would dainage the aoft aluminium. Studs must never be allowed to work lonse, as the threarl in the hole would soon be dest roved.
All vil-retaining joints should be made with thick brow'n paper coated on butle sides with gold size. or with a suitable juinting compound. When the (:n-acting faces are roughly finished.

Crassula. Flower heads of the
or one of thens, such as the sump is made of flexible sheet metal a cork washer or gaaket may be used.
In motor cycle practice a crankcase is usually divided through the centre, i.e. verti. cally instead of longitudinally. In all other respects the principle is virtually the same, cxcept that the one-piece casting, meaning the cylinder and top half of crankcase in one. is not emploved See Gasket; Lubrication.

CRANKSHAFT. The crankshaft is one ot the oldest methods employed for mechanically converting power developed by a reciprocating motion into a rotary force, and as used in internal combustion engine practice differs only in accordance with the needs of the design of the engine. As commonly employod, there are the throws or cranks, according to the number of connecting rods and the main journals.

The crankshafts of modern internal combustion engines show considerable variety both in the number of cranks combincd in one shaft and in the brrangements of the cranks and main bearing journals.

In nearly all cases the crankshaft is designed to run in anti-friction bearings, which are of the split type formed of brass or phosphor bronze shclls, lined with white metal ; in fact. practically identical to the big-end bealing. The perfect rotary balance of a crankshaft ulways receives careful attention, because with this lies to a great oxtent the perfectly sinooth running of the engine. See Big-End: Internal Comburtion Engine; Motor Car.

CRAPE : A Dress Material. Crispness and a crinkled surface characterise all crapes and form the justification for the namc. In the manufacture of such fabrics the threads are twisted so much beforehand that when they aro woven they do not naturally lio straighi. and this feature is seen alike in wool. cotton and silk crajues
Black silk crapres used for mourning are inade more crisp by being treated with shellac, and as this is not a gum soluble in water it tends to remain. The stiffness of such crapes returns if the fabric after wetting is dried before the fire. Waterproof crape should be asked for. In wool or cotton crépes, as used for summer and indoor dress, the original character returns after washing. although cotton crapes should not be ironed. Siee Crêpe-de-Chinc : Mourning.

CRASE : A Linen. Originally a rough linen imported from Russia and used for kitchen towelling, crash has now a wider range of meaning. Coarsc fabrics of various collpositions sell under the name, including rough linen towelling, dress and household linens, unbleached or in fancy colours. See Linen.

CRASSULA. Plants of the genus crassula pupularly known as thick leaf, require greenhomme treatment. All the specien may be success. fully grown in a compost of two parts loam, one part leaf-mould, and a sprinkling of sand, with some broken brick ur mortar rubble. Propagation is by cuttings of the tops dibbled into sandy soil, under glass, which strike more readily if laid out to dry before being inserted They need a sunny, airy greenhouse and little water in winter. It is usual to shorten the shonts which have Howered in late sum. iner, and to re-pot in spring. The best species are : coccinea, scarlet, 18 in., a summer bloomer ; jasminea. white, I ft., spring bloomer; and actea, 1 ft., white, at its bost in September.

CRATE Crates are marle both of wicker size. whichithorbstheorsyon, and the drawing to the falls or levels of the path, and and of wond, and their main use is for holding goods that are sent away by rail or mad. China. cruckery, glass and similar wares are usually packed in crates for transportation Crates made of slata of wood are largely used for conveying pnultry, rabbite and other domeatic animals by rail, as they are for bicycles. perambulators and certain articles of furniture.

CRAWFISH. This crustacean is a species of rock lolister common round the British coast It is larger than the lobster and is conked in much the same way The Heah. however, is coamer and the llavour inferior though it is often substituted for lobster in salads It is totally difierent from the crayfish
CRAYFISE. The small Ireshwater crayfish found in the rivers of Great Britain is of a delicate flavour and is highly esteemed as an article of food. Quanti ties of crayfish hre imported into Great Britain from the Continent the home sup ply being limi ted They are usually boiled before being put on the market; where this has not been done they should be plunged in boiling fish stock for a bout 10 minutes.
Soup made with river crayfish is considered a great
delicacy A quart of fish stock will be
Crayosu. tue dencarety navoured
Crayosu. sue dencarely navoured required with 18 crayfish. Remove the gut from the centre fin of the tail of each, shell the fish, and pound the shells and half the tailmeat with 2 oz butter and 2 boned anchovies wiped frce from brine. Put this pounded mixture into a saucepin and atir it with a wooden sponon over the fire until it is hot ; add 2 oz . washed rice and fry the whole for 5 min . during which it must not be allowed to colour even slightly.

Add the fish stock and a small onion atuck with 2 cloves: allow these to simmer until the rice is soft. stirring frequently. Soak the soft part of a French roll in milk and add it before rubbing the soup through a hair sieve Reboil the soup, finur in gill crenm, 1 tea. spoonful lemon juice, and some seasoning. finally adding the remainder of the meat from the tatils, cut into dice. Serve the soup with cmūtons or sippets of hot crisp toast. See Mayonnaise.

CRAYON: How to Use. The variously coloured pencils made of chalk or pipeclay and used for drawing purposes are known as crayons. In addition to the use made of them by artista, etc., they form popular presents for children, especially when accompanied by uncoloured picture books.
Cheap crayons should not bo given to children. since they are apt to melt quickly in a warm hand and are a source of real danger if placed in the mouth. Crayon drawings made on paper which is not specially prepared for the purpose easily become sinudged. They may, however, be fixed by washing the paper with a strung solution of isinglass. When it is dry, the drawing may be made upon it, after which it shnuld be inverted and held horizontally over steam. The steam melts the
thus becomes fixed. This process may be repented saveral times while the drawing is being made the effect being increased on each occasion.
CRAZY PAVING. The name of crazy paving is applied to stone paths, compored of random or odd-shaped pieces roughly fitted tngether to preserve a generally straight line at the edges of the path. Crazy paving is not reat ricted tu paths. but has many applications as a pasing for courtyards, the surmund to the base of a sundial, and for terraces and other orna. mental features in the garden

Crazy Paving Fis. 1. Section of path snowng how the Hags are set in sand on a foundation of rubble and large stones to ensure proper drainage
The materials are often in any hollow places a few rough agricultural drain pipes widl prevent ponls of water forming on the pathway. In miany cases the drain pipes can be so disposed that the rain water is directed towarda the Hower bed or other Incation where it will be beneficial
The laying of the stoncs can next be com- obtainable from housebreakers, or rom a menced, and it is worth while to surt roughly stone quarry, while old paving stones are over the materials and assemble the pieces excellent for the purpuse when they are in groups according to size The stones vary available Thay generally arrive sumewhat in thickness. size and shape. Fur the edge of broken, which is no detriment, as the suc the path use the straighteat edge of the stone cess of the crazy paving depends upon and commence by laying a lied of asand upon irregularity. No two stones are alike in which to sot the stunos The atones are set form or size, but the whole must be so upon the sand by moving them abuut slightly arranged that the boundarics of the pavement and bedding them in using a truwel to maniare in regular lines. It is not sufficient to lay pulate the sand, and a heetle or heavy rammer the pieces of stone directly upon the ground to leat down the stone. Eivery atune must lie firmly without ien.
 dency to rocking or movement. wtherwise it will never settle. lay the the outer edges of the path first and then fill in the centre, but complete the whole width of the path as the work jiroceeds.

When finushed the path should present a level surlace. any irregularities in thicknese of atunes may be compensated by idding more and underneath to make up for any deficiency in thickness. The stones are sometimes set in cement mortar
a properly drained subsoil and a suit able lied for the stones are easential.
The proper method of constructing such $\Omega$ path or paved area is firat to marli out the site, using pegs and the garden line to define the bnun. daries. The turf and soft top soil are removed to a depth of at least 6 in., and more on a very light soil. The earth is well rolled or rammed, and broken brick, gravel or other ballast or hard core laid down and covered with a layer of finer but rough material, so as to provide drainage for rain wuter. Regard must be paid

Crazy Paving Fik. 2. Irregularly shaned flags worked Into a path and linking up divisions of a large garden. Fig. 3. Crazy naviny in a small town garden, the old stones torming an ideal background for Howers thronghout the year
2. R. Neal \& Sons, Wandsworth: 3. Humplirely \& Vera Joct
especially when it is deased to prevent the growth of grass and tlowerets be. tween the stones. In this case the cement mortar is laid upon the sand and the surface of the stones brushed over with cement slurry completely to fill all crevices The path should be washed later on. so that the natural colour of the atones is revealed.
An edging of brickwork forma a pleasing finish to a large area of crazy paving. An alternative method is to set larger stonew directly upon the grass. when a Japanese ot stepping-atone type of path is wantod To do this the turf is cut away to the shape of the slone, which is then bedded on sand laid directly upon the earth
A reasonabile estimate is that a ton of stone will cover anything between six and ten square yards of crazy paving. See Cement : Concrete: Path: Wall

CREAM: Its Food Value. Cream consists of the fatty globules of milk in which are contained the carbonaceous portion constituting the principal food value. It has heen found, on analysis, to contain 74.0 parts water, 2.5 protein, 18.5 fat. 4.5 carbohydrates, 5 ash. All the nutriment contained in cod-liver oil is contained in cream. and invalids and children for whom the former is recommended find in cream a perfect substitute which is much pleasanter to the palate. Consumptives benefit from a diet in which cream has a liberal part. and it is much given to other kinds of invalid.

Cream is separated from milk for commercial purpsses by mechanical separaturs. To separate it at home without mechanical aids, simply allow the milk to stand from 8 to 10 hours. The fatty glubules, which contain the cream, are lighter than the other constituents of the milk, and they thus rise to the surface, where they combine and are skimmed off. The milk should be fresh and immediately placed in a wide, shallow vessel and left th stand in an even temperature of about $52^{\circ} \mathrm{F}$. in summer and $60^{\circ}$ in winter.

Double cream is obtained by allowing the milk to stand for 24 hours before being skimmed. The vessel in which the milk is placed should on no account be covered so that the air is excluded, but with a piece of muslin in orter to protect from dust ot Hies.

Cream Jug. Antique ozamples in silver. 1. \& and 4. Lussed and piain jnge, somp. igte cteorze 1 end easly Ceorge II. 2. Ornamented with beading, clasaical period, late 18th cent. 5. Creamewer, dated 1801

Cream Bun. Plate of these lught cream pastries covered with coftee icing and crystallised fowers

Creain can be kept fresh lor two days if it is just brought to boiling-point without being alluwed actually to boil. If sugar is anded. it will keep in a cool place for about 36 hours. It can be obtarned in hermetically sealed tins, and in this form should keep for a considerable time. Once the tin is opened, however, the cream should be emptied into a basin or jug and used immediately

Whipped creain goes further and is used for many sweets. A little sugar, wine, or Havouring can be added before creant is whipped, if desired. The cream should be poured into a cold basin and whipped with an egg whisk in a cuol place or in a current of air. so that cold air can be incorporated into the cream to make it light and atiff. Care must be taken that it is not over-whipped. or it will turn into butter. As soon as the cream autheres to the whisk it has been sufficiently whipped.

In addition to its chief use for the vily substance that forms on milk, the word creain has several other meanings, all, however, derived from the prime one and all implying some form of excellence. It is used for cosmetics. such as face cream, and for certain mixtures for cleaning boots; also for various preparations in which chocolate is the inain ingredient, and for other sweetmeats. See Butter; Clotted Cream : lce : Nilk; Trifle, etc.

CREAM BUN. These cakes are also known as cream puffis. To make them, melt 2 oz . butter in a saucepan, adding half pint hot water, and let the two boil. Take the pan off the fire and beat in 4 oz . dried and sieved Hour. Add a few grains of salt and, with a worden spoon, beat the mixture briskly until all lumps have disappeared: then put the pan over a slow fire and stir the mixture until it can be rolled about without sticking. If overcooked the butter will noze out. and the panada, as the mixture ts termed, will be spoilt. When cooked let it cool, and beat in 2 whole eggs and 1 extra yolk, adding each egg separately and working it in. Add vanilla essence and castor sugar to taste.

To form the cakes use a forcing bag with a plain pipe, but if this
 courlesy of Spink \& Son, Lid.
is nut available use 2 deasertapronts, lurcing or shaping small round heaps of the mixture on to a greased baking sheet and leaving a space of 2 in between each cake. Bake them in a moderately slow uven for about 30 to 4.5 min When cooked they should be light, hollow. and biscuit-coloured.
When cold cut each cake open down one side, and fill in whipped sweetened cream The buns when culd arc cuated with chicolate or coffee icing and sprinkled with crystallised tlowers. See leing.

CREAM CHEESE. While must dairics have their own methods of making cream cheeses from either double cream, containing 50 per cent. of fat, or from thin creain, thickened with rennct hefore drainage takes place. the fullowing method is a simple one for making about six $i$ Ib cheeses from a quart of crean. The cream should be cooled to $65^{c} \mathrm{~F}$. and a drop of rennet, together with a little starter, should be added immediately the cream is cooled. This starter may be cither a pure culture of lactic acid bacteria used by most cheesemakers, or it may be a little clean sour milk. On no account should the cream be soured naturally, as the Havour depends on its freshness. The cream is then left for 8 to 12 hours before draining. Salt may be added at the same time as the rennet, one teaspoonful to a quart of cream being ample.

The cream is drained in fine longcloth spread over a wooden form, which is provided with a loose buard which can be weightod to press out superfluous moisture. The longcloth is thrown over the form and pressed down to the level of the table on which it atands and the cream then poured in to the depth of $1 \frac{1}{\mathrm{l}} \mathrm{in}$. covering the inner area of the forin. Drainage must be gentle at first, or the mesh of the cluth gets filled with cream. The cluth should be opened once after the first half-hour and scraped down, when the cream should be reweighted with a 14 lb . weight. The oream should be ready to mould in 3 or 4 hours. The cheese is filled into small moulds lined with parchment paper. A wooden knife should be used. On removal from the mould the separate cream cheeses are wrapped in muslin. See Cheese.

CREAM JELLY. Prepare half a pint of claret or raspberry jelly, using twice as much gelatine as usual, or, if preferred, use a l-pint packet of jelly, and prepare it as directed on the packet, but using only half the stated a mount of water. Put half a pint of gond cream into a basin, whisk it until it thickens, but not sufficiently to make it hang on the whisk. Then whisk it gradually int, the warm, but not hot jelly, adding any extra colouring or Havouring desired. Continue to whisk the whole gently until it is on the verge of setting, then pour it into a mould that has been rinsed out with cold water. Ieave it until it sets, then dip the mould into hot water and alip the jelly out on to a dish. It may be decurated by putting round the cream a border of chopped sweet jelly, of a contrasting coluur.

CREAM JUG. The carlicst cream jugs known to collectors are silver ones, having a bellied bottom and straight neck, no lip and simple bow handle. Thev arc sometimos found in sets of three small uncs and one somewhat larger. Early in the 18th century the short luw-bellied jug with a small lip and bow hendle came into use. These jugs stond on a ring foot, but soon they were made with three cast fect, and this type became popular. The body was decorated with chasing, and as other elaborations were intruduced the lip became an elongated spout, and for the bow a shaper handle was substituted. The three fect were replaced by a round foot and a short stem, as is seen in two of the illustrations.

Late in the 18th century, owing to the classical style of decoration in vogue, a less ornate pattern was again adopted. The foot and stem were left, but an oval helmet-shaped body came into fashion Severity of outline and restrained beaded or reeded ornnment were retained. but jugs with fuller bodies and short nesks were made. Another style is one in which the foot and part of the body are cut off. Many of these are graceful pieces of work, and many beautiful modern cream jugs are reproductions of 18 th century designs. Cream jugs are also obtainable in glass and in chinn to match services.

CREAM OF TARTAR. This is the common naine for the bi-tartrate of potassium. Two to six teaspoonfuls in orange marmalade is sometimes used as a purgative. The Inperial drink, a favourite household remedy for slight fever, may be male by adding $n$ teaspoonful of creum of tartar a little sugar. and a quarter of a lemon to a pint of boiling water. 'Ihis tends to keep the kidneys active.

CRECHE. A crèche is a daily boarding estahlishment for infants and young children under school age The standard varies according to the income of the parents who wish to have their children cared for during the hours they are unable to lonk after them.

The mother leaves her child or children at the creche early in the morning, and pays 2 d or 3d. per child. In many cases she alao brings the food it requires for the day. If an infant is breast-fed, arrangements are made for the mother to call in the dinner-hour The chil dren are cared for by the creche attendants, and frequently bathed and washed, superintended and fed until the muther or guardian calls for them at ahout 5 o'clock. They are given as much fresh air as possible, amused and trained in orderly ways Most large cities have crèches in their midst, and infornia tion about them can usually be oltained from the local infant welfare centic
CREDIT : The Legal Aspect. Credit is a matter of agreement. If a lady orders goods and makes no agreement that she is to have credit, the law implies that she is to pay for them on delivery. She should, of course, be allowed an opportunity to examine them before paying. If slie wants credit she nust agrec with the tradesman that she is to have it, and agree how long the credit is to be. Once it is agreed that credit shall be given, the seller of the goods cannot go back on it and demand cash on delivery ; neither can he demand payment before the period agreed upon has expired. Thus if the lady buys on the lat Jan, upon the terms of a nonth's oredit, she has until Feb. Ist in which to pay, and cannot be sued for the money until Feb. 2nd

The word credit is used by bankers for the money or other reserve which a person has in the bank. In bookkeeping the credit side of the account is the one where payments are entered See Accounts; Banking.

CREEPER. A term correctly applied to rigorous selfeclinging plants like ivy which are used to cover walls. It is applied to many climhing plants. See Canary Crecper : Clematis: Climbing I'lant: Wistaria, etc.

CREEPING JENNY. This is a good trailing plant and useful alike for window boxes. rockeries and hanging baskets. It thrives in shade and bears yellow llowers in summer. The golden-leaved variety, aurea, is attractive. It is easily propagated by detach. ing rooted pieces

CREEPING SAILOR. The common name of creeping sailor is given to Saxifraga sarmentosa, $n$ pretty creeping plant, which is also known as inother of thousands (q.v.). It may be grown in pots suspended in room, window or greenhouse.

CREMATION. When it is desired to liave a body cremated, the best course is to telephone or telegraph to one of the cremation companies, who will at once send a repre sentative or give instructions as to what steps should he taken I special form of application will be supplied, and this must be filled up and signed by an executor or a near relative of the deceased. Ansong other things the applicant must state that decensed had expressed no objection to being cremated, and whether any near relative of the deceased objects to the proposed ciemation: if so, on what grounds

Procedure and Regulations Two medica certificates are needed One is filled up by the medical man who attended the deceased in the last illness, and who has seen and identified the body. The recond certificate may only be given by a medical practitioner of not less than five years standing who holds one of certain specified appointnients, such as medical officer of health, police surgeon. physician or surgeon to a public general hospital containing not less than 50 beds, or has been appointed specially for the purpose. The registrar's certificate of death must also the produced for inspection by the medical referee of the cremation company When the medical referee of the cremation company is satisfied that all the requirements of the Act have been complied with, he authorises the superintendent of the crematorium to cremate the remains
Any form of religious service may he conducted before the actual incineration Friends may see the coflin placed in the chamber, but are not permitted to witness the burning The ashes are placed in an urn, which may be deposited in a chapel or buried in a grave or handed over to the fiends.

The following is a list of the crematoria in Great Britain, with the addresses to which application sliould lee mande

## See l)eath: Funeral

CREME DE MENTHE. This is a flea. sant and wholesome liqucur made from peppermint It is of light green colour, and

Creeping Jenny. Leaves and goluen dowers of tuis spreading, trailing plant
the best brands are highly matcomed an digestives It should be served after luncheon or dinner in liqueur glasses A lavourite methor, eapecially in hot weather, is to serve it trapué, i.c. with crushed ice, when it should be drunk through a straw

Crème de Menthe Square. Take 1 lb of granulated sugar, I teaspoonful peppermint essence, I gill water, I sheet gelatine, and a little gicen vegetable colouring Dissolve the gelatine in half the water in a saucepan, and boil it for 2 or 3 min . Place the sugar with the remainder of the water in another saucepan, and bring it slowly to the boil Take it off the fire, and when it is slightly cool add the dissolved gelatine, stirring all the time

Then add the peppermint essence and vegetable colouring to taste After it has atood for $10-15-\mathrm{min}$., strain it into a llat tin that has been rinsed out with water When quite cold it may be unmoulded by dipping the tin into a basin of warm water Cut the mixture into rounds or spuares, or any other shape desired, and roll the picces in icing sugar. Leave them in the sugar lor a day or two, then shake it off, and pack the sweets in boxes between layers of waxed pajer,
CREOSOTE. An oily and transparent liquid with a strong penetrating odour, creosote is obtained by lieating wood or coal tar, and has a strong antiseptic action: it is less caustic than carbolic acid and is very much less poisonous
Apart from its use in medicine for certain cases of indigestion and for treatino painful teeth, it is employed for croosoting timber, and is of value in the household and garden in preventing wood from rotting Fences are preserved from decay by painting them with creosote, which penetrates the wond and keeps away insects. In the building ol pergolas or garden houses, those portions of the timber which are to be buried in the ground should be treated with creosote Inside the house. plain furniture and lloors can also be so protected, but the penetrating smell is against its use for this purpose. A good disinfectant powder is obtained by mixing one part of creosote with four parts of slakied lime See Disinfectant.

CREPE-DE-CHINE. Originally made in China and imitated in France, crépe-de-Chinc is now produced in all the silk weaving centres. Its characteristic appearance arises from the use of hard-twisted silk which is woven without removal of the natural gum that forms ahout a third of the weight of raw silk This gum is removed after weaving and the threads exhibit a new fullncss and lustre The cloth is dyed after weaving

What are called schappe crỏpes-de-Chine are made wholly or in part of spunsilk and are generally firmer and more clothy than those made from raw silk In addition to the self-coloured fabrics selling under this name there are striped sorts. largely of Englisli make. especially suitable for shirt-hlouses and washing dresses This is onc of the most suitable silks for wear next the skin, and can be ensily Inundered at home in a lather of majp Hakes and hot water, allowed to grow tepid before using. Squeeze and knead the garments gently in the lather, rubbing only when it is absolutely necessary Wring them thoroughly, then rinse them into two howls of warm and one of cold water, adding a tahlespoonful of vinegar to the lust. In the case of white crope-de- Chine, n little hlue may te substituted for the vinegar

Coloured cripe-de-Chine should be ironed as anon as possible after washing, othemvise the colours may bun. Ironing is best done by Inying the material right side $1 p$ on an ironingboard or table smoothing it out, and covering it with a piece of muslin When nearly dry finish ironing on the garment itself

CRESOL. Often known also as oresylic acid. this is a light brown liquid which smells like tar It is a disinfentant. and is employed to make liquor creas) saponatus, which resembles lysol and is used in the same way In whooping-cough the frequency of the paroxyrms may sometimes be leasened by impregnating the air with vaporised cresol This can be done by heating a large spoon in the fire and prouring in a teaspounful of creal or the drug may be put in the lid of a tin which is fixed over a nightlight Vaporisers may also be brought lor this purpose. Cresol is round in must of the proprietary disinfectants on the market See Disinfectant.

CRESS. The term oress is popularly applied both to watereress and the cress which is eaten with tho loung leaves of the hardy annual inustard plant.

Mustard and cresa grow very easily and rapully, so that a conatant supply is always obtainable for small salad. It is a mistake to plant both at the same time, as the cress grows more slowly than mustard, and should be given a three days' start. See Salad.

CResting : On Furniture. This term is used for any ornamental detail aurmounting a piece of furniture and reaching right acmes from side to side It refers (1) a decorative addition only, not to a constructional part. Cresting may be described as a peiforated, carven and pilded, or silvered ornament superimpneed above the top moulding, such as is found on lacquer cabinets of the late 17th century In a chair a creat rail refers to a top rail which has sume ornamental character. Chairs of the time of Charles II and William and Mary have decorative crest rails.

CRFINISM. Ferbleness of mind is one of the symptoms of cretinism, a cundition originating at birth or developing at any time up to puberty, tugether with a large and perhaps protruding tongue, poor development of hair. awelling of the abdomen, or dwarfing of the body. The diseaser is due to lack of function of the thyroid gland, which is aituated in the neck junt below the Adam's apple.
Treatment consists in giving the thyroid extract to make good the deficiency from which the patient suffers, but it should only be undertaken by a dicetor

Under this treatment rapid increase in height may take place, perhaps 5 or 6 in . in as many months. Early cases receiving prompt thoriugh treatment may grow up into apparently normal individuals, though it may be neceasary to continue the treatment at intervals throughnut lifa.

CRETONNE. This cotton fabric is unglazed. and is lonmed in several widths, 31 in , 36 in ., and 50 in . It is durable and washable and its wide range of patterns and colourings and its soft appearance renders it suitable for curtains and loose covers for furniture, and upholstery. When buying it for furnishing purposes care should be exercised in the choice of the deaign in order that it may harmonive both in colour and style of pattern with the furniture and decoration of the rom. These cretonnes can be obtained in Jacobean designs, in old English flower designs, in bold geometrical patterns. or sprigged with Victorian pusies.
As tu colour, it should be remembered that deep tonee, such as orange or red, are more expensive to produce, and that falrics in these colourings must be of good quality to obtain pleasing effeots Bright culours in cheap dyes are crude.

When choosing a pattern remember that a large pattern is more costly to make up because the design must be matched in joining the material, thus occasioning mure waste than when the pattern is small. Buy rather more material for upholstery purposes than the net quantity obtained by measurement. When
making up cretonne into lonse covers take measurements and a careful plan of each piece of furniture on hand before attempting to cut the material. Where the widest part of the furniture exceeds the width of the material an oxtenaion, or piece to be added by a seam. should be placed on each side, and not on one side only

In laundering cretonne, pure curd siap, or soap not containing caustic soda, should be employed: bran-water should be added to the water the latter being tepid Cretonne should be starched in boiling-water-starch thinned down. i.e. 3 pints of water to I pint of starch. Covers for furniture can lee dry cleaned by brushing over them a thick paste made by starch and cold water See Cuver: Curtain: Upholstery

CRIBBAGE. This is a card game for iwn, three, or four persons. but it is most commonly played by two persons only, and the two-handed game is the one that is here described. There are three varieties of cribbage, the five. six, and seven card game, the latter, huwever being seldum played. The game is 61 121, or 181 points up respectively. and a special cribbage board is generally used for scoring purposes.
The full pack of 52 rards is used, and players cut for deal, the one who cuts the lowest card dealing. Ace counts as the lowest card. The cards are dealt one at a time, until five are dealt to each player, and the pack is then placed batween the players. Each rhouses two cards from his hand, which he places face downwards on the table to form the crib, a hand which belongs to each dealer in turn As this crib gives a alight advantage to the original clealer. his opponent scores three points or holes, known as three for last to equalise the advantage.
When the cards have been thrown out for the crib the non-dealer cuts the pack and the draler takes the top card of the bottom half of the cut and turns it up. This card is known as the turn-up, and is used by buth players for scoring purposes. If the card happens to be a knave the dealer scores two points, known as two for his heels.
The scoring during the play is as follows, the non-dealer leading the first card. Two points are sconed for a pair: that is, if one player puts down a card, say, a three, and his oppunent plays a three. the latter acores twn for a pair. If the player can follow again with another three, he scoros six for a pairroyal, and if his opponent is able to place down the fourth three. he scores 12 for a double pair-myal.

Three or more cards of any suit in numerical succession, as, for example, the three of diamonds, the four of hearts, and five of epades, count one for each card to the last player. Thus a player who completes a run of three counts three points. The run need not be in rogular order. Thus in the example given the four might be played, then the five, and lastly the three. If the next player can play a two or a six be scores four points for a run of four, and 80 on.
When a player plays a card which makea with the cards already expused a total of 15 pips, he scores two points, 15 two. Thus if a player plays a nine and his opponent a six the latter scores two points. Three or more cards may make up the 15. A score of 15 two und a run may be scored by the same card.

When the total of the pips on the cards approach 31, the player whose turn it is to put down a card may find that any of the cards in his hand brings the total over 31. In that case he says, "Go," and his opponent has the right of play. If the latter alau finds his cards are too high, the player of the last card scores one point for last. If either player can make the total exactly 31 he scores two points. In counting pips on the cards the knave, queen
and king count as ten. When both players "Gu" or the exact total of 31 is made, the hand terminates, and the two players, beginning with the non-dealer, show their hands and count them.

In this final count the turn up card is also reckoned as part of cach player's hand and also as part of the crib. The hands are counted for each 15 they contain, the points being reckoned for each 15 as in play. Every separate combination possible is counted. Thus a king and three fives in a hand count as eight points for 15 's, since four distinct 15 's may be made. Any pairs count as two points, any three cards alike as three fives, six points, any four 12 points. independently of the fact that these cards may already have been counted for 15's. Thus three fives count two points for 15 's and six points for a pair royal A run of three, four or five counts three, four or five points There may be three cards in a sequence and a fourth card which is a duplicate of one of the sequence cards. In that, case a double sequence is counted, that is six points, and two points for the prir. Similarly with four cards and the fifth as duplicate Three of the cards may form $n$ requence, and the remaining two be duplicates of one card, in which case a treble run of three can be scored: with six points for n pair royal.

When the three cards held by the player are all ol one suit be scores three points for a flush, and if the turn-up is also of the same suit, four points If a player holds a knave of the same suit as the turn-up, he acores an extra point known as one for his nob The dealer scores his hand after his opponent has done so, and then his crib in the above manner A flush does not count in crib unless the turn-up is also nt the same suit, and then counts five points A tlush counts in addition to any other point also scored. In throwing out cards for crib a player naturally throws from his hand such cards as are likely to be productive of scoring if it is his own crib, and non-productive if his opponent's crib.
CRICE. Sudden painful stifiness, occurring in the neck or back, is known as a crick, and is probably due to muscular spasm, though it is also suggested that it may mean rupture of a few fibres of a ligament or muscle. The treatment is gentle massage with the tips of the fingers, using warn oil, a liniment, or the following: nethyl salicylate 1 diam ; menthol 1 dram ; lanolin 3 drams: vaseline to 1 oz

CRICKOT. The cricket usually shelters around the kitchen fireplace, often excavating burrows in the mortar between the bricks; these may be made untenable by injecting carbolic acid with a fine syringe. It is a very thirsty creature : and a plate of water to which a few drops of formaldehyde has been added will kill many. It feeds on all sorts of sciaps and fragmente of lood that have been left accessible to it: a piece of bread covered with the phosphor-paste sold for

Common Crietret of
the Areside the destruction of cock. roaches will be consumed readily, with fatal results. Any of the remedies suggested under cockroach may also be tried. Crickets especially favour the large open fire. places often found in old houses.

CRICKJT. The devotee of this game, which is also played by women and girls, usually provides himself or herself with a bat, and a pair of pads to protect the legs In addition most players wear gloves to protect the knuckles and the back of the hand, and men wear boots of a special kind. The pads
and gloves can be bought in șizes, to suit the needs of the particular individual, from any sporting outfitter

The Cricket Bat. Undoubtedly the best thing to do when buying a bat is to go to a firm of repute and take the bat which suits, even if the price be the highest In taking up sereral bats, one after the other it will be found that some do not seen to balance well. some seem too heavy others too light But in nine cases out of ten one of them will feel as if it were an old friend. If on examination it seems perfect in every way, this is the best bat to take

Many batsinen liave a great objection to knots, and if there are any near the handle it is always safest to discard the bat Some hatsmen prefer a narrow grain in the wood others like a wide grain There is no royal road to success in choosing a bat, and despite their experience and skill the greatest of batsmen will occasionally find that, when they have hought their hat, it will not drive as well as a proper bat ought to do. But anyone whon has the right instinct, a little conmon sense, and knows what he wants will very seldom make a mistake

## Preservation by Oiling

Not so very many years ago cricketers who bought a new bat treated it almost with reverence. They did not think of using it until it had been well viled for a long time, and they oiled every part of it, except the handle and splico To-day good batsmen often use a loat which has just come from the maker or a sliop, and it is claimed that by a new process in the manufacture bats are hardened sufficiently for immediate use. Nevertheless, it is certain that no wood of any kind has ever heen discovered which does not deteriorate if proper attention is not paid to it. Hence batsmen, or most of them, still look carefully aftel their bats when they are not in use, and more especially during the winter montlis.

The usual way of oiling to-day is to spread linseed oil on the surface of the front of the blade with a bruslı such as is used in oil painting, from the bottom about twelve inches upwards. This is done about onee a month, and then the bat is stored upright, in a place which is neither damp nor too highly heated. The theory is that the oil penetrates right through the bat, and that thercfore there is no need to oil the back part. If in wet weather the bat gets very dirty, and the owner does not like its appearance, a little fine sandpaper before oiling will do all that is necessary.

Cricket Boots. The most expensive kind of cricket boot is made of white buckskin, but in order to turn out a smart-looking boot at a cheap price, various imitations classed as mock buck are used. There is little to dis. tinguish the real article from the imitation when made up, but most of the latter quickly stretch out of shape and wear into holes. It is better, therefore, to buy good canvas boots, as they are usually more satisfactory in wear and appearance than the mock buck.

As comfort is so essential, the seams on the inside of the boot must not be bumpy or rucked. A chrome sole usually gives longer service than a bark-tanned leather sole, and it is waterproof ; but it tends to draw the feet, and persons with hot or perspiring fect should a void chrome-soled footwear.
Cricket boots are made with and without heels. It is claimed that the heelless variety allows greater foot-flex, but this is really a matter of opinion. The cheapest and most effective cleaning material is pipeclay. In cleaning the boots should not be made too "et. This has a tendency to cause the uppers to shrink if made of canvas, and in the case of buckskin is liable to render the uppers hard and brittle.

CRINOLINE. Otiginally applied to the stiffening of horsehair and cotton or linen threads used to expand women's skirts, the word came to include the steel and whalebone boups employed for the same purpose

Crinoline used for women's hats was manu lactured from horsehair, but now artilicia! silk is largely used for this purpose

## Crochet Work: IN Varied Styles

## Simple, Double, Filet and Picot Stitches Described

For the application of this work readers should consult such entrics as Luncheon Set; Tablecloth. Associated articles are Bead; Embroidery; Lace. See also Bell Gauge

First known as Shepherd's Knitting, crochet derives its name from the French word croc, meaning honk, as it is performed with a hook of steel for fine work and bone for coarser work The first stitch is chain-stitch, generally given in directions as the foundation chain, and all crochet work must have a foundation chain.

The first loop is made with the fingers, thus: Hold the end of the thread with the thumb and forelinger of the left hand, and with the right hand pass the main thread over the end to form a loop, holding both down under the left thumb. Insert the crochet hook from right to left through this loop, and draw the thread through. Draw the loop up close, when the first chain will be made. *Pass the thread round the hook, and draw it through the chain-stitch on the hook, then repeat from * for succession of chainstitches, Fig. 1.
Single crochet or slipstitch (Fig. 2) is the same stitch under two names. It is sometimes used to join one stitch to another, such as at the end of $n$ round, when the last stitch is slipstitched to the first to join : sometimes it is em. ployed to get from one position to anot her without breaking off the cotton and restarting. To make this stitch, simply put the hook in the stitch and draw the cotton through the stitch and the loop on the hook in one action.

This stitch is employed in every form of crochet, from the finest Irish lace (where it forms a length of chain into a picot) to big garments. When working the latter in rounds instead of rows, a slipatitch joins the last stitch to the first

## Double Crochet.

 1)ouble crochet is a very useful stitch, and there are two varieties, ribbed and flat, both worked in the same manner, but the hook is placed differently at the beginning. For rihbed double crochet (Fig. 3) put the hook in the back loop of the two seen at the top of the stitch after working one row (in the first row it just goes through the chain) cotton over hook, and
 draw the wool through. wool over

Crochet. Figs. 1-7. How some of the principal stitches are made
both 100 ps at the top of the stitch, as shown in Fig 4 tor flat doulile crochet

Double treb!e (Fig 7) is similar to treble. but the cotton is put twice round the hook at the beginning. then all the loops workel off by twos Sometines long treble is olitained when the cotion is taken round the hook three and four times. but the number is generally given in the directions

word worked not repented
which part to repent.

Picot (Fig 10) is a little loop ol chain stitches formed into $n$ ring with a slipstitch and forms the background of 1rish clochet It uanally conaists of 6 chain, and slipstitch into the 5 th chain from the hook to form $\pi$ nicot A single picot loop is mater thus $\dot{7}$ chain slipstitch into 5 th chain Iroin hook 2 chanin then 1 double crochet on the founda tion to lasten down the picot loop A wulute picot tonp has 2 picots ol 5 chain with 2chain afterench
Two tormis ol cro. chet buttons are shown in the illustra. tion The materials required for making the barrel button are some ordinary crochet cotton (No. 24) and a No 5 book.

Kegin with 14 chain stitehes and work the first row as fo'lows : Misa one chain. 13 double crochet and turn with one chain For the 2nd row work 1 double crochet in

Lacets and bars (Fig 8) are used chietly to form a background Sometimes there is a row of laceta, then a row of hars ench bar spanning over a laret A lacet is 3 chain, miss 2 stitches. I douhle crochet in next stitch, 3 chain misa 2 stitches 1 treble in next atitch A har is 5 chain miss 5 stitches, 1 treble on next stitch When it aprans over a lacet it is necessary to miss the 3 chain, 1 douhle crochet, and 3 chain, and put the trehle on the treble at end of lacet. Lacets and hars are often used alternatoly along the row forming a pretty background.

Filet Crochet. Filet crochet (Fig 0) consista of groups of trehles and open apaces 'The spares ure made thus: *2 chain, miss 2 atitches, I treble on the next stitch. and reppeat from * for as many spaces as required. Where a group of treble is given, 1 treble is put into each stitch conser:utively along the row whether that atitch be a chain or treble. and these groups form the solid part of the design. the spaces being the background
Note that the treble finishing the last apace before a group is not counted in the group of trebles. because it is already counted in the last space, and if counted twice the symmetry of the design is spoiled. The actual number of trehles should be divisible hy 3. hesides the one at begonning of the group which finishes the last space or lacet, as the case may be
When working the first row of filet crochet. the first treble is put into the 8 th chain from hook to form the first space. this making 2 chain for the foundetion, 3 chain for the treble, and 2 chain for the top of the space. If the work has a treble border, then the row is turned with 3 chain, and this stands for the first treble of the following row. The treble over which this chain stands is not worked into, and when the end of $a$ row is reached always work the last stitch into the top of the 3 chain which is at beginning of previous row If there is a apace at end of row instcad. then work intothe third chain When there are directions in brackets, this portion is always worked the number of times stated immediately after the brackets. 'lake note of the

Crochet buttons made accordlag to
instructions given in tnis article
instructions given in this article
each stitch to end, but do not work into the one turning chain. The 3 rd row consists of 2 double crochet in the first stitch, and I double erochet in each of the next 12 stitches For the 4 th row do 2 double crochet in the first stitch and I douhle crochet in each of the next 13 stitches and make the foth row 1 double crorhat in ench of first 4 donble crochet, 2 double crochet in next stitch 1 double crochet in each of four more stitches, 2 double crochet in the next double crochet, and I double crochet in each of the last five double crochet The (ith and 7 th rows consist of 1 douhle crochet in each atitch, while the 8th and 9th rowa represent 2 doublc crochet in first atitch, and 1 double crochet in cacli atitch to end
The IOth row should be * I louble crochet in ench of fire double crochet 2 double crochet in sixthatitch; then repeat from * once, and work I double crochet in each remaining stitch Let the IIth row consist of 1 double crochet in each stitch, and for the 12 th row do * if double crochet, miss the seventh: then repeat from * once and work I douhle crochet in each stitch to end For the 13th and 14 th rows, miss first stitch, I double crochet in each stitch to end For the 15 th and 1 Gith rows work 1 double crochet in earh stitch and work the 1 ith row ns follows: * 4 double crochet,

larder use

CROCKERY: Its Repair. It is always easier to repair crockery if the job is taken in hand at once, as the fracture is then quite clean. There are various methode, but the simplest is to stick the parts together with one or other of the numerous patent adhesives on the market
The usual method employed is to coat the edges with the adhesive and press the parta together, holding thein in contact while the glue sets, or blucking thein up, or strapping the parts together with bands of linen or paper, which are subsequently removod when the cement has set firm
This method will generally keep the parts in contact, although it seldom results in a thoroughly satisfactory job. Fither the joints give when the article is put into service, or the thin film of glue becomes conspicuous by the coating of dust that always accumulates along the line of fracture.

When restoring a valued piece that has broken into many fragments, patience must be exercised and only two pieces joined together at a time, allowing the joints to set
hard before attempting to complete the whole piece of work. If a few tiny parts are missing they can olten be moulded in fine plaster of Paris made into a cement with liquid glue and just sufficient warm water to make the material intu a workable paste. When thoroughly dry it can be smonthed with sandpapier, and coloured to match the original work
The Use of Rivets. The most effective way of re. pairing cruckery so that it can be put into evcryday use is by riveting. For this ןiurpose a drill stock specially devised for such work is indispensable, and the gencral appearance is shown in Fig. 1. Such drills are made with a diamond joint, and are far more effective thinn using $a$ hard steel drill and diamond dust or carborundum as all abrasive. To use the drill, the spindle is twisted so that the cord is wound round the stem; when the crossbar is presser downwards the cord untwists and rotates the drill. The hand is then raised quickly and the momentum of the drill again winds the cord around the stem, so that by rugular and repeated movements of the crossbar the drill can be kept in motion. The drill is worked with the right hand, while the left hand holds the piece of erockery.

Crockery. Fis. 1. Drill stock employed lor making rivet boles in crockery and chins

Courtesy of R. Melluish de Co.. Ltd. ties, e.g. Sir IValter Scott, growing in llower-pots for the greenhousc.

The corms of autumn and winter Ylowering crocuscs are planted in July and August: they are usually planted in the rock garden among low-growing tufted plants which prevent
the bottom of the hole, otherwise they will never br flat on the surface of the china. When all is in orter the rivet is bedded ints the holes with a little plaster of Paris made into a paste with water and a trace of glue A typical repair is shown in lig. 3
CROCUS. There are three classes of crocusspring, autumn and winter Ilnwering: all are hardy. The crocus root is technic ally known as a corm. Spring crucuses are planted il) August or September. 2 in . deep: they lonk best in grass and flourish beneath large, leaf-losing trees They also do well in heds and Lorders, and may be left undisturbed indelinitely. There are several handsome large-flowered named varie-

## Croquet and the Croquet Lawn

The Rules of an Attractive Outdoor Gama
Other articles on outdoor games played in the home garden which appear in this Encyclopedia are Badminion; Bowls; Clocis Galf; Lawn Tennis

This outdoor game for four players can be
played on any level lawn that is of sufficient played on any level lawn that is of sufficient dimensions. The standard size is 35 yd . in
length by 28 yd . in width, hut a lesser space can be utilised, provided its length and breadth can be utilised, provided its length and breadth
are in the proportion of 5 to 4 . The boundarics are marked with white lines.
The implements required are mallets, one for cach player, and four balls that are coloured red, black, blue, and yellow, the mallets being usually marked on the handles to correspond. The balls should be $3 \delta_{k}^{6} \mathrm{in}$. in diameter, and weigh about 16 oz ., 164 being the maximum. Stuck into the ground are six hoops and two posts. Each hoop should stand 12 in. out of the ground and be not more than 4 in . in width across the inside.

Each of the four outer hoops are 7 yd . from the side boundary and 7 from the end of the ground nearest to then. The centre hoops are 7 yd . from each other and 14 from the houndarics on either side. The posts or pegs are in line with the centre hoops, each being 7 yd . from the boundary, and in line acmss the ground with the side hoops. The posts should he 18 in . high and $1 \frac{d}{d} \mathrm{in}$. in diameter.

Sonnetimes, however, the gane is played on it ground sct out somewhat difierently on a plan known as No. 2 or Willis setting. In this there is only one peg, not two, this being placed in the centre of the ground with the central hoops ench 7 yd. from it in a line parallel with the side hoops.
The game is played by two players in partnership against the other two. The pair using the blue and black balls always play those using the red and yellow ones. A game consista in making the balls traverse the coursc twice. once in each direction, and the pair who finish first win, i.e. both must finish before the second of their opponents does so. All the hoops must be passed through in regular order once on the outward and once on the homeward journcy, and the posts must be struck by the balls once each, one when the player is half way round and the other for the finish. The posts may be hit from any direc-

Crocus. Groun of sprink-towering crocus, whlte
the hlooms being spuilt by sail splashed up in wet weather. They make charming plants for the unheated greenhousc if grown in pots: this is really the hest way to grow the winter crocuses. Of those that bloom in autumn some of the hest are

Aaturicns, Illac-manve; hadriatienw, white: pulehelthes, lavender-blue: sativis, violet: ; and speciosus. lavender-blue. Bome of the chief whiner-flowering wochseg are chryanthus. yellow ; Inperati, palr tommasinianus, pale lavender.

Crockery. Fig. 2. Diagrams illustrating a chins rivet bent for use and the melbod by whioh it is
iuserted in the drilled boles

## Commence

 by moisten ing the drill print with oil, and then drill n slanting hole down wards into the china and about $\frac{1}{4}$ it. awny froon the edge of the fracture. The rivets are simply bent to shape from soft brass wire ahout $x_{6}$ in. diameter, a pair of flat-nosed pliers lieing handy for this work. The shape of the rivet when made is shown in Fig. 2. Some judgement is needed in placing the rivets so that the fewest number accomplish the required result. On plates and dishes the rivets are best applied to the back, where they are out of sight, but on a jug with a broken spout hero is littls chance to do more than ineert sonie of the rivets on the inside and the remainder on the outside.To insert a rivet, take care to flatten the inner surface of the wire a little so lhat it bears more effectively on the china, and sce that the legs are not too long; they should not quite reach

Crockery. Fir. 3. Bedroom ewer with side and lip mended witt riscts
tion, but the hoops can only bo passed through from the front. The players play in turn, lolowing an opponent. The usual order is blue, red, black, yellow. The game can alsa he played by two parsons, one against the other. In that case each takes two balls, playing them alternately, ns- would be the case if there were four players.

Such is the older and popular wry ol playing croquet, but many play according to rules introduced in 1914. The "either ball" law provides that as regards the single game, when it is the turn of a player to play, he may play with either hall. blue or black, or red or yellow, as the case maty be. In doubles, either player miny play the turn. Under another law, passed in 1923, the partuers suceed each other in playing any turn after each point is minde.

The game is started from balk. i.e a space behind the first hoop on the left-hand side of the ground. The tivo hoops in front of him must be taken by each player in turn. after which he crosses the ground and takes the two on the other side, but in the reverse order to the lirst two. He then makes for one and then the other of the centre hoops, after which he strikes the turning peg, which is at the end of the ground fartheat away from balk, with the ball.

The reverse journey is then bagun. The two hoops he took first arc again taken, but in the other direction, as are the two on the ot her side of the ground. He then goes to the centre, and this time, leaving the turning leg, passes in turn through the tivo hoops and finally drives his ball against the winning peg, which is the one near the balk. If, in hitting, a player drives an opponent's ball through the hoop which that player has next to negotiate, the stroke counts, and when his turn comes the opponent jplays for the next one. A player can also drive a partner's ball through a hoolp, the score counting if the hoop is the next in order of play.
The game begins with the first player diving off frombalk. If he suecceds in passing
bis ball through the first hoop he has another shot and can continue playing until he fails to score a hoop The game, however, can hardly begin in earnest until all the balls are played, so we will assume this has been done The first player then plays again. He can either drive his ball through $\Omega$ hoop or hit one of the other balls with it. In vither case, provided with the subsequent croquet strokic neither his own ball nor the ball from which croquet is being taken has been driven out of the ground, he is allowed another stroke.

If he has hit another ball this atroke must take the form of a croquet To croquet he places his own ball against the one he has struck, and hits the former. Having thus moved both, he can play his ball again and again drive it through a boop or hit another ball with it, and be can continue this as long as he is succeasful, with the important proviso that he must not croquet off the same ball twice, unless in the meantime the player has passed his own bal! through a hoop next in order or sconed a peg.

The object of the game is thereforc very much as in biliards, to use the other balls as means of scoring, and to be careful to finish with onc's upponents' balls, especially that of the opponent who will play next, in dis advantageous positions This is far more important than an extra score Formerly this was often done by wiring the ball of the opponent who plays next, i.e. leaving it lying close against a hoop on the side away from the three other balls, the hoop being thus between the next player and his objective This made a good shot almost impossible Early in the 20th century an alteration was made in the laws, and now a player whose ball is wired can remove it and play from balk, provided it was put there by an adversary

Mallets and Balls. Croquet maliets consist of two parts, the shaft and the head. For the shaft, hichory is a useful and popular wood, but some are made of malacca cane, and a few of ash and elm. The heads are made of boxwood or lignum vitae, the former having the advantage of being less brittle than the latter. Many mallets are furnished with grips to prevent the hands from slipping. These may be formed by binding the shaft with string, or fitting it with cork or rubber. Of these, cork is perhaps the best, although, like rubber, it lessens slightly the force of the stroke.

In other mallets the player relies for his grip upon the shape of the handle. Such may be octagonal, or oval, or round. The octagonal, with grooves down the side, is for most players the most satisfactory. The oval handle is

II Measurements in Yards III

unsuitable for centre play, and the round one cannot be recommended. The choice of a mallet depends very much upon the style of play adopted For side play a light implement is desirable, but for centre play a heavier one The former should not weigh more than 3 lb ; the latter may well weigh $\frac{1}{2} \mathrm{lb}$ more The length of the shaft should be about 33 in . The head should measure 9 in . and have a diameter of 3 in But whatever the style, a mallet should answer to the following requirements. It must be well balanced and the whaft nust be straight The liole in which the shaft fits into the head must be accurately bored, and the shaft must be set into the head with the grain of the wood at right angles to the head.

Formerly croquet balls were marle of wood. and were, therefore, linble to oliip, but they are now made of composition, and are thus free from that defect
Where handicapping is carried out in croquet tournaments, it is done by means of bisques. i.e extra turns which a plager can take at the conclusion of his ordinary turn The weakent players are handicapped at $1 \$$ bisques and the strongest at -3

The game is controlled by the Croquet Association, 4, Southampton Row, London, W C., and under its rules tournaments are held all over the country throughout the summer. The croquet open championships are played at Roehampton, ncar London, every yenr in July

CROQUETTE. Scraps of meat, fish or poultry can be utiiised to advantage in making croquettes, being minced and blended with various Havourings and some rich thick sauce A litile cooked ham or bacon is always a satisfactory addition Should the meat be very dark, egg and crumb the croquettes twice.
To use the remains of a cold chicken, remore the skin and bone and chnpr up enough of the flesh to make 3 lb . Mclt 2 oz . of butter in a saucepan over the fire, stir in 1 cz . of flour, and then add $\frac{1}{2}$ pint of chicken stock or milk. Stir this sauce over a slow heat until it thickens, then let it cool slighily before adding the clicken, $\ddagger \mathrm{lb}$. of cooked and chopped ham, and a teaspoonful of grated lemon rind
Mix all well, season the mixture carefully with salt, pepper, and nutmeg, and if it is ton dry add a little more stock or milk. Turn the whole on to a plate, let it cool, and then mark it into even-sized divisions, forming each into a neat shape. Rull the croquettes in Hour, brush them over with beaten egg, and cover them with breadcrumbs. Put 4 oz of fat in u frying-pan over the fire, and when a blue smoke rises from it put in the croquettes, two or three
at a time, and fry them a golden brown. Drain them on paprr, and serve garnished with Iried parsley See Crab.
CROSSBANDING. In lurniture design this is a method ol using veneered strips at the outer boundaries of the panels. It is done so that the grain rins at right angles to the constructional edges

CROSS CUT SAW. This type of saw is employed for cutting across a log or large piece of timber, or for similar heavy work
The one-man crors cut saw is adapted for single-handed use, although both hands are generally needed to push the saw Thev aro

Cross Cut Baw. Bow a two-man cross cut saw is used for catting trec trunk.
made from 3 ft to 5 ft in length, and most have a supplementary handle that can be bulted to the end of the saw blade, and are then usable by two men. The two-man cross cut saw is only usahle by two operators, each grasping an end of the saw and working in unison. Such saws are made from 4 ft . to 7 ft . in length; the handles are either bolted to the saw blade or fixed into sockets riveted to the ends of the blade
The tonth shape varies according to the nature of the work, but for general use the great American type of tooth is the best, advantages being that the set can be put on the small or peg teeth: the deep slots give freedom for the chips, and prevent troubles which would otherwise be caused by local distortion of the blade.
The teeth are sharpened and set in the usual way. In using ruch raws a regular, steady stroke is essential, about 20 to 25 strokes per minute being all that is needed. When not in use wipe the blade with a greasy rag, and hang the eaw up so that the blade does not get bent or twistell. See Saw

CROSS-EYE. This is a condition of squint or strabismus, in which both cyes are not focussed on the point looked nt. If something small is held in front of the patient's evea, say, at about 18 in., it may he readily seen that the gaze of one eye is not dirccted towards the object. If it is difficult to determine whether this is so or not, a piece of paper should be placed in front of the eye which appeara to be looking straight at the object, and the other eye may then be observed to swing into its correct position. The condition may he due to paralysis or weakness of one or more of the muscles which move the eyeball, or it may result from over-action of a muscle when some error of refraction is present. See Eye; Spectacles; Squint.

CROSS GARNET HINGE. These are extensively used for the commoner variety of doors both indoors and for external work. The ordinary type is made from pressed steel, japanned black, and from 6 in. to 24 in . long. The T-shaped end is screwed to the upright, the long part to the door. Cross garnets are casy to hang, as they are generally secreved on flush with the door and the post.

thas Garnet Binge. Patterns ol
this door hinge in common use

The Lanca shirc oross garnet type is a superior quality made of wrought imn with a wrought eye at the extremity; they areprefer:able for hervier doors. Best heavy Lan. cashire cross garnets are desirable for duors such as those on a garage or stable They are made from 12 in . to 24 in . long. The 12 in . weigh ahout $2 \& \mathrm{lb}$. per jair. the 24 in ahout 10 Ih. per pair.

In hanging a donr on ordinary cross garnets always fix the hinges to the donrpost first, block up the door wo that it is tight up against the lintel, then fix the straps of the hinge to the dour. On remuving the blucks the door will drop slightly on the hinges, and it will then swing properly. See Hinge

CROSS STITCH. Lending itself equally well to embroidery on house linen, children's gavments, sainplers and chair scats, many decorative and uscful articles are patterned in cross stitch or completely covered by this wa...t: in cottun, silk, or wool. The double stitch, employed is formed by two oblique stitches, placed one across the other and crossing each other in the centre. The top stitches in a row must always lie the ame way. In the illus. tration more than one mesh of canvas is used to enlarge the stitch. When embroidering on linen, muslin, etc., a transfer pattern marks the stitches, or the design may be carcfully drawn with a pencil.

If coarse material he used the threads can be counted, and the cross stitches worked directly on the material, if not, an auxiliary canvas may be used This should he sewn securely in position over the material, and the pattern worked into the ground material through the canvas, the threads of the latter acting as a guide to the right posi tion only, as they areafter. wards pulled away, leaving the com. pleted design behind. Suftcient margin of the can vas must be left so that the threads can be drawn out easily after wards.

This is useful when borders of simple design are worked on cushions, or for cross stitch embroidery on silk bags and pochettes.

When solid cross stitch is worked for chair seats or stool coverings, etc., the geometrical or floral design is usually worked in colours, so that it forms a contrast with the background stitches. This also applies to figure designs which can be worked by means of a transfer ironed on the canvas in the ordinary way. Canvas can be obtained on which the design is traced. See Calendar: Canvas; Sampler.

CROTON OIL. One of the most active cathartics (purgatives) used in medicine is croton oil. Usually given $\frac{1}{2}$ to 1 drop on a lump of sugar, or in a little pat of butter, croton oil is chieHy used in cases of sudden unconsciousness, paralytic stroke, etc., where it is
important to clear out the bowels without delay The hutter is placed on the back of the tongue. Internally the drug should only be used under the direction of the dnctor

CROUCH WARE. This term properly pertains $t$ the early kinds of salt-glaze stoneware made in Staffordshire. The oldest is a drub ur huff fabric. but about 1721 crisp, white salt-glaze pustery was producerl, and that is the style of Crouch ware which is usually onllected. Baing mixed with Derbyshire pipeclay, its paste was dense and well finished, at first greenish. but afterwards whiter. Salt-glaze is easentially English, and looks particularly pleasing when it is contrasted with old brassware of plain English design. See Pottery

CROUP. The chief symptom of this ailment of childhood is the peculiar hoarse trumpeting cough and difficulty in breathing In flammation ot the larynx and trachea is attended by more or less swelling of their lining mucous membrane. and the narrowing of the air passage may hesuffioient to produce a c. ויוpy cough. In false cruup, however, there is is

Crouca Ware. Luaracteristic bowl in salt-glaze ware, with aolled urnamentation, c. 1720

Should attacks follow cluse upun one another, place the child in a hot bath and sponge the head and neck at the same time with cold water See Bronchitis Kettle. Child. Rickets.
CROUSTADE. For a suvoury, small entrée or breakfast dish, croustarles of fried bread are a nice way of serving cheese and egg mixtures. tomatoes, sardines, anchovy and egg, or savoury minces To make. cut circles of stale bread, each about \& in thick and 3 in in dianieter. Mark out an inner circle with a smaller-sized cutter and fry the circles in hot dripping Take them out of the pan and drain them carefully, then remove the inner ring of bread. The croustades can be then filled with the savoury mixture See Curry. CROUTON.
Thesc thinly cut pieces of bread, variously shaped and fried in hot fat. are used for garnishing such dishes as mince, hash, ragoûts, and savoury dishes of chepse, etc., or cut into dice as an accompaniment to thick soups. When cutting eroûtons the crusts. which can be used for puddings, are renoved. When spasm of the vocal cords in addition, and servad as a bnse for a savoury crouttons are the result is the onset of such difficulty of usually termed croûtes.

The child may spring up in bed, the attack usually occurring at night. In drawing in the breath the child may make a crowing noise. Suffocation may appear to be imminent. This may go on for an hour or two, and then the child dmps into a restless slcep. Next day there is still hoarseness, but otherwise comfort may not be much interfered with. In the night there may be another seizure, but not so severe, and aftera few days recovery may be complete

Frequently there is a tendency to the recurrence of croup. To prevent this the child's throat should be examined, and if the tonsils are enlarged and adenoids present these should be removed. Further, the child should be warmly clad, with flannel underclothing, and should not be allowed to sleep in damp ronms or be exposed to cold winds. The onset of a croupy cough should be brought to the notice of the doctor

True or membranous croup, in which a membrane forms on and about the vocal cords, may be due to scalding from hot liquids or steam, or to swallowing corrosive poisons; but it is usually due to a micro-organism, in most cases the diphtheria bacillus. Certainly, apart from the scalding cases, one should always treat the case on the assumption of its being diphtheria. In this form the crowing on breathing in may precede the dyspnoer, which usually comes on gradually, though at any time it is liable suddenly to become urgent. On the occurrence of crowing the doctor should be summoned.

In spasmodic croup, or Laryngismus stridulus, which is most common during the first two years of life and is associated with rickets, the child suddenly stops breathing and the face becomes purple. Then suddenly the child succeeds in drawing in the breath, making a peculiar crowing sound. Sometimes there is only the holding of the breath without the crowing. These infants are also liable to convulsions. Recovery is usual.

Treatment consists of trying in every way to build up the general health of the child Any irregularities of diet should be scen to, constipation should be remedied, and if rickets is present the disease should be actively treated.

Crowfoot. This is an old English name for the genus ranunculus or buttercup

CROWING: In Children. It is mostly in rickety children that the ailment known as crowing occurs, a peculiar spasm in which the child suddenly has great difficuity in drawing its breath, and makes a croaking noise Frequently there is a liability to convulsions. The mother will often tell the doctor that the crowing begins whenever the cliild is crossed or excited in any way; or it may follow on waking up or being exposed to a cold draught.

For treatment sponges wrung out of hot water should be placed over the throat, and the chin should be drawn forward If the child becomes pale and ceases to make any effoit to breathe, artificial respiration ( $q, v$. ) should be carried out, the child being placed on a rug on the floor for the purpose Between the attacks the state of the digestion should be looked to.

To begin with, give $\frac{1}{d}$ to $\frac{1}{2}$ teaspoonful of confection of senna or a dose of castor oil. The physician may order bromides. If convulsions occur the child should be put in a warm bath. To prevent a return of the condition the general health should be built up. by giving the child more outdoor exercise and plenty of nourishing food, with a fair supply of fats A teaspoonful or more of some emulsion of cod liver oil, taken threc times a day after meals, is useful. See Croup.
The crowing of a cock may constitute a legal nuisance See Animals

CROWN DERBY. It is usual to regard the period of about 30 years after 1784 as preeminently the Crown Derby period.

Crown Derby includes the best undecorated biscuit ware ever made in England, comprising rustic and classical figures and groups, besides statuettes of British generals and admirals. Crown Derby Japan shows imitations of Eastern designs. The French sprig or Chantilly pattern, usually a bluc corn-Hower, sometimes edged with gold, is prized

For many lovers of old china Crown Derby means the well-known painted and gilded ware, either scen in pieces of elaborate design with decorated pedestals and sometimes with lids
and handles, or in the form of dinner and dessert services: alan in lall, squarc-based vases. enriched with blue. canary yellow, pink, or apple green grounds. and delicats. landscape scones The modern ware, started in 1877 and atyled Royal since 1890 includes reproductions of the obaracteristic decoration ol the old inodels. See China

CROWN GALL. The swellings or galls termed crown gall occur on a greal variety of herbaceous and woody plants The effects of crown gall are seen in dwarfing of growth or direct injury to roots or branches

It has been shown that the hacteria invade the plant through wounds, and that in all probability they cannot enter an uninjured surace The curved ahopes greatest care, therefore, should be exercised in not injuring the stoclis more than is necessary.

The removal of a gall from a plant doss not necessarily free the plant from the diseasc The bacteria in certain plants in any case, spread in the tissues by means of the tumour strands, nnd, if the gall is merely cut off, the disease may break out again later. On the ot her hand, if a deeper wound is made witl, the object of cutting out the whole infected area, it may injure or even kill the trec. If the galla are on the lateral roots and only a few are attacked the affected roots shoulil be cut out, hur if badly galled the trees should be burned. This information is given by the Ministry of Agritulture in Lraflet No 245

CROWN IMPERIAL (Fritillaria imperialis) This hardy bulb in spring bears chusters of drooping bell-shaped flowers on the top of $n$ stem about $2 \frac{1}{2} \mathrm{ft}$ high. The blooms are of various colours, yellow, orange, and reddish. Bulbs should he planted ${ }^{6}$ in. deep in carly autumn and left undisturbed, for they hecome established slowly. This jlant likes deep, loany soil, and does not mind slight shade. See illus. below.
CRUELTY. Whether practised on human beings or on animals. cruelty is an offence against Eng!ish law. Jersons can be prosecuted and punished if they starve or otherwise ill-treat children, while dogs, horses, and cats are likewise protected To ensure conviction a specific nct of cruelty, as defined by law, must be proved before a magis. trate Persons who suspect others of acts

Crown Imperial, a bandsome hardy, apring flowering bulb. See article above

Crown Derby. Heautilu vase made froma classical model, 17 in. high
curied shapes a lifetime, but in present day households the brush and tray have lather given place to the scoop, which combines both ill use. See Brush

CrumbScoop. The design given for a crumb scoop is purposely simple, and intencled for easy construction. in any desired metal about $\frac{1}{3^{n}}$ in. thick. Copper or brass is convenient, as the joints are readily soldered.

The scoopis made by cutting a shect of the metal scoop. lacquering. well on both sides.
th:e rim to shape on a block of hardwood. A raw hide hammer is desirable, as it does must be silver soldered and thoroughly the socket, and secured with a fine pin driven in after the final polishing and lacquering. The handle should be dyed black and wax polished. The final treatment may be by electro-plating and buffing, or by simple 1 oz . ol it in a pint of lukewarm water to which a pinch of salt has been added. Stir in sufficient flour to make a light, smooth batter, then cover it and leave it for an hour to rise. Beat the batter. leave it for about 20 min ., heat it again, and pour it into greased crumpet rings placed on a baking sheet. It must be cooked

To make crumpets without yeast, use 3 eggs to 1 it, of self-raising flour and a teacupful of milk. Stir a dessertspoonful of sugar into the flour, and make a hollun in the centre Mix the eggs with the milk, nad lightly stir these into the flour, working the whole up as quickly as possible into a light clough. Then roll it out and cut it into circles each about $\frac{1}{2}$ in. thick. Prick these with a fork and cook
rom for sweeping up crumbs fibre, horsehail (drter meals are composed of The better qualities, with all bristle linots draun into the stocks with wire, will last
保 lo the shape given in the drawings, hammering not bruise the metal. After bending, the joints cleaned and scraped. The handle socket is bent to shape round a block of iron, then silver soldered at the joint and to the crumb

The handle is cut from hardwood, fitted to

CRUMPET. If yeast is to be used, dissolve
of cruelty should, in the them on "girilc or in the oven untir they are casc of children, inform the firm and light brown in colour Serve them National Society for the toasted on both sides and buttered

CRUTCH A crutch is a stalf which may be single throughout or bifureated for part of the distance, with a concave headpiece to inke the weight of the body at the armpit It should be as light as is consistent with strength. Pressure of the hend of a crutch on the nerves in the armpit may bring on paralysis of the upper limb, crutch paralysis, the com monest result being wrist-cliop ( $q$ v.), though the whole arm may be allected A crosa-piece lor the hands, taliing somo weight off the armpit, helps to avoid this, also a spring support at the top A modilied crutch may be used which only reaches as ligh as the middle of the upper arm, which it grips by a horse-shoe metal band. There is a cross-piece for the hand, which takes the weight.

In omergency, a crutch can be extemporised by wrapping the head of a broon in a clean piece of cloth. See Artilicial Limbs; Cripple

CRYSTAL. Although this word is used to describe glass ware ol a tine quality, ical erystal is hardly evor inade into vases or other omamental and useful househoid articles, as it would he too costly it is chielly seen decoratively in the form of cut bead necklaces and has many uses in the manufacture or eye glasse. 3 lenses for hinooulars, and cameras, ctc in the casn of large cut glass or crysial ornaments, it in advisable to have small rubber or oork disks cemenced on the base to prevent dannage when the art:cle is placed on a hard surface. Cut crystal beads may be distinguished froms glass imitations by toucling one wish the lijes. Real crystal will remaill almost icy cold, whilst glass will quickly be come warm when held in the hands and tested against the lips. See Glass.

CRYSTAL DETECTOR. Certain kinds of mincral ore, when placed in contact with certain metals or other minerals, act as rectifiers or detectors of high-frequency oscillations. The crysial although still used in simple. witeless roccivers, has been largely supersedcd by the ralve detcetor which is more sensitivennd stable. Kincite and bornite, galena or
 been removed. Above, crystal of carborundum

Crystal Detector. Permanent type suowing crystals
beld in contact by springs : surrounding wax has
silicon and brass carborundum and steel are sensitive combinntions, but careful adjustment of the contact pressure is necessary to ensure maximum results Carborundum is robust, but has the disadvantage of requiring a small battery and potentiometer. Sce Detector

CRYSTALLIZED FRUIT, Cherries, slicee of orange green figs and greengages. small apricots, and lemon, chunks of pineapple, and melon may be crystallized or candied by the folloring method

First make a strong syrup by dissolving 1 lb . loaf sugar in $\frac{1}{2}$ pint water. Then boil it with the lid off the pan, and without stirring it, or the syrup granulates. When it has boiled for about 10 ntin., or reaches $245^{\circ}$ on the sugar thermoineter, test the syrup by dropping a little of it into very cold irater and taking out the little lump that forms Roll it up in the fingers and see if it will form a firm ball. If so, take the pan of the fire, add a teaspoonful of lemon juice and put the pan over another one containing boiling water to keep the syrup from candying too soon

Take the prepared fruits up on the point of a fine sliewer, or a coarse needle, and immerse each piece in the syrup. Lift them out and drain off the excess of syrup by laying then on lightly oiled or buttered trays, and dry them off in a warni, dry place. Clicrries sliould be stoned before dipping, and oranges ahould be preeled and divided into sections without breaking the inner skin, as all fruits nust be perfectly dry.
CUBIC MEASURE. This is used for measuring volume or capacity It is as follows 1,728 cubic in . $=1$ cubic ft ., 27 cubic ft . $=$ 1 cubic yard.

CUCKOO CLOCK. In the wood-frame cuckoo clock a mechanical toy bird imitates at each hour the sound of the cuckoo or a hammer strikes the hours on $n$ gong and the bird merely emphasises the time. It is actuated by weights suspended on chains. The pendulum is sometimes hung on a wire loop, which requires frequent oiling.

The striking mechanism has two hammer arbors resembling the ting-tang device in a clock that strikes the quarters. As the hour at rikes, the two hammer arbors lift up amall bellows in the clock by means of rods The brllows fall one after the other, and give a puff of wind to a pipe or reed which produces the cuckoo note The hird is frequently made with a jointed head or beak interconnected with the bellows, and so arranged that the bird makes a movement simultaneously with the sound.
The bellows may sometimes fail, due to a leatiage, which can be repaired by re-cover-

Cuckoo Clock. Mechandsm of the clock, with connexions for striking the gong, working the bellows and making the bird start from its door ducing the Iruit. hcated pit or frame with a temperature o! $60^{\circ}$ or upwards the sced will soon germinate The soil must never be allowed to get dry, nor must the at mosphere be permitted to get arid. The plants may be planted out when 6 in. high, but. except in frame culture, it is usual to transfer then to 5 in pots and to grow them on.
It is a good plan, when planting. to set them on mounds of lumpy soil. When taken out of the pots they should be planted with the ball of soil and roots entise, tahing care not to bury the ball very deeply. As the roots show through
sticking a patch over the hole. The connecting wires may be damaged or displaced, but this defect is easily remedied, either by replacing with a new part or by restoring the piece See Clock

Cuckoo Flower. The popular name of Cardamine pratensis, or Lady's Sinock (q.v.)

Cuckoo Pint. One of the popular names of the wild Arum maculatum, which is known also as Lords and Ladies and Wake IZobin

CUCKOO SPIT. The presence ol Hotly spittle-like masses on many plants in the garden is quite common in summer If the froth is blown aside, a thick. bull-headed, greenish insect is revealed It is the sos-called cucliot-spit or frog-hopper (Aphrophora spumaria) It is not vely injurious unless present in large quantitice, which is unusual. A vigorous syringing with paraflin emulsion will get rid o! it.

## Cucumbers: The Several Varieties

## Growing the Vegetable and Preparing it for the Table

## This artele descrites the cultivation, whether in the open air or in frames, of the vegetable, and gives recipes for serving it. Sec also Frame; Kitchen Garden

Although cucumbers can be raised in the cucumber It tinc soil is used and airexcluded open air, the reaults are rarcly satisfactory, and from the roots, a stem gangrene called canker they are almost invariably produced under glass in Great Britain The plant is an annual with creeping stems and tendrils. rough heart-shapicd leaves. and yellow Howers of two kinds, male and female, tho latter pro-

As it is convenient to have the voung plants in separate pots, cach seed inay be sown in a 3 in. jot with a compost well enriched with leaf-mould. In a warin house or manuiofresh soil muss be added. A flower stake part of cresylic, or liquid carbolic acid, in 4(1) supports them in the mound until they parts of water. The plantathat are ruined by reach the wires, which should be stretched the eelworms should be burnt. beneath the glass of the house at a distance of about 1 ft. from it Once on the wires the plants will makn rapid progress. The main shonts should be trained thinly on the wires.

Cucumbers require a warm, saturater ntmosphere, which can be maintained by syringing the vines and the surfaces of the house once or twice a day. Water should be used to keep the mounds moist and tepid. When the plants nee in full bearing applications of liquid manure twice a week will increase the vield and size of the fruit.

Gnod varieties are Everydav, Delicacy, Improved Telegraph nod Rochford Market.

Several fungoirl disenses attack the
commonly starts The soil sliould be drawn away and ime or sulphur rublied in

Cucumbers are often affected by a diseasn induced by the root-knot celworm The first symptoon of attack is a drooping and yellowing of the foliage, followed by the stem thecoming limp, and a collapse of the entire plant. To destroy these eelworms the soil inust be thoroughly saturated three times at intervals of a fortnight. witlı a solution of one
 Cucumber. Lett, suort, rougs-skinned variety, grown in the open air. R1\&ut. specimens faised under glass : tney are double the length of the outdoor ones

Cucumbers in Frames. It is quite practio able to grow excellent cucumbers in an ordinary frame, provided the hothed has been properly prepared, and steady bottom heat maintained. Inside the frame there should be mounds of soil consisting of loam and leafmould, one plant being placed in ench mound. The roots must be covered with freal compost from time to time. I'lanting is done in April and May. A good serviceable size will be 12 ft . long and 5 ft . wide.

Ridge cucumbers can be grown out of doors in summer by putting out the plants in May in rich soil ; in a cold, wet season they are liable to fail. Suitable varieties are King of the Ridge and Stockwood, and the gherkin for pickling purposes.

How to Cook. Cucumbers may be treated in most of the "ays suitable for marrows and aubergines, but are most popular in salads, when they are peeled and very thinly sliced. Tuin slices of cucumber are also served with cold salmon. W'hen used as an accompaniment to cold meat, they are usvally covered with vinegar, and served in $n$ glass dish. If they are to be eaten raw, cucumbers should be young and firm, and free from seeds.

Stewed cucumber, served with sauce made from the stuck in which it was boiled, malies a
gord dinner vegetable. To prepare it, pees 2 cucumbers, cut them lengthways into quarters, and, if they are old, remove the sceds Place the pieces in boiling salted water, simmering them there until they are tender then drain and heat them in a sauce prepared from 1 oz of margarine, a little cucumber stock, 1 oz. Hour, 1 tablespoonful unsweetened condensed milk, and two tablespoonfuls cow's milk

Cucamber. Diagrams illustrating the culture of the plant. 1. How seed is ombedded in sand and sown plant. 1. How seed is ambedded in sand and sown in loamy soil. 2. Seedling. 3. Stage when ready Outdoor growing. $a$, hole flled with manure; $b$, ridge of soll above manure : $c$ 。 olant. 7. Bow to plant in frame. 8. Points of laterals pinched out at X

Melt the margarine, add the llour, and blend the two ingredients well Pour in the milk gradually, with 5 or 6 tablespoonfuls of stock, atir the whole in a pan over the fire until it boils, and then simmer it for 5 minutes. Lastly, add the condensed milk and the cucumber, heat up the whole, and serve the cucumber with the sauco poured over it.

Cucumber Cassolettes A good way of using up balf a cucumber which has been left over from salad-making is to peel it thinly, cut it into 4 pieces, and carefully scoop out the centre of each. Stew these very gently until they are tender, in $\frac{1}{2}$ pint of milk and water, mixed it, any proportions, then take them out of the pan and Hake $\$ \mathrm{lb}$. cold salmon or other cooked tish. Season the Hakes well, and stuff them into the hollow pieces of cucumber. Thicken the liquor the cucumber was stewed in with $\frac{1}{2}$ oz conntlour or barley-Hour mixed with a little milk, add 2 teaspoonfuls of chopped parsley, and then pour in a little hot water in which has been melted 2 sheets of gelatine. And a squeeze of lemon juice, and pour the sauce over the cucumber cassolettes, coating them neatly, and garnishing them with cold peas. Serve cold with potato salad

A similar dish is prepared by cutting a large cucumber into rounds each about 2 in. thick, peeling these thinly, and scooping out the insides till a thickness of only $\frac{1}{2}$ in. is left. Put the rounds into boiling water with a little salt and castor sugar, boil them until tender. and then leave them to cool. When cold, fill them with a mixture composed of peas and some carrota and turnips scooped out a bout the size of a pea. Before being used for filling the vegetables should be boiled, and when cold mixed with mayonnaise sauce to which some whipped cream has been adderl.
Cumin. The plant of this name, which is brought from the Levant, contains an aromatic oil and acts as a carminntive ( $\mathrm{q} \cdot \mathrm{v}$ ).

CUP : The Drinking Vessel. One of the oldest of drinking vessels, the cup has taken a number of forms, some of these being known by speria names, such as flagon. goblet loving cup and tankard Many of these were made by English silversmiths in the 17 th and 18 th centuriea

Tumbler cups so-called berause they are shaped like a tumbler and are without handles, are found in silver and in Sheffield plate One example of the time ol Charles II is embrased with tlowers and toliage. A variant of this cup, known as a taster, is fitted with a handle, and is shallower than the tuinbler form Another variety is the wine cup, which stands on a stem and a foot.
Cups with saucers to match are made in a number of shapes and sizes. but can be divided
intu threc main categories-breaktast, tea, and cotfee cups. Most brealifast cupls hold a hout $\frac{1}{2}$ pint, while teacups hold roughly a gill They are genorally fatter and wider-mouthed than cither breakfast or coffee cils, but should not be chosen tou wide, as the wider and shallower the cup the sooner the tea will cool Cups for black coffec usually hold only 2 tableapoonfuls. Special cups for invalids are made with n spout, and with the top partially covered in to prevent the contents from spilling. See Breakfast ; China Coffee Crockery.

CUP. This is a kind of drink, made usually from claret or the lighter white wines mixed with soda water, sweetened, and with various herbs and thavourings added Recipes will be found under the headings of suitable beverages. See Cider Cup, Claret Cup Hock Cup.

## Cupboards and Their Construction

## Decorative and Usetul Pieces Described and Hussrated

Other entrics similar in scope are those dealing with Burcau; Wardrobe, cte. Sec also Corner Cupboard and the articles on Amateur Carpentry; Cabinct Making; Drawing. Other forms of cuphoard are shown under Bachelor Flat; Bedroom: Bookcase, ete.

The oldeat existing cupboards date $f \mathrm{~mm}$ the reign of Elizaheth The original cupboard, known as a court or livery cupbord, was the equivalent of the modern sideboard or buffet Such cupboards were used to assist the service of meals, and many were elaborntely carved. the lower part being simply n chest. which opened by means of two doors

Cupbrairds are divided intu two kinds, those built intu the house and those that are inovable. The built-in cupboard was used in the Queen Anne period for the display of china and porttery it had fittod shelves and sometimes dours: it was either a enmer fixture or built in each side of the chimney breast. This idea is adapted by modern architects for suitable houses, and by decorators in treating corners and recesses in rooms and halls which lend themalves to a Qucen Anne or Georgian style of furnishing.
Built-in cupbards increase in importance with space and labour-saving exigencies. Linen cupbaarls geyser cupboards. fixture cupbuards that shut off sinks, baths, wash standa and dressing tables in bachelor flats and bed sitting romms; niring cupboards which make lome laundry possible in the small Hrit. and dining room cupboards painted or panelled to fit in with the decorative scheme and made to con. tain all the table equip ment. dessert, etc., and ingredients for drinks, are cleverly introduced into recesses or form at integral part of the architect's plans for small houses.

With the exception of the corner cupbrard decorative movablo cup. boards are not much seen to day. They tend to become severcly prac tical, but are exceedingly useful to supplement landlord's fixtures when the tenancy of a flat or house is only for three years or so. The illus tration of a inodern dining room cupboard gives a useful iden for the furnishing of $n$ recess in a small ruom.

A Hanging Cuphoard. A useful and easily made cupboard, designed either

Cupboard. Beautiful old oak Court cupboard. It is of the Elizabethan period and is elaborately carved and inlaid Courlesy of M. Marris \& Sons
ns a hanging cupboard or for shelves, is shown in Fig. 1. The ends are 1 in deal, the full height of the job and 1 in. less in width (i.e 15 in .). the orld inch being taken "p by the pilasters fixed on the tace of the carcass. Theso are the same thickness as the door, so that the whole front will line up. The ends, dovetailed to take the top (Fig 3), are grooved near the bottum (Fig. 4), and the bottom shaping cut to form the feel., as seen in Figs. 1 and 2. A rebate is ronn at the inside cdge in which the hack fits. this measuring $\frac{1}{2}$ in or 3 in. for the panels.
The top and bottom are both the full width of the job. less the thickness of the back panels ; they are cut away at the front ends to take the pilasters. and will thus be Hush with the front edge of the ends. The top, 3 ft . in length, is through dovetailed, the ends of the dovetails being hidden by the cornice moulding. The length of the botton will be the inside distance between the ends, plus twice the depth of the groove in the ends. The carcass should be glued up, using nails

Cupboard. Dining room cuphoard in osk with portable table on ball castors for service. The table stands inside the cupboard
Courlcsy of Wartng a Gillow. Led
to strengthen the gronve joint and commer blocks, ns indicated in the diagram at Fig. 4.

When dry, fix the back, which consists of three panela and two muntins. the later being gronved to talie the panels. Now true up the face of the joh and fix the pilasters, these being previously cut to shnae at the bottom. They are dowelled into the ends and screwed up top and bottom, the screws being hidden by the mouldings. A corner block, rubbed under the bnttom between the pilasters and the ends, will strengthen the feet. Both mouldings should be mitred mund, and glued and pinned. The domer is mortised together with $\frac{1}{\frac{1}{2}}$ in. grooved-in panels and hinged with three butts: a turn-buckle or acrew-on lock may be used, with a stop fixed to the inside of the pilaster near the top to prevent the door from pushing in too far. Shelves or hooks may be fixed, the shelves being supported by square fillets serewed to the encls.
Kitchen and Linen Cupboards. The kitchen cupboard, which is illustrated in Figs. 5-8, is a similar type of job to that shown in Fig. 1, except that the doors fit over the carcass and an applied plinth is used. The work pinceeds as in Fig. 1, but the ends are cut off about $2 \frac{1}{2} \mathrm{in}$. short at the bottom (Fig. 8). This sketch also shows how the plinth is fixed with screws. A corner block should be rubbed at the inside of the mitre of the plinth. Three or four shelves are placed at convenient heights. supported by slips screwed to the ends.
A linen cuphoard is of similar construction, except that. in place of shelves, a series of alata running from back to front nre used to facilitate airing. Fig. 9 shows how these are constructed. Three rails meas. uring 3 in. by 1 in. are made to run fmm side to side, and to these rails the sats are screwed.

A Corner Cupboard An example is shown in pair of dividers to just the width ol the Fig. 10 Theends or backn do not fit up close opening left above the skirting Using one to the wall, but stand away 1 in ., thus allowing point as a gauge, mark the pilasters with the the pilasters to form a close fit to the walls. other, drawing the dividers along the face This is necessary in the case of the angle of the wall not being square, also to allow the pilastery to be scribed over the akirting
The top and bottom are first prepared. The top. dovefailed into the ends, as in sions being indicated in Fig 15. Made in Fig. 12, finishes at the fonnt in a line with mahogany, it embodies the characteristic the inside of the doors. the frieze being features of a swan-neck pediment with fretted fixed to this. The hottom is grooved into the backs, so that the size will be taken from the inside, adding the depth of the grooves; this also finishes to the inside of the doors. Having cut top and bottom to size, the width of the two backs is taken from them These are $\}$ in deal, screwed tugether at the corner (Fig. 12). They orcupy the full height of the job and are dovetailed and gronved When glueing, screw the backs tngether lirst, then the top, and tinally the buttom, which is nailed frum the outside; corner blocks are rubbed underneath
The pilasters are fixed to the edges of the ends with dowels; two screws may be put at the top and buttom hidden by the inouldings. The joint is alsor strengthened with comer blocks (Fig 13) These pilasters are bevelled on the inner edges, to form a true mitre with the dours. The frieze to the top is screwed to the top, the top of the pilasters being eי't. as in Fig 13, to recoive the
 ends The shaped plinth is secured in a similar way. putting corner blocks under the bottom to strengthen it. Tho three mouldings, i.e. coinice, frieze and plinth, are mitred round,
 as indicated in
Figs. 10 and 11 , and fixed with glue and pins. panel, and a geometrical arrangement of glazing The doors are framed together out of 1 in . bars. The hottom board is rehated $f$ in deep atuff and have $\frac{1}{2}$ in. grooved-in panels. The to take the sides and back pieces Tho top outer edges are bevelled at the same angle buard comes inside the side pieces, and as the pilasters. A centre door stop is fixed the cornice moulding is planted on it. behind the frieze, and screw-on bolta and locks The pediment moulding is saiwn to shape, used. Three $2 \frac{1}{2} \mathrm{in}$. butta are used for each door. carved and rehated to take the fretwork To scribe the pilasters over the skirting, panel, the whole being gluad and screwed in place the job close into the corner and set a place. It is shown in detnil in Fig. 18.

The stiles and rails, the sides and the bottom board are 1 in. thick. The a pron beneath the bottom is of $d \mathrm{in}$. atuff, mitred at corners and fixed with glue blucks. The $\frac{1}{8}$ in plywond back boardy are nailed to tup and bottom, and to rebates in side pinces The construction is made clear bpe Fig. 16. A triangular fillet supports the plyword at the angle.

Details of the cornice and door framing are illus. rated in Fig. 17.

The door stiles extend frmm top to bottom of the opening and the rails are tennned to them The glazing bars, shown in Fig. 15. are mitred at all juints. glucd together, and planted on the glass. Shelves in thick have curved fronts. and are glued and nailed to the plywoul back. The cabinet, which should he lined inside with velvet, is suspender by four mirrorplates, serewed to the back edges of the top lurard
A Recess Cupboard. A recess cuphoard is shown in Fig 19, As the walls of the recess lorm the back and sides, a framework must be erected at the Iront Having decided upon the height. make a framework as in Fig. 20 , consisting of a cross piece tenoned into two uprights of ld in. stutf, 4 in . wide. The cross piece is $6 \underline{d}$ in wide. the extra $2 \underline{d}$ in being allowed to talis the cornice noulding, which is of this width This frame is glued together, and when dry should be trued up to fit in position, the lower ends being scribed over the skirting. The fixing depends to a certain extent upon the interior nccommodation required. For the example illustrated, a series of shelves, as in Fig. 21, is intended. Battens

Cupboard. Figs. 10-13. Convenient corner cuphoard for hanging clothes, with explanatory diarrams of the nrincipal parta
or hearers are tixed at each side of the recess. at equal heights, in the position required for the shelves; also lor the top. These hearers, 2 in by 1 in., are as long as the inside depth of the cuphoard.

If the recess is of a good depth. allow the face of the frame to stand in sufficiently to permit the cumice moulding to butt into the sides of the recess. This obviates the necesaity of making a return end to the moulding. The shelves and top are of 1 in . atuff, all of equal width, and are nailed down to the bearers. To these the france is nailed. a acries of naile being also driven in along the top. The nails should be punched in.
Should the cupboard le required for hanging purposes, there being no shelves, the wrill should he plugged at intervals and the Iramework skew-nailed from the inside. Having fixed the frame, the cornice moulding is put up with pins. The duors are made from 1f in stuff, framed together and hinged to the uprights of the frame. The inner styles of the doors are relinted so that the right door will fit over the left, making the cupboard dustproof. Allowance must be made in the event of a centre carpet being on the floor. Screw on bolts are fixed to the lefthand door and a turnbuckle or lock to the other.
Kitchen Cupboard. The cuphoard at Fig. 22 conceals a full-size sink, incorporating a boot

ing dimensions. Figs. 16 and 17. Details of construction. Fig. 18. Fretwork panel in the pediment

Capboard. Fig. 19. Recess cupboard for a hedroom. Fig, 20. Details of lintel and frameroork. Fig. 21 Interior of the cupboard, showing bow the shelves are supported by bearera secured to the walls
and whoe cupboard on one side of the sink, n capacious cuphoard with shelves on the opposite side. and a handy cupboard under the sink. Four amall cuphoards are provided at the top of the cabinet, one ventilated lig a perforated zinc panel and intended as a miniature larder. The cupboard is made throughout with 6 in. by $\mathrm{in}^{\mathrm{in}}$. tongued and grooved floorboard and 2 in. by 1 in . batten, built up on the site. Approximate dimensions are given, but they may be modified where necessary to mect existing conditions. It is important to allow for adequate head mom above the sink, so that the top cupbonrds must not come ton low down. Prepare the ends first, then screw hattens to them to take the various shelves. Set up the divisions on each side of the sink, then set up the two end pieces, Fig. 23, and nail the helves into place.
Fit up the lower cupboards with shelves and boot racks as shown, then malic the doors in the usual way with ledges and braces, and hang thein on stout butt hinges. A draining rack is provided to fit into the sink opening. and when in use this is placed on either side of the cupboard top. Add a narrow moulding
to the tup, and linish by staining and varnishing, or use a coloured rnamel.
A Boot Cupboard. The bout cuphoard for a berlsitting rooms shown in Fig. 24 is made with ply wond about in thick The top honrd is cbated at each end, and the side pieces fitted into them. The cuphoard shelf is s $\Omega \mathrm{wn}$ to size, planed square on the ends. and glued and nailed between the side pieces

Cupboard. Fip. 22. Kitchen cupboard which conceals a sink and provides ample storing accommodation. Fig. 23. Showing constructional details

The whole of the back is then covered with ${ }_{s}^{1}$ in. plywoorl, glued and nailed to the edges of the shelf, top and side pieces.
The boot racks are pieces of hmom handle or similar round wooll which fit into hules lored through the side pieces. The ends of the bars are rounded off, and all are glued intoplace.

Cupboard. Fig. 24. Compact arrangemeut for holding boots and shoes,
useful for a bed-sitting room Thecuphoard dour is made up with "cup. board door moulding," obtainable readygrooved and tenoned. The panel is a piece of 36 in. ply wood. Hang the door on two amall hinges. and fit a cuphoard turn or lock. A curtain. litfed on a rod beneath the cupboard,
conceals the boots and shoes. The cupboard can be finished by staining and varnishing, or inay be treated with a bright enamel.

CUP CAKE. Rich cup oakes, flavoured with wine, brandy and cinnamon, can be made by mixing together in is basin five cupfuls of Hour, three of sugar, one of butter and one of milk, and also three well-beaten eggs, a wineglassful of wine, the same quantity

CURB. This type of fender may be defined as one without a botlom plate, usually slightly raised from the hearth and, in the case of bricl, stone, tile and marble curbs, of the ame fabric. 'The simplest form of curb is one made of stone, being just three picces of polished stone round the hearth. These are miale in standard sizcs. In some modern fireplaces the curb is mercly a flat edging to the hearth made by reversing the laying of brichs or tiles Curbs are alan obtainable in oak and in copper, brass, and steel, in antique silver finish and in chromium plated metal, the chorice having relation to the grate or nccessories See Fender; Fireplace.
CURD. Curd is the nitrogenous part of milk, the solid substance left when the whey or liquid is separated. When milk suurs, the curd coagulates by the action of the lactic acid formed in the mill:. Chepse is made from the curd. See Cheese; Junket; Milk.

CURLY KALE. An indispensable hardy green "inter vegetable. Secds are sown on a prepared bed of fine soil out of doors in A pril, the seedlings are transplanted at about 6 in. apart to give them room to develop, and are put out in June or July at 2 ft . apart where they are to remain. Curly kale is the name given to the Scotch or curled liale which has densely crisped or curled leaves. Therc are many other varieties of kale or borecole, e.g. asparagus, cottager's, sprouting, Drumhead and thousand-headed. Cottager's is an old and popular variety. In this the habit is upright and the leaves are plain. The central leaves are tinted blue or reddish purple.

All these are uscful winter vegetables and need the asme treatment as curly kale.

How to Cook. To boil it, first wash and trim the kale ridding it of any hard stalks, and then place it in a pan of boiling water. and boil it rapidly for 5 min . Then claange the water for a similar quantity of fresh boiling water, adding a pinch of couking sodia and a leaspoonful of salt to every quart. When tender, drain of the water, press the kale well and chop it up, adding it lump of butter and a little salt and pepper and mix all together, stirring them in the pian over the fire. Fill a hot vegetahle dish with the kale, cutting it across acveral times with a knife.

Curly tiale may be conked in a casserolo Wash it thoromghly in salted water, and then shred it coarsely and boil for 5 minutes hefore putting it intu an earthenwas casscrole, logether with a gill of water and a lump of fat ahout the size of a hen's egh : cover the pan and cook its contents gently. stirring then oncasionally until the greens are tender. This should take about I hour. Finally, season it with pepper and aalt and serve it in the casserole. Sce Brocculi: Kale.

CURRANT. Red and white currants will thrive in any anil that is not too heavy and damp, but black currants give of their best in a moist. heavy soil. The former bear fruit on spurs upon the old wond at the bottom of the previous year's growth. Black currants give their finest fruit on last year's wood, and thercfore too much old wood should not ber allowed.

Fresh currants of fine quality and quite ripm nasy be fmated, and in this lorm proville all altractive dessert dish Prepare them by sieving some castor sugar on in a saucer or plate, and warming it without letting it melt In the meantime, beat up the whites of 2 eggs and add to them 3 or 4 dessertspoonfuls of water. Divide it of currants into neat bunches, dip these into the ogg mixture, and then intos the enstor sugar. making sure that they are well conted. The fruit inay then be left to dry on a shect of paper. See Black: Currant: Red Currant: White Currant.

CURRANT: The Dried Fruit. Driel currants ance a small variety of raisin imported from the levant, and an ingedient in the making of many cakes and puddings, and of mincemeat. They should not be bought in large quantities, as they do not keep well. anil shosuld be placed in an airtight tin. Jo clean currants for use they should he rubbed in a drv, clean clotlı on which a little llour has been sprinkled, and shaken on to a sieve so that any salks can lie picked off, ur they may be put straight on to the sieve. a handful at a time, and two or three teasporn. fuls of llour sprinkleal over them. Then rub them with the hand so that the stallis will come off and fall through the siere. Unless

Curly Kale. A favourite hardy winter vegetable with densely crisped or curled leaves

currant and goosoberry bushes. It looke like a small butterfly, and is vellow in coluur, with a hlack patoh in the centre of the back The pest id usually bnen early in spring. and commences to eat the young leaves of the busher an they expand Somatimes a second brood of these cater pillars appears later in the season
Spraying in no uncerrain wity with paraffin emulsion is the best remedy In chronic cases it is best to remove all the soil round the bases of infected trees to a depth ot 4 in in winter time and burn it This usually
there is plenty of time in which to dry them, destroys the cocoums, which would be the currants are heat cleaned by means of tour parents of the next season's pesta. A dressinstead ol by water. tor if used while damp they will muke tbe cake or purlding heavy ing of lime to the soil is also recommended The currant clearwing moth is a similar CURRANT SAWFLY. This is an insect pest. and requires the same treatment. See pest called Nematus Ribesii which attiaks Black Currant. Guoseberry: Red Currant

# Curry: Ingredients and Flavourings 

Recipes for Meat, Chicken, Fish and Vegetable Curries

The reader interested in cookery may consult the articles Casserole; Chicken; also such entries as Bombay Duck: Chutney; Rice

If carefully prepared and nicely halanced is beat for stirring the mixture in the cassemle, with regard to Havourings. curry stimulates and curry should be eaten with a fork, or the appetite and digeation Many foods are suitable for curry dishes, including ment. poultry and rabbit. corsked or raw : also tish. vegetables and hard-boiled egga A number of ingredienta are contained in Indinn curries, the superior flavour of which is due to the use of frosh and dried spices and fruits inatead of the curry powder relied on by many British conks Some of these ingredients are obtainable nt good stores ans. for example. green ginger. turneric chillies bottled tamarinds, garlic and caffron A really good imported Indian curry powder should supply deficiencies in home conkery aided by curry piste. coconut milk or shredded coconiuta. npple (which can be subatituted for tamarinda). pickled glierkins and lemon juice Flavouring is a question of taste. hut no one flavour should be detectable in a well-halanced curry which should not be ton hot. tor sweet or ton acid.

A curry should never appear on the table with a thin gravy though there are wet and dry varieties. in the former the sance is suificient practically to corver the fond curried : in the latter it has heen absorbed during cooking by the other ingredients Boiled rice, grated coconut and chutney should be served on separate dishes with meat curries; Brmbay duck (dried fish) may also accompany these. Rice is often placed as $n$ border ot the same dish with amall quantities of fish, egg and dry ment curries Vegetable and fiah curries nay be served at lunchenn or informal supuers in individual pipkins gnrnished on the top with a spounful of chutney, a small piece of fried red herring with chopped gherkin or a olice of hard. boiled ega, surrounded by a little boiled rice Anything with curry sauce should not be touched by steel; a wooden spoon

boiling water Keep this builing briskly with the lid off for about 20 min . and atir the rice frequently When the grains are thomughly anft. turn the rice into it warmed colandler. and then pour boiling water over it. This will separate the grains When this method is employed it is unnecessary to dry the rice over the stove or in the oven It should be heaped on to a hot dish, and arranged with a fork

Meat Curries If frosh meat is used for a curry it is a good plan to fry it in butter or margarine before laying it in the curry sauce As curry is such an excellent method for doing up left-nvers ol joints etc. cooked meat is more often used for this purpose. Any of the ingredients already mentinned may be used to flavour the snuce or added to the curry whilst conking The recipes given suggest variations suitatule for the particular disb

For a curry of cold cooked veal, first prepare the asuce For this, nielt in a casserole 2 oz . butter and fry in it, withoul colouring. a large onion and a medium-sized apple, both prepared and chopped amall Strain off the fat from these and reserve them, then return the fat to the pan Add a tableaponnful of curry

Curry Croustades, which can be made either with flaked tish or with minced meat
powder mixed with a dessertapoonful of flour and let these cook gently for 12 min. Add the reserved onion and apple and stir in about a pint of white stock Let the sauce boil up and mix in a dessertsponnful of curty paste, foz. blanched and chopped almonds, $\frac{1}{}$ gill cream or inilk. the juice of hall a lemon, and seasoning to taste

Cut 1 lb . of lean cooked veal, previously freed from akin and hone, into cubes, place it in the casserole and simnier gently until thoroughly heated through, but do not allow the curry to boil Serve with cut lemon, bniled rice and chutney

A good mutton curry is prepared from the following ingredients: 1 lb . mutton cut into cubes, 2 oz. mint Havoured butter, 1 large shredded onion, 1 tableapoonful cach of curry powder and corntlour I finely minced apple, a teaspnonful each of curry paste, lemon juice and chopped gherkin, salt to taste.

Rub an aluminium frying-pan with a crust of bread flavoured with garlic. Place the mint-butter and onions and meat in the pan and fry lightly. Remove meat and onions to casserole, and gently stir into the butter in the frying.pan the curry powder and cornllour. When smootl add $\frac{3}{3}$ pint stock and salt to taste, and bring to the boil while stirring. Pour this sauce over the meat and onions in the casserule. add the other ingrodients, stir the mixture well and allow to simmer until conked. Serve in the same way as the veal curry, but without sliced lemon

Kidneys are excellent curried; either calf's or sheep's kidneys may be used, but the formor require longer cooking. Split, skin and slice neatly four kidneys and put into the casserole with I oz butter, one thinly-sliced onion, one amall chopped apple and a squceze of lemon juice.

Continue cooking for a few minutes, taking care that the whole does not burn; then stir in $\underline{b} \mathbf{~ o z}$. of rice flour, $\frac{1}{2}$ dessertaponnful of curry powder, a little chutney and seasoning. When these ingredients are thoroughly mixed, pour over them a brenkfastcuplul of stock, and stew the kidneys for $\frac{1}{2}$ hour, or until they are tender.

Betore taking the curry from the pan, add a little cream to it and serve it with a border of boiled rice-

Rabbit and Chicken Curries. To curry a rabbit, cut the flesh ints convenient sized pieces, season them to taste, and fry them lightly in a lump of butter about tivice the size of a hen'a egg. Add 3 or 4 dessertspoon. fuls of finely chopped onion, and continue conking gently for about $f$ hour. Then stir in 2 teaspoonfuls each of llour and curry powder, mixed smoothly with a little cold water. Add a bunch of mixed herbs, a dessertsponful of chutney. and $1 \frac{1}{2}$ breakfast cupfuls of stock Simmer for about it hour. or until the meat is found to be tender The bunch of herbs, of course. should be removed before serving
For curricd chicken, having cut the bird into neat joints, dust these with flour. Cut two onions into sinall pieces, slicing them down from the crown: fry these in 4 oz . of margarine or butter, then strain them and lay them aside. Add 2 tablespoonfuls of curry powder and the pieces of chicken to the butter in the pan, fry these gently for 15 or 20 min ., then ardd a smai chopped apple, the fried onions, $\Omega$ few blancherl and chopped almonds, a fow sultanas. and t pint of white stock. Pour in a teacupful of coconut milk. and add a teasponnful of curry paste: then season and cook all gently unti the liquor is thereby reduced in quantity by one third

Befure serving, catrefully remove all fat from the surface and add a dessertspoonful of lemon juice Send the dish to the table very hot with boiled rice served on a separste dish. I liked, the chicken may be removel from the casserole. placed round the heapred rice on a dish and the siluce passed through a sieve before being relieated and poured over the pieces of chicken. Any poultry or game may be curried in this way.

Fish Curries. A good curry saluce in which fish can be afterwards cooked is prepared by sprinkling a amall finely-chopperl onion with : little flour, and then frying it in $\frac{1}{2}$ oz of butter When it is light brown, add I dessertspoonful of curry powder, and continue frying for a few minutes before putting in 1 dessertspoonful rach of chopped chutney and Hour. Add it gills of veget able atoch, and atir the mixture until it boils and becomes of a creamy consistency. Then grialually add $\frac{t}{2}$ gill or less of cream or milk

Curtied prawns are made with it pint of curry sallce, using fish stock or a stock made froni hoiling the bruised prawn shells. Add 1 pint of prawns and let them simmer for a few minutes. Serve them on a hot dish with $u$ border of boiled rice. An illustration of this diah is given in the previous pige.

To curry lobster cut up the llesh into pieces of a convenient size, heat them in curry saucc and dish in the same way as curried prawns. Chutney should be served separately: Any conked white fish can be conrsely Haked and reheated in curry sauce, first simmering the latter for 10 minutes The addition of a little chopped apple and a squeeze of lemon to the cury suluce is sometimes liked.

Vegetable Curries. Any vegetables, such as small turnips, onions, carrots, pieces of cauliflower, French beans, peas, and small potatoes, may be used for a vegetable curry. First cook the vegetables until they are soft but not pulpy, and then add them to the curry sauce. Simmer for $\frac{1}{2}$ hour, add a squeeze of lemon juice and a lump of sugar, serving the curry with boiled rice.

Cooked lentils, butter, or haricot benns may be curried separately. Add I pint to sufficient heated curry sauce to cover the vegetables in the casserole. Slice in two scalded and peeled tomatoes, add a tcasponful of curry paste. and serve in individual pipking with chopired gherkins and rice

Curry Croustades. A useful way of serving up an egg and brush a little wvel eatch liaste a neat little curried dish at breakfast or supper is to place a tablespoonful of Haked fish or minced meat heated in sufficient curry sauce to llavour, but not to make too moist. in croustades. To prepare thesc, cut 2 or 3 slices of bread about 2 in . thick and stamp them out into rounds with a plain cutter the size of a wine glass, scooping out the crumb from the centre until only cases of bread remain. Let these soak in a little milk for 3 min., then beat

Cover them with breadcrumbs ind fry them it golden brown.

CURRY COMB. This form of eomt is used for grooming horses, its object being $\uparrow 1$ Ireu hem from the dirt that adheres to the siin The comb should be used first from the neck to the shoulder; the operation should then he continued downwards to the legs. ent finally along the breast and underpart of tho finally along the bre
animal Sce Horse.

## Curtains: How to Choose and Make

## Decorative and Practical Ideas for Window Treatments

## This article concludes with information ahout the fittings and other accessories of curtains. Sce American Cloth; Bay Window; Bedroom; Cascment; Colour; Drawing Room, etc.

Curtain treatments may lic simple or used with great advantage on a pelmet of thic elaborate, but they must hear a definite type; or it may be simply bound with ribbon relation to the colour scheme of the surrounding interior. Occasionally a thought should be given to the view through the window. Jade green curtains, for instance, will not look well fraining a mass of summer foliage, nor will bluish pinks, or luchsia shades of red, har monise with the view of a red brick wall A certain agrcement is also pleasant hetween the various window curtains of the bome as seen from outside. This is easily achieved. without being tied to one colour or fabric by a lining in one set, by the ground of a cretonne in another, by the pattern in a third and by the solid colour of a fourth, all introducing the same shade, which in turn should contrast happily with exterior paintwork.
Colour and Pattern. With regard to interior colour schemes, curtains should nccentuate a note in a room or afford a good contrast. Sometimes they may do both, as, for instance, when a patterned material is used which matches the loose covers, but in the case of the curtain is hordered and edged with a plain material, which is repented for the valance or pelmet; or the pattern may pick up the colours of tiles and paintwork, while the plainer material of the horder matchics the upholstery. This scheme is a pleasing treat ment for printed linen or cretonne with a rep border and is particularly attractive for an informal sitting room or a town bedroom with glass curtains of ivory net woven in square mesh. It may equally well be utilised for a French window, or a double sash window, hut in the lirst case the net curtains are hest fitted to each half of the window and held in place at the hottom hy a second mod so that they do not swing out when the windows are unfastened.

For French windows in the more formal room. the type of curtain shown in the first illustration is suitable, especially if the ceiling is low, as the long line of plain fabric with the narrow gracefully braided pelmet gives height. Such curtains would look equally well in shot artificial silk, in satin or, for a dining room, in furnishing velours or velvet. Such pelınets could he trimmed with motifs bought ready embroiderel and only requiring to be lightly sewn on, connecting the design with a braid which can be bought to match. For a mom with any Chinese lacquer furniture the pelmet could be bordered with strips of Chinese embroidery or with motifs in the dragon design. Hand-worked appliqué designs can he

sitting room, while the braided pelmets are designed with corves to corre-
Curtain. Plain satin curtaing frame the French windows of the formal
sittirg room, while the braided pelmets are designed with curves to correspond with period furniture

For the double sash window in a town house long outcr curtains may frame lace store curtains to the sill. The advantage of the latter is that they can hide out a depressing view if necessary without ohscuring light

A good formal treatment for a large bay window is to make an outer frame by means of pelmet and long curtains of rich plain fabric These curtains are pleated on to a band so that they keep their rather narrow line Practical curtains in a contrasting colour are hung on an inner rod hent to the shape of the bay, while lace store curtains fit the windows. This treatment looks well when carried out in deep hyacinth blue for the framing curtains. pelinet and curtains bordered with silver hraid, the former having two long silver tassels that hang down over the: curtains at the outer edges: the practical curtains are of artificial talfeta shot with a lighter blue and mauve and the store curtains are an ivory shade. Whatever the colour scheme selected to suit the nom the framing curtnins should he unpatterned and of darker tone than the practical ones. Vitrage laces may he utilised instrad of store curtains for bay windows. These laces are made in panels and can be cut along t.he joins, one or more panels adjusting theinselves to the fitting of nnrrow or wide windows. Brise-hise nets can he used for casements, or for lower sashes of hedroom windows with outer curtains to the sill. Crispleffects can be olbtained by tho use of organdie mualin, self-fitted

Striped artilicial silk fabrics bring a gay note into a room otherwise neutral in tone A small dining mom, carpeted with brown, and having parchment-coloured walls and a cold north light. was transformed hy window

Curtuin Treatment to. a ball or lounge mindow whth braided and tasselled pelmet copied from an Elizabethan design
curtains in bold stripes of orange with narrower atripes of gold, blue. greell and chestnuthrown The valance was composed of two layers of scalloped material, each scallop measuring six inches acruss. The pinints thetween the scallops were well delined, the lower scallop being placed beneath the cut up point of the lop layer. This top layer was of chestnut-brown fwhich colour also lined the curtains), and the under layer of the predominating orange stripe. A sunny glow was introduced into the room with fine artificial silk net curtains in pale gold across the window Beautiful curtain fabrics for lounge or dining room can also be had in patterned damaska and tapestries. The latter need plain walls to show off their beauty

Short Curtains. For casement winclows, the frilled or pleated valance with short curtains will look well in thinner materials Valances may he box pleated on to a tape to which small rings are attached at close intervals. Hooks can then be screwed into the valance board so that the valance can be hung and not nailed to the hoard if no valance or pelmet is used the curtains inust be very neatly gathered into a heading at the top or ugly gaps may be an eyesure between curtain and rod. If the top of the curtain is firmly pleated to a depth of several inches by means of rows of stitching it will give a delightfully neat heading. Cretonne gathered valances need not be lined, but straight acalloped valances or pelmets in any matcrial require this additional support and atiff ness.
liedroom curtains are better lined it they are practical and blinds are done away with; also, with the exception of tafieta and furnish. ing satin. fabrics hang hetter when lined. short chintz, check ginghain. hordered casement cloth or coloured bolton sheeting curtains do not require lining unless it is particularly desired to darken the room at night. l'ale coloured voile or spotted muslin are dainty fabrics for glass curtains in simply furnished bedrooms.
The sccond illustration shows a charming treatment for a hall window, the diamond points of the pelmet heing trimmed with gold tasuels, while gold braid is used to make the design. Either velvet, vclours on heavy artificial silk rep would lend itself to the making of these curtains, which would look equally well in a small sitting room.

Plywood pelmets are sometimes seen with short curtains, and have cleanliness and neatness to recommend them ns well as possi bilities of decorative treatment. They can be painted the same colour as the woodwork of the room, decorated with a stencil pattern, or repeat the groundwork of cretonne curtains The edge of such a pelmet can be left straight or curves can be introduced by means of a fret saw. Painted with gold or silver metallic paint and outlincd with a colour, they are decorative in a modern room. They are right for the up-to-date kitchenette where coloured paint is to be used for woodwork, and also for the nursery with stencilleal animals or fairy

Curtain Poles and Rods. Figs. 1-4 and 6. Common fitings for bolding one or more brass curtain rods. Fig. 5 Device for opening and cloging curtains. Figs. 7-8 Diagrams abowlag how to fitacurtain pole to a bay window
tale characters. They may combine successfully with American cloth cretonne or chintz for these rooms. The third illustration shows a curtain treatment that is particularly suitable for a bungalow window, having a painted plywood pelmet decorated with twa lines of colour

Bathroom curtains may be of brightly patterned towelling, rubberised cotton fabric or oiled silk, though washable checked or striped materials are also suitable

Details for Making. Several labour-saving devices are on the market which simplify making and washing. A heading tape can be obtained in three sizes for light, medium and heavy curtains which only requires to be machined to the back of the curtain heading and then drawn up to the width required when finished. Rings and hooks are sold with it which may be detached or fixed in a moment, while the headings can he let out

curtuins and polmet in deaigns partloularly suitable for a seaside bungalow
so that when the curtains are washed and ironed they are straight. A curtain gliding rail is also obtainable which simplifies hanging light or heavy curtains and can be supplied with a valance extension. The hooks on the heading tape fit into the rings on the rail, so that the problem of taking curtains down for cleaning or washing and putting them up again is reduced to a minimum.

Flexible and adjustable wires with rings at the ends which fix on to small hooks on the window frame are the best means for hanging lace and net glass curtains. These wires are simply threaded through a hem and, being stretched to the width of the windows, keep the top of the curtains taut.

Poles and Rods. Curtain poles averaging 1 in . or more in diameter are adnpted for large windows, doorways and openings. Curtain rods are of smaller diametcr, used generally for casement windows. The materials are hrass-cased iron tube and wooden dowel rods. the latter from $\frac{5}{16}$ to $\frac{1}{2} \mathrm{in}$. diameter, up to 6 ft . long. The patent curtain rod brackets shown in Fig. 1 may be used for supporting rods up to $\&$ in. diameter.

When it is only possible to fit the rod between the jambs of a window opening, the fitting shown in Fig. 2 is especially useful The brass fcrrule is arranged to unscrew from the base to facilitate removal of the curtain rod. This type of fitting is available for rods from $\frac{1}{2} \mathrm{in}$. to $\frac{3}{2}$ in diameter.

For fitting two curtain rods parallel tn each other, one for the curtain and the other for the valance, a double bracket fitting, as in Fig. 3, is most convenient. It is adjustable, and the inner rod can be sf in. from the window frame, while the outer rod extends another 3 in . The other ends of the rods are carried in simple projecting hrackets, as shown in Fig. 4.

All these fittings are screwed to the window frame with countersunk hrass screws The litting of curtains to a small bay window or oriel is greatly simplified by using spring wire, hought by the foot from any ironmonger, with the hooks for supporting the wire and the eyes for screwing into the ends of the spring wire. The hooks are fixed at each angle of the window frame, the spring wire prasing over them

The Valance Board. In a house with concrete walls and metal-framed casement windows, to which the usual curtain fittings cannot he acrewed in the ordinary way, the plan is to fix a valance board on hrackets screwed to the wall on the rawlplug system. Where there is no pelmet or valance hoard long curtains arc generally attached to a number of wood or brass rings, free to slide along the horizontal pole supported on brackets at the top of the window frame. The pole is provided with detachable ornamental ends large enough to keep the rings from sliding off.
In the case of a plain pole and no cords the curtains have to be pulled or jerked along by liand when opening or closing. An improvement is to have pulleys fitted to the ends of the pole and cords hanging from them and connected to the rings, so that the latter can be drawn along the pole by the cond. With a pair of curtains divided in the middle this movement must be in opposito directions, and the pulleys are arranged so that the pulling of one cord accomplishes this. The principle is indicated in Fig. 5.

This is done by using the opposite directions of travel of the cord, which goes to the far end of the pole, passes over a pulley, and comes hack. The middle two rings, $A B$, of the set are attached to the cord, so that in its travel it pulls one in one direction and the other in the opposite. The pulleys are generally fitted into slots in the pole. In other cases the pulleys are attached to the hrackets, an exaniple of which is shown in Fig. 6. For hay windows the pole must be in lengths and at angles to suit the bay. A typical cxample is shown in Fig. 7, the required dimensions being marked D. A is the pole, and C. C, the supporting brackets. The angle joints $B$ must be cut to the correct angle, which can be ascertained as follows: On a sheet of paper draw the two parallel lines, E F, G H (Fig. 8), the distance between them heing equal to the cliameter of the curtain rod. Then cut a card template to the angle of the window, as at $L^{\circ}$, and draw lines, A B, C D.

The points of intersection, marked K J, should now be joined with another line, which shows the exact angle to which to cut the ends. When cutting the rod keep the end faces perpendicular, otherwise the rod will not be flat when jointed. All trouble may be avoided by using the metal connexions made for the purpose. These screw into the ends of the pole, which in this case is out square at the ends, and mensurements are taken to the centre of the joint. Onc of these metal connexions is shown in Fig. 9.

CURVATURE OF THE SPINE. There whe several forms of curvature of the spine, to each of which a distinctive name is applied. In scoliosis, or Interal curvature, the spinal column or backbone is bent to one side; kyphosis is an increase in its main backward curve, and lordosis is an increase of the hollow at the loins. A more serious condition is angular curvature or Pott's direase. This is due to disease of the vertcbrae or to fracture.

The predisposing cause of scoliosis is weakness of the back muscles and general debility ; the curvature may be induced by habitual faulty postures or by carrying weights which overtax the strength. Examples of this are : writing at a low desk with one shoulder higher than the other; standing with the
weight on one leg carrying a weight hahitu ally on one arm, as in the case of a nursemaid This type of curvature is common in young people of about 14 years and upwards Other causes which may bring it abnut are rickets, knock-knee, empyema, unequal length of the legs, dislocation of the hip from birth, and paralysis of the muscles of the hack on one side. The advice and supervision of the doctor should be obtained Rickets, if present, must be cured, and the general health brought up to and maintained at a proper standard by fresh air, indoors as well as out, sufficient good, simple food, tepid hathing, sufficient rest and sleep, and if there is anaemia, an ron tonic.
Kyphnsis is an increase of the natural backiward arch of the spine from the neck down to the amall of the back. It may occur in rickety infants, in children with weak hack muscles, and in grown people who follow atooping occupations. If the infant is trcated for rickets and kept in a lying position, the curve will in nearly all cases disappear as he gains strength. In growing children this form
of curvature develops from the practice of stooping when writing, reading, sewing, etc Short sight is sometimes answerable for this aulty habit. The treatment is the same no for lateral curvature. Glasses should be worn when the sight is defective

In angular curvature, or Pott's disensc, tuberculosis attacks one or more of the vertebrac, as a result of which the hones as well as one or more of the cartilaginous disks be tween them soften and crumble away. The part of the hackbone above the point of disease then settles down on the part below, and bending forward results The disease may occur at any age, hut is most frequent in children. Frequently it follows a blow on the back or a strain.

In treating Pott's disease the usual measures for tuberculosis in any part of the body are to be carried out, and complete rest munt bn secured for the spine The patient's room should be airy and sunny, and he should be carried into the open air as much as possible. His diet must be abundant and nutritious See Spine.

## Cushions: Materials and Designs

## Pleasing and Colourful Aids to Comfort

Helpful information will also be found under the headings Applique; Embrnidery: Raffia; Woolwork. Sce also Drawing Room

Though cushions should always he selected with due regard to the type of room and also to the style of furniture on which they are to rest. too much cannot be expected of them as a means of decoration. In no case do a number of miscellaneous cushions look well. Even when the various colours chosen are in actual harmony with the adjacent colour scheme, the effect of too many contrasts when dotted alout the room is disturbing. When several cushions are piled on $n$ divan it is in better inste to make the foundation of the pile a couple of square pillows and a bolster to match the upholstery or lonse cover of the divan, and place on these one or two round cushions related to the others in colour by means of embroidery or applied trimming.

As too many patterns in a room should always bo avoided, when loose covers are chosen for sitting mom chairs and settee in a boldly patterned cretonne, it is often a mistake to place silk and brocade cushions on them, and the whole effect of the room will be more harmonious if the cuahions are alan made of the cretonne, piped with plain linen in a colour selected to match either carpet, curtains or woodwork. Another good scheme for cushions to be placed on $n$ Hower-patterned cretonne is to cover them with plain linen matching the ground colour of the cretonne and apply flowers cut from scraps left over from inaking the covers This treatment looks particularly well when a cretonne is chosen with a grey or pale grcen ground and having a definite pattern of mauve and pink flowers from which a neat design can be cut for the centre of a round, the corner of a square or the apex of a triangular cushion covered in plain linen. The groups of flowers are tacked on each piece to be trimmed and sown down with satin stitch A little embroidery in stem-stitch may be aulded to emphasise markings on the flowers or leaves in coloured silks to tone.

With If yards of 31 -inch material, either a round or square cushion of average size can be covered. Cut two circles, $21 \frac{1}{2}$ inches in dia. metor (a paper pattern can be out first from the cushion to be covered), or two squares of $21 \frac{1}{2}$ inches each, and also a band 4 inches deep to be set all round the sides to make the cushions mattress shape. The seams may be piped to match or with a contrasting colour. If to be appliqué or embroidered the one side of the cushion will be worked before making
up. Such cushions lend themselves to an endless variety of designs. Terry towelling makes delightful nursery cushions either patterned or in plain bright colours

Garden Cushions. Raffia cloth in the natural colour is a good covering for outdoor cushions, with a lining of satecn or other close fabric. and bias linding for the edges if munded. Simple wool or raffia embroidery can be used to trim such cushions. Hessian is another excellent covering material This coarse canvas may be stoncilled or lends itaelf to embroidery in oross-stitch; simple garclen or flower bed designs cook well and transfers are obtainahle which are quickly worked in wools. Crash cushions embrnidered with a group of circles in darning atitch are also suitable. The circles can be traced on the crash by pencilling round the inverted edges of small cups and saucers. American cloth provides a damp-proof reverse side for garden pouffes and mattress cushinns. Waterpmof cretonne cushions are obtainahle to match the coverings of deck chairs.

To brighten cane or canvas chairs for the verandah, loggia or garden, a useful and attractive cushion can be male in the form of a Japanere Inntern. This has an appliqué

Cushion. Lantern cushion for a garden ohalr. The design is applique with stem-stitch

lesign ot three little Japanseso lanterns which might be carried out in pint, green and yellow respectively, and is made of either crash or casement cloth in n contrasting colour. Two oval pieces of the material are cut 20 inches by 16 inches for the body of the cushion, and two pieces of hlack sateen for the Inp and hottom of the cushion, measuring 8f l, 3 inches ench. The threc amall lanterna nre npplied with stem-stitch, and apparently hang from a spray ensily draun on the material with pencil and also to he stemmlitched and decorated with a few little pink llowers in buttonhole-stitch

To make up the cushion these two ovals are joined together with a piping inserted, while the two black satin oblongs are placed in the middle of the long sides of the oval pieces to represent the top and hottoin of the lantern A black cord is attached by which the cushion is suspended to the back of the chair. This obvintes constant slipping when the occupant moves. Leather, dyed clamois, ir air cushions are most suitahle for use in cals, coverings heing selected to match or Ione with the upholatery

Cushions in Richer Fabrics. For the more formal type of sitting room, lounge or dining room whero the furniture is upholstered in relvet, silk rep, leather, or damask richer materinls are needed for suitahle cushions. (On a dining ronm settec with brown velvet lonse sent cushions, large round brown velvet extia cushions will look well trimmed with leather panels in a contrasting colour. Round cushions are also often particularly suitable for n window scat, as they help to reduce the apparent squareness of an old-fashinned
window. Oval and pillow. shaped satin cushions look right with 18 th century styles. Floor cushions give a luxuriously comfortahle look to the hearthrug in winter These should he large, deep and made of a suitably heavy materia' such as damask. furnishing velours or rep. Cloth inay a lso be utilised hound with gold galon and ornamented in the centre with motifs of gold hraid, as shown in Fig ?

Although cushions for rooms in period or special styles should be of rich materials they need not be costly. Setting naide for the line needlewoman the beautifully embroidered designs, there aie some effective methorls of trimming which demand no special skill For n room with lacquer pieces of furniture Chinese atrips, munds or squares of emhroidery can he used, either placed to form a patternon a plain colourel or hlack cusbion and applied by means of a narrow galon, or (as in the case of rounds and squares) laid llat in the centre of the cushion, and the silk, or other material with which the cushion is to he covered gathered round it on a gauging cond

A holster cushion shape can he hought and covered in strips of velvet, with ende either out into rounds and piped to fit the holater and tasselled ornament applied (Fig. ©), or pleated into a hunch of padded tlowers to hold the folds Gold-coloured cushions in crinkly satin have the appearance of heing tissue-covered. but are soft and do not tarnish. This satin is good trimmed with self piping on a thick cord, and coloured wooden heads devised into tassels, or into flat ornaments at three of the corners, with a large dangling one of pradied satin and beads to hang over the elge of a sofa, for the fourth.
Round, square or holster cushions covered with satin or shot taffeta are ornamental when trimmed with appliqué worh, or covered with patchwork in modern geotnetrical patterns. This wark costs nothing where there is a scrap drawer containing odd piecos of silks, satins, ribbons and tinsel brocades. The simpler the designs the better. They are cut out first piece by piece in paper, pinned on the cushion cover to judge the effect. and then cut out in the various materials. The designs may be traced by means of tracing paper or drawn frechand hefore cutting out. Figs. 3 and 4 show effective patterns which are applied by buttonhole atitch. For the former three colours should be used to malie the circle, the stitchery matching the piping. In the latter design the path should be nutlined in stem stitch.

CUSPARIA BARK. In medicine cus parin hark, which is an aromatic bitter obtained from a $S$. Americnn tree, can lic employod to increase aplictite. Two prepinations are used of which the doses are Infusion of cusparia, 1 to 2 fluid oz.; concentrate of cusparia, ! to I Huid dram.

CUSTARD. T'o make a simple boiled custard, allow 2 eggs to 1 pint milk, and use 2 dessertspoonfuls castor sugar, with Havouring to taste. Beat the eggs well and stir in the sugar. Bring the milk to the boil and then pour it gradually on to the eggs, stirring all the time. Pour all into a stone jar or a jug and put this into a pan of boiling water. Stir the custard until it thickens. Then remove it from the pan, add Havouring essence, and pour it into a bowl to cool. If lemon flavour is desired, let a little lemon rind boil with the milk.

Confectioner's custard is aontetimes used as a substitute for cream in lilling chocalate éclairs, etc. It is prepared by mixing a little more than 1 oz cornflour with $\frac{3}{3}$ pint milk, and atirring the paste in a small saucepan over the fire until it boils. Then let it simmer for several minutes, afterwards adding the yolks of 3 eggs, $\frac{1}{d}$ oz sugar, and a little vanilla essence. Cook the custard slowly, stirning it all the time, and when it thickens take it from the fire and allow it to cool

Custard Powder. A custard powder can be made at home from cornflour and riceflour These should bo mixed in equal parts, and it is essential that the ingredients should be quite dry and that they should be sieved to ensure their being free from lomps. The powder can be coloured yellow with powdered turmeric Onc tableapoonful of custard powder should be used to every pint of milk. The powder should he mixed to a sinooth paste with a little cold milk, and the remainder of the milk hrought to the bail and then poured on to the paste, atirring being continued all the time. Flavouring and sweetening are added to the mixture as the milk boils.

Steamed Custard. To prepare a steamed custard pudding, heat up 2 egge with sugar to taste, and add a pint of milk and the desired Havouring. Pour the whole into a greased basin, cover it with greased paper, and put it into a stenmer or into a pan half filled with boiling water. Let the water simmer very gently for a bout half an hour, until the pudding is set.

A good variant from plain custard pudding is provided by this recipe. Put $\frac{1}{4} \mathrm{~b}$. jam into the bottom of a greased pie-dish, and sprinkle over it a tumblerful of breadcrumbs. Pour over the whole a pint of custard made as a bove, taking care not to disturb the jam at the bottom of the dish, and bake the puddling in a moderately hot oven for 20 to 30 min .

Custard Tartlet. The pastry for these tartlets is prepared by sieving 8 oz. Hlour. adding a pinch of salt, and then rubbing in 2 oz margarine and the same quantity of lard. Add enough cold water to mix the whole to a stiff piaste. Roll it out till it is a bout $\frac{1}{f}$ in thick, then cut it into small rounds and line some deep tartlet tins with it. Line each case with a piece of greased paper and then fill it up with uncooked rice to prevent it from tising in the centre. Bake the cases for about 15 nin., or until they are lightly browned. Then take out the paper and rice, and leave the cases on a sieve to cool Make $\frac{3}{4}$ pint of

Custard Tartlet. Dlsh of these deen tarts flled with thick custard and sprinkled with nutmer
thick custard, flavour it with vanilla and leave cotton, wool, or clean linen should be used for hole with hrass bush is also sunk into each it to cool. Then put it into the cases, and grate the purpose. As soon as bleeding stops bring a little nutmeg over the top of each. A little raspberry jam may be placed in the bottom of each case before the custard.
Another variety of custard tartlet is pre pared by lining patty pans with a short crust. and three-parts filling them with custard Bake them until slightly browned and leave them to cool on a sieve. Make some sugar icing by mixing the whipped white of 1 egg with l oz. of castor sugar, spread this over the tartlets, sprinkle some more sugar on top, and then bake them slowly until the icing is crisp. These tartlets can be made still richer if a lit tle jam is put into the cases under the custard.
CUT: How to Treat. Slight clean-cut wounds, such as are made with a knife, should be cleansed by holding under a tap for a few moments, or by bathing the part with clean cold water, or, preferably, carbolic acid lotion (1 in 40) or a solution of boric acid. Lint,
the purpose. As soon as bleeding stops bring thin covering of boracic powder, a dressing of int or clean linen, and bandage. A little boric ointment may be applied, or the wound may be covered with flexible collodion, Whenever festering occurs, dress with some antiseptic, such as boric, salicylic, or cyanide gauze, after thoroughly washing with one of the above mentioned or another antiseptic lotion

A cut of any size, or a deep cut which bleeds profusely, should be covered over with a towel soaked in cold water (or, better still, a 1 in 40 solution of carbolic acid and water) while waiting the ductor's arrival. Efforts should be made to control the bleeding by applying pressure over the wound, or, if this does not succeed, on the main vessel supplying the part. If there is any delay in the doctor's arrival a tourniquet may be put on. See Bandage: Blceding: First Aid: Tourniquet. op edge of same. The finishing depth of the upper tray will be 1t in inside. of the upper drawer 1 in in. full, and lower drawer $2 f$ in. full. These receptacles should have bottoms and sides covered with green baize or a suitable cloth. If the bottom is lined first, the sides and back can be fitted with cloth-covered slips of three-ply.

For the lid, two pieces $15 \frac{1}{2} \mathrm{in}$. by $1 \ddagger \mathrm{in}$. net will be needed. and two pieces $12 \frac{1}{2}$ in. by 18 in. net for the sides. The top finishes $15 \frac{1}{\mathrm{~g}} \mathrm{in}$. by $2 \frac{1}{2}$ in by in. thick. The sides should be mitre. dovetailed together, and the top rebated in $\ddagger$ in. deep, the remaining $\frac{1}{y}$ in forming the top edge, to be ruunded or bevelled off.
The hinges should to a special kind of quadrant box hinge, as at Fig. 8. The lock is fitted to a block inside centre of front of lid, to permit the lid to close down flush with the alosed pilasters. A corresponding link plate is fitted to front rail of case. A couple of brass pin plates are also fitted to lid so that they drop

## Cutlery and the Cutlery Canteen

## Directions for Making a Useful Recaptacle

Demiled information about the various kinds of cutlery will be found under the headings Fork; Knife; Spoon, etc. See also Cabinet Making: Drawer,"erc.
Under this general name all small cutting up clean and true. For the back a piece instruments are included, such as scissors, of equal thickness to finish $15 \frac{1}{\frac{1}{2}}$ by $6 \frac{1}{2}$ in. razors, knives and carvers for fish, poultry and meat. Table cutlery sold in sets in a canteen or cutlery cabinet may, in addition to knives in two sizes, contain forks and spoons, fish and fruit knives and forks, tablespoons, gravy spoons and carvers. Sets may contain sufficient articles for twelve or six persons.
Making a Canteen. A cutlery canteen, as at Figs. 1 and 2, has much to recommend it. Fig. 1 shows the cabinet closed by means of locking pilasters, sunk handles being fitted to drawers and also to the cabinet ends for lifting

Cutlery Canteen. Figg. 1 and 2. The canteen, which in in olished wood and has a tray and open

and becks of the drewers
purposes. Fig. 2 shows the cabinet opened out including a lift-up lid with well immediately under it, and also a couple of drawers or pull-out trays.

It can be made in oak, well seasoned and sound, stained to a rich nut-brown colour an polished. An inlaid tablet of brass on the lid will heighten the finished effect.

The length of cabinet is 1 ft . $3 \frac{1}{\mathrm{f}} \mathrm{in}$. by. $12 \frac{1}{\mathrm{t}} \mathrm{in}$. wide by $8 t$ in. over all. The lift-up lid is $1 \frac{1}{4}$ in. deep outside, to be fitted as a tray for cheese knives. The upper well is $1 t$ in deep, with special fittings. The upper drawer should be allowed 17 in . deep over outside front, and the lower one $2 \frac{1}{4} \mathrm{in}$. deep. Each of the latter has special fittings for the various items to be contained in compact dozens or half-dozens.

Two sides of the case can first be got out to finish 11 in in. by $6 \frac{1}{6} \mathrm{in}$. by $f$ in. thick after planing to allow the locking pilasters to close in Hush, will project $\frac{i n}{}$ in. at front and finish $\frac{1}{\frac{1}{2}} \mathrm{in}$. thick, to fit Hush at sides and back. It should be screwed up to sides and back with brass screws.
The drawers (or pull-out trays) should be made as dust-tight as possible. Fronts had beat finish of in. thick sides and backs in. thick, mottoms $\ddagger$ in. thick, let in flush.
The fronts, sides and backs of the drawers
ane dovetailed together, each front being fitted with a sunk or flush brass handle or a cup handle. All should close in flush ready for locking the pilasters. These finish $6 t$ in
long, hinged with brass piano hinges. At in.
 will be required these parts being preferably mitre-dovetailed together, or housed and screwed or dowelled together. The front has a top rail $1 \frac{1}{2} \mathrm{in}$. by $\frac{4}{4} \mathrm{in}$. dovetailed into position for preference, but may be tenoned or dowelled instead to the sides. The upper tray bottom can be of $\downarrow \mathrm{in}$. wood cleaned up and grooved into sides and back, and the front edge rebated, glued and panel-pinned into front rail. A bearer rail under the upper drawer to finish in. thick may be continued from front to back to form a dustboard. The bottom,
into the holes in top edge of pilasters previously referred to. The fittings are slips of deal cut out with a fretsaw, then covered with cloth, using liquid glue, ordinary glue, or shoemakers' paste as an adhesive.
The lid, Fig. 3, can be fitted for 12 cheese knives, each fitting heing about $1 \frac{3}{3} \mathrm{in}$. wide by 1 in . high, and shown to larger scale at Figs. 9 and 10 . The slip will be a shade under $\frac{7}{3}$ in. high, notched out at intervals $\frac{7}{8}$ in wide by $\frac{f}{8}$ in. high, to receive the handlea. The capping can be of three-ply with a $\frac{8}{3} \mathrm{in}$. slip of same to lift up and be fastened down by clips as Fig. 3. The blades enter notches $\frac{7}{8}$ in. by $\frac{1}{\frac{1}{2}} \mathrm{in}$., as Fig. 10, the fitting being cloth-covered beforc inserting into position.

The top tray of case (Fig. 4) will have fitting.a for carving knives, steel and forks, and 12 table knives, the blades of which interlie. An enlarged detail of slips is shown at Fig. 7 for carvers and steel, the cuts being 4 in . by $t \mathrm{in}$. 3 in . by 1 in : 21 in . by $\ddagger \mathrm{in}$., and 1 in . by $\frac{1}{\mathrm{f}}$., out of slips it in. high, $\frac{1}{6}$ in. thick, with the cuts right through. The table knives can le in slips as Figs. 13 and 14, height being $1 t$ in. full and thickness $\frac{5}{8}$ in. for Fig. 13, with the cuts $\frac{2}{8} \mathrm{in}$. wide by $\frac{1}{} \mathrm{in}$. apart: and for Fig. 14 cuts are $H_{b} \mathrm{in}$. high by $\frac{1}{2}$ in and $t$ in. alternately, each cut heing $t$ in apart.

The upper drawer can be fitted for, say, 6 teaspoons, 12 dessert forks, and 12 table forks. Size for slips is $1 \frac{1}{t} \mathrm{in}$. high by ${ }_{8} \mathrm{in}$. thick. The bottom drawer would take 6 tablespoons, 12 dessertspoons, and the remaining 6 teaspoons. Slips can be $2 t \mathrm{in}$. high. A plan of drawers is seen at Figs. 5 and 6 An enlarged repeat of the slips for these items is given at Figs. 11 and 12. The locking pilasters are shown closed and open respectively in Figs. 1 and 2.

CUTLET : How to Cook. To prepare cutlets, trim away all pieces of fat, and if there is any bone in the centre cut this away. The bone at the end must be scraped bare and fres from fat. Beat the cutlets with a wet cutlet bat or rolling-pin to make them tender and to improve the shape. They should not be more than $\frac{1}{2}$. thick. Dust with flour that has been seasoned with salt and pepper,

Cutlok. Dist of grilled matton cutlets, garnighed with green peas and decorated with paper trille in the same way as a chisel.
firmly wedging it in place. A rebate is formed by backward and forward strokes with the gauge, cutting on the forward stroke. When one face of the work has been so cut, it is turned over, and the same procedure repeated. The cutter should be ground and sharpened

CUITING-OUT. As applied to tailored clothing for men and women, cutting-out is a highly skilled trade, but the process of cutting out simple dresses, undergarments, etc., is easy with a good paper pattern to work from.
Three pairs of scissors are necessary, viz., a large, sharp pair for cutting large garments or thick cloth, a smaller pair for moderate-sized garments and silk, and also for cutting round curves, while a small pair is wanted for slots, slits, buttonholes, etc. A measuring tape is necossary for measuring the material and taking measurements of the
then coat with egg and breadcrumbe, and fry them. The cutlets can be dipped into melted butter and breadcrumbs, instead of egy. Cutlets can also be stewed in a casserole or plainly grilled.

Cutlets are usually served on a mound of mashed potatoes, the cutlets being arranged with the bones pointing in one direction and wrapped round with paper frills. Various sauces can be served with them. Veal cutlets should be garnished with slices of cut lemon. lamb aud mutton cutlets with chopped parsley. Tomatoes, grilled or made into a puréc. spinach sauté in butter, or green peas, are usually served with cutlets.
To make cutlets from the remains of cold veal, lamb, mutton, or fowl, mince the meat finely, season, add chopped parsley or any Havouring desired, and mix with the yolks of eggs until a firm mixture is obtained. Shape the mixture into cutlet form, coat with egg and breadcruinbs, and fry them. Cooked and Haked remains of fish can be treated in the same way. See Casserole: Mutton.
CUTIING GAUGE. This tool is for cutting lines on woodwork, making small rebates and for similar purposes, and serves

Cutting Gauge. How the tool is used for cutting a rebate on a piece of wood
the same purpose as a marking gauge. It consists of a steel cutter fixed to a hardwood stock or bar by means of a wedge. A sliding head moves on the bar, and is fixed at any desired position from the cutter by means of a wooden thumbecrew.
Its general form is seen in the illustration. It is used by grasping the stock with the left hand when marking out work, in the right hand when cutting a rebate. The method is to adjust the distance between the cutter and the face of the head, which determines the width of the rebate. The cutter is set to the requisite depth by loosening the wedge, pushing the ontter through the stock as far as needed, and
pattern, to compare it with the size wanted, and also for measuring any straight or crossway strips that may have to be cut for frills or trimming bands.
As a rule it is easy to determine which is the right and which is the wrong side of a material. Woollen materials are generally bought folded with selvedges together, with the right side folded inside, while longcloth and similar cotton fabrics are folded with the right side out. If materials are of single width, and therefore not folded with selvedges together when bought, the right side can generally be deternined, as it is smoother than the wrong side. The right sido of serge, gabardine, or any cloth with a fine crossway grain can be determined by holding a length down with selvedges right and left, and one cut end under the chin. If right side is outermost, the grain should run from left down towards the right.

Some materials are woven to be made up so that a certain way bengs downwards. Thus worn, it wears longer and looks better.
This up-and-down way is so pronounced in some fabrics that they have a bloom, which means that viewed from one end of the length the material shades lighter than it does when looked at from the opposite end. To determine the right way down of a material, lay it out flat on the table, and pass the palm of the hand first up one way then down the other. It should be smoother one way than the other, and should be made up into the garment so that the cloth smoothe downwards
Velvet and Velveteen. Materials which have an up-and-down shading or bloom are made up so that the dark way shades down, and the darker way can be ascertained by folding the length of material to bring the

BU perniission of IIM.M. Stutioncry Ontice
of five kinds, soft-wonded, hard-wonded, heeled, root, and leaf. The first named is generally the easiest to strike.
As a rule, a soft-wonded cutting should be severed just below a joint, and should consist of the upper part of a growing, not flowering, shoot, with three or four leaves. In some cases the wood should be young, in others half-ripe, in others quite firm. In nearly all cases the best compost for soft-wonded cuttings is loam, with abont a third of leaf-mould, and enough sand to make the whole of the conipost thoroughly gritty and porous. The cutting is made firm at the base by pressing it with the blunt edge of a lead pencil passed diagonally through the soil. Cuttings strike best round the edges of a pot.

Acacia, boronia, epacris, and erica are examples of hard-wonded cuttings. On the whole they are less reliable than the softwooded. In most cases the usual favourable conditions are: small pieces of the upper parts of non-Howering shonts, a compost of peat and sand, wond fairly firm and ripe, bell-glass covering. A heel is a small strip of the older wood, about an inch long. The cutting of young wood is pulled or cut off with this strip instead of being cut clean across under a joint. Some plants root better and are less liable to damp off with than without a heel. By leaf cuttings are not meant leaves laid on the soil, but leaves with the slalk inserted. The indiarubber plant is a familiar example. They require a good deal of moist heat. Gloxinias, begonia Gloire de Lorraine, and pelargoniums generally ront when thus propagated

Evergreen shrube are increased by cuttings placed in sandy soil in a frame in August. Leaf-losing trees and shrubs are propagated by cuttings set out of doors in OctoberNovember. Certain plants, e.g. seakale, anchusa, Japanese anemone, oriental poppy, are propagated by pieces of the ront which are inserted as cuttings. See Apple; Gooseberry; Grafting; Raspberry.

CUTWORM. The larvae of the turnip moth, the heart-and dart moth, the yellow underwing and others are known as cutworms or surface caterpillars, and cause much damage to cultivated plants. As a rule cutworms spend the day in the surface layer of the soil or hidden under leaves, thick grass or stones. At night they come out and feed, some. times on the leaves of plants, but more often on their stems, both a bove and below ground, and are specially fond of the thick, fleshy parts of such crops us mangolds, turnips and

Cutworm. Potatoes damaged by the cater pillar
potatoes They also bite through the stems of plants.
Since the caterpillars are often of the same colour as the soil on or in which they live, they are not ensily seen. An examination of the crop after dark is perhaps the simplest way. They rre often epecially troublesmie on foul, weedy land, and potatoes are likely to be attacked. When crops of potatoes or mangolds have been badly attack ed it is risky to sow winter whent unless the pests have first been destroyed.

Undoubtedy the best method of dealing with cutworm-infested land is to run poultry upon it, and wherever this is possible it should have precedence over all other treatments. When young root crops are being attacked above ground, the plants may be sprayed with lead arsenate ( 1 lb . lead arsenate paste to 25 gallons water). Provided the plants are small so that the greater part of the root has yet to he made, there will be no risk of poison. ing stock when the roots are finally eaten. Lead arsenate is poisonous to man and domestic animals and must be carefully used.
In allotments hand-picking is often the most simple method of dealing with the pests, which can generally be scraped out of the

Cyclamen. The Persian cyclamen a beautifal greenbouse plant soil near the plants last attacked by means of a blunt knife or pointed stick. Theymay also be col. lected atnight when they are feeding or crawling about on the surface of the soil. These measures are advised in Leaflet No. 33 issued by the Ministry of Agriculture. See Cabbage : Potato ; etc.

CYCLAMEN : Bow to Grow. The Persian cyclamen is a valuable greenhouse fowering plant in full beauty in early spring. Handy cyclamen are low-growing plants which flourish out of doors and bear small flowers in autumn and spring.
The Persian cyclamen is raised from seeds sown in August in a well drained box of sifted compost of loam, leaf-mould and sand placed in a frame. When large enough the seedlings are placed singly in $3-\mathrm{in}$. flower pots, and when well rooted in those they are potted finally in $5-\mathrm{in}$. or $6-\mathrm{in}$. pots, in which they will bloom. During the winter months they should be kept in a greenhouse temperature of about 50 degrees. In the summer they thrive best on a bed of ashes in a cold frame; they need cool, moist conditions. From seeds sown in August the plants will bloom in the following February twelvemonth. When potting cyclamen care must be taken to keep the corm on the surface. Well drained pots are necessary, and a suitable compost for the final potting consists of loam, two-thirds, leaf-mould and decayed manure one-third, with a scattering of sand and crushed charcoal.

When cyclamens have finished flowering they should be dried off by gradually giving less water. When the leaves have fallen the soil must be kept dry and the pots placed in a sunny greenhouse or frame. Late in July the corins should be taken out of the soil, repotted in fresh compost, watered and set in a frame. They will soon start into fresh growth. These plants are long lived and may be kept for many years. They are often grown successfully as window plants. There are many varieties, with flowers in crimson, rose, salmon, and other colours.

Hardy cyclamen should be planted out of doors in well drained soil with which leafmould and mortar rubble have been mixed freely: they like slight shade. The cormis need only a slight covering of soil except those of Cyclamen ncapolitanum and africanum, which should be set an inch or so deep. Some of the chief kinds are: africanum, reddish flowers, September; coum, rose-red, April; europaeunı, rose, September; ibericum, rosered, March; neapolitanum, reddish, September; repandun (bederaefolium), reddish, spring. The corms of the autumn flowering cyclamen are planted in July-August; the others in September. Pron. Sik-la-men.

CYCLE. Both a tricycle and a bicycle are called a cycle, while cycle shed and bicycle shed are interchangeable terms. See Bicycle; Motor Cycle; Tricycle.

Cycle Car. See Three. Wheeled Car.
CYMBIDIUM. A beautiful winter and spring-flowering orchid of which innumerable new varieties have been raised in recent years The flowers, in shades of rose, buff, pink, and green on long arching spikes, are most decora tive. They are vigorous plants and are grown in pots in a mixture of loam and peat with sand. They thrive in the intermediate house in which a minimum temperature of $55-60$ degrees is maintained. Pron. Sim-bid'i-um.

CYPRESS. The cypress is a graceful evergreen conifer of which there are many species; some of them are ideal lawn trees. They flourish best in moist districts in deep loamy soil; they are less satisfactory in gardens near large towns where the air is impure, or on very chalky land. One of the chief species is Cupressus lawsoniana, of which there are many varieties, e.g. lutea and Stemartii, with yellow leaves, Silver Queen, with silvery-green leaves, and gracilis pendula of droop. ing growth Cupressus macmearpa is a beautiful quick - growing conifer and its yellow leaved variety lutea is attractive: both these are better suited to comparatively mild than cold districts. Sem. pervirens, distinct columnar growth, so conspicuous in Italian gardens, is less hardy than others.

Cypress. A favorite coniler, Cupressus lawsoniana

DAB: The Figh. This small flat fish of the flounder apeciea, scasonable all the year. is found in abundance mund the coast of Great Britain. To fry, the dab should be cleansed, well dried, and rubbed with anlt an hour or two before onoking. and dipped into egg or milk nnd bread. crumbs. It should then be garnished with fried paraley

To noil a dab sufficient wnter is needed to cover the fish, a little salt and vinegar being added About 10 min . is the time required, nod any fish sauce can be served

DACE. A fresh-water fish, resombling the roach. found in nbundance in English streams. The fleah is somewhat coarse but it can be fried or boiled.
DACHSHUND. In spite of his unprepossessing rрpesrance, the dachshund has a high reputation as a domestic pet. being affec-

Dachshand, a short-haired breed of German dog tionate in disposition, a a plendid playmate for young children, and $n$ good watchdog Al. though not used for sport in Great Britain, his German name, signifying badger-dog, indicates the purpose for which originally he wns bred.
The body of the dachshund is exceedingly long, and the legs very short. the front pair oronked. The long head tapery to the sharp muzzle. and the ample ears hang flat beaide the cheeks The tapering tail of the animal is carried with a rather low curve The type usually acen in Great Britain has a short. olose cont which may be some tint of red, black brown, or grey, or n combination of two coluurs. There are also long-hnired and roughhaired breeds See Dog.

Daddy Long Legs. This is the popular name npplied to several of the larger kinds of crane ties. Sce Crane Fly.

DADO : For Decoration. Wherc there is $\Omega$ dado there should not be a frieze is $n$ rule which holds gond in average homes, but occasionally both are seen in the case of exceptionally large and lofty rooms, or on a staircase where there exists a wide expanse of wall between the stairs and the ceiling.

The dado, which may be described as a decorated space letween a base consisting of a akirting and a moulding, may be of one of various materials. Ahout 3 ft . to 4 ft .6 in . is an ordinary depth from the floor to the dado-moulding. The dado bas a tendency to cut the height of $n$ room, especially when there is marked contrast in colour or tone between it and the rest of the walls. Prnelled wood is used in oak colour for stairense, hall and lounge, and is a saving precaution against dirty marks on light-coloured walls, where there are children. Hand-made Jnpanese embossed leather papers make $n$ substitute for auch panelling. They are good in colour, and durable, heing impervious to the action of amoke and gas.

Decoration for rooms in Adam or Queen Anne styles utilizes the dado in wooden panelling, while above the dado rail the walls are painted and mouldinge applied to simulatc the big panels of those periods.

A tiled dado is clean and labour-saving in kitchen or bathmom. See Annglypta; Decoration; Moulding.

DAFFODIL. The beat hardy spring-flowering bulb, suitable for planting in flower beds nod borders, in grass and for cultivation in pots in the greenhouse and in bowls indoors.

Forred bulbs will bloons in Jnnuary and a suecession of flowers can be maintained unlil March, when the earlics! of those out of (loors enme into blunm.
Daffortil is the popu lar name of the trimpet variety of narcissus. auch as Emperor and Empress A modern classification deacribes tell groups of narciasus The classification is based on the comparative length of the outer or perianth scgmente and that of the central part which is variously deacriled as trumpet. cup or crown according to its length. The chief olasses are ns follows:

Trumpet daffodils, in which the trumpet or cmwn is as long as or Innger than the seg. mients of the perianth Favourite yellow varieties are Emperar, Golden Spur, Laril Roberts, King Alfred and Maximis. White varietien are Madame de Gmaff, Pcter Barr, Beersheba, Alice Knights and W. P Milner. Others with white perianth and yellow trumpet (called bicolors) are Horsfieldii, Empress. Weardale Perfection and J. B. M. Camm.

Chalice Cupped or Incomparabilis: the oup or crown is not less than one-third the length, of the perianth segmenta. A few gond varieties

Daffodil. 1. Challee - copped Sir
Watkin 2. King Allied. 3. PoetiWatkin. 2. King Allited. 3. Poeti-
cus narcissus.
4.
Variety known as the Boop Petticoat dafodil
are Sir Watkin, Gloria Mundi and Blackwell.

Star. Barri or Short Cupped : the cup or crown is less than one-third the length of the perianth seginents ; the perianth

Eucharis-flowered or Leedsii: distinguished frmm the atar narcissi by having a white perianth and white or pale cup or crown. Duchess of Westminster, Mrs. Langtry, Maid of Athens, and Snowsprite are typical ones.

The remaining groups consist of varietics of Narcissus triandrus, cyclamineus (both of these are miniature kinds), jonquil, the bunch. Howered Narcissus tazetta. Poet's Narcissus and the double narcissi.

Dafiodils never look
 better than when grouped in grass; the bulbs ane planted in September. October about 3 inches deep. Suitable varietiea for this purpose arc Emperor, Empreas, Prallidus pracenx, Barrii conspicuas, Mrs. Langtry and Sir Watkin. For planting in formal flower beds Eniperor, King Alfred. Empress and innumersble others are used.
The ministure hoop patticont daffodils (bulbocodium), cyolnmenHowered (cyclamineus), triandrus, minor and minimus, are suitable for the rock garden: they need well-drained soil.

Varieties for cultivation in flower pots under glass to supply early blonms nre Golden Spur, Horsfieldii, maximus, Victoria, jonquil. IV. P. Milner and the bunch flowered or poetra varietics. The hulbs should be potted carly in September, placed under old asbes out of donss for 6 weeks and then brought under glass, a few at a time, to provido a succession of bloom.

Daffodil Pests. Two main troubles afflict daffodils. First, there is the narcissus fly, which lnys is yellow or white and the cup is coloured. eggs on the lenves in May and June, and the Among the few favourite varieties of daffodil are grubs that hatch cat out the heart of the bulbs. Barrii conspicuus, Red Bracon and Red Chief. The flies resemble small dark huinble-bees,
but being true flies have only two wings, and have no visible antennae on their heads. They should be netted on bright sunny days. The bulbs sbould be examined at lifting time, and gently pinched: if soft they should he cut open and the grub destroyed. The other diaense has been proved to he due to eelworm, which, in addition, is particularly troublesome in connexion with cucumbers and similar plants. See Bulb: Cucumber; Floiver Garden

DAHLIA. There are many types of dablia. and some are nore useful for garilen decoration than others. Those chiefly to be recominended for this purpose are the star, charin or dwarf. peony-flowered. mig. non, decorative, collar. ette. tall peonyflowered, single and some of the cactus varicties. Other typos are the show, pompon and fancy.

The tubers of tho dahlia are not hardy, therefore they must he lifterl as soon ns the tops of the plantes lave been cut down by frost and stored in it írost pronf place for the winter. They keep well in boxes of soil or sand. In April the old tubers mily be planted out. of doors; they

Lahlia. 1. Sapho, a stagle variets 3. Yeoman, cactos dablia.

2. A characteristic show dahlia. Patrol, a collarette variety

A separate room is desirable tor the washing up of the utensils, and this is arranged quite easily by putting up a thin partition.

Windows that will open can be placed on one or mnre sides of the dairy. as ample light is highly desirable. Fine wire gauze or similar material can be fixed outside the windows to keep out insects, while allowing air to circulate freely The dairy should be provided with ventilators, preferably both below and above, in the walls. The walls should be smooth, which can be accomplished by cement. ing the interior; they can be either washed down frequently. or, better still. they can provide a profusion of bloom. Finer flawers are obtained by starting the tubers into growth under glass in February and taling cuttings from the young shonts. These are inserted in pots of sandy soil : after having been hardened off in May they are planted out of doors early in June. Dahlias may also be raised from seeds sown in a heated greenhouse in January-February; they will hloom late in the summer. There are innumerable varieties of the types referred to above. and fresh ones are introduced annually. They are described in catalogues.

Dahlias need deeply dug and manured soil, a sunny position and full room for development. They must he stalied carefully, for the shonts are brittle. The best display is assured by removing many of the side shoots.

DAIRY. To fit up a small dairy is by no means a difficult matter. A building can oftell be altered to fulfil the necessary conditions, such as a shed about 15 ft . by 12 ft . It should be situated at a sulticient distance froin the cowshed, the dungheap, or other source of contamination. The aspect should be northern, if possible, as this keeps the dairy cooler during the hot weather. The entrance to the room should be from the open air, and not from the cowshed or other farm building. and the room should be used for no other purpose than for the treatment of the milk.
also the a washing-up room, and there should adapted for sterilitsink. The copper can be hole through the centre of $n$ wooden lid and

fitting a plug in The steam Irom a properly boiling copper is sufficient to sterilize the utensils in 0 min . Pails and churns can he sterilized by inverting them over the opening in the lid, and smaller articles by placing them in a steamer, which may be improvised by using the receiver of a milk cooler or separator, placing it over the opening and covering it up with a thick cloth Alterna. tively all the utensils can be put into boiling water for several minutes.

After use, nll utensils should be rinsed, with cold water as soon as possible, thoroughly scrubbed inside and out with hot water, and then scalded or steamed and inverted on $a$ rack provided for the purpose. Floors should he washed and scrubbed with a brush, swilled with boiling water, and dried with a cloth or squecgee. See Butter: Checse: Churn Cream : Milk, etc.

DAISY. The named varicties are showy flowers lor spring heds. Rob Roy, Alice. Dresden China, and link Beauty are favour ites. For giant double daisies sow speds in June. The sedlings are put on a reserve border and planted tinally in autumn. They should be lifted and divided after Howering: the pieces are grown on a reserve lwarder during the summer. The variety popularly termed the hen-and-chickens daisy has the peculiarity of forming small Howers round a large central bloom.

DAISY CREAMS. To make these, cut a fresh Swiss roll weighing 1 lb. into slices about $\frac{1}{2}$ in thick. Prepare $\frac{1}{2}$ pint jelly in the usual way, then chop it rather fincly and put a heap of it on each slice. Whip $\&$ pint cream and mix it lightly with a stiflly-whipped white of egg. With this the jelly should be covered.

Daisy Creams, an attractive swee!
Then blanch I oz. of sweet almonds, splititins each in half lengthways. and cut 2 or 3 candicd apricots into small. thin rounds, each about the size of a threepenny piece. Soak a little angelian in warm water till it is soft. then cuc represent leaves $\mathrm{On}_{1}$ the top of each sweet put a daisy formed froin the halved almonds, using these as petals, and a round of apricot for the yellow centre. Thic angelica should bo arranged to form stallis and leaves.
DALMATIAN In certain respects the Dalmatian dog resembles a spotted pointer, and from the numerous dark spots on his white coat he has been called the plum pudding or spotted dog. He is usually very clean-built, strong, and agile, with straight lega and feet, powerful loins, deep chest, and nicely-moulded neck,
the short coss. olcek, glossy, and casily groomed. Weighing about $\overline{5} 5 \mathrm{lb}$ on the average, the Dalmatian is of medium size, and not too big for an indoor companion. He is not noisy. seldom barking when it is not his duty to do so; but if he does bark, his deep voice is an effectual warning to atrangers. In chonsing one, remem ber that the markings may be either

Dalmatian Dog, a large breed ol carriage dog, also nown as the plum pudding dos
black or liver-coloured on a brilliant white ground Experts insist upon the spots being clearly definerl, without touching one another, and in proportions they may vary from that of a sixpence to $n$ llorin They should bo pure in colour, not lareing any white hairs mixed with them The dog is bardy. easily kept in condition, and an oxcellent breed in every respect Sce Doz.

DAMAGES: The Law. Anyone who breaka a contract or who by his treapass, or nuisance, or negligence callses injury to another in person or property must pay damages in wome classes of cases, e.g. libel or slandor, the damages awarded may be punitive or exemplary: that is to say, they bear no relation to any monctary loss sustained by the person uggrieved.
The same is truc in claims for assault or breach of promise. But in most cases the damages to be awardod are such a suin as will make up to the individual the actual loss sustained by roason of the wrong or the breach of contract In the case of peraonal injuries, a man may claim what it has cost him for doctor's fees, special food, the cost of a holiday to recuperate, earnings lost, and, in addition, a fair sum for the pain and suffering he has undergone, and for any permanent injury.

When a husband, wife, child, father, or mother is killed by somebody's negligence, or otherwise, under such circurnstances that if he or she had only been injured and not killed, an action for dannages could have heen brought againat the wrongdoer, the widow, or children, or widower, or either parent, can recover damages proportionate to the pecuniary loss sustained. Nothing is allowed for injured fcelings, but only for the loss of the pecuniary benefit which the widow or other dependent actually received or might reasonably in the future expect to receive from the decensed.

A person breating a contract is liable to pay some damnges, cven though the other party has suffered no loss: but these may only be nominal-a few shillings. But the other party to the contract can also recover any pecuniary damage for any loss which was the natural and reasomable and direct result of the breach of contract. If anyonc agrees to supply goods and does not send them, the buyer is entitled In purchase them elsowhere, and if he has to pay a higher price, he can claim the difference. If a householdar orders work by a tradesman at a price, and the work is badly done, the householder is antitled to linve it put right by
another man and olaim from the lirst man as damages what he had to pay to the second See Accidente: Contract : Einployer's Liability Serrant

DAMASK : The Fabric. There are linen, cotton, silk and wool damasks, and the feature common to them all is the method of construc tion. The patterns are usually large and floral, and are formed of satin-like twills in reversed directions.

Damasks are made more for houschold and furnishing purposes than for dreas Silli damasks made for church use have stood for centuries. Victorian worsted damasks, used as winter window curtains, and tablecloths, have, in many instances, stond 50 years of wear with little barm. There are two kinds of linen table damask known as double and single damaak. The latter has the atronger weavo. Cotton damask tablecloths are innde in the same patterns na linens. but they lack firmness and brightnoss.

DAMASK ROSE. A very old type of rose, said to have been introduced into Great Britain in the 16 th century. Damask roses do well as dwaris, but are not suitable for growing as standards. They require gencmus cultivation, and all their wenk growth should be thinned out in March or April, leaving strong shoots pruned to about one-fourth their length.
Several varicties are obtainable, among the best being: Lady Curaon, large single pink; Crimson Damask, bright crimson: York and Iancaster, white, striped red: Old Rose Damask, red The Dainask rose is largely used abmad for the purposo of making attar of roses. See Rose

## Dame's Violet. See Rocket.

DAMP : Precautions Against. Excers of moisture or damp may be present in the soil, the dwelling, the atmosphere, or the clothing, and so affect health. A cold, damp climate, dwelling or workshop favours the development of theumatism and chest com. plaints, including consumption. Sitting in damp clothes predisposes to chills.
In the house damp needs to be carefully guarded agninst, and during the winter no room containing a piano or any other musical instrument, valunble pictures, or furniture that is heavily parlded, should be left long without $n$ iirc. If the drawing mom is not used daily, a fire should be lighted in it ance or twice a week. Pictures that have heen hanging on a damp wall should be taken down, the moisture wiped off with a clean duster, and then placed with their faces to the wall in $n$ warm room. Furniture or perishable articles which are being atored in a cellar should be placed on battens and should not be pushed close against a wall.

Beds left unóccupied for several days can be kept free from damp if hot-water bottles are placed between the sheets at frequent intervals This obvintes the need for removing the berdding and niring it hefore the fire. Damp in heds can be detected by placing a mimor in the bedclothes. If it remains unclouded, the bed is dry enough to he slept in. If damp cupboards are sprinkled with quicklime and then left for two or three days, the moisture will be $n$ bsorbed

Damp in Walls. The cause of damp in the house is not alwnys easy to discover at first. although the general position of the trouble will often indicate its probable source. For instance, if the wet patch is at or near the top of the room, and $n$ gutter is just outside, the gutter will probably be found to have got choked up with leaves and rubbish, thus impeding the frec flow of the water, and causing it to overHow. It may do this on the wall side of the gutter, when the dampness will appear near the top of, the room, or it may overflow on the outer side of the gutter, and
be driven by the wind on to the wall at a considerable distance away.

A nother caruse of dampness is the failure of the gutter brackets, which may work loose and sag down, or even be broken off altogether The trouble will probably disappear when the slack brackets are wedged and cemented up. or roscrewed to woodwork. Cane must be taken to see that the guttering has a sufficient and regular fall. Should n section of gutter sag bedily, it will cause a pocket in whiclı water will accumulate when a heavy rainstorm puts oxtra pressure on the gutters

Some old-fnghioned houses with curb roofs, those with a mansard roof, or a brick of masonry parapet, have inconveniently arranged internal gutterings, generally made or envered with shect lead or zinc. These oither perish with age or, more frequently, are punctured by falling matter, or the pasage of somicone wearing hobnailed hoots When dcaling with this class of gutter, always wear felt slipjers or smmething soft, such as a rubber golosh over the boots, or take care to walli on duck boarda laid down for the purpose.

Holes are very difficult to locate in auch gutters: the only thing to do is to hrush or clean all suspected parts, and persevere until the perforation is found. It can then be repaired by menns of a wiped joint, a new aection can be laid. or $n$ temporary repair effected by applying one of the many compounds sold for the purpose of rendering lealiy mofs watertight.

Damnged slates and tiles are ubvinus causes of dampness : but it does not follow that a damp place on a wall is necessarily made because a tile is missing immediately above it. A diaplaced tile may allow rain to drive in, or, worse still, to llow in by convection: it inay then drip off on to, say, a raiter, and run down the rafter for a distance of several feet before it finally drips on to the wall. Generally, however, it is the tiles at the eaves that should be auspected; all those that are damaged must be replaced, or the cracks and holes made good with cement, mortar, or slurry. The rain-water heads and downpipes may be choked with debris, and cause damp places on the rall, the plain remedy being to clear away all obstructions

Treatment of Porous Bricks. When a lonuse has been built with inferior or porous bricks, the wet may drive through the wall. The cure is by rendering with cement mortar, rough casting, or by a cont of one of the waterpronf compositions. A waterproofer known as Pudlo may be adiled to the cement used for rendering n damp wall. This preparation is mixed with the cement in the proportion of one part in twenty, in the dry state, beforo the cement is added to the sand. A preparation of emulsified paraffin was, painted or aprayed on to walls in warm, dry weather, will till up the pores, and render them impervious to damp. Sold under the name of Sprawns, this can he obtnined frmm ironinongers and buildery' merchants. It is also available for inside work. Another method is to apply two or three coats of silicate petrifying liquid to the outside wall.

Besides dampness duc to falling water and driving ritin, snother cause of tronble is found in defective damp culurses, which allow the wet to rise upwards by suction in the bricks or by convection. In addition there are purely local oauses, such as a burat waterpipe or an unexpected flood in the district. Treatment must be determined by circumstancea First ascertain that there is a damp coursc by examination of the lower courses of brickwork. If there is, nnd the defective spot can be located. it can he remedied by removing the brick course above and helow the damp course, and resetting a new onc.

All sudditional precaution in houses situnted in a damp locality is to provide adequate
surface draingge. This ensures that the land in the vicinity is relieved of all surplus water, and any chance of sodden or waterlogged ground eliminated. See Cottage: Gutter: House: Roof, etc.

DAMP COURSE. This is a layer of impermeable inaterial built into all walls to prevent the damp from rising out of the earth. Suitable materials for use comprise slates, sheet leid, asphalt, or bitumen.

In all probability slates are cheapest and best in the long run. They are purchased in convenient sizes and known is D.C. slates, generally monsuring
18 in. Iong and 9 in. wide for the ordin ary 9 in. wall. They are lais intwocourses, breaking joint and well and we 1 l
Damp proor Course
soils, but best in ground containing lime. After the trees have been shortened oncc, or perhaps twice, in their carly daya, they require practically no pruning. Propagation is generally by budding and grafting on to plum stocks. The best varieties arc the Merryweather, Bradley's King, Shropshire Prune. and Farleigh Prolific.

How to Cook. The small purple fruit im. proves with cooking. but requires plenty of sugar to be cooked with it. Sugar added after the damanns are cooked will not remove
the acidity To atew damsons, pick over and the acidity To stew damsons, pick over and
rinsc l lb, and simmer them in a stewpan with 3 heaped tablespoonfuls sugar and a breakfastcupful of water. If the damsons are first slit

bedded in cement mortar. Asphalt and with a knife they will cook more quickly. bitumen damp coursing is generally used in the form of long slieets, the end of one sheet overlapping that of the next. It should be laid on $a$ bed of cement mortar flouted off smooth, and eare taken that the inaterial is not punctured or tom while being laid. It is advisable to use only the best quality. Trarred roofing felt, which is sometimes employed as a damp coursing, is an inadequate protection for the walls of a building.

Horizontal damp courses of all kinds must be laid on walls, piers, chimmey breasts, sleeper and fender walls; they must cover the full width and be laid beneatly the lowest timbera, and at a height not excceding 12 in . nor less than 6 in. above the ground. Fig. 1 shows a simple horizontal damp) course. When the lloor level is below the ground level, three damp courses aro needed-first a damp course 6 in . above the ground level; secondly. one below the wood sleeper plates of the lowest floor, and the third is a vertical dump course connecting the others, thus preventing any possible passage of dampness (Fig. 2).

Damp courses may also be necessary in or near the top of walls to prevent rain water working downwards, as for cxainple is garden wall that abuts on the housc. Slate damp courses are laid in chimney stacks at the point where they rise above the roof, for the amme reason See Air Bricli; Architecture ; Brick; Bungalow: House; Wall, etc.

## Damper. See Range; Stove.

DAMPING-OFF. In gardening this term is commonly applied to the premature decary of seedlings, cuttings and tender plants it is caused by a fungus disease which in the main is the result of overcrowding and careless watering. Seedlings should be watered by immersing the flower pot almost to the rin for a few minutes in a veasel of water.

DAMSON : Tree and Fruit. Being very hardy, the damson thrives in bleak places, and does not suffer from strong winds to the same extent as most other cultivated fruits. It is consequently often planted on the outsides of plantations, generally as a standard.
The treatment advised for plums quite suits the damson. It succeeds in most fertile

Any stones rising to the top should be removed. The Havour will be improved if apples are mixed with them, $\frac{1}{2} \mathrm{lb}$. apples to 1 Ib. damsons.

Damsons are excellent when prepared in this manner for llans, tartlets and pics. A damson pudding is made in a similar way to other fruit puddings. Line the basin with a auet crust, and fill it with sound damsons, or damsons and apples, and sugar. Two pounds of fruit will need five tableapoonfuls of sugar and $\Omega$ teaoupful of water. Cover the basin with $\Omega$ mund of the crust, tie over it a scalded, floured pudding-cloth, and steam it for 3-3! hours.

Damson Preserves. Damsons make good preserves. The following is a recipe for making damsun jam without stones: Take 8 lb . ripe damsons, and boil them in a stewpan with a very little water until tender. Sirain them through a coarse sieve to remove the stones, and add to the pulp) 6 lb . prescrving sugar. Let the whole boil until a little of the jam will set whel dropped on a plate, then pour it into dry, warmed jars and cover at once.

The fol.

Damson. Fruit of the Farleigh Prollac. one of the best varieties
any stones that scparate from the fruit. Then add 8 lb . of sugar and continue the proceso until the jam is done.

A very rtiff jelly made with damsons is known as Damson Cheese, and caten as a preserve. To make it, pick over some sound, ripe damsons, and put them in a covered jar in a anucepan of cold water. Bring the watel to the boil, and let it boil for 2-3 hours, replenishing it with more hot water as it boils awny. When the damsons are tender. remove them from the juice and strain them through a conrse sieve to get rid of stones and skins.

Weigh the pulp, and add sugar in the proportion of $\frac{1}{2} \mathrm{lb}$. or more to every lb . of pulp. Put this, with the juice, into an enamelled pan, and let it boil fast, stirring frequently, until it becomes a stiff paste, so stiff that it will leave the pan clean when it sticks to the spoon. Have ready some shallow, buttered inoulds-odd saucers will do-and pour the cheese quickly into them. If covered with jam puper when cold it will kee! well

DANCE : How to Give. One of the most popular entertainments that a hostess can give is it dance. If a very big dance or ball is given. a large number of invitations are sent out, an elabnrate supper is offered, the floral decorations are on a grand scale, and bands provide the music for dancing.
Such a dance can only be given in a house with very large rooms, and it is generally necessary to hire a hall or assembly roonis Many hotels have a suite of moms kept for the purpose, and when a dance is given the hostess can lessen her responsibilitics by leaving the lighting, decoration and arrangeinent of the ronms to be done by the hotel.
In the hostess' own house the refreshment arrangements can be entrusted to a firm of caterers, who make a fixed charge per head and take the whole responsibility of seeing that the food, service, and general details are suitable and adequate. There are many hostesses who feel that, provided their house is lange enough. nothing is really more enjoyable than a privato dance given in a private house, and they do not mind the trouble it entails.

The largest room is sot apart for dancin: It should be complotely emptied, and where there is parquet flooring covered with rugs it is an cayy matter to roll up and put aside the latter and polish the floor until it provides a good surface for dancing. The lighting arrangements must be adequate, for the gaicty of a dance does to some extent depend on the bril. linncy of the scene. At a New Year dance a feature in the programme may be $n$ - Twilight' dance, during which lights are switched off, with the erception of coloured electric hulbe in the overgreen decorations

Besides the ruom set apart for dancing, anitable provision must be made for sitting out and for cloak-room accommodation. If people who do not dance am also asked, it is a good plan to arrange for bridge to be played in another room. There may be a band, or several musicinns; though a good gramophone is often successfully used for a small dance in a private house.

The invitations are sent out two or threc weeks beforehand, and, if the dance is very small, may take the forin of a little note. For larger dances, printed at-home cards are used, with the time the guesta are expected and the word dancing written at the bottom right-hand corner of the card. It is usual for girls only to be invited with a partner. This arrangement saves the hostess much trouble.

A Cinderella dance ends at 12 o'clock, begins at 9 , and supper would be served at 10.30 . Other dances may be carried on to the small hours of the morning. A cotillon may be introduced, but this calls on the hostess for presents or the distribution of favours. Just tefore the guesta depart it is usual to offer each a cup of hot. moup or coffce.

## Dancing : Its Fundamental Principles <br> Some Modern Ideas on-an Ancient Art

In addition to this general article, our Encyclopedia has entrics on the various dances, e.g. Fox Trot: Quick Step; Waltz. See also the preceding article on Dance

Correct hallroom dancing is one of the most and ahort-lived crazes that come and go during heneficial of pastimes, it uses the muscles in a the dancing season.
natural manter and is conducive to preserving a good figure. But the form of dancing must be correct, balance and ease of movement being essential

Formerly far fewer muscles were used, and dancing was done almost always on the ball of the foot. This last was a most injurious practice, not only because of the unnatural strain on the leg muscles, but on the big toe joint as well, causing in many cases the mal formation of the joint. Now the heel comes into play and the ankle is used naturally as in walking: in fact all motern ballroom dancing is hased on natural novement. A good teacher endeavours to make a pupil dance as naturally and comfortably as he or she walks; and to a ceitain degree adapts thic stepa, or rather the size and manner of the steps, to the hahitual walk of the pupil, providing, of course, that it is a good walk. Therefore anything in dancing that scems uncomfortable and awkward for the peraon to nerform must he wrong, whether the fault is on the side of the girl following or the man leading

Before taking up dancing it is an excellent plan for anyone to make sure that his walk is correct. The back should be straight and the stride coming from the hips; feet should be neither turned out nor in, and should be close together when one foot passes the other as close as if walking on a plank

Basic Movements. Dancing, like any other sport or pastime, has its rules, etiquette and technique, and if the basic movements are learned correctly in the beginning more complicated movenients are easily performel later. The person who has thomughly mastered the groundwork can learn a series of new steps in a quarter the time it takes a person who has never learnt the basic movements, but dances "naturally." This applies to any dance. whether it is one of the established dances such as thic waltz. and slow fox trot, or the new

The movement is always from the hips, the legs swinging like a pendulum. The girl and man should both stand erect and naturally. the girl resting her left hand along her part ner's right arm near the shoulder, the man holding her firmly, but without strain or effort. just under her left shoulder blade, his left arm held so that his hand is on a level with his ear. One of the chief faults seen in the man's hold is that he clamps his arms from shoulder to elbow to his body, instead of holding them easily in a nice straight line from the shoulder.

The Correct Hold in Dancins
The fact that one of the partners is very lall or short should make no dilference to the form of the hold. A rall man should guard against clamping a short girl or straining at a tall one He neted only alter the position of his arm from the elbow to the wrist, just raising or lower ing it a little, as the individual may need. The position of the upper part of the arm should remain the same. The actual formation made by the hands, whether the girl's or man's, is immaterial, or rather it relies, like many other things, on the individual sense of gomil taste, heing neither clumsy nor affected. The man's hand should rest on the girl's hack in a light natural position, and the girl's hand should he the same, not spreading the lingers nor yet "curling" them.
The hips of both part ners are always slightly forvard in clancing, as they respectively lead and follow from the hips, not by meane of the man squeezing and clutching with both arms and the girl hanging on with hoth hands. If this hip movement is tried it irill be seen at once that the girl must know what step is coming next, without any extra pressure of the hand on her back. The only time when this may be needed is when the man decides to do an outside step. then the icry slightest pressure with two lingers is enough to indicate this change. Thi girl must not. under any
circumstances, anticipate, but must remain supple and ready to follow. To enable her to do this ensily, the man must lead definitely and from the hips.

Poise and Balance. Balance is obtained principally by correct distribution of weight, and this is a simple walk backwards which the beginner can practise. Done correctly it will ensure accurato balance, which is more than half the secret of graceful deportment.

First Position
Second Pasition
 corresponding arm movements noted. First position beels lozether. arms outstretched at sides. Second arm extended upward Third sosition correspondink arch of other por and arm acrosa dy beel against level Fourth position : one font estended in front of other in open or crossed position. correspondina arm extended upward, other arm crosaing bods in downmard direction. Fifth position: heel to in both arms extended upward
whether in walking or dancing. Take $\Omega$ long step from the hip, the ball of the back foot meeting the floor; kcep the pressure of the iront foot on the heel whilst travelling backwards, and never let the back he el drop until the fiont foot passes it. The knees must

Dancing : the correct hold. 1. The woman's hand is placed just below the shoulder, the fingers resting naturally 2. Correct position for the man's band. 3. Hold for the tango, the partners being closer torether, the man's left band more curved and the elbow lower and closer to the side

Courlesy of Vcrllu Dancing Stullo never be stiff in dancing, but never really bent. They must be atraight and relnxel altern. ately, the travelling lcg being straight and the knee of the supporting log relaxed. Here, agair, one must remember that dancing is natural movement. and this straightening and relaxing of the knee alternately is exactly what should occur whether a person is walling in the street or running on a tennis court.

The dircction for all dances is anti-clock wise. For the comfort of others on the lloor it is corroct to travel around on the outside of the floor, and everything in dancing has been composed with the view of making all movements progressive. It is when two pcople either try to invent now steps, or the man's dancing consists of a few steps forwarils, $n$ turn, and a few steps backwards. that "crushes" occur and second lines are mado in the ballroom. Generally speaking the line of dance is oblique, the steps and combinations of steps forming a zig-zag pattern around the room; in the case of the tango these lines are curved.

Style and Rhythm. With regard to etiquette, grey, and from rod brown to pale fawn If the apart from the position of the hands, which has upper parts arc black or grey (pepper), the lega already been dealt with, good manners and the should be brown or fawn: if brown is the upper comfort of others should be the guiding rule. colour (mustard), the head should be creamy It is not etiquette to make up fancy steps if white, and the legs a shado darker than the they interfere with the progress of the others. Nor should any deviation from the occupation of correct ballroom dancing occur, for it usually means bumping into another couple. which is as bad $n$ brench of good manners as if it happened in tho street
In modern ball. room dancing the feet are always parallel, unless performing a twist, e.g. the Charleston. In this case the fcet are in a straight line with the toes, and neither foot is turned out. The rule for placing the feot in $n$ forward movement is heel first, except when two quick steps follow each other. This is contrary to the old form of dancing, which was always "point toc," and is just the same as a natural walk, which is always "heel first." The only difference between the natural walk and the modern ballmon dancing step is that the latter glides along more.
There are two ways of turning, right hand, or natural, and loft hand, or reverse. Contrary hody movement is turning the body from the hips so that the opposite hip and shoulder move forward, or back, if stepping back with the moving feet. This movement applies chiefly to slow steps, and curves are governod by that. When a foot has to move from an open-that is, feet apart-position to another ojen position it must pass close to the stationary foot on the way. This is known as brushing.
There are threo popular times for danco music, $4 / 4$, which embraces the slow foxtrot, quickstep, blues, mid-way rhythm: 3/4, which is waltz time ; and $2 / 4$ for the tango.
DANDELION. In a cultivated state the dandelion makes an excellent salad, and the improved varietics, such as large-leaved French, are grown in many large gardens. They are raised from seed sown in spring and thinned to $n$ foot apart.
In late autumn the roots may be lifted, placed in boxes of soil and forced into growth in a dark, warm place. Or the fresh spring grawth can be blanched by covering the planta with pots.
The dandelion as a weed on the lawn must be dug or spudded out, and a little salt or weedkiller dropped into the hole. One way of deatroying is to dip an iron skewer into sulphuric acid and force it into the heart of the plant. In medicine the dandelion, or taraxacunt, is sometimes used as a simple bitter and stomachic. It is also laxative. The common preparations are : extract of fresh dandelion root, dose 5 to 15 grains; liquid extract of dandelion root, dose $\frac{1}{2}$ to 2 drams: juice of dandelion root, 1 to 2 drams

DANDIE DINMONT. The affectionate and intelligent little terrier known by this name is often confused with the Aberdeen and the Skye terriers.

The head is large, the muzzle strong and the nose black. The broad-based, tapering cars hang closely to the cheelis. The legs are short, and the rather short, feathered tail with a slight curve is carried little higher than the line of the back. The hard, but not wiry, coat is about 2 in . long, and has a mixture of softer hair. On the head the hair is silliy. The colours of the terrier range from bluish black to silver

The voltage of a Daniell's cell is just over one volt. They are particularly suitable for lieavy ystals.

The porous pot is filled with a dilute solution of sulphuric acid, and the space between the glass jar and the porous pot is filled with a saturated solution of copper sulphatc. The copper sulphate solution is kept saturated by adding a number of crystals of copper sulphate; these must he added to from time to time, as thoy dissolvo when the cell is in operation. A shelf is sometimes lixed to the copper cylinder to receive the supply of copper sulphate

Although thero are systems of developing photographic films or plates in full daylight, a liark room is a necessity for photographic work.
It is quite practicable to do alnost any kind of photographic work in an ordinary room which is temporarily darkenerl. Soveral patterns of darkroom cabinet arc sold. They provide a convenient and not unsightly storage place for dishes, bottles, etc., whilst the door of the cabinet, in some models, forins a bench or table. A hathroom is most convenient for usc in this occasional way.

In fitting up an ordinary mom for photographic use any window has to be blocked up. It is best to do this so that the full light from the window can be quickly obtained if required, for there are many operations that are preferably done by daylight, and also it is then much casier to keep the room in its necessary state of cleanliness. Most windows can be fitted

and continuous work, and are em ployed for closed circuit burgiar alarm systems. When a Daniell's cell has been charged with clectrolvte the two terminals should be connected by a picco of thick copper wire so as to short circuit the cell, leaving it thus fortwelve hours or more. See Burglar Alarm

DAPHNE. ()f the hardy daphnes the favourite is the mezereon (Daphne mezcreum ). a slow-growing shrub 3 ft . or more high, which bears reddish-purplo fragrant llowers in Feb-Mar. It is suitable for the rock garden or the front of the shrubbery border. It likes soil containing lime. Daphne encorum (alpine garland flower) with fragrant, rose-coloured

Daphne mezeraum, a Daruy apectes ot tue fowering shrub which will thrive in the open
blooms, and blagayana, cream-coloured llowers. flourish in the rock garden in peaty soil; the branches of the latter should be pegged down. Daphne laurcola, spurge laurel, is an evergreen which will thrive in the shade. The height is from 3 to 4 ft . It is commonly raised from seed, and has glossy leavea and yellowish-gi cen flower in winter. Daphone indica is a favourite winter greenhouse plant with fragrant flowers.

## The Dark Room and Its Fittings

## How to Adapt or Construct a Room for Photographic Work

The processescarried out in the Dark Room are described under Developing; Enlarging; Printing, etc.
with a wooden frame covered with two thicliuesses of stout brown paper or black blind material. A few wooden wedges will prove sufficient to keep it in place.
An effective and cassly titted dark room blind can be contrived with an Acme or similar type spring roller fixed on brackicts well above the window frame (Fig. 1). Down each side of the window hinged shuttera are fitted to cxclude light at the sides whon the blind is drawn (Fig. 2). Dimensions will vary with the size of the window, but the blind should be arranged to overlap the inner shutter (Fig. 1, a) at least lit in. The blind should be made of thoroughly opaque material. such as unglazed American cloth fastened to the roller with glue. This doss not prevent the use of ordinary curtaing and blinds.
Ventilation must not be neglected. If the room has a fireplace, this will be sufficient; but
if there is none, an inlet and outlet of nir must be con trived somewhore, if only in the tup and bottom of the door Right-anglotubcpieces, like stove pipes but rather smaller, can be bought for dark room ventilation and can be fitted to the covered frame which is used to close a window.

Much lahour is saved if a water-tapsink and waste pipe can be provided: but thesc are not absolute necessitics. If water cannot be laid on, an excellent substituto is $n$ tank holding a few gallons. fixed on a stout shelf a foot or two above a sink. Such a tank, of zinc fitted with a tap, is a stock article. The sink should be shallow (about 3 or 4 in.) and of fair size, about 3 ft . by 2 ft . It is either of earthenware or of lead in a wooden casing. If a pije for carrying off the waste water cannot be arranged, a large bucket server the purpose. n rubber hose being fitted to the sink outlet. If constant How and escape of water are not available, washing of negatives or prints can be easily and readily donc in the domestio bathroons.

It is convenient to support the sink on a pair of cupboards: those sold as ordinary meat mafea answer well and serve for the keeping of dishes, tanks, etc. The sink itself should be covered with $\Omega$ rack of stout wooden slats, which forms the work bench and allows all

drippings of solutions to pass througlt and drain away. Some narrow shelving, not more than 3 in . wide, for the bottles of solutions completes the fitting of the work bench. It should be placed so that it stands on a firm support, any nails scrving to hold it upright on the wall Lighting is nost imporlant and it is economy in the long run to pay fur the best. The smail oil or candle ruby lamps sold for a shilling or two are useless 'The essential is to bave olenty of light, and that of a kind whioh is sale for the particular kind of sonsitive material. The lamp should be fairly large: the size of the safelight. which is the coloured screen of the lamp, should be about 10 by 8 in .

The most convenient form of dark room lamp is electric with a two-way switeh, by which a bulb outside the lampe can be instantly brought into operation whencrer white light is required. For bench use the lamp should be of the pattorn in which the front is vertical or slopes slightly forward. A hanging lamp in which the safelight is horizontal gives a flond of light straight down on to the work bench. This form is by far the best for the derelopment of prints. the progress of which is judged hy looking on them, not though them, as with negatives.

If gas has to be used, it is necessary to buy a Jarge lamp on account of the heat which is developed, and if the dark room is very small it is ailvisable to place the gas burner itself outside, fixing the safelight ats $\Omega$ window. The same considerations apply to an oi! lamp.

When the bathroom is used as a dark room it will be found very tiring to lean over the bath or kneel down in front of it for lengthy periods This can be avoided by arranging is hinged table over the bath at the height of a person sitting (Fig. 3). The inethods of construction aro shown clearly in the diagrams. Sizes will rary accoading to the width of the bath and the height of the table.
Malie the table of slats of wood about $\frac{1}{2} \mathrm{in}$. apart, so that spilt liquid may fall straight into the bath. If a trickle of water from the bath tap is allowed to mon thero will be no risk of staining the bath enamel with developer. Hypo has no offect on enainel. If possible, dishes sbould be kept in the bathroom, and a plate rack or slatted shelving put up to provide easy drainage and to keep them free from dust. Dust is the photographer's principal cnemy.

A Portable Dark Room. A sinall dark room, as is shown in lig. 4, made in sections so that it can be moved from place to place, is extremely useful to the amateur photographer. The door is arranged to fit into ono section, and virtually forms one wall of the building. The other sections are covered on the outside with weatherboard, and lined on the inside with 3 -ply wood.
The floor rests upon 3 in . by 2 in . floor joists, to which it is securely mailed with 2 in. oral brads. The roof is formed of $\frac{3}{4} \mathrm{in}$. matchboards, nailed to 2 in . by 2 in . rafters, and bolted to the frame of the building. It should he covered on the ontside with good waterproofed material. The window is formed opposite the door, and should be glazed with olear glass. Separate frames are made to fit over the window frame; thesc are covered with fabrio or glass of any desired cofour, and may be rebated and fitted with a panel of safelight coloured glass. These frames are held in place by turnbuttons, securely sacewed to the window framing and arranged to bear on wedge-shaped slips of hardwood fixed to the removable fraines, as shown in Fig. 5. The edges of the frame may be corered with felt, so that when the turn-buttons are twisted they bear on the wedge-shaped slips and thus close the frame
up tightly. Detnils of construction are shown in Figs 6-10 The joints are simple, being merely halved together. The door (Figs 7 and 0) is made double by first constructing an ordinary ledged and braced door, and covering the inside with ardinary 3 -ply board, having previously glued and nailed make-up pieces to the inside of the door in the inanner indicated in the drawings. A good stopping of 1 in. square stuff is requisite, and it should be faced with felt to exclude all light.

Th allow for ventilation, an air inlet is provided (Fig. 10), and slotted and so fixed that air can enter but light cannot pass.

DARK SLIDE. The old-fashioned wooden double dark alide opening like a book is now Largely displaced by the single metal sheath holding one plate. These metal slides should not be allowed to become rusty, and should always be carefully dusted out before inserting fresh plates Attention should be paid to the etrip of velvet on the top of the plate-holder which traps the light when the slide is with. drawn during exposure in the camera. If the velvet is worn or flattened, light will leak past and fog the plate; if the velvet is brushed up after unloading a slide, it will not only be kept free from dust, but will be less liable to allow light to enter.

To blacken slides when worn, wash in strong sodn water; which removes rust and grease. followed by immersion in a weak sulphuric acid solution in the proportion of 1 dram of strong sulphuric acid to I pint of water. They are then blackened by boiling in the following solution
Hyposulphite of sodn
Copper sulphate

## Water

## See Camera: Photography.

DARNING. Too heavy a mending yarn pullsand strains the material to be darned, and soon leads to further holes ; too fine $\boldsymbol{\Omega}$ one only fills the rents with twico as much labour as is necessary, and does not last long. The idea is to counterfeit the weaving of the material, first one way and then the other, till the hole is filled with closely interlaced thseads going over and under each other at tight angles.

Start on sound material well outside the edges of the hole, running the needle (threaded double for all but small repairs) in and out of the stuff in a straight line. Return as close as possible to the first line, going under the stuff where that went over, and vice versa. At the end of each line do not pull the thread tight, but leave a tiny loop, Fig. 1; this allows for the slarinking of the new thered in the wash. Continue darning up and down till well sutside tho hole on the far side and on sound atuff again. Then darn closely across at right angles, alternately under and over the original lines of atitches, Fig. 2, until the hole is completely filled. Thin places should never
be niluwed to run intu hoics. If they are darned one way only they will last for a long time

When mending a ladder stop the dropped stitch from running with a temporary stitch. An ordinary crochet hook will assist the repair. as shown ill
Fig 3 Noto that the hook drawseach line of thread through the stitch scparatcly and restores the actual pat. tern. Darning balls or eggs, over which the hole can be ytretched

Darning. Fig. 3. Mending a ladder with an ordinary crochet hook g moothly while in coursc of repair, make the work easier and less cramiping to the hand. Anything of a delicate nature should he repaired before being laundered, or the cleaning pro. cesses may make the damage much worsc.

On woollen gar.
 ments of a uniform colour a piece of canvas large enough to overlap the edges of the hole should the cut out and tacked in place on the wrong side of the material, so that the lines of the canvas run exactly parallel with those of the wear. ing. This may be coarse or fine, according to the texture of the material. The raw edges of the tear are cut away to form square, and

Fig. 4. Straipht darning stitch used in embroidery
the wool is darncel across, backwards and for wards, stitches being caught into the material, on either side. as in Figs. I and 2.

Darning. Figa. 1 and 2. Method of darning a bole, illustrated on open-mesh canvas to show gtitches

Darning Stitch. The straight darning stitcl for simple embroidery is shown in Fig. 4. The rule for straight darning is to take up half as much material as that passed over, the latter forming the length of stiteh. In fancy darning the stitchea are spaced to suit the design, as shown in Fig. 5, where the material taken up and missed is of equal length. This ligurc also shows how darning stitch can be adapted to fancy designs, with the aid of a few satin stitches for the solid part. Sec Mending; Stocking: Wool.

DART: In Dressmaking. A dart is a wedge-shaped piece of material taken up on the inner side of a garment, to remove any unneccssary fullness. It must be carefully made by taking up just the amount of material that is not required and gradıally sloping it off to the point where the dart is to finish.

DATE : The Fruit. The dessert varietics of this fruit are generally bought in boxes weighing between $\frac{1}{2} \mathrm{lb}$. and 1 lb . These dates should be a shiny, golden brown in colour, large and soft. Cooking dates are usually bought by the pound. Before using thein, the dates should be separated and washed in

Date. Dish of appetising sweets made from this fruit
tepil water. They will improve if soaked in cold water overnight.

To stew dates, split open 1 lb . of them, and remove the stoncs. Put them in a saucepan, cover with cold water, and simmer them until they ate soft. They need no sugar

Attractive swects can easily be made if some good dessert dates are split open, the stones removed, and a roll of almond paste, coloured with cochineal, etc., inserted instead. The stuffed dates should be warmed in an oven for 15 min . in order to set the paste, then allowed to cool, and put into paper cases.

A blancmange can be flavoured with chopped dutes, and this fruit also makes a good compóte. Stone 1 fl lb . dates, and put them into a clean jar containing the strained juice of a large lemon, 6 oz. sugar, and It gills Malaga. Havo ready a pan of boiling water, place the covered jar in this, and then conk its contents as slowly as possible over a very low firc, or at the side of the gas-stove. Leave it thus for an hour or more, and let it get cold before serving.
DATE PLUM. These are small yellow plunis, extremely astringent before ripe, but awect and of good flavour when ripe. In America the date plum is known as persimmon. It is used in the same way as other plums, and can be eaten raw or cooked. For jam-making, I lb. of sugar should be allowed to each lb. of fruit. See Jinn ; Plum
DATE PUDDING. Peel and chop up fincly a good-sized apple, and mix it with ? lb . of washed, stoned, and roughly-chopped dates. Make a suct crust, using about 5 oz . Hour, and roll it out fairly thin. Line a greased pudding basin with the pastry, then fill it up with alternate layers of date and crust, pastry being on the top. This pudding, which will need sten ming for 2 hours or more, should be turned out and served hot with boiled custard.
Another dato pudding is made by chopping $\$$ Ib. dates very small, and mixing them well
with 3 oz . sugar, 6 oz breadcrumbs, 4 oz flour, a little baking-powder and $n$ gond pinch of salt. Now beat up together 4 oz . of dripping or laird, I gill milk, I tablespoonful treacle, and 1 egg. Nix the wet with the dry ingrediento. and put the whole intoa greased pudding basin, so that it fills only ${ }_{3}^{\frac{2}{3}}$ of it. Twist sonic greased paper over it and steam for a good 3 hours

DATURA : The Thorn Apple. Thedatura is a half hardy annual and shrub belonging to the potato family Of the shrubs the favourites

Datura. Sweat scented Howers, leaves and prickly seed pods of the Thorn Apple
are Datura (brugmansin) suarcolens, with white, and sanguinca with red, Howers in late summer; they may be grown in tubs or large pots and placed out of doors for the summer, but nust be brought under glass in autumn. The annual daturas are raised from seeds sown in alight heat in February-March and planted out of doors in May. A few of the best are cornucopia, double floteers, purplish whito: Metel, white scented blooms; and ceratocaula. white fragrant flowers. These bloom in summer and grow 2 to 3 feet high. The common thorn apple (stramonium) has white Howers which arc followed by spiny fruits.

DAVENPORT TABLE. This type of writing table, or escritoire, is chielly associated with Victorian furniture, and consista of a deek placed upon a pedestal, below which are a set of drawers. These do not open at the front, but at the side. The desk is the same width as the pedestal, but is made to slide forward, so that a person can sit and write at it in comfort. It has a hinged lid, below which is a receptacle for papers, ctc., and in which small drawers are sometimes fitted.

In some of the pieces there is also a sliding shelf that draws out at the side and is used to hold paper, etc. These desks are usually covered with leather and have a low rail round the top to prevent the pens from falling off. See Bureau; Writing 'Table.

DAVENPORT WARE. This Staffordshire ware, including porcelain, stone china and carthenware, was produced by a family of that name at Longport for about a centiry after 1793, and usually hears the potter's surname,

Davenport Ware. Porcelain plate and sugar bowl, with delicate foral design, c. 1815. The mark, an anchor and the word Davenport, is printed in red B!! permussion of the Director. British Museum
either with an anchor or sometimes with the place-name.

The porcelain is a line bone-paste, sometimes white, cream-coloured and blue-printed Collectors usually look out for the tea and dessert services with deep blue, rose du Barry or npplegreen grounds. and attractive panels of scenic and floral subjects. There are also choicelypainted vases, and all have massive gilding on the rims, handles and feet Except for the mark, such ware is not easily distinguished from Derby or Coalport china of the same period
The willow pattern with only 25 apples on the tree is readily recognized, as the corres fonding Werlgwood, Sporle and Adams patterns have not less than 32 apples. Davenport ware has a tendency to become covered with minute surface cracks, and some of the cups appear as if tea-stained, $n$ defect which cannot be removed. See China; Staffordshire Ware.

DAY LILY (Hemerocallis). This lily is a beautiful hardy flowering plant, 2 to 3 feet high: in Junc and July it bears lily-like llowers in shades of ycllow and orange. It thrives in ordinary soil in a sunny or slightly slisdy border, and is increased by division in early nutumn. Some of the best sorts are aurantiaca, a pricot, flava, fulva and Queen of May. Although the individual blooms Inst. only for a day, the plant continues to Hower throughout severnl weeks. See Lily

DAY BED. Thesc sofas or couches were fairly common in the latter part of the 17 th and the 18 th centurics. They are reprodnced to-day for rooms furnished in period styles, but the modern day bed is in two pieces-a head piece, which is a comfortable armehair, and a foot rest-in the form of a separnte stool of the same height ns the chair
summer time begins at 2 occlock in the morning of the day after the third Saturday in April, unless that day is Easter Dry If it is, summer time begins on the day after the second Saturday in April It ends at 2 o'clock on the morning of the day after the first Saturday in October. This means that the clock is put forwand one hour on the appointed day in April and put back one hour on the appointed day in October.

The law applies to Great Britain, Northern Ireland, the Channel Islands and the Isle of Jan, hut not to the Irish Free State France and Belgium have adopted the same period of summer time.

DEAD FINGERS AND TOES. The blanching and coldness of the fingers or toes, due to disturbance of the nervous control of blood vessels, is often popularly referred to as dead fingers or tocs. The condition is an example of what is described as Raynaud's phenomenn. See Circulation of the Blood: Rrynaud's Disease.

DEADLY NIGHTSHADE. The common name for the belladonna plant is the deadly nightahade. Medicinal preparations are obtained from the leaves and the root, but the active principle, atropine, is found also in the lecries, and poisoning has resulted from eating these: they arc about the size of a small cherry, violet-black in colour, and have a swectish taste. If the patient is able to swallow while waiting for the doctor, vomiting should be induced at once by tickling the back of the throat or by an emetic. He should be given draughts of strong hot tea, and kept warm in hed with hot water bottles. See Atropine: Belladomma.

DEAD NETTLE (Lamium mactilatum). This common wild plant has purplish llowers and green and white leaves. The ycllowleaved variety aureum and puralbum, which has pinkish llowers, are sometimes giown in gardens

DEAFNESS. Injury or disease of any of the three portions into which the hearing apparatus is divided may cause deafness, or it may result from a foreign body blocking up the outer passage of the ear and in this way preventing sound waves from reaching the drum.
seat, upholstered in the same material There is usually an 18th century uuggestion in cabriole legs, curves of the chair back and upholatering fabric.

DAYLIGHT SAVING. This term is used for the system, known also as summer time, of putting formard the clock by one hour at the beginning of summer and putting it back an hour at its end. The nominal time remains the same. thus avoiding all changes in time-tables and the like.

Daylight saving was introduced into Great Britain in 1916, but it was not made permsnent until later. For some yeurs the opening and closing dates of summer timo varied. hut in 1922 uniformity was introduced. As the law now stands

Children frequently cause the latier variety of deafness by poking huttons or hard jreas, etc., into their cars. No attempt should be made to remove the foreign body by means of a hatpin. The child should be talien to the doctor, and if the foreign body is a pra or bean, no one must attempt to syringe it out. In the case of a live insect, however, is little warm oil may be put in the car.

Frequently the obstruction of the passage is due to an accumulation of ear wax. A little "arm almond or olive oil in the call overnight, and gentle syringing with a ten per cent. solution of botacic acid and warm water the next morning, may be the only trentment needed. Care should be takien not to push the point of the syringe into the ear passage. The strean should be pointed not dipectly against the drum but against the back wall of the passage, while the ear is drawn upwards and bacliwards.

If the wax does not come away eusily, never altemp! to remove it with a halpin, or otherwise, nor b!! forcible syringing. See the doctor aboul ì.
The deafness of a cold and the frequent attacks of deafness in children who suffer from
adenoids is accounted for by catarrhal swelling of the Eustachian tube which connects throat and ear. But in this latter case and alao in any condition of catarrh of the nose and throat, either acute or chronic, inflammation mav extend up the Eustachian tuhe actually into the ear itself.

Suppuration may take place and may lead to the perforation of the drum and disease and destruction of the hones connecting this with the inner ear. Here again there is deafness but much more serious than the denfness is the suppurative process going on in such close proximity to the hrain. Sometimes there is acute inflammation without suppuration, and frequently the effects of this do not clear up properly, and some degree of deafness results. The risk of this happening will be lessened by seeing the doctor at once.

In other cases is found ant increasing deaf ness due to chronic eatarrh of the middle car, in children and young persons, accompanied by an exudation, but in older people taking the form of "dry catarrh." These cases are practically always associnted with catarrh in the nose and thmat, and it is clearly of the greatest importance that adenoids and other conditions which provoke this catarrh should be early and efficiently dealt with.

Diphtheria, searlet fever, and other infectious disorders are often complicated by middle ear disease. In long-standing chronic inflammation of the middle ear, with persistent discharge, the hearing usually becomes gravely affected. In all cases of acute or chronic eatarrh or inllammation the utmost pails must be taken, under the doctor's directions. to clean up the ear.

Where there is internal car deafness, the actual nervous structures, us distinguished from the merely conducting structures of the ear, are at fault. This nerve deafness may also be due to the action of drugs, e.g. quinine, salicion, etc., and particularly in those whose cars were otherwise affected See liar

Care of the Deaf and Dumb. Where a child is born deaf, mutism, or inability to acquirc speech by ordinary methods, necessarily follows, though the vocal organs may be quite normal. This is due to the fact that all children learn to speali by imitation; the deaf child, hearing no spoken language, acquire none, and instead develops a series of natural gestures This hed in the past to silent methods of finger spelling and signing: hut the methods now employed have in view to teach the deaf to understand what is said to them by means of speech reading, or, as it is commonly called, lip-reading.

A simple and effective method of testing the hearing is the following. Place the child with its hack towards you, and step, backwards two steps, roughly about 6 ft ., then whisper some simple command or question. If the child does not respond, it is deaf or partially deaf, and the casc should be reported to the local education authority, whose duty it is to sec that the child is placed in a suitable school. either for the deaf or the hard-of-hearing The denf child is entitled to free education though if this entails removal to a residential sehool the parents may be required to contribute.

The child should be trented as nearly as possible as a normal hoy or girl. Bad habite, a shulthing gait, mouth noises, ugly grimacing and gesturing, should be checked. He should be spioken to a little more slowly than other chiliden, and his attention should be directed towards the lips. Every member of the family should try to kecp up his interest in persons, places, and things, just as though he could hear. During the last years at school there will have heen some definite trade bent in the manual instruction received, and the boys readily find occupation in carpentry, cahinet making, bakery, bootmaking, etc., while the girls
secure openings at laundry-worli, dressmaking, millinery, fancywork, etc. Usually an Aftercare Association will assist in placing the dea child, and will further continue to visit and report on its progress during the first ycars of cmployment. There is also usually an agency or mission which provides special services for

beating and breathing ceases Rigor mortis, or stiffening of the body, may come on quickly. but on the average it appears in about six hours, and lasts for ahout 24 liours.

In view of the fact that a state of trance closely resembles death, and to avoid any possibility of the person being huried alive, certain signs that life is extinet should always le looked for. A mirror held before the mouth and nose may hecome dimmed, perhaps very slightly, hut sufficient to show that breathing is taking place By using a stethoscope the doctor mav be able to hear very faint heats of the heart, or hy tying a ligature tightly round a finger he may find that the end of the finger becomes red, while on the removal of the ligature a white mark is left - thus slowing the presence of some circulation of blood
The Legal Side. Every death must be notitied to the local registrar of births and deaths within five days of the event, under a penalty not exceeding-iflo. The person to give the information to the registrar is tirst of all the nearest relative present at the death or in attendance during the last illness. If no such relatives, then any relative of the decensed living in the same registrar's subdistrict. If none, then the oceupier of the house where the death took place; and if he docs not, then every innate of the liouse is bound to sec 10 it.

One of the next things to tre done is to find out whether the deceased had made a will, and. if so, who is the executor, as the latter is the only person to look after the property and elfects of a deceased person. If there is no will, or a will but no executor named in it or the executor is dead, then the proper thing to be done is to see that letters of administration are taken out as soon as possible The administrator then becomes the propel person to take care of and distribute the property and effects.
Death puts an end to all contracts of agency, so that, for example, a widow who orders goods for herself or the household after her hushand's death, does so at her own expense, and has no claim to be reimbursed out of his estate. A banker may not honour his customer's cheque after he knows of the customer's death. Every contract depending in any way involving personal qualifications for carrying it out, comes to an end by the denth of a contracting party.

If two people are killed in the same accident, e.g. a railway collision, the younger is presumed to have survived the elder. This is sometimes important in questions of family inheritance. The death of a member of a family on whom other mem hers are depentent sometimes gives rise to a clain for damages on the part of the dependents.

Laying Out the Dead. When denth takes place under natural conditions from illness or old age, and there is no necessity for the immediate inspection of the body by a doctor or the police, certain duties should he at once performed by those in attendance

If the deceased person is already in bed such duties are siniplified, but if death has taken place in otlier than a hedroom it is hetter to sclect and prepare a hed hefore the body is laid upon it. When possible a mackintosh should be placed over the mattress, or if that is not obtainable thick brown paper or a spare piece of linoleum or American cloth. This can be covered by a clean sheet. If death has talien place in bed, it is presumed that some such provision has been made. l'illows, bolsters, water-beds, hot hottles, and any surgical appliances should be removed The body should be divested of all garments and laid quite straight, the arms to the side and the ankles tied together

A small pillow for the head can be kept it required, but it is hetter at first to use none. The head can be turned gently on one side
to allow any fluid in the mouth to escape The cyelids should be closed and kept in position by pads of wet cotton-wool, or a henvy coin. False tecth and rings should be removed, if required. A bandage or cloth should be tied under the chin around the head to keep the jaw in position until rigor mortis has set in. Cover the body and leave it, if possible, for half to one holir.

This time can be spent in clearing the room of unnecessary fittings and signs of illnesa, preparing a clean gown and sheets, and dressings if required, a basin of clean water, somp and towel. The body should then le washed and cleaned all over, and the hair brushed, parted and plaited as occasion requires. Avoid the use of pins of all kinds Small plugs of wool may be used in the ears and nostrils. Any wound or sore should be covered with n wet dressing of strong disinfectant, and a thick pad of wool bandaged sccurely over.

The deccased should then bo clothed in a shirt or gown, or if preferred wrapped in a sheet. White socks or stockings may be used on the feet and a small pillow placed under the head. Cover the body completely with a clean shect, or, alternatively, the sheet may be turned down on the bed in the usual way, and a handkerchicf used over the facc It is better to keep pads or weights over the oyes for the first 24 hours. If the body is a heavy one it is of great assistance to the undertaker if towels are laid under the shoulders, hips and fect. See Cremation: Exccutor: Funeral; Mourning; Will.

DEATH DUTIES This is $\mathfrak{n}$ collective name for the duties paid on the property left by a dead person. In the United Kingdom, since 189.4. they have consisted of the estate duty and the legacy duty. Australia, Canadn, and other parts of the British Empire raise revenue by death duties of various kinds. The payment of the death duties is the business of the executors. who are responsible for the valuation of the estate and must satisfy the inland revenuc authorities about the accuracy of their figures. See Estate Duty : Executor: Intestacy ; Legacy Duty: Will.

DEATH RATTLE. When vitality is very low fluid collects in the windpipe and bronchial tubes, and the air entering or leaving the chest in breathing, passing through this Hluid. produces a gurgling sound, popularly named the death vattle.

DEATH'S HEAD MOTH. The largest of British moths may be known by its grey. brown fore-wings mottled with yellow, the yellow hind wings crossed by a broad and a narrow dark band, and by the black-belted yellow hind-body with its central stipe of blue. Most striking is the yellowish patch on the fore-body, which has a curious resemblance, stronger in some specimens than in others, to a human skull The usually yellow-green caterpillar when fully grown is nearly 5 in . long and thicker than one's finger. It feeds chiefly upon potatohaulm, also on the ten treo and snowberty.

It does not appear in such numbers or so commonly as to constituto a menace to the potato crop, but the moth has a bad reputation as a honey stealer. In all stages the insect is so large that hand-picking is the surest means of controlling it. See Moth

DEBT: In Law. In law a debt is a sum of money which one has coniracted to pay as distinct from damages, which is a sum one

is urdered to pay for some wrongful ibct or breach of contract $A$ debt is due the moment it is contracted. but if it is to be paid on a future date, or on the happening of some event, it is not paynble until the rlate arrives or the event happened

A debt cannot be sucd for until it is both due and payable Unless there is a contract to that cffect, a creditor is not bound to go to his debtor, or to ask him for the monev ; it is the debtor's business to go to the creditor and pay him. If there is any disputc as to how much is owing, the debtor should tender in cash (not a cheque) the amount he says he owes.

A husband is very often sued for debts contracted by his wifo. If a wife contracts debts of her own, her husband is not liable for them: but if she purports to act as his agent. he will be liable in certain circumstances. Thus, if she manages his household, she has implied authority to order on his behalf such household requisites, including food and clothing for herself and the children, as are reasonably necessary, having regard to the husband's position in life.

If a husband turns his wife away, or by his cruelty or misconduct compels her to leave him, he is still, unless he makes her a reasonable allowance, lia ble to pay for board, lodging, and clothing to a reasonable extent, that is, for neccssaries. If they are seplarated owing to her misconduct he is not liable for anything.

When husband and wife are living tagether and he makes her an allowance for house keeping or for dress, she cannot pledge his credit. When a wifo has once contracted debts with a tradesinan, and the husband pays, and he afterwards puts her on a ciash allowance, he must warn the traulesman to give no more credit. It is also better to warn the local trade protection socicty, so that they can circularize their members.

An infant, that is to say in law a person uncler 21, is, as a rulc, not liable under his contracts; but an infant is liable for clebts contracted for necessaries. Thesc include food, drink, clothing, lodging, and instruction according to the infant's rank in life. Even when an infant owes $\pi$ debt for clothes (say) which are suitable to his station, the deht may not be enforcable, because the infant may plead that he was already supplicd. For instance, if an undergraduate at Oxford ordered an evening suit he would, prima facie, be liable to pay for it : bnt if he could show that he already had two evening suits in good condition, he is not liable to pay for the third. Debts can be attached. i.e. if A owes money to 13 and B owes money to $\mathrm{C}, \mathrm{C}$, being unable to get his deht paid by 13 , can apply to the court for an order coin. pelling $A$ to pay the debt to hims instead of to $B$, or such part as will satisify his claim. This is known as a garnishee order. Debts can be assigned by one person to another; but in such cases the assignment must be absolute and in writing.

DECANTER. The decanter developed from the wino llasks made in Italy in the 16 th century. In the 17 th they were inade in England, ind those of the early 18th century long tematined the standard type. In the middle of the century some decanters were made with the vine pattern of grapea

Decanter. Antigue decanters in cut glass, showing three of the mang beautiful and graceful shapes that are obtainable
and leaves, while others of about the same time belong to scts of Jacobite glass
A little later came the decanter with rings round the neck, this variety, like many of its predecessors, being of finely cut glass. Small decanters were also made to go with a set of liqueur glasses. lior them ruby coloured glass was popular in the early part of the 19th century

A decanter stand or coaster is an article sought by collectors whether made of silver or old Sheftield plate They were fashioned to hold a decanter and so prevent the wine from staining the table, and first appeared in England ahout 1770. Most of them have woolen bottoms and the sides are ornamented in various ways. Sce Glass; Sheflield Pato: Silver

DECARBONIZING. This is the term employed for the remosal of the carbon deposit which forms $0: 1$ the inside of internal combustion euginos. After a motor car or ib

Decarbonizing. Black and Decker process, in which carbon deposit is removed from the cylinder head bs means of a rotating wire brusb

Courlesy of A. Perraris. Lld
motor cyclo has been driven for a distance varying betwcen 3,000 and 3,000 miles or so, the engine will show a steady falling off in power, a tendency to overhcat and to knock on hills, chiefly due to the deposit that has been formed in the cylindor and on the piston. Such deposit is remnvable in several ways: by hand, by means of oxygen, or by a mechanical process. The deposit on the piston head can be seraped off with a blunt linife or a screwdriver. It will often be found that a deposit is formed on the piston ring groovos, and this should be carcfully removed
To remove the deposit on the cylinder head by hand is often a laborious joh. The usual tonl for the purpose is an ordinary long sereirdriver, with which the deposit is carefully chipped off. The grentest care must be taken during the wholeoperation not to scratch the nalls of the cylinder. Much of the deposit formed is due to road matter get ting throngh the carburetter, nad the fitting on of $\Omega$ new gauze will often leasen the trouble considerably. The use of the correct oil and avoid. ance of over-oiling will also go n long way to obviate carbon deposit in the engine.

If a motor car ofigine has it removable hoad it is easy to take this off, and then chip and scrape out the deposit in it, and also on tho top of the piston If the engine has not a removable hend, a simple, but not very thorough, method is to remove the valve caps: then with a straight scraper the tops of the pistons can be reached, and with a bent one the ends of the cylin. ders. Scrapers for the purpose can be purchased.

If it is decided to remove the cylinders. they should be raised bodily off the pistons, and then the block can be haid on $n$ bench nud tho deposit removed. While the pistuns are exposed, the opportunity should be takon to make certain that their rings nef free in the grooves, and that the gudgeon pins are tight. When cleaning the tops of the pistons, pieces of rag should be stuffed in the openings of the crankcase, so that the charred matter docs not fall into the latter and mix with the oil.
The oxygen process for removing carbon deposit is quicker and somotimes more effective and it obvintes the need for dismantling the cylinder. The process depends upon burn. ing the carbon away by the use of an oxygen jet.

The Black \& Decker method of decarbonizing, available at n number of garages, consists in the use of wire brushes which are rotated by a powerful high speed electric drill. This method is very much quicker than the ordinary hand scraping process, and the job of decarbonizing can be completed in a day. An
alliod process is used for cleaning the valves and guides, and reconditioning the valve seats. See Internal Combustion Engine ; Motor Car ; Motor Cycle.

DECEASED WIFE'S SISTER. Marringe with tho sister of a deceased wife is now lawful in England, ns it has been for many years in most British dominions, but a clergyman of the Church of England cannot be compelled to celebrate such a marriatge. It is also lairful for a woman to marry her deceased husband's bmother. It should be oliserved that it is still unlitwful for a man to marry the sister of a woman frum whom he has been divorced, ss) long as the divorced wife is living. The Act of Parliament logalising marriago with a deceased wife's sister came into force in 1907.

## Notes for the Month

Decemaer 25.-Christmas Day. Quartcr Day
Deceyner 26.-Boxink Day. Bank Holidyy (not in Scotland)
December 31.-End of the year. Various licences expiro

DECIMAL SYSTEM. The decimal sys. tem of coinage and of weights and measures, naso known as the metric system, and so called because it is based upon an arbitrary unit, the motre, is one by whioh everything is reckoned in tens and multiples of ten. It has not been adopted in Grent Britain, but the traveller meets with it when he goes to France nud some other foreign countries. The franc consists of 100 centimes, and goods are weighed by the gramme and measured by the metre, as for length and breadth, and by the litre as for volume, all these being used also in multiples of ten and in divisions of ten. forexample, deca. litro, decimetic.

DECK CRAMR. This name is used for a light chair which folds up. The frame is made of crossed picces of wood, across which canvas is nailed to form the scat. Some are made with a canopy for protection from the sun and some without, but in botb cases the frame workis the same.

A chair of this kind is ensy to make. A rough idea of the finished chair is scon $n t$ Fig. 1. From

Dect Chair. Fig. 1. Folding chair canopy which can be easily made by the amatear

Fig. 3 the genoral method of construction will be clear, and the plan at Fig. 2 shows exactly how the article (without canopy) will appear when folded. These chairs are made in ash, beech, birch, and sometimes oak Any

| 17 | 13 | 2 |
| 10 | $1\}$ | 11 |

tough wond will serve the purpose, but obviously the timber must be sound The parts required are few, and are given in the cutting list appended.

The tivo seat rails (A) are shown $17 \frac{1}{2}$. apart over all, and are joined at the ground end by a turned rail (D). At the seat end they arc joincd by the flat rail (E) The seat rails (A) are notched with, say, five notches, which adjust the lcan of the back. These notehcs must be deop, enough to take the square part of cross bar (J) witliout any chance of slipping. The leg rails (B) are 19 in apart over all. At the ground end they are joined by the tumed rail ( $F$ ), and at the top end by the flat rail (G). The leg rails are pivoted to the sent rails nt H (Figs. 2 and 3) by means of bolts. The position must be determined after the framework is made, but the bolts come approximately 12 in . from the front end of A , and 131 in . from the lower end of 13 .

Thus far it will be scen that the chair is made of two frames: the inner one consisting of $A, D$, and $E$, and the outer one $B, F$, and G. This may be followed from the plan, Fig. 2. The frames should fit closely, but sufficiently free to permit of metal washers being placed between them at the bolts.

From a glance at Fig. 2 it will be seen that the chair has a kind of third framo, consisting of the two support rails (C) and their cross bar (J). The support rails are bolted to the legs (B) about $16 \frac{1}{2} \mathrm{in}$. from the top end, and arn joined by a cross bar (J) which engages the notelics cut in the seat rails (A). The cross bar is usually turned, but with square blocks left to rest on the notches. If this plan is adopted it should be $1 \frac{1}{4}$ in square; otherwise it may be $\frac{7}{8}$ in., turned throughout.

A sketch of the usual method of bolting is given at Fig. 5. To prevent friction, the inner disk of the bolt is sunk into the wood, and the end of the bolt riveted to the disk. A thin washer is placed between the rails. The canvas selected for the sent ought to be stout and durable. It is folded over the rails ( $E$ and G) and firmly tacked (as Fig. 6). When the seat is folded (as Fig. 2) the canvas should lie practically flat, but not strnined tight.

A canopy is somewhat cumbersome and is apt to attract earwigs and other insects, but

Deck Chair. Figs. 2-7. Constructiona, diagrams showing how the various parts of the lolding chair and canopy should be joined and fited together
in bright weather it is of great advantage when reading out of cloors. If a canopy is wanted, the parts required ars thesc (Fig. 4):

|  | Long It. in. | Wide in. | Thick in. |
| :---: | :---: | :---: | :---: |
| 2 back arms (K) | 14 | 11 | 8 |
| $\because$ front arins (L) | 110 | $1 \%$ | $\stackrel{3}{6}$ |
| Back turned rod (M) | 19 | f diain. |  |
| liront turned rod (N) | 1103 | ${ }_{8}^{8}$ diam. |  |

The arms ( $K$ and $L$ ) aro holted to the leg rails ( $B$ ) about 9 in. frons the end, the method of bolting being indicated at Fig. 7. Each pair of arms is joined by a turned rod ( $M$ and $N$ ), and the canvas covering-say 6 in. deepmay be tacked on or left loose.

DECORATION : In Cookery. The appetising appearance of food is enhanced by decoration and garnishes. The former term usually denotes ornamental colour touches to the food itself, while the latter more particularly refers to accompanying fruit, vegetables, forcemeat balls, croûtons, parsley, etc., which trim the dish

To decorate hors d'oeuvres coloured savoury butters such as anchovy or maitre d'hôtel may he put through a forcer. Corallino pepper, strips of pimento, shrediled unchovies, fincly chopped parsley, ghorlins and truftles, the white of hard-boiled egg cut into shapes aud the sieved yolk are all useful for ornamenting cold savoury dishes. Olives are ilccorative whon stuffed with anchovy butter and placed on a ring of white of egg, a larger ring of beetroot and a round of brown breail and butter. Radishes nuy be cut into flower shapes, with picces of olivo to form leaves and ured to clecorate tho centre of small individual Russian or other salads. A glace cherry or a black grape is placed in the centric of a prepared grape fmit, which may also be cut into points round the calge with a sharp garnishing knife.
Soups may be given a decorative touch by using a pleasing colour contrast. Chopped pars!cy is suitalile for a tomato or white purce, chopned mint for pea soup, cooked asparagus heals or green peas for fish soups, small fancy shapes of Italian pastes or dried vegetables for clcar soups.
Even the nsual trimmings of lemon and parsley can bo tastefully placed on whole fish such as turbot or plaice served hot. The lemon should be cut into very thin half slices which overlap each other down the centrc, broad way on, and down the sides are placed so that tho semicircles mako a scalluped edge to the fish resting on a paraley border.

Decorating Cold Service Dishes. Mayonnaise of lobster or salmon lends itseif to effective dishling. The sauce inny be reddened with the nid of tomato purce or greened with vegetable colouring. A flower design enn
for galantines and pressed boel, together with vegotahles cut
into dice and stars, and butter put through a forcer.

Cold swects such os flans, trifles and fruit jellies can be decorated in much the same way as cakes, except that whipped cream maybc morelavishly usod. Besides patterns made from crystallized fruits and angelica (q.v.), crystallized flowers are a suitable decoiation in such cookery and also for chocolate and other confec. tionery. Theso flowers can be obtained at any good giocery store, and they need to be (f good quality, inferior prepara tions often being cither faded or are tor) highly coloured.
The process of crystallizing requires care and somo knowlcdge of sugar boiling, hut it is not too difficult to be done at home. IRose petals, orango fowers, lilac, cowslips and violeta may all be crystallized. A simple method is to pour over the flower or llower petals a cooled syrup made from refined sugar and water, allowing 3 lb . sugar to cach lb . llower petals. The syrup must he boiled to $230^{\circ}$. Then place the petals in a cool oven; when they

fed with flowers in icing dragces, coloured lices or comfits Almonds and pistachios sliced and formed into the petals and leaves of flowors aio attractivn. Simall cakes may sither to baked in rarjous.shaped little tins or may be cut out of a slab of Genoose, spongo or chocolate mixture, and the trimuings formed into Rursian cake. Small prortions of the Cenoesc may also be shaped, moistened with sherry, coated with marzipan and coloured to resemble such fruits as apples and peaches, with pieces of almond or angelica for stallis.

## Decoration : Ideas for the Home

## Some Aspects of the Trend of Style

For further information see the articles Ceiling; Painting; Panelling; Paperhanging. Sec also
Christmas ; Colour; and the entries on Adam Style; Chippendale Style; Qucen Anne Style, ete.

Never before this period has there heen suoh trades. Theso in turn all help to place quickly a gencral interest in attractive homes and such on the market, by the aid of inndern machinery, conscious desire to achieve good interior effostive adaptations which will he within decoration by simple means. It is in the comparatively small houses and ilats that the great movement towards practical lieauty is being quietly carried on. To-day, as in the day of Robert and James Adam, beautiful houses arc being designed-equally expressive of our time as theirs were of the 18th century. Built and decorated by noted architects, in spite of their costly nature such houses are not so far removed to-day from general appreciation as their prototypes were then. They are described and pictured in magazines and papors, while the ideas and designs originating in these buildings percolate through the brains of the army of artists and workers in the decorative
reach of the ordinary homeninker.

Sometimos old houses are reconstructed beyond recognition inside nnd out, or the nrchitect-decorator will merely get rid of offending interior features and bring all elso into a pleasing scheme by clever adaptations and innovations suitable for life to day. Again thesc uscful and beantiful ideas are handed on for inspiration to the many.

Architectural Decorations. In quite a number of the small recently built houses architects have made the choice of decorations, and even of furnishings, comparatively simple. Natural and artificial lighting has been considerch, alao the well-balanced heights of
ceilings, and loors, and the sizes and shapes of windows. Where there is a horizontal line of panelled dado it is frerpuently continued in built-in cupbords, fireplace and corner seat.

In another type of ronm with light. painted walls, hookshelves are a decoration in them selves. They are placed either side of the chimney piece in recesses, the tops of which are architecturally designed to suit the style of the furniture, and the hack of the shelves and borders of the recess painted in a colour contrast to the walls and to mateh the skirting. Such recesses, or built-in cuphoards with ginzed doors, somewhat reniniseent of (ueen Anne style, are also utilized in dining rooms to hold glass and china, and a delightfully decorative touch is given to them, especially if they are placed in dark corners, by an inside coating of silver mint, the silver note being repeated elsewhere in the room in lighting fittings. curtain trimmings, or other paintwork. In yet nnother style the architect will, with utmost severity, insist on square clfects, even refusing architraves to doors and windows and a shelf to the chimney piece, but making up for this by beauty of texture in woodwork and flooring.
A home to be lovable and livable in to day cannot be like a museum, however keen the owner is on a periol style. Un the other hand, not to awail oneself of the rich heritage of past beanty in architecture, decorntion and furnishing designs is to be either lacking in culture, or an extremist in the craze for startling novelty at all costs. Strictly period rooms become alosurd when provision has to be inade for the wireless, the gramophone, the radiator, or even the telephone and electric lighting fixtures, while there is something too unfriendly to most homcloving people in the room of squared lines, the elimination of all gracious movahle furniture, and in substitutes reminiscent of ship's cabins and saloons.

Texiure as Decorative Patterns. Apart from extremes, one of the pleasantost things about the various materials now Iargely employed in decoration is that they can form beautiful backgrounds for genuine ald furniture, for reproductions, for Oriental pieces and for morlern chairs and tables. There is already a hreaking away from startling colour schemes-except on rare occasions when the furniture demands it, in the extra sitting ronm where experiments are interrsting, and in otherwise glonmy halls, where such decorations may be cheery and inviting nold do not "eary the inmates of a house as they might in a living-room in constant use. Another exception is when brilliant "nll paintings are expcuted by a mural artist, but suchadecora. tive trentincut is necessarily rare in the ordinary home.

Colour for decorntions should he pure and beautiful. The trend is away from fierce con trasts or primary huesexcept here and there

Decoration. In this room the wallpaper has a woven texture eflect and its pale colour forms a harmonious background to the applied tree motlfs and border colour lormsa harmonious background to the applied tree motlfs and bord
strips. Pictures are neither necessary nor degirable in a room so decorated Courlasy of sauteraon of Co

Panel effect obtained upon a gold-flecked wallpaper by an applied decoration of delphinjums. The borders are outlined in gold and should ave plain wall space on either side. All paint work is in solt blue Courlesu of Sanderson \& Co. and Thomas $H$ allis $\&$ Co.. Lid
ns colour notes- walls: or again the gratin of a wood is and towards delicate copied hy means of paint or reproduced in bendings, tone in wallpaper designs. Surfaces are not merely tonceffeots in Hatly covered, but interestingly broken up by woven fabrics, patterns founded on texture.
marbled, inottled. grained, blurred texture effects in paint, wondwork, plaster, wallpapers and lloorings. Pale colours are usual, but white is no longer considered helpful in the decoration of ceilings, friezes or woodwork. Rough surfaces, which respond to the play of light and shade, arc seell above pine panclling, stripped and wased. Where walls are painted, a subtle colour pattern is sometimes obtained hy an under. cont of $a$ deeper shade than that eventually required, and over this two thin coats of white paint, which in turn is rublied down to let the original colour show through at the odges of panclsand on mouldings. Marble texture is imitated, or two shades of a neutral tone arc stippled, to give varicty to the

Motifs and Pilasters. Wallpapers, too, have advanced in practical use and beanty, and are now olitainable in really washable varieties. For those who do not wish for the expense of painted wallw, there is the choice of a patterned paper in one of the simple rest ful designs. using a paler shade of the ground colour with which to distemper the ceiling; or n paper in a mottled. flecked or woven texture effect may be selected in a cream or pale shade with an applied lecoration as ahown in the lirst illustiation. This tree motif is stuok on wherever ornament is needed, the border strips forming a further colour contrast which yet blends the skirting to the wallpaper. Such decoration obviates the use of pictures. It is also exceedingly satisfactory for a small staircase treatment and can be applied to a mottled paper of pale amber tint with the happiest effect, the woodwork being painted in a lighter brown than the border strips. This style can be associated with modern or with lacquer pieces of furniture.
The other illustration shows a panel, or pilaster. which can be placed to create interest wherc desired. The styling, or strips, with which such panels are bordered is obtainnble with an outline of gold to emphnsise a gold. llecked wallpaper suitable for the decoration of a charming sitting room with paintwork in the softest shade of delphinium blue. These pilasters are also designed with other tall flowers, such as foxgloves. Plain wall space is essential on either side of such $n$ decoration, which should not be overdone-two pilasters in a amall room may be sufficient. Applied decorations can also be obtained which are cut out to form central sprays for simulated panels, or groups as skirting or frieze borders.

Notif sprnys for corners of walls and extending over the ceiling corners may also be used with decurative effect, but discration is necessary in blending the whole scheme of the room harmoniously, or such ornamentation may be disturbing rather than pleasing.

DEED: In Law. A deed is a dooument which is senled and delivered by the person or persons exccuting it. A deed is necessary for a lease of upwards of threc years; for a conveyance of land; and for a contract or promise made without valunble consideration. By valuable consideration is meant money or money's worth, and future but not existing marriage-marringe is always reckoned valuable consideration. If a husband desires to settle nnything on his wifo after marringe, it should always be done by deed.

The sealing of a deed is generally dono by $\Omega$ wafer or piece of sealing-wax being affixed to the paper or parchment, the maker of tho deed touching it with his finger; but this, though advisable, is not nccessary.

In addition to sealing, $\Omega$ deed requires dolivery beforn it becomes operative. lly delivery is meant that the maker of the deed parts with it unconditionally. So that if any. one signs and seals a deed purporting to sell his housc, and hands it to his solicitor, not to be parted with by him until ho gets tho moncy, there is no effective dolivery of the deed ; it is only delivered when the solicitor hands it over to the purchaser or his ngent in exchange for the money. See Agreement.

DEEREOUND. The deerhound is a member of the greyhound family, resembling the coursing dog in general lincs, but of more

Deerinound. "Noel of Ruritauia," a Hae specimen of this gracesal breed of dag
robust build, and standing several inches higher. The cont is shaggy, harsh and wiry, the length being about 3 or 4 in . A soft, woolly cont is undesirable. A dark blue-grey is preferred, but also recognized are dark and light greys, brindle, yellow and sandy-red or red-fawn. White often appeapy on the ohest or toes, but it is not liked, and $\Omega$ whito blazo on the head or a white collar would disqualify in the show ring.

The front legs must be perfectly straight, hind legs well bent, with grent length fromit hip to hock, vory dcep chest, and a well-arched loin. The neck should be long and shoulders sloping. Deerhounds are somewhat delicate as puppies, but when once through distemper they are hardy. A dog measures from 28 in . to 30 in. at the shoulders, bitches bcing usually about 2 or 3 in. less. See Dog.

DEFORMITY. A departuro from the normal shape or position affecting the body, or any part of it, is a deformity, e.g. dwarfism, spinal curvature, club foot, wry neck, fingers in excess of the usual number, hammer tocs, cte. Deformities may be congenital, or may be acquired in the course of life through injury or disease. In addition to unsightliness, most doformities intorfere to a varying extent with the proper function or use of the
part. Various methods of treatment may be adopted according to the nature of the casc, including operations, the use of an apparatus, csercises of nll sorts, massage, eloctricity, etc. See Artificial Jimbs; Clıb Fout: Hammer Toc, etc.

DELAINE. Originally called mousseline delaine, or wool muslin, delaine is not invari. ably all voul. The weave is plain, the fabric is crisp to the touch, and usually bears a printed design somewhat like a cotton voile. The crispness is the outcome of $n$ ohemical process whioh makes the fabric nearly unshrinkable.
Good delaine wenrs well, and does not ensily soil ; it oreases less and is warmer than cotton. Used as casement curtains, it requires washing less often than cotton.

Delaine requires careful washing if it is to retain its softness Launder in tho samo way as flannels, and in order to brighten up the colour add a little ammonia to the last rinsing water. Iron dolaine while slightly damp.

DELFT WARE. As introduced at the Dutch town of that name in the 17th century, Delft waro wis a soft-prste faience with a tin-onamol surfice which skilfully imitated the effect of Chinese porcelain before it was successfully reproduced in true glazed hard. paste ohina at Dresden. The secret of real Delft is the tin-enamel, usually painterl in blue on tho whito surface while still soft. Its vogue lasted to the end of the 18th century, when it was displiced by the technical improvements of tho Stafordshire potters.

Tho carliest pieces, in red olay, had biblical and rustic scenes in blue, or bluc and purpla Some oxcellent work was produced on a yollow or palc-brown body, enamelled in rich colours, with polychrome imitations of Japanese designs. Old Delft is recognizable by its smooth onamel, which seldom crazed, whereas modern Dutch tiles are ordinary glazed earthenware. Among more than 150 marks, mostly initials, dates and other devices, only one shows the place-name.
Tho manufacture of enamelled Delft became popular in England early in the 18th century, beforo porcelain was attempted. The first in the field was Lambeth, whose fabrio was harder, coarser, and with a more opaque enamol than Dutch. From this it can be distinguished by its being decorated after firing the onamel, by its roas tingo, and by its slight glaze.
The Delft ware whioh started Inter at Bristol often has a bluish-green tingo in the thin cnamol. Chinesc imitations were favoured styles, and fireplaces werc adorned with pairs of dog and out pictures, each of nine tilcs. Liverpool later still produced Delft ware. See Faience ; Lambeth Ware: Liverpool Pottery.

Delft. Dish of Datch earthen arare, Orieuial design, dating from the 18th century
rieloria and alberl Muscum

DELFRIUM, The state of montal excite. ment occurring in ncuto febrile disorders, ag. pricumonia and other conditions, is known as delirium. Tho onset may be sudden, or to begin with the patient may talk in his sleep and may be somewhat confused when he wakes. Ho fancies he sces strange things about the room. If spoken to he may answer apparently rationally, but aimost at once he wishes to talk of his fears and fancies All this time he is tossing restlossly, and may attempt to get out of bed, and too often such patients hare mannged to throw themselves out of a window. Ho may imagine that soncoone in attendance on him is an onemy who is attempting to do him an injury, as by putting poison in his food. This state may go on for some days, and then tho patient begins to sleep and may wake up moro rationsi.
Children who are fovered become delirious very easily, but this noed oconsion no unduo alarm. l)eiirium may come on after severe injuries in healthy people quite apart from any addiction to alcohol. It begins after about 48 hours and is usually associnted with septio poisoning. Poisoning with belladonna and similar drugs almost always produces this condition Acute delirium, or Bell's mania, is a form which affects women mainly, and a family history of insanity is comnon.

Tho treatment will be supervised by the dootor. The room should be kept well nired, darkened, and as quiet as possible. The patient must be constantly watched, lest he do harm to himsclf or anyone elso. Sponging with warm water, a pack, or, when practicnble, a warm bath, are useful soothing measures. The forehend may be bathed with vinegar and water, or an ice bag may be applied to the head. A sleeping draught may be necessary. The diet should be fluid

Sometimes active delirium passes into what is known ns tho typhoid state, and this nlso occurs apart from previous active delirium at the end of any severe illness when the vital powers are sinking low. The patient lies with tho oyes half open and kceps muttering to himsolf. The fingers are constantly picking at the bed-clothos, and he may make movenuents in the nir as if he were attempting to catel imaginary flies. The tonguo is dry and covered with brown fur. Here tho wholo ain is to maintain the patient's strength. Nourishment, in liquid form, must be given at short intervals night and day. The sick-room nust be aired, but it should also be warm, and hat wator bottles must be used if necessary, cspecially in the early hours of the morning.
DELIRIUM TREMENS. This is an acute temporary insanity devoloping in the habitual drinker. The common symptoms aro delusions of a suspioious and fearsome character. Thero is $\Omega$ constant babbling or shouting, $a$ trembling of the hand and tongue, and inability to sleep. Tho pationt struggles violently with his attendants, and frequently resists all attempts to feed him. Occasionally there is fever, the pulse is weak, and finally the patient may pass into a state of dangerous exhiustion.

Every effort must be mado to make him sleep. He should be kept flat on his bed, if necessary by straps or long bath towels, tying down his armes and legs to the sides of tho bed. Unremitting observation and care are cssential, us if left to hitnself the patient may commit sticide, or do some aot of violenco to another person. He must be carefully guarded from ohill and exposure, and his strength kept up by giving every two hours smail smounts of strong soups, meat broths, and milk. Chloral or some other iypnotio may be required to induce sleep; but suoh a remedy will only be used by the doctor's direction. An ittack of delirium tremens usually passes off in from two to thrce days under appropriate reatment.

DELPHINIUM (Perennial Larkspur). The delphinium is one of the most beautiful of all hardy herbacenus perennials. Tho plants grow from 3 to 6 feet, or more. high, and bear tall spires of bloom in shades of lavender, blue, purple $\quad$ nd mauve. They should be plantod in autumn or in spring in deeply dun and wel manured soil and left undisturbed for In an y years. If an increased stock is ro. quired it is better to raise secdlings from seeds sown in frime or greenhouse in March than to disturb old plants. Or the voung shoots may be taken off in spring, when
 this handsome border plant about 3 inches high, for insertion as cuttings in pots of sandy soil under a propagating case in frame or greenhousa. IVhen well cleveloped, delphiniums make a magnificent show and are in full beauty in Junc. An annual top.dressing of manure in spring is bencficial. When the young shoots are pushing through tho soil in spring they are apt to ve eaten by slugs. A laycr of ashes placod round about thent affords protection from thesc jests.

There are two chief types of delphinium, tho tall, vigorous varieties, and those of the belladonna type, which arc of branching, slender growth and 3 to 4 feet high. Beautifvi varicties of the latter arc Cipri. sky bluc : Lamartine, purple-bluc: Mocrheini, white, and grindiGorum, light blue.

Varictics of tho vigorous tall-growing delphinium aro innumerable and overy year fresh oncs are introduced. The following are particularly finc: Blue Boy, bluc; Millicent Blackmoro, light blue and mauve; Mrs. Townley Parker, blue and whito; Sir Douglas Haig, dark blue and purplo; Rov. E. Lascelles, dark biue and white; Noir Ferguson. light blue, mauve and rose.

The annual delphiniuns, popularly called larkspur, is raised froin sceds sown out of doors in March-April wherc the plants arc to bloom in summer. They reach a height of 2 to 3 fect and have flowers of various colours. One of the most beautiful is the msc-pink varicty. See Border

DELTA METAL. The alloy known as delta metal, and noted for its strength and toughness, consists mainly of copper and zinc with some iron and tin. It can be cast, drawn, or rolled, and can be forged at a dull red heat. When finished it takes a high polish, and does not tarnish so rendily as brass, nor is it so susceptible to verdigris. Delta metal is used in the manufacture of certain types of wire rope. When drawn to various sections or extruded, it is suitable for ornamental mould. ings found on shop fronts.

DELUSION. In every form of mental unsoundness delusions may be present, arising chiefly from inability to correct the imagination by what should be the normal
judgement. The person drifting into delusional insanity is often at first very suspicious, touchy, and eccentric.
Although delusions are of infinite varicty, they roughly group themselves into two classes-delusions of persecution and delusions of exaltation. To tho former class belong those of the person who thinks that other people are conspiring to injure him. A man in this state is often very clangerous, for ho may attack anyone whom he suspects. In delusions of exaltation a person has extraordinary ideas of his own greatness. He may believe himself to be a prophct, a king, the greatest orator, poct, military genius, ctc., in the world. Very uften these delusions of exaltation follow delusions of persecution.

In the case of old people making their wills, it is often a matter of great importance to decide whether they aro influenced by delusions; for a man may belicer that ho is made of glass, and yet make his will with sound judgement. But if ho suffers from insane delusions with regard to the conduct of his relatives or the amount of his property, his will is likely to bo faulty. See Insanity.

DEMULCENT. White of egg, honey, starch, glycerin, gelatinc, liquorice, olive oil, arc oxamples of demulcents used in medicine. Their object is to protect and thus lessen irritation of mucous membranes; so in corrosive and irritant poisoning thin arrowroot or gruel, white of egg, or olive oil is giren frecly. See Gelatine ; Honcy ; Starch.

DENTIFRICE. A proparation for cleaning the tecth may be in the form of powder, paste, or liquid. In tho first of the following recipes for a powder the carbolic acid should be mixed with a little of the kaolin in a mortar before adding the other ingredients. It is necessary to sift the powder through a fine sieve. Tho antiscptic tooth paste is made into a pasto with as much as may be required of a mixture of glyecrin 4 oz . and water 1 oz .

## Carnolic

Kaolin, of oz. ; infusorial carth, 2 oz. ; quillaia extract, 1 draun ; carbolic acid, 2 drams.

## Saponaceots

 Powdered white soan ${ }^{1} 102$. ; powdered orris root,2 oz.. ; precipitatell chalk, 5 oz..; rose geratiun oil, 10 drops.

Antiselptic Tootil Paste
Prectitated clalk, 5 oz. ; powdered soan, 5 oz., drops; wintergreen oil, 20 drops.

## Itiquid Devtifuice:

Quilluia bark, 4 oz. ; glycerin, 3 oz.; alcohol, 5 ou.; carbollc acld, i dram; ; rose geranium oil, 10 drops; clove oil, 10 drops ; cassia oil, 10 drops; tincture of rlatany, $1 \frac{1}{3} \mathrm{oz}$. ; rose water, $1 \jmath^{\prime}$ pints.

The quillaia bark, glycerin and alcohol are shaken together occasionally for 4 days and then the other ingredients aro added. Theso aro again shaken occasionally for a period of 4 days, and then the liquid is filtered through absorbent paper. A few drops of the liquid dentifrice on a wet toothbrush is used night and morning. See Artificial Tceth; Tceth.

DENTIL. Dentils are the small toothlike omaments found in furnituro fashioned by Chippendale, Hepplewhite, Sheraton, and their imitators. Sometimes cach tooth is cut away in the centre, thus leaving a raised or filleted edge, and less frequently there are dentils which are deeply undercut. One of the most frequent blemishes found on pieces of furnituro of the late 18 th century is the absence of $\Omega$ few of these dentils, which have been knockerl off through careless handling.

DEODORANT : Its Uses. Substances which mask or absurb foul odours are termed deodorants. Examples are smoke from brown paper or tobacco; perfumes like eau de Cologne; oil of eucalyptus and thymol; hydrogen peroxide, wood charcoal, potassium permanganate and chloride of lime.
Intiseptic; Disinfectant.

DEPILATORY. A preparation that is used for removing superfluous hair is known as a depilatory.

Barium sulphide is the active principie of most of the depilatories on the market. The following is a simple prescription, cheap and readily made up

## faritim stilphide <br> Orris root

Make a little into a pasto with water and apply to the hairy parts. Leave on for 5 min ., or until the skin begins to tingle slightly, then scrape off with a bone knife and wash the part with cold water. Dry, and apply a little boracio ointment or cold cream to the skin.
The treatment may be repented from time to time as the hairs grow again. The paste should not be left on longer than 5 min ., and it should not be persisted with if it causes irritation of the skin. With shaving, it shares the disadvantage of possibly making the hairs grow stronger and stiffer. See Elcctrolysis; Hair.

DEPOSIT : Of Money. A deposit is a sum of money placed in a bank with the intention that it shall remain there for some time. This distinguishes it from money put into a current account. Banks give receipts for money taken on deposit and pay interest on it, generally 1 per cent. below bank rate Money placed on deposit cannot be drawn out by cheque, nor usually without notice being given. In another sense a deposit is a sum of moncy paid down when a contract is made to show that the purchaser is in earnest and as a guarantee that ho will carry out his sharo of the undertaking. It may tako the form of 5 or 10 per cent. on the amount of the purchase moncy. Sce Banking: Contract. Savings Bank.

DERBYSHIRE NECK. This name is sometimes used for tho complaint isnown as goitre. It was believed to be specially prevalent in that county, and was duc to the peculiar properties of the water. Sec Goitre.

DERMATITIS : A Skin Affection. The general narue of dermatitis is used to denote any inflammation of the skin. The area affected may be reddened, swollen, hot and painful, as is the face after severe sunburn; but in other cases moro or less numerous papules appear. Thesc may be small, like pimples, or considerably larger; or blisters may be found, a small blister being known as a vesicle and a large onc as a bulla. If a vesiclo is filled with pus or matter it is described as a pustulc. After the skin has been reddencd, with or a part from the formation of papules, it may become scaly. if resicles or pustules are present they will dry up as crusts or scabs. Itching may possibly accompany any of these changes.

Some forms of inflammation are given dis. tinctive names. A chronic inflammation with papules covered by silvery scales is known as psoriasis. Grouped vesicles such as often occur at the corner of the mouth with a bad cold constitutc herpes, and inflammation which is characterised by large bullac is styled pemphigus. Eczema is an inflammation of the skin in which the skin is reddened and in which papules, vesicles, and pustules may all appear.

The term dermatitis is used in spealing of inflammation when it has been produced by a definite known agent. This may be heat, light, X-rays, cold, drugs taken inwardly, c.g. bromides, iodides or arsenic. It may be due to the action of poisonous plants, e.g. some primulas or poisonous ivy when they come into contact with the skin, or the landling of irritating substances in the course of many occupa. tions, as by paraffin workers, stcel grinders, etc.

Other forms of the condition are dermatitis exfoliation, in which the skin all over the body throws off crops of large and small scales; dermatitis herpetiformis, so called
because ita inHlammatory manifestations tend to be grouped like the vesicles in herpes; and seborrbocio dermatitis, in which rounded reddish or salmon-pink scaly patohes appear on the back, chest, face or elscwhere. It is associated with dandruff. Much may be done by scrupulous cleanliness to prevent the occupa tional form of the disease. Unless the case is very slight the doctor should be consulted In slight cases zinc ointment may be useful See Eczema; Skin.

DESENSITIZER. Just as curtain aniline dyes increase the sensitiveness of the emulsion of the photographic plate, so it has been found that others, in particular phenosafranine, decrease its sensitiveness to light. Solutions suoh as desensitol. prepared by the Ilford Plato Co., make it possible to develop the most. sensitive negative by ordinary candle light. The negative is placed for 2 min . in a desensitizing bath, consisting of 1 part of desensitol to 50 parts of water, and no light except the ordinary safe dark room light should be allowed to fall on the negative. If it be a panchromatic plate no light of any kind is permissible. After the 2 min . immersion ordinary weak white light, such as a candle or a strong yellow light, can be used throughout the process of development. It should not be exposed to daylight or a strong artificial white light.
The desensitizer stains the negative a deep red, but this is got rid of by increasing thic period of washing, a faint pinky stain does no harm to the negative beyond increasing the time in printing Any difficulty in getting rid of the red stain can be overcome by the addition of an acetic acid and alum clearing solution to the fixing bath.
Phenosafranine dyes stain the fingers rather badly if care is not taken; but pinacryptol green, which serves exactly the same purpose, is free from this defect, and stains neither plate nor hand. It is obtainable in the solid form, 1 gramme being diasolved in 500 c.c. of hot water. For use one part of this concentrated solution is added to 10 parts of water. Negatives can cither be immersed in this desensitizer before developing or it can be added to the developer; the negatives in the latter casc being shielded from light by covering the dish during the first minute of development. See Developing.

DESERTION: In Law. In England, desertion for two years is one of the grounds for a judicial separation. In Scotland either husband or wife may have a divorce for desertion. If a wifo is descrted at all, she is entitled to an order from the magistrates for maintenance. A husband who goes abroad temporarily on lawful business, or state service, though absent for two years, is not guilty of desertion, because it must be proved that he has descrted -i.e. abandoned-his wife, and not merely that he has been absent from her, which absence may have been duo to business or some other perfectly legitimate reason.
A father who deserts his children can be summoned for not maintaining them, provided they are under 16 years of age or are, by reason of infirmity, whether mental or bodily, incapable of maintaining themselves. See Child Cruelty ; Divorce; Separation Order.

DESICCATION. This inanufacturing pro. cess is applied to articles of food to render them suitable for storage. All moisture being extracted. the articles are considerably reduced in bulk. Desiccated coconut is the commonest commodity thus produced.

DESE. In its origin a desk is a tablc for writing on, some being flat and others sloping. While the plain form was retained for use in schools, something more elaborate was introduced into the home. A drawer was added, and there are some fine examples in which the table with a single drawer beneath it is supported by carved legs or columns. Some
beautilul pieces of this type were made in Buhl work From this the familiar writing-table was evolved, the pedestals or supports being formed by drawers, one upon another, on either side, leaving a space for the knces between.

The bureau is one form of clesk, while another is the roll-top desk, the idea of which originated in France in the 18th century The bureau du roi, which has been described as the finest piece of furniture in existence, is of this type. It was made for Inuis XV by several of the greatest artists and designers of the day, and is now in the Louvrc. See Burcau: Writing Table

DESPATCE BOX. A despatch box is made of tin or sheet steel, and usually contains separate compartments for stationery and a lift-out tray, beneath which is a space for storage of important documents. The best qualities are litted with a reliable lever lock, and have a rolled edge reinforcel-with an iron or steel bar and a strongly fitted bottom. The lid in particular should be stiff and ridged.

Another type of despatch box is strongly made of leather, and usually fitted with an ink. well, blotting-pad, spaces for pens and pencils, and divisions for paper and envelopes. These are more appropriatc when travclling or for personal usc.
DESSERT: How to Serve. The last course at dinner is often omitted when the meal concludes with a sweet of the fruit salad or ice type, but where a savoury is included in the menu, dessert usually follows.

In winter, when flowers are scarce and expensive, fresh fruit in ornamental dishes of pottery, china, glass or silver, or in gilt baskets, forms a charming table decoration. A centre piece can be arranged with mandarins and ordinary oranges (supplies from West Indies and South Africa are sweetest), pale, shiny, yellow Newtown pippins, a few brilliantly crimson apples for contrast, russet winter pears, and bunches of black and white grapes.
In addition, for the ordinary dessert, a dish containing either pulled figs, almonds and raisins, crystallized fruits, or French plums or dates with walnut or maraipan stuffing, and one of nuts, with two sinaller dishes of chocolates and fancy sweets, would bo sufficient : but for a larger party a pineapple and a dish of South African cherries might be added. Ginger preserved in syrup is best served in its own jar. Salted almonds, which may be bought ready prepared in bottles, are always popular, so also are a fow small silver dishes of marrons glacés and other bonbons.
In summer the more juicy fruits should be arranged in separate dishes. Strawberries may form a complete course. Removo the calyz from each berry, pile them in shallow bowls and serve them with cream and sugar.
Dessert Servlces. The charm of this course is greatly aided by attractive ware. A service usually consists of six or 12 plates and three or five fruit dishes. In old china it is often highly decorated, Coalport, Worcester and Crown Derby services being unexcelled

The old green-leaf service-vine or lotus is the usual pattern-can often be picked up more or less complete at a bric-d-brac shop, and has a decorative value with its malachite green on a polished table. Venetian glass services are beautiful and costly, and there are other glass varieties in plain crystal, coloured or gilt patterned at more moderate prices. Italian fruit-painted pottery has a gay appearance, and there are many good varietic.s of English china and semi-porcelain fruit sets.
Dessert sets of knives and forks can be ob. tained with twisted pearl handles, plain or filigree encased. Green-stained ivory and silver gilt alse make $\pi$ good handle, also black, silver mounted. A dersert set comprises a dozen pairs. Sez Cutlery; Silver: Spoon: Table

DESTRUCTOR. A lurnace which is used by a district for burning up its refuse is known as a clestructor. The refuse burns itself; the heat provided may be used for generating steam, and the ashes, which are known as clinker, have various uses. Small destructors may be used in the homc, but their power of consuming refuse is very much less than the largo ones, and in any case the kitchen fire is usually able to burn up domestic refuse. In the caso of a large house and garden, a small destructor in the grounds is of value to deal with the garden waste and all house refuse as well. See Refuse.

DETECTOR. In a wircless receiver this is the device which effects separation of the high and low frequency components of the oscillations picked up by the acrial. Either a valve or crystal may be employerl. but both devices provide an easy path to earth for the high frequency component, while the low frequency component is made to operate a sound reproducer diroctly-e.g. 'phones-or indirectly via a low frequency magnifier, e.g. a loud-speaker The crystal. ulthough simple and ecunomical, is comparatively unstable, whereas the threc-electrule valve or triode is both stable and sensitive.

Among the various methods of valve detection are leaky or cumulative grid, anode or lower bend, power grid. and diode rectifica. tion. A leaky grid detector utilizes a fixed condenser laving a value of $0001-0003 \mathrm{mid}$., and a grid leak, one end of which is usually connectod to a point in the circuit at prositive potential in respect to earth. In the case of an anode bend detector, a negative potential of $1 \frac{1}{2}$ volts or more is applied to the grid of the valve, and a grid leak and condenser may or may not be employed

A power grid detector is a special form of distortionless grid leak rectifier, the method entailing the use of an anode voltage of the order of 200 volts or more, and a medium or low impedance valve.

The diode detector as a distortionless rectifier is highly efficient, but owing to its insensitivity is usually only employed in designs in which fanltless reproduction is essential. See Carricr Wave: Crystal Detector: Grid Leak : lmpedance ; Oscillation: Valve.

DEUTZIA. This is a beautiful hardy flowering shrub which needs a sheltered position because it starts into growth early and is liable to be cut by frost. Deutzias thrive in ordinary well-tilled soil and benefit by being top-dressed with manure annually in spring. They are pruned by thinning out the oldest shoots as soon as the flowers have faded. A few of the beat are gracilis, scabra, crenata and corymbosa, all having white

Deatsia. Mowering spray of D. crenata, a hardy shrab

Howers. Sevcral note. "lorthy large. Ilu wered sorts have been raised: some of the best are candidissima, magnifica. and Pride of Rochester. Deutzia gracilis is a favourite shrubforforc. ing: if potted in early autumn and placed in a hcated greenhouse in December it will be in full bloom in the springtime.

DEVELOPER: In Photography. So fir as all ordinary plates and films are concerned the selection of a devcloper is principally a matter of convenience Any good standard developer, used correctly, will give similar printing results Some stain the negative, others give a good black-looking negative, but so long as development has been properly carricd out the result in print or enlargement will not vary to an appreciable degrec
Generally the amatcur will do best to follow the inaliens' instructions given on the box of plates, or with the films, which will entail the purchase of developing powders in packet form (or tablets), ready weighed and in correct proportions for dissolving in water. It is, however, always more economical to buy in bulk and prepare a portion as and whon required. If it is in powder form (amidal, pyrogallic acid, metol, hydroquinone) accurate acales nnd weights are needed. If it is bought as a single solution (azol, certinal, kodol, molinal), or in two solutions (metol-hydro quinone, pyro-soda), which have to be made up with water, liquid measures only are required, a small one measuring in drams or cubic centimetres for the developer, and a larger one measuring up to 8 or 10 Huid oz. for the water.

It is a sound plan to select a developer and adhcre to it. Uniform results cannot he cxpected and failures must be increased if the
 develapers or other photorraphic chemicals
amatour repeatedly changes his developer Many practised photographers use nothing but amidol, keep it in powder form and make it up freshly when required. It is an excellent non-staining developing agent, giving soft negatives, and particularly suitable for bromide and gaslight papers. Pyro-soda, being a staining devoloper, can be used only for negatives Metol-hydroquinone devclopers have a slight tendency to stain if not correctly used, hut are Inrgely employed for gaslight papers

In dissolving powders, tablet developers or other photographic chemicals, useful methods to adopt are shown in ligs. 1 ind 2. As the solution is formed it falls and frcsh water is continually coming into contact with the powder until the solution is complete. The method shown in Fig. 2 is particularly suitable for the solution of amidol, pyro and metol, filtration being effected at the same time. These dovelopers are not easily soluble, and if undissolved particles are permitted in the dish bad sponts will occur in the negatives If solution is not complete at first the fluid can be passed through a second time. Filter pajer, folded as a funnel, can be used instead of cotton-wonl.

Once a developing solution is made up it must he used and not kept. Stale developer is certain to give bad results. About 10 oz . of solution is necossary to develop six 1 plates at one time, and if a further batch of plates is to be developed fresh solution must be used. Amidol, metol and pyrogallic acid must be kept in well-stoppered bottles and not exposed to the air longer than is necessary, to avoid deterioration. See Amidol; Hydroquinone: Metol ; Pyrogallic Acid; Pyro-soda.

## Developing Photo Plates and Films

## Methods which Give the Amateur the Best Results

Characteristics and uses of the more important developers are discussed under their own headings, e.g. Amidol: Metol, etc. Associated articles are Fixing; Photography; Washing

Developing is purely a chemical process and thercfore precision and absolute cleanliness are required, but the systems which have been evolved make it a matter of easo and simplicity. Negatives or films may be developicd by one of three methods : by observation, by factors. and by time and temperature.

By the first method each exposure is developed separately in a dish, observing the progress of development by means of $\Omega$ red or other actinically safo light, and judging the point at which development should he stopped. To develop plates or flat films by this method, take the plate from the dark slide or sheath (taking particular care not to) touch the sensitive surface with the fingers) and lay it film side (creamy surface) upwards in the dish; next pour on the developing solution in an even swcep so as to cover the whole surface of the plate as cuenly and as quickly as possible. Then rock the dish very gently so that the solution is kept moving over the plate. Care is also taken to see that air hubbles do not cling to the cmulsion surface of the plate, since they will cause round holes in the finished negative.

After 3 or 4 min the progress of development is observed by holding the negative up to the red light and looking through it for a second or so It must be viewerl by transmitted light in this way, since in most cases it will appear black in the dish, and all sign of the image will have disippeared sonie time before development is complete.

This method is one that requires $n$ good deal of experience, and moreover suffers from tho disadvantage that with modern fast plates and filins the necessary exposure to red light is liable to cause fogging. It cannot he used at all with panchromntic plater, which are specially sonsitive to red light, unless a desensitizing solution is used. If development is likely to he slow, cover the developing dish with a pieco of cardboard. The edges of the plate which have been covered by the edges ol the dark slide should be clear glass when fixed. If they are at all grcy the plate has been fogged, the reason probably being undue exposure to the dark room light.
If a flat (not roll) film is to be developed by the observation mothod in a dish, fist fill the developing clish with clean water and immerse the flat film until it becomes thoroughly wet on hoth sides and fairly limp, then pour off the water and apply the cevcloping solution as is done for plates.
If a roll film is to be developed in the hand and in a llat dish do not attempt to cut it up hefore devoloping, but devolop the whole strip at one time fill a fairly deep developing dish with devoloper, say, to $\Omega$ dopth of 1 to 2 in . then unwind the film from the spool, crast aside

the black paper covering and thoroughly wet t in the basin of cold water.
After allowing the film to soak for about a minute take the two extreme ends of the film. one in each hand. so that the filnı hangs in the form of a loop, like the letter U . Take the film from the water and pass it to and fro through the developer in the dish, raising one hand and lowering the other, keeping up the see-saw movement so that the whole atrip of film may be acted upon by the developer. A special type of dish is made (Fig. 1).

The Factorial Method. The second and hetter method is Watlins' factorial development This consists in noting accurately the time which clapses between the flooding of the plate with developer and the first appearance of the image This time is then multiplied by a factor for the particular developer used. thus ohtaining the total time for developenent of that particular negative.

To take a single example, it is found that $a$ negative developed with nzol talies 15 scc . for the first appearance of image after the developer is poured on. The known factor for azol is 30 , and 30 by 15 sec , or 450 sec . (i.e. $7 \frac{1}{2} \mathrm{~min}$.) is the time required for complete development. As soon as the time of the applearance of the image has been noted the dish should be covered with $\Omega$ card. Factors have been worked out for practically all the devclopers on the market For instance. metol-hydroquinone, 14; amidol (2 gr. jer oz.) 18 ; pyro-sodn ( 1 gr . per oz.) 18

The factorial method only applies to correctly exposed plates. The appearance of the image is delayed in the under-cxposed plate and hastened in the over exposed plate, with the result that in the first development is carricd too far, and in the sccond it is not carricd far onough Caro must be taken that the red light used is as actinically safe as possible and the exposure of fast films to it kept to a minimum
Time and Temperature Method. The third and on the whole the soundest, mothod for the amateur is that known as development by time and temperature Makers of practically all the standard developers on the market have now published tables showing the times required for development at different temperatures of all the standard plates.
Scientilic rescarch has demonstrated that for all ordinary purposes, given a particular plate and a particular developer at a certain temperature, the time reguired for completc development cannot usefully be varied, whether exposure of the negative has heet accurately judged or not. To get good results negatives must always be properly exposed Under-erposed negatives may be intensified

Developing. Fig. 3. Kodgk tan's for developing roll flms by time and temperature without a dary room Courtesu of Kodak. Lid
and over-exposed negatives reduced if they are properly developed.
Tank Development. The time and temperature method can be used for ordinary development ol single negatives in a dish or batches, either in a devoloping lank or in a large dish, the latter generally being known as stand development In both cascs a very weak developer is used and the time of development is somewhat prolonged

A developing tank is a light-tight box in which exposed plates or films may be placed, and water and the necessary developing and fixing solutions poured in and out again without light entering. Thus the whole process of developing, fixing, and washing is possible without touching the negntives with the hands. When tanks for plates are used it is necessary to have a dark room of some kind so that the worker may transfer exposed plates from the dark slides to the tank, after which no dark room is necessary. But when tanks for roll filns are used it is possible to insert the film, unroll it, and to develop, fix and wash it without a dark room. The methods of inserting, unrolling and treating a film in a tank are very ingenious and vary according to the make of the tank. All makers of tanks, however, supply booklets giving full details

A simple type of plate tank is the Watkins (Fig. 2). Plates ane loaded horizontally into the inner portion (A). When this is done and the tank closed, the remaining operations are conducted in daylight. Points particularly requiring attention are to take the temperature of the developer before pouring it in, to agitate the solution by repeated shakings, or by pouring the developer out and in again, and, above all, to keep the tank rigorously clean. The slightcst trace of hypo during development is liable to cause stains. The Kodak developing tank for roll films (Figs. 3 and 4) consists of a wooden box in which the exposed film is unwound from a spool carrier (B, Fig. 4) by rotating the handle, C , the light-tight lid of the box being, of course, in place. I light-tight apron, $A$, is at the same time wound over it so that when the exposed film is completely wound off the spnol holder it is rolled up inside the apron. The box is then opened, the crank and handle, $C$, withdrawn, and the celluloid apron with its enclosed film removed. The circular tank (Fig. 3) having been previously filled with. developer; the apron and film are inserted. The corrugations on the edge of the
apron (A, Fig. 4) permit the free entrance of developer but not of light. Time of development varies according to temperature, tables for this purpose being supplied with the Kodak tank developer.

Another type of roll film tank is the Carbine (Fig. 5). The spool in the holder, $A$, is inserted in the tank previously filled with developer. The lid is put on with the long plunger, $B$, withdrawn. Next, the plunger is pushod down, extending the film. During development the solution is agitated by pressing the rubber ball, C.

Stand Development of Plates. For stand development of glass negatives or fint films a large dish is required to take six or more nega. tives lying flat on the bottom of the diah The negatives are unloaded from the dark slides (preferably in the dark), the developer having been prepared in a large jug beforehand. Make up plenty of solution so that the negatives are well covered, pour it over the negatives without delay, counting the seconds from the moment that the negatives are wetted.

When all the developer has been poured into the dish make sure that none of the negatives liave been disturbed or are overlaying one another. and cover the dish with a card or piece of board; take the total of the seconds counted during these operations and, turning on or going to the

Developing. Fig. 4. Sectional olew of box employed with Kodak fllm tank for wrapping alm in light-proof apron before inserting in developing tank. Fig. 5. Carbine daylight developing tank for roll allms Courlesy of Koalali, Led. and E゙nsion, Lid.
light, note the time when development began (i.c. when the negatives were first wetted) and the time when, according to the table for the developer used and temperature of the solution, development will be completed.

As in any case the devcloper in the dish will acquire the temperature of the ronn before development is complete, have it ready half an hour or so before it is required and test its temperature just before use.
This will be found a particularly useful method for developing panchromatic plates where no red light can be used at all, and in most cases total darkness is essen. tial. A very little practice is required to gain confi. dence in handling the negatives in the rark. It is only necessary to have everything conveniently to hand on the bench.
In most cases the tables for time development by the time and temperature method given by the makers of developers and plates are oalculated for what is known as " normal contrast." This produces a negative which, if it has been properly exposed, gives a print on

Devon Ware : characteristic example. Aller Vale jus with motto
gaslight paper which Las the amount of contrast of light and shade most suitable for the amateur's ordinary snapshots. If the negatives are to be used for enlarging, or if they are portraits, shorter time is needcd for development. All that is necessary in the second case is to deduct 25 p.c We thus get what is known as a thin negative. In gencral, developers work hest at a temperature between $60^{\circ}$ and $70^{\circ} \mathrm{F}$. Hydroquinone hardly acts at all below $60^{\circ} \mathrm{F}$.

In all photographio work, but particularly in developing, absolute cleanlincss of dishes and measures is of the greatest imporiance. Always wash out dishes thoroughly immediately after use; never leave them until the following morning. It is best to keep scparate dishes for developer and fixer. Also, after washing a dish, rinse it with a solution of spirits of salts, which can be kept and used repeatedly. By care in these directions mysterious stains and markings can be avoided
DEVILLING: In Cookery. The name is given to a method of coohing in which cayenne pepper or hot spices are used. Tho legs of a cooked turkey or chicken arc very suitable for devilling. They are first soaked in a sance prepared from equal quantitics of Worccster sauce, vinegar and melted butter, to whioh is added enough mustard, cayenne and salt to make the sauce hot and appetising. After being soaked well in the sauce the legs are fricd and servel hot with toast.

To ןrepare devilled game the remains of it cooked bird should be cut into neat joints, rubbed over with margarine, aprinkled with salt and cayenne, and then grilled lightly. A sance is prepared from one inblespoonful vincgar, one sliallot, one dessertspoonful each tomato saluceand margarine, a pinch of cayenne, and a leacupful stock or gravy. The vinegar is brought to the boil with the cayenne and the finely chopped sliallot. and the other ingredients added with the exception of the inargarine. Bring the whole to the boil again, talie the sauce from the fire and stir in the margatine. The sance is then poured round the game, which is served on rounds of toast.
Devilled Savouries. Fried and boned sardines dipped in this satuce and served on crontons of fried bread make a good savoury. Finely chopped ham may be used for tho same purpose with a little devilled snuce.

Good after-linner savouries are also preparel by mixing $\frac{1}{2}$ oz. butter with a small pinch of cajenne pepper, $\frac{1}{2}$ teaspuonful made mustard, and a teaspoonful curry paste. Spread the mixture on onc side only on some dry, unswectened, finger-shaped biscuits, dredge them well with grated cheese, and then cook them on a baking-sheet in a sharp oven or under the grill. When lightly browned they are ready for serving

DEVON WARE. The potterics in Devon. shirc are the nutcomo of the art movement which set in during the late.Viotorian age. On the south coast Watcombe ware, made ncar Torquay, includes green and straw pieces, and barbotine designs of marine objects. ${ }^{\text {a }}$ Aller Vale is noted for its motto warc, brown inside and yellow outside, besides a crocus pattern, and the simple and dignified Sandringham ware.

North Devon clays are used at Barnstaple for the favourite Barum ware, which onmprises simple shapes treated with bold coloured. slip designs, or with applied mouldings, such as clragons and sea creatures. A variation made at Fremington
possesses an iridescent glaze of local creation. This may be had in fruit dishes, puzzle jugs and other forms. See Pottery.
DEWBERRY. A variety of bramble or blackberry is the dewberry, which grows abundantly in the woods and hedgerows of England. The fruit, large and glaucous back with a pleasant acid taste, can be used for the same purposes as blackberries. See Black berry.

DEXTRINE : Its Adhesive Uses. Known nlso as British gum, dextrino is prepared by heating starch that has been previously moistened with dilute acids. The chief use of dextrine is in the manufacture of textiles, but it is an adhesive which finds favour with photographers for mounting purposes A snitablop mountant is made by heating 2 oz of white dextrine with $\mathbf{0} \mathbf{~ o z}$. of boiling water until it is dissolved, thon allowing it to become nearly cold and stirring in an ounco of methylated spirit to act as a preservative. Sce Mounting.
DIABETES. There are two varieties of diabetes, in both of which the pratient passes constantly large amounts of urine. Diabetea mellitus, generally referred to simply as diabetes, is characterized by rapid wasting and the passing of sugar in the urine in the form of glucose, and complete recovery is rare. In diabetes insipidus thore is no such passing of sugar, and it is mostly children and young adults who are affected.

Men arc more likely to develop diabetes mellitus than women, and it is commonest in middle life. A tendency to fatness in youth, a highly nervous disposition, a too strenuous business life, an undue fondness for the good things of the table, have all been suggested as predisposing causes of diabetes.

There is a close connoxion between the health and activity of groups of colls in the pancreas or sweetbreal and the symptoms of this dise:se. These cells secretc and pour into the blood a substance to which the name insulin has been given, and its function appears to be to ensure the buming up of sugar in the body. The injection of insulin into patients who are suffering from diabetes has been followed by the disappearance of sugar from the urine and marked improvement in the general condition.

Advice on Diet. The basis of diabetic treatment is to reatrict carbohydrates (atarch and sugar) in the diet, and sometimes also the proteins (lean meat, etc.), as sugar may be formed from them. What must be done in any particular case is to find out the amount of carhohydrate which the pationt can take without sugar appearing ; in other words, the sugar tolerance. One method is to put the patient on a diet of meat, eggs, green vegetables, and a linsited allowance of carbohydrate say, 4 oz . of breakl. It is known how much sugar is produced by this allowance, and if the sugar appenring is less, it shows thint there is some tolerance. If the amount is taken without tho appearanse of eugar, it is gradually increased. This increnso is also made possible by the daily use of insulin, the requisite number of units being injecter under the skin, usunlly before the morning and evening meals. Insulin has proved of immense value in cases of diabetic comil, a condition of blood poisoning commonly callerl acidosis, which resulta from tho perverted body chemistry.

The diet should be as varied as possible. The following may be given: Clear soup, ter and coffee (without milk or sugar), sodn water, unsweetened lemon drinks, bread and biscuits made with almond, gluten or bran, cucuinbers, celery (sparingly), tomatues, asparagus (the green pirt), and nll green vegetables, all kinds of fish and shellfish (excent cod's liver), all meats
(excopt liver), and poultry, milk (very moderately), eggs and butter, and all acid fruita, particularly oranges, currants and sour berries.

The following may not be given: Bread of all kinds, rice, tapioca, potatoes, beets, turnips. vegetable marrows, parsnips, artichokes, all malted liquors including beer. ale, stout, sweet wines and sweetened be vcragcs. Saccharin tabloids or powder may be used in order to sweeten tea, coffee, and lemonade, etc., and may also take the place of sugar n cooked dishes.
DIACHYLON PLASTER. This is a lead plaster, used to give support and protection to the skin and superficial tissues over which it is applied and so promote hoaling. It may thus be used for bruises and sprains. It enters into most other plasters. e.g. resin or adhesive plaster. Alixed with an equal amount of vaselinc it forms diachylon ointment, which is employed in eczema
DLAMONDS: How to Choose. When selecting diamond jewelry, the soundest investment is to purchase good quality stoncs. Blue-white stones of fino quality always have a good market value, no matter what their size may be, but large stones which are not of good colnur and which have flaws in them are never really good investments, no matter how advantageuusly they may have been aequired.

The sotting of diamonds requires apecial consideration. The stone should be set in platinum, but on account of the high cost it is usual for the setting to be of platinum, backed with a mount, either of white or ordinary 18 -carat gold. The most effective diamonds are round in shape and deep: but in higher-priced ornaments oblong. shaped or pearl-shaped brilliants are used which, if blue-white and without litws, aro extremely valuable.
Methods of Cleaning. Tho simplest way to keep diamonils clean is to brush them lightly with warm water with a little soap or soda added, and thon to dry out the moisture from the back of the stones by means of cotton wool, which can bo easily fixed on some pointed article, such as an orange stick usod for manicuring. Annther way is to brush the back and front of the stones with a soft brush and a little gin or whisky, aftor which thore is no necessity to dry the stones, as the spirit is quickly absorbod.

Dianthus. Botanical name of the carna tion, pink and sweet william. They are all described under those headings.

DIAPER. Little more than a name for a woven design, dinper at one time inplied linen cloth with a diamond or lozenge pattern. Linen and cotton tablechoths, napkins, and towels woven in small geometrical designs, alternately bright and dull, aro callod diaper indiscriminately, and are made in all qualitics of material.

In furniture design diaper is the repeating pattern in which the repeat is small in comparison with the space occupied. It is not applied to anything repeated on a largo scale. Diaper is frequently seen in marquetry on furniture of the later part of the 18th century.

DLAPHORETICS. These are substances that are used to incronsc perspiration. One purpose of sweating is to lessen tho temperature of the body and keep it at its normal level. If, then, we increase perspiration in fevers, we benefit the patient by reducing the fever. Another purpose of sweating is to get rid of the waste products, and when the kidneys are inactive, as in Bright's disease, increased swating will relieve the strain on the kidneys and remove from tho blood subatances where retention is dangerous.

The simplest means of inducing perspiration is to wrap the patient in hot hlankets giving him at the same tume plain water to drink. A very hot bath followed by hall an hour in bed with plenty of bedelothoy. will usually bring un profuso perspiration. Turkish or Rusaian baths or Iry hot air bath or bot vapour batha are very ellicient means of inducing perspiration

Amnng the most uselal diaphorctic drugs aro the solution of ammonium acplate. dose 2-8 drams, and sweet spirits of nitre. dese 15-60 minims Duper'q powder, a combination of opium and ipecacuanha is much used as a diaphoretic. At the beginning of a foverish cold an otherwise healthy adult may take 5 grains at bedtime, washing it down with a glass of hot lemonade or hot whisky and water. Within a short time profuse perspiration will set in, and care should be taken that the patient does not throw off his bedclothes and contract a fresh chill in the night. See Bath : Perspiration

## Diaphragm. See Stop

DIARREOEA. The commonest callses of diarrhoes or looseness of the bowels are the ingestion of poisonous substances or unsuitable food, chill and fright or excitement. The condition may occur as a symptom in the course of some specific disense. nuch as cholera. typhoid or dysentery. Colicky pains, rumblings in the intestines, a coated, furred tongue, great thirst. and more or less weakness and collapse are the chief symptoms.
Where the attack has come on suddenly and unsuitable food is probably the cause, a $\frac{1}{2}$ oz or 1 oz . of castor oil, or a smaller dose in the case of children, may be given at once. If this does not produce speerly improvement, or the pain is scvere, the patient should be put to bed between warm blankets with a hot-water bag or fomentations on the a bdomen. and the doctor should bo sent for The diet should be milk, to which an equal amount of soda water or lime water may be adiled. In hot aummer weather the milk should be boiled. As the attack gradually passes off arrowroot and smooth milk puddings may be nided. then parched eggs, stoamed lish, leading up to ordinary diet : but precautions should be taken for some time to kcep out things like tough, stringy meat, fruit skins and similar indigestible substancos.
Chronic diarrhoca may follow an attack of acute diarrhoea or may result from chronic indigeation, disease of the pancreas, or from chronic ulceration of the intestinal lining, as in tuberculosis. The physician should be called in, as it is only by a skilled examination that a correct diagnosis can the made

The Complaint in Children. Diarrhoea in infancy may take the form of infantile cholera or of simple acute diarrhoca The latter is commonest in the summer months, and is usurlly due to indigeation brought on by improper or excessive feeding It may also follow chill or a sudden change in the weather. If the child is feverish from any cause, e.g. teething, diarrhoes is a common accompaniment.

In a mild case of simple acute diarrhoen, carcful protection from chill or from overheating, a cutting down of the amount of milk and diluting it further, perhaps with barley wnter, and a teaspoonful of castor oil comprise the treatment. In all cases of chronic diarrhoea medical advice is urgently cssential. The child should be kopt comfortably warm and carefully protecterl from all chill or exposure.

Infantile cholera, a very fatal form of diarrhoea, occurring during hot weather, affects children mostly in the first two years of life, chicfly those who are hand-fed and brought up in squalid surroundings. It is duo to germs in the milk which is impure or has
been kept tro long. A noteworthy symptom is loss of elasticity in the skin of the abdomen, and there is viouent sicknoss and diarrhnea with a tempern ture rising to $102^{\circ}$ to $10 t^{\circ} \mathrm{F}$., and dropping perhaps to $08^{\circ}$ with extrome prostration.
Preventive mensures are of the utmost importance. At the beginning of any hot spell. nore than ordinary precautions should be taken over the baby's food. Its bottles and nipples should be thoroughly scalded after each fecding, the milk should be perfectly fresh, and should be stcrilized. All milk should be kept in tightly closed receptacles in a conl place, and it is better to buy half the daily quantity needed morning and evening than the whole day's supply at once. The use of a baby's comforter is highly dangerous.
The baby should be seen by the doctor as soon as possible. but in the mcantime a pack inay be used. A towel or piece of sheeting is wrung out of cold water and wrapped mund the child from the arinpits downwards. Then a blanket is wrapped round and the baby is tucked up in its cot. Till vomiting has censed only cooled boiled water should be given; but after that albumen or whey is allowed. If signs of collapse appear. put the child in a hot bnth and give it a very little weak brandy.

DIBEER. This small gardening instru ment is used for planting potatoes, builus, groen crops, eto. The most useful form is the handle of a disused spade cut down to about 12 or 15 in . The point should be shod with imn as it keeps cleaner, works easier and laste longer. If not shod, the point should le charred with fire and then rubbed down with sandpaper. A foot-driven dibber is sometimes used for planting potatocs, but it is not recommended hy the beat authoritiee. See Cabhage : Chryanthemum; Dafforlil.

DICE. Dice are used in several games of chance for instance, backgammon: also in the class of games known as race games. They arc small piecers of ivory or wood, each having six equal sides. On cach side are dote, or pips, 1, 2, 3. 4, 5 and 6 in number respectively, these being arranged so that those on opposite sides shall together total 7. Thus 3 is opposite 4 and 1 is opposite 6 .
The dice, generally two but sometimes more in number, are thrown by the players in turn, either from the hand or from a dice bux. and the player receives the numbers that are uppermost as the dice lio on the table. Dice can be made by cutting pieces of wood into the neoessary shape and marking them with ink to make the dots. Great oare should be taken that the pieces are cut quite evenly ; otherwise tho dice will be unreliable and should not be used. See Backgammon.
DEE. Tho word die is applicd to various tools. The die used to stamp an address upon notepaper is known as an embossing die, being engraved with the let ters to be embossed on the paper. It is fised in a cast-iron frame, having a hand lever at the upper part which when depreseed forces the die down on to the paper. The paper is placed upon a counter. part having corresponding letters raieed on its surface. Dics for cutting screw threads are dealt with in the articlc Stocks and Dies. See Screw Plate.
DIELECTRIC. This is the non-conductor or insulating substance which separates the plates of a condenser. The actual capacity of a condenscr depends upon the nature of tho dielectric, i.e upon the dielectric constant, which for air is one, while for mica it may vary from 4 to 8 (according to the type of mica used). 'Thus the capacity of a condenser having a inica dielectric might bo as much as eight times that of a similar condenser eniploying air as the dielectric. See Capacity; Condenser.

## Diet: Its Scientific Principles

## Cardinal Rules Governing the Nutrition of the Body

The correct balance of the constituents of a dietary is discussed here. Particular aspects of the sublect are treated under such headings as Egg; Milk; while information on special diets required in disease will be found in the articles Consumption; Diabetes: etc. See also Digestion; Eating: Food
'l'he easentials of a proper diet are that t. should provide for growth and for the replacement of waste, that it should furnish the heat and energy required by the body, and that it should furnish also a measure of stimulation to metabolism and to the functions of the alimentary tract. An analysis of fondstuffs shows that they are made up of certain constituents, namely, proteins or nitrogenous substances, carbohydrates, fats. salts, vitamins and water.

The protcins, of which white of egg and lean meat are examples, are the tissue-builder and make good the loss of tissue due to the wear and tear of living: they also go to the making of the sccretions of the body. A growing person requires a liberal allowance of proteins. Thesc substances are contained in Hesh, fish and fowl and also in wheat and other vegetable foods, but those of animal origin have in addition a certain dynamic quality which explains the oraring for animal food in cold climates, and the lessened inclination for it among dwellers in tempernte climes during the hotter weather. Protcins also furnish a certain amount of heat and encrgy, but tho proper sources of most of our requirements of theac are carbohydrates and fata.

## Calorie the Unit of Enersy

The amount of heat, and incidentally of energy, as heat and energy arc convertible into one another, furnished to the body by fixed amounta of protein, fat and carbohydrate can be estimated by burning them outside the body. The amount of heat is calculated according to a unit known as a calorie, or, as is usual when dealing with foodstuffs, a large, or kilogramme, calorie.
A calorie, or small caloric, is the quantity of heat required to raise the temperature of 1 gramme of water through $1^{\circ} \mathrm{C}$. ; a large caloric, that required to raise the temperature of 1 kilogramine, or 1 litre, of water also through $1^{\circ} \mathrm{C}$. In what follows, when the erm caloric is used it is the large calorie that is meant.

It has been found then that 1 gramme of either protein or carbohydrate produces 4 calories, while the same amount of fat produces 9 calories. The excellence of fat as a source of heat is apparent, and, for a reason to be mentioned hereafter when treating of vitamins, fat is an essential part of any diet. It might appear then, that fat might be used altogether in place of carbohydrate, but this is not so; the body cannot burn up fat properly unless in the presence of a relatively large amount of carbohydrate. Otherwise poisonous sub. stances accumulate in the blood. The optimum balance differs, however, with circumstances. In cold climates and in cold weather an increase of fat is indicated.
From experiments it has been found that the number of calories expended and required in tho 24 hours by various classes of persons are as follows:

| Man dolng hard inuscular work <br> Man dolug moderato muscular | $\mathbf{4 , 0 0 0}$ calorles |
| :--- | :--- | :--- | :--- |
| work. |  |

Different opinions have been expressed regarding the relative proportions of tho three food constituents which should be represented in the diet. Two scales which have been suggested as suitable for a man
doing light muscular work, that is, requiring 3,000 calories, are as followe :

| Proteln | Carbohydrate | Fat | Actual Calorle |
| :---: | :---: | :---: | :---: |
|  |  |  | value |
| 120 granmea | 500 xrammes | 50 grammes | 3,007 |
| 100 | 350 | 100 | 3,000 |

The salts in foodstuffis include those of iron, calcium, magnesium, sodium and potassium, and are necesarary in tissuo building or, in various rays, in the chemical processos which go on in tho body.

Even should a diet be corrccted, however, in all the particulars mentioned up to this point, it will not be a good diet. unless the foods included contain certain subatances known as nercesory fond factore or vitamins. Screral of these vitamins have been recognized. namely, threo which are soluble in fat, but not in water, and known respectively as $A, 1$ ) and F, and three which are soluble in water and known as B, B2 and C.

Fat soluble A prevents xerophthalnion, D prevents rickets, and E has been shown to be neccasary to reproduction in rats fed on an artificial diet in which A and D were present: the absence of rater-soluble $B$ leads to beriberi, and it is thercfore also known as the nntineuritio vitamin: B2 preventa pellagra; while tho absence of water-soluble C leads to scurvy and it is therefore called the anti-scorbutic vitamin. It is probable that ill-delined discases nccurring in those who feed on artiticial foods is cxplained by vitamin starvation.

In the following table the vitamin content of various foods is set out :

| Foodstull | $\underset{\text { Fat }}{\substack{\text { Foluble } \\ \text { S }}}$ | Water Soluble I | Winter Soluble C |
| :---: | :---: | :---: | :---: |
| Milk | + + | - | + |
| Hutter . | $t+t$ | - | - |
| Cream | + + | - | $+9$ |
| Figa yolk | + + | + + | - |
| Beef fat |  | - |  |
| Mitton fat.. | + | - |  |
| Lard .. . | - | - |  |
| l'ork .. . . | - | - |  |
| White flah . . . | - | - |  |
| licrring .. .. | - | - | - |
| Cod-llver oll ... | $t++$ | - | - |
|  | + | - | - |
| Vegctabic olls . | + | - | - |
| Wheat (wholc graln) | + | + + | - |
| White flour. . . . | + | + | - |
| Polished rice . | - | - | - |
| Fresh Prult (especially orange, lemon, grape frult, tomato) | - | - | t- + + |
| Nuts .. $\quad .$. | - | $t+t$ |  |
| Qreen (ravi) vegetables | + + | - | $t+t$ |
| Green vegctables |  |  |  |
| (cooked for a short time |  | - |  |
| Potato . . . . . |  | + | + + |
| Swede turnij) | - |  | $++$ |
| Yeast .. . | - | $t+$ + | + |

Foods which contain vitamin A generally contain $D$ also, and the statements in the first column above, regarding the presence and richness of vitamin A, may be taken as applying equally to vitamin $D$. Therc is very little vitamin $\mathbf{D}$ in green vegetables, however and conversely the body fat of fish contains no vitamin $A$ but a fair proportion of vitamin D, so that herrings, for example, may be used as a source of the latter. What is said about
vitamin B above appliea more or lesa to vitamin B2, but mill, which does not contain the former contuins the latter, and this also ocours in lean meat. fish, cheese and eggs.
Other characteristics of a good diet remain to he considered. It must excite the digestive functions and must contain a sufficient amount of indigestible material, or, ns it is called, roughage, to stimulate the muscular movements of the gut and so promote regularity in the action of the bowels.
Appetite and digestion are improved by variety in the diet and by good cooking. Foods which require chewing are helpful because they allow time for the action of saliva, and the act of chewing stimulates the flow of gastric juice. Moreover, it should be recognized that chewing crisp food, suoh as an apple, is n natural method of clennsing the teeth. Roughage is supplied chiefly by the cellulose contitincd in vegetables and fruits
An excessive diet strains the digestive and exeretory apparatus of the body, leading to indigestion and auto-intoxication. Some of the excess is laid down as fat, and a flabby obesity is also the common result of an excessive consumption of carbohydrates, another result being Hatulent indigeation. In some diseases adjustment of the diet is the most important part of the trentment.
After a perann has passed middle ago his dietary ahould be reviewed frequently and the quantity should diminish pari-passal with his output of work ns the yenrs go on. For old age ford must be simple and easily digested and na the body heat is less easily maintained, it should contain an adequate amount of fats and carbohydrates.
DIFFERENTIAL GEAR. The dificential, or balance, gear as now used in a motor car is always inoorporated in the live axle. The differential is employed so that the relative movement of the back wheels shall be capable of self-adjustment to the needs of the moment. When tho vehicle is turning a corner it will be ohvious that the wheel on the inside of the curve is travelling much slower than the outside whicel.
Two Designs of the Gear. There are two designs of differential genrs employed, viz. the bevel and spur pinion types. The betterknown and more easily understood is the bevel. First of all it has to be remembered that the road wheels control the diferential.
In the diagram, A is the crown whecl driven by the bevel pinion B. The crown wheel A is mounted solid with the differential case $\mathbf{C}$, which rotates on the same centres, hut independently of the axle-shafts $\mathbf{D}$ and $\mathbf{E}$ The differential case C carrics the bearing pin $\mathbf{F}$, on which the two smal! bevel pinions $G$ are mounted. These pinions are capnble of independent rotation, but are both in mesh with the large bevel pinions mounted solid on the axle shafts D and E. Therefore, so long as the axle shafts $D$ and $E$ are rotating at an squal apeed (owing to the car travelling in a atraight line) there will be no movement of the pinions G , the whole rotnting as though solid through the medium of the crown wheel $A$, which is a part of the differential case $\mathbf{C}$.
Now, assume that the car is travelling to the right of the page and an is turning to the right. During this movement of the car the road wheel that is a part of the sxle shaft D will have to make a greater number of revolutions, ns it is on the outside of the curve, than the road wheel that is a part of the axle shaft $E$. and is on the inside of the ourve. To allow of this movement, it will be obvious that the two small hevels $G$ will be turned through the medium of the large bevel pinion on the axle shnft D , in the direction of the two curved arrows shown in the small dingram. thereby allowing the rolative differences of
speed between the two aslo sha!ts $D$ and $E$ to take place.

The two small hevel pinions $G$ are in reality a compensating coupling hetween the axle shafta $D$ and $E$, their novement being governed

solely by the variations of speed between the two road wheels. In all other respects they act ay the driving medium to the axle shafts so long as the road whecls are in contact with the ground

If, however, one of the wheels should be lifted free of the ground, and the crown wheel A rotated, then the small pinions $G$ will be freo to rotate, and by so doing will reverse the direction of rontation of the wheel that is lifted free, the other wheel remaining stationary On high-powered vehicles three or four of the amall pinions $\mathbf{G}$ arc employed. Sec Genr ; Notor Car:

DIGESTER : Use in Cooking. Strong iron boilers used for making soups, etc., are known as digesters They have lids which screw down tightly so as to confine nll the steam, and by this means the water miny be heated several degrees higher than boiling point. So that the vessel will not burst, the lid is fitted with a safety valve by which the hent of the steam can be regulated. Meat cooked in thesc boilers may be entirely dissolved and honcs reduced to jelly.
A specinl type of digester allows the steam to eacrpe through the valve on the lid, and for this reason should be ouly three parta filled with water. When cooking begins, it should be placed near a slow fire and its contents allowed to simmer for 8-10 hours. The soup should then be strained through a hair sieve or colander, put back into the digester, vegetables and seasoning added, and the whole boiled for 1-2 hours. Digesters of this kind vary in capacity from 4 quarts to 10 gallons. Sucepan and stewpan digesters mave on the same principles hold from 1-8 quarts. To olean digesters, wash them in hot water to which a little sodia has been alded, and then scrub them inside and out. Finally rinse them and dry them with a clean cloth. The digester has heen largely superseded by the casserole, at least as far as stews are concerned. See Casserole; Soup; Stockpot.
DIGESTION: Its Functions. The food that we eat would fail of its purpose wero it not altered into products suitable for the nourishment of every part of our hodies These products are carried in the blood and must, thercfore, be soluble. The process of alteration is known as digestion. The changes involved are many and complicated, but all are supervised, without conscious cffort, by the nervous system, which has filaments at every point of the canal, 30 ft . long, traversed by the food.

In the mouth, digestion of starchy foods is begun by the salivn, while movements of oheek and tongue aid the teeth in crushing the food into a anft muncled mass or bolus.

Swallowing is hegun by the tongue pushing bnck the bolus into the grasp of the muscles surrounding the throat. These pass it quickly over the air passage, which is pmetected by a small hap called the epiglottis. The musclea of the cesophagus next puah the food into the stomnch.
The stomach is a rensitive muscular tuhe changing frequently in shape and position. Its lining produces gastrio juice, which renders the food acid and digests to a lange extent the meaty portion of the diet. The formation of gast ic juices is increased when one sees food nnd when chewing takes plice, ns well as at the time of its arrival in the stomach. Hence the inportance of food being cooked in an appetizing way and attractively served.
An ordinary meal remains for some four hours in the stomach and is then pressed out. in a liquid atate. into the upper end of the small intestine, or duodenum A short distance down, a duct brings to it the secretions of the liver and pancreas. The fluid formed by the liver is called bile, and this is an importaut agent in digesting fatty foode The pancreatio juice acts on starehy or farinaceous suhstances and also causes further disintegration of meat products
The long coils of the small intestine lie in many lonps packed in the central part of the abdomen, and the absorption of feeding. stuffs mainly occurs while the food is heing propelled by regular waves of contraction. called peristalsis, along the seven yards of these coils:
In addition to the digestive juices mentioned above, there is a secretion from multitudinous amall glands which dot the lining memhrane of this tube. This secretion aids digcstion and makes the food alkaline. The lining mem brane is also onrrugated into transverse rilges, so that an extensivo surface is presented to the digesting food and its rate of flow delayed. All over the surface occur minute pinjections whioh have inside them a network of bloodveasels and lactenls. These villi, being bathed in digested food, suck ont from it the nourish. ment which serves to renovate all parts of the borly. The special function of the Incteal vessels is to collect the digested fats. These are carricd into the thoracio duct, which dischargea them into the great veins near the heart.
The contents of the small intestine pass into the large intestine, at the commencement of which is situated the vermiform appendix. This is the worm-like hlind pouch so well known as the site of appendicitis. The largo intestine is provided with many mucous glands, and single lymphoid glands which probably serve to drain off deleterious substances. It incasures a bout 2 yards in length and terminates in the rectum, where the undigested remmants of fond and the remaina of digesting tluids collect until voided. Regularity in passing the excretions should bo taught in infanoy. If such errors as insuff. cient exercise, unduc restriction of drinking water and the use of tight clothing are avoided, the linhit will remain regular provided the diet is reasonable in quantity and quality. See Dict: Indigostion.

DIGESTIVE. A substance which rein. forces the digestive juices of the body, and therefore is useful in dyspepsia and digestive weakness generally, is termed $n$ digestive. The digestive may be given inwardly to he of rasistance in the process going on in the alimentary tract, or, as in the peptonizing of milk, etc., it is added to the food and allowed to act for a certain time before this is taken.

Some digent the proteins, like lcan meat and white of egg, c.g. pepsin. This ferment, dose jo to 10 grains, may be given in powder, pill, crohet, or tablet, or in liquid form as the glycerin of pepsin. dose 1 to 2 drams, and in this case is usually combined with $\Omega$ little dilute hydrochloric acid. I'ancreatio solution,

Digging. Pigs. 1-12. Diagrams illustrating effective ways of digging a kitchen garden. Figs. 1-4. Double digging. Figs. 6-10. Single dirging. Pig. 11. Emergency digging, 12. How to dig a large plo:
dose 1 to $\because$ drams, contains trypsin, which is a protein digentant, and also a ferment which digests starch.
Bencer's food cont:lins whesten flour, with the addition of the digestive ferments of pancreatic juice, which convert its contained starch into sugar, while tho milk used in the preparation of the food is partially peptoni\%ed. The rood as prepared can be giaded to the patient's digestive powers by allowing a longer or shorter time for the action of the ferments, hefore finally stopping this by bring. ing the food to the boil
Among other digestives of starch, mention may be suade of taka-diastase, obtainable in capsules, dose 1 to 5 grains, and extract of mult, dose 1 to 4 drams. The latter may be useful in dyspepsia in children in a dose of a easpoonful thrioe daily.
DIGGING. The successful management of plants depends chiefly on deep oultivation of the soil by digging and trenching. 'Trenching cultivates tho soil three spits (a spit is the depth of soil removed by the spado when thrust straight down) : (louble digging cultivates it two spits, and in ordinary digging the surface only is turned over.

The way to dig a piece of cultivated ground is to take out a trench 2 ft . deep across one end of the plot and to place the soil at the opposite end of the plot. The bottom of the trench is forked over and garden rofuse or strawy manure is mixed in. The top layer of the next 2 ft . strip of ground is then placed in the bottom of the first trench and stable or farmyard manure, if available, is forked into it. The second layer of soil is placed on top of it. thus filling the first and opening the second trench. And so the work is continued until the end of the plot is reached, when the soil excavated from the first trench is used to fill the last one. This method of cultivation is sufficient for general purposes ; those who grow produce for exhibition sometimes trench the ground three spits deep; manure is placed in the second spit of soil and rough garden refuse, or coarse inanure, in the bottom of the trench.
A different practice is followed when dealing with fresh lind-that is land which has not
been previously cultivated ns a garden. If it is covered with turf this should be stripped off about 3 in . deep and stacked for a year. It may then be dug into the ground. A 2 ft . wide trench is dug across one end of the plot and the soil taken out is placed at the end as already described. But the next detail is different, becausc it is essential that the top soil and subsoil be kept in the same respective positions.

This is assured by taking off the top spit from the second 2 ft . strip of ground and placing it also at the opposite end of the plot. Thus the first trench is empty and the second trench is half empty. The subsoil from the second trench is then placed in the bottom of the first trench and the top soil from the next strip of ground is put on it. Thus the first trench is full, the second is empty, and the third is half empty. The method keeps the subsoil and the top soil in the same positions ns they were before. In subsequent years their positions may be reversed by adopting the ordinary metzod of trenching as already described.

The Diagrams Explained. The accompanying diagrams picture three inethods of digging. Figs. 1 to 4 cover what is known as double digging, which, although entailing much hard work, ensures perfect preparation of the soil. Commence by taking out a trench two spits deep and carry the soil to the spot where digging will end. Break up the subsoil A, transfer the top aoil $B$ on to this, and then lift the second spit C on top. Fig. 2 shows the resulting position. Now break up the subsoil at the bottom of the new trench, dig down the top soil $E$ to second place, and again transfer the second spit to the surface Continue the operation in this order until the whole plot is completely dug.

The position at the end of the first digging is show $n$ in Fig. 3; the subsoil A is broken and loosened, the good top soil has taken the place of the original second spit, while the whole of the second spit has been brought to the surface for weathering. This first digging is done during the autuinn. In spring the second digging is carried out in precisely the same manner, which restores the freshened under-
spit to its original position and brings the old top spit to the surface again. The soil taken from the first trench is used to fill the vacant trench left at the end.

Figs. 5 to 10 show a single digging method which will be found highly satisfactory when time cannot be devoted to double digging Take out a trench one spit deep, as in Fig. 5. follow with another half the width (Fig. 6), and conclude by breaking up the bottom spit, as in Fig. 7. Dig over the second spit D, as in Fig. 8, and then loosen the bottom spit E. Now lift the top soil F on to D (Fig. 9), which refills and completes the first trench (Fig. 10.) The operation is continued in the same manner -that is to say, the next portion of undug second spit is put above the broken bottom spit, the next top spit carried to the surface. and so on. Fill the last hole with the soil taken from the original trench.

Another method, easier still. is shown in Fig. 11. Simply take out a trench one spit deep and break up and manure the soil beneath. Dig the next top spit on to this, continuing as directed by the arrows in the sketch.

An excellent way to dig a large surface methodically and regularly is to divide the plot into three sections, as pictured in Fig 12. Commence by taking out a trench at $A$, and deposit the soil at A A. Step backwards and transfer $B$ into trench $A$, and work down to $C$, as directed by the arrows. An empty trench will consequently result at $C$, and into this dig the soil from i). Then face the open trench at $D$, and continue until you have an open trench at $F$. Now face this trench, and dig on in the same order until the end of the plot is reached. An open trench, of course, results at $G$, and into this place the soil A A from the original trench See Garden; Spade.
DIGITALIS. This powerful and useful drug is obtained from the foxglove. Its chief action is to slow the beat of the heart and to increase blood pressurc. It is often used when the blood pressure is low, and is of value in cases of heart disease and dropsy. But when taken over a period it may accumulate in the body and lead to poisoning. The first symptoms are palpitation and unevenness of the heart beat. In severe cascs the patient turns livid, with shortness of breath, and should be put to bed at once, avoiding all exertion until the doctor arrives. Strong hot tea, diluted spirits, or sal volatile should he given. When poisoning is due to an overdoso, an emetic must be given to start with, and vomiting encouraged by draughts of tepid water: See Foxglove; Heart. Pron. Dij'i-tã-lis.

DILAPDDATIONS. This is a subject of increased importance to the householder owing to the high cost of labour and the consequent necessity of doing his own renovating wherever possible.

In purchasing a house, due regar! should be paid to those parts which are likely to prove vulnerable from the standpoint of dilapidations. Externally, these may be summed up, as the brickwork and the roof. $\mathrm{R}_{\mathrm{f}}$-pointing brickwork that has perhaps becone unsound enough to be no longer weatherproof, owing to percolation of the mortar, the bricks themselves, or both, is an expensive business, and can hardly be tackled by anybody not possessing practical knowledge of building; nor is the repliscing of slates or tiles any leas an expert's job.
Internally, however, there are certain dilapidations which can be put right without much trouble. Papering and painting are among them. Other dilapidations likely to call for attention more frequently than the walls or woorlwork are those of door handles, electric or other bells, the stained parts of floors, the catohes of windows, painted metal baths, etc. These are comparatively small matters which can be dealt with as occasion
demands. The major dilapidations involving papering and painting lose much of their formidableness if they are taken in hand gradually and systematically See lBuilding : Cottage; Lease : Repnirs.
DILL. Aromatic herb with finely divided toliage resembling fennel, but of much smalles growth. It mny be raised from sced sown in spring, the plants being thinned to about 1 ft. apart. The laves are used for flavouring soups and sauces, and the seed for distilling oil of dill and for making the carminative known as dill water.
Dill Water. For infants and children a useful corminative is found in dill water, which is prepared from the dried seed of the
plant. The dose is 1 to 2 fluid oz; for children, a teaspoonful. For Hatulence and hiccough an infant may be given half a teasporonful with a little pinch of bicarbonate of soda sulded.

DIMORPHOTHECA (Nsmuqunland daisy or star of the veldt). This is a bcautiful hardy annual hearing daisy-like llowers in orange, yellow, salmon, apricot, and blush. The sceds are sown out of doors in April where the plants are to bloom in suminor they like a sunny position and well drained soil Star of the veldt also makes a good pot plant for the greenhouse. Sceds are sown thinly in 5 inch pots of soil and the seedlings are thinned out, not transplanted.

## The Dining Room and its Furnishing

## Practical Suggestions for Small and Large Houses

The entries on the various pieces of furniture should be consulted, e.g. Chair: Sideboard; Table. See also Alcove; Carpet; Colour; Cupboard; Curtain; Decoration, ect.; while attention is drawn to the article Dinner

In recently-built houses the position of the dining room is generally decided with due regard to aspect Under other circumstances, where choice is possible, a window facing cast is a desirable feature in the room selected as a dining room, in order to get the advantage of any sunshine at breakfast time.
The ideal arrangement in a detached house is a corner mom with a window facing south and another east, especially if possessing French casements opening on to a veranda or loggia so that the dining room may be practically oxtended in the summer hy meals being taken outside. A uscful piese of furniture for this is a threo-tiered service trolley, obtainable with a locking device, which when released allows the three tiers to swing into a level position, forming $n$ table at which several people can be seated comfortably for a meal, the trolley being loaded with requirementa and easily wheeled from the kitchen. thus frilitating service.

Dining Room. Fig. 1. Room in Spanish style, this note belng atruck in the tiled floor, distinctive table equipment. nail-studded leather chnirs and wrought fron sconces

Aids to Service. The most practical con. sideration in connexion with the dining ronm is service with the kitchen. In the ambll house, where the room is next to the kitchen and one maid is kept. a service hatch saves many footsteps in the day. It may be arranged, as shown in the third illustration, with a china cuphoard to balance it on the other side of the oak Welsh dresser. In this case the hatch in itself forms a useful place for storing china and glass. On the lower shelf on the dining room side glass is kept, while china is stored on the
glazed upper portion on the kitchen side.

A service feature in some of the smaller modern dining moms is a built-in sideboard with a hatch forming its upper part which

Fir. 2. Small dining room in Empirestyle. The prevailing tones in this roomare sbades of rrey, deep coral pink and black, with farniture in accord with the period

The frieze and When the cutlery ceiling could be distempered a creanis. and china liave been apricot. Dinner services should always be uashed up they are chosen with regard to the decorative scheme placed on shelves of the dining room. accessible from tho dining mom side so on the litchen side, are simply obtainal by the use of browns an
that they are ready for laying the next meal.
Sometinies the service hatch looks like a small wall cupboand which, when opened in the dining room, reveals circular trays, revolved when necessary on a central pivot.

For dining rooms which are not on the same lloor as the kitchen, a small service lift cithes worked by eloctricity or hand-power with pulley ropes, is the only method of obviating the necessity of loaded trays. Such lifts can be installed without muoh difficulty if the dining room is directly above the kitchen and there are no reatrictions to preclude it. For the long corridor in a flat or house between kitchen and dining room the tiered service wagon is practically a necessity.

In the larger type of dining room, a good arrangement is for a liatch to open into a small pantry, which amounts to a cut-ofi lobby separating the kitchen from the dining room. Such a pantry should be well ventilated, and fitted with shelves and a sink.

Attractive Schemes. Styles in decoration and furnishing for rlining rooms are so many that choice is almost bewidering when confronted with this problem in a fresh home The type of house, size of room and question of expense will all he decisive factors. If $n$ houso has been fairly recently dosigned it will probably he equipped with a built in side. board. Should cuphoards and a window seat also have been added, the fooring be laid parquet and the walls panelled, the furnishing question merely resolves itself into suitable table and chairs, with well designed carpet and curtains in such n room beautiful effects
effect is oftell used tor the walls. A room in Spanish style is shown in Fig. 1. The nail. studded leather upholstered chairs, wrought imon sconces, and table setting stress the Spanish note. A dining ronm inspired by this schome could have tiles in black and grey marble rubher flooring, salmon pink tinted plaster walls and curtains in velvet of a dark olive green.
Extreme styles in turnishing include a dining table with a heavy pexdestal instead of legs, and chairs with steel tubes instend of woodwork and cane upholstery More uni versally admired are charming rooms with a suggestion of period setting like that seen in Fig. 2, with its simple yet formal Empire style. The ropes and huge tassel instead of a pelmet are a happy thought. as they exclude no light, while the treatinent of the chimney picco is in perfect taste
Such a furnishing would be suitable tor a simaller dining room in a llat and vould be one of which the inmates would not tirc. The colour of the wall paper could be in two shades of grey, a black note for the medallions and playues, the pantwork in the deeper grey scuinbled over a silver powder undercont and tinished with egrshell gloss varnish. The line of moulding between ceiling and walls would be in black. which would be repented for the curds and tasels. while the curtains brighten the colour scheme with deep coral pink, a paler shade heing used to distemper the ceiling.

Fig. 3 also shows a scheme of furnishing suitable for a small room, but of less formal type with ite gate-legged cak talile, Welsh diesser and rush sented chairs. An onk chest and brick fireplace would complete the scheme which would be pleasant carried out in a golden ainber shade of water paint for the valls, with a paler shinde for ceiling. a Wilton enrpet in Persian design and curtains of shot fabric suitably hlending the colours of the carpet.

In lig. 4 is illustrated a good arrange ment for tho tiny bungalow dining room, or a hall dining mom, sometimes met with in a small flat. The simple oak stools are enriched with mamon coloured velvet cusbions. liaving gold tassels at the corners; the golden note could he picked up in the brass candlesticks and the Ianternshaped lighting fitting. The iralls of the room and ceiling could be dis. tempered a pinkish stone with frieze moulding of light brown to match the weathered oak colour of door and furniture. The carpet wrould be of natural baircond. For the winter there would be curtains of maroon velours.

## Dining Tables, Practical and Pleasing With Details about the Construction of Expanding Tables

Further articles in this work deal with other types of gable, e.g. Bed Table: Console Table: Table Writing Table. See too Billiard Table; Sideboard. The craftsman should consult the entrics Amateur Carfentry; Cabinet Making; Joint, cte.

The iirst dining table was just an ordinary table put to this use, square and solid, and quite plain Dining tables soon became more elaborate articles of furniture, made to harmonize with the other pieces in the rnom. They were of nak, mahogany, cedar or chestnut. but the cheaper wonds snon came into use.

Making a Table. Of all the various ty pes of extending tables, the draw table (Fig. 1) is stilt in many reapects the best. It is simple in action, durable and absolutely rigid, and has passed the test of time. as is amply proved hy the inspection of the old 16 th century draiv tables. Their only disadvantage compared with the telescopic type is that whereas the latter can be oxtended to over four times its normal length. the draw type will only open to nearly double the length However. this is ample for ordinary purposes
Differing from other types, the legs and underframing remain stationary. While the eaves or extentions arc contained under the main top and aro pulled out at each end when required, being supported by bearers tupering townads their extrenities These bearers are screwed to the extensions and fit into notches cut in the end rails of the table. W'hen pulled out the effect is to raise the extensions up to the height of the main top, which is lonse, forming a flush join The top. linwever. can-

Dining Table. Extending table made in the Adam style. Above. lett. circular table in Chippendale style with claw and ba!] feet Courlesy of wh initeley. r.ed

At the end of the 8th century the dining table was, as a rule extremely well made. The usual type in the best houses wrs one supporter upon pillans and claws, four claws to each pillar, and run ning upon brass castors. By this time the idea of the expanding table had been evolverl, ind patents for this werc taken out before 1800
Then came the expinding table woiked by not be lifted off or moved sidellsys, its it is means of a long screw. By turning this the kept in position by guides To close the table, tablo can be opened out and loose lenves the main top is lifterl to allow the extensions inserted theroin, thus, if necessary, doubling to pass undernenth. the length of the original table. In the 19th century a circular or oval expanding table wis introduced into the English dining room.

Dining Room. Fig. 3. Design for a small room with light walls and oak furniture. There is a chlna cuphoard and service batch on either side of the dressar. Fig. 4. Charming arrangement where apace is limited Fig 3. courtes॥ ol Our Homes \& Gardens

Success lies in the corrcct making of the beirers, and it is advisable to set these out full size before commencing the job The legs are cut from 4 in. squares and are mortised to take the rails, the tenons of which should be as long as powsiblo to obtain the maximum strength. They are also pinnerl. Note that at one end the notches for the bearery occur inmediatcly againat the legr, so that the width of the tenon willonly be from the bottom of the notch to the bottom of the rail (Fig. 3). A grooved moulding is worked on the rails, though this may be omitted if desired: the samo applies to the lower rails or stretchers Having tumed the legs, the table may be glued together ; the underframing does not differ from that of an ordinary tahle except that allowance is made in the height for the thickness of two tops.

Below the main top and between the two extensions is now fixed a centro cross picce (Fig. 2). This measures in length just the width of the top; it is 1 ft . wirle, and the same thickness as the top. Tivo slots are cut, as in Fig. 4. to take the two top guides; the cross pioce is screwed to the rails. The top and two extensions are now made as in Figs. 5 and 6. The 1 in . framing is mitred and tongued at the corners, with two centre cross rails tenoned between and having $\frac{3}{} \mathrm{in}$. panels tongued and gronved between them ; panels are not glued.

When the framing is glued together, the whole should be trued up and thicknessed.
making sure that it is perfectly straight and flat and out, of winding. Two packing pieces are then fixcd to the centre panel at the sides so as to obtain extra thickness for the two top guides which are stub-tenoned underneath. These guides are $3 \frac{1}{2}$ in deep with slots cut near the bottom into which stops are fitted after the top is put in position, thus preventing any possibility of the top being lifted right off.
The bescers are cut from $1 \frac{1}{2} \mathrm{in}$. stuff, 2 in thick, and tapered at one end. Fig. 2 shows where taper commences. As the top is 1 in . thick, it will be required to taper the bearers $l$ in. so that the extensions will be raised just this amount The taper commences about $\mathcal{Z}$ in. in front of the inner edge of the extension, so that when open the main tnp will rest upon the same surface as the extension. (In the middle, of course, the top is supported by the centre cross piece.)
The notches are now cut in the end raila of the tahle, so positioned that the bearers at one end will fit just inside those at the other end ; in depth they are cut just the thickness of the bearcrs at that point when the table is olnsed. The bearers are now screwed to the

extensions and the whole job is assembled. Guides are fixed as in Fig 4: these are deep enough to take the cmos picces, which are screwed on to prevent the extensions from being lifted up. Apart from this they take no actual strain, the whole weight being divided between the end rails and the centre cross piece (Fig. 2). Stops are fitted to the underside of the bearers to prevent them from being pulled right out. When the movement is tested,
the table should be tried to see that when onened the whole top

is in a straight line; also that the extensions bed right down firmly without any give in any of the corners. A good lubricant for the bearers is ordinary candle grease

A Telescopic Table. Fig. 7 is an example of the telescopic table. To open, it is simply pulled out at each end and $n$ loose leaf inserted in the centre. In this cass the legs move with the top, there leing two rails at each side, kept rigid by a tongue.

A table of this description could, by the addition of extra rails or slides, be made to extend oonsiderably, being operated by means of a revolving screw.

The legs are made out of 4 in mahogany, and are marked out for the mortises, allowance being made in the height for the castors. It aliould he noticed that in the one pair of legs the mortises are set nearer to the middle to take the inner rails (Fig. 12). The mortises are $\frac{5}{4}$ in. wide and should meet; the legs are then marked out to shape and tapered accordingly. The end and outer rails are 4 in by $1 \frac{1}{2} \mathrm{in}$, and the inner rails 3 in . by $1 \frac{1}{\mathrm{in}}$. The reason for the latter being 1 in . lass in width will be obvious from Figs. 8 and 9, since the cross rail fastened to the onter rails will have to pass under them.

The tenons of all the rails are marked out and cut, and-it will he observed that thoae of the inner and outer rails occur at one end only, the other ends being cut off square. The grooves in the rails are gauged from the top edges and ploughed to a depth of $\frac{1}{1}$ in. : they are $\mathcal{J}^{3}$ in wide. The tongue is then glued into the groove of the inner rails and allowed thoroughly to set. All rails and tongues should be of hardwood, which is essential for all work of this kind.
At a distance of $1 \frac{1}{2} \mathrm{in}$. from the square ends of the rails cross rails are dovetailed under
neath (Fig. 10). It is essential that these cross rails should be marked out to the eract length, as one pair of rails must fit just inside the other, forming two sets of exactly parallel rails (Figs. 11 and 12). The dovetails are supplemented with screws.

The various parts are now glued up, each pair of legs with its accompanying rails forming a complete set. When dry the two parts are fitted into each other and two stope screwed to the top of the lower cross rail (Fig. 11). When fixing these, allowance must be made for the table to open about 1 in. more than is required when the leaf is put in, as this is fitted with short dowels (Fig. 13). The moulding is then glued to the outer rails, as indicated in Fig 10.

For the top thoroughly seasoned timber must be used; it will be necessary to joint this, the shape being cut afterwards. The best way to mark this out is to use a thin lath
with a pin driven through near one end to use as a centre, and revolve the lath round this, holding a pencil at the other end. The two fixed tops are pooket-screwed to the rails, as in Fig. 10. Short dowels are glued into one side, and fit into corresponding holes at the other (Fig. 13). The leaf is also dowelled at one side, and with holes at the other, so that it will always be put in the same position whatever size of table is required.

Having screwed the top on, the joint is planed level with a trying plane: the leaf is also put in and levelled. The ends of the leaf are quite straight, and form a continuous line with the semicircular shape of the fixed tops. The edge is rounded off, as in Fig. 10. while the leaf is in, thus ensuring their coinciding. Candle grease is a good lubricant to use should the slides run stifify; oil or any other liquid tends to expand the wood, thus making them run more tightly, which may perhaps cause them to jam.

## DINNER AND DINNER PARTY

## Suggestions that Housewife and Hostess will Appreciate

## The reader may with advantage consult the article Table and the entriea on the various dishes mentioned in the contribution below. See also Dining Room; Service Wagon

The home dinner need not be elaborate, and the dishes may contain very simple ingredients; but the cooking should be good, the hot food served really hot, and the table should be attractively laid.

The meal should be served punctually. In many homes the dining room has to serve several purposes besides its use at mealtimes, and will need a little tidying and readjustment before it is ready for the family dinner. During the winter the fire should be made up and the hearth swept before the table is laid, and the windows opened to ventilate the room.
Menus should be as varied as possible, and the likes and dislikes of the members of the family considered. A good arrangement when a three-course meal is taken is to have soup. grapefruit or melon, followed by a joint, savoury or dessert, three evenings of the weak. and fish, entrée, or a vegetable dish such as asparagus or salsify, and a sweet on the alternate evenings.
For evenings when the cook is out, or time for the preparation of dinner is short, soup can be prepared, a meat pie or stew that only needs re-heating left ready, and a cold sweet made in the morning.
The Sunday evening dinner usually becomes in reality supper. Soup may be the first course, and cold meat or a pie can be served with an inviting salad or sliced beetroot and hot potatoes baked in their skins; or a mayonnaise is generally liked in summer. In winter a casserole meat dish is more suitable than cold food, and a tart or steamed pudding can soon be warmed up, while a cold extrs sweet can be prepared and served in the event of unexpected guests, and also additional dessert.
Such arrangements serve for an informal dinner with one or two guests, but the formal dinner party needs careful planning.

Dinner Party Etiquette. Dullness should be guarded against by inviting the right persons to meet, in the case of a small party, or by arranging the table, in the case of a large party, so as to bring together the people who are likely to have subjects of conversation in common. Another important factor of success is to give a well-cooked and wellchosen dinner; also to see that any wines to be drunk are good of their kind, and the service smooth and efficient.

In England, in large towns, the time of invitation varies between 8 and 8.45 ; in the country, between 7.30 and 8 ; about 10 minutes' grace being allowed for the guests to collect in the drawing room. Men on
arrival leave their coats and hats in the hall or in a cloak-room ; women are taken by a maid to a bedroom to remove their wraps. The host and hostess receive the gueats in the drawing room, where they are announced by a servant. Cocktails are usually offered.

At a ceromonious party all the arrangements of guests at the dinner table, and the order of preoedence into the dining room, are carefully worked out beforehand according to rank and importance. When dinner is announced the host offers his right arm to the most important woman present and takes her into the dining room. The hostess pairs off the other guests in the order of their social precedence, with the erception of the most important man present, who goes in last with her. The host places the woman he takes in on his right at the bottom of the table, the woman of second social importance being on his left. He stands until the guests are seated. The hostess sits at the top of table, with the man who has taken her in on her left.
At large parties it is quite usual to put a card with the name of a guest in each place, but where this is not done the host would tell each couple as they entered the dining room where they should sit. The necessary carving of joint, game, or poultry is done bv a servant, unless the host prefers to do it, other dishes being handed round, from which the guests help themselves. The guests on either side of the host are served first, and then straight along, or round, the table to each guest in turn, finishing with the host.

If champagne is to be drunk, it is first offered after the fish, the same rule applying to claret or light white wines, and any of these would be drunk until the savoury. At dessert it is oustomary to place decanters containing port, sherry and claret in front of the host. If a cloth is used, it is generally removed for dessert, and in any case peppers, salts, eto., pieces of bread, crumbs and glasses are cleared away, and fresh wineglasses are placed with the dessert plates and finger-bowls. After dessert is on the table, the servants withdraw.
At the end of dinner the hostess bows to the most important woman guest and rises. This is the signal for the women to leave the dining room, the hostess going out last. Coffee is served with liqueurs and cigarettes in the drawing room and dining room. At less formal parties coffee may be served before the women leave the dining room; otherwise the men join them in the drawing room in about a quarter of an hour. In town houses, when the regular staff is not large it is sometimes supplemented by engaging skilled assist-
ance. There are able women who specialize in cooking for dinner parties at a moderate fee. and private waiters can be obtained.

To give a successful party the hostess must not be worried over the dinner while it is in progress. It is better to think out a small menu of well-chosen dishes, comprising a soup, fish course, entrée, game or poultry, cold sweets and savoury, within the scope of her resources, than to attempt a banquet, which may be spoilt.
Dlnner Service. A well laid table is essential to entertaining and the charm of thia is enhanced by a good dinner service. These are usually made for twelve or six persons, and can be had at moderate prices in earthenware or semi-porcelain. The regulation servico for 12 persons starts with three sets of plates-meat. pudding, and choese, two or three dishes, two vegetable dishes with covers, and either a sauce-boat or sauce tureen with cover and stand. To this may be added 12 fish plates, soup plates, and a tureen with dish and cover. In small households and when entertaining the last item is often dispensed with, soup being served directly from the kitchen into plates, speoial cups or sets of bowls.
As with a breakfast service, the stock pattern may be reoommended, with the sug. gestion, where economy of space has to be considered, of choosing the same pattern for breakfast and dinner service. In any case thought must be given to colouring and style to ensure harmony with the room or any coloured glass that may be intended for use with the service.
For better services, modern Wedgwood and Coalport china are in perfeot taste and are decorated with many of the old designs.

DIPETEISRIA. The bacillus known as the Klebs-Loeffler is the germ of diphtheria, and the most striking local symptom of the disease is the formation of a greyish-white or yellow membrane on mucous surfaces, most frequently at the back of the throat and tonsils. The disease is highly contagious Germs may be found in the throats of apparently healthy people, and in some the microbe is not virulent, but in others it is, and they are diphtheria carriers.
The disease may begin with chilliness and other signs of fever, the tempersture being raised 2 or 3 degrees. Next day the throat is sore. angry and red, and some hours later there is a grey or yellowish patch on the tonsils or the back of the throat. Frequently there bs no complaint of sore throat, and diphtheria may exist for several days without its prosence being suspected. Parents would probably save much trouble if they would make a practice of looking at the throats of young children when they are "off colour."

The earlier the anti-loxin is given the better. If given on the first day, the dimease is almosi alvoays cut short. The prospects become rapidly worse. however, the longer serum treatment is delayed.
On the first suspicion of diphtheria the patient should be isolated, preferably in a large top-Hoor room with plenty of fresh air. One person only, who is to look after the case throughout, should be allowed to visit him. Clothing should be put to soak in a disinfect. ing solution before removal from the room.

It is important throughout the disease and sometimes well into convalescence to keep the child constantly lying down in bed, as there is always a risk of heart failure occurring. After the second week paralysis of various muscles may set in. If it affects the soft palate there is a regurgitation through the nose of any fluid the child may be drinking ; if of accommodation, near objects such as print cannot be seen distinctly ; if of the limbs, there is weakness in using them.

Cleansing the throst is not neoessary after anti-toxin has been given unless there is
foetor, when the throat may be swabbed or sprayed with buracic lotion. If the child struggles against swabbing it is better to discontinue it rather than riak exhaustion. The nurse ahould wear a inask or protect the eyes with gnggles. and if any mucus is spluttered on ber fice it should be washed off with an antiseptic Intion Swabs of cotton wool should be used tor wiping the face and cleansing the nose They slinuid be burnt at once If a croupy cough develnps, a bronchitis licttle (q.v.) should be used. To relieve the pain and swelling in the throat, hot applications may be applied to the neck, or cloths wrung out in iced water The diet ahould be entirely liquid, milk und bmoths, and as much water as the patient wishes. Steel drops or tincture of perchloride of iron is a useful medicine in doses of 3 to 5 minims.

The patient is not allowed out of isolation till 3 weeks after the throat is normal in appearance, and not till 2 swab tests at 3 days' interval are negative. I'ersons who have been in contact with cares should be in quarantine for a week, and each day the throat should be inspected for evidence of the disease. "Carriers" must have their throats disin. fected. By inoculations into the skin, in the Schick teat. it can be determined whether or not a person is very liable to contract the disease. Proteotive innculations can be given to those who show little or no resistance. See Disinfection ; Notification

DIPPING FORK. A two-pronged fork that is known among manufacturing confectioners as a dipping fork is considered essential for sweet-making purposes. It is used for lifting out centres which have been dipped in chncolate or some other coating mixture and placing them aside to dry. Dipping forks can be obtained at amall cost from nny ironmonger's. See Chocolate
DIPSOMANIA. Periodical attacke of an uncontrollable craving for alcohol, coming on at intervals of a few weeks to a year, and due to hereditary influences, are the symptoms of dipsomania. Between the attacks the victim has no desirc for alcohol and may even dislike it. An alteration may be noticed in the patient just before he is overwhelmerldifferences in his behaviour, sleeplessness, and loss of appetite After having taken a certain amount a distaste miay arise, ind the drinking stops, or retching and vomiting may come on and determine the attack, or he may drink himself into delirium tiemens.

Aprmorphine, by producing nausea or sickness, may be successful in preventing or cutting short the attack. Capsicum and cinchona have been suggested as a useful substitute for alcohol in relieving the craving, as in the following mixture: Tincture of capsicum, $1 \frac{1}{2}$ drams : fluid extract of anchona, 2 drams; syrup of ginger $\frac{1}{2} \mathrm{oz}$; chloroform water to 6 oz . Take a tablespoonful, when necessary, in a wineglassful of water. When employed by experts, hypnotism has been most successful in some cases in combating the craving and preventing attacks. See Delirium 'Tremens.

DIRECT CURRENT. This is an electrio current which fows round a circuit in one direction, as distinct from alternating current (q.v.), which is constantly changing its direction. See Electricity.

DIRECTOIRE : The Style. This style of furniture originated in France at the time of the Directory (1795-99). It was based on a study of Greek ideas, and its artista used in the main the constructional lines of Louis XVI furniture. The ornaments, however, were discarded and griffons, caryatides, honeysuckles and other classical figures were sub. stituted. After Napoleon's return from Egypt the sphinx and other Egyptian decorations were introduced. During the period marquetry
was no longer in demand but chased bronze mounts in ormolu weno the principal mode of decoration Carving was mainly used in gilded imitation of ormolu work. Mouldings were comparatively little in favour The Directhire was succeeded by the Empire style See Empire Style.

DISBUDDING. This means the removal of surplus shoots or Hower buds so that those left on the plant shall have full room for de. velopment. Dishud. ding is an important detail in to e cultivation of peach and nectarine trees and vines, for miany more shoots grow than are needed "Taking" the buds of ohrysan themums grown to provide large blooms meane disbudding or removing the small shoots which appear beneath the flower buds ín August Disbudding is practised on carnations, roses and other Howers grown for exhibition; nany

Disbudding. Diagrams indicating where this operation is carried ou: on typica nlants. 1. Rose. 2. Danlia. 3. Carnation. 4. Tomato. 5. Chrganthemum $B_{y}$ apecial ariangement with amateur Gardening of the flower buds
are taken off in order to ensure that those left shall furnish large blossoms.

DISH : In Various Wares. Dishes with covers for entrées are made in silver and Sheftield plate. Plain or cut-glass dishes are used for serving dessert. trifles. jellies, etc while earthenware and china dishes are included in dinner services or may be purchased separately in many atock patterns and in plain kitchen ware. Fireproof dishes are to be had in glass, china and earthenware with covers to match.

Dish Cover. The heavy silver or plated covery of the Victorian ern are seldom seen now on account of the cleaning involved Plain electro-plated covers arc used for joints, fish or poultry dishes when necessary.

The well-gquipped kitchen has a supply of wire-mesh dish covers. These should be used to cover all kinds of fresh food, cooked remains of dishes, and anything which might be dis. turbed by Hies, bectles, mice, or other vermin. After being wushed in warm, soapy water they ahould be shaken and dried. and then placed over the rack above the range to dry thoroughly. See Entrée; Fireproof Ware: Washing-up.

DISH : In Photography. Dishes for photographie work must be kept sorupulously (i.e. chemically) clean. If a trace of fixing solution is left behind in a dish which is afterwards used for developing, mysterious stains will appear on the negatives or prints being developed. The best plan is to kecp each dish for one purpose only.

Dishes should be thoroughly washed out immediately after use, and not allowed to stand all night with the stale developing solution in them. After washing they should be rinsed out with a strong solution of spirits of salt (hydrochloric acid). This need not be thrown away, but can be used repeatedly. Earthenware or china dishes are easier to keep
clean than enamelled iron dishes, which are liable to chip ; but the latter aro lese expensive In either case it is well to see that they have llat bottoms. Curved dishes repuire more solution, and plates and paper do not lie well in them. See Developing.
DISINFECTANT. Disinfectants are agents used for destroying the germy of disease and so preventing the occurrence and spread of illness. Thesc germs may be present in the air in furniture, in clothing. and a variety of means may have to be employed to secure disinfection. Sunlight and fresh air kill most germs, while plenty of soap and water is one of the cheapest and most efficient methods to prevent their growth. Polluted water may be made safe for drinking if bailed for 10 min Infected articles of no value should be burnt.
Chemical disinfectants include carbolic acid, corrusive sublimate (perchloride of mercury! biniodide of mercury, lysol and other substances derived from coal tar, permanganate of potash, etc. Formalin is a liquid with a strong. irritating odour. It is usually used in $n$ strength of one part to 20 parts of water. Lime is a good disinfectant, employed when diseased animals are buried. a thick layer of the lime being made to surround the carcass
Linen may be disinfected in many ways Exposure to steam for a lengthened period, repeated boiling, or boiling in soap and water and then exposing the linen to tho sunshine for several days, are some effective methods. A good means of disinfecting is to soak the linen for an hour in a solution of carbolio acid, using one pint of prepared carbolio to 20 parto of water. See Carbolic Acid: Formalin.

## DISINFECTION: Of the House. After

 an infectious illness it is necessary to have a house or a room disinfected. The problem is much simplified if the room has been previously prepared for the reception of such a patient. The carpet will have been replaced by one ortwo light ruga, heavy hangings by washable curtains. Unnecessary furniture and all books and pictures will have been removed. The only books allowed should be such as can afterwarda be burnt
In the sick ronm sputum and nasal diacharges are beat collected in paper and burnt in the fire. Infective faeces and urine should be received in a bed pan containing anme carbolic or a coal tar disinfectant. Enough solution ahould be added to cover, and the mass broken up and allowed to stand for two hours before being put into the w.c. or buried. Lime or bleaching powder may alao be used. Before and after attending to a case of illncss. the attendant should wash her hands and then soak them for half a minute in a coal tar disinfectant solution.
To disinfect a room all articles of little value should be burned. Metallic substances should be removed from the mom and washed over with a disinfectant. Furniture ahould be drawn away from the walls, cupboarda and ilrawera opened. If possible the wallpaper should be stripped or rubbed down with breadcrumbs. The ronm is then sealed by placing gummed paper over the window-frame and over the fireplace, after blocking the chimney with paper.
Sulphur is easiest to use as a fumigant, and for every 1,000 cubic ft . of space 4 l . of roll sulphur should be used, or it can be obtained in the form of sulphur candles. The walls and floor should be well sprinkled with water, as sulphur vapour is only active in the presence of moisture. The sulphur is placed on a shovel, preferably at some height above the Hoor, moistened with methylated spirit and ignited. The door is then closed and the margina of the door and the keyhole sealed with gummed paper. The room is left for 24 hours, when it is opened and well ventilated till the sulphur smell has disappeared, and then thoroughly scrubbed down.
The fumes of ammatic vinegar, obtained by pouring a few drops on a heated ahnvel, form a grod disinfectant in fever cases, as also dnea chloride of lime, the latter being aprinkled freely over the Hloor.
If the local authority undertakes disinfection, the sanitary inspector assumes responsibility for the treatment of the room. He will also arrange for the treatment of the inferted bedding and clothing. He may destroy infected articles and compensate the owner. There are statutory penalties for expnaing a perann suffering from a dangerous infectious disease in any public place or conveyance, for letting an infected hnuse, and for giving. selling, transmitting, lending, or exposing infected articlea. Bonks may not be taken frum a free library for use by an infected person, nor must a bonk used by an infected perain le returned to a library. Notice must be given to the sanitary authority, who will disinfect or deatrny the book. See Formalin : Fumigation, etc.
DISLOCATION. Displacement of one or more bones at a joint is the general meaning of dislocation. The ligaments which hold the bones in position are tom: the synnvial membrane or lining of the joint and the blood veasela and nerves may alan be injured.
Where great force has been applied the end of a bone may pmotrude and form a compound dislocation. Comparison with the corresponding joint on the other side of the body will show either a lump or a hollow which is abnormal. The whole joint will also awell up. Firat aid consista in sending for the doctor and putting the parts at rest by alings, cushions, and, if necessary, splints, and cold applications to relieve pain. If shock is present, warmth ahould be applied by hotwater bottles and blankets. No attempt ahould be made to reduce the dislocation. that is, to put back the bones into their normal positions.

This must be left to the doctor to perform, as unskilled efforts may aggravate the injury. Dislacation of the ankle usually occurs in combination with fracture of one of the long bones of the leg In dislocation of the elbow, the arm is fixed at an sigle. In the commonest type there is an sbnormal bony prominence at the back of the elbow. The limb should be reated in a greater arm sling. When a thumb is dislocated the arm has to be rested on a greater arm sling In dislocation of the hip, the leg is usually bent at the hip and knee, fixed at the hip, and the limh twisted so that the toes point outward. In dialncation of the jaw the mouth is open and cannot be closed This may be duc tn external violence or to opening the mouth widely as in yawning. When the diaplacement has been corrected, the patient must not open the mouth widely or there may be a recurrence.

Dislocation of the shoulder is much the commonest of all dislocations, and is usually the reault of a fall or the sudden twisting of the arm. Because there is no real cup for the joint. and on account of the wide range of movementa at the shoulder. the head of the bone may be dislocated into a number of different positions. The limb should be rested by a lesser arm sling. After one dislocation of the shoulder, the accident is liable to occur again. the patient should therefore learn the combination of movementa most likely to cause dislocation, so that he can beat avoid them. See Ankle : Bandage: Collarbone: First Aid : Shoulder.

DISSEMINATED SCLEROSIS. Disseminated or insular sclerosis is commonest in young people and has often followed acute infectious disorders. It is a chronic disease in which nervous tissue in the brain and spinal cord becomes gradually replaced by connective tissue.

Stiffiness of the legs, with perhaps slight pain and loss of power, is the first aymptom. Then the patient may notice that whenever he tries to use his fingers for any particular purpose, such as lifting a aponn or glas of water to his mouth, his hand trembles more or less violently. Any action that requires accuracy of muscle control, such as writing. becomes difficult or impossihle. As the disease advances, this condition of jerkiness, known as intention tremor, may affect the head and legs as well.

Other symptoms are staccato speech. oscillation of the eyeballs, known as nystag. mus, impairment of vision and loss of feeling, perhaps of one side of the body, defective memory and emotional excitement. There is a tendency to sudden improvement in the symptoms, rousing false hopes of recovery.

Care should be taken to protect the patient from chill and exposure, and from either mental or physical fatigue. Full doses of arsenic are frequently given. In the later stages of the disease a careful watch must be kept for the appearance of bed sures.

DISTEMPER : How to Apply. A sanitary water paint like distemper has advantages over wallpaper, as it can be perindically washed and the cost is much less. Before distempering the walls of a room they must be froe from nail holes and similar blemishes. If the ronm to be redecorated has proviously boen papered, the walls must be stripped, and any picture nails removed.

Having done this, mix some plaster of Paris with cold water to the consistency of thick cream, and with it stop all the nail holes, cracks, etc., in the surface of the plaster.

The distemper may he purchased lonse from any oil and colourman, but it is more satisfactory to purchase a well-advertised brand of washable distemper. Careful mixing is required to ensure an even texture. Three-parta fill an old hucket with cold water, and add the powder a little at a time: stir well with a stick. It is important not to sdd all the package at once. or to put the distemper in first and add the water.
The liquid should be of the consistency of whitewash when ready lor use, and the first coast should be applied evenly with a distemper brush. Make the strukes horizoncally and work the distemper well into the wall. as when painting wond. The distemper should be stirred well during use.
 $\begin{array}{ll}\text { Distemper. } \text {. How to take a full } & \text { during use. } \\ \text { brush or diatemper trom the pall. } & \text { If the ronm } \\ \text { 2. Corret was to apply distemper } & \text { is furnished } \\ \text { is by worting at arm's lengto } & \text { witha picture }\end{array}$
 contrasting colour for the frieze. It is unwise to attempt a frieze unless a picture rail is fitted, as a ragged dividing line is almost sure to result. See Colour: Cottage: House: Paint: Paperhanging: Wallpaper, etc.
DISTEMPER : In Dogs. The deadliest disease from which dogs suffer is distemper. If a young dog shows signs of ailing and is indifferent to food, he should be watched A husky cough follows a rise of temperature, and usually, but not always, there is a diacharge from the nose.

To treat a dog auffering from this disease, put the animal in a moderately warm place, well ventilated, but free from draughta, and coat him in Hannel; take an old blanket a bout the right size, and make two holes 6 or 9 in . from one end, through which the front legs are placed. Sew it up along the back, while it is all the better if the chest and sides aro further protected with ganıgee wool. Diet with nourishing slope, no solids.

If food is refused, he must have it poured down. Put the Huid in a wide-mouthed bottle. Hold the lips on one side, and on the other insert the bottle, drawing un the lips to prevent spilling. Several times daily clesnse the nostrils. and wash the gums and inside the mouth with a solution of permanganate of potash. Cleanse the eyes with warm boracio lotion. On no account get on to solid food or perinit exercise until temperature has been normal for nearly $n$ week If the case becomes serious a vet. should be called in. See Dog.

DISTLLLED WATER. Distilled water is water which has been converted into steam by bniling and then cooled and condensed into water again. It is therefore pure water, having been separated from all the solid matters, such as chalk, which ordinary water usually contains.

This water is used for making up hair washes. It should be employed for dissolving shampoo powders, as ordinary water tends to destroy the efficacy of the powder. In making up boracic lotion for inflamed eyes distilled water should always be employed. It is also used for the accumulator of a motor car. (See Accumulator.)

In photographic work the use of distilled water is highly desirable, and in the casc of
some developers it is obligatory. The purest drinking water contains traces of salts which by combining with photographic chemicals may form insoluble deposits that cause damage to negatives.

Preparing the Water. A simple means of making small quantities of distilled water, such as are required for developers and for other purposes, is provided by the kettle. The spout is inserted in a thistle funnel, obtained from a chemist or dealer in scientific apparatus, which is bent at right angles in the flame of a Bunsen or mẹthylated spirit burner. It passes through a large tin, which has a hole cut in the bottom fitted with a cork; through this a hole, just large enough to allow the tube of the thistle funnel to be pushed through, is bored with a red-hot nail. This tin is liept filled with cold water.

A bottle, or other thoroughly clean recep tacle, placed beneath the tin receives the water as it is condensed from the steam rising from the spout inserted in the mouth of the thistle funnel. Only glass tubing should be used, since impurities in rubber and metal tubing will be carried over with the steam. Sce Developing.
DISTORTION. This term when applied to a wireless receiver indicates that the received signals are not an exact counterpart of those sent out by the broadcast transmitter. Distortion may be cansed by the use of too much reaction, by an unstable high frequency amplifier or low frequency magnifier, overloading of the detector or of a low frequency valve, incorrect high tension or grid bias voltages, a run down accumulator or high tension battery, a faulty component (e.g. a grid leak), loss of emission of on of the valves, an oscillating nearby receiver, ctc.

Overloading of the output valve is a cominon trouble, and for satisfactory loud-speaker reception the high tension voltage applied to this valve should be not less than $1 \because 0$ volts. If two stager of low frequency magnification are employed, it is adrisable to use a low impedance valve of the super-power type in the last stage, and to adjust the grid bias voltago with care. Instability in the high frequency amplifier may be caused by inadequate screening or poor design; and in a low frequency magnifier by insufficient de-coupling between the valves and the high tension supply. See Amplifier; Eliminator; Grid Battery ; High Frequency; High Tension; Impedance; Low Frequenoy; Oscillation; Reaction; Valve.

DISTRAINT : The Law Of. The law regarding distraint has been modified by the Rent Restriction Acts, passed during and since the Great War. Under thein no distress may be issued for the rent of any houses to which the Acts apply without the leave of the county court. Such houses are those of which the standard rent or rateable value clocs not exceed $£ 105$ in the metropolitan police district, $£ 90$ in Scotland, and $£ 78$ clsewhere

Apart from these temporary exceptions the law allows the landlord whose rent is overdue to enter the house by himself or by a certified bailiff betwcen sunrise and sunset, seize the goods found there, with certain exceptions, and ultimately sell them to pay the rent and the expenses of the distraint. He may not break open the outer doors or windows, but he may open still more a door or window already partly open, or break open on inner door. Rent is overdue the day after it ought to be paid. All goods and chattels on the premises may be seized in distress, except the following

## Loose money

Things in the custody, by way of his trade, of a teuant who carrles on a public trade-e.g. olothes gent to a tailor to be repaired, material sent to a
dressmaker to be made ur, and the like.

Aulmals or things in actual use at the time-c.g. a sewing-nachiue which is actually being used when hie ballilf enters

Bedding (including bedsteads), and wearing apparel of the tenant aud his family, and the tenant's tools of his (or his wife's) trade to the value of $£ 5$.
Fixtures which cannot be taken aivay without to their former state. o their iormer state.
of ener angh Peris goods in satisfy the claim
Persiable goods whe could in the
This condition prevails also to-day when the landlord, having obtained the leave of the court, proceeds to distraint.

Legal Position of Lodgers. If a lodger's goods are scized, he may get them back by giving notice in writing to the landlord or bailiff. He must send a list of what he claims as his, and state that the tenant has no interest in them. Then, if the landlord refuses to return them, the lodger may at once proceed against himi in the police-court, for which purpose it is better to emp!oy a solicitor. But tho lodger must also state in. his notice what his rent is, and if he owes anything; and the landlord can then insist on the lodger paying the future rent and arrears to him. Similar protection is accorded to an under-tenant, provided he is one who pays his rent quarterly, or not more than quarterly (e.g. monthly, weekly). There is no protection for a sub. tenant (not a lodger) who pays, say, halfyearly.

If goods are seized which do not belong to the tenant, or a lodger or sub-tenant, the owner may serve a written notice on the landlord or bailiff, setting forth that the tenant has no right of property or benelicial interest in the chattels seized; and to this declaration must be appended an inventory signed by the owner. It is a misdeneanour, punishable by fine or imprisonment, to malic a false and fraudulent declaration or inventory. The Acts do not protect goods belonging to the tenant's husband or wife, nor under bill of sale, nor held under a hire-purchase agreement ; nor do they apply to goods belonging to the tenant's paitner, nor to goods stored in an office or warehouse where the owner, after a month's notice, refuses or neglects to take them away.
If a tenant fraudulently removes his goods so as to evade a distress, the landlord may follow the goods and distrain, and may even breals open doors or windors to get at them. But he must do this within 30 days of the fraudulent removal. Goods distrained on may be sold by the landlord after five clear days from the distraint. It is a criminal offence to take away goods which have been impounded, ie. distrained upon. See Rent.

DISTRICT MESSENGER. District messengers are boys who, for a fee, can be engaged to go on errands, also to act as guides.

The service is contined to the London area. Persons can employ them to take messages or parcels, and they are sent sometimes to hold a place in a theatre queue. The boys, who form an organized sorvice, wear a distinctive uniform of dark blue. The head office is 100 . St. Martin's Lane, London, W. 2.

DIURETIC. A substance which inereases the secretion of urine by the kidneys is termed a diuretic. Water. bland mineral watere, and milk are diuretics. Exannples of drugs which increase the flow of urine are sweet spirits of nitıe, 15 to 60 minims: mindererus spirit or liquor of acotate of anmonia, 2 to ( drams; and alcoholic beverages. There are also the acid tartrate, the citrate and other salts of potassium, digitalis, squill, turpentine. copaiba and drugs of its class, calomel, broom, etc. Diuretics are called for in the state of fever, and the following prescription would be useful Tho dose is $\frac{1}{2}$ to 1 tablespoonful every 3 hours

Solution of ammonium acetato .. 3 drams
Snirit of nitrous cthe
syrup.
Pepperinint water to make

At the same timo the patient is allowed to drink water, milk, and lemonade frcely. The best form of lemonade consists of Fresh lemon juice, 2 drams; cream of tartar, 1 drain boiling water, 1 jint. Pron. Di-yu-ret-ik.

DIVAN: How to Construct. As a piece of Surniture a divan is a long seat formed of a mattress on is raised structure or frame Sonetimes it is a built-in fixture with a padded and upholstered back part against the wall. or it may be a movable piece of furniture. From Turkey this seat was introduced into England about $18 \% 0$.

A method of making $\Omega$ divan is to use $a$ box spring mattress and mount it on feet, as in fig. 1. Fig. 2 shows the method of fixing these. The bottom canvas or covering is stripped off at the corners and a $2 \frac{1}{2}$ in block rubbed into the inside comer, the grain running vertically. It may also be screwod into place. Four feel are then turned (or they may be bought already turned, having a $\frac{3}{4} \mathrm{in}$. dowel), and a corresponding hole bored into the block, and the foot glued into this. When set the canvas is cut to fit round the foot and tacked back. It will be found advisable to polish the fect before fixing.
Making the Mattress. Our illustrations (Figs. 3 to 5) show methods of constructing a box mattress suitable for the divan. In Fig. 4 is indicated a method of raising the mattress on legs. These box spring mattresses usually finish about 10 in . to 12 in . high, and are based on a sort of tray frame. A sketch of such a frame is scen at Fig. 3, made out of 1 in material, the sides being about 4 in . high. blocked in the angles and well serewed.

A scries of stretcher rails is cut in Hush and screwed to under edge of sides-numbering

Divan. Fig. 1. Divan made from a box spring mattress mounted on feet. Pig. 2. Method of attaching feet Figs. 3-5. Diagrams showing construction of mattress frame and how it is sprong and stuned
even, including the two end pieces, and each about 31 in. wide. In some cases, instead of all sidee being of equal width, the head and foot sides are higher, say 7 in . wide, and the blooks are prolonged to form feet of required height. the sides being notohed or let into them and sorewed (Fig 4).

The aprings are placed on the rails and screwed to them by staples, and the tops of the springs are tied together with oord to counteraot lateral play. They are then covered with canvas, and above this the stuffing is packed to form the mattress, and also covered with canvas (Fig. 5). The whole surface is then covened with the outside ticking. whioh finishes at the bottom edges of the sides, the bottom of frame being neatly coverer with canvas.

It will be understuud from the above descrip. tion that the completed box-spring is compressible at the extreme corners in addition to the centre, or not, according to the style of frame which is adopted.

Divan Bed. A divan bed, as it is oalled (Fig 0) is one that serves the dual purpose of a seat by day and a bed by night. It can be made of a box ottoman (q.v.) and a mattress. The ottoman should have a stout wooden frame padded and covered with figared material, the box being used as a receptaole for the bedding. The lid of the box should consist of a spring mattress on whioh the loose inattress is placed The latter should be covered on the top with the same material as the ottoman, but underneath it should have an ordinary mattreas covering. The ottoman ahould be fitted with castors so that it oan be

moved easily. By day, with the mattress for the seat and cushions placed thereon, the pieoe will serve as a divan. See Attio: Bedroom; Bed-Sitting Room; Sofa, eto.

DIVIDERS. These are measuring instruments, with whioh the utmost precision oan be obtained from hand work. Typical dividers consist of two legs of equal length, joined together at one end, and finished with a fine point at the others.

Draughtsman's dividers are frequently fitted with a fine adjustment device, consisting of a small millod-headed screw, which, when

Dividera Use of spring dividers for cotting out woodwork turned, moves oneleg to. wards or away from the other. For marking out woodwork the ordinary black spring dividers are made from one piece of steoh, the action of the dividing legs being pro.
vided by the springincss of the metal. A long screw and a butterfly-nut provide a fine adjustinent.

Dividers are used to set out and measure a pieoe of work, acourately to determine limits and proportions of a design, and by them almost all geometrical problems can be solved. See Compasses ; Drawing.

DVEANESS or Vertigo. Any passing attaok of giddiness is probably due to disorder of the digestion or constipation, but it may be the result of any one of a large number of causes. Chronic gastritis is very likely to be accompanied by dizziness

In these cases the patient should carefully inquire into his diet, the state of his teeth, and his habits with regard to taking food. In some cases it will be found that abstaining from liquids at meals, and taking them only between
meals, is helpful. Fats and pastry should be to either husband or wife for infidelity alone. taken moderately. Old people should eat In Scotland, adultery or desertion for four years is enough on the part of either spouse. Desertion means a wilful absence for four years or more without lawful cause. It is a lawful excuse if the husband is away on business, or, being in the servioe of the orown, is ordered abroad.
If the offended spouse, with knowledge of the offence, oontinues to have marital relations with the offender, the offence is said to be oondoned; but, if a new offence is cominitted, the old offence revives. Husband and wife must not act in collusion to get a divorce ; if they do, they lose the right to one.

At the trial, if successful, the petitioning party obtains a deoree nisi, that is, a decree which does not dissolve the marriage, but the matter comes before the Court again in about six months' time, and then, unless the King's Prootor intervenes, the deoree is made absolute and the marriage is at an end. It should be noticed that until the decree absolute is pronounced the marriage vows are still in force, and must be faithfully kept, otherwise the King's Proctor may intervene.
Sometimes husband or wife petitions for a divorce who has, on an occasion, been unfaithful to the marriage vows. In such a case, if he (or she) makes a clean breast of it to the judge, his lordship may grant the divorce notwith. standing the petitioner's own guilt. In all divorce cases it is hopeless to proceed without legal assistance. Pctitions for divorce can be heard at various arsize towns in the provinces, as well as in Lundon and Edinburgh.
Persons who have less than $\mathbf{5 5 0}$ (in some cases $£ 100$ ) and whose usual income is less than £2 (in some cases £4) a week may apply for a divorce as poor persons. In this case the costs will be very small. Application should be made to the Poor Persons Department at the Royal Courts of Justice, Strand, Londun, W.C.2, or to a local registry. See Desertion; Husband ; Marriage : Separation Order.
sparingly. Hasto at meals of ten causes digestive trouble. If necessary one may take an occasional mild aperient (q.v.). Excess of tea. alcohol or tobaooo may be responsible.

In neurasthenia dizziness is a common symptom. Treatment must be directed to the causc. People getting on in years whose arteries are becoming inelastio, find that they often suffer from dizziness. It is not wise for them to get up quickly when sitting or lying down; to empty the bladder immediately on getting out of bed in the morning: to make any sudden violent movement such as jumping on an omnibus. Excitement should be avoided as far as possible, and the food should be light and nutritious.

Ear and Eye Trouble. The ear is often a source of this trouble. Collections of hardened wax, mixed as they frequently are with hairs and dust, may for a long time be the unsuspected cause of dizziness. The wax should be removed by soaking for a night with oil and gently syringing with warm water. A running ear may be accompanied by dizzincss. In Menière's disease of the ear, dizziness is a most prominent symptom.

The eye may also be the cause of the dizziness. Errors of refraction are indeed a very common cause of a slight degree of this trouble which is cured by suitable glesses. Dizziness is associated with many serious affections, such as disease of the heart, tumours of the brain, syphilitio affection of the brain, epilepsy, etc. Much worry will be saved by a timely visit to a doctor, as in the great majority of cases the cause is one which can easily be remedied.

DOESEIN. A material muoh used for gloves, doeskin is a leather which has been degrained by the removal of the upper surface. Thicker and fuller than ordinary kid, it is less heavy than buckskin, and is obtained from the skins of rarious animals. See Glove.

## Dogs: Choosing, Training and Feeding

## With Information on Other Matters of Daily Interest to Dog Owners

This entry is supplemented by articles throughout the wort on the various breeds of dog, e.g. Airedale: Collis; Retriever: Scalyham, etc., where the illustrations of the various types appear. See slso Animals; Distemper; Kennel

At the present time between 80 and 90 soaked, stale bread or hound meal, squeezing Hifferent breeds of dog are recognized by the Kennel Club. There is thus a very large selection from which to make a choioe: but a great deal depends upon individual taste, as well as the accommodation at hand. The heavy breeds comprise the St. Bernard, Newfoundland, mastiff, Great Dane and the bull mastiff, all of which aro costly to keep and require a fair amount of exercise to keep fit and well. Any one of them will cost from 88. to 108. per week to keep, no matter how care. fully fed. The mastiff, the bull mastiff and the Great Dane are smooth-costed dogs and so give leas trouble with regard to grooming than do the St. Bernard and the Newfoundland. All are equally useful as guardians of personal property, and the Newfoundland is an excellent water dog.

Following these doge in point of size, mention must be made of the Alsatian wolf dog, Irish wolf hound, deerhound, Afghan hound, bloodhound, Old English sheep dog, elkhound, groyhound and collie. All these dogs can be trained for companionship or specifically as guards. Their cost of keep ranges from öe. to 8 s . 6 d . per week. The most popular of all is the Alsatian, if we except the greyhound and the retriever.
The retrievers and spaniels are particularly useful dogs. Porhaps the most aseful all-round dogs are the terriers, which comprise the Airedale, Bedlington, Border, Cairn, Scottish, Dendie Dinmont, West Highland White, Skye, Fox (smooth and rough), Irish, Kerry Blue, Sealyham, Bull Terrier and Manchester. Here we have a group of first-class dogs. equally gond for waterside work or for watching and companionship. The terriers cost very little to keep and make excellent friends with man. Two terriers recently introduced are the Schnauzer and Lakeland. The terriers of Scotland are all short legged, big boned and broken coated, but the bull torrier and the Manchester terrier, likewise the smooth fox terrier, ane smooth oosted. Handy little dogs are the Cairn terriers, likewise the Sealyham and Welsh terriers, but perhape the most popular are the Kerry Blues, the wire-haired Fox Torrier and the Sealyhams The Dal. matian, the collie, the ohow-chow, the bull dog, the Pekingese, the Brussels griffons, the King Charles spaniel, pugs, poodles, Pomeranians, whippets, French bull dogs, Dachshunds, Keeshonds and Samoyeds, aro admired by many people, and it is purely a matter of personal choice as to which of these may be seleoted.
Feoding. Given the ordinary standard of health and not leas than a year old, a dog should be fed onoe a day, and the best time for this purpose is between one and four p.m. If it is convenient it is a good plan to exercise the animal beforehand. Dogs differ considerably in their habits of feeding. The pet should not be spoiled by feeding it on tit bits, but should be trained to eat properly cooked fleah food, which all dogs must have in order to maintain health. Supplemental foods such as dog biscuite, boiled rice, bread, etc., are useful for giving bulk to the food, but the use of oatmeal or maize meal will sooner or later lead to the production of skin trouble. Such doga as retrievers, spaniels and collies, etc., should have one pound of flesh per day, the terriers $\frac{1}{2}$ to $\frac{7}{2} \mathrm{lb}$., whilst toy dogs $\& \mathrm{lb}$. to 2 oz., with or without bread, hound meal, etc. Dry foods are better for dogs than those of a sloppy nature, more especially old dogs, but it is generally necessary to nix the meat with

Table scraps and bones commonly form part of the domestic dog's menu, but the dog's stomach should not be mado a receptacle for the kitchen refuse. One large bone per woek may, however, be allowed for a tooth brush and to assist digestion. Dangerous bones are found in chickens, hares, rabbits and fish, and these are liable to become lodged in the back part of the mouth or throat, whilst their sharp edges may easily laccrate the gullet, perhaps with fatal results. Boiled carrots are the best vegetable of all and improve tho con. dition of some dogs. Dog biscuits in their various forms usually contain dried meat and are extensively used (either dry or soaked) as a food for dogs.

Water for Dogs. Dogs that are free drinkers generally thrive better than those that take very little water. No matter whether a dog is kept in or out of doors, it must always have a plentiful supply of fresh water. In summer all dogs drink more water than in winter, so the water trough should be refilled at least twice a day and kept in the shade. Both milk and tea are very good for dogs, the former being an excellent nutrient and the latter a mild stimulant. From 1 gill to 1 pint of milk per day will increase the weight of a debilitated dog.
Exercise. Roarl traffic renders the highway very dangerous for dogs and quite a number of people exercise their dogs on the leash only. This does not take the place of freedom, but it is better than no exercise at all. Facilities for exercising vary, and the majority of dogs can bo easily exercised, whereas greyhounds and whippets require training on hard roads in order to keep their toe nails properly worn down. Dogs that are too fat must have gradually increased exercise in order to tone up heart, lungs and muscles. Never exercise a dog behind a motor car, or at such a speed as will entail suffering. Sore feet may easily be produced by prolonged exercise, especially on flinty or sandy ground.
Tralning the Dog. The sooner the training of a puppy cominences the better, whether to be trained for work with the gun, for ratting or for some other particular purpose such as minding sheep or cattle, the guardianship of person or property, etc. Every dog must be taught to be clean in its kennel and in the house, which can be done by the force of habit and suggestion obtained and obtainable by tho repetition of exercise at frequent intorvals and by feeding the animal at the same time daily. Dogs have a desire to urinate frequently, and when two or more are kept together one or the other will suggest this act and become a nuisance, eapecially if living in the house. It is, therefore, very much better to keep them apart or in separate kennels if this can be dono. Further, allow very little liquid after 4 p.m. Puppies are, of course, nearly always urinating, so that they require to be lifted and taken into the open four or five times a day.

Every dog must be trained to follow at heel, as this constitutes the basis of obedience, and training to follow in and out of traffio is the best safeguard against accidents. This schooling may begin when the puppy is two or three months old. Put a collar on him and to this fix a check cord, say three or four yards in length, 80 that you can gradually shorten the cord as each lesson proceeds; bring the puppy closer and closer to heel at the word of command, which is "Come to heel," gradually substituting the word "heel." To prevent the
puppy from chasing other dogs, cats, fowls, etc., use the word Ware (pronounced war) thus "ware cat," etc., the frequent repetition of which will prevent the puppy from breaking away and render it free from chase. Never allow a dog to roam the streets, as this leads to most objectionable habits.

Groomlng. A healthy coat means a healthy skin, and the health of the latter depends upon a healthy constitution. The appliances necessary for keeping the coat in proper order comprise a dandy brush, or one with stout bristles, a hair glove, a chamois, a comb, and a stripping comb. This appliance has very fine and short teeth: therefore it must be used with a certain amount of caro in order to avoid abrading the akin. Pass the comb through the long, soft hair and at the same time use the fingers to remove it, so that plucking and combing run together. The shoulders, around the ears, behind the elbows and the hind quarters should receive special attontion.
When a dog comes in wet and muddy it should be allowed to go into a deep bed of straw, and when thoroughly dry should be rubbed down with a wisp of straw and the mud brushed off with a dandy brush. If a long-coated dog is not combed daily, the coat and feathering become felted and then trouble begins. A coat that is healthy has a pleasant feel, whilst the skin is soft and pliant, and free from any redness or irritation, or causes which produce the latter, such as flcas, lice, ticks, etc. Take particular care to see that the inside of the ears are kept clean by sponging them out occasionally with equal parts of hydrogen peroxide and water.
Care of the Teeth. Never neglect to makc periodical examination of the $\log ^{\prime}$ s teeth: otherwise trouble may arise, as nothing can be worse than offensive breath from a foul mouth. Incrustations upon the teeth are common and the discoloration of the latter frequently occurs during distemper, but can be minimised by cleaning the teeth with equal parts of hydrogen peroxide and watcr. Loose teeth, spongy and bleeding gums (pyorrhoea) are the precursors of digestive disturbance.
The Dog's Bath. Grooming should obviate the necessity for frequent bathing, but the bath sometimes becomes a necessity. Soap and water will cleanse the coat, but it renders the hair soft, and in course of timo destroys its texture. Under ordinary circumstances a bath at the commencement of the four seasons of the year ought to be sufficient for any dog. The proper manner to bath a dog is to wet thoroughly the back and hind quarters, under the tail, between the thighs, and on the belly (reely with warm water; then rub in the soap) with the fingers, leaving no part untouched. For adult dogs a good carbolic soap is the best. Repeat this process on the fore partthen rinse the soap out with warn water. This will kill the fleas if the work has beell properly done. A medicated bath consists of the addition of somo drugs, such as 4 oz . of Epsom salts to each gallon of water for the cure of simple skin irritation, or else 2 oz. of sulphurated potash to each gallon of hot water, but it is much better to dissolve this in a quart of boiling water and then add to bath. This last remedy is useful for destroying lice, Heas, etc., but it must be repeated at least twice weekly for threo weeks in order to render it efficient.

Administering Medicinos. Dogs, like all other animals, are liable to a variety of diseases and accidents. To give a dog medicino, either in powder, pill or liquid form, is usually, but not always, a simple enough matter to those who have had practice. The pill and the tabloid are the simplest to administer. First of all open the mouth with the left hand, take the pill between the tips of the index and second
linger of the right hand and then, with dezterity, place it on the extreme back part of the tongue, closing the mouth almost simul tancously, keeping it shut until the dog swallows. Some dogs will hold their medicine a long time ; others swallow immediately.

Powders are usually simple to give and may bo dropped on the back part of the tongue, whereas liquids require to be given slowly. To administer the latter put the fluid in a small vial and with the right hand insert the neck of the bottle into a pouch formed by the dog's cheek on the right hand side, keeping it in position by encircling the bottle neck and cheek with the fingers. Sometimes tasteless medicine can be mixed with the food, or dissolved in the drinking water, whilst a very good way to give pills and tablets is to camouflage them by sinking them into a piece of meat. Worm medicines usually require to be given on the empty stomach, or one that is partially so ; therefore adult dogs should be fasted 24 hours beforehand, but puppies need only to be kept without food from six to twelve hours. These are commonly infested with round worms, and the best remedy is santonin given in oil, say castor oil. The dose ranges from $\ddagger$ to 2 grains for puppies about one inonth old. A common medicine is areca nut in powder and the dose is 1 grain, or 2 grains for each pound weight of the dog, given in milk or mixed with butter to form a bolus.
The normal temperature of the dog may be said to be $101^{\circ} \mathrm{F}$., but slight variations up to $102^{\circ} \mathrm{F}$. are common and the temperature rises during exercise. Temperatures of $104^{\circ} \mathrm{F}$. and $105^{\circ} \mathrm{F}$. are frequent in febrile affections. The clinical thermometer is used for taking the temperature, and the right situation to ascertain the body heat of the dog is the lower end of the bowel, i.e. the rectum.

Diet In Slckness. When a dog is ill it is necessary to devotc attention to its food and feeding, in fact in severe illness everything de. pends upon attention to this matter. For instance, if a dog is troubled with vomiting. it must have small quantities of milk and soda water, keeping it entirely without water. Boiled fish, boiled tripe, malted milk, Brand's essence, Valentine's meat juice, Ovaltine, etc., should constitute the sick dog's diet and the greatest point of all is that of giving the nourishment in small quantities and often. The white of egg beaten up is excellent in stomach and bowel troubles, whilst for urinary affections barley water is best.

Diseases and Accldents. Catarrhal diseases affecting the dog are distemper, catarrb, laryngitis, bronchitis, and pneumonia. Tho commonest of these is distemper (q.v.).

Intestinal maladies coinprise worms, diarrhoea, dysentery, inflammation of the bowels or stomach and vomiting. Jaundice or the yellows is not uncommon in the dog : in fact, it has been the hound master's bane

Cutaneous affections are very common amongst dogs, more especially those which are fed on unsuitable food and lead sedentary lives. These skin complaints are known under various titles such as red mange, blotch, surfeit, eczema, etc., most of which are constitutional in their origin. In these cases professional advice is necessary.
Eye affections are fairly frequent in dogs, and comprise ophthalmia, opacity, ulceration of the cornea, and cataract. Cataract is a disease of the crystallino lens and mostly occurs in old dogs, as senile cataract. It causes partial or complete blindness. Eye troubles. like those of the ear and skin, require professional skill for their proper treatment.

Fractures and contusions are usually the result of direct violence. A fracture may be simple or compound. In the latter case there is a wound in addition to the broken bone, and this complicates matters. Very often the organs contained in the chest or belly are
contused: therefore it is necessary to take the dog to a veterinary surgeon.

Wounds. These are usually produced either through fighting or direct violence, and owners should always be careful to ascertain the extent of the injury. A wound may appear to be a slight one externally, yet considerable laceration may have occurred. First of all cut the hair off all around the wound, and soak it well with tincture of iodine, but do not wash it. The bleeding must be stopped. Wounds on the ear, especially the margin, as a rulc bleed very freely; therefore dress with iodine and fasten on a compress by means of glue or seccotine, leaving this dressing on until it drops off, unless circumstances demand other treatmont.

Poisoning. Dogs are sometimes accidentally or maliciously poisoned, and very often through rat or mouse poison, though occa. sionally by strychnine. As a rule the best plan is to give a smart emetic, for which purpose there is nothing better than ipecacuanha or antimonial wine given in doses from 1 dessertspoonful to 2 tablespoonfuls without water. The dog will usually vomit shortly afterwards.
Mother and Pupples. The normal period of gestation in the bitch is 63 days, but a fow days before or after the prescribed period for labour to occur is common. It may, however, be delayed through the death of the puppies or some other cause. If the owner has any suspicion that all is not well he should immodiately consult a vetorinary surgeon. The signs of approaching labour are restlessness, lacteal secretion, and abdominal pain. Owners should always prepare suitable accommodation for a bitch about to become a mother, and this ought to be in a quiet place. Disturb her as little as possible, but as soon as she has completed her task give her a dose of castor oil, cleanse her with soap and water, and take care to feed her generously on cooked meat and broth, boiled rice, etc. Wean the puppies when they are four weeks old, and as soon as weaned feed four times per day on milk and farinaceous food with a little minced meat. Later on feed three times per day on more solid food.

Homes for Dogs. There are several homes to which dogs can be sent, the oldest being at Battersea, London. Anyone losing "a dog in the metropolitan area should at once inform the police, and then visit the Home, where all strays are taken except those found in certain parts of north and east London; these are sent to Willesden and East Ham. Unless they are diseased they are kept for seven days, and may then be sold or destroyed. All dogs not claimed within the seven days become the absolute property of the committee. A purchaser will have to give an undertaking that the dog is not to be used either for experimental or or stage purposes.
At Shooters' Hill, London, S.E., the Blue Cross Society have kennels for dogs that must go into quarantine. The society also take charge, for a fee, of dogs when their owners go away from home, Many veterinary surgeons also take in dogs at such times.

Clubs and Shows. The chief club for dogs is the Kennel Club at 81, Piccadilly, London. W. Another is the Tailwaggers' Club in Temple Chambers, London, E.C., and, in addition, there are a number of others, some being specifically devoted to the interests of a particular breed.

The breeding of dogs is encouraged by numerous shows. Some of these are general, while others are devoted to a single breed. The chief show is Cruft's Dog Show, which is held in the Agricultural Hall, Islington, every February. It was started in 1886 for terriers only, and has now nearly 10,000 entries, these including every recognized breed of dog.

Licences for Dogs. Throughout Great Britain every person who keeps a dog over six months old must take out a licence, obtainable at any post office. This is not necessary in the case of farmers, who may keep up to two dogs to assist them on their farms, for the purpose of tending sheep or cattlc. A shecp farmer may obtain exemption for more than two dogs. Exemption must be obtained by inaking a declaration, the form for which may be obtained from the local post office. Dogs used by the blind are exempt ; so are hounds under 12 months if they belong to a master of hounds. The cost of the licence is $7 / 6$ in Great Britain and 5/. in Northern Ireland.

If any person is found in custody or charge of a dog, or the animal is found in his houso or premises, he will be deemed to be the person who keeps the dog, unless the contrary in provod. The penalty may be as high as $£ 5$ : and any excise officer or police constable is entitled to ask him to produce his licence, and he may be fined up to $£ 5$ if he does not comply with this demand within a reasonable time.
The Law About Dogs. For some purposes a dog is not property, i.e. it cannot be stolen at coinmon law, but in 1861 it was made an offence punishable by six months' imprison. ment to steal a dog.
The Ministry of Agriculture and Fisheries may make orders providing for the regulating and muzzling of dogs and keeping thein under control in any particular district, and for preacribing and regulating the seizure, detention and dispossil (including slaughter) of stray dogs and dogs not muzzled or under proper control. A local authority may, if satisfied that there is a mad dog, or one suspected of being mad, in its area, make an order placing such restrictions as they think expedient on all doge which are not under the control of any person during the period of the order. Such an order must be published prominontly. Anyone who thereafter contravenes it is lisble to a fine of 20 s . The owner of a dog alleged to be dangerous may be summoned before a magistrate's court and ordered either to keep it under proper control or to have it destroyed. Any person failing to obey such an order is liablo to a fino not exceeding 20s. a day.

Stray dogs must not be kept by the persons finding them, but must be either returned to the owner or taken to the nearest police station. If the finder wishes to keep the dog ho can obtain a certificate stating full particulars of the dog. In this case he must seep the dog in his possession for at least one month. Police officers have the right to seize dogs which appear to be stray dogs, and detain them until the owners claim them and pay the expenses. Should any stray dog so seized be wearing a collar giving the address of its owner, or should the police know who is the owner of the dog, due notice must be given to the owner in writing saying that the dog will be sold or destroyed if not claimed within seven clear days. Imported dogs may, by order made by the Ministry of Agriculture, be ordered to be detained in quarantine for a particular time. Orders of this description are commonly made when there has been an outbreak of rabies.
It is the duty of anyone possessing a dog which he suspects of being afflicted with rabies to give notice to a constable of the police area in which he resides. The constable must at once telegraph the information to the Ninistry of Agriculture and also pass the information on to an inspector of the local suthority. This inspector must promptly go to see the dog and take such steps as may be necessary in the matter, even to the destruction of the animal. Every dog which is suspected of having rabies, or of having been bitten by an animal with that disease, may be slaughtered. When there is an
outbreals of foot and mouth diseasc an order prohibiting the removal of animals may include dogs. It is illegal to use dogs as draught animals.
Damage done by dogs is the subject of a rather curious order. At common liaw the owner of a dog was not liable if it bit or worried any person or animals unless he knew that it was a vicious animal.
Later the owner wins made linble for any damago done to cattle or sheep, without proof of knowledge, and in 1928 the principle was further extended. In Grent Britain the owner of a dog is now liable for any injury done by it to poultry, just as he is for injury done to cattle, horses and shcep.
DOG: In Woodwork. Employed for temporarily holding two picces of woodwork together, a dog consists of a bar of steel bent over and pointed at each end. The ands are driven into the wood. The dog is placed so that one end is fixed into the standing part and the other end into the other pioce, so far as possible in a diagonal manner.

Many otherwise difficult jobs can be put together with dogs, such as the erection of a framed building; the first section is erected, and the next held in place with the dogs while the bolts are adjusted, the dogs being then removed.
Flooring dogs, employed when laying a flooring of boards, have two prongs formed on the end of a bar, which is tapped to take a screwed rod having a handle at one end and a pad piece at the other. The prongs grip the floor joists, and the screw is used to tighten the boards in the manner shown in the diagram, one dog at each end of the board. This ensures a good teght joint, and is of advantage when the timber is not perfectly seasoned.

Dog. Flooring dog, showing how it is used to close up floorboards

DOG CART. This is a high, open, twowheeled vehicle drawn by one horse. It has two seats, placed back to back and each holding two persons. The rear seat usually folds up, and the back footboard can be fixed up so as to enclose the body of the vehicle. This type of carriage is very suitable for persons who wish to got about the roads quickly. See Carriage: Driving.
DOG FISE. Beiunging to the species of smaller sharks found off the British Isles, the dog.fish is so named from its habit of pursuing in packs the smaller fish on which it feeds. It is dreaded by fishermen, the value of whose ceatch is frequently seriously diminished owing to the dog fish biting at the fish hanging on the line and attacling and damaging the nets.
DOG'S TOOTH VIOLET (Erythronium). These are beautiful littlo spring-flowering bulbs suitable for planting in the rock garden. They thrive best in peaty or leafy soii in slight shade. The popular name is derived from the shape of the bulb which bears some resemblance to a dog's tooth. The flowers of the common kind (dens-canis). are of various colours, rose, purplish-pink, etc. ; they are on stems

Dog's rootn Violet. Clump of Howering plants of the European species, dens-canis
6 inches or so high. The American Dog's Tooth viclets, which need a sunnier place, arc finer and more varied in colour. Some of the best are Hendersoni, pale purple; revolutum, purplish pink, and Hartwegii, ycllow. The bulbs ought to be planted in September or October about 2 inches deep.

DOGWOOD (Cornus). These are hardy shrubs or smal! trees which are valued for their flowers, omamential leaves or coloured bark. The commonest of the tlowering kinds is the cornel or Cornelian cherry (cornus mas) which grows wild in Britain : it makes a big
bush and bears a profusion of small yellow flowers in February-March Cornus Nuttallii, which bears large white flower-like bracts and autumn-tinted leaves, is very beautiful, but, being loss hardy than some others, it needs a sheltered position. Florida, mac. rophylla and liousa are others which produce attractive, pale, flower-like bracts. They need a sumny sheltered spot.

Of the dogwoods, grown for the sake of their coloured leaves, the two finest are Cornus alba Spaethii with green and yellow, and alba variegata with green and white leaves Cornus alba and stolonifera have red stems, those of flamiramea are yellow. These. which are bcautiful in winter, should be hard pruned amnually in March for the bark of the now shoots is more brightly coloured than that of the old stems. ['ropagation is by layers in summer or by cuttings inserted out of doors in autumn.

DOILY. Doilies may be round or square, and are made for dessert use of real lace, Irish crochet, hand painted gauze, oriental embroidery on muslin or silk. Lace paper doilies can be bought in varying sizes in silver and gold paper as well as in white. Their use should not be overdone. For cake plates they are not necessary, but they are a good finishing touch for serving small savourics, sandwiches and pastries. See Luncheon Set.

## Dolls and Their Homes

## With Details for Making these Fascinating Playthings

This arricle describes how to make a simple doll, a doll's house and also its furniture. For other information of a similar kind sce Christmas; Knitted Toys: also Toys and Toymaking
While freakish dolls. sophisticated dolls in stuffed doll is available, is to unpick the fancy dress and purposeful dolls, whose wired doll, remove the stuffing, iron the case to crinolines conceal a telophone or a bottle, are a smooth out creases and take the pattern matter of passing fashion for the grown up, the real toy doll retains a permanent position as a nursery favourite. It inay be of rubber or wood, or soft and cuddly of the knitted wool or plush-covered variety ; it may be made completely of wax, china or composition or have its face, arms and legs of one of these fabrics and the rest of its body of linen stuffed with horsehair or other material ; it may possess an automatic equipment for walking and speaking, a wig of real hair and almost deceptive eychrows, eyelashes and teeth, or it may be merely a sixpenny doll with no merit but the one common to any of the others, its capability of becoming the intimate friend of its possessor.

When grown beyond the stage of her lirst cuddly toys, a little girl is normally attracted by a doll dressed more or less as herself ; small boys quite often like dolls dressed as soldiers, sailors, or Red Indians. It is certain that many girls who love their dolls do not want to hother about dressing or undressing them, but young children of both sexes will frequently be interested for hours playing with a doll's house and ite furniture.

Easily Made Dolls. Printed covers for rag dolls, ready to be cut out, made up and stuffed can be hought at many toy stores. Having laid such a cover flat on the table, with sharp scissors cut round the outline, leaving a narrow margin for making up. This is turned in and if the seams are neatly oversewn on the right side stuffing can be donc as the sewing proceeds. Kipok (vegetable down) is the hest filling to use and should be well worked into the cover.

Another method, which can be used when an old bought
 of the old doll. It may not be necessary to go to the trouble of unpicking it, for if the shape is simple the pattern can be obtained by measurement. 'The old stuffing, provided it is quite clean, can be used to fill the new doll. The accompanying diagrams give ideas which can be supplemented by individual taste.

Fig. 1 shows how to cut out and place pattern on material to make a doll. For one of medium size the distance from shoulder to knee should neeasure 10 in., and across hips 4 in . The leg and foot are cut in a scparate picce, also the $\operatorname{arm}(A, C$, and $B)$. For making the body-case, holland, glazed linen, or wash-leather are suitable. When the pattern is cut out place back and front together, right side inside, and stitch all round, leaving $f$ in. turnings. Lenve the neck open for stuffing.
There are many different materials besides kapok that are suitable for stufling dolls. Brown rugging wool, provided it is clean, is a
cheap and solt filling. Flock is another to the upper leg, but instead stitch on a piece material which can be used. Sawdust and bran give a good shape to the doll when filled. Before using, care must be taken that the filling is dry; this especially applies to bran. which, if p rcked damp, soon goes mouldy and

Doll Fig. 1. Stufied doll showng how to cat out the various pleeed, The method of mating a movable joint ia thown it $D$
smells unpleasant. Fine wood wool is much employed for stuffing dolls, and is suitable for big oncs that will be subjected to hard wear. This can be bought at glass and china shops.

Whatever filling is used, it must be parked in tightly. Force it well down into the legs, using a pencil. When both legs are well filled and a good shape, machine or stitch by hand a straight line across the body; this forms the hip line (Fig. 1). Continue to fill in the samc way until the trunk is firm and a good shape. Close the neck with strong stitches placed closely together.

The lower leg and foot should next be made. When filled the leg is ready to attach to knee. The following contrivance, which is extremely simple, makes the knee move as though jointed (Fig. 1, D). Do not attach the lower leg directly
of the same material, it in. deep, from whioh the body was made around the bottom of the upper log. Sew the top of the lower leg to the outer edge of this band of material. This leaves about $\frac{?}{i} \mathrm{in}$. between the two limbs, and will allow for movement sideways as well as backwards and forwards. The arms can be entirely made of material, or the lower arm, wrist, and hand can be bought made in compo sition or plaster, and glued to the upper arm. Attach both arms to the neck.

As this particular doll is intended to be for older children who would appreciate a realistic one, it is better to buy a head, obtainable at toy shope at varied prices. The heads are provided with good shoulder pieces, which must be glued over the top of trunk and arms, thus doing away with any unsightliness where the arms join the body.
Clothing for the Dolls. Clothes for dolls may be copied from national or fancy dresses, but are more often merely reproductions on a small scale of those made for girls, babies, and, to a lesser extent, boys. Their making is therefore only an adaptation of the ordinary principles of dressmaking, knitting. etc. Usually the more nearly the doll's clothes resemble those of its prospective owner the greater pleasare will it give; and for some children the larger its wardrobe, the greater amount of interesting occupation it will supply.
Socks can bo made on fine needles, just a straight strip decreasing a little towards the end; when sewn together at the back, and pulled on to the doil's leg, they will shape themselves. Shoes may be made from old gloves and fastened on with a button and loop. A vest can be knitted or crocheted. A straight piece of knitting with stitches cast off in the centre for the neck and shoulders and picked up again to complete the back is all that is necessary. A crochoted border for the neck will allow of a ribbon or string to pull it up.
Patterns of dolls' clothes, together with detailed instructions for cutting out, etc., are

Doll's Rouse. Fis. 1. Eacily conatrueted doll's hoaso. Fig. 2. Plan. Figs. s-5. End and sectional elovationn and plan of rool Figa. 8-7. Carcass of house and detalle of roof. Figs. 8-10. Opening fronts, doorway and bey window
sometimes issued with fashion periodicals, while various books and papers dealing almost exclusively with clothing for dolls and everything pertaining to the toy are obtainable.

Dolls for Christmas trees, party favours, eto. can be dressed in cripe paper. This can be bought from most toy stores in rolls of various sizes and in a wide range of coloars. A combination of different shades is often successful.

Because of its fragile nature, crêpe paper should be sewn with care and a fine needle used. This precaution applies particularly to gathers where the thread has to be drawn up very gently.
Renovations and Repairs. Thore are certain doll's hospitals in London and the provinces to which a damaged doll can be sent for repair. New wigs can be supplied quite inexpensively, new itmbs, new eyes, and new heads. The body of a large well-made doll will stand two or even three decapitations, and be worth re-heading at intervals. It is quite possible to repair a broken doll at home provided the face is not cracked and ruined. Very often the back of the head gets orushed in. The best remedy is to stuff the head with paper or cotton wool and glue over the whole aporture a fairly large wig. The jointed limbs of dolls can often be fixed in again. In the case of a hair, wool or sawdust stuffed doll, the detached limb can be sewn on again securely.
If the body is of celluloid or composition the limb can be securely tied on with strong thread or very fino elastio. The latter is knotted through one linb, threaded through a coarse darner, and then drawn through the doll's body, and the limb on the other side attached. If the outer covering of the hair or wool or sawdust stuffed body becomes torn, a neat patch sewn over the hole prevents the doll from " bleeding to death." In the case of a cracked face, the only remedy is to melt a little wax from a candle and pour it into the crack, smoothing it first before it sets to make it look as even as possible.
The Doll's House. An inexpensive, quickly made, strong and attractive doll's house is shown at Fig. 1. Oddments and three-ply board are almost wholly employed in the construction of these houses, the whole nailed together, and the walls and roof covered with doll's-house paper.

The entire front is constructed as two large doors which open over the ends and disclose the whole interior with four roomy compartments. On the ground floor is a kitchen at the left, and at the right a lounge living-room. The first floor may be used for two bedrooms; or the right-hand half may have a partition across, making space for a bathroom. In the lower lounge there is room for a neat staircase. The roof is so built that it may be lifted off; elevations and plans shown are drawn to scale. The elevations and plan at Figs, 2, 3, and 4 will give sizes and quantity of timber. Fig. 6 shows how the skeleton framework is built. There are four corner posts (A), for which lengths of about 2 ft . by in . square will be wanted. The middle upright ( $B$ ) is the same length, but 2 in . wide by $\frac{1}{2}$ in. thick, and is rebated for the partition (C), which will be 3 -ply board. The bottom (D), ends (E), and back (F) are three-ply, nailed on. The top (not shown in this sketch) is also 3-ply, the same size as the bottom.
The 3-ply floors (G) are cut at the corners to fit the posta, and fixed to narrow mould nailed to the 3 -ply sides and partition. The right-hand floor (G) should be cut back in the middle as indicated to allow for the recessed doorway part.
The front is a pair of large doors, hinged to the posts (A), and opening from bottom to top. The left-hand door, 13 in . wide, shuts on the upright (B), which is a fixture. The right-hand door is 17 in . wide, and includes the recessed
doorway portion of the house. Thus, the righthand opening front is not flat, but has a break (Fig. 8). The fronts of the house may be of $\frac{1}{8}$ in. wood, strengthened top and bottom with battens.
Screwed to the underside of each opening front is a $\frac{1}{2}$ in. platform which carries the bay windows. This plntform is 30 in . long by 3 in . wide ; but, as it opens out with the doors, it must be cut across as at $X$ on plan (Fig. 2) At Fig. 8 are given outline persjective sketches of the left and right opening fronts as they will appear in carcass. The bay windows and doorway are not show $n$ on this sketch. The narruw break piece $(\mathrm{H})$ should be of in. wood, nailed to the main parts of the little building.

Each door should be hinged with three good butts, and the platforms should be raised about $\frac{1}{8}$ in. from the basc. The base of the house may be framed up of $\frac{1}{2}$. or $\frac{3}{8}$ in. material, halved at the corners. The front stile will be 6 in. wide ; the back stile and rails may be 2 in . A stiffening cenire rail. 2 in . wide should be added.

## How in Make the Rool

A scale plan of the roof is given at Fig. 5, and at Fig. 7 a simple method of its construction. First make a frame of $\frac{1}{2}$ in. material, 32 in. by 15 in ., to overhang 1 in . at front and sides, but flush at the back, haived at the corners, with four holes bored to enter dowels fixed in the top. From Fig. 7 it will be seen that two gable pediments and a back piece (all of in. material) are nailed to the frame. Over these the 3-ply roof may be laid.

The shapes of the three inner slopes should be cut in stiff paper to secure the correct angles. The flat back portion of roof is approximately 18 in . by 6 in ., and will take a balcony rail. The front gables may be overlaid with $\frac{1}{8} \mathrm{in}$. fretwood cut to a width of $\frac{1}{2} \mathrm{in}$. The arrangement of the strips is shown at J, Fig. 7.

The doorway has two steps, $\frac{8}{8} \mathrm{in}$. or $\frac{3}{3} \mathrm{in}$., the lower one cut back close on the left-hand hinged front (Figs. 2 and 8). The door pilasters, (K, Fig. 9), of $\frac{1}{4} \mathrm{in}$. fretwood, $10_{\downarrow}^{3} \mathrm{in}$. long by in. wide, are sur mounted by a ledge sup. ported by two shaped brackets. The ledge may have an ornamental rail as shown in Fig. 1. The door may be 8 in. by 4 in . with is in. veneer mounted on to form panels. The fanlight above will be treated as a window. The arch shown above the doorway should be of $t$ in. or $\frac{1}{8}$ in.

Doll's Furniture. Fig. I. Complete set of sitchen furniture. Fig. 2-6. Diagrama ghowing how io make the various pieces

As the arch opens with the right-hand house front, it must be made rigid at the left-hand side by glucing in a smali piece of wood to secureit in the recess. If preferred, the lower step may be cut flush with the upper one, so that the left-hand door may be made to open before the right hand one. bay windows, of $\ddagger$ in. material with three-ply roofs, the plinth (M). and moulds (N) being glued on. The upper windows are nade up of $\frac{3}{16} \mathrm{in}$. fretwood glucd on in strips. Narrow moulds are planted on above a

Fig. 2

Fig. 10 shows the
 should below. All windows To secure the effect e glass being bended in veneer may be glued to the glass as at 0 , Fig 10. The construction of the little dormer window, shown at Fig. 7, calls for no comment.
Tbe chimney stack (Fig. 7) is a block of whitewood 5 in . wide, $3 \frac{1}{2} \mathrm{in}$. high and if in thick. Above is a flat piece of $f$ in. fretwood, and three sinort lengths of 1 in . dowel rod will serve as chimney pots. For the top balustrade
 Between these, on the roof floor, are glucd strips of fretwood in. Wide, whilst the rail itself may be $f$ in. beech dowel rod with little turned balls on the post tops.

A special feature should always be made of the outside and interior decoration of a doll's house, for it is this touch of reality that appeals to the child. The exposed woodwork may be

 painted a soft cream, the stand green, and the chimney pots red. The outside walls should be covered with doll's housc redbrick paper, and the roof with blue tile paper. For the inside a great variety of miniature patterns is available.
The Furniture. If the floors have been smoothly planed, the $\gamma$ can be stained, but if rough, it is better to carpet thom all over, cutting the carpets from any odd pieces. The floor of kitchen and bathroom can be covered with linoloum, and little rugs can be made of tiny pieces of carpet in contrasting colours. Long side curtains of cretonne or casement cloth surmounted by a little frill in the same material across the top of the windows look well.

Little net or muslin half curtains can be placed across the lowest sashes.
Charming little beds can be made out of notepaper boxes, chocolate boxes, etc. arranged so that the lid of the box forms the head of the bed, and trimmed with a frill of muslin to form valances and curtain Mattresses and pillows stuffed with cotton wool, and calico sheets, are added. The bed curtains in the different rooms can be tied with different coloured ribbons and the coverlets made of ribhon to match. An eiderdown can be made by stitching up about 12 in . of 5 or 6 in. wide satin ribbon to form a bag. stuffed with a layer of wadding. The bag is then sewn up, and the rows of stitching added by machine, which produce a facsimile of an eiderdown quilt.
The kitchen equipment should include a stove, pots and pans, wash-tub, mangle, irons, and all the usual outfit. Tiny brooms can he made by tying a fow wisps of fibre to a thin skewer or a few little feathers to a matchstick. A set of kitchen towels, dusters, etc., can be made, and, of course, the usual complement of cups, saucers, plates, etc., obtained. Sets made of aluminium are quite inexpensive, and minute cutlery, spoons, forks, etc., are obtainable in tin.

## Furniture Desisned sor the House

Doll's furniture may roughly be divided into two classes. There is the miniature furniture that a child can use with her dolls on the nursery floor-chairs, tables, beds, etc., made on a scale proportionable to the size of an average doll. Then there is the toy furniture used to decorate the doll's house, and it is to this latter type that the accompanying illustrated suggestions chiefly apply. Almost all the designs shown, however, have been so prepared that they can be marle to any size-in miniature form for the doll's house, or to larger scale for floor amusement. At Fig. 1 is a group of toy items for the kitchen. Constructional details are shown at Figs. 2-6

Miniature dining room and bedroom fur niture is shown in Figs. 7-13. Hints for other items may be gathered from our furniture articles on other pages of this work lior the smaller toy furniture odd scraps of iretwood

DOLLY. A dolly is employed for washing clothes in conjunction with a tub. The peg dolly consists of a vertical rod forming the handle; the lower end carries a disk on whicl are mounted a number of wooden pegs. The clothes are washed by using the dolly to propel the clothes, employing an undulating and rotary movement for this purpose.

The chump dolly has the pegs formed by shaping thom from the solid, and are
considcred stronger, as thero are no separate Almost any kind of cake, preferably white, can parts to work loose. Many of the hand and be used for making these sweet cakes See power driven domestic washing machines consist essentially of the washing tub and a dolly that is mechanically actuated, as by turning a handle or pushing a lever. See Laundry.
DOMETT. A cotton imitation flannel, unbleached or white, twill-woven and with a Heecy nap on both face and back, domett corresponds closely to tlannelette (q.v.) and serves the same purposes.

DOMICILE. A man's domicile is the place where he actually lives with the intention of making it his home. It is quite different from his nationality. The intention is very important, because many people live in a country for a very long lime without any intention of making it their home. Thus British nembers of the Indian Civil Service do not luse their English or Scottish or North-Irish domicile by any number of years' residence in India, because it is presumed that on the expiration of their service they intend to come
back to the country they back to the country they always call home.

But mere intention without the fact of
esidence will not do. Thus if 1 , who was born residence will not do. Thus if 1, who was born and have always lived in England, make up $m y$ mind to go and live in Scotland, but do not go-postponing my departure from time to time-my intention does not make me a domiciled Scot.

Until attaining 21, a person's dumicile is that of his father. The domicile of origin is retained until another is ncquined, either by the person when over 21 going to live in another country with the intention of making it his home, or, in the case of a female, by marriage with a man of another domicile.

Domicile regulates a person's matrimonial status and the disposition of his personal property, wherever situate, on his death. Thus, personal property in England of a person domiciled in Scotland must be disposed of by Scots law A will should be made accord. ing to the law of the testator's donicile, and if it be good according to that law it will be recognized by British courts.

Any person seeking divorce must apply to the courts of the country of his domicile, and if he obtains a divorce clsewhere the British courts will not recognize it, and will send him to prison for bigamy if he marries again. In England and Scotland a marriage contracted according to the law of cither country is legal ; but British girls marrying foreigners should be very careful to ascertain that the marriage will be lawful according to the law of the husband's own country. See Naturalization.
DOMINNO. A domino is a kind of loose cloak with wide sleeves and a hood, worn at masquerades by men and women who are not personating a character A small nask, generally covering the upper part of the face only, is worn with a domino. Dominoes are made in a variety of colours and in any suitable material. Taffeta, satin, Italian cloth or sateen are the materials most frequently used. See Fancy Dress.
dOMINO CABESS. Cut some Genoese pastry into small rectangles, split them lengthways, and spread the insicles with raspberry jam. Coat the little sandwiches with royal icing, and when set decorate them to resemble dominoes This may be done with the aid of a forcing fipe and a little chocolate icing.
 Dolly. Loth, peg ; and right, champ Co.. Lia. The block game, which is nore can, usually hy two persons, although wards and then let the players draw for the lead, unless, as is frequently done, the one holding double six or the highest piece in play takes it. This decided, the leader takes the number of dominoes agreed upon, and his opponent follows his example. They look at these dominoes themselves, but must keep from the view of the other player.
The leader then places a domino on the table, and the other player must fit to one of its ends one having the same number of pips as are at that end, e.g. 3 must be fitted to 3 . If the player plays double 3 or any other doublet, which is placed crosswise, he is allowed another turn, while if he cannot fit a domino he loses his turn. Conditions are the same if three or four people play.

A variant of the game is to leave a certain number of dominoes, generally 14, in the pool or centre of the table. These are drawn upon by a player who cannot fit one from his own hand. As he draws when they are face downwards, if he draws one that is unsuitable he increases his holding and thus suffers a disadvantage. The pool is not drawn upon after only two dominoes remain in it. A game is usually for 100 points, these being made by the winner of each round counting the pips that remain in his opponent's hand or hands.

Matador. Another popular domino game is called mataclor. In this, instead of fitting the dominoes with ends like to like, e.g. 4 to 4 , each player in turn must fit one to make up a total of 7. Thus, if the line of dominoes on the table have ' 2 and 4 at the ends, he can play one having 5 or one having 3 , or he can play a matador, as four of the dominoes are called. These are double blank, and threc

Domino Cakes condsting of raspberry gandwich decoratod with rojal icing and chooolate pipa
that total seven, 6.1, 5.2 and 4.3 If he cannot play he must draw from the pool, losing his turn if he cannot find one suitable. If a domino having ono end blank is played, no dominoes can be fitted to it, except one of the four matadors. When no further play is possible the winner, i.e. the player who has the fewest pips on his remaining dominoes, scores the number held by his opponent or opponents.

Other Games. Two other games are known as All Fives and All Threes. In the former two, three or four players can take part. Each takes an equal number of dominoes, provided that at least two remain untaken and that no one has more than seven. They are shuffled and distributed with the faces downwards. The object of the players is to make the two end pieces five or a multiple of five when the pips are added together. All double dominoes must be placed transversely.

All Threes is a variant of All Fives, the essential point being that three and its multiples score instead of five and its multiples. The scoring numbers are therefore three, six, nine, 12, 15, and 18, which score respectively one, two, three, four, five and six. The game is usually played for 61 points.

Another game is known as fortress. Four players take part, each having seven dominoes. The one holding double six leads and the others must play to it, as in the orlinary game, until they can go on no longer. The game owes its name to the fact that the players have the right of placing tho dominoes at right angles to those already down, as well as in line with them, thus forming them into a fortress-like plan.

DONEEY. For people of modest means or for teaching children the rudiments of horsemauship the donkey is very useful. Costing not more than a few pounds to buy, his yearly keep is equally inexpensive, especially if there is a paddock in which he can run. He is hardy, dooile, sure-footed, and seldom is ailing. He measures generally well under 12 hands.

Donkey. Useful anjmal for teaching the olements of
horsemanship to joung ohiddren
If one is bought young, treated in a kindly manner, and given a little corn and hay, he should be able to trot well, and grow up free from the stubbornness so characteristic of the race. Ladies living in the country find an animal of this description must useful for conveying luggage, etc., to and from the station. A light village cart is the most suitable and brown harness looks the best.

In choosing an animal select one of the darkcoloured sort with fine, clean legs. They are said to be preferable to the lighter. If kept out at grass all the year round they cannot be expected to do as much work, or trot as quickly, as if they are fed more like a horse. Children may began to ride a donkey is panniers as soon as they can sit up, later on coming to a saddle. When old enough they should be encouraged to ride bare-backed.

# Doors: Making New \& Improving Old Ones 

## Styles and Methods of Work Explained and Mlustrated

Among the many headings in this work that contain information on doors are Adam Style; Architecture ; Cottage; House. See also Amateur Carpentry; Architrave ; Bolt; Bracing; Burglar Alarm

After the solidly plain doors surmounted by the beautiful arch of Tudor times, Jacobean dnors were elaborately panelled, but towards the end of the 17th century panelling became simpler, doors often showing only two panels each. In the 18th century, however, there were usually six panels or more, but the mouldings retained simplicity. At the end of the century Robert Adam fully appreciated the decorative importance of benutiful doors and designed doors and architraves enriched with fine mouldings and carvings to suit the style of his buildings. Unfortunately a great many ugly doors were constructed during the 19th eentury.

While the doors of the modern house are usually designed by the architect to suit the character of the building. whether modern or influenced by Tudor, Jacobean, Queen Anne or Adam style, much may be done to improve the appearance of existing doors when reconstructing or redecorating the housc. Front doors should never look shabby. This is not likely to happen when the door is of mahogany or matured oak and only needs the ordinary care given to such woodwork and the regular cleaning of the door furniture. It does, how: ever, happen in the case of painted hall doors which have been allowed to remain dusty, dirty, splashed or blistered owing to neglect, wet weather or lack of a sun curtain

Though bright colours for doors in a town street or terrace are attractive, it is well to remember that they will not continue to be so unless paint with a very hard, glossy surface to withstand the weather is uscd. Blaok or dark blue gives a door a dignificd appearance. lut any dark colour is apt to show dust collected in the panels unless carefully kept. Green is an uxcellent front door colnur, the colder greens such as malachite or jade being good with wrought-iron door furniture for a terrace door, while the warm leaf greens form

Door. Iron door with hammered enrichments suitable for the inner hall door of a large house Courtesy of Bayliss, Jones if Bauliss, Lidd.
a pleasant contrast to a red brick house and harmonize with any surrounding trces.
The illustration in the previous column shows a good design for the inner hall door of a large house. It is of hammered iron, panelled with glass.

Improving Ugly Doors. Inside many houses badly made and badly proportioned doors have to be endured or camouflaged. Such a door may be rendered unobtrusive by painting it the same colour as the walls and placing a draught screen so that it is partially hid den, but apart from this expedient there are small improvements which can be made without much expense or trouble. Where panels are shallow, strips of nalrow picture moulding, sold by the foot. can be applied all round inside the panels. The strips are held in place bytiny pins, and may be painted before applying if the door has already been repainted. A good idea is to use a different colour for the moulding, contrasting with the door and match ing the frame, or the mouldings may be painted in gold or silver metallic paint, the pate requires owering while the panols in a pressand the metallic paint used to outline the frame. Such details necessarily depend on the decorative scheme of the particular room

An insignificant door in a room of fair height can be remedied, as shown above on the right, by the use of a plywood pediment and pilasters made of thin boards. This treatment would be particularly suitable for a room with decoration and 'urniture based on an 18th century stylc. Applied mouldings are used to border the pediment and to ornament the pilasters, pioked out with a contrasting colour

Another improvement which can be carried out is also illustrated. The door is cased in plywood and is thus made panelless and Hush. This treatment is suitable when a brilliant enamelled surface is given to the plywood and a rioh colour is used, the architrave of the door being in a paler shade which matches the skirting and cornice of the room. Coloured glass or painted china door furniture to tone make such a cloor highly decorative.

Defects and Remedies. The practical test of a good door is that it opens and shuts easily ; inferior doors tend to drop and drag, being susceptible to damp. Unsatisfactory working of a door is nearly always the result of swelling, warping or other such change in the wood. A common trouble is sticking when shut. Passing a piece of paper all along the crack between the top of the closed door and the lintel, and between the calge of the door and the jamb, working from inside the room, will reveal the region of contact by the fact that the paper cannot be passed along the crack there. The door can be kept open by a wedge inserted under the botton, while the high place is planed down. To plane the bottom the door must be taken down and then rehung.

Sticking can be cured without planing if there is a good wide crack between the door and the jamb on the hinge side when the door is shut. If the sticking region is located between the door and the jamb towards the top, or if it is betwcen the bottom of the door and the floor or carpet, the door should be taken down, the recess in the jainb which receives the top hingo should be cut deoper with a chisel, and the door replaced. If the tight place is over the top of the door, or if it is between the door and the jamb towards the bottom, the same procedure is to be followed, except that in this case it is the bottom hinge, not the top one, that is to be sunk further into the jamb).
A door that will not stay shut or that has to be forced to make it latch or that cannot le locked, can usually be curcd by moving the perforated plate which is provided on the jamb to receive the latch and bolt. If the Intch works correctly when the door is forced home in shutting it. then the plate should he moved a little outwards towards the room. If latch. ing is facilitated by lifting on he door handle, ing down on the handle makes the latch work, then the plate must be raised. In bad cases all three tests will fail, and it is necessary to resort to measurement. The door should be nearly shut so that the height at which the latch meets the plate can be marked Then on opening the door the worker will be able to sce at a glance whether the plate needs raising or lowering.

If the height proves correct, then what is required is to move the plate out towards the room, the exact amount being found by shutting the door and measuring the position of the latch by inserting a knife-hlade in the crack, this measurement being compared with the position of the holes in the plate on opening the door. The plate is moved as required by unscrewing and removing it and then custing an extension of the recess it has occupied in the jamb. The deep holes in the jamb which admit the latch and bolt will probably require extending, an operation which demands care, and the old screw holes must have plugs of wood hammered in and cut off Hush before the new screw holes are made.

The latch trouble inay be due to an entirely different cause from the above, i.e. a broken spring or excessive friction in the lock; the test is to see if the latch springs out frecly when the handle is turned and released with the door open. If this test shows that the mechanical action is at fault, the lock should be taken off the door by removing first the screw securing the handle to its square bar, then the handle, then the bar, then the screws which hold the lock in place in or on the door. and finally the lock itself.

When a door yields at the joints, take it down, drill out any dowels, and take the door to pieces. Then refit all the joints, glue and
 from the illustrations as a guide and varied to suit any particular design, provided that strength and durability are always evident.
Ledged and Braced Door. Fig. 1 is sometimes handy for a cellar door or for temporary use. The battens, of such a width that to. gether they make up the exact size required are 1 in. thick, tongued and grooved together. The tongue of the one outside batten and the groove of the other batten will both be removed.
First cut off all the battens slightly longer than the finished length, select one for the outside and mark the pusition of the ledges, which should be in seotion as in Fig. 2. Nail these on firmly at right angles and place the re. maining boards in position and cramp them together.

Door. Fig. 7. Fine oak door in Jaoobean style. Figs, 8 and 9. Derails of the mouldings, which should be in the solid upright or muntin, the thestyle. panel gruove (Fig. 6).
in and the holes filled in
All the rails are then A rim lock and cross garnet hinges are used, marked out, also the centre and a beaten iron handle is in keeping with
shoulders for which are It is necessary to allow a small clearance all marked from the stiles. round when fitting a door, excopt at the top When cutting the tenons of corner opposite the hinged side. whioh will be the top and bottom rails, found gradually to drop in time. When allow haunches at the out- ordinary butts are used, a fairly big clearance side edges to fit into the is allowed at the bottom for the carpet. If a

Having cut all mortises a plain surround it is customary to use skew and tenons, the panel groove hinges. These take the form of a spiral

properly driven through to moke a secure joint by drawboring ( $\mathrm{q} \nabla$.).

The bottoms of the side posts are mortised into the threshold or tread and two stout galvanized iron dowel pegs driven into them, leaving about 2 in projecting, their purpose is to hold the bottom of the frame socure.
to project on either side of the door post for building int.o brick work, or cut of flush if it has to be set into existing brick. work or conerete which it is not desired to dis. turb. The threshold or step is then prepared and rebated or not as required. The side posts ure mortised and tenoned into the head and sccured head and sccured
by wooden pegs ded in cement mortar and set in holes cut in the brickwork. If the frame has to be set up in new work, it is braced
by dingonal struts of rough wood about 3 in by 1 in., placed as shown in the illustration, to prevent the door frame from racking or getting out of the square.
The iron dowels are fitted to the brickwork and the frame bediled down on cement mortar, set up plumb and square and held in that position with a temporary strut to the ground, guch ts the light scaffold-pole seen in the illustration. The brickwork is thon built up to the framework

Finally, the joint between frame and brickwork is made good on the outside by a cement fillet, and by a wood or plaster lining on the inside. In cases where a new frame has to be fitted to an existing opening. the frame is set up plumb and square and secured by wooden wedges driven in hard, over the top of the door posts and at the ends of the head. The joint is then made good with a cement fillet and an inner lining as before.

It is frequently found in old buildings that the door frame has perished at the bottom, and when the expense of a new frame is not desired an excellent repair is pussible by splicing or scarfing on new feet. Remove the frame and take it to the bench if possible, but whero this is not practicable strut the posts to the ground or the floor while the joints are being cut.

Before fixing a new frame, or refixing an old one, it should be treated with wood preservative if it is to be finished with stain, or with two conts of red lead priming if with paintwork.

## DOORS: THEIR FURNISHINGS AND FITTINGS

## Choosing and Fixing Knockers, Handles, Knobs and Springs

Thls article, together whth the preceding one on Door gives the householder much useful Information oa a subject of interest to every home

Furniture for doors includes knockers, cleaning with metal polish. Such cleaningleaves letter plates, handles, knobs, finger plates marks on the surrounding point and even. and key plates. Front doors usually have tually may rub it off. When in doubt with a knocker, a letter plate and a handle or linob. regard to a handle or set for a painted door The last is generally for ornament rather than it is advisable to choose plain glass, which use on $\pi$ town house door. Sets for interior is always in good taste. Sets in raised Chinese doors are commonly made in three picces, lacquer work or in painted glass are handsome namely, a finger plate, knob and key plate, but in a suitably furnished room.
sometimes there is a second finger plate fixed Door Knockers. The appearance of a front below the key plate. It must always be borne door can be greatly enhanced by the knocker. in mind that the style of the door furniture On massive wooden doors such a design as should accord with that of the door, and choice of metal or of the material and colour used for fancy sets are points of decorative importance.

Fancy sets, suitable for the less formal type of bedroom and sitting room doors, are made in white or coloured glass. There arc also pretty sets obtainable in painted china with wreaths and bunches of old-fashioned flowers. For bedroomdoorscoloured scts in milk coniposition are suitable and aro made in numerous shades. These materials are an improvement on the brass furniture which requires

Door: examples of knockers. Beautiful specimens in bnth wrought firon and brass, from which choice can be made for doors of varying size and period. See text
suitable in wrought iron. Equally striking brass knob, fitted to the spindle by a screw would be the brass knocker in Queen Anne thread and set screw, which sometimes gets style (Fig. 2) on a panelled mahogany door slack and fails to turn the lock
or on one painted in dark colour. Another Tho remedy is to screw up the handle, or to beautiful design is the snake knocker, Fig 3, which is an excellent choice in hand wrought iron for the brightly coloured town house door. The Adam style of Fig. 4 is graceful in brass and suitable for a flat door. The door of a Georgian style house would be perfectly completed by a brass knocker like that shown in Fig. 5, while for the country cottage or bungalow. either Fig. 6 or 7 would strike a pleasing note. Painted metal door knockers are obtainable which are suitable for small front doors. They are made in many designs, from sailing ships to dogs, and Punch and Judy figures. In smaller sizes such knockers are used for bedrooms in some houses. Combination door knocker, handle, and letter plate sets are known as pustal handles. The letter flap of such combination sets is cither horizontal or vertical.

Most knockers are fixed to the door by bolts and nuts, which should be recessed by counterboring the door so that the nuts are below the surface. The holes for tho bolts should be accurately marked out on the door and drilled the suit the size of the bolt ined in conjunction witha latch, or forming an D o o P Norfolk latch (Fig. 5). Among various classes of door handles the first consists of the type in which the

Door. Designs for bandles. Figs. 3-10, showing various types of attractive and decorative patterns, including a door bandle with back plate, lever bandle, Norfolk latoh Gotbic Rate latch, drop cupboard door latch, fush bandle, and handles for cabinets

to which is attached a small lever or furn Latches and locks are dealt with in their respective articles.
The door handle in its simplest form. unconnected with lock or catch, forms a third class. It is used for cabinet work, and on doors fitted on swing hinges and not intended to be latehed Decorative handles are madn in great variety, modelled, for example, on the lines of a lion's head holding a ring in ito mouth. An example of the flush-fitting handle is the drop ring, hinged at the top and ly:ng in a recess formed in the back-plate. When required for use the ring is swung outwardy. Fig. 8 shows one of this kind Of the numerons types of cabinct door bandles the drop bandle is a popular form, and two examples are shomn in ligs. 9 and 10.

Door Knobs. The cheapest types of doar knob screw simply into the door. A hole is hored with a bradawl or gimlet, the knob screwed in as far as possible with the finger 4 and tightened by means of gas pliers, a piece of cloth being wrapped round the handlo to prevent damage by the pliers Frequently this typo of knob is longer in the screw than the thickness of the door. The method of treatment then, shown at Fig. I, consists in reinforcing the door by screwing or nailing hehind it a piece of wood into which the screw can bite.

Wooden handles are sometimes screwed to the door by a wood screw put in from the back, as in Fig. 4. Others aro made with a wooden serew that fits into the handle (Fig. 2), the screw being conted with glue belore insertion.

Metal knobs are often fitted with a screwed shank having a nut and washer with which to bolt them to the door (Fig. 5). A neat "ay to fix such a knob is to counterbore the door and let the nut and washer in Hush, as in Fig. 3.

Door Springs. The term door spring covers all kinds of resilient controls adnpted to the closing of a door. The simplest device comprises a coiled spring having a metal plate at cach end, one attached to the door, the other to the frime (Fig. 1). The spring is set at a slight angle upwards across the door: it is tensioned by turning one end of the spring with a tommy bar, the other end being fast to the plato fixed to the door frame. The number of turns given to the spring deternines the pressure that it can exert, and therefore the speed at which the door will shut without slamming.

The nethod of securing the spring varies, but a common form comprises a steel pin inserted through a hole in the fixed part of the spring plate, and engaging with a groove in the moviable end piece of the spring. Other holes are provided to take the tommy bar, which in emergency may be a stout nail Another type (Fig. 2) comprises a plate with lugs supporting a long arm having a spring in the hub. Une end of the spring is attached to the plate, the other to the long arm. The intter presses on the door. A wheel is fitted at the end of the arm, and runs on a door plate, to prevent damage to the door.

A neat device is a pair of spring hinges (Fig. 3), as there is nothing visible on the exterior of the door, and generally the hinges permit the coor to move in either direction, or are double hung. These springs are wailable

lound in some snug hole waiting for the first signs of mild weather.

Dormice require $n$ roomy cage, and preferably two should be kept together. Their food should be as natural as possible, mainly nuts, acorns and beechmast, with
sulficient water to drink Failing these, they may be given bread and milk.

Doronicum. A hardy plant whioh bears long. stemmed yellow, daisy-like thorns in spring. It is called Ieopard's Bane (q.v.).

DORY. Known also is the .Iohn Dory, this fish resembles the turbot, and is The forcgoing are examples of door springs particularly adapted to domestic requirements. Heavy doors may be fitted with one of the more claborate devices, such as those on a pneumatic system which combine a door spring and check combined. There are several excellent types available, and the requisite directions for fixing and adjustment nre sent out by the makers or factors.

Door Sprlak. Fig. 1. Common spiral spring attached to door and jaub. Fig. 2. Long arm type of door

DORKING FOWL. This fino old Englisin breed is without a rival as a table fowl, having more flesh in proportion to the size of its frame than any other, while in colour, quality and flavour it leaves nothing to be desired. It is a moderate liver, and excels as a sitter and mother. There are five varieties, viz. dark, silver grey, white, cuckon and red, the first two ranking as best. The Dorking is not adapted to confinement, but is an ideal fowl for the farmyard. See Poultry.
Dormer Window. This type is a small attio win. dow built vertically into the sloping roof of a building. See Attio.: Window.

DORMOUSE. This little animal is easily tamed and makes a good pet for children. The time to look for it is in winter, when in a somnolent state; it will generally be

Dorking Fowl. Cock of the old
English breed of table fowl

DOSAGE. The estimate of the amount of a drug or of X-rays, etc., to bo given in particular circumstances is known as dosage. In the British Phirmacopoeia and similar publications an exact amount is not usually advised, but an upper and lower limit are given, e.g. tincture of opium, 5 to 15 minims, the lower amount being what is necessary to produce any useful effcct at all, and the higher the limit of safety. These doses are meant for an arlult, i.e. a person of 21 or over.

People for whom the average dose is far too much are said to show intolerance for the drug, and a person who has discovered intolerance for particular drugs should mention the circumstance to any doctor who mav be called in to treat him.

The dose of a drug injected undor the skin is about half of the doso by tho mouth, but injected into the bowel it has to be twice as much, with one or two exceptions. If it is intended to give a single dose of a drug this will be larger than if the drug is to be given in repeated doses.

Opium is very badly borne by infants and young chiddren, and hercin lies the danger of mothers giving their babies soothing syrups containing opium. On the other hand. chitdren stand largo doses of some drugs very well, like bellailonna and calomel. A rough rule for linding the dose of medicine suitable for it young ohild is to give a fraction of the adult dose calculated by taking the ohild's age as the numera. tor and the age plus 12 as the denominator. Thus the fraction of an adult dose of 20 minims for a ohild of 8 would be $\frac{8}{8+12}$ or $\frac{2}{5}$ of 20 ,

## that is, 8 minims.

## DOUBLE CHEESE.

 This term is used for ohecse made of whole milk, or in the case of soft cheese, viz., cream cheeses, of doublecream, or of a very rich thick cream containing 50 per cent of fat. See Cheese.DOUCHE. As used medicinally a douche is a stream of water or air directed against a particular part of the body, and is used to cleanse or apply tluid medicaments. Astringent douches are employed to allay the discharge resulting from catarrhal inflammation of a mucous surface, and nntiseptic douches are valuable for destroying germs.
The simplest and safest apparatus consists of a tin douche can connected by 6 ft . of rubber tubing, with a hard rubber or glass nozzle, which is easily disinfected by boiling. A warmed solution is poured into the can, which should be held above the head to let the fluid flow out with the requisite force. A useful astringent douche is made up of alum, 40 grains ; eino sulphate, 20 grains, and water, 1 pint. For a mild antiseptic douche. lysol or permanganate of potash solution may be employed.

A douohe may also be used for washing out the nosc in chronic catarrhal conditions, and a convenient form of apparatus is the glass nasal douche. It is filled through a funnel let in at the side, and if the opening of filler is closed by putting the thumb over it, the contents will not cscape at the nozzlo at an untimely moment. When the nozzle is properly applied to the nostril the other end of the douche is raised, and if the pressure of the thumb is somewhat relaxed the fluid runs into the nose. While the fluid is running in at one nostril tho patient bends his head slightly over a basin, opens his mouth widely and breaths deeply in and out The Huid
 masses to the back of the nose and then returns through the other nostril. The following is a useful lotion: borax doz., sod i u m chloride, 1 dram . distilled water 10 oz Add 1 tablospoonful to a pint of warm water and use. Pron. Dush.
DOUGE. By this term is understood a mass of tlour moistened and kneaded, but not brked. Sour dough (leaven) can be, if necessiry, used instead of yeast to raiso llour for bread-making purposes. The dough, or sponge, rises, that is, inereases in bulk and becomes porous, owing to the fermentation set up by the action of yenst, sugar, moisture and warmth, resulting in the formation, entanglement, and subsequent expansion of bubbles of carbon dioxide gas, which, in their efforts to escape, lift up the flour and make the solid mass spongy and light.
Tho quality of bread-dough depends ohiefly on the llour used, that containing the largest percentage of gluten yielding the best bread. and tho management of the yeast. Dough is also leavened or "raised" by two other methods than the use of yeast. One consists of mixing the flour with water which has been saturated under pressuro with carbon dioxide gas, the bread made from this dough being termed merated bread. The second method is by mixing it with various baking powders. See Baling Powder: Bread; Yeast.

DOUGH CAKE. Beforo mixing the fruit and other ingredients for dough oakes grease 2 or 3 cake-tins and line each of them with 2 layers of greased paper, which should reach $\tilde{j}$ or 6 in . above the tops of the tins. Then clean and stalk $\& \mathrm{lb}$. each of ourrants and sultanas. In a large basin rub $\& \mathrm{lb}$. butter into 2 lb . flour, using the tips of the fingers. Afterwards mix in the fruit, 吕 lb . moist sugar and $\ddagger \mathrm{oz}$. of allspice.
Put loz. compressed yeast in a small basin with 1 tenspoonful of eastor sugar, mix them togetiter vigorously with a wooden spoon, and,
when they are creamy, add I pint tepid milk. Pour this liquid into the flour, etc., mix to a light dough, knead it well, and put it into the prepared tins. Put these in a warm place for 1 huur or inore, until the dough has risen to twice its original size : then bake in a hot oven for about 2 hours.

DOUGHNUT. With 1 lb . Hour must be uscd 1 oz yeast, 2 eggs. $\frac{1}{2}$ pint milli and $\frac{1}{2} \mathrm{lb}$. cach of sugar and margarine. Spices, such as cinnamon and grated nutmeg, can be added, and raspberry jam is usually placed in the iniddle of the doughnut.

The yenst should be dissolved in the milk, previously alightly warmed, and the sugar and about $\left.\frac{1}{2} \right\rvert\, b$. Hour stirred in. This mixture is then covered over and put aside in $\Omega$ warm place. When it has well risen and fallen again it is ready for the iddlition of the eggs and the margarine. The eggs should be braten and the margarine melted before they are added, and a pinch of salt sprinkled in.
The dungh having been well mixed, another I lb . flour is stirred in, and the dough is again put aside in a warm place. After about 10 min . it is laid on a Houred board and kneaded into balls, with a small spoonful of jam placed in the centre of each. The balls should he dropped into a deep pan containing boiling lard and cooked for 10 to 15 min . When done they require to be well drained on kitchen paper and rolled while hot in castor sugar.

Dovecot. Fige. 1-7. Small dovecot for attaching to a wall, with diagrams showing method of construction
monly known as the great wood pigeon, is a native of Great Britain; the other two are migrants. The ring dove is a very handsome bird, and its crescent-shaped mark of white, which ncarly encircles the neok, stands out in striking relief against its dark, ashen-grey plumage
Making a Dovecot. In Fig. 1 is shown $\pi$ hanging dove or pigeon cot which providea accommodation for five pairs of birds, three

Doughnut. Four stages th the cooking of dougbnuts. The dougn ready formed on the board, and being dipped in boiling iat ; and the finisbed cakes, draining on paper, and ready for serving Courtesy of Our Homes and Cardens

Doughnuts can also be made successfully on the lower storey and two above. The front with baking-powder instead of with yeast. Beat 4 oz . butter, or butter and lard, to a cream, then add 4 oz . white sugar, a beaten cgg, and a pinch of salt and of allspice. Mix well together, and add 1 lb . self-rasing flour, or household Hour, with which a level teaspoonful of baling.powder has been mixed. If the paste is not damp enough, add milk. Turn it on to a floured board and roll to a thickness of about $\frac{1}{i} \mathrm{in}$. Cut into rounds and push a thumb through the centre of each to make rings. Alternatively in the centre of half the rounds, put a dab of jam, and cover with the plain rounds. These will lose their resemblance to sandwiohes. when cooked as described above.

DOULTON WARE. In its more limited sense, Doulton ware, produced by the Doulton potteries at Lambeth, and elsewhere, conaists of salt-glazed stoneware produced with a single firing, decorated with applied mouldings or scratched patterns, called sgraffito, filled in with neutral colours. A speoial form, called carrara ware, has a crystallinc enamel, sometimes finished with gold and colour.

Various forms of twice-fired carthenware are also produced. Doulton faience has a terra-cotta or biscuit body, decorated with scenic or floral paintings and fired under a dull glaze. One of its forms, called impasto, has thin layers of coloured clays, applied to the smooth surface. See Faience; Pottery.

DOVE. There are three kinds of dove must usually kept as pets, viz. the ring dove, turtle clove, and stock dove The first-named, com-
of the cot is inade to open for cleaning purposes, and when in position it is secured with two turn-buttons.
Almost any wood 1 in. thick may be used. Fig. 4 shows a general view of the construction Required are two sides (A), 1 ft .9 in . long by 1 ft .5 in. wide, strengthened with 2 in . battens fixed as shown at Figs. 2, 3 and 4. The bottom of the lower nests $(\mathrm{B})$ is 3 ft . 1 in . long by 1 ft .5 in . wide, and it rests upon battens fixed to the bottom of the sides, to which it is nailed. The bottom of the upper nesta ( C ) is 3 ft .1 in . long by 11 in . wide, fixed to the upper battens on the inside of the sides.

There are two divisions (D) dividing the lower nests, whioh are 11 in. wide and simply nailed in position. The centre division ( E ) of the upper nests is 11 in . wide by 11 in . high, and fitted above is a ridge piece (F), 1 ft .5 in . long by 2 in deep, nailed to the division. The end divisions (G) are 11 in . wide by 7 h in . high. It will be necessary to bevel the top edges of the sides, divisions and ridge to suit the slope of the roof. The back boards should befitted horizontally, and nailed

Dovetail. Fig. 1. Simple balf-lap dovetail joint. Figs. 2-8. How to mark out and make a common dovetail joint
arider at one end than the other. The case upening, a single duvetail suffices, as shoulders, or sides, of the groove are cut with the saw, and the wood chiselled awny to form the groove. The other part is sawn to the same taper, and half the thickness of the wood sawn away, the joint being finished off by chisel work until a perfect fit is obtained

The conmon dorctail, Fig 2, is much used on drawers and similar cabinet work Suppose the dovetnil is wanted on a drawer side, about 9 in decp, first plane the ends of the wood true and at raight ; then, with the marking gauge, scribe a linc on all faccs of each piece, and at a distance from the edge equal to the thickness of the wood: this is known as the shoulder line. The number and shape of the dovetails have now to be set out on the wood, making use of a scriber and the dividers

First settle the thickness of the pins at their narrowest part, say $\frac{1}{2} \mathrm{in}$., for example. Set off one half this thickness from each end of the shoulder-linc, on the outer face of the wood, as the dovetail has to resist outward

Dovetail. Figs. 10-12. Examples showlag various forms of the joint commonly used in cabinet maklog and joinery
illustrated in Fig. 10. When a dovetail is not to show on the face of the work, as for the front of a drawer, it is known as a lap dovetail. It is set out by seribing a line on the end grain at a diatance from the face of the front piece corresponding to the thickness of wood required for the lap or solid part. The pins arc then set out in the same manner as before and the waste wood removed by saw kerfing, and careful horizontal and vertical paring. The sockets mny be marked out as before and shaped with the saw, and by paring with the chisel

A developinent of the same idea is the secret lap dovetail, in which no dovetail is visible on any face of the work (Fig. 11). This is accomplished by leaving a lap on each part instead of only the face piece: the work of construction is similar to the previous example, but calls for more skill. When the two lapping parts are mitred instead of being lapped, the joint is known as a mitred secret dovetail (Fig 12) The construction of the mitred secret dovetnil is similar to the Inpped sccret dovetsil, except that the mitre is first set out and roughly shaped. the pins and sockets arc formed, and the whole is then very carefully fitted together See Joint

DOWELLING. This is the term given to the method of jointing timber and other materials by wooden or metal jega called dowels.

Iron dowels are used to secure the uprights of door frames to the stone step, and dowels made from iron naila are occasionally used for packing. case making

For cabinet making and similar work straight-grained heech wood dowels may be
pressurc. Then divide the distance between these points into any number of parts, say five, and from these points mark on each side the half thickness of the pin Square off with a try-square, and mark off from these points to the end of the wood. ts shown in Fig. 3.

Set the bevel square to an angle of about $15^{\circ}$, and mark on the end grain the shape of the dovetail (Fig. 4) ; then squarc off from these points with the try-square to the shoulderline on the opposite side of the wood. Set the job upright in the vicc, and cut just inside the lines with a fine-touth tenon saw, then cut away the waste wood between the saw cuts, either with a bow saw (Fig. 5) or by chiselling; in any casc, finish and fit with the chisel.

## How to Mark Out the Sockets

Now mark out the socliets on the other piece. This mny be done in the way described above or with a scriber, marking direct from the pins of the corresponding piece. In the latter method the position and shape of the pins is scribed on the wond (Fig 6), keeping the scriber on the inside, so that the point will not tend to wander from contact with the sides of the pins Squarc off on to the end of the wood (Fig. 7), set it up in the vice and saw to the inside of the lines (Fig. 8) Cut away the waste as before, and all that remains is to fit the parta accurately together, doing this with a chisel, and watching the progress of each set.
When much work of the kind has to be done, it is a convenience to use a metal template shaped to the correct angle for marking out the dovetails (Fig. 9). This tool is obtainable from the shops, or is easily madc from a piece of thin sheet metal.

When two pieces relatively thick have to be dovetailed, as for the framing of a stair-
bought in lengths of about 38 in , and of any desired diameter. Fig 1 shows a dowel with a small groove running along its entirc length. The objeot of this groove is to allow the air and superfluous glue to escape and thus a void splitting the work on hand; the groove also sccretes a certain amount of glue, which increases its loold on the timber

Fig. 2 illustrates the method of marking out and ganging two boards for dowelling. The cdges of the boards are first shot to a truc joint; then the face sides are placed together and the lines for the dowels are marked across

Dowelling. Fir. 1 Grooved dowel. Figs. 2-3. Marking ont and fining dowels to doint two boards.
Fig. Mitre joint. Fir. Fig. 6. Table leg and tramlag
the edges. The boards are then gauged from the face side, thus giving the points indicated in the sketch. A safe rulc for the spacing of dowels when jointing sideboard tops, dressing table and wardrobe ends, etc., is to place the dowels 9 in to 10 in . apart, and place two dowels at cach end, as shown at Figs 2 and 3. The length of the dowels should be about \} in

Fig. 3 shows the two boards prepared ready for glueing. The one on the left is bored to receive thic dowels, and the one on the right shows the dowels glued in position It is customary to warm the cdges of the boards before spreading the gluc. Cramps, to squeeze the joint tight, should be left on the jointed board from one to four hours.

Fig. 4 shows the sketch of a mitred and dowelled frame One corner only is shown The dowels should be at right angles to the line of joint, and consequently the dowel at the outside edge of the frame will have to be shorter than the others. Fig 5 is a leaf for the telescopic screw type of dining table Ciroular dowels are shown at one end, and rectangular wooden pegs at the other: both methods arc good, and, of course, the dowels are only glued into the leaf. The object of these dowels is to guide the shelf into its propes position when the leaf engages with the tahle proper, and tc makc the table and leaf register correctly
Fig. 6 is a dining table leg and portion of the fraining, showing the nethod of dowelling the frame to the leg Cbairs, coucl frames, etc. are made in a similar manner. See Cabinet Making : Joint

DOWER. I: English law this was the life interest which a widow formerly had in one third of her husband's landed property This right has been abolislicd in the case of peraons dying after 1925 In Scotland a widow has a right called 'terce,' equivalent to dower, which entitles her to a life interest in one third of her husband's property in land This right still survives See Marriago.

DOWN. The word down is applied to the soft liair found under the feathers of fowls it also describes kapok, a vegetable donn obtained from such plants as the thistle, etc
For ordinary purposes, a mixture of down and fine feathers gives excellent results, provided that the mattress, cushion or pillow is given frequent and thorough sliakings to prevent lumps from forming. Vegetable down or kapok, which is much cheaper than real down, needs to be separated carefully with the fingers before use to ensure freedom from lumps. The best kind of down is that obtained from the neck of the eider-duck; less expensive varieties include cygnet, duck, and goosedown See Cushion; Fiderdown; Pillow: Quilt; Swansdown.
DRABA. Sometimes called whitlow grass, this is a low growing hardy, evergreen alpine plant whioh must be planted in very gritty soil in a sunny position in the rock garden During winter it is wise to provide protection by placing pieces of glass over them to keep off excessive rain; the glass slould be raised a few inches above the soil by wires Aizoides, yellow., aizoon, yellow; bruniaefolia, yellow; and pyrenaica, lilac-rose, are some of the chief kinds. Propagation is by sceds sown in gritty soil in the rock garden in spring or by division in September.
Drachm. Apothecarics weight equalling 3 scruples or $\mathbf{6 0}$ grains. It is distinct from the avoirdupois dram, which containa 27d grains.
DRAINAGE: Of the Soil. Surface draingge is important to the householder, as waterlogged soil is a menace to health. Systems of land drainage include grading or sloping the surface of the earth, the provision of ditches and trenches, lnying agricultural drain pipes, digging a trench and placing brushwood or

Drainage.
Figs. 1-8. Diagrams illustrating the principles of garden drainare bere described
By special arranocment uith Amalcur Gardening
can be about 3 ft or more acconding to the space a vailable.

The upper surface must have semicircular grooves formed in it, and spaced about 3 in. apart. The underside of the board is strengthened by ledges 3 in wide and 1 in. thick. A hardwood skirting board $\frac{3}{4}$ in. thick and 3 in. wide should be screwed to the board with brass serews to protect the walls from wet. A similar skinting at the front, but only projecting 1 in. above the surface, is a safeguard for crockery
A draining boardshould have a fall towards the sink of about 1 in . in every foot of length; moreover, for sanitary reasons, the board should rubble in the bottom of it, and then closing in the top with soil.

There inust be adequate means for disposal of the surface water at the termination of the pipe lines or trenches These can generally deliver into a brook or pond; failing that, a soak-allay drain must be constructed

This talies the form of a cavity filled with gravel, rough stone, rubble or any porous material, the water collecting in the cavity and ultimately soaking away into the earth The site for a now house or bungalow should drain naturally ; if it does not, a system of surface drainage must be provided. At the same time some pipes must be introduced through the foundations to dispose of any vater that may accumulate beneath the building and cause damp walls or dry rot.

Garden Drainage. Water lying stagnant in a garden instead of passing a way fairly quickly is proof that the natural drainage is insufficient. In draining a garden first ascertain by levelling what fall the land has and in which direction it runs. Then take out a narrow trench a foot or so deep at the top end, letting it slope evenly and gradually till it reaches the lowest print in the garden (Fig. 4). If one main drain is not sufficient, secondary drains, herring-bone fashion, must be added, as in Fig. 7. In this diagrain the main drain is shown running from A towards C, while the sucondary drains are labelled B.

There are three styles of drainage, plain pipe, rubble, and pipe-rubble, illustrated in Figs. 1-3. Secondary drains must bo packed with broken tiles where they join the main drain (Fig. (i)
juints between pipes should be covered with a turf (Fig. 5). The pipes used should have a bore of not less than 2 or 3 in . When rubble is the medinm, layers of 6 in . will be found satisfactory. Generally one drain running obliquely, as shown in Fig 8, will be sufficient in the average small garden, or one main drain and secondary drains:

Where there is not opportunity to take the outfall into a ditch or road drain, let it empty into a tank sunk in the soil. Water will not lre carried off readily if drainage is laid on the level. In clay garden lands drains should not be farther apart than 15 ft . See Drains: Sanitation.
DRAINING BOARD. A draining board is a wooden structure erected at the side of the sink in a kitchen or scullery to facilitate ivashing up, the dishes as they are washed being laid on it to drain The draining board should be made from hardwood such as beech or sycamore at least 1 in . thick; its width slould equal that of the sink, and the length
terminate llush with the walls of tho sink and avoid any crevices where dirt or dust could accumulate. Draining boards can

Essentials in any house dramage systenı include disconnexion of drains from the sewer by means of traps : disconuexion of rain, bath. and other water waste pipes, by discharging thens ints the open air above a trapped gulley: adequate ventilation and self-cleansing apparatus.
The following notes illustrate the general requirements of a small house in the matter of drainage A typical installation comprises the provision of drains for a bath, lavatory basin and sink, a water closet, and means for disposal of rain water. The latter may or may not be a part of the house drainage system, but at least some of the rain water from the roof should be adnitted to the drains

Drains. Fig. 1. Exterior of house showing drainage pipes corresponding to those depicted in Fig. 2
frequently be lixed on deal hearers, secured to adjacent walls, otherwise the best plan is to construct a pair of gallows brackets from sound deal's in wide and 1 in thick. as shown in the illustration. These brackets comprise thrce elements, (a) a vertical strip to attach to

Draining Board supported by a gallows bracket; right. detail of joint between board and edge of sink
the wall, (b) a Lorizontal bearer to support the board, and (c) a diagonal strut or brace. The joints can be screwed together, or preferably mortised and tenoned and securely wedged.
Draining boards are kept clean by scrubbing with white sand or using one of the many brands of cleaning powder which are now on

## Drains: The Domestic System Explained

Points of Importance to both Landlord and Tenant
See further the articles on the various types of house, c.g., Bungalou; Cottage; House; also Cesspool; Disinfectant; Refuse; Sanitation; Septic Tank: Wotet
to ensure periodical cleansing and flushing. In general the whole of the rain water is disposed of by the house drainage systeru. except where a rain-water storage tank is providerl, into which the rain-water pipes would discharge.
The apparatus required is shown in Fig .2. from which it will be seen that the bath and lavatory basin wastes deliver into a separato waste pipe which should be carried up as a ventilating pipe, the open end being above all window openings; usually it is taken just above the caves.
In modern patterns the bath, lavatory basin and sink have special overflows moulded in the stoneware, and these discharge above the seal of the trap underncath the fitting. Where these overflowe are scparato they are treated in the snme way as the Ilushing cistern overflow, that is, the pipe is run through the outer wall for about six inches and cut off in a sloping direction. Should the ball valve of the cistern go wrong, or the taps to any fitting be left running, warning is given by reason of the water pouring out of this pipe.

The waste from the water closet passes down the soil pipe, through the manhole and thence to the disconnecting trap. The bath and lavatory basin dischargo through the waste pipe under the grid of the trapped gulley. The aink waste discharges in a similar way. and both gullies deliver into the manhole and thence to the disconnecting trap.

The bath, sink, and basin are all fitted with a trap or interceptor, which acts as a water seal; the closet pan incorporates a similar device; hence adequate protection is provided against the entry of foul gas.

A pipe is connccted from the manhole to the disconnecting trap, which is situate in a second manhole, marking the termination of the drainage system and the commencement of the sewer. A typical arrangement is shown in Fig. 3, and comprises a disconnccting trap with cleaning eye, a connecting channel, an air inlet or ventilation pipe, and manhole cover. This completes the drainage system.

It is absolutely essential in any system of drainage that sewer gas should be prevented from working back from the sewer (Fig. 3)
into the drains. From this arises the import ance of the disconnecting trap-a bent or U-shaped pipe, so arranged that water lying in the hollow effectually seals or stops up the channel, the water being impervious to sower gas. Every time the drains are flushed this water seal is renewed An inspection or cleaning eye enables the connexion between the trap and sewer to be uscd for drain rods should that portion become blocked; the eye is closed by means of an air and gas proof plug.

The manhole is built in brickwork and well rendered with cement to guard against leakage The cover is generally made of east iron, embedded in cement mortar and sealed with cart grease and sand The air inlet or vent pipe has a flap or non-return valve at the top: this pipe should be some 2 or 3 ft . aliove ground level. The purpose is to admit fresh air to the drains : the air ultimately escapes through the air vent pipe which forms the upper termination of the soil pipe, and thus provides a constant current of air through the whole system. The manhole enables any obstructions to be cleared away in case of a stoppage.

The pipe line between the disconnecting trap and the house manhole must be at raight and continuous, with a regular fall of at least 3 inches in 10 ft ., and nowhere less than 12 in . bclow the surface of solid earth. The house manhole serves a similar pus ose to the disconnector, with the adilitional duty of collect. ing together three separate delivery pipcs.

The pipes from the bath and sink waste are brought to the trapped gully, which terminates at about the level of the surrounding ground, and is hedded in concrete and provided with a brick and cement rendered curb. The waste pipes from bath and sink terminate in shoes which discharge over or under the grid of the trapped gully. This acts in the same way as the disconnector, having a similar water seal. A removable cast iron giating is fitted
The soil pipe is taken by a pipe sloping up. "ards slightly from the manhole to a bend and thence perpendicularly to a junction branch, the arm of which connects to the water closet which incorporates the water seal or trap. The soil pipe continues upward and terminates at least 3 ft . above the roof level, and is provided with a globular wire cap. Fig. 1 shows the usc of a swan neck to avoid

leading the pipe past the bathmom window. The provision of trapsor water seals, Fig 4, at hath and sink outlets in conjunction with those already described entirely closes every possible inlet for poisonous gases.
Sewagedrains must comply with the by-laws and requirements of the sanitary authoritics. No alteration must be made spithout due notice being given, and the work has to be approved by the local authority's inspector

Stoppages. The task of rectifying stoppages is one that brooks of no delay, and the practical man can set about it himself in most cases. If

Drains. Fif. 3. Sectional diagram through disconnecting tran and manhole
$t$ is the sink or lavatory basin that is choked, made on the ground as exhibited by water remaining there instead of running away, the stoppage will probably be found in the waste trap. This should have a screw plug at the bottom, and what is required is to place a bucket or receptacle beneath it, remove the plug with a spanner, and with a flexible cane or soft wire endeavour to remove the obstruction Take care that the receptacle is sufficiently large, as the trap itself holds a fair amount of water, and if much remains in the sink or basin a small bucket might fill to overflowing.
made on the ground liable for repairs if a the landloril is certifies that the house isnnitary inspector for habitation.

If a drain gets out of order by stoppage or foul smell, the tenant should at once inform the landlord, after first endeavouring to remedy the nuisance, e.g. by flushing with hot water and soda, or by using a rod and plunger. If the landlord fails to make the drain right and the householder feels that his family's health is being imperilled, he can call in the local sanitary authority.

Where the drain is condemned as faulty the owner has no alternative but to takeit up and substitute an entirely new one.

Fig.4. Water seal ortra ror bath or sink wastc
A tenant who takes a house for a term of years is hound to keep the drains in proper order. If a drain bccomes faulty through the breaking of a pipe, owing to subsidence of the soil, the liability to repair is the landlord's. If a tenant or his family become ill owing to faulty drains through no fault of the tenant a clain may lie against the owner of the house. Anyone building his own house must have the scwage drain pipes passed by the local authority before filling in.

DRAUGHT : How to Avoid. A draught is frequently due to faulty ventilation, as for example in a small room, when the doors and windows are closed and a fire is burning. Under such circumstances air must be admitted to the room, and unless the doors and windows are absolutely airtight, the heated air will ascend up the chimney and a strong suction be exerted upon any cracks and crevices, with a draught as the result.
The most effective curc for a draught is to give attention to the adequate ventilation of the room, as by opening a window at the top, by the provision of air bricks, or any means that admit sufficient fresh air at a low velocity. When the air is admitted slowly an objectionahle draught is not created. It is the large quantity of air entering at high speed through a small hole that gives the tmuble. Adequate treatment on these lines is more in the nature
of building construction and should have

Draught greluder. esge 1-J. Dovices tor aloging the sap betwean door and Boor. Nig. \&. W astherboard atted to an outade door
through a crevice that would otherwise be draughtproof. Doors and windows are the chief offenders, and the trouble is generally due to defective workmanship and material. The remedy is, however, simple and effeotive. India-rubber draught tube with a canvas flange can be glued or nailed round the window frame so that it seals the joints or covers the cracks. Felt or cloth strips are more durable, as they nevor crack; rubber is prone to dry up and split in hot weather.

Sash windows are effectively protected by cloth-covered sandbags made in the form of long rolls.
Draught Excluder. Fittings of various kinds are obtainable to close the gap between door and flowr. Fig. 1 shows a device consisting of a cloth or plush-covered roller loosely mounted in brass brackets ecrewed to the door. This rolls over the floor when the door is opened or closed, but when at rest the roller lies upon the ground and checks the draught. One type of automatic device is shown in Figa. 2 and 3, and comprises a moulded strip attaohed near the bottom of the door. The end of a sliding member projects and is pushed back by the door frame, thus forcing the movable strip down on to the floor. A tight joint is ensured by means of a tlexible rubber strip at the extremity of the slide. A concealed spring lifts the strip clear of the floor as the door is opened. Owing to the method of outting the diagonal sluts, this type of excluder may be readily reversed to suit the hand of the door.
When considering the application of draughtexcluding devices it is best to inspect the door-frames and to make sure the door shute up tight against the door-stop. If it dnes not, the stopping can be removed and replaced so that it abuts against the door, and this will stop the draught. The door-latch may be slack, allowing the door to rattle. This can be remedied by overhauling the lock or by resetting the socket or staple.

Outside doors are often improved by the addition of a weatherboard (Fig. 4), but this must be throated or grooved as shown, or the
rain-weter will work its way in onder the door. A narrow metal slip projecting slightly above the surface of the threshold will often be a boon in checking a draught.

DRAUGGETS. This game, in America called checkers, is played betwoen two opponents on half of the squares of the chessboard, either on the 32 white squares or on the 32 black squares. For convenience it is here assumed that the white squares are used, in which case the board is set with a black square to the right hand of each player. Each side has 12 pieces, all of the same shape, which are placed at the start in the position shown in Fig. 1. In the notation which enables $g a m e s$ to be recorded the squares are numbered as in Fig. 2.

A draughtaman moves one square forward diagonally. If a man of the opposite colour stands in the way, with a vacant square immediately behind him on the same diagonal, that man can be captured by jumping over him gon to the vacant square, and removing him position black (who invariably has the first move in draughts) plays from 11 to 15 and white replies by moving from 22 to 18, black jumps from 15 to 22 and removes the hostile man from 18. Further, not merely one man can be captured at a time, but a succession of men, all in the same move. Suppose a black man to stand on 1 and three white men on 0 , 15 and 23. Black can jump in succession to 10,19 and 26 , removing the hostile pieces.
The object in draughts is to capture all the opponent's pieces or to reduce them to such a position that they cannot move at all, in either of which cases the game is won. When a capture is possible it must be made. If by error it is not made, there is a penalty called huffing, which consists in removing the piece which could have made the capture off the board, this huffing not counting as a move. It is a player's option either to huff his opponent. to insist upon his making the capture, or simply to let the wrong move stand.
When a man reaches the farther side of the board (the 8th rank away from the player) he becomes a king, with the power of moving and capturing backwards as well as forwards A king is shown by crowning, i.e. putting a spare piece upon him The reaching of the 8th rank completer a move. Suppose a black man to stand on 21 and two white men on 25 and 26. Black can play to 30 , capturing the man on 25 and making his own man a king; but he cannot

## Draughtsmanship. See Drawings.

DRAW-BORING. This method is employed for pegging the components of a mortise and tenon joint so that the joint faces are drawn tightly together. The method consists in drilling a hole through and at right angles to the mortise. Next put the tenon into the mortise, and drive it home : then mark on the tenon the position of the hole in the mortise, by scribing a circle on the tenon, using the hole in the mortise as a guide.
Remove the tenon, and, supporting it on a block of waste wood, drill a hole, the same size as that in the mortise, but nearer the shoulder of the tenon, the usual amount being slightly less than the half diameter. Prepare a tapered hardwood pin of a size to suit the hole, put the joint together after removing any ragged edges around the holes, and drive the pin home with a hammer or mallet. The peg then acts as a wedge and draws the shoulders of the tenon very tightly against the mortise, and to a certain extent obviates the need for a cramp. If the joint is to be permanent it can be secured with glue and the peg glued in as well When tho glue is dry the projecting ends are cleaned off smooth and flush. If it is considered desirable to be able at a subsequent time to take the joint apart, the thin end of the peg should be left projecting so that it can be knocked out when desired.

Draw-boring. Varioas stages in this mothod al making tight-Atting mortive jolnts
The peg hole should be nearer the edge of the wood against which the shoulder fits. A common practice is to drill the hole so that its centre is $1 \frac{1}{1}$ times the diameter from the edge of the wood. The various stages in making this joint are illustrated.

DRAWER: How to Make. For drawer construction dovetails are the ideal joints to use, since by their formation they exert resistance in the direction of the chief strain to which a drawer is exposed, i.c. the forward pull. The ordinary hand-cut drawer dovetail does not vary much in form, except, of course, when the particular construction or formation of the job requires different treatment Fig. 1 is typical of the average drawer. When making one of medium size, it is usual to use 1 in . or $\frac{1}{c}$ in. stuff for the front, and $\frac{1}{2}$ in. or $\frac{1}{8}$ in for the sides and baok. At the front the dovetails do not run right through, a small lap being left on the front. This is necessary to
hide the ends of the dovetails, which rould otherwise diafigure the front. To make a drawer such as Fig. 1, all the st uff is first planed up and thicknessed, and marked in the relative positions which they are to ocoupy. The front is then planed to fit exactly between the rails. A good plan when fitting this is to cant the edgee very slightly inwards, so that the front wedges in between the rails. The sides are also planed to fit just hand-tight, and both ends squared off.
The back is now squared up at both ends to coinoide with the job, but it does not occapy the full width of the drawer. At the top it stands down about $t$ in., and stands on the drawor bottom (Fig. 2), so that the position of the bottom must be decided apon; $t \mathrm{in}$. is usually sufficient for this to stand up, so that the distance, added to the thickness of the bottom, will give the bottom position for the back.

When marking out the dovetails, note that the groove for the bottom is contained within the lower front dovetail, as the groove would otherwise-show a gap in the pins. At the back, the square lower edge of the bottom runs right through along the pin, so that when the side is marked out this is cut square (Fig. 2). When all the joints are cut, the front is grooved for the bottom and the top edge of the baok rounded over: the drawer is then glued up

Figs. 3 and 4 show how the bottom is held at the sides, grooved alips being glued to the sides. The objeot of using these instead of grooving the sidos is partly to present a greater width underncath, thus giving greater wear resistance to tho runners, and partly to avoid weakening the sides. The bottom is either nailed or screwed to the back, and is made sufficiently wide to stand out from the baok about $\frac{f}{8}$ in., so that in the event of it shrinking the screws can be taken out and the bottom pushed forward.

## Centre Support for a Lons Drawer

In the event of the drawer exceeding 18 in . or so in length, a centre support for the bottom should be fired. This is about 2 in . wide, and is grooved in the same way as the slipa. A stub tenon is out at the front to fit into the groove in the drawer front, and the support is held at the back with screws, the upper lipping being cut away to bring the groove against the baok. The drawer is then fitted and the top baok corners bevelled off (Fig. 2). The running of the drawer is facilitated if the sides are slightly bevelled off at the baok along the dovetails. Ordinary candle-grease is a good lubrioant to use to ensure smooth running.

In cases where it is required to place the bottom flush underneath, as, for instance, in the trinket drawers of a dressing table, a rebate is run round the front and sides, as in Fig. 8, and the bottom dropped in this. It is also neoessary to arrange the dovetails as illustrated in Fig. 5 to provent any gaps showing at the sides See Birds' Egg Cabinet Bureau; Chest; Chest of Drawers: Desk ; Dressing Table; Wardrobe, etc.

Drawer. Fign, 1-8. Diagrame showing the component pasts and details of constriotion of an ordinery drawer oircles. 32 in . by 23 in ., and it may be of the cheap. clamped variety or, preferably, with battens on the underside. For mechanical drawing it should be truly square on the left-hand side, the left edge being used to guide the stock of the tee square. The ordinary cheap clamped board made of sound, dry pine, will last for many years, and has the advantage that both sides are available. The best quality boards are made with battens on the underside, and are grooved to allow the wood to expand and contract. For the same reason the battens are secured to the board with slotted plates and screws. They usually have an ebony or hardwood slip inserted in the left-hand edge for the tee square to work upon.

Eseential qualities in the toe square are straightness of the ruling edge. This can

## Drawings: Their Preparations and Use

## Some Practical Hints for the Amateur Craftsman

The ficts given in this costribution, together with the Illustrations, are intended to help those who wish to make any of the constructional articles described in this work

The ability to produce an intelligible drawing round one. For fine work a hard pencil, tors. The tools and materials required need not be expensive, but it is well to bay reliable instraments. A mininum outfit comprises a drawing-board tee square, set squares with angles of $45^{\circ}, 60^{\circ}$, and $30^{\circ}$, one or two ruling pens and a 6 in . half set of drawing instru ments (the latter comprising compasses with ink and pencil points, an extension bar, and a pair of dividers) : drawing paper and pencils, some Indian int, a piece of indiarubber and a few drawing pins It will be well to add a pair of mall spring bow compasses with ink and pencil points, as these are handy for drawing small

For all-round use the imperial-size drawing board is the most oonvenient. This measures be tested by ruling a line, turning the square rotating the upside down, and ruling anotherline on top of dividers or the first one; if the edge of the tee square is $c o m p a s s e s$ true the two lines will coincide and appear as while the one. The preferable form of tee square is made in mahogany with ebony edge.

In ohoosing set squares, those made of celluloid or a transparent material are to be preferred, and should have one edge bevelled, as this minimises risk of the ink running under while using the ruling-pen Compasses should have fine sharp points, preferably those with a needle t.eld in a clamp; should have firm joints and exhibit no shake or play on any of the joints. The various types and qualities are disoussed at length under the heading Compasses (q.v.). The same remarks apply to dividers. prises a fixed and a movable steel blade, the ink being inserted between them by means of a small brush or an ordinary pen. It is essential that the exterior of the blades be free from ink, otherwise it will be liable to cause a blot when ruling a line.
The pencils are preferably of the heragonal type, as these do not roll off the board so easily as the
is of great value to all amateur construc- such as an H.H., is to be preferred: but

The ruling pen com where much rubbing out has to be done, a softer pencil. such as an H.B. or B. is more convenient. as it is more readily erased Pencils should be sharpened to a chisel point.
For ordinary working drawings cartridge paper will be found quite suitable, but for more highly finished drawings inink, a smooth surface prper should be used, such as a Whatman H.P., or hot pressed paper. The only inks that are of any practical use for mechanical drawings are those generally known as Indian inks.
In using compasses or dividers, place the metal point exactly on the line or centre from which measurements are to be taken. If equal on both sides of a centre line, mark them by Plan

Drawing. Piga, 1 and 2. EjevaDrawing. pigal and 2. Eimple rooden bor Mig. 8. Bectional
 jection. Fig. 6. Porspective wing of boz needle point
 upon the centre line; as far as possible take all dimensions from a few centre lines When using ruling pens or the pen points in the compasses, charge them with ink from a brush or pen, wipe the points of the blades clean with a piece of rag wrapped round the finger, and before ruling long lines see that the blades have sufficient ink between them, as it is difficult to join up the two parts of a straight line. The pen should travel at an oven speed over the paper, be held nearly upright, and always at the same angle to the paper. Before laying the pens aside, wipe off the ink with a piece of rag or blotting paper. The points of all drawing pens should be kept sharp but perfectly smooth by setting them oocasionally on a piece of fine oil stone. Other instruments used in mechanical drawing comprise proportional compasses, French curres, parallel rulers, scales, and other special appliances

Methods of Projection. There are several ways in which an objeol may be depicted. Simple projection assumes that every part of the object visible in, say, a vertical plane is projected upon an imaginary flat surface, although, in fact, the object may be curved or of any other shape. It is usual in mechanical
 shown in Fig. 7 trangio:red to the wood
drawing to show a plan of the object, that is, the appearance as seen from above, and a front elevation or view of the object as seen from the front and projected upon a plane at right angles to that of the plan ; an end view is also drawn upun a plane at right angles to that of the plan, and alsn at right angles to that of the front elcvation

Where the object is differently shaperl on both sides and both ends, elevations are given of all these four sides. Suppose now the object were hollow and that the cavity could not be scen from the extcrior, this would be depicted by means of a section, this being neither more nor less than projections on a vertical or hori. zontal plane imagined as passing through the object, and it thus shows its shape as if it were parted asunder with a saw.

Isometric projection is a method of showing three surfaces of an object simultaneously, whercas plain projection shows only one face on any one elevation. In drawing an object in isometric projection, all horizontal lines are measurad from ono centre point along lines inclined at $30^{\circ}$ to the horizontal. Vertical dimensions are taken at any necessary place along these inclined base lines.

In Figs. 1 and 2 a simple wooden box with the planes marked on the drawing shows the various elevations. The sections through the box are shown in Figs. 3 and 4. The same box has been drawn to the same scale by isometrio projection in Fig. 5, and in Fig. 6 again in mechanical perspective.

Comparison of the three processes and their relative advantages can thcrefore to made.

Drawing. Fig. 8. Conventional methods of treatin; various materials in mechanical drawing

By the first system the actual shape and good Error may be avoided if the elevation size of the object is depicted either full of the piece of furniture is set out to scale. size or to any convenient scale. The It is equally desirable to know how to set isometric projection gives a better im. out the complete vertical and horizontal scopression of the appearance of the finished object, and dimensions can be scaled off from it. In the thind illustration the appearance of the article is extremely good, but it is not practicable convenicntly to take any dimensions from the drawing. Hence for a working or mechanical drawing, the first system is the best for
amatcur puramatcur pursecond system is very good, as it indicates something of the external appearance of the object and provides the necessary, means of measurement The third system is of value to the architect or constructor who wishes to show the correct appearance of the article when it is finished.
No special instructions are required for the preparation of drawings of objects that are made from flat material with straight or angular surfaces and edges. It is in drawing curved surfaces that greater difficulty is mot with, and as an example Fig. 7 shows one method of drawing part of a chair back, and clearly indicates what has to be done in preparing a drawing for such a piece of furniture. To transfer the ourves to the work it is desirable to draw lines at right angles to one or more of the edges of the piece of wood from which the chair back is to be made; and
 We know exactly then what we are doing, and every dimension-length. width and thickness -may be taken from our set-out. It is not only that the work itself is rendered easier, but again and again we are saved the mortification which results in the discovery that, through some trifling miscalculation, we have cut a costly bit of line wood the wrong size. Careful setting-out, indeed, is the first step towards the attainment of good results in all cabinet work.

In making a full sized dra wing of some detail, e.g. a chair back, squares may be ruled on the small sketch and the drawing transferred square by square to paper similarly ruled on the enlarged scale. By numbering the squarcs vertically and horizontally the chance of error may be eliminated. Where necessary in our constructional articles a squared detail sketch is given, the scale being indicated.

Certain conventional treatments are generally followed in draughtemanahip to indicate sections, different materials, scrow threads, and the internal shape of an obiect, examples of all of which are given in Fig. 9.
The Flaishing Touches. Drawings are usually finished after completion in pencil by going over all essential lines with Indian ink, using the ruling pens, and ink points on the compasses, after which the dimensions are given and the points from which they are taken indicated by dotted lines, the latter conveniently drawn in a different coloured ink. If a drawing is to look well it should be neatly lettered; simple sloping letters are easier to draw than those to set off the distances along these lines and transfer them to similar lines simple letterings and methods of ruling for
drawn upon the wood itself, drawing the them are illustrated in Fig. 10 . drawn upon the wood itself, drawing the them are illustrated in Fig. 10 . curve through the points thus found. The When a drawing has to be copied, it is as method is illustrated in Fig. 8.

Scale Drawings. The amateur cabinet paper or linen. This is pinned over the pencil maker should try his hand at a scale drawing drawings, and wiped over with French chalk of the article he is about to construct, practis. to clean the surface. Subsequent work is pering until he is able to draw mouldings or other formed as if on paper, the pencil lines showing details full size from a scale sketch. There is through the tracing oloth and acting as a guide. nothing really difficult in this; it is a matter When completed, blue prints or black line of knowing how to use the T-square and rule, prints on white paper can be obtained by and rarely involves freehand drawing. The sending the tracings to a firm of photogreat advantage of a scale drawing is that it engravers, or the amateur can make his own shows at once whether the proportions are sun prints in favourable weather.

## Drawing Rooms in Several Styles

## Suggestions for Furnishing and Suitable Colour Schemes

For related information see Chair; Colour; Decoration; Furniture, and for detalls about accessories Curtain; Cushion; Mirror, etc. See also Carpet and the entrles on varlous styles, e.g. Adam; Chippendale; Queen Anne, etc.
There is a certain formality which dis scheme. Small tables instcad of being dotted tinguishes a drawing room from the orlinary about the room aro produced as required living room and from the lounge At the same from a "nest" of four; the larger occasional time, except in a big house where there table is often a useful book table. Comfort are four or five recreation or sitting rooms of is still ensured by the inclusion in the furniture different types, a drawing room should have of a good settee or Chesterfield, and one or a lived-in aspect and express to some extent two lounge chairs, supplemented by several the personality and taste of its owner, so newer types of chairs designed to take up that it does not look mercly a room set apart little space and yet for ease. If a piano, to entertain visitors.

Perhaps one of the best things noticeable in many modern drawing rooms is the tendency to do away with overcrowding, not only of furniture, but also of superfluous ornaments, pictures and cushions. Things have a meaning and a definite place in the music stool, bureau or writing-table and bookcase are added the essential furniture is collected. Niches with shelves for china are always delightful features in a drawing room, while a recess provided with shelves is an excellent place for a gramophone. The records are kept in neat compartments on the
under shelves and the gramophone on the top trave of the door one about thre feet from the floor. It is thus both easily got at and out of the way should the room be required for dancing. A light fitting should be placed conveniently for seeing the records. In small rooms the piano sometimes has to be omitted.

Whatever the furniture already possessed may be, it can usually be improved by good choice of furnishing fabrics. When starting to redecorate, renovate or furnish a drawing room take a view of the whole of its possibili. ties and determine the essential things to be done or bought, and the styles and colours needed to enhance it. This method precludes buying a carpet merely hecanse it is a good hargain, a piece of furniture that is not in accord with others in the room, or picking up cushions at a sale merely because in themselves they are pretty. Such haphazard methods have spoilt many rooms that could have been charming with far less money spent on them than was lavished to produce an unsatisfactory medley.

Country House Drawing Rooms. A drawing room in the country is often simpler in treatment than the onc in a town house. Freshiness and the happy nature of the colour scheme will make up for a mixture of styles in pieces of furniture. Loose covers rightly play ail important part in the scheme of such a room. If they are to be of a patterned cictonne, it is useful to remember that the larger the room the bolder can be the nature of the design on the fabric, but that such a design requires a plain setting. An attractive idea is to have the curtains of the gaily printed material and the covers in plain linen. This looks particularly well in a room where the windows are a feature.

A charming scheme for a sunny drawing room, which hoasted no beautiful architectural features except a well-proportioned group of outward swinging casement windows, was evolied from a colourful cretonne used for the short curtains and box-pleated valance. The ground of the cretonne was dark smoke grey with large bunches of old-fashioned flowers multi-coloured, but with pink and red rose shades and the green of the leaves predominating. A grey wall paper was chosen with a faintly suggested brocade pattern in an oyster shade. The paintwork was carried ont in the latter colour except for the archi.

based on a dignifed yet simple Queen Anne style enbanced by flower paintings Courtesy of llampton \& Sons, Lid.

Adam style in designs of doors and chimney pieces, more or less suitably adapted to unpretentious rooms. As a rule this has to lie made the hicst of, as structural alterations are impossible during a threc-year tenancy. A successful method is to paint the walls a suitable pale colour and simulate panels with applied mouldings. Such a scheme forms a good background for most furniture whether of modern, antique, lacquer, painted or reproduction varieties. A ceiling paper of silver is a highly decorative finish if the furnishing of the ronm permits it.

## A Pleasing Colour Scheme

Another scheme which is pleasantly noncommittal is to distemper walls and ceiling a clear pale yellow or in flesh pink, paint the woodwork in a cold sea green picked out with silver, have a settee upholstered in a deeper shade of the same grcen in damask or heavy moite ; repeat this colour also for the curtains, the pelmet for which is trimmed with silver braid and fringe. Loose covers for the chairs would be in a cretonne with a pale green ground patterned in a small conventional design introducing pink and ycllow. A carpet of modern pattern in which the predominating colour is green might be used or one of plaingreen pile. Tiles which are not harmonious in colour can be toncd to suit the woodwork. Waxed walnut furniture with one laoquered or painted piece and a floor standard lamp in the sea green colour would look particularly well in such a room, but the scheme is not one that necessitates any particular style in furniture.
For a town house drawing room the simple Queen Anne style, illustrated in Fig. 2, could he carried out without great expense. The curtain treatment would be beautiful in plumcoloured silk with dull gold trimming. The carpet could be an oriental one introducing plum colour and old rose shades, the upholstery a modern silk tapestry in which the colours of the carpet are blended with a gold thread running through the design, and the walls are painted a soft apple green, while the ceiling is n pale gold colour. The panclled llower painting over the fireplace and the gold net glass curtains brighten the room.

A contrast to this room would be one in which the scheme was hased on a biscuit, fawn and pink wallpaper of classical design. This could be completed by a light brown pile carpet unobtrusively patterned in fawn, taffeta curtains shot with pink, fawn and gold, and loose covers made of a shadow tissue in which these colours blended with a soft blue. Either oak, mahogany or walnut furniture would be at home in such a room.

DRAW KNIFE. This is a tool used by carpenters for roughing out along the grain. It consists of a heavy blade to which two wooden handles are fitted and riveted to prevent them being pulled off in use, the blade being ground to a chisel edge. When using a draw knife the operator stands astride of the woorl to be cut and, holding the knife by the two handles, draws it towards him along the wool, while keeping the blade at an angle to the wood. The result is to draw off inassive shavings slowly and steadily. The action should be one of drawing, not chopping, though chopping has to be resorted to when cutting through knots in the timber.

DRAWN TEREAD WORK. This work is mostly executed on linen of an open weave, which allows the threads to be casily drawn, and is suitable for afternoon teacloths, table centres, and all kinds of house linen. The soft canvases used for duchesse sets and sideboard runners, and also crépe-de-Chine, georgette and satin dress materials can be decorated with drawn thread work.

Modern drawn thread has many additions in the way of fancy lace stitches, from which have crolved the beautiful designs seen on the corners of tablecloths. In its initial stages it began with punto tirato, threads drawn one way of the material, then punto tagliato, threads drawn both ways so that they cross, and these were followed by opum tiratum, the fancy stitches worked on the loose theads.

Draw Knife used in rouglung out timber
needle from right to left under three or four threads, according to thickness, and draw the thread through. Insert the needle in the same place and bring it up again through the hem just above the place where it was brought out before. Insert the needle under the next three threads and repeat, Fig. 1. Fig. 2 shows the hemstitch used as an insertion.

Fig. 3 gives the pattern of a single crossing evolved from Fig. 2 after hemstitching both edges. The clusters of threads are crossed thus. Put the point of the needle from left to right under the second cluster, then let the point travel from right to left under the first cluster, still lieeping the second cluster under the needle, and bring the needle up to the left of the first cluster. Repeat along the line, turning every second cluster over the preceding one, and this will give a running thread through all the clusters. Fig. 3 shows the needle in position for beginning this stitch. Fig. 4 depicts trellis hemstitch. Hem. stitch one elge as at Fig. 1, but when doing the opposite edge tako half the strands from one cluster and half from the next.

Drawn Thread. Figs. 1-5. Simple and more involved forms of hemotitching. Figs. 8-7. Stages in working the drawn thread work corner shown in Fig. 8

The Faggot-Stitcn. Fig. 5 introduces faggotstitch and the punto tirato knot. The latter is used largely in the most beautiful drawnthread designs. Prepare the henstitch insertion as in Fig. 2, then three or four clusters are bound together with the knot, when thev resemble faggots of wood. The thread should be joined at the end of the work, or where there is not a hem it can be tied to the finst three clusters to make the first faggot.
The knot resembles chain-stitch in em. broidery with a slightly different placing of the needle. Take sufficient length of thread to do the whole length of insertion.
Now, working down the line of insertion, turn the cotton towards the left and hold it down with the left thumb; bring the point of the needle over to the left of the cotton held down and insert it down the upper part of the space between the faggot just tied and the next faggot. Pass it behind the three clusters that will form the next faggot and bring the point up over the cotton that is held down by the thuinb. Draw the needle through with sufficient tightness to bind the faggot and let the thread lie in a straight line between the faggots. Fig. 5 shows the accurate position of the needle and thread, which is very important.

Fig. 6 shows how to finish $\pi$ comer so that the threads are not drawn right to the hein Buttonholo the two outside edges of a square along exactly the number of threads that will be drawn on each side, then cut the threarls under the pearl edge of the buttonhole stitches and draw out the threads on both sides, when a square hole will appear, as in Fig. 6. This can be filled with a fancy pattern as in Fig. 7, or with the spider web. Fig. 7 shows a comer where two insertions of faggots cross each other. The working thread crosses the square hole from both sides, then two other threads are laid obliquely across these from corner to corner and secured firinly on the linen. Now join a new working thread in the very centre of the star of threads and work point de reprise under two threads, a comer one and a side one. This stitch is like simple darning-stitch and goes over one thread and under the other until the spokes are nearly covered.

Point de reprise forms the groundwork of the most beautiful drawn-thread designs, wherc a large number of spokes are laid and the stitch darned in and out all the threads aceording to formation of design. A spider's web can be worked on the spokes by weaving round and round the threads, taking care to keep them flat against each other so that thej do not overlap. Fig. 8 shows a completed centro with two rows of faggot insertion and point de reprise fillings at the corners. In this case the threads are drawn right to the hem of the cloth. See Embroidery; Linen; Tablecloth, etc.
DRAW STRING. A draw string of tape or ribbon may be slotted through a casing or hem, and attached in the middle to prevent its being accidentally pulled through the slot too far. A double draw string is often used where fullness is only required for a fow inches, or in drawing up bags, etc. Two lengths of ribbon tape or corl are used, ono being
attached at one end only, the other at the opposite end, and threaded through the slot; the two lonse ends drawing up easily and evenly.
DRESDEN CHINA The best period of Dresden ohina, which is porcelain made at Meissen in Saxony, extended from 1720 to 1775, and the mark is the famous crossed swords in blue under the glaze. To this period belong the breakfast services and other useful wares, with moulded decorations, painted on mauve, yellow, green or marone grounds, with tiny landscapes or flowers the figures and groups, the best are in white, but those with painted decorations arc much favoured. Therc were also clockcases, mirror frames, cabinet-panela, tables, candelabra, and other furniture accessories. word Dresden.
During the 30 years preceding 1814, called has no historic value, such as that which perthe Marcolini period, marked with a star tains to Crown Derby. See China.

## DRESSERS FOR DINING ROOM AND KITCHEN

## The Welsh Dresser and other Kinds Described and Illustrated

Sec further Dining Room; Dining Tahle: Kitchen, and the articles on the woodworking processes involved in making one of thesc articles of furniture, e.g. Amıleur Carpentry

The dresser developed from the buffet, and took its present form soon after 1600 . Oak was used for most of the early ones, but afterwards mahogany became popular and fine specimens were inlaid with box and other woods. The piece of furniture known as the Welsh dresser is made of oak and inahogany combined.

The plain kitchen dresser of deal, with its drawers and cupboards and unbacked superstructure of shelves, is a fixture, whereas the dresser which is sometimes substituted for the sideboard is a movable piece, and the shelves of its upper part are backed with plain wood or panels, and very often enclosed in order to keep the dust off the china that may be stored there Some attractive modern dressers or built-in sideboards are made with glazed doors at the top, arranged either to swing or slide, as well as the cupboneds and drawers in the lower portion. The unenclosed super-structure is inost common: but there is always scope for the architectural treatment of the dresser, and both parts of it may be elaborated up to a certain point without diminishing its usefulness. The chief difference between old and new is in the material. Mahogany is now too expensive a wood for most people. Weathered oak has largely taken its place, and the cheaper woods, stripped and wax polished or atained, often give good results.

Where a dreaser is intended for the display of good china, the shelves should be lightly grooved for the plates and saucers. A few good pieces carefully arranged will show themselves and the dresser to the best advantage.

The real Welsh dresser is easily distinguishable from the many faked ones on the market. The wood is oak, frequently with a simple inlay of inahogany, dark polished, with severe rectangular mouldings, and there should be plain brass droppers for the drawers.

One is constantly aeeing examples, alleged to have heen restored, with dark oak stain on the wood, ourved Queen Anne legs, curved mouldings, or Sheraton shell ornament on the anels, and other contrivances designerl to bring them into line with the popular conception of the period. In a good miany cases the restored Welsh dresser is simply built up on an English foundation, with top back panela supplied from Victorian church pews. A useful test, though not, obviously, an infallible one, of genuineness is the condition of the brass furniture. The brass in a genuine antique will have become browned by the passage of time. Drawer handles looking like new should, therefore, be suspected. Many good furniture makers construct reproductions of period dressers, copying detail with artistic precision, or modern types are designed in limed onk.

Making a Deal Dresser. The particulars of a dresser given here will apply to any length up to 6 ft , and any reasonable height up to 7 ft .6 in ., in which case an extra shelf might be fitted.

For present purposes the dimensions are put at 3 ft .6 in . "ide. Depth back to front can be between 1 ft . 6 in . and 2 ft . Common deal will answer all purposes.

The legs, from 3 in. by 3 in material, are 3 ft . long. The top side rails or ends are double mortised into the legs and are 10 in . wide. finishing flush with the bottom

 in. wide at top and shaped as Fig. I. are cut back $\frac{7}{i n}$. below each shelif to 4 in . wide at bottoin, where they drop into grooves in the top. In marking the heights of the two or thice shelves, first measure the plates and dishes, or any other items that hase to be mounted. Usually the lower shelf is at. least a

Dresser : two antique examples of this piece of qurniture. Left, enclosed dresser of Sussex make, with drawers and cupboards. Right, old Welsh dresser, with panelled back, cuphoards and drawers

Dresser. Fig. 1. 8implo dresser Atted with shelves drawers and cupboards. Figs. 2-3. side elevation and diagrams showing how the pieces are fited
foot above the table top, the others graduated in space as necessary. The stop for plates on edge is formed by lengths of $\frac{1 \mathrm{in} \text {. bead cut to }}{}$ butt between the ends and panel-pinned to the shelves. so that they ensure a safe angle when the plates are tilted. These shelves are fitter into corresponding grooves in the ends, each groove being stopped back $\frac{1}{2} \mathrm{in}$. from the front edge and the shelf corners notched to agree.

A face piece ( J ) is cut into the front edges of ends at top, and upon this the cornice mould will bed as at K, Fig. 3. The mould, a 3 in . by 1 in . section, is mitred to return round ends The face piece can be cut 5.! in. wide, and shaped as Fig. 1 to ease the line. A back of $\frac{3}{3} \mathrm{in}$. matching is best. A length of $\}$ in. mould, cut to butt between the bottom parts of ends, makes a good finish. Brass dresser hooks of suitable size for the safe hanging of jugs are obtninable. A cutting list for the 3 ft .6 in . size is given. Lengths and widths allow for juints and paring, but thicknesses are net.

Dresser for a Recess. Fig. 4 depicts a Iresser fitted to a recess 5 ft . by 18 in . The main face of the lower part, i.e. the legs and drawers, etc., stands forward 1 in ., and is fitted with a set of drawers at the back. Fig. 7 shows the ends made flush with the inside faces of the legs, so that irregularity in the sides of the recess will not makc a difference to the fitment. A batten nailed to the wall (A, Fig. 6) gives ample support. The top rests on the batten and is nailed to it. The legs, cut from 2 in . squares, are mortised for
ion ; it will be necessary to scribe in posiover the skirting. Having fixed the legs to the batten (previously secured), the top is cut out and nailed down. This projects at the front round the walls. The potboarl is best made from matchboarding, and is held at the back by a batten (Fig. 7).

Drawer runners and kickers are fixed as in Fig. 7, and the drawers made. The set of sniall drawers at the back of the top are made separately and screwed
 to the top. The carcass for thesetakes the form of a

DRESSING: What to Wear. The art of good dressing lies in the right selection of material and colour for garments, keeping in touch with fashion, in appearing always to be in the correct clothes for the occasion, and in the careful attention to suitable accessories.
Most people like variety, but this liking, where means are limited, should be curbed before it leads to buying cheap and badly-cut clothes, which will look what they are after a few times of wearing, or of spoiling the appearance of a good dress or suit by shabby footwear and gloves. Clothes which really fit and have been cut to suit the figure, avoiding passing extravagances, look smart for a long time.
Hints for Women. Horizontal lines have a broadening effect. The clever manipulation of st ripes. of trimmings which descend in an unbroken line from shoulder to hem, or of garments in which the waist is only defined at the sides, the elimination of materials with sprawling deaigns or of ton bright a colour, all these are important details and considerations when it is desircd to produce a slimmer effect. Another point is the avoidance of anything strained or tight.
Severe tailor-mades, classical evening gowns of heavy-patterned brocades, floating draperics to wraps and street coats, large hats and collars are not suitable to the small woman however successful for her taller friends On the other hand, she will look well in dresses of light materials ; in soft and Huffy or quaint and picturesque evening frocks, and in leas formal coats and skirts Clothes for the businces woman or girl should be smart but simple, and the style of day or tailor-made drees most becoming to their wearer is the best cloice.

Men's Wear. The hard and fast rulea which govern men's attire make for a standard level in their dressing. With the exception of some of the younger men who take a real intcrest in their clothes, and of a few who actually make suggestions to their tailors, every man's desire is to look

Dremer. Pitg. 4. Usoful dresser made to at into a recesa. Figs. 5 and 6. Front and side elovations. .Fig. 7. Their clothes are too easily supported by bearers nailed to the wall. recognized and too quickly out of date to be They should be nailed down on to the bearers.
recognized and too quickly out of date to be
the front rails and the ends. These latter are rebated for the back (Fig. 7). The front rails are cut from 1 in. stuff, exwhich is whis is 12 . bated, as in Fig. 7 to take the pot board and bevelled at the front.

Glue the ends up first, then clean the inner surfaces and glue the front, lastly fitting in the back, which is glued and nailed. Now fit

for all ordinary occasions by the posscsaion of adviashle for the woman who hits to study one suit of evening clothes. a couple of white waistconts. and a dinner jacket suit, white bow ties to wear with the first, a black how for the last and, in addition, correct evening shirts.

Colour in Dress. Although to a certain extent influenced by fashion, a woman's choice of suitable colours for dress ahould be guiderl by personal considerations. Clothes should not be merely fashionable but should enhince the personality of the wearer. The fine complexioned girl, with hair varying from light to medium brown. lonks her best in soft or pale clear colours. Violent hues clash with her personality and dull the brightness of her skin She will probably look well in navy blue, grey, or brown, but unrelieved black must he worn with discretion, as it depends for success not on colouring, but on its cut and line and on being able to carry it with an air of diatinction in the way that a French woman will wear it.
A judicions mixture of hlack and white is suitable to nearly every lype; it has the effect of enhancing a brilliant complexion and of putting tone into a nondescript one. This is one reason why evening dress is becoming to most men, and why waitresses or housemaids in regulation uniform look smart and well dressed.
The fair-haired girl with delicate complexion can wear white and many deep shades of blue, brown, red and green, which are rich and not hard. In pale colours she may look insipid. The possessor of brown eyes and fair hair should weir brown or touches of brown as much as possible.
With green or blue eyes, rather palo fair skin and dark hair, bright blues, orchid and fuchsia shades and bright greens are possibilities, hut not reds, browns and orange. The lastnamed colours are for the brunette with rich complexion and brown eyes.
Auburn and red-haired women look well in pale neutral shades, rich copper or chestnut browns, neirly all greens, and the range from straw colour through the yellows up to orange and flame. Brown eyes may belong to this hair, but if they are hlue, most shades of that colour can be worn. The grey-haired slender woman with fresh complexion can wear shades of blue or mauve, also black and white. Black, deep purples, dark blues or mole oolours will apparently reduce the figure, but vivid colours should be avoided by the woman who is not slim.

Sallow-skinned people should avoid purple, which is the complement of yellow, green and unrelieved grey or black.

Testing Colour by the Eyes
Speaking generally, the brunette can wear any vivid and striking colours which are fashinnable. She can wear black, unless her complexion is very sallow, when also she should not chuese arange and amber shades, but rose, brown and beige. The question of whether a particular shacle is suitable can be determined by standing before a mirror and holding a piece of material of the same colour near the eyes. If it makes the eyes appear more colourful than usual it can be worn with becoming effect.
White and grey sliades for gloves or shnes seem to enlarge the hands and fect, while fawns, browns and black make them appear smaller. The wearing of lighter-toned stockings than the shnes diminishes the apparent size of the feet.
The secret of a succesaful schense lies not only in the choice of the principal colour adopted but also in the matching or blending of accesaories. A harmonious effect is often missed hecause the wearer will not keep to one or two colours; while an att ractive appearance results if she chooses her shocs, stockings, gloves, and hat, either to match or to tone with her coat or dress. It is
economy to plan her whole season's wardrohe according to a definite oolour scheme, so that these important accessories can serve to complete more than one of her costumes.
DRESSING: In Surgery. The term dressing is used in surgery for any material applied to a vound to cover and protect it and further its healing. A simple aseptic dressing, that is, one which itself is germ frec, can he prepared by balking ordinary absorthent cotton in an oven until it is slightly scorched.
Whatever the material applied to a wound, a burn or other breach of the surface, it mist be clean and it must aborh diacharges. To provide for absorption of discharges it is usual to cover the wound, etc., with lint or gauze. and over this put a thick layer of absorbent cotton-wool or wood-wool. The dressings are then fixed by a bandage.

In the case of a clean wound it is desirable that the dressing should be dry, hecause moisture filvours the growth of micinhes: but where there is a considerable raw surface and it is desired to keep the dressings moist to prevent them from sticking into the wound, the lint or gauze is wrung out of an antiseptic lotion and covered with oiled silk or gutta. percha tissue, the latter heing cut smaller than the area of lint to be covered.
The smooth side of lint should the applied to the wound, as the Huff of the other side tends to stick in the sore Two useful kinds of lint are ordinary surgeon's lint and boracic lint. Useful gauzes are plain gauze, cyanide gauze, and iodoform gauze.

Among Intions which may be applied for moistening dressings are the following: or chest of drawers used for tailet purpuses. a mirror being placed upon it for assistance while dressing As a distinct picce of furniture. it dates from the end of the 17th century. In the time of William and Mary and of Anne heautiful dressing tables were made in walnut and other fine woods. These were often fitted with drawers. and on them a lonse swing mirror was placed. This stylo has been revived in the 20th century

In the elegant styles for which the 18th century was notahle, dressing tables are remarkable for grace of design and beauty of ornament. On them are found the various decorative features that distinguish 18 th century furniture-the cabriole leg, for instance-while marquetry and inlay are frequently seen. These pieces are of rosewond, satinwood, and other rich woods, and they were designed by Chippendale and other great cabinet makers of the time. who made them alsn in mahogany. In some the mirror, either swing or triple in form, remained separate from the table, but more often it was fitted into the back

Fig. I in the next page shows a finely decorated piece of the late 18th century classical period It is of satinwond, with a how shaped front in which is a drawer. It is supported on slender legs connected by carved rods, at the junction of which is a box. Ahove the table proper are five irawers, and ahove these are two pedestal cuphoards, between which a toilet glass shaped like a shield is swung. The heautiful design is enhanoed by the graceful decoration of medallions painted on the cuphoard doors and garlands of tlowers round the mirror

Fig. 2 shows an older example, being of the time of William and Mary. It stands on twisted legs, strengthened by a stretcher. The mirror and the drawer handles should be

DRESSING CASE. Dressing cases for men and women are intended to hold the various toilet accessories and requisites arranged compactly so that they can be taken about easily when travelling. The case itself is usually made of leather of various qualitics, and should be cared for as other leather articles. The sizes and contents vary A typical case for a man measures 24 in . by 16 in . by 8 in.; that for a woman is somewhat smaller The fittings are usually of silver but may be of ivory, enamel, tortoiseshell and gold or silver, or even of gold

DRESSING ROOM. In small flats, the bathrooin is sometimes arranged as is hathdressing room. Furniture must be of suitable material to withstand damp and clothes may be kept in the bedronm provided there is sufficient wardrobe acoommodation Failing this roon may possibly be found for a smail wardmbe in the passage Convenient wardrobes are devised containing space for hanging clothes, shelves, and a set of narrow drawers with glass doors, so that a man can see which drawer contains tics. which handkerchiefs, and so on. In the case of the dressing room proper a dressing chest or table must also bo provided. but it is not usually necessary to have a wash-stand. as the modern house gives good accommodation in the bathroom. A small hed or a practioal divan is often also included in dressing room furniture.

## Dressing Tables: Practical and Decorative

## The Choice and Construction of this Bedroom Piece

Other articles upon allied subiects include Bedstead; Chest of Drawers; Wardrobe. See also Bedroom; Bed-Sitting Room; Furniture; Table; and for the accessorics Tailet Mirror: Toilet Set, etc.

In origin the dressing table was a table noticed. Such triple mirrors are largely re
produced to day, both framed and frameless.
In the 18th century Sheraton. Hepplewhitc. and other designers made diessing tables of the type that close up by means of folding doors on the top. The various partitions into which the well under the !id is divided were intended for combs, powders, pstches, and other accessorics demanded by the toilet of fashion. The glass, whach is fitted into the well, rises on hinges in front and is supported by a foot fixed in the back. These articles were made in mahngany, but the cheaper woods also were employed.
In the 19th century the drcssing table became an essential piece of furniture, but many of the tables manufactured in the latter half of the century are of poor design, especially those made to form pieces in hedroom suites of heavy so-called Victorian style.

Modern Dressing Tables. At the beginning of the present century the dressing table was ncarly always bought in a suite of bedroom furniture, and was of the duchesse variety with mirmor attached to supports rising from small drawers on either side. These were manufactured in designs hased on Jacobean, Chippendale. Sheraton and other styles. While there are still many suites made in both modern and antique styles in walnut, mahogany, oak and other woods, and also in painted and lacquered furniture, separate picees are often again preferred, knee-hole and drop-end tables are utilized with separate toilet mirrors, or the dressing table takes form as a corner or wall fixture. Extremes are seen in Figs. 3 and 4 of modern dressing table treatment, showing the severely plain and the daintily trimmed.

The wall fitment of bracket shelves with a drawer on either side of the mirror is both practical and space saving. It would be an excellent arrangement for dreasing table
accommodation in a small dressing room or the article just mentioned (p.230). The Joint Martise cte Fig 9 showa the base in a study bedroom. The other treatment centre mirror is hung with special brass move(Fig 4) is an exampie of a fashion revived from menta made for the purpose, and the side Victorian dave This particular dressing table mirrurs are hinged with ordinary brass butta is of painted wond The curtain is made of let into the inirror framing. art-ailk taffeta to match the bedspread in the roon, and trimmed with silver braid. The top of the table has a scparate cover of the taffeta under plate glass These petticonts for tables can be carried out in a variety of materials suitable for elaborate or simple lurnishing schemes. With transparent fabrics, such as spotted and organdie muslins or voile, a separate lining of sateen is required. In country hedrooma chintz or cretonne dressing table petticoats may matoh the curtains Such waslable materials can be made up as complete covers with topa to fit the corners of the tables and the petticonts gathered on at a depth of about 6 in , or separate tops may he made edged with a 6 in. frill. the petticuat being attached to the table underneath the frill Sumetimes the petticoats have tiers of scallops, or three tiers of contrasting colnurs. as, for instance. three shades of ruse pink voile on a pink sateen fuundation

The most useful dressing table, with ample accommodation for all toilet requisites, is certainly the pedeatal style, as shown in Fig. 6 eapecially when painted to matoh the woodwork of the ronm or carried out in limed oak or pickled walnut, or other wood to suit the rest of the furniture.

Construction of a Dressing Table. Adress. ing table of the more usual type has two or more drawers with mirrors above. The general construction may be gathered from the article on Chest of Drawers ( p .230 ), which also deacribes a man's dressing chest with shaving mirror When making a dressing table with framed three-fold mirror it is important that the stiles or uprights of all three mirrors should be marked out together. to ensure uniformity in size. The method of framing and fixing the glass is indicated in

Dressing Table. Fig. 1. Late $\begin{aligned} & \text { 18th century example of the piece in satinwood. Fig. 2. Reproduction of a William } \\ & \text { and }\end{aligned}$ and Mary dressing table, with triple mirror, in walnut

1. Vietoria \& Albert Museun, S. Kensington; 2, courlesy of Gill \& Reigate
might be made of 1 in whitewood. the boards being glue jointed to the requisite width. The ends are dovetailed to the top and bottom, or in a simpler form of construction these parts might be tongued together. The drawer rail and runners are grooved to take a dustboard, the rail being tenoned to the end, as shown in Fig. 10. The runner is housed to the end, and enters the groove of the rail with a stub tenon. The back of the pedestal (Fig. 8) is of plywood,
The two driwers may bo made up as described in the articles Chest of Drawers and Drawer, the relative depths being adjusted to taste. The handles are shown in Fig. 10. The mirror is 6 ft . by 2 ft . or so, and may be framed up in the manner doscribed in the article on Cheval Glase. The method of securing the glass is shown in Fig. 13. The tubular electric light fitting may be obtained fromi any electrical dealer, a switoh being fitted inconspicnously under one of the bracket shelves. A white or cream coloured switch
would be suitable. Of course, one of the existing lights might be converted, when the switoh in its usual position near the donr of the room would control the mirmr light. The mirror is attached to the wall with plated brackets and screws utilizing rawlplugs

The wondwork of the pedestals, stool. mirror frame and bracket shelves should be cleaned off nicely and prepared for painting One of the cellulose enamels would be eminently suitable for this job, the edges and details being finished in coral pink or delft blue. say, and grev for the ground. One or more coate of cellulnse undercoating should be applied to the wond before the colour coat and on an open grained wood a cellulose paste wood filler night first be employed with advantage.

- A rubher-net brush must be used, as the solvent in the enamel will lonsen the hairs of the ordinary sort of brush. The brush should be used in one direction only in applying the enamel, and on vertical surfaces the strokes should be from top to bottum, ns far as possible

DRESSMAKING. This requires a know. ledge of the correct methods of cutting out and sewing together the various parts that make a garment, though the anme main principles govern the making of all clothes

With regard to cutting out the garment, which is often done with the aid of a paper pattern, it is necessary to know how to set each part of the pattern correctly on the material, so as to got the right hang to the garment.

Fitting and pressing are very important complements to sewing and making. For fitting purposes the garment is roughly put together in the first instance with temporary stitches, known as tacking, and, after the arrangement of other minor details, the garment is tricd on the wearer for the fitting The seams, at this stage, are adjusted to fit the wearer more correctly, and the exact length estimated.

After fitting the seams are fixed permanently. durable stitching replacing the tackings, while the pressing, finishing, and trimming are also done. Presaing in itself is a highly important factor, and can easily make or mar a garment. Various stitches are used in the sewing together of the dress. Simplest of all are the temporary stitches used at the first stage, these not only including tacking as just

Dresgang Table. Fig. 5. Modern design in Ggured oak with a irameless triple mirror Courtes/l of Williamson \& Cole. Lid

Dressing Table. Fir. 6. Two movad e pedestas containing drawers glank a large mirror on which is a tubular shaped light. Small shelves carry toilet requirements. and in front is a dressing stool
described, but also basting. The permanent stitching which replaces the tacking may comprise machine-stitching, running, hemming, gathering, over-sewing, eatch-stitching, herring-boning, etc.

With regard to machine-stitching, it is very mportant that the dressmaker should have a thorough knowledge of the working of a sewing machine, as some models can be adjusted to do all kinds of stitchery, such as hemming, also decorative or trimming stitches: for example, tucking, embroidery, openwork. hemstitching, etc. The sewing machine in fact, is one of the most important tools of the dressmaker. Others include scissors in two or three sizes, sewing needles in mixed sizes, pins, white and coloured tacking cottons, and ordinary sewing and machine cottons and silks, thimbles, buttonhole twist, an inch tape, pieces of tailors' chalk, llat irons, and nn iron-ing-blanket ; also a sleeve-board on which to press sleeves, and a skirt-board for skirts Hooks and eyes, fasteners, etc., can be bought as required. A dress stand should be included.

How to Learn. As a business, dressmaking offers possibilities of a good livelihood, if a thorough knowledge of all its branches is acquired. In order to obtain this, the would-be dressmaker can enter a dressmaking tirm as an apprentice, and afterwards pass through various stages, until she becomes a full hand. capable of working without supervision

Another way of learning dressmaking is in trade schools. There are several of these in large industrial centres, such as the trade schools of the L.C.C. in London, into which a girl may pass directly she leaves achool. In these she is taught every branch of the business, the course, when completed, enabling her to take a place in any house of business. Dressmaking classes are also held at various technical institutes throughout the country for those who cannot afford to give the time for an apprenticeship.

Anyone with an intelligent acquaintance with ordinary needlework will find it possible to make her own clothes at home, with the aid of the various fashion journals now on the market. These journala supply paper patterns of various garments, together with diagrams and instructions showing how to cut out in
material and make up. while the $y$ often include in addition practical articles on various aspects of dressmaking See Cutting-Out.
DRESS STAND. A dress stand is a frume of light wond, or wire, partly covered with canvas or drill made to the measurement of the figure, upon whioh a dressmaker drapes and fits a gown. Dress stands are $h$, le bought in all sizes or made to order: those inade in wire are sometimes partly collapsible and adjustable.

A stand padded to about 9 in below the waistline is the most useful type for fitting on and moulding a bodice or coat
DRESS SUIT. This term 18 given to the suit of clothes worn by men at dances dinner parties, and in the evening Except for thewaistcoat, which may be white, a dress suit is invariably of black cloth See Dressing.
DRIED FRUIT. These Iruits especially currants, sultanas, and raisins constitute important ingredients in many kinds of puddings. cakes and fancy breads Among the varieties dried are apples, apricots, figs, peaches, pears and prunes Before nse, these should be washed thoroughly and soaked for 24 hours in cold water When they are ready to be conked stew them slowly until tender in the water in which they have been soaked. adding sugar to taste.
Fruit drying may be done at home without the aid of any special equipment, but if the result is to be successful the iruit must be perfectly sound. Apples should be peeled, cored and cut into rings. and if thev are not

Dresging Table. Figs. 2-13. Diagrams showins zonstruction of the pedestal dressing table set
to be dried immediately, immersed in 2 quarts cold water to which loz. salt has been added. to prevent discoloration.
Pcars, pceled and cut into hal ves, should be left in the same solution for 15 min ., while, except for stalking, cherries, plums and damsons need no preparation, though the two last-named are better if pricked before heing placed in the oven. The oven itself should be cool, and the drained fruit placed in it on an ordinary wire tray. In order that the fruit may not scorch, the temperature must be kept low and the fire not allowed to burn fiercely. The time of drying will depend upon the kind
of iruit used. apple rings requiring about 5 bours and halved pears a whole day The smaller fruits will not take so long. See Compôte; Currant: Fig: Prune; Raisin.
Dried Fruit Pudding. When fresh Iruit is diffioult to obtain, this pudding is specially welcome Matie it by washing 2 or. each of

Irequently to prevent it from hurning. Leave it to cool slightitly. then pour it over the fruit but do not mix them together. Whisk together to a stilf froth 2 whites of eggs and 1 gill cream. fold into the mixture about 1 teaspoonful castor sugar. and then shake it on top of the emolina etc finally decorating it with strips of angelica If a plainer pudding is required, the cream and white of egg may be omitted
DRIERS. Driers is the namegiven to a group of preparations used to ensure the proper drying of the fatty oils in pnints and varnishes. Litharge (oxide of lead), minium (red lead), and white lead are those usually
drice apple rings, dried pears and dried poaches, and 3 oz of raisins, cutting each of the poaches and pears into 3 or 4 pieces. Put all the fruit into a basin, cover it well with cold water, and leave it to soak for 24 hours Then put it into a saucepan with the water in which it has been soaking. Add 3 oz Demerara sugar, and cook the fruit until it is quite enft. Then put the fruit into a piedish, and continue to boil the syrup for a fer minutes until it thickens. When cold, pour it over the fruit.
Put a quart of milk into a sancepan over the fire, sprinkle in 4 oz semolina, add the grated rind of a small lemon and 2 dessertspoonfuls granulated sugar, and cook nll together until the mixture is soft and creany. stirring it

# Drills and Drilling Methods 

## Boring Tools for Use on Metal

This contribution is one of the group that includes Bent Iron Work: Metal Work. Sec also Bit; Boring: Brace; Chuck: lathe: Rivet

A drill is a small, sharp-pointed instrument with cutting edges, fixed in a stock which is revolved to pierce a hole in metal
Drills are made in two chief grades, carbon steel and high sueed steel, the latter removing metnl faster. For practically all ordinary anateur purposes the carbon is quite satisfactory, and costs considerably less.
For all-round use there is the twist drill, so named from the shape of the double helical Huting, made from to in. to 1 in . or more in diameter. For drilling holes in thin sheet metal and any holes in brass or copper, the straight Huted drill is preferable The flat, arrow head, and diamond point drills are useful, especially in the larger sizes, for drilling holes with n ratchet brace, and are equally effective on iron, stecl, or brass. They are also convenient for use in a lathe, esperially those made from tlat strip metal.
Expansion drils comprise n short twist drill fixed in a ahank, and an adjustable cutter, for drilling large dianneter holes in slieet metal, as when making holes in hot. water tanks, cisterns. and other houschold appliances. Centring drills are used to start the hole when intending to drill one of large diameter, and also to form a properly sloped centro on the end of a bar to be mounted nad turned hetween the centres of a lathe. l'in drills have a central pin or pilot, which guides the drill while it counterboros or enlarges a hole already drilled The general form is shown at Fig 5 .
The limit of size that oan be operated effectively with a hand drill is seldom ovel IG in to $\frac{1}{}$ in. dinmeter. A breast drill will tackle holes up to is in to in in diameter ; a small band-power hench dilling machine will handle diilla up to $t$ in diameter, nnd a powerful hand-power drill of the blacksmith's type will tarkle work up to ${ }^{8}$ in. in diameter. A treadle drill will take up to this size, but for

Inrger sizes a power-driven machine is required Drills are purchasable in millimetre sizes, in letter sizes corresponding to the gauge sizes of wire, and in ordinary fractions of an inch, the latter being the best for general purposes Very small drills are made for watch and clock work and similar delicate apparatus
There are a number of different types of stock, but the amateur may well do with a
hand drill as illustrated at Fig. 3, eflective up tob or ${ }_{i}{ }^{3}$ in diameter holes An example of a powerful wall or bench drilling machine is shown at Fig 4 A reciprocating drill onthe $\wedge$ rehimedean principle (Fig l) drives the drill buth on the upward and downward stroke, by having right and left hand threads formed upon the spindle.

Having selected the right drill for the size hole, place it in the chuck and screw it ip tightly Next inake a centre punch mark exaotly on the centre for the desired hole Then, using a hand drill, hold this so that the drill is perpendicular and in an axial line with the position of the hole, Fig. 3) lintate the drill by turning the crank liandle with the right hand, while keeping the drill and the stock in position with the left hand Exert sufficient pressure with the left hand to make the drill cut properly; this will be evident from the turnings, which should curl up and away fros the drill if working in steel or iron, or in the form of chips or powder from brass or cast iron.

It is necessary to hold the drill stocti steadily, and to rotate the drill at the correct apeed, which varies with the size of drill and the nature of the material Using a $\frac{t}{}$ in diameter drill on steel, the speed would lie about 300 revolutions per min. : on cast imn, ahout 200 revolutions; and on brass, about 650 Smaller sizes of drills should be miated faster, and larger sizes more slowly. If the drill turns off nico clean chips or shavings, all is well ; if not, try a different speed, with greater of less pressure on the drill Drills should be lubricated with light machine oil while working, except on cast iron. which drills dry

The Breast Drill. Breast drille are used in the same way, but pressure is brought to bear by leaning the waight of the body on the pad at the top of the stock, and holding the guide handle with the left hand. The work nust always be held securely, as if the work moves the drill will nlmost certainly be broken. Drills should not lie used to enlarge a hole that is only a little smaller than the drill, as the hole is then apt to jam or tear, or smash the drill A reamar is the proper tool to use for this purpose. If a large hole has to be made, drill a small pilot hole first

The correct shape of the cutting edges can only be maintained by nccurate grinding. Fssentials are that the angles of botli cutting edges are alike, that their length is uniform, and that both faces slope back at the same angle The use of a drilling gauge to teat these
 it drives the drill on both opmard and downward strokes. Fig. 2. Straight shank twist
drill with double helical Guting, the best for all-ronnd use. Fig. 3 Hand drill
in use Fig. 4. Powerful bench two-speed drill in use Fig. 4. Powerful bench two-speed drill
angles is recommended, hs well as an ordinary drill or wire gange plate for testing the size of drills.
laper is drilled with $a$ tubula drill shaped as shown in Fig. 10 A serviceable drill for making holes in bricliwork is made from iron gas harrel, shaped as in Fig. 9 Marble can be drilled with a twist drill.

Glass is drilled in several ways.

chuck on the tail. stock. Flat drills are generally used in a suecial holdeı lield in the slide. rest.

DRILL: In Gardening. The drill is a straight furrow, made in the soil, in which secds are sown It varies in depth from hall an inch to 2 in.. aceording to the wize of the seeds. A wide. llat drill is usually made for large seeds, p.g preas and heans, and a the take a piece of brass double row is sown. the distance betwern tube of the desired diameter and cqual to that the drills depends on the height of the plants of the hole. Revolve the tube slowly, and use carborundum powder moistened with oil, applying the drill tube to the abrasive. Which

DRILL: Linen and Cotton. White linen drill, so much used for men's'suits and ridingbrceches in the tropics, owes its popularity to its coolness in use and a great durability which enables it to withstand frequent washing Ton substantial for dresses, it is excellent for hotwesther inilor-miale costumes, and for boys' sailor suits Blue drill is also ohtuinn ble

Drill is more largely made in cotton tha: linen, and khaki cutlon drill used for the trompy in liclia and extensively for civilian wear in the Colonies. is servicpable also for summer wear in England solid and cempact, didls are woven with twilled or sateen laces, and wear well, because of the strength and number of threads forming the surfacc 'The closeness and solidity of their structure make then some

what diflicult to sew. drills make excellent pocketings, and remnants s!ould lie saved to that end. Certain lighter cotton drills, called drillettes, are made tor this purpose.

## Drill : Healthy Exercises for Childden

## How to Secure Balance and a Good Carriage

Other information on the important subject of physical finess will be found under the headings Breathing: Exercise. See also Child; Diet; Food

Suitable exercises keep every muscle in
good condition, strengthening weali anes and making supple those which are tight. Girls especially suffer from weak abdominal muscles, and very often those across the shoulders and the back of the thighs arc too tight. Exercises also help to attain a perfect balance which is the secret of good deportment.

No child should be allowed to overdo these exercises, and they are hest nerformed for five or ten minutes hefore breakfast. Those illustrated have been chosen because they give the maximum result with the minimum amount of expended energy. Hence their advantage over skipping exercises, for exainple, in which an enormous amount of energy is spent in lifting the body off the ground so frequently, much extin work is placed on the Leart, while comparatively little benefit accrues to the muscles.

At school, exercises are usually performed to a rbythmic time, -a piano being used, with the beats well marked But at home, it is
quite enough to clap the hands while the child is getting into the rhythm, and afterwards it can be dispensed with, the youngster doing the counting. Naturally, this rhythmic time is not absolutely essential, but it will he found that it not only prevents the exercises from being rushed through, but gives a certain amount of grace to them as well. Also, a child enjoys doing a thing to rhythmic measure more than without this aid.
Fig. 1 shows an exercise for developing balance. This is most valuable, not only for deportment but for exercising the muscles as well. When the child has become more efficient at balancing, the exercises can be performed with a hook resting on the head. If this stays in position it is a proof that the balance is being strictly kept. Count two for each movement.

First, hands on hips and lift the left leg, pointing the toe; raise the leg and place the hands on the shoulders. Keep the leg raised and stretch the hands sideways. Lastly,
lower the leg and hands, then teet together all in the one count. Repeat with the right leg. When balance has become more assured, while the leg is raised, the hands can be slretched torwards as well as out wards. making it a longer time on the one ley.

The last exercise cill be followed up by the simple une of raising and lowering the heels (Fig. 2). This is esplecially good for the arch of the foot and lor the loot museles, and is also $n$ corrective for Hat fret. Count two for mising the heels and two for lowering. and repeat soveral times. Another exercisc lor the same purpore consists simply of "feet apart and feet together." Count tivo for each movement and repent several times as in the last exercise

Fig 3 illustrates an excreise tor strengthening the back and ablominal muscles Suoh excreiser, us has already been noted, are particularly important for girls. whose abdominal muscles are often weak. The tirst movement is feet apart with a jump. then with a swinging movement raise the two hands and lowet them, taking hold of the ankle with hoth hands, as in the illustration Next body upright with hande oulstretched then repeat the swinging movement, taking hold of the other ankle. Butly upright again with hands outstretched, then hend. taking hold of cach ankle with either haml. lastly, stiaighten up, hands outstretched then down, jumping feet together

The next exercise (Fig. 4) is for the neck muscles and for developing a good carriage for the head. The first movement is done in a sitting position with the legs lucked underneath, as in the photograph. Stretch out the first hand and look towards it, giving the head a smart turn and hold it erect. With the next count of two, place both hands on knees, now repeat the lirst movement with the other hand, taking care of the position of the head. Place hands on knees for the next count of two : now bend the head right down between the knees (as in Fig. 5), counting two: then up again, counting two. Repeat this three times, for this is the most important part of the exercise Now stretch out the legs and stand.

If the child should tire at all during the exercises or after, she should lie flat on the ground with the knees bent and the legs as near to tho body as possible, as in Fig. 6. It is an excellent position of completo resting. and should be used for a tired child even if it is not connected with drill.

The trunk muscles are most important and should he given a chance to be in good condition together with the other muscles. The exercise shown in Fig. 7 is quite simple, but it must be done smartly, with head erect and hack straight. 'Ihis does not mean quickly ; the count of "one." "two." is to be used i" this, as in the others. First, jump the feet apart and place the hands on hips. Now stretch out the hand straight and turn it with the trunk backinards as in Fig. 7 Hands at sides and eyes front. Now repent with the other hands, doing it to time, yet smartly. Hands at sides and jump the feet together. Repeat this three times.

Another exercise for abdominal muscles is the one illustrated in Figs. 8 and 9. This is rather more strenuous and should not be performed more than twice at a time. First lie flat on the back with the legs outstretched and the hands underneath the head, or at the sides, ns shown. Now begin the counting "one," "two," raising the left leg upwards and pointing the toe. Lower leg to the count of two, then hegin with the other leg, pointing toe upwards, then lower. Next raise the two legs together and lower. The last part of the exercise is to draw the legs up, placing hands in front, as in Fig. 9, then on the ground to raise the body. It must be remembered that

yome of these movements, such as the last one, nre to aid the counting or the rhythmic effect. They are not really essential in the sense that they arc conditioning the muscles. Each exercise has its share of both the one helping the other.

With regard to drill costunse, most schools bave their regulation dress, which consista of n y ymnasium tunic and blouse, such as is worn by the child in the illustrations. This can, of course, be varied, the yoke being slightly different, or a blouse with a kilt may be worn. For exercises nt bome any dresy and knickers will do providing they allow free movement.

DRINKING. All the tissuce of the body contain a certain amount of water, and ill addition to this there is a Inrge quantity of free fluid in the form of lymph, cerchro-spinal fluid, and blond. If the body is deprived of water, the tissues become dry and shrunken, the blood is thick, and the circulation sluggish. The body thus refuires to contain a certain amount of water to maintain healtla and life

The natural beverage for mankind is water. and its place can only be taken to a limited extent by other beverages. Milk can replace it largely when the solid diet is restricted, but is usually only drunk in such quantity when it is a matter of duty to one's health, while tea, coffee, and alcobolic drinks in large quantity are injurious. It is is mintter of importance to health that a sufficient supply of water should the taken into the body daily. Water enters into the composition of the tissues and provides for the circulating lluids: it forms more than two-thirds of the body weight. On an avernye nbout $3 \underline{2}$ pints are necessary each dav. and a certain amount of

Drill. Firs. 1-9. Exercises for chlldren des/gned to keep the mascies in good condition and to ensure rood balance and carriage of the body. They are described on the previous page
this is taken in solid food. But the bulk of the day's supply should take the form of beverages.

Tea and coffee arc consumed by most people and are beneficinl, apart from their affording water to the hody, ind harmless if they are tivien properly prepared and in moderate nmount. Cold weak tea is a good thirst quencher, and this or oatmeal water proves very grateful to those who are engaged at hot, Inborinus occupations which cause free perspiration. Milk alone or with sorla water should be taken freely by those whose nutrition is poor.

Alcoholic liquor, if taken as spirits, should be froely diluted, as neat spirit drinking is a fruitful source of gastric catarrh : the same is

ruo of takilly lange umonnts of alcoholic liquots in any form, especially when they are taken apart from food. Beer or light wines are agreeable heverages and tend to increase the appetite and aid digestion, but the heavier brands should he taken sparingly. As summer drinks lime juice or lemon juice in water or sodn water are very wholesome. Cider makes another wholesome drink and appears to bencfit some people who suffer from rheuma tism. The natural table waters may be taken alone or as diluents of other liquids.

Only a moderate amount of liquid should be taken at menls, and then only when there is no food in the mouth. A liberal allownace of fresh, wholesome wnter may be taken with great bencfit in botween meals. It is a mistake to take liquids very hot, as they may easi!y cheok the llow of gastric juice; nn imminderate use of acid liquids, e.g. lime juice, lemonade, etc., in hot weather is a bountiful source of dyspepsia

Drinking Water. Not only must drinking water be free from the gross contamination which sets up diseases like typhoid and alimentary dianoders, but it must not contain too much mineral matter. Gross contamination may gain access to the water not only at its source but also when inside the house.
The source from which the water is drawn should first of all he considered, and the following classification is useful :
Wholesome $\left\{\begin{array}{l}\text { Spring water. } \\ \text { Deep well whter. } \\ \text { Upland sulfere water. }\end{array}\right.$
Suapiclous $\begin{aligned} & \text { Badly stored min water. } \\ & \text { Surface water from cult }\end{aligned}$
bangemus $\left\{\begin{array}{l}\text { Unflitered river water }\end{array}\right.$
In the homo, drinking water should be stored in vessels or cisterns placed in n light and well-ventilated position and kept scrupulously clean. Where there is a main supply, drinking water should never be drawn from the cistern but always from a tap on the riaing main. In districts where rain water, collected from the roof, is used for domestic purposes it should be atored in a covered concrete tank. It should not be allowed to stand in confact with metallic lead, as soft waters are often able to dissolve lead, which may causc poisoning.

Where the source is dangerous or there is suspicion that the water is polluted, ns happens in times of epidemic, it may be purificd at home. This is done most conveniently by bringing the wnter to the boil. Heating it in this way will destroy all germs likely to
produce disease, and has the added advantage of rendering hard water softer than it was before. Some people object to the flat, vapid faste of boiled water, but this may be counteracted by pouring it backwards and forwards several times from one jug to another. This causes the air to circulate once more through the water, lack of oxygen being responsible for its lifeless taste See Alcohol : Beer: Cider : Coffee; Diet: Filter: Milk: Tea; Water: Wine : etc
DRIPPING: How to Prepare.
The dripping from beef is less hard when cold and devoid. of the tallowy and sometimes even rank flavour of that from mutton Spread on bread or toast, beef dripping is a nourishing food often given to children. In cookery, for frying, etc., it is invaluable, and is sometimes used for mixing with the flour for making cakes and pastry.

There are two methods of preparing beef dripping. The first is as follows. After a joint of beef is roasted, pour all the melted fat from the baking-tin into a jar or basin. Pour about a gill of hot water on to it, stir it well, and leave it until it is set and hard Then raise the cake of fat, scrape off any soft or dark part from under it, and usc as required. The water under the fat will often contain a little of the gravy from the meat, and should be saved for stock. If the fat is left on the water for long, it will absorb some of it and go sour. The second method consists of putting all the dripping from the joint in a saucepan with about $\frac{1}{2}$ pint water. Boil it with the lid off the pan, until the bubbling ceases; then take the pan off the fire and cool it a little Pour off the fat, from which." by means of the boiling, and its resultant evaporation, all water has been extracted, into a olean basin and it is then ready for use. Mutton and pork dripping are prepared in the same way. See Clarifying
DRIVING. In driving a single horse the reins should be taken in the left hand, the left or near side rein being held between the forefinger and thumb, and the offside or right hand one bet ween the second and third fingers, the palm of the hand being uppermost. The reins should pass out under the remaining fingers, which should close tightly over them. The arm should be held at almost a right angle across the body with the hand about 6 in. in front of the bottom button of the waistcoat. This will enable the right hand to be used casily when it is neoes sary to enploy both hands, while it can also be used when the whip is required. In driving, the whip should always be used from the wrist, not from the arm

The seat should be above or at least on a level with the horse's head. It should be placed so that the driver can, if necessary, use his lega and feet to nullify the pull of the horse The reins should never be allowed to hang loosely, although it is a mistake to grip them at all tightly. The driver should always feel the horse's mouth. The term hands used in connexion with driving and riding refers to the exact weight and pressure put upon the horse's mouth in guiding him and the give and take of the driver's hands

In driving a pair the reins arc held in the same manner, but as there are two horses to control instead of one, the tank is more difficult, because they may not pull equally.

In Great Britain the rule of the road for driving is to kcep to the left. If another vehicle is overtaken, the one that overtakes
t must leave it on his left, himself taking the right. See Bit ; Horse : Motor Car ; Reins, etc
DROPSY. An accumulation of fluid, derived from the blood vesscls, in the tissues and in the cavities of the body constitutes dropsy. This takes place when the preseure in the veins becomes high, when the vessels' walls are damaged and made more permeable, and when the blood becomes thin. The first condition occurs when the veins are obstructed or when the heart is feeble and oannot drive the blood efficiently through the veins. The second condition exists when the oiroulation is poor or the blood thin and when poisons are present in the blood stream; and the third in anaemio and debilitated states
When it affects the tissues it is called oedems, and if superficial causes visible swelling. If firm pressure is made on the swelling, particularly over bone, a depression is made in the skin by the diaplacement of the fluid, and the skin shows pitting Oedema of the leg may be caused by a garter heing too tight, and it also occurs in varioose veins Oedema may occur in both legs in people who have been on their feet all day, particularly if they are somewhat ansemic. If there is definite anaemia and debility, it may appcar even when the patient is in bed. The same thing applies to the dropsy of heart disease, which, eventually, may appear all over the body. Dropsy also occurs in Bright's disease
Treatment of dropsy depends on the cause. but includes rest, and in some cases messures directed to increasing the discharge of fluid from the body by diuretios (q.v.).

## Dropwort. See Spiraea

DROUGHT. The effcots are more apparent on heavy land than upon that of lighter texture, but the harm to crops during hot, dry weather is in both cases shown in starved and stunterl vegetation During days of drought the value of dcepcultivation becomes apparent, for it is then that the hoe may be put to work to stir the surface carth to some depth. and thus prevent undue evaporation

A thorough and frequent pulverization of the soil a few inches down is one of the best aids possible to counteract in measure the effects of drought, and there is no implement more suitable for the purpose than a three or five-pronged oultivator. A thin covering of some non-absorbent retentive substance is also of assistance, and one of the handieat materials for this purpose is short grass mowings from the lawn.
Watering should be done in the cool periods of evening or early morning. Effectual watering of the soil, overhead sprinkling,
or spraying, to freshen leaves through their pores and wash dust from the foliage, followed by surface stirring and mulching, yield success in droughty seasons. See Soil.

DROWNING: The Treatment. In all cases of death from immersion in a fluid, what oftenest happens is that the fluid is drawn into the air tubes and produces suffocation. It will also be found that there is a large amount of Huid in the stomach. In some cases death is not caused by asphyxia, but by shock, due to cold or fright, or exhaustion from prolonged efforts to keep afloat.
The first thing to do in the treatment of the apparently drowned is to lay the patient on his back, turn his head to the side, examine, and, if necessary, clear the mouth and throat of mucus or anything else found there. Then, without delay whatever. carry out artificial respiration. No matter though the patient
gives no sign of life, and has been immersed in the water for a long time, a persevering effort should be made to resuscitate him

When he commences to breathe of himsell, the rescuer's efforts should be turned to en. couraging the oirculation and bringing back a natural warmth. The patient's wet clothes should be got off, the limbs should be chafed, the direction of the rubbing being towards the heart, and he should be well wrapped in hot blankets, while hot-water bottles, adequately protected against burning, should be placed in the armpits and at the feet. A few teaspnonfuls of hot water may be given, and thereafter a cup of very hot black coffee, or a $\frac{1}{2} \mathrm{oz}$. of whisky or brandy, diluted.
The patient should be kept in bed for at least 24 hours, to allow the heart to recover from the results of the strain thrown upon it. See Artificial Respiration

DRUG. The continuous taking of certain drugs is apt to produce an irresistible craving for them, despite their injurious effect upon both mind and body. The commonest instances are addiction to alcohol, and smoliing. The less frequent drug habits, such as the taking of opium or cocaine, may originate in taking the drug in the first instance under medical orders
To check the serious growth of the drug habit, an Act of Parliament was passed in 1925 which aimed at the suppression of illicit traffic in cocaine and other dangerous drugs. More over, certain drugs can only be obtained by the general public on presentation of a doctor's prescription, which is afterwards retained by the dispensing chemist. The habitual drugtaker can be certified like an habitual drunkard.

When a drug habit has bcen formed, the only satisfactory method of 1 reatment is to get the patient into an institution where it will be impossible to obtain the drug Tonic inedicinal treatment may form part of the cure, but moral treatment is what is really valuable. in the form of helpful advice and encouragement. Little or nothing can be expected from nostrums. See Alcohol: Cocsine; Opium ; Poison ; Tobacco, etc.

DRUGGET. This is a common felt or coarse woollen fabric, frequently printed with a pattern on one surface only, cither used as a protection or substitute for a carpet. A lighter glazed linen drugget is sometimes laid to protect stair carpets and is used for table covering.
DRUNKENNESS. Over indulgence in alcohol causes loss of control over the movements of the body and over the speech, which becomes thick and indistinct. The same loss of control affects the mind, and the mood may become bellicose or maudlin and silly. In some cases a condition resembling somnambulism results. Frequently nausea and sickness ensue. Drowsiness manifests itself sooner or later, and may deepen into coma. This state is very like that of various other oonditions, e.g. apoplexy, uraemic or diabetic coma, poisoning by other narcotic drugs like onium, chloral, etc.
It is often a matter of difficulty even ior doctors to distinguish between these cun ditions and drunkenness, and obviously the greatest care should be exercised in dealing with such persons. It should not be hastily assumed that because a person smells o drink he is simply drunk, for he may be both drunk and ill. It is nccessary to emphasise this point, as serious mistakes have been made and people suffering from apoplexy have bcen left to die because they were sup posed to be simply drunk. A doctor should be summoned at once and in the meantime the person should be kept warm if necessary.
In the treatment of acute drunkenness the patient should be made to vomit and wash out
his stomach with large draughts of tepid water. Strong coffee or sal volatile in teaspoonful doses in water may also be useful. Chronic drunkenness is very difficult to treat and will fail unless the victim can be induced, by beginning his cure in an institution, to give up alcohol altogether. Some of the graver results of chronic drunkenness are sterility, multiple neuritis, a tendency to apoplexy, delirium tremens and insanity, and the likelihood of epilepsy in the drunkard's offspring.

The Legal Aspect. In law drunkenness is a punishable offence in the following circuntstances: being drunk in a highway or public place ; being found drunk on licensed premises: being drunk and disorderly or rintous in a highway or public place; being drunk and in possession of loaded fircarnis ; and being drunk when in charge, on any highway or public place, of a carriage, horse, cattle, or stean-engine. It is also an offence to be in charge of a motor vehicle while under the influence of drink to such an extent as to be incapable of having proper control of the vehicle. A driver may lec convicted of this offence although he is not drunk.

Where husband or wife is an habitual drunkard, the other spouse has the right to apply to a magistrate's court for a separation order. An habitual drunkard is a person who not legally a lunatic is yet, by reason of habitual drinking, at times dangerous to himself, or herself, or to others, or incapable of managing himself or herself. or his or her own affairs. A person who, in intervals of sobriety, is quite harmless and capable of business, may yet be an habitual drunkard. See Alcohol ; Cirrhosis: Deliriuın Treınens: Dipsomania; Separation Order.
DRY CELLL. The term dry cell is applied to the unit of all forms of primary electric battery in which the electrolyte is in a paste or semisolid form, as distinct from the liquids used in wet batteries and accumulators. See Battery.

DRY CLSANING. Soiled garments of a delicate texture which cannot be subjected to the ordinary laundering processes may be sent to a professional cleaner, or the work can be done at hoine, special care being taken when using petrol or other highly inflammable cleaning agents.

Light coloured cloth garments are simply treated by the application of kitchen salt on a pad made from a large piece of white linen or nainsook. Lay the garmient on a table, and zcatter salt over it with a liberal hand, spreading it gently with the finger-tips until a thin powdering of salt is evenly distributed over the entire surface. Next take the pad and rub the salt into the cloth with long downward sweeps, not round and round, since this tends to roughen the surface and destroy the sheen of the matcrial. Finally brush out all the salt, and the cloth will be found quite clean. If there are any badly soiled parts, such as on the hem of a skirt or the cuffe and collar of a coat, repeat the process two or three times.

Silk and satin garments are thoroughly cleaned by the following method, which should on no account be used except in the open air. Spread a clean shect on a table placed out of doors, and have ready two large wash-hana! basins, a tin of petrol, and a soft-bristled nail brush. Half fill one of the basins with petrol, dip the garment into it, giving it a gentle mueezing, then spread it out on the sheet, and brush it all over with long downward sweeps, going the right way of the material, from top to bottom. Rinse and squeeze it in the petrol again, and rub it vigorously with a folded pad made of white cloth. Pour some clean petrol into the second basin, rinse the garment thoroughly in this, squeeze it well, and hang it up to dry in the open air. Pull the garment carefully into shape before hanging it up. When quite dry and free from the smell of petrol, it may be brought indoors and ironed.

Cleaning Furs. Most furs, when really dirty, can be cleaned with hot bran, but this should rarely be necessary if they are wiped with a damp towel immediately after wearing. Children's white furry caps, coats, and capes can be cleaned with cornflour, which is scattered thickly over the fur, rubbed with the tips of the fingers, and then brushed out with a soft, white-bristled brush. This process creates a great deal of white dust, so that it is wise to tic a large handkerchief round the hair and to conduct the operations in the bathroom, where the powder can be easily wiped away with a damp oloth.

It is easier to clean things the first time than the second or third. Surfaces roughen with use, and dust and smoke fasten more quickly. to a rough material than to a smooth one, and are also much more difficult to remove. For this reason the rubbing of the finger-tips on garments during dry cleaning operations should be done as gently as possible, and a hard brush should never be used.
Removing Grease Spots. Alinost all kinds of grease spots will yield to treatment with a hot iron and a sheet of blotting-paper, while fuller's earth, dry pipeclay, magnesia, and French chalk are also effective if spread over tho affected parts, left for a while, and then shaken off. Two applications are usually sufficient.
Another method of removing grease consists of putting a pad of clean cloth under the material, and sponging it on the wrong side with benzol, gasoline or tetrachloride. Use such cleansing agents at an open window and away from any naked light. To prevent the grease spreading as the spirit begins to dissolve it, surround the spot with a ring of French chalk, which acts as an absorbent. French chalk may be used with safety on any light coloured and delicate fabric. The article to be treated is placed on a clean towel, and rubbed all over with the chalk, extra attention being paid to those places where there are definite marks to remove. The garment should then be rolled up in the towel, laid aside for three or four days, and afterwards brushed lightly to remove all traces of chalk. See Clothes.
DRYING: Of Clothes. The ideal method of drying clothes is to hang them in the fresh air on a breezy day. Fresh air, and especially bright sunshine, have a bleaching aotion, and will remove stains and any yellow tinge caused by the soap and soda used in the washing process. More important is the fact that fresh air is a powerful disinfectant, therefore woollen and silk garments which cannot be disinfected by boiling can be rendered free from infection if exposed to fresh air.
In the country the washing may be hung in a meadow or small orchard, which removes from tho house windows a view of the necessary posts and line, somewhat unsightly in small gardens. Strong tall posts, preferably of oak, are required if there are no trees or other supports, such as a brick wall, to which the lincs can be attached.
Galvanized iron wire and hemp rope are the usual kinds of lines used. Rope lines must not be left out of doors longer than neccssary. as rain, with particles of dust and soot, soon causes them to become discoloured and rots the fibres. A soiled line is often responsible for dirty marks on clean linen. After use the line should be coiled up and put away with the clothes pegs, in a linen bag in preference to a basket.

Whoever is hanging clothes out to dry should stand with her back to the wind and peg with the garment facing her, this arrangement allowing the wind to blow well into the garment. Avoid placing the pegs in any very conspicuous part, e.g. peg blouses by the waist and not by the collar. Pillow-cases should be hung with the open end uppermost. Before jregging out, all garinents
should be turned if they are not already on the wrong side, in case the damp clothes inadvertently touch trees or bushes.

The ordinary clothes horse placed around the kitchen stove is a very general way of indoor drying. Woollen garments are the most difficult to dry indoors. Place these on a cciling dryer or on lines hung across the kitchen. Drying in front of the fire often causes woollen and flannel garments to shrink. When indoor drying is a necessity, open the windows and doors to allow a current of fresh air to pass through. This is the best alternative to drying in the open air.

There are fitted cupboards heated by gas, electricity, or oil specially made for drying clothes which are designed so that a current of fresh warn air constantly passes through the cabinct, and arranged that the heavy and moist air is extracted from the bottom. These are specially useful for flats and houses where there is no hot cupboard for airing clothes They answer the doublc purpose of dryer and airer. See Airer: Clothes Horse; Clothes Line: Laundry.

DRY MDEASURE. Dry ineasure is used for potatoes and vegetables generally, also for grain of various kinds. Analogous in some respects to liquid measures, it is as follows:

## ${ }_{2}^{4}$ gills pints $=1$ pint <br> 2 pints $=1$ quart 4 quarts al <br> 

$\$$ yecks $=1$ bushel
36 hushels $=1$ chalifron
A peck or stone of flour weighs 14 lb ; a bushel or 4 pecks of flour 56 lb ., and five bushels or a sack of flour 280 lb . A quartern (or quarter-peck) of flour weighs 3 lb .8 oz . There are a number of local bushels. A bushel of Finglish wheat is 60 lb ., of foreign wheat 62 lb ., of English barley 50 lb ., of oats 39 lb .

DRY MOUNTING. This is a process for mounting photographs and prints of any kind perfeotly flat on any kind of support. Between the print to be mounted and the card or other support a thin sheet of tissue paper impregnated with shellac is placed. This tissue can be obtained from photographic dealcrs. Heat and pressure are applied. under which the shellac melts and firmly cements the print to its mount. No moisture of any kind is required.
The amateur can obtain good results with the ordinary flat iron. A special electric iron is also available. To mount a photographic print by this method, take a sheet of dry inounting tissue of exactly the same size as the print to be mounted and lay it Hat upon the back of the print. Touch the tissue lightly at the two upper corners with the point of a fairly hot iron; this causes the tissue to adhere where it is touched. If the print requires trimming it should be done at this stage so that print and tissues are trimmed together.

Lay print and tissue down on the mounting card in its right position, lift the print and touch the tissue at the bottom corners with the hot iron, so that it adheres to the mounting card. The print is now ironed all over with an iron heated to such a temperature that water applied to it sizzles slightly, i.e. it should be just above the temperature of boiling water. If the tempersture is not right it will be impossible to carry out the mounting process succersfully.
The print should be covered with a sheet of thin tin or a piece of brown paper which has previously been well ironed on both sides, and the heated iron then applied with considerable pressure for about 15 or 20 seo., moving it about so that cach part of the print obtains heat and pressure. If the print is a large one the ironing will have to be done in portions. If the print adheres to the tissuc but the tissue does not adhere to the card, the iron was not hot enough. If the tissue adheres to the card but not to the print, the iron was too hot. See Mounting; Printing.

DRY ROT. The most prolific cause of dry rot is the use of timber in a wet condition, such as might be seen on new buildings when the timber is on the site but lies uncovered perhaps for montha before it is used. If such timber is then placed in position, certian parts heing built in the walls, often covered with mortir, there is no chance of it ever getting dry in a natural way

Combined with the nbove cause the ground on which the building is taking place is often inade up; that is. it has been used as a public tip, whereon any and everything imaginable has been deposited to fill it up to the required level for building

The house is kept down to as low a level as possible to save expense, and perhaps no earth is carted away from under the floors. The consequence is that the wet wood and the foul earth encourage fungus to start.
Preventive Measures. To prevent dry rot the timber should be kept as dry as possible. and if it cannot be kept under cover it should he so piled that the water will run off instead of soaking in. When timber is built into walls, allow it to lie on the bricks: any bricks which are built up to it or which lie on it should have no mortar intervening. Not only does mortar encourage the growth of fungus. but if the bricks come to the wond they will fit sufficiently slack to allow a certain air-space between. The mortar does not do this. Avoid the use of wond bricks. Even if put in dry they are unsatisfactory, but when cut out of the ordds and ends on the joh, usually sonking wet, and bedded in mortar like ordinary bricks. they are a fruitful source of trouble. It is better to plug the walls after: the risk will be practically nil.

Dry rot cannot be cured, but where the fungna has already got a hold it may be destroyed Take out every piece of wood which shows the least sign of being affected. The disense runs further on the inside of the wood than it does on the surface, and unless every trace is cut away it will certainly start again. Next clear out the fungus from the adjoining brickwork, from openings in the
walls, and from the bedding of all bonds, etc. The fungus and the affected wood should all he swept up nnd burnt to prevent the new wood from being attacked.

Before any old wood is replaced with new, the surrounding walls, the old wood left in, and all the new wood should be costed with an intiseptic solution, such as corrosive sublimate mixed fairly strong. This can be obtained from any chemist and nust be used carefully, being a deadly poison. See Wond.

DUBBIN. Dubbin is a greasy preparation for dressing leather and rendering it waterpronf, and is used especially for fishermen's bonts or for boots worn in wet weather. The dressing, which is not glossy, may be made by melting together tallow, 2 oz.: paraffin war, 1 oz. : and heavy mineral oil, 5 oz. and perfuming with a few drops of mirbane oil. Another recipe is to melt together Russian tallow. 8 oz .: paraffin wax, 1 oz ; cod liver oil, 16 oz ., and add aufficient mirbane oil to cover the odour of the fish oil. Dubbin is freely rubbed into the leather after washing off the mul and drying the boots.

DUCHESSE COVER. This type of tnilet cover came into fashion when dressing tables were first made with the looking-glass attached to supports rising from trinket drawers on either side. It is usually a straight strip of white or coloured linen embroidered and hemstitched or inlet with motifs of the lace which forms the border, and is sold in two or three lengths and widths to suit the average size of tables. Duchesse sets may be purchased, with three extra mats to match the cover.

Large squares or oblong motifs in real or imitation filet lace of gond design can be used joined together and bordered with narrow filet insertion. Fine crochet, let into linen or worked to form handsome corner pieces with narrow edging to match, wears better than anything for this purpose. Embroidery or drawn-thread work can be used in combination with crochet or as separate trimming. On coloured linen of rather coarse weave wool embroidery is effective. See Crochet; Drawn Thread Work: Dressing Table.

## Ducks: The Breeds, Their Care \& Cooking

## Methods of Breeding and Feeding with Preparation for the Table

Related information will be found under the headings Apple Sauce; Aspic; Boning; Casscrole Forcemeat: Pastry; Salad. Sce also Chicken; EgR; Incubator

Duck keeping in Great Britain is practised mainly for the purpose of producing ducklings for the table, but there is also a tendency to maintain comparatively large flocks of ducks for egg production Ducks of a good laying breed and strain usually begin to lay when about five months old, and may be kept profitably for egg production at least one season longer than hens.
Types of Duck. The fawn and white Indian runner, the white Indian runner, the khakiCampbell and the buff Orpington hreeda can all be recommended for egg production. Both the Orpington and the khaki-Campbell produce good marketable ducklings of moderate size for the table, although they are not equal in size or quality to Aylesburys.

As a table duck the Aylesbury is unequalled, owing to the superior quality of its flesh, to its size, and to the rapid growth of the young ducklings: but it is not as a rule a goorl layer. Ducklings can be produced weighing from 4 tos 5 lb . apiece at about eight weeks olda reault impossible of achievement with any other duck. Adult drakes occasionally turn the scale at 9 or 10 lb . The plumage is pure white, the bill flesh coloured, and the egga a bright orange. The bodly should be massive with good girth, deep and straight keel, a full breast carried low, the conp almost touching the ground.
The Indian runner is characterized by an almost upright carriage. As a utility breed
it is in the front rank and, although not a large bird, its flesh is of fine quality. As a layer it excels all other varieties, its eggs being large and white-shelled. It is an excellent bird for the smallholder, as it need not necessarily have water for swimming.

The Pekin and Rouen ducks have the merit of size, and the former, besides being rapid in growth, is superior to the Aylesbury as a layer. Taking the average, a dozen Pekin eggs will weigh $2 \frac{1}{2} \mathrm{lh}$., and this is not excelled by any other duck. As a table bird it does not equal the Aylesbury. but its hrenst is wide anil carriea a lot of ileah of a particularly nice flavour and of fine quality.
An adult Pekin drake should weigh 9 lb . to 10 lb ., and a duck 8 lb . to 9 lb . From stock birds of such weight can be bred ducklings which weigh 4 lb . to 5 lb . at 8 weeks, 7 lb . at 10 weeks, and 8 lb . at 12 weeks

Pekins are a canary colour, the bill is bright orange, and alightly convex in shape; the lega and feet are orange, whilst the eye is a dull leaden blue colour.

The Rouen drake has a greenish-yellow bill. dark green head and neck, claret hreast, greenblack back; the thighs are silvery grey, pencilled with a darker shade. A glossy blue hand. bondered by a narrow black outer clear white bar, runs across the wing; the legs and feet are hrick red. The duck is brown, the feathers being laced with bright black lacing;
the wing bar is like the drake's. Stock Rouens in breeding condition weigh-drakes, 10 lb . to 11 lb . ducks! lb . to 10 lb . When fattened they weigh 2 lb . more They are not so white in skin as the Ayleshury and Pekin, and for this reasnn are not quite an popular as table ducks: the flesh, liowever, is extremely rich and luscious. They are a hardy and very profitable breed.

Duck Breeding The breeding of ducks upon a small space is not advisable, and although the smaller laying varieties will hreed without access to water for swimming, better results are secured in the case of the larger table breeds when the birds are able to obtain swimming exercise The cost of feeding an adult duck upon a limited apace exceerls that of a hen, without, as a rule. yielding a proportionate return

Ducks are not sufficiently mature for mating purposes until they are about eight months old, and drakes should preferably be a month or two older. For the best results, young drakes should be mated with ducks from eighteen months to two and a half years old. With the large breeds four or five ducks may he mated with one young drake, while with the smaller breeds one drake may be sufficient for from five to eight ducks. The stock should be kept in active condition by only giving sufficient food to supplement foraging, but when a large number of eggs for consumption is required diet on a more genernus scale may be given.

As regards the duck house, one can either he purchased or a disused shed aclapted to the purpose. It need not be morc than 5 ft . high. hut the more air space the hetter. Ducks and ducklings must have dry bedding.

The use of incubators for the hatching of duck eggs is less commonly practised than in the casc of hen eggs The temperature for incubation should be run at $102^{\circ}$ if a hot-air machine, or $103^{\circ}$ if of the hat-water type. Preference should be given to the use of broody hens. It is seldom worth while permitting a duck to hatch her own egge.

When hatched, the ducklings of the larger table breeds are stronger and more easily reared than chickens, and if mothcred by $a$ hen it is seldom necessary to leave them with her for more than 3 weeks, and from 10 to 14 days or even less will prove sufficient in warm weather. If reared with artificial heat, the temperature of the foster-mother should lie kept lower than for chickens. Plenty of air is required in the heated compartments, and the ducklings should he accustomed to do without heat as quickly as possible. The ducklings of the smaller laying breeds are rather delicate for the first few weeks, and ahould be well protected from rain and damp. No food should be placed before the ducklings until about 36 hours after hatching, and then some damp earth may be supplied in a saucer: in which the birds can find particles of fine sand or grit. For the first feed, bread and milk or fine biscuit meal scn/ded and dried off with middlings or ground oats, or coarse steeped oatmeal with a little naize meal, are among the most suitable.

Feeding Ducklings. This fool, and in fact all the meals, should he given in a moist crumbly condition. At about a week old, hoiled rice can he given for variety, and a little finely chopped cooked ment with this is beneficial. Fresh cooked meat can he given daily in small quantities, or fish meal can be used, or meat meal, provided this he free from hone, fur and hair-frequent causes of impaction of the crop. Both these meals are better if scalded hefore mixing with other meals, and a proportion of five per cent of fish or meat meal in the whole mash is sufficient at first.

From a month old barley meal may be substituted for ground oats. The fish meal can be increased to 15 per cent after the first
month and boiled rice may be included in the morning during hard weather, or if natural diet several times weekly. Fcerling should food cannot be ohtained by foraging. A set take place at 2 to 3 hour intervals cluring the lirst month, and the ducklings will benefit by frequent feeds in small quantity, but this must depend upon the amount of natural fooll which they can obtain for themselves by foraging.
If the ducklings are intended for table, they should not be allowed swimming water, and shonld have their range restricted at the age of five weeks. While fattening they should be given as nuch food as they will consume three times a day. The fattening food should consist largely of barley meal and good quality middlings. A small proportion of maize meal can be added, and ground or crushed oats used as an alternative to barley meal. Boiled rice can lie continued, mixed with middlings, and it is an advantage to boil the rice in water in which nettles have previously heen well hoiled. Fish meal should he omitted when fattening and cooked meat offal supplied in its place. Duckilings for the table should be killed when about 10 weeks old, and in any case beforo they begin to show the adult feathers. Ducklings intended for stock

Treatment of Roup. Ducks and ducklings are subject to fewer diseases than fowls and chickens. Like fowls, they suffer from roup, but of a far less virulent type. There is no dis. charge from the nostrils, but there is from the eyes, which water copiously and damp the feathers all round Foam and dry matter collect, giving the duck a very peculiar appearance. The eyes should be bathed and wiperd, and if the eyelids look sore a little vaseline should be rubbed round. and the birds should also be given roup powder or sumitable pills. When the sun's rays are

powerful. ducklings should never be let out in the middle of the day, or some are sure to lie alfected by sunstroke, as the covering of the skull is very thin. They will be found lying on their backs licking feebly, and seldom if ever recover. Adult ducks are not affected in this way. as their purposes thrive better upon free range and feathers afford protection from the sun's raye. with only sufficient food given to supplement Plucking the Birds. All hirds should be their needs after foraging. Similar food as for tahle hirds may be used, except that fish meal may be continued and barley meal replaced with middlings in larger proportion.

Adult ducks upon frce range only require one feed daily for about eight months of the year. This should be given in the evening. and should be a moist mash consisting of simple ingredients such as middlings, bran and maize or oat meals, with about 10 per cent. fish meal. A moderate feed of steeped
grain or of meals should be given in the
tarved for a full 24 hours before killing, in order that the crop and intestines may be emptied of food. The best method of killing is to dislocate the neck just where it joins the head. This method, when properly performed. results in the breaking of the jugular vein, and the blood drains lions the hody veins into the neck. Some persons like the fowls to be bled by a knife passed through the slot in the roof of the inouth.

Birds should always be plucked while the body is still warm, as the feathers then come
out more easily and there is less danger of tearing the skin. If this is not possible the operation should be post poned until 24 hours after killing. In plucking. fowla should be held by the legs, with the head hanging downwards The feathers should be drawn by a firm yet gentle pull towards the hend The plucking should begin at the tail and be continued in the following orler: back, neck. wings, sides, lags, and breast. The breast bone should not be broken. The wings and half the neck must be left unplucked The legs and feet should be quite clean.
When plucking has been completed. the birds should be singed and packed tightly, breast downwards, in a shaping trough with their heads hanging over the front board They are left in position for the flesh to set and cool. A long, narrow board should then be placed along their backs and the board weighted, a common method being to use a 9 Ib. brick to every two birds. In placing the birds in the trough, the stern is pushed hard up against the back board, thus giving the birds a shortened appearance

How to Cook. Ducks repuire a shorter time for cooking than either fowls or turkeys, since their flesh is much firmer and closer When buying ducks, it is well to remember that they are at their best uncler a year old. Their bills and feet should be yellow and pliable. If they are red and feel hard, it is an indication that the bird is old

When roasting a duck after truasing spread plenty of beef dripping over it. Put the giblets into a pan with a pint of atock and six neppercorns and stew these to make the gravy. Put plenty of dripping into the baking tin tor basting and allow about 1 hour for couking. The oven must he hot when the bird is put into it. After 10 min . lower the heat alightly and continuc cooking in the same temperature until the duck is done. A quarter of an hour to each pound of meat and a quarter of an hour over is a good average time to allow for cooking. Frequent basting with the dripping is necessary, and must be done quickly, as heat is lost in opening the oven door.

When cooked, remove the bird from the oven and untruss it. Place on a hot dish and mix the dripping with a little llour before browning it over the fire. Stir in any brown particles clinging to the sides of the tin. then add a little giblet stock and also $\frac{1}{2}$ pint brown sauce or water and a seasoning of salt and pepper. Buil up and cook for $\overline{5}$ min., then strain the gravy into a liot turecn. Garnish the dish daintily with watercress.

The duck should be served very hot with apple sauce, green peas, roast potatoes. celery or other seasonable vegetables, and a little of the gravy should be poured round the dish.

Braised Duck. Duck is excellent braised in a casserole. Wash 1 lb turnips, 2 carrots and a stick of celery, and peel an onion. cut all into large pieces and then put then into the casserole. On these lay 2 slices of ham, then 1 good-sized duck, trussed for roasting, and lastly another 2 slices of ham. Put in a bunch of parsley and herbs tied together, $\frac{3}{3}$ pint brown stock, a little salt, and a dust of nutineg. Lay a piece of buttered paper over the bird, put the lid on the casserole. and let its contents cook gently for about I hour or until the duck is tender. When the duck is ready, remove the skewers and string, replace in the casserole, and serve.
Savoury Recipes. Salmi of duck is prepared from a roast bird. Put the gililets into a saucepan containing a little stock, 3 fincly shredded shallots, and a little cayenne pepper and salt, and stew them gently for 25 min . Then cut the roasted bird into neat pieces. add it to the gravy, and let it simmer until it is thoroughly heated. When this is done, arrange the pieces of duck on a hot dish. boil up the gravy and add the juice of a bitter
orange. Strain this gravy over the duck and serve the whole very hot accompanied by an orange salad.

A rich dish known as terrine of duckling is prepared by first making a forcement with ducks' livers as the chief ingredient. Season 5 or 6 of these with pepper and salt, and sprinkle over them a little powdered hay leaf and thyme and half $\Omega$ small chopped onion. Have ready heated in a frying pan 3 oz butter and the samequantity of chopped fat bacon, and in these put the livers over a fierce fire to heat, but not to cook thoroughly Leave them to cool. and then put them through a sieve.

Bone and stuff a duckling with the force meat. tie it into a more or less natural shape, and put it into a terrine. Sprinkle over it a wineglassful of brandy and lay on it a alice of fat bacon: then cover the terrine, and place it in a bain-marie in the oven and cook the bird for about $\frac{3}{4}$ hour. Makea savoury jelly with the bones of the bird and some good veal stuck. and use it for covering the duck. Before dishing the bird, make certain that all grease has been removed: coat it with the jelly, and serve it cold in the terrine on an oval dish.
Duck Pie. Duck pie is a baked pie and makes it welcome change from the more usual methods of cooking duck Prepare it hy cutting an average-sized bird ints neat jointe, and frying these in a pan containing 2 or 3 oz dripping. When the pieces are of a delicate brown tint. lift thens out of the pan, drain them thoroughly and mix them with a little sage and onion stuffing. Simmer any trimmings left over in a saucepan containing just enough water to cover them, and add half a chopped onion and a pinch of aalt.

Parhoil a few large potatoes. then cut them into slices and arrange them, with the joints of duck and stufting, in alternate layers in a piedish. Moisten the whole with a little water hefore covering it with puff pastry and bake it in a fairly hot oven for about if it hours. Before serving the pie, pour a little of the stock from the trimmings through the hole in the pastry.

The Eggs. Slightly larger than hens' egge. ducks' eggs are either light green or white in colour and contain a greater proportion of oil. They are, too, more strongly ilavoured, and because of their richness are not suitable for invalids.

The eggs may be boiled, poached, or cooked in any other way as directed for hens' eggs. The time required for cooking them is approx. imately the same as that required for other eggs. In the preparation of puddings, cakes, pastry, etc.. where the use of eggs is recommended, duclis' eggs may be used with excellent results. Employed in this way, they are most economical, one duck's egg being equal to two small hens' eggs.

DUCK: Linen and Cotton. Serving in its heavier form for tent cloth, duck in its lighter makes is used for sailors' white uniforms and for men's suits in the tropics There are both linen and cotton lucks, and the former are the inore expensive and last longer The cloth is not twilled, but plain, and is often made in hopsack pattern for suitings. It is stiff and wears well.

Uppers of gymnastic shoes are of ten marde in white cotton duck. Awnings, sunblinds. stretchers for deck chairs, hammocks, boat sails, motor car covers, kit-bags, are other uses for heavy duck.

DUCK BOARD. The name is npplied to $n$ form of slatted framework used to place on muldy or aoft ground io act as a temporary footpath Such boards can readily he constructed from odd material : convenient sizes are 6 ft long and 18 to 2.4 in wide.

The term is also applied to a board used by plumbers and tilers when building or repairing a roof; it is used to preserve the roofing matcrial from damage by the workers' boots

DUFFEL CLOTH. Taking their name from a Flemish town, dufiel cloths are winter overcoatings Warm without being too heavy, they are a useful alteruative to nap cloths, and have generally a plain surface with a short lluff of fibre. soft and spongy
DUMB BELLS. Dumb bells are grasped one in each hand. and it is claimed that their use brings every muscle in the body into play. Iron ones, weighing from $\ddagger$ to $i \mathrm{lb}$. each. are the most general, but wooden ones are also used The weight depends upon the age and strength of the user. It is a mistalie to use bells that are too heavy, as they cause undue exertion, while those that are too light are almost useless
The best times for using the bells are in the morning, just after a bath, or before retiring to bed. Most persons will find 4 or 5 min . quite sufficient for this exercise. although usually men train. ing will give much morc time to it. There are a number of useful exercises which may be repeated for 20, 30 or 40 times. Onc is to raise the arms horizontally and rigidly till they meet over the head, and then to lower them in the same way. Another is to hold the hells at full length in front of the hody, then raise the arms vertically and lower them in the same way. A more elaborate exercise is to place the bella on the ground, then, hending from the hips with the legs quite stiff, take them in the hands and raise them with rigid arms over the head. This exercise is an excellent means of improving and trengthening the muscles.
The dumb bells illustrated are constructed in the form of the hands, so as to give a hetter grip than is given by the ordinary bella. By turning the ring $A$ in the direction of the ariow the pressure resistance is increased ; by turning it in the opposite direction the resistance is decreased The minter 13 indicates in pounds on the scale the pressure exerted to close the dumb bells. Whilst exercising, the user should keep the two halves firmly closed, and to emable him to do this a bell $C$ will ring when compression is complete. To begin, the spring should be set at a minimum resistance ind gradually increased. See Exercise.
DUMB CRAMBO. This is a variant of charades and may be played under similar conditions. Sides are picked, and one side goes out of the room while the other selects two words which rhyme with each other, e.g. nose and rose. They decide that the other party shall act rose, and accordingly tell them that the worl rhymes with nose. The outside party proceeds to act in dumb show any word which thymes with nose until they guess the right one.
The spelling of the word is unimportant providing that the sound is the same. In the case given they might act the word as if it were spelt mws. The hest results are obtained when the guide word is one which has many rhymes to it, and if the most unusual of these is chosen in order to tax the ingenuity of the acting party. See Charadea; Crambo.

DUMBNESS. The condition of dumbness arises from inability to produce articulate speech and its most. frequent cause is deal. ness (q.v.).
DUMPIE FOWL. This is a Scottish breed characterised by remarkably short legs giving it a curiously squat appearance. It is a verv fine layer, a good table bird, and an excellent sitter and brooder. It is bred in several culours the most popular of them being cucson or tiarre I like the Scotch Grey. See Fowl : Poultry.

DUMPLING. Dumplings are male Irom the same ingredients as a plain suet pudding. and cooked, tied in a lloured choth. in boiling water. J'hey can be served plain, in soups. stews and hashes. or made savoury and served with gravy
To make dumplings, $\frac{1}{2} \mathrm{lb}$. suet should be allowed to 1 lb . flour and I teaspooaful baking powder. These ingredients are atirred together with a pinch of salt and mixed with cold water into a suft paste. This is divided into balls, and these are ticd up in the corners of a floured pudding clotla which has been wrung out in hot water, and are then boiled for about $1 \frac{1}{2}$ hours.

Savoury dumplings are made by adding to the above ingredients 2 tablespoonfuls of chopped parsley and I tablespoonful of mixed herbs. pepper and salt. They should be dropped into the stewpan an hour hefore dishing up the stew. See Apple Dumpling
DUNDEE CAKE. This fruit calic is very simply made. Cream together 5 oz granii lated sugar and 7 oz. margarine, afterwards beating in 3 eggs. one by one. When these are mixed stir in $1 \frac{3}{2} \mathrm{oz}$. ground almonds. \& lb flour. if oz. sultanas. and $\frac{1}{2} \mathrm{lb}$. currants.

Beat all theae ingredients for $n$ few minutes, and put the mixture in a greased cake tin lined with greased piaper reaching 2 inches ahove the top of the tin. Cover the top of the cake with halves of blanched almonds ind bake it in a moderately hot oven for about 2 to $2!$ hours, lessening the heat after the first 20 minutes, and corcring the top with paper when lightly browned

Dundee Cake, a ricn ruit cake the top of which is covered with blanched almonds

DUNGAREE. For making overails dungarce is extensively used. It is a cotton fabric, usually blue or brown, a strong twill. often rough to the touch, not easily torn and made from hard-twisted yarn. See Overall
DUNNING. Although appetising when thus trented, cod loses much of its nutriment in dunning. The tish is opened, well ole:Incal. and the non-edible parts removed, then washed and scaled. It should be rubbed inside and out with common anlt and left to hanns in a cool place for 24 hours. A mixture is made of 1 oz. brown sugar and 1 oz. saltpetice tu $20 \%$ bay salt, and this is rubbed intot the fish. The fish is sprinkled with common salt and allowed to stand for 24 hours mora It is then drained, well dried, and liept in a conl. dry place until needed. See Corl.

DUREAM CUTLET. Prepare these cut lets by putting 1 oz. butter and the same quantity of flour into a saucepan, and mixing them over the fire. Add $\downarrow$ pint stock or water, and let it boil, stirring all the time, then put in a pinch of salt, pepper and cayenne and 1 dessertspoonful of bottle sauce. Then pour the liquid into a bowl add 3 or 4 tablespoonfuls of breadcrumbs, and $\frac{1 \mathrm{lb} \text {. of any minced meat, }}{\text { a }}$ mix them well. and spread the mixture on to a plate.

Lay it aside to get oold and firm, then cut into triangular shapes with a floured knife, starting from the centre. Sprinkle the hands with flour, and shape each piece into a neat cutlet. putting an inch of macaroni into the narrow end of each to represent a bone. Egg and crumb the cutlets, fry them in hot fat. and arrange them in a circle round a hot diah. Mashed potatoes, spinach or green peas might be heaped up in the centre of the dish.

DURHAM PUDDING. Put a table. spoonful of Demerara sugar and gill water into a saucepan and boil them for 5 min . to produce a syrup. Stalk and wash $\frac{1}{\mathrm{lb}}$. red currants, add them to the syrup in the pan, and cook them slowly until they are tender, which should take about 20 min . Dissolve the contents of one packet of red currant jelly in a pint of hot water.

Line a pie-dish with sponge cake, splitting the cakes in halves, and placing the top halves to the bottom and sides of the dish. Mix the stewed fruit with the jelly, and pour the mixture over the sponge cakes until the dish is full. Then place the remaining halves of the sponge cakes on the top of the dish. with the cut side inside. Press these well down so that the fruit and jelly soak into them, and cover the top with a dish, pressing it down with a heavy weight, and leaving the whole until it is cold and set. Turn it out to serve. Any kind of stewed fruit can be used for Durham pudding.

DUST : A Menace to Health. In large towns the air is laden with particles from fires and furnaces, and dwellers in those places show the effects in pigmentation of their lungs. In coal and other mines, and in certain classes of workshop and factory, e.g. potteries, steel grinding shops, eto., unless the ventilation is attended to and spraying adopted, workers who do not wear masks are liable to suffer ill-effeots from the irritation of the lungs by dust. In occupations involving the deposition of dust on the skin, inflammation of the skin or dermatitis is likely to result, unless strict cleanliness is practised. (See Spring Cleaning.)

The air passages have natural protective powers against dust, but when a large quantity is inhaled the defensive meohanism is overpowered, and some of the dust remains and produces discoloration of the lungs. The lungs of an infant are pink, but after years of residence in a town or elsewhere, if there is much dust in the air, they become grey, apparently without any bad effect on the lungs or the general health. But if the accumulation goes beyond a certain point, or if the particles inhaled are irritating, a reaction is produced in the lung tissucs, and catarrh of the bronchial tubes is set up. The general health suffers, the patient is anaemic, and later consumption may occur.

The risk to life involved in the chest diseases due to dust varies even among dusty occupations, but the tin miner certainly stands the poorest chance. The terms grinders' rot and potters' asthma convey the menace to health in other occupations : the list is a long one, including workers in cotton and grit mills, tobacco factories, sawmills, brickworks, etc. Preventive measures are carried out in most factories and mines by improved ventilation, keeping the air damp, etc., with immense
benetit to all concerned Workers in dusty trades should always wear respirators, however truublesume they find these to be in the course of their employment.

DUSTBEIN. The metal sanitary dustbin is secure against insects, and also against pmoling animals, pruvided the lid is always kept on. as it should be The lid also keeps the contents of the bin from getting wet or being blown about when there is a wind.
The dustbin should be kept clean, both inside and out, by means of hot water and aome disinfectant, such as permanganate of potash. It should be placed outside the house on a firm. dry foundation in a spot readily accessible for the dustman. The contents should be emptied at least once a week. Dustbins should be used, as far as possible. for dry refuse: all damp refuse should be burnt See Refuse Sanitation
DUSTER. Bought dusters, unless extremely low priced, are satisfactory, but it is economical to make dusters at home from material which would otherwise be thrown away. Ordinary cotton materials are unsuitable, as they are non-absorbent, but wincey, Hannelette, and old sheets all cut up into serviceable dusters when hemmed. A slightly damp (not wet) duster colleots dust more readily if a room is really dirty. To wash out the grime and grease from soiled dusters, the best medium is a soapy lather to which a little soda has been added
A soft piece of chamois leather soaked in cold water and wrung out tightly makes an excellent duster It can be used on the finest furniture without fear of scratching, and will remove the most obstinate fingermarks. An additional advantage is that chamois leather leaves no threads or Huff behind it. When polishing any kind of furniture. a great saving in labour can be effeoted by using a hot duster. It is a good plan to keep a couple of dusters in a cool oven and use them alternately while they are warm. A high polish will then be easily seoured. Care must be taken to see that the dusters are not soorahed.

DUSTING. A house should be dusted throughout every day. In the living-rooms the fireplaces should be done first and the room swept. and no dusting ought to be attempted until the dust caused by the sweeping has had time to settle.

All dusting should be done from the top to the bottom-that is to say, mantel pieces and the higher pieces of furniture are done before fenders. etc., ss the dust dislodged from them will sink on to the lower places, and be finally removed from them. Every ornament must

Dutch Garden. Pigs. 1-4. Plans of examples of formal gardens, the laying out and planting of which are described in the text
be moved: it is not enough merely to go round them. as that will leave an ugly ridge of dust.

Among things which are frequently neglected, vet which provide harbourage for dust, may be mentioned picture frames bars of chairs, and electric-light shades or gas-lamps. for which a light dusting brush may be used. Last of all, the surround of the floor should be dusted For this purpose a slightly damped duater may be used. or a long-handled mop.
Dust Sheet. Made usually of coarse sheeting, dust sheets can be cut from any spare length of material They are eapecially useful when spring-cleaning, white-washing, or distempering is being done, or when the occupants of a house are leaving for holidays If they are not bought ready-made, the sheets should be hemmed down on all four sides.

The amount of material required depends upon the size of the article to be onvered, but for an armchair about $2 \frac{1}{2}-3$ yards of wide material should be sufficient. See Brush.

DUSTPAN. The tin scoop with a handle into which dust is swept by means of a small brush is chiefly used for colleoting the dust on stairs. The dustpan and brush have been largely replaced by the use of vacuum cleaners and carpet sweepers. See Carpet Sweeper :

## Vacuum Cleaner

DUTCE AUCTION. This method of selling goods is the exact reverse of the one in ordinary use. A high price is first named for the article or property offered. and this is reduced by stages until a bidder is found. See Auction

DUTCE CEBESSE. A true skim-milk cheese, the Dutch product is mild in flavour and has many good points, although it is less nourishing than the whole-milk cheese, and is frequently a little salt. This class of cheese is best for keeping purposes, as it dries and hardens, wheress the rich, fatty varicties of cheese are prone to decomposition. Its shape and colour vary, some being round, othery oval and either coloured a brilliant red or left yellow on the outside. See Cheese.
DUTCE GARDEN. With its trim and formal beds and borders, carefully trained yews and clipped dwarf box edgings, tho Dutch garden has a charm of its own, and though no longer so fashionable as it was in tho 18th century. many fine examples are still to be found in England, the result of gonerations of careful treatment. Directions and plans for laying out a Dutch garden are given in this articlo.

A Dutch garden should be enclosed by a clipped hedge of yew or box, and if possible laid in a position where it can be looked on from above. Planning the forination of beds and borders is a simple matter, with such a diversity of geometrical shapes availablo, among which squares, circles, hexagons, and rectangular forms, such as those shown in the diagram, will be found most suitable. In the centre of the garden may be placed an ornament to which the beds converge, and this may take the form of a trained tree, a stone figure, a weeping or pillar rose, a sunclial, a fountain, or a fine stone vase to be kept filled with seasonable bedding and bulbous plants. Crazy paths of York stone, having wide crevices
between, planted with tufte of lowly plants, are at the top, under the very old-world in appearance. Well-rolled gravel will also serve
In planning the beds all angles and circles should be carefully pegged out with wooden stakes, and, as far as practicable. boards should be nailed against these to outline the shapes desired. Gravel should then be laid for the paths, and after this has been rolled thoroughly hard, the boards may be removed, and the beds filled to a proper level.
Box edging may afterwards be inserted, but it is advisable to use a garden line when planting to ensure regularity of outline. Although construction may be carried out at any time, autumn or spring is the best, as the dwarf box required for edging is then in suitable condition for planting. Clipping or training of the box is best performed during May, and after planting due attention must be given to watering until the roots have taken hold of the soil

The Dutch garden is usually planted with low-growing plants which do not obscure the lay-out. A modern variation, now more popular, is the Formal Garden in which free-growing plants are set in beds and borders of formal design.
Plans for the Gardens. The accompanying plans suggest four arrangements for typical Dutch formal gardens. The first example would result in a charming old-world garden.

Corner heds, A, B, FIG. ${ }^{\text {C }}$ D, cubbage, Provence, anask, and Clina roses

Fig. 2 displays a somewhat elahorate and not uncommon type of bed. The darkest portions show the inner and outer edgings of dwarf box, the tinted parta signifying grave and the white spaces where flowers are to be planted around dwarfed shaped trees. Such beds entail hard work and great attention if they are to be successful ; but the result is well worth the trouble that has been taken See Crazy Paving; Garden; Path; Tile.

DUTCHMAN'S PIPE. Popular name of a very vigorous hardy climbing plant valued chietly for its large leaves, Aristolochia sipho. The curious shape of the small brownish flowers has given rise to the popular name. Some of the hot-house kinds of aristolochia have evil-smelling flowers of extraordinary appearance.
DUTCH METAL. This is a copper zinc alloy with a high proportion of copper; it is so ductile that it can be worked down to a thickness comparable to that of golil leaf This fact, coupled with its yellow colour, leads to its use as a cheap substitute for genuine gold leaf in gilding work ; it is also sometimes used in powder form for so-called gilding.
DUTCH OVEN. Formed like a miniature roasting ecreen, the Dutch oven is made to fasten on to the bars of an open grate or range. It is fitted with two or three meat hooks ood, and contains adripping pan below, which is sup ported on iron rests The oven is designed to enable a smal joint or fowl to be cooked in front of the fire when other means of roasting are not available.
The fire should be clear and the suspended meat must be turned and basted precisely as if cooked on a spit. This method, if properly carried out, gives the joint the same Havour as if roasted in the old-fashioned
way. It is really a form of toasting or grilling. A Dutch oven may also be used for cooking chops, steaks, bacon, or fish, and it is adapted for browning the top of macaroni cheese, scallops or other savouries. For this purpose the dishes should be rested on the dripping pan

For those persons without a kitchen range or gas cooking stove the Dutch oven presents a solution of the difficulty of rossting, but it must be kept scrupulously clean. It should be scoured in the same way as tinware See Roasting

DUVETYN. The cloth known as duvetyn derives its name from the French word for down, duvet, and it emulates the downy softness of peach skin or the slin of young animals. Silk duvetyns are the best known, and their surface approaches that of hatter's plush. Ornamented with stencilling or embroidery this cloth is suitable for such articles as blotters and Hoor cushions.

DWARF BEAN. The French or dwarf bean is one of the best summer vegetables. The pods, which should be gathered while the seeds are immature, are of more delicate flavour than those of the runner bean. Deeply dug and manured soil is necessary to ensure good crops.

Sceds may be sown out of doors at fortnightly intervals from early May until the middle of June to provide a succession of produce in late summer and early butumn. The seeds should be set about 3 inches apart and 1-2 inches leep. The seedlings must be thinned out so that they are 9 inches or so from each other. The rows ought to be 20-24 inches apart. Canadian Wonder is a good variety, though most scedsmen sell their own special sorts.

Farly crops of dwarf beans under glass are obtained by sowing the seeds at intervals in August and September in 8 inch pots filled with lonmy soil, keeping them in a frame until October and then placing them under glass in a temperature of 55 to 60 degrecs.
The climbing French bean, which needs the aame treatment as the dwarf kind, provides pods of excellent Havour throughout many weeks It is less vigorous than the runner bean. Tender and True is one of the hest varieties.

The waxporl or but ter beans are grown for

Dutch Oven Useful roasting contrivance in metal provided with four meat hooks and dripping pan
the sake of their pale yellow pods, which are conked without being sliced ; both dwarf and climbing types are available and they need the same treatment as advised for French beans. Mont d'Or, climbing and Golden Waxpod, dwarf, are favourite varieties.
The ordinary runner bean can be grown without sticks if the ends of the shoots are pinched off frequently: the plants thus remain dwarf and become well branched. They cover a gond deal of ground, and it is necessary to support them with short sticks to keep the pods off the soil. See Bean.

DWARF TREES. The miniature Japanese trees of larch, orange, maple and various evergreen conifers have become popular in Great Britain and are imported in considerable numbers. Some of those exhibited are said to be over 100 years old, yet so restricted are the roots that they remain dwarf and the stunted branches give them a very picturesque appearance.

The trees may be grown in a room window or unheated greenhouse, but they need careful treatinent to preserve them in a healthy condition. Incorrect watering is likely to affect them adversely. The soil should be watered only when it is moderately dry, but sufficient water ought then $t_{1}$ ) be given to moisten the soil thoroughly. If the soil is kept in a sodden state or if it is allowed to dry out, the trees are certain to suffer. They must be placed in a light position though not in strong sunshine. Grs-heated or gas-lit rooms do not suit them. Every year it is advisable to take off some of the surface soil without damaging the ronts and to replace it with fresh compost of loan and a little sand.

During mild weather in spring and summer the trees benefit by being placed out of doors, for they are hardy trees. Branches which tend to spoil the symmetry of the trees should be shortened whenever necessary. If a tree shows signs of ill-health it should be turned out of its pot. the latter being scrubbed clean and provided with adequate drainage. The tree should then be repotted in loamy soil containing sand and a little crushed charcoal.

Miniature trees can be grown at home by setting seeds of various trees in pots, repotting them seldom, and pruning the branches to force the trees to grow in the ahape desired.

## Dyeing Fabrics at Home

## Hints on an Economical Form of Domestic Renovation

By following the instructions given in this article clothes and furnishings an the tinted not Byly in one but in two colours. Consult also cnirics on Batik: Colour Schemes, etc.

The many varieties of dyes on the market prove the popularity of home dyeing. Articles. both n! dress and houseliold hangings, may hecome faded and shabby a considerable time before they are worn out. With the expenditure of a little money, time, and tiouble they can be renovated by tinting to match their original colour, or the colour may be entirely changed. One immeraion in a dye bath completely recolours articles of plain material. Patterned fabrics may require two immersions or even three bcfore the pattern is quite hidtlen by the new colour.
The usual forms in which dyes are sold are cakes, Hakes. powders and tubes of paste. Some are soap dyes, the dye being intimately mixed with soap. others are merely colouring matter put up in convenient forms for use

Cold water dyes are chiefly used for giving pale and delicate colours th fabrics of fine textures such as silk, muslin. eto. Some lycs are prepared for woollen and silk fabrics. some for cotton and linen, the reason being that animal fibres take dyes differently to those inale from vegetable fibres. If a cotton and wool mixture fabric is to be dyed, choose a cotton dye because wool. will take a cotton dyc. but cotton will not take a wool dyo. lsuy plenty of dye. It is far better to buy one packet too many than not enough.

Initial Preparation. Before commencing, remove all buttons, buckles, bead or other trimmings, which obviously could not be expected to dye satisfactorily Any stitcheddown parts, such as turned-bick cuits, collars, hems, revers or pleats should be unpicked. This allows frce access of the dye solution to all parts of the garment. Thoroughly wash every article before attempting to dye. This parlicularly applics to new materials: any sfarch remaining in the fabric will prevent the dye taking evenly. Grease and dirt act in the same way Although the directions on a few soap dyes distinctly state that previous washing is unnccessary, gond results must not be expicted if the washing is neglected. It is a well known fact that a really dirty garment is not thoroughly cleaned by simply immersing it in hot soapy water Rubbing or friction of some kind is essential. Further, any dirt coming from a soiled article when mixed with the dee solution will naturally prevent the dye giving such a clear or brilliant colour.

Weigh the articles carefully before making the dyc solution: this avoids waste, and ensures sufficient solution being ready. The

Dyeing. Fig. 1. Straining the dye through fine muslin. Fig. 2. Two wooden spoons are used for stirring the dye bath
directions supplied with some makes do not hut only how much anlution can be miade from the packet. In these circumstances individual judgernent must be used, remernbering that a small thick article, eapecially of wool, will often require much more liquid than a large one of fine texture

Method of Dyeing. For the dye hath ohoose a hasin or washing tuh large enough to take the article to be dyed conveniently. The utensil selected. if required for cotton goods, must be caprble of being heated over the fire. White enamelled iron ware is the most suitable. Ordinary china basins can he used for all dyeing that does not actually require to bo boiled.
Make sufficient dye solution not only to cover the fabric easily, hut to allow room for stirting and moving the article about All dyes, whether soap dyes or not, should he completely dissolved in hoiling water. If the packet is hard it requires to be shrediled or crushed. Should the dyc not dissolve eusily, place it in a small enamelled jug or basin and boil for a few minutes. When quite dissolved strain the concentrated dye through muslin into the dye bath (Fig. 1), and dilute with water. Before adding the material, test for colour by dipping $n$ small piece of the same material into it If this is not possible, take a small piece of fabric resembling the article in colour, and texture. Rinse well and dry; if the result is satisfactory. it is safo to proceed. If a decper or paler tone is required, nore dye or water must he added.

Should the test not give the exact colour, try judicious mixing of one or morc colours until the desired shade is obtained. Most makers prepare dyes for sale in about 20 different shades but by mixing these $\pi$ much greater number of colours can be produced Details about the particular dye are printed on the package and dircctions should be carefully read. When the dye bath is ready, open out the article, which has been previously washed and rinsed, but not dried, and place it in the solution. Use two smooth wooden sticks or spoons (Fig. 2) to inove the fabric ahout. On no account should the dye bath be left, as it needs constant stirring whilst being heated Unevenness of shade may result from carelessness at this stage.

Most makery advocate the use of salt, some also of vinegar. Salt is particularly useful when dyeing cotton goods, as it enhances the depth and brightness of the colour. The average time required to dye is from 10 to 40 min ., according to the tone required, deep shades requiring longer than pale ones. Navy blue, for in stance, would require 40 inin., while a pale blue would be dyed in 10 min .

Thedyeing completed, the colour must be fixed by thorough rinsing in several changes of cold water until no colour comes from the newly dyed article. A certain
amount of unabsorbed colour is always lost in rinsing, and this must be taken into account when preparing the dye bath Wring the article lightly and hang it out to dry. taking eare to put the pegs in some inconspicuous part. When nearly dry take the article fiom the line and roll it up ready for ironing.

Delicate fabrics such as georgette or chiffon do not require to be hung up: any surplus moisture can be removed by rolling the garment in a clean cloth. Such materials and certain crepes are apt to shrink after immersion in hot dye. They should be pulled into, shape during the ironing process while the fabric is still damp. When irnning newly dyed material protect the ironing sheet from stain by placing a piece of muslin or thin cotton between the shcet and article being ironed If much dyeing is being done, it is advisable to wear a rubber apron Ruhber gloves are useful when rinsing after dyeing dark colours, such as black or dark brown, as there is sometimes sufficient dye in the first rinse waters to stain the hands Lemon juice will usually remove such stains, or an application of peroxide of hydrogen

Skilled treatment is required for such articles as suede, kid, or huckskin shoes or gloves, furs, carpets, rugs, waterproofs, overcoats, woollen costumes, or any heavy garments having interlinings and paddings, and the dyeing of these should not be attempted at home.

Knot Dyeing. Certain articles such as straight scarves, unlined curtains and cushion squares, made of thin fabrics, can be decoratively treated in two hiarmonious colours by means of knotting after having first been dyed in the ordinary way. The article should be rinsed and then knotted tightly in the middle with smaller knots at each corner, oras in the case of curtains-at each lower corner. The knotted fahric is then dyed in a second deeper colour in the same manner as before, rinsed and unknotted. The two colours will blence into each other with a pretty shaded effect without hard lines of division between the tints.

Should it be wished merely to give a contrasting horder effect-to a scarf, for instance -the article may be tightly bandaged with cotton raga, after the first dyeing and rinsing have been accomplished, leaving exposed for the second immersion only the ends. The scarf is then simmered as hefore, rinsed, and the bandaging removed before drying and ironing. This method of dyeing gives a charming effect to short curtnins made of natural shantung silk.

DYNAMO: Working Principles. The dynamo is a machine employed for converting mechanical energy into electrical energy. and consists essentially of an armature rotated in a magnetic field.

The general arrangement of a dynamo is shown in the diagram. The magnetic field is produced by a cast iron frame or yole into which are fixed an equal number of iron poles, each pair being diametrically opposite. Upon each pole is mounted a magnetizing coil, the coils heing so connected as to influence each alternate pole as it $N$. pole, and cach intervening pole as a S. pole. The yoke is necessary to provide a path for the magnetic lines of force outside the armature, while the magnetic circuit is completed across the air gaps between pole tips and armature. The armature takes the form of a cylindrical iron structure inounted between bearings. Electrical conductors are carried by this structure, each cutting the magnetic lines of force as the armature rotates, with the result that a relatively small clectric current is set up in each conductor. Upon the number of conductors, the number of magnetic lines of force produced by the field coils. and the speed of rotation depend the value of the electric
current generated by the dynamo. The current is collected by the brushes from the commutator, a motating contact device
Any convenient mechanical power, such as a gas, steam, or oil engine, may be employed to rotate the armature, the imporiant point leeing to have sufficient power at the speed necessary to enable the dynamo to deliver the voltage for which it is wound
Types of Dynamo. Certain tyres of dynamo have been evolved for eprecific duties. Thus. the dynamo on a motor car has a duty different from that of the appar. atus which is used for lighting a private house, while a dynamn for charging accumulators would not he suitable for lighting purposes. charging dynamin delivers a heavy amperage at a low voltage, whereas a house lighting dynam" gires a lower amper. age at a higher voltage

Typical windings are the series, shunt. and compound respective!y. In the serics winding the armature conductors and the ficlal coils form one continuous cirouit, it being characteristic of this winding that the voltage varies as the load tluctuates. For
this reason the series dynamo is not suitable either for charging or lighting. In the shunt winding the armatureconductors and the field coils form two separate circuits, and a handoperated regulating resistance is introduced into the field circuit. The purpose of the latter is to control the voltage genernted in relation to the load fluctuations plus the voltage drop due to the heating of the coils. IIthin well defined limits a shunt wound dynanio can be considered a constant voltage machine The compound method of winding combines both serics and shunt. Its utility lies in the fact that it accommodates itself to load fluctuations by virtue of the series winding, which increases the magnetic field as the load increases. Such a machine is cxcellent where the current demand varies within fairly wide limits. Details of the windings and the spced of the dynamo should be found on the maker's plate fixed to the machine.
A dynamo to give the hest reaults must be properly installed upon a sliding base fixed to a firm foundation. The sliding base enables the machine to be properly lined up with the engine, and allows the driving belt or chain to be adjusted to a nicety. A dynamo bolted direct to an engine shaft through a coupling is said to be direct driven, and when once lined up needs no further adjust ment:
It is important to house a dynamo in a dry place, as damp has a detrimental effect "pon the insulation and may canse " earthing" troubles. Dust also should be kept away from the machine. If fixed on a wooden Hoor, a thick bed of incombustible material, such as asbestos. should be placed heneath the dynamo to insulate it. All wires and connexions must be properly protected, as, for example, by enclosing them in steel tuhes, or in any manner that will ensure them being out of the way of gas-pipes, a hot flue, or heat or acids that might tend to destroy the insulation.
Regular attention has to be paid to replenishing the oil boxes. The used oil should

Dynamo. General view of small dynams snowing commutator, armatuie. brushes, feld magnets, and driving pullep
be drawn off and replaced with a fresh supply No oil must get on any part of the insulation. as oil is a solvent of rubber, and if it be allowed to get on the rubbered wires the rubber will perish, and ultimately cause a failure

Commutator and Brushes. The commutator and brushes give the most trouble and should be regularly inspected When in good order there should be no sparking at the points of contact. The contact face of the brush should be of the same curvature as that of the commutator. and this can he ensured by
placing a piece of glasspaper between the brush and the commutator and then rocking the Iatter so as to rub the paper on the brush and thus shape it to the desired curve. This applies to the usual carbon type of brush. those made of copper gauze are shaped with a very fine file and emery paper In either case see that there are no loose ends to cause sparking.

The pressure of the brush on the commutator should bo adjusted if requisite, by altering the tension of the springs The rocker Hrms should be properly spaced, two being diametrically opposite, and four spaced at $90^{\circ}$ a part. A slight movement of the rockers will often correct sparking and ensure perfect running, but this can only be determined by trial. The commotator should not be lubricated. When all is in good order it should be a dark coppery colour: if blackish it indicates that the brushes are too soft. A bright and scraped appearance indicates either that the brushes are too hard or the pressure is too great.

DYSENTERY. Under this name are included several forms of intestinal inflammation. In hot countries cases are constantly cropping up. In Gieat Britain epidemics are not infrcuuent in asylums and other institutions.

The disease is spread by germs in the excreta of a patient suffering from the discase finding their way either into food or drinking water. This may happen in several ways. Flies may feed on infected excreta and then defilo food, beverages, or food utensils. Infected excreta may be drained into shallow wells or washed into surface water This water may be drunk or used for washing raw food, e g. salad or food utensils. Lan food may be infected by polluted soil, and not washed clean. Persons found to be carriers of the disease frequently havo been amongst those handling food, c.g. cooks, waiters, nurses, etc.

There are two main forms of the disease: bacillary and amoebic. For one or two days an attack may resemble ordinary acute diarrhoea, and then the stools are found to contain
mucus (slimel streaked with blood. Soon the motion may consist of mucus and blood only. There inay be scvere straining and griping pains The patient may die Irom weakness or from perforation of the bowel, or may become the subject of chronic dysentery

The patient should be put to bed at once between hot blankets and hiave a hot-water bottle at his feet. The abdominal pain will he relieved by hot fomentations. He may have whey or albumen water at 4 -hour intervals. Armwroot may be useful. In the bacillary form 1 dram doses of sodium sulphate should be given every hour till the straining is relicved, and then at less frequent intervals The doctor will treat basiliary dysentery by injections of anti-dysenteric serum and amoebic dysentery with emetine.

Preventive Methods. The stools of the patient should he mixed with a disinfectant before being disposed of preferably by burning Efiorts should be inade to diminish the number of flies. No fond or beverage should be left without a cover if llies are about All water for drinking or washing fond or food utensils should be hoiled or otherwise sterilized unless it comes Irom an unimpeachable source The hands should be washed thoroughly before partaking of food Salads should be avoided. and care should be taken to prevent chills and to correct constipation and diarrhoea (q.v.).

DYSMENORRHOEA. Pain occurring ut the menstrual periods in women and girls. and felt in the lower part of the abdomen It is always more or less disabling, and may be very severe. The causes are numerous, but always include some abnormality in the sexual organs

The patient's general health is important. Iron in some form will be necessary in anaemia. Constipation must be corrected If the pain is severo the patient should remain in hed, and the abdomen and fect should be kept warm. Much relief may be obtained from hot mustard hip haths or foot buths. Aspirin, grains 10. or phenacetin, grains 7, with citrate of catfeine, grain I, may be given to a woman, and will frequently lessen the suffering. Alcohol in any form should never be given.

Dyspepsia. See Indigestion

E
AR : Anatomy and Diseases. The human ear is divided into three parts -the external. the middle, and the internal ear The first consists of the auricle or pinna, the ear in the popular sensc, and the external auditory meatus or passage which runs if in. inwards from the earhole and ends at the tympanic or drum meniliane stretched across the passage Sound waves entering the passage strike against the membrane and cause it to vibrate.

The middle ear lics inside the membrane. Its chief contents are the ossicles, three tiny bones which connect the drum with the actual hearing apparatus, or internal ear In the posterior wall of the middle ear there is the opening into a small passage leading to the mastoid antrum, a hollow space in the mass of bone to be felt inmediately behind the ear In suppuration of the middle ear infection may thus pass through and cause mastoid discase. In the anterior wall there is the opening of the Eustachian tube, which leads directly to the back of the throat. The importance of this tube is that through it air can find its way into the iniddle ear, so that the air pressure on the two sides of the drum is always kept the same. The deafness so commonly noted in chronic catarrh of the nose and throat is generally due to the catarrh spreading up the Eustachian tube and closing it

The intarnal ear or labyrinth is divided into three parts: the cochlea, the true organ of hearing, in front; the semicircular oanals,
which control balance, and the vestibule, between thear others.
Sound vibrations can reach the inner ear otherwise than through the air Thus if a tuning-fork is sounded and the end of the handle placed on the bone hehind the ear or elsewhere on the skull. the note will be clearly heard if the internal ear is healthy If it is not heard we imply that the patient suffers from nerve deafness due to discase of the internal aar or the nerve connecting it with the hearing oentra in the brain The tuning-fork will be heard distinctly, however, where the deafness is due to blocking of the external passage as by wax, or to disease in the middle ear causing stiffiness or destruction of the membranes and the conducting bonex

Discharge from the ear is most commonly due to inflammation of the middle ear, with the formation of manter which escapes through a perforation in the drum-membrane. This condition is a frequent complication of the convalescence of measles or scarlet fever in children, or it may result from simple cold in the car. The treatment of discharge coming from the middle ear must be supervised by a doctor

Perforation of
the drum mambrane may be caured by some shar it instrument poked into the ear, or by the impact of water in diving. etc., bul most commonly it is the result of middle. ear inflammation. The ears should be pmoneted in high diving by plugs or otherwise. It is $n$ dangemus practice to box children's cars, as this is a frequent cause of perforation of the drum membrane.
A foreign bolly in the ear may be in living insect or something which has been pushed in. It is safer to have it syringed out by the doctor, and the sooner the better. If it is a pea or a bean, no one should be allowed in the meantime to put water in the ear, as this causes these to awell and renders their removal more difficult.

On no account should alteinpls be made to remove a foreign body with a hairpin or other inslrument.
Mastoid disease is most usually due to infection from the middle ear through the opening above mentioned. The symptoms are sudden fever. pain behind the ear, shooting over the head and down the neck, swelling, redness and tenderness on pressure on the bone behind the ear, and usually a profuse discharge. Suppuration occurs in the spaces within the mastuid process, and as the pus cannot readily escape through the narrow opening into the ear or through the hard bone on the surface of the mastoid, it tends to turn inwards, and may produce meningitis or abscess of the brain. Early surgical treatment is imperative.

Nuises in the car may be the result of $n$ large number of causes, e.g. chronic inHamma. tion of the middle ear causing partinl deafneas, certain drugs, such as quinine, sodium salicylate, etc., catarrh of the nose and throat, etc. Treatment will depend on the cause. Wax in the ears may be remuved by gentle syringing as deacribed under the heading Deafness.

Earache. This pain in the ear may be due to a number of causes. Among these nre neuralgis, a boil in the meatus, impacted wax, the presence of a foreign body, or inflammation of the middle ear. Teething in children is a nother cause.
To relieve the pain, heat should be applied. A hot-water bottle may he covered with
flannel or a shawl and laid againat the ear, or a fiannel bag may be made and filled with common salt which bas been roavted on a shovel. This should be applied as hot ss it can he boine. If. however, the pain is con: tinuous, a doctor should be consulted.

Ear Cap. The purpose of ear caps is to correct prominent ears in children Made of mercerised cotion or of silk, they ans worn round the head at night, being held in position by straps firmly but not too tightly tied They can he obtained in most sizes frimm chemists, surgical instrument makers, and diapers.

EARLY CLOSING.
In Great Britain, since the passing of the Shops Act of $191 \%$, it his been ommpulary for shops to close for one half-day a week, and this is the early closing day. The term is also applied to the movement which resulted in shops closing earlier in the evening, the result of Aots of Parliament paased in 1922 and 1928
The day chosen varies from place to place. being fixed by local authorities alter consulta. tion with the shopkeepers: buta shopper should acquaint herself with it in her own locality so as to avoid disappointment In oentral London the early closing day is Saturday, but in other places it is more usually a day about the middle of the week, Wednesdny and Thursday being the days that are most requently selected.
EARRINGS: Choice and
Care. While never quite out of fashion as ornamente, atyles for earringa change frequently. especially during periods when "omen are wearing much fancy jewelry and new deaigns are evolved in keeping with various dress fushions When long earrings are being worn, good examples may be purchased at shops whioh specialise in antique jewelry. Many such carrings are made in two parts, a top or atud and a long dmp, or an intricately deaigned lower part, which houks on to the upper patt. These ornaments posscss an advantage for those who do not care for elaborate earrings in the mornings as the studs can be used alone, the lower parts being added for formal wear.

The two main types of fastening for earrings are illustrated, the first being suitable for pierced cars and the second for unpierced. The latter type are nttached by menns of screws to the lobes of the ears. They should be light in weight or they are linble to drag the lobes and either to hurt or to be lost.
Fastening Methods. The fastening of valuablecarrings should never be of the type which serews on the lobe of the ear. It causes unbearable discomfort if the fastening device is screwed so tightly to the ear as to prevent the possibility of the ornaments falling off. Those who possess diamond or other valuable earrings ahould have the lobes of their ears pierced. This can always be done by a practical jeweller without any risk and with very little pain.

Before purchasing earrings inquiries should be made as to whether the wires or fastenings
are of silver or gold The less expensive varieties may have metal fittings which might possibly poison the ear, though the extra cost of silver is infinitesimal. For anfety when wearing earrings the style of fitting that is most reliable is what is known as the Brissure fastening. This is an old French atyle, consisting of a wire which. when passed through the ear, is covered by means of a grooved loop of gold or silver affixed to the ornament by means of n spring hinge. Withdrawal of the wire from the lobe of the ear is thus renderel impossible without the hinged loop being first opened ao us to uncover the car wire at the back of the ear.

EARTH : In•Electrical Work. Any part of an electrical circuit which is connccted to the ground or earth is said to be at earth or zero putential

A good earth system is very necessary in wireless reception. The wire from the eartls terminal on the set to earth should be as short as possible. It is immaterial whether this wire is of the bare or covered type, but it should be of a substantial cross section: copper acrial wire, $7 \cdot 22$ gauge, is suitable. A main water pipe makes a satisfactory earth, provided the earth wine can be attached close by the point where the pipe enters the ground] If. for example, the set is to be used in a room at the back of the house, the earth wire can be joined near the tap in the kitchen or scullery. The lead pipe should be acraped clean anil bright for a diatance of about one inch, and an earthing clip attached. The earth wire from the set is then connected to the torminal which is provided on the clip

Gas pipes make unsatisfactory earths owing to the fact that high resistance joints are employed. Moreover, considerations of safety make it undesirable to utilise a gas pipe for this purpose.
If the receiver is not conveniently placed in relation to the main water supply, a buried earth may be employed. The earth wire is soldered at several points to a large sheet of zinc or copper, which is buried cdgewise in damp sail to a depth of about three feet. After cleaning off any excess flux with methylated spirit or petrol, it is advisable to protect the joint with a coating of paint in order to prevent corrosion.

An alternative to the metal earth plate is an earthing tube, which is driven into the ground and has a terminal at the top to which the earth wire is attached Besides this connexion it is as well to lead the bare wire down through the tube, and out through one of the holes near the bottom, where it may be soldered or ot herwise attacherl to the tube Earth tubes arc usually perforated, and should be filled with
water at regular intervals during dry weather to ensure satisfactory electrical connexion with the surrounding soil.

A counterpoise earth is sometimes used for shortwave reception, and may comprise one or more wirea. running beneath the serial and a few feet above the ground The wires have to
Earring with Spring Brissure Pierced Ears
biced Ears
Earring. Types o ng. Types of fastenings for both Screw Fastening for Unpierced nierced ears

be insulated in exactly the same way as the aerial, and may be passed through an ebonite lead-in tube to the earth terminal of the set.
If a decrease in volume or Hatness of tuning is observed, it is as well to inspect the parthing
system, making sure that any terminals or other jointa have not become dirty or otherwise defective. A faulty earth may alan produce high frequency and low frequency instability. See Aerial.
Earth Switch. This is ab device for disconnecting the receiver and joining an outdoor serial direct to earth, so that atinospheric discharges (e.g. lightning) How etraight to earth instead of passing through the aerial circuit of the set A stoutly constructed single pole change-over switch having a forcelain base is suitable, and should preferably be mounted outside the house. near the nerial lead-in insulator. It is advisable to provide a cowl or other covering to prevent laaknge of the aerinl currents to earth over the surface of the switch in wet weather.
The connexions are as follows: The aerial lead-in is joined to the centre terminal or nim of the switch. One side of the switch is then connected via the lead-in insulator to the aerial terminal of the set, and the remnining side is joined to earth. Thus in one position of the switch arm the acrial is connected to the receiver, while in the other position the serial is joined direct to enrth. The serinl should alwilys be earthed when the set is not in use

EARTH CLOSET. In country districts where no public sanitary arrangementa exist, an earth or chensical closet. located in an outbuilding, takes the place of the town water closet. A simple form consista of a movable receptacle or pail beneath the seat. Dry loamy

Earth Closet. Sectional diagram showing method of construction and hopper for earth supply
the seat, feeding through a hopper to a shoot terminating above the pail at the back. A Ilap can be fitted to regulate the flow of dried earth, as shown in the figure aloove.

The outbuilding for an earth closet con advantageously be built of hrickwork and should be frequently lime-washed. A wentherboarded erection is cheaper, but the numerous crevices harhour a great number of insects. The floor should be of concrete raised three inches above the level of the ground, with a fall to the entrance door. The chcapness of the best earth closet system is a great recommendation, and if constructed to embody the foregoing features it will prove entirely satiafactory in country districts for a small-sized housc.

It should be noted that dry loamy parth is the best niaterial, as its deodorant properties are greater than those of ashes, etc. In fact. unless earth be used, the closet may be treated by local by-laws as a privy, with the result that more frequent cleansing is insisted upon. This applies particularly when a fixed receptacle is used See Cesspool: Refuse; Sanitation; Water Closet.

EARTHENWARE. This term is used for household and other articles made of clay and similar substances. Glazed and unglazed earthenware of fireproof quality is largely used

Earth. Aerial-eartb switch, single pole change-over type. Io this switch a simple form of lightningarrester gap is incorporated
as a substitute for imn, tin aluminium cte. in the minufacture of saucepans and other kitchen utensils. It is casily kept clean and does not rust, besides which na in the case of casseroles, the dish itaelf may be brought to the table. Earthenware utensils require no scrubbing or polishing, but should be washed in warm soapy water immediately after use. In case of stains, soak the pans in hot water to which a little soda has boen added, or apply some finc sand: then rinse and dry thoroughly. See Chin』; Crockery ; Delft ; Fireproof.
EARTHWORM. The ordinary earthworm is the friend rather than the enemy of flower gardeners. because of the work that it does in mixing and lightening asoils.
Few people would object to worms in lawns but for the fact that at certain periods of the year there is a heavy crop of casts which entirely spoil the appearance of the grass. The application of worm killer (a preparation sold by seedsmen) which must be thoroughly watered in, will destmy the worms.
EARWIG. This pest damagos the petals of dahlias, chrysanthemums, carnations and other Howers. Most damage is done while the gardener is sleeping. At dawn the earwig oneepa into a place of refuge, such as a dahlia petal, into the openings of $n$ sponge. a wisp of hay in a flowerpot or a hollow stem such as that of a dead sunflower The gardener should, therefore, place one or other of the articles mentioned among his planta to serve as traps. In the case of sponge or hay, he imnierses it in boiling water in order to kill the insects; if they are in hollow stems, he must either shake or blow the pests out into boiling watcr. The traps should be set in the plants in the evening and examined in the morning.

EASTER. This Christian festival falls in March or April. In England it has come to be a general holiday which includes Good Friday and Easter Monday, and often extends from Thursday evening until Tuesday or even Wednesday morning It is celebrated by the giving of Enater eggs. and sometimes by presents of other kinds, but is more popular as the first holiday season of the year.

For some years business men and others have carried on an agitation in make Easter a fixed date. A measure to this effect was passed into law in 1928, but it will not become operative until the Home Secretary
makes an order to that effect. The Act fixes Easter Sunday as the Sunday immediately after the second Saturday in A pril.
The dates on which Easter Sunday falls during the ten years 1931-1940 are as follows :

| 1931 | April ${ }^{\text {a }}$ | 1936 | A n H |
| :---: | :---: | :---: | :---: |
| 1832 | March 27 | 1937 | March 28 |
| 1833 | April 16 | 1938 | Aliril 17 |
| 1936 | April 1 | $193!$ | Anir |
| 1035 | 1 pril 21 | $19+0$ | March 2 |

EASTER EGG. Among the leas costly varieties of Easter egg are the small chocolate ones. either filled with cream and marzipan. to imitate the yolk and white, or hollow. and sometimes containing chocolate drops or other sweets. There are also fancy neats filled with cggs ; the nests are usually made in eardboard or light hasket work, and the egga may be of almost any kind of sweetstuff.
For more costly gifte there are the large egg cases, made of painted cardhoard, silk. satin, or some decorative materiab. Thess can be filled with a piece of jewelry or with chocolates or perfurne.
An Egg Hunt. An Easter egg hunt is an inexpensive way of entertaining children the eggs being hidden in the garden. . Small chocolate eggs aliout the size of a bantam's egg. and done up in silver puper, are most suitable, two or three eggs apiece being allowed The hiding of the eggs in the garden should not be done too carefully, and a note should be kept of each place chosen. in order that any not discovered may he retrieverl at the end and earh child have a fair share Clumps of rock plants or low growing shrubs offer excellent hiding-places. Two or three eggs may sometimes be bidden in the same place to look like a nest. The children should all start seeking at the rame time, and the hunt should not last too long : in most cases half an hour should be suflicient Should the weather be unfavourable the hunt may be equally woll arranged indonrs. where many ingenious hiding places are available.
EASTON'S SYRUP. Syrup of iron phosphite with quinine and strychnia, known as Easton's syrup, is an excellent tonic for conval eacenta in alight anaenia. loss of appetite, general debility. ctc. A dose for an adult is $\frac{1}{2}$ to I fluid dram in a little water. It can be obtained in tablet form in $\frac{1}{2}$ dram and dram strength.

EASY CHAIR: How to Make. For making the framework for an easy char such as Fig. I, either beech or birch is a ruitable wood, and the joints are the inortise and tenon in preference to dowelling. Fig. 2 is a perspective view of the framework, and the dimensions are indicated in the working drawings at Figs 3-6. Sot the job out to full size, as this will then show clearly the various anglea at which the shouldera aro cut. Fig. 6 shows how the back is marked out. The log is tapered away at the bottom on the inner edge to the height of the stuffing rail, $6 \frac{1}{2} \mathrm{in}$, a piece being glued on at the back to ture the shape.
Economy may be exercised in cutting out
the front legs. Two pieces of stuff are glued the front le

Easy Chair. Fig. 1. Padded cholr, which can be easily made by the amateur. Fig. 2. Framework
lugether, and the shipe cut out afterwards The scrolls at the top are obtained in a similar way Having cut out all the stuff. Whe joints are marked out and cut, all the various lengths and sizes being obtained dinectly from the setting out. Glue the front and back up separately, and allow them to sot hefore glucing the side rails. The joints may te further strengthened by pinning then with $\ddagger$ in. dowels. When the whole is glued up, all sharp edges must bo removed with a raap, and the bun feet fitted, with s in. or 1 in . dowels. It is advisable carefully to stain and polish them hofore fixing.

The fitting of the castors is important, as in the event of these becoming louse and sagging, strain is throw on the joints of the framing. Full instructions for the springing and covering of this lype of chair will be found in the article Üpholstery. See Armchair: Chair; Chail Bed.

EATING. The mastication of lood is necessary for its thorough subdivision into small enough portions to make digestion easy. The operation should not he hurried, as it too oflen is, the ill-mnsticated fond being swallowed by the assistance of Iraughts of liquids This can be avoided by refrailling from the use of liquids throughout meals. See Diot; Digestion: Drinking: Fish; liond: Fruit: Indigestion, etc.

EAU-DE-COLOGNE There are excellent English makes on the market, or this perfume can be prepared at home if preferred. refiesling on a railway journey and, in addiCare inust he inken to pmeure the best rectified tion, does much to alleviate a headache. alcohol. The following ingredients are placed in an ordinary glass bottle.

| Ractified a lenhol |  |  |  |  | 12 plats if drams |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Esprnce of | lemon | $\ldots$ |  |  |  |  |
| - | lurganmot | $\cdots$ | + |  | 11 | - |
| . | cedrat. | $\ldots$ | $\cdots$ | . | 12 | " |
| " | lavender | -. | $\ldots$ | . | 1. |  |
| - | mosemary | . |  |  | F |  |
| $\checkmark$ | thyme |  |  |  | I |  |

The mixture must he well shaken until the essences dissolve in the alcohol. The liquid is then strained through a filter paper, which can be oblained from any chemist, and put into hottles with close-fitting stoppers
The toilet uses of eau-de-Cologne are many Rubbed into the palms of the hands after washing and drying them, it keeps them free from perspiration in hot weather. It is a good facial astringent for use nbout once $n$ week. A pad of cotton wool should be squeezed out of cold water and then further moistened

Eaves. Fig. 1. Showing now and where the tascla and sofft boards are fixed. This arrangement is
particularly suitable for cottage property particularly suitable for cottage property afterwards at night Eall-de-Cologne is EAVES; Of a Building. Eaves oon-
stitute the lower portion of a sloping roof which projects beyond the wall of a house. making, with the aid of an eaves chamnel or gutter, an overhanging drip for rain Witer A projection of 18 in ., and in some cases from 2 to 3 ft . will not be too much. The advantage of wide eaves is that hesides protecting the walls and upper windows from the weather, they give good shadows and thus remove the hleak appearance of a too rigid roof line.

In designing the eaves the questions of the indispensable gutters on the fringe and the down pipes must be studied. If the envos arecontinuous along the front or side of a house-not broken, that is, by gables or other interiuptions-the question of down pipes is greatly simplified. As regards gutters, the half-round variety is better than those with mouldings.

A simple form of eaves in course of oonstruction is illustrnted in Fig. 1. which shows very clearly the arrangement of the fascia board, as the vertical board is called, and the position of the soffit hoard. which is fixed in a horizontal manner to the feet of the ruof rafters. This arrangement is very effective on cottage property. A convenient and economical scherne is to use a 4 in . fascia board, I in. thick, and a 6 in . soffit board, $\frac{3}{4} \mathrm{in}$. thiok. These boards are fitted to the feet of the rafters by outting the latter to shape, getting them all in line by stretching a
with eau-de-Cologne. The face should be cord between the end rafters and cutting all hriakly patted with this pard and then sponged the rafter feet accordingly The boards are with cold water. Skin food may be applied then nailed securely to every rafter The gutter, if of the O.G. type and, say. 4 in wide. is then screwed directly to the front of the fascia, thus saving the expense of the usual gutter brackets.

A more elahorate arrangement is that shown in Fig. 2, where an eaves course of brickwork has been introaluced for the purpose of effecting a better appearance. The soffit is enolosed by a buard supporled on brackels. See Architecture; Bungalow: Housc: Roof.

EBONITE. Ebonite is a hard usually black material made by incorporating rubber with other ingredients. It is amenable to a high finish, and has many domestic applications, examples heing gramoplinne records, fountain pens, electrical apparatus. for which last named purpose it pussesser good insulating properties. It is procurable in the form of rods, sheet or tubing from ironmongers and dealers in electrical apparatus.

Ebonite can be cut with a hack saw in the ordinary way. When drilling holes in it, the drill is apt to clog, and should be backed out frequently. soft soap can he used as a luhricint. Filing is hest accomplished with very coarse or rough files.

EBONY: The Wood. There are several kinds of ehony, which is a hard, dense, and heavy wood, often quite black in colour. Generally the heartwond is black, or nearly so, and the sapwood yellowish grey or brown, or nearly white. The wood too is of ten streaked with whades of lighter or darker colour. Ebony is valued ohietly for its colour : it is used for veneer, for inlaying, for amall turned articles. and for small cabinet work; heing a scarce wood, it is often imitated. The artificial sort, sometimes known as German ebony, is mostly stained sycamore, pear, or boxwood, and is used for the backs of certain hrughes of the cheaper aurt.

Ebony furniture which has hecome dull and shabby looking may be restored by the application of olive oil. If it has lost its poliah, it is hest treated with a preparation consisting of vinegar 3 oz, linsced oil 6 oz., methylated spirit 3 oz.. and butter of antimony $\frac{1}{2}$ oz. See Wood.

ECARTE. This is a card game for two persone which is plaved with a piquet pack of cards. The rank of the cards is king (high), queen, jack, ace, ten, nine, eight, seven (low), the ace coming between the jack and the ten.
The cards are cut for deal, highest dealing, and five cards are dealt either three at a timie and then two at a time, or vice versis. The 11th card is turned up as the trump; if it happens to be a king the dealer scores one point. After the trump has been turned up, the two players look at their hands If the dealer's opponent is willing to play his cards as they atand he says, "I play." If, however. he is dissat isfied with them and wishew to strengthen his hand by discarding and drawing, allowing the dealer the same privilege, he says, "I propose." The dealer may refuse, and say, "Play," or may accept, in which case he deals his opponent na many fresh cards as he discards. The dealer hiinself
then may discard and refill his hand, and the players may repeat this procedure until one or the other declares his willingness to play.

Disearded cards are placed face downwards on the table, and are not looked at by the opposite player. If a player docs examine such cards he may be called upon to play with his cards exposed, face upwards on the table If a player, asks for more cards than there are left in the pack he must take back into his hand enough cards from his last discard to fill his hand. Players may discard any number of cards up to five, and have their cards replaced by an equal number. If the dealer's opponent proposes and the dealer accepts them, the dealer's opponent must discard at least one of his cerds.

Before leading a card, the dealer's opponent says, "I play," and thereafter the winner of each trick leads for the next trick. If a player holds a king and wishes to score it, he must announce it before any card is led, but he is not bound to announce or score it if he does not wish. Players must follow suit, and take the trick if possible. If a player cannot follow suit or take the trick with a trump, he discards If he fails to follow suit or win a trick when he could have done, or trump when he could have followed suit, it is a "renounce," and the cards are takien up and the hand played again

Scoring. Should a player thus renouncing take less than five tricks on the replay, he cannot score. If he takes five tricks he scores one point. Tricks are turned down as taken, and must not be examined afterwards during play. If a player throws down his hand as not being worth a point he cannot score, even though he would have won if he had played If he puts down his hand and claims one or two points he may score them if his hand substantiates his clain.
The king of trumps turned up counts one point to dealer: held in the hand one point to holder if declared as already explained. Dealer's opponent who stands or dealer who refuses counts one point for taling three tricks and two points for five tricks, called vole. If a player stands or refuses and fails to talie three or more tricks his opponent scores two points. The first player to make five points wins the game
ECLAIR. The small finger-shaped cakes known as ćclairs are prepared from chous pastry, the mixture used for making cream buns, etc. The top mny be iced cither with chocolate, coffee, or other icing, and the inside filled with confectioner's custard or whipped and swectened cream. See Banana; Chocolate Eclair; Cream Bun: Custard, etc.

ECRU. Silk before it has been boiled and cotton and linen before being bleached are écru, which in French signifies the natural colour. Iace and curtain nets can be bought either in white or écru, implying in this case a alightly brownish shade.
ECREMA: Its Treatment. The commonest of skin diseases, eczema is characterized by reddening of the skin, by little hard pimples called papules, and watery blisters or vesicles containing matter known as pustules. When the skin is raw there is a sticky discharge.
In the causation of eczema two factors that must always be looked for are external irritation and increased susceptibility of the skin. The external irritant may be something employed in one's occupation or hobbies, e.g. augar in haker's eczema It may be eold or heat, friction of clothing, or otherwise. Strong sorp, cosmetics, thoth pastes, may produce eczema about the lips: decomposing sweat is another cause. Irritants may be brought to the skin by the blond.

Every effort should be made, by better personal hygiene in respect of exercise, sleep. fresh air, and diet, to increase bodily and
mental tone Alcohol in all forms must be given up. Sugar must be reduced Tea and coffee should be discontinued in acute eczemar. and may have to le watched subsequently. Salted ineats, pickles, chutney, and highly seasoned dishes must be avoided. It may be found best to restrict the patient to milk diet. Woollen underwear miny have to give place to silk or cotton. Mild or super-fatted soaps should be used, and none at all in acute eczema.
For erythematous eczema or redlening, lotions or powders are applied, such as calamine lotion, or the following dabbed on and allowed to dry.

## Tinc oxide powder Solution of lead subacctate On .. .. $\begin{aligned} & 3 \\ & 1 \text { drams } \\ & 1\end{aligned}$ Alycerin <br> Camphor witer to minke <br> 1

A useful powder is made up as follows. and is dusted on to burning red areas occasionally : Zine oxide powder

2 drams
Talcum bowder
Starch.
4
Papules are usually found on the arms or legs Burning is not so pronounced, but the itching is often intolerable. The lotions given above may be used, or the following ointment applied locally twice a day:

## Carbolle acid <br> Calonel <br> 15 kmins 20 20 <br> Zinc oxide ointment.

 2 ož.When vasicles occur, the skin of the face, particularly in children, is the cominnnest site of this varicty of eczerna. The lotions mentioned above may be used, and when the discharge lessens, Lassar's paste, which is composed of zino oxide powder and powdered tale, 2 drams each; vascline, of oz ; salicylic acid powder, 10 grains. Pieces of lint or old linen are used, the paste being spread evenly all over. The dressing is changed when it becomes moist. For children, equal parts of zinc ointment and lanoline could also be applied in this way.

Making a Starch Poultice. To clean the parts and remove the crusts, gently sop off with a little cotton wool wet with olive oil. If the crusting is lhick a starch poultice or dinchylon ointment mny be used. The poul. tice is inade by making a paste with a heaped teaspoonful of fine starch, and then making up to a pint with boiling water. Allow to cool and apply on six or eight layers of bulter muslin. Anoint with cold crean before applying the poultice.
For reducing the inflammation the parts may be sopped every hour with a saturated solution of boracic reid, and then treated as for the vesicular stage. In the terminal stage, characterised by redness, thickening of the skin and scaling, this ointment may be used: Liquor carbonis letergens, $\frac{1}{2}$ dram; white precipitate ointment, 1 dram; lanaline and vaseline, equal parts, to 1 oz . This will also be found useful in most cases of sub-acute and ohronic eczema.

EDAM CHEESE. Of the two varieties of Dutch checse, Edam is round in shape and Gonda is tlat. The Edain cheese is made of milk deprived largely of its oream, so that although highly nutritious, it cooks badly, the reason being that it is deficient in fat. See Cheesc.

EDELWEISS. This favourite Swiss mountain Hower (Lcontopodium alpinum) can be grown without difficulty in rock gardens in Great Britain. It neerls a sunny place and should he planted in loany soil with which stones have been mixed. The plant grows about six inches high and has grey leaves: the small yellow Howers are surrounded by greyish-white woolly bracts, which are more curious than beautiful. It is propagated by sceds sown in pots of soil in a frame in spring: growth is slow for the first year.

EDGING: In the Garden. There are two kinds of garden edging, known respectively
as " live" nnd " dead" The former consigts of plants. the !atter of various materia!s, e.g. wood tiles, briclis. concrete, or rockery stone A rockery edging is very aitractive : if the spaces between the stones are fillerl with sandy loamy soil many pretty lowgrowing rock plants will thrive there Strips of wood fastened at intervals to short stakes driven into the ground provide $a$ chenp and convenient ellging to Hower beds and borders but tiles or a narrow edging of concrete are more lasting Bicks set in various ways are often used, and if hard hricks are chosen they. last indefinitely Soft bricks are soon dunaged by frost A concrete or cement edging is made by setting up a narrow trough of boards and filling this with home-made concrete or cement. When it has set the hoards are ramoved
Live edging., that is those composed of plants, are more attractive and gencrally to be preferred. There nre auilable kinds among both perennials and annuals: the former ought to be used if a perinanent edging is roquired Edging plants in a border which runs alongside a lawn are apt to spread on the grass and ruin it: this can be prevented by having a narrow paved path alongside the border. Not only does this prevent the grass being drmaged, hut it provides a dry fonting when the lawn is sodiden, and the plants look very charming when trailing over it. The best perennial edging plants are thrift (armeria), mossy saxifrage, pink, London pride (Saxifraga umbrosa); Campanula muralis. stoneca op, Veronica rupest ris, aubrict in. yellow alyssum, arabis and viola. P'ink, aubrictia, alyssum, arabis. mossy saxifrage, Iondon pride and viola should be cut well back ufter llowering to keep them compact

Some of the low-growing annuals make charming edging plants: sceds are sown out of doors in March-April to produce plants that will bloom from June onwards; they perish after the flowers arc over. Some of the best are Virginian stock, dwarf white alyssum (best of all), leptosiphon, limnanthes, candytuft, nemophila and nemesia. The last named is sown under glass early in Dlarch. Golden feather (Pyrethrum aureum) and half hardy plants such as mesembryanthenum, echeveria, and lobelia are often used as edgings to formal summer tlower beds. The edgings can be kept trim by the use of the tool called the edging iron. Sec Border: Flower Garden: Path. etc.

EEL: How to Cook. Fels are at their best. during the autumn and winter months, and are usually stewed.

After being skinned and cleaned, the fish is cut into small pieces, $2-3 \mathrm{in}$. in length These are placed in a jar with a sliced onion, is tablespoonful of chopped parsley, 1 oz. of mar. gerine, pepper, silt, and a squeeze of lemon juice. A clove or a teasponful of anchov: sauce may be added. The jar is then covercd and placed in a saucepan of cold water, being allowed to simmer until the cel is tender. which takes about two hours.

To serve eels fried they should be cut into short pieces, dipped in scasoned flour, and

Edelweiss, a ropular Swiss mountain flower which can be grown in British rock gardens
coated with egg and breadcrumbs or hatter, and fried until criap and brown They should be well drained before the dish is served, and garnished with tried parsley The amaller fish are best cooked in boiling salted water to which a little vinegar lias been added and served with butter and parsley.

Baked eels can be prepared by cutting the akinned and cleaned fish into short lengths, and standing these in an upright position in a shallow baking-tin Pour in a little water, add salt and pepper to taste a little minced parsley. chopped shallots, and some sweet herbs. and balie the whole in the oven. When the fish is ready take it out of the tin, and thicken the gravy with a small lump of butter rolled in tlour. A little white wine may be used for flavouring
Collared eel is prepared by cutting off the head and tail of a fairly large fish and then skinning it and slitting it down the centre. removing the backbone. Lay the eel Hat on a table and spread over it a seasoning made from two finely chopped sigge leaves, 2 cloves and 2 blades of maoe, a small bunch of herbs (chopped). and pinches of allspice, salt and pepper to taste.
Roll up the fish and tie it securely with a piece of tape. Put the head, tail, and backbone into a pan of well-seasoned water. Boil down these trimmings, then add the fish to the stock. and stew it for $35-40 \mathrm{~min}$., or until it is tender.
To pickle eels, skin the fish, slit them down the centre, and. after removing the bones, rub the flesh over with salt. Lay the eels aside for 3 days, turning them daily : then wash and dry them thoroughly Season them with a little nutmeg, cloves, macc, and bayleaf, then roll up and tie them in a cloth. Bnil them until tender in equal quantities of white wine and vinegar, take them out of the pan to cool, and put them, with the liquor, into clean jars.

Eel Broth. A nourishing broth for invalids is made by simmering lb . of small eels in a
pan containing 2 quarts of water: a lew sprigs of parsley, 2 or 3 thin slices of onion. and a few peppiercorns. Continue simmering until the fish is broken. then season the broth sparingly and atrain it off

Eel Pie. To make cel pie the ecls should lie washed. skinned, cut into short pieces. and placed in a pie-dish on a foundation of forcemeat. Lemon juice, chopped parsley. and seasoning should be sprinkled over them. and the pie covered with a crust of short or puff paste. The pie should be baked from $\frac{3}{3}$ to I hour in a moderate oven, and a white sauce can bo served with it

Eel Spitchcock. This dish is prepared by cleaning an eel, rubbing it over with salt, and then slitting it up the middle and removing the bone. After washing and drying it, cut it into pieces 2 or 3 in . long. dredge these with llour to dry them and then shalie it off Make a thick egg batter, to which a little seasoning, minced parsley, sage and shallot have been added. Dip the piecea of fish in this, and then rull them in fine breadcrumbs Repeat the process, and then broil them over a clear fire until they are pale brown in colour. See Batter: Conger Eel. Pastry.

EELWORM. This is a minute garden pest which attacks cucumbers, tomatoes, daffodils and other plants.

The first symptom of attack is a drooping and yellowing of the foliage, followed by the stem becoming limp, ind the collnpse of the entire plant. The finer branches of the root are more or less studded with swollen portions or knots, varying in size up to $\downarrow \mathrm{in}$. acruss ; knoty of larger size are also often present on the thicker branches of the root. To destroy these eelworms the soil must be thoroughly saturated three times. at intervala of a fortnight. with a solution of one part cresylic, or liquid carbolic acid. in 40 parts of water. The plants that are ruined by the eelworms should be hurnt

## EgGs and Egg Dishes

## The Best Ways of Preparing a Staple Article of Food

See also the entries Batter; Curry: Custard; Onieletre: Savoury Souffé, etc. The articles
Diet and Food may be consulted, as may those on Chicken; Duck; Poultry Diet and Food may be consulted, as may those on Clicken; Duck; Poultry

Like milk. an egg is a pertect food, as it together: the mixture is lighter, colouring and contains all the requisites of a diet-proteids, fat, carhohydrate salts, and water. The volk is rich in fat and in lecithin, a substance which is important in the nutrition of the nervous system and in growth A duck's egg contains more fat than that of a hen. The digestibility of an egg is impaired by keeping, hence the value of reah eags. Digestibility is alsu affected by conking. raw, lightly boiled, or poached eggs being much more easily digested than hard-boiled. Hens' eggs arc those most commonly eaten: ducke' egge are larger, and stronger in Havour. Turkeyse eggs are considered to be delicately flavoured, and the small, spotted egg of the plover is regarded as a delicacy.

Beaten Eggs. The binding properties of a heaten egg are utilizal in the mixing of dry ingredients, such as dried fruits, sugar. and llour, for puddings and cakes; minced meats and fish, for the making of rissoles. cutlets. etc. Snvoury mixtures are most successfully fried if dipped in heaten egg, as the egg cooks round the outside and makes a coating that prevents the frying fat from reaching the food Eggs, hoiled or poached, are much used as an nddition to simple dishes; the hoiled whites and yolks, chopped finely, are a favourite garnish for cold service meat dishes. Hardhoiled eggs are a feature of most salads.

Fggs a re beaten into batter to give lightness and substance to the coating mixture. When hoiled or steamed puddings are mixed with them, the ingredients adhere more closely
together: the mixture is lighter, colouring and
flavouring richer, and the whole more nourish ing Eggs hind the ingredients of a cake, and help to inake it lighter, especially when the yolks and whites are beaten separately
The yolks add colour and richness to sa voury dishes, and make woups for invalids more strengthening Pastry is given a deep hrown gloss if it is brushed nver before baking with a little egg Yolks of eggs are the foundation of mayonnaiso sauce, and also of almond paste for cakes.

Whisked white of egg with the broken shell is used for clarifying clear soups. Adrled to jellies when they are alnust set. and whisked into them. it makes the jellies light and foamy. A jelly will turn out whole if the mould has been smeared with white of egg, and circles of kitchen paper brushed over with white of egg make excellent jampot covers.

White of egg is particularly useful in cooking for invalids, as it is rich in albumen, and more easily digested than the yolk. The beaten whites of two eggs added to a tumbler of hoiled water that has been left until tepid, with a pinch of salt added. make a nourishing drink for an invalid who can retain no other food.
Boiling and Poaching Eggs. To boil an egg, it should he lightly placed in a pan and covered with boiling water, then drawn to the side of the fire where it vill simmor, but not boil. In ten minutes the egg will be cooked with a firm white and soft yolk. To boil an egg hard 15 min boiling over the fire or gas ring should be allowed, and if required
for use cold the egg should immerliately be plunged into cold water to prevent the yolk becoming discoloured. and to make the shell leave the white When boiling cracked egge, wrap them lightly in tissue paper
To poach an egg, if a poaching vessel is not available, a shallow pan should he half filled with boiling water, to which a pinch of salt and a teaspoonful of vinegar are added. The egg should be broken into a cup. gently slipped into the pan. and drawn to the side of the fire. As soon as the white has set. the egg is cooked.

ESg. roacoea eges on coasc. au aupelfang
Poached eggs are served on toast, and garnished with parsley, or are served over a dish of mince. To fry an egg. use the frying-pan containing the fat from fried bacon, or heat a small piece of fat Break the egg into a cup and alip into the boiling fat The pan should be placed over gentle heat, and the egg is ready as soon as the white has set. If preferred the egn can be turned with a thin egg slice and fried on the other side before serving.

An egg poacher is an appliance which comprises essentially an outer pan or water vessel with an inner plate whereon are located the egg divisions. These may he any convenient number, but four is a useful size for the average household

Scrambled Eggs. Scrambled eggs served on rounds of toast inake a good brealifast dish Prepare them by breaking 2 eggs into a brsin, whisk them and mix in 2 tablespoonfuls milk, and a little salt and pepper: Melt 2 oz. butter in a saucepan and, when hot, pour in mixture. Stir with a fork over a gentle heat until the mixture sets, and then turn it on to pieces of toast.

What are sometines known as Scotch eggs lire made by shelling 2 hard-hoiled eggs and. rolling thern in a little flour to dry. Skin 2 raw sausages, season the meat and wrap it round the eggs. Coat the latter with beaten egg and then roll them in breadcrumbs Put them into a deep frying-pan containing smoking hot fat and fry them alowly, to make certain that the sausage-meat is thoroughly cooked. When fried. cut each egg in half, place each half on a hot cronton, and garnish it with fried parsley. Tomato sance makes a good accompaniment to this dish.
Egg Dishes. Egg-and-tomato cutlets is a dish that does not take much time to cook. Melt 1 oz . of fat in a small saucepan, and in it fry 2 tomatoes. When cooked remove them and rub them througt: a sieve. Add to the fat 2 hardhoiled eggs, chopped into small pieces. Put the tomato pulp hack into the pan and add 1 teaspoonful of chopped parsley and seasoning, and 1 gill of thick brown sauce. Then heat up the yolk of an egg, pour it into the pan, and stir the whole over a gentle heat until the mixture

binds. Turn it on to a plate to cool, shape the mixture into cutlets, brush them over with the alightly whipped white of an egg, and coat them with breadcrumbs: then fry them in smoking hot fat If the inisture is ton soft to shape into cutlets, add some breadorumbs to it When the cutlets are ready for dishing. drain them and arrange them on a paper doily on a hot dish

Eggs au Gratin. Eggs treated in this way form the basis of a tasty supper dish Put 2 oz of sliced oheese in a casscrole or baking-dish. well greased with butter or dripping Sprinkle with pepper and salt, a little chopped parsley. and a piece of butter or margarine Pour over it $\frac{1}{}$ gill white sauce, and break on the top sufficient eggs to cover, or allow one egg to each person The yolks should not be broken

Sprinkle the eggs with breadcrumbs and grated chcese and place a few pieces of butter on top. Bake in a hot oven for ahout 10 min . The remains of any savoury white sauce can be used to pour over the cherse in place of the milk and Hour A few drops of anchovy essence added to a plain white sauce mixture give a piquant flavour

Egg Jelly. A jelly that is made from eggs is much used in sickroom cooliery To make it, dissolve $\frac{1}{2} \mathrm{oz}$ of gelatine in 1 gill of cold water. Add $\mathbf{4 ~ o z}$ of castor augar and the juice and rinds of an orange and a lemon Stir over gentle heat, on no account allowing the liquid to boil. Remove the lemon and orange rinds and beat separately the white and yolk of one or two eggs

Add to the yolks a wineglassful of sherry or brandy and stir in the gelatine liquild Stir in lightly the stiffly heaten whites of the eggs and pour the jelly into a wetted mould

Egg Mayonnaise. This favourite hotweather dish is one made from 6 handboiled eggs, the same number of tomatoes, 1 pint of thick mayonnaise sauce, and a little pepper and salt Shell the eggs, and cut them into halves lengthways. Then cut the tomatoes into halves, put them on a bakingtin, and bake them in the oven until they are just tender. but not bmken

Let these get cold, and then arrange them in two straight lines down a pretty dish, dusting a little salt and pepper over each Lay the halves of eggs on the top. with the out side downwards. Flavour the maynnnaise nauce with tarragon vinegar, and then pour it gently over the eggs until they are smoothly contor Garnish this dish with pickled chilliea cut into small diamond ahnpes. (See Mayonnaise)

Eggs sur le plat are prepared by melting a small piece of butter in a fireproof dish and then hreaking 2 egga into it Season to taste with salt, pepper, and chopped parsley, and then pour over them 2 tablespoonfula of cream and put one or two little lumps of butter on the top. Bake the eggs in a slow oven until they set, and then serve them in the same dish

Poached eggs served on squares of toast with a little green sauce poured over them make an appetising dish Poach 6 egga as already described, and prepare the sance by washing 2 oz . of leaves of tarragon, chervil, parsley chives, and watercress mixed Pound these together in a mortar. mixing with them n few dmps of anchovy essence. and pass the mixture through a wire sieve. Add to it $\&$ pint of white sauce, and atir the whale in a pan over the fire until all the ingredients are well blenderl.

Poached eggs may also he served on spinach Rub lb. of cooked spinach through a wire sieve, or chop it finely, melt 1 oz . of butter in a saucepan, and put in the spinach with a little seasoning When quite heated through place the spinach on a hot dish, and arrange 2 or 3 poached eggs on top.

A tasty and economical dish is given the name of vegetarian egg. To prepare it boil 4 eggs
hard, put them into cold water, then remove the shells. Buil 4 oz of lentils until tender. Melt in a saucepan 1 oz . of butter or margarine. atir in 1 oz of flour and a tablesporonful of milk of water in which the lentils were boiled, and cook until the mixture leaves the sides of the pan. Add the lentils, a teaspoonful of mixed herbs. and pepper and salt. Mix all together and turn on to a Houred plate. When the mixture has cooled and become stiff, divide it into small pieces and cover the eggs with it Dip them into beaten egg, then mill them in breadorumbs Fry in hot fat, cut each in half, and serve hot, garnished with fried parsley.
Egg Drinks. Egg flip is a drink prepared fmm beaten eggs. sugar. and brandy, though the last-named ingredient is anmetimes replaced by sherry or port.
Egg nog is prepared by beating up an egg, strainıng it into a tumbler, nad adding to it 2 teaspoonfuls of brandy and halt that quantity of castor sugar fill up the glass with $\frac{1}{2}$ pint of scalded milk

Substitutes for Eggs The various substitutes on the market include egg powders, custard powders and dried eggs, but it must be remembered that although these may give to any dish an identical appearance, they cannot supply the food values of the real article

In a simple cake mixture eggs can be omitted and a level teaspoonful of baking powder used to each cupful of flour A dessertspoonful of vinegar in which half a teasponful of bicarbonate of sodla has been dissolved can be used in place of 2 eggs in a cake containing fruit or ginger. The vinegar should be the last ingredient to be added. Milk must be used to bind the dry ingredients When using eggs for cakes or puddings, one egg can serve for two if yolks and whites are beaten up separately Instead of an egg with a milk pudding, a teispoonful of grated suet can be used. In making custard, instead of 2 eggs to a pint of milk, one cgg and a tahlespoonful of corntiour can be substituted. The comiflour should be blended with a little cold milk and added to the milk just before it boils, and brought to the boil in the pan Stir in the egg after the milk has been removed from the stove

Testlng Eggs. There are various ways of testing the freshness of egga. The shell of a fresh egg is dull and frequently has almost $n$ bloom, while that of n stale egg is glassy and smooth. An egg with a stained shell has probably heen preserved in lime, and if a musty smell clings to the shcll it has probably been preserved in bran One of the surest testa for the freshness of cggs is to place them in a bowl of water. A fresh egg will sink to the bottom of the versel and lie in a level position. and a bad egg will tloat on the surface.

Another test is to hold the egg up to the light, in front of artificial light if possible. A fresh egg has an almost transparent alicll: the yolk is discernible and the white unclouded A black speck inside the egg or a thick and clouded appearance is a sign that the egg is not fresh. A stale egg appears to be more transparent nt the end than the middle, whereas a fresh egg gives a reverse effect.

Preserving Eggs. Waterglass is one of the most widely sold preparations for preserving cggs: the process really is preservation in lime. The freshness is su successfully retained that the eggs treated in this fashion can be used for all the purposes of fresh eggs.
To make the lime preservation at home, pour 6 quarts of boiling water on to 3 lb . of lime Add 1 oz of cream of tartar and $\frac{d}{2} \mathrm{lb}$. of salt When the preparation is cold, plunge the egge

They will swim in the liquid, and should be kept in the tub or vessel in a cool room. or on the shelf of the larder, and taken out as required It is important that they should be kept at a low temperature, so that the air and Huids which are in the shell do not decompose.

Clarified butter and gum arabic can be used as outside preservativen The eggs are dipped several times in clarified butter and hung in nets, small end downwards. in a room that is kept at an even temperature of about $33^{\circ} \mathrm{E}$ I gum arabic is used, paint over the agge with a brush dipped in the gum, and afterwards pack them in dry charcoal

New laid eggs may be atored in racks, that is, on wooden shelves containing holes for the insertion of the egge, with the small ends downwards. They can be kept fresh for months provided they are preserved straight from the nest and are perfectly dry and kept at a low temperature in the summer, but secured from freezing in the winter. It is unsafe to keep them in a refrigerator, as a fungus forms inside the egg.
Eggs can be preserved by pickling in the following manner They are first boiled for 10 min ., then placed in cold water The shella are taken off, and when the egge are quite cold they are put in jars and covered with spiced vinegar The jara should then be covered with nirtight covers, and the egge can be kept until they change colour

Cups and Spoons. Eggcups are generally made of china or pottery, but are also to be had in aluminium, nickel, or silver, and in wood China eggcups should match the breakfast service in colour and pattern Some are provided with sancers to match. or four or six eggcups are made to fit into a single stand when they are bmught to the table For the nursery, sets are made with nppropriate designs. Individual eggeups are alao made to order. with cach child's name painted on his own cup

The eggspoon is a variant of the ordinary small spoon, and is used for eating a boiled egg It is somewhat smaller than the typical tea spoon and somewhat shallower in the bowl Four or six of these are often made to go with an eggstand, and sometimes the bowls are lined with gilt. (See Spoon.)

Uses for Eggshells. Eggahells are used both for cooking and cleaning purposes, and conatitute a valuable ingredient in food for poultry For whitening enamel-lined pans, the shells should be finely crushed and, in the case of stains, mixed with ordinary salt. Crushed eggshells are effective for removing discolora tion from glass water bottles and decanters. The shells should he put into the lottle with warm water and a little shredded soap. allowed to stand, and shaken occasionally Eggshells are poundec and mixed with other foods for chickens, or with hard-hoiled eggs in the case of small chicks. In cookery cggshells are sometimes userl in order to clarify clear soups and broths.

EGG - AND - TONGUE ORNAMENT
This is a form of carved ornament used on furniture and for panel mouldings It is also

Egg-and-Tongue Ornament, used in furniture and mural decoration
a favourite style of moulding for picture frames and is frequently found on ohimney pieces in Gcorgian style It is also known as egg-anddart urnament, as the character of the decuration is made by egg-shaped forms alternating with tongues or arrows. It was used by botli Adam and Chippendale.

EGG BOILER. An article that served this purpose existed in the 18 th century. It is usually an ovoid or tlat versel in two parto, with a ring for 3 or more eggs. The body is supported in a frame with legs, and under it is a small spirit lamp An antique egg bniler in silver is illustrated in page 410 . It is made to hold 8 egga, and on the handle is a sand glass. The lid is divided and opens outw ards on
hingea at either side w discluse the egg ring which is attached to the handle and is remeivabic from the vessel

Thn egy warmer wae made to serve a slighily difterent purpose, i.e. to keep the egga warm, not en bril them. It had no lamp. but was provided with a liner or hot water jacket and a light tray by which the pggs could be let. dowil or raised from the bowl.

EGG COSY. Egg cosies are designed to keep boiled eggs hot when they are put in their eggcups. They are unually included in breakfast tray sets, with tray cloth. napkins and tea cosy to niatch Tiny detachable linen or lawn covers are worked in coloured crosestitch to match the china used. The padded cosy is made like a miniature tea cosy. Egg cosies can also be made from white blanket cloth stitch. ed in colour. Two semicircular pieces are nefderl. When "kewn together they should be large enough to cover the egg and ege cup. See Crossestitch: Tea Cory

Egg Plant. This is an alternative name for the aubergine. a plant of the natural order Solanaceas. See Aubergine

EGG SEAMPOO. The beaten yolk of an egg either used alone or mixed with hot water makes a good shampeo for a greasy scalp.

The yolk of an egg is beaten up in a gill of tepid water. This is rubbed thoroughly into the scalp and hair, and then the head is douched repeatedly with warm water till the hair is clean. The shampoo is effective, and cloes not have the hardening effect on the hair of soap, ammonia, or apirit. If liked, a few drops of oil of lavender may be added. See Hair: Shampon.

EGG STAND. Stands made to hoid a number of eggcups for use on the table can be had in a variety of materials and styles. Some are of china and others of earthenware or metal. The eggcups aro placed in holes in an article which is shaped not unlike a basket, from which they can be removed when required. Silver or clectro-plated stands usually have pegs on to which the cups fit, and a device for holding spoons. A handle, often in the shape of a ring, is provided for lifting the stand. The screws or other fastenings of these articles need inspecting occasionally.

Egg frames, as they are called, existed in the 18th century, when they were made in silver and Shefficld plate. They are sometimes found in combination with a toast-rack or salt-cellar. One fine example stands on ball feet and is decorated with shells and the gadroon. It is fitted with cut-glass eggcups.

EGG WHISR. Various kinds of patent egg whisks can be obtained from the ironmongery stores. One of the most satisfactory types is manipulated by means of a small wheel with a handle attached. This wheel, when set in motion, causes the wires to rotate rapidly so that the egg is whisked to the required stiffness in the minimum amount of time.
Eglantine. This is a name sometimes given to the fragrant sweet briar (q.v.).
EGYPTIAN STYLE: In Furnishing. Sometimes if it is wished to give aspecial character to a sitting ronm, or to make an
appropriate setting for ornamental Egyptian porsessions, this style is auggested in the decoration and in the furnishing fabrics The latter may be woven or printed in the conventional stripes or in the figure and animal designs of ancient Egypt, while views of pyramids, the Sphinx. and fallen pillars half buried in desert sand appear on lampahades and are embroidered on cushions, or are painted on screens or wall panels.

Browns, from sand colour to the darkest shade are used with Nile green and scarab blue to show the Egyptian inspiration, which also appears in trimmings and beaded tassela, srabesquedesigns on rugs or carpets and carved wooden screens. Such a furnishing scheme must be kept as simple as possible or the owner of the room will quickly tire of it.

EIDERDOWN. Owing to its extreme lightness and the large quantity of air and downit encloses, an ciderdown gives extra warmth with only a negligible increase in weight, air and down being nonconductors of heat. Ventilation is provided
by small circular holes, which are strongly buttonholed to provent fraying and any eacape of down.

Down quilts, as well as pmoiding extra warmth, are decorative when covered in silks and sateens of beautiful colour and design. The most important matter is to get a perfectly down-proof material that is light in weight and soft to the touch. Down-pronf printed sateen, cotton-back satin, fancy shantung, Jap silk, and artificial silk taffeta are the materials chictly employed. The last two possess the disadvantage of easily slipping off the bed unless sateen is used for the under side. See Down: Quilt.
ELASTIC. The elastic used for garters, suspenders, braces, belts, corsets, surgical stockings and many other purposes owes its stretching quality to rubber. The more strips of rubber there are in a given width the better the elastic.
If overheated the rubber loses its virtue. Moist heat is less detrimental to it than dry, so that an elastic article that may stand wash. ing will suffer from artificial drying: rubber is ruined by hot ironing or by overstraining. Oil is detrimental. After a certain time any rubber perishes and must be renewed.

Elastic Stocking. A stocking made of a woven elastic fabric is used to exercise equable pressure on the leg from the foot upwards, and so assist in the return of the blood from these parts when the veins are dilated and varicose. It should always be properly fitted. A woven elastic bandage has the advantage that it can be freshly applied each morning and the preasure properly adjusted. See Varicose Veins.
ELBOW. The region at the elbow or bend of the arm possesses two joints, the elbow joint and the joint between the upper ends of the radius and ulna, the bunes of the forearm. The elbow joint is of the hinge variety

Dislocation may take place at these joints, a common one being a backward displacement joint and forming a prominence on the back
of the elbow The troatment of dislocations is to support the arm in a sling and apply cold to the joint while awaiting the doctor Fracture of the Inwer end of the humerus near the joint is liable to be followed by stiffness for a long time.

Sprains of the elbow are treated by the application of cold water and suppurting the limb with a greater arm sling. Tennis elbow is a painful affection of the arm. it dues not interfere with the coarse movements of the limb, e.g. lifting weights but it renders very difficult movements calling for a finer adjust ment of the muscles. e.g. handling a tcacup It has been suggested that it is caused by using a racquet with too big a handle for a comfortable grasp. See Bandage. Disloca. tion: First Aid : Fracture.

ELDER. The common elder (Sambucus nigra) is a hardy shrub distinguished by its soft stems, lobed leaves, the odour of its white Howers and its clusters of black fruits. It will Hourish in shady places and is useful as a shelter shrub in seaside and other windy gardens There ars several varictios with coloured leaves, e.g auren-marginata : the variety laciniata has deeply cut ornamental leaves The golden leaved varicty of the redberried elder (Sambucus ravicmisa aurea) is a handsıme shrub of considerable garden value The branches should be hardy jruned each spring, for the leaves are mont highly coloured on the fresh shoots. Propagation is by cuttings sel out of doors in autumn
ELDERBERRY WINE. For elderberry wine, take 5 gallons of water, buil for half an hour. and then stand till just cool to the hand Add this water to a tub in which have been placed 20 lb . of Malaga raisins, choppred with a knife or shredded and the stalks removed. A wooden tub is best for this purpose, but a glazed stoneware vessel will serve.

Stand the tub for 10 days in a moderately warm roon, stirring at least three times a day in order to kerp the raisins submerged At the end of this time press the juice out of 10 lb . of fully ripe elderberries, and to this juice, which should be about 5 pints in amount, add $2 \frac{1}{2} \mathrm{lb}$. of sugar, boil for half an hour, cool, and add to the raisin liquor Stir the mixture thoroughly and strain it off into a $4 \frac{1}{2}$ gallon cask.

Slight fermentation may go on for some days, and the cask should be bunged lightly to let the gas escape; better still, bore a hole in the bung and fill it loosely with ontton wool. Keep the cask full. and do not allow it to get chilled. The wine should be ready to bottle in a couple of months. If the raisin liquor should show no sign of fermentation after 5 or 6 days, 2 or 3 oz . of brewer's yeast may be added; but this should be unnecessary if it has not been allowed to get too cold.
ELDER FLOWER WATER. To make this water, take 8 oz . of elder Hower blossom and 1 pint of raw alcohol. The Hower blossoms are steeped in the alcohol for 10 days, and the liquid is strained through filter or blotting-paper A few drops of simple tincture of benzoin is then added. The mixture is placed in small bottles with airtight stoppers. Elder flower water is soothing and whitening when applied to the skin it can be added to the washing water

EIECAMPANE: In Medicine. The drug is obtained from the ront of Inula helenium, a bug plant, and is used for many medicinal purposes. It is found useful in dropsy ; it acts as a tonic and stimulant. and it may also be used as an expectorant and as an emmenagogue. Externally it has been found helpful in scaly skin diseases. The dose is 20 grains to 1 dram.

ELECTOR. An elector is one, whether man or woman, who is entitled to vote at elections for members of Parliament and for
town councils. countr councils and other Incal authorities. To became an elector onc's name must be placed upon the electoral roll, which is drawn up twice a year The ordinary qualifications are residence or the nccupation of business premises for six monthe, and the attainment of 21 years. Thuse who are in doubt about their position should apply to the town cleck if they live in a borough. or, if not. to the clerk of the urban or rural district council. See Vote.

ELECTRICITY: In Medicine. Treat. ment by electricity may be employed in various kinds of discase The best-known forms used arc those of galvanism and faradians. The former is consiant current electricity : the latter is an induced curient of an alternat. ing nature. A high frequency current is one which reverses the direction of its llow so rapidly that there may be as many as two million alternations per second. Diathermy, which is a heat-producing agent, is carried out by an intense current of this description.
The galvanic current is used in ionisation for treating neurasthenia and other constitutional diseases: to stimulate paralysed muscles: for norve and muscle testing: in electrolysis for the removal of birthmarks and superfluous hairs. The faradio current
is of value in the regencration of wasted muscles. in obesity this form of electricity being used in the liergonié method: and in certain gynaecological conditions

High Ïrequency is especially valuable in conditions of pain and congestion, and in treating skin lesions such as boils and ulcers. Diathermy is used to destmy piles and various kinds of tumours: to increase metabolism to relieve neuritis: in pneumonia. and for other purposes. Diathermy is much superior to poultices and similar hot applications, because the heat is produced in the tissues themselves.

The application of electricity to the diagnosis and treatment of disease can only be carried out properly by a doctor or under his immediate supervision. much of the work is done by specialists.

Indirectly, electricity is used in medicine to operate the electro-magnet, used for removing metallio Ioreign bodies from the eye; burrs, used in operations on bone and on the teeth : and vibratory machines for massage Instruments on the principle of the tclephonc are used as aids to the deaf. Eleotric lamps are used for radiant heat baths, and clectric currents, with suitable apparatus, are necessary for the production of artificial sunlight and of X-rays. See Electrolysis.

## Electricity in the Modern Home

## Devices which Lighten Labour and Increase Comfort

This article describes the wiring and fittings desirable for an up-to-date housc, and explains how to mike the best use of electrical equipment. Sce also Belts ; Cooker ; Fire : Fuse; Kitchen, etc.

In a house that is connected to a public electric supply main the possible applications of electricity for lighting, heating, cooking and the driving of small machines are almost endless. If the wiring of a house is carried out in accordance with the recognized rules (and it is the business of the supply undertaking to see that this has been done before the installation is connected to its system). the chance of any accident is negligible. A wire cannot canse a fire unless its temperature has heen raised to a red heat or more; but while heat is developed in any conductor through which a eurrent of electricity passes. wires such as arc used in the electrical insiallations of houses do not hecome appreciably heated unless the current passed through them is a great deal larger than that which they are intended to carry.
Safeguards Against Fire. The circuits are always provided with fuses, which are in effect weal places that. in the event of the current lecoming excessive through some accident, give way at points so arranged that no harm can be done. These fuses consist of short lengths of metal which melt at comparatively low temperatures, so that if the current in the circuit becomes too great, they are heated and melt before the rest of the eircuit becomes unduly hot. In so doing they break the circuit and cut off the current, which cannot be reatored until a new fuse is put in.

A small supply of projer fuse wire should always he on hand for emergencies. This can be purchased from most electricians, and should be of the same thickness as beforc. For any ondinary house lighting circuit it should not be larger than that known as $5-\mathrm{amp}$. wire. The use of too large fuse wire may be an infringement of the wiring rules approved by the fire insurance company. Full direct:ons for replacing a burnt out fuse are given in the article liuse. If after replacement the new fuse should melt also, then some definite reason should be looked for and the fault removed. This is a job for a practical electrician. It may be that the lights and small appliances on the circuit take a total of more than 5 amperes, when,
in emergency, the fuse might be strengthened to two strands of wire-not morc. The main double pole switch should be open while any such repair is in progress, so that no current can pass.

Mains and Meter. In the case of a public supply, the main wire. or service cable as it is properly called, will be brought into the house, and terminate in the basement or other convenient location on the ground floor. The company will also fix two safety devices known as fusc-hoxes. and, when the installation is complete, will test the whole system. If all is correct, they will fit the fuse wires and close and seal the fuse-boxes. Both the meter and the fuses remain the property of the company and must not be interfered with

From these fuse hoxes the current is taken to a double pole switch, so that the current can be entirely disconnected from the housc at will, and from this point to a meter, to indicate the amount of current consumed. The current is taken to various fittings known as distribution hoards, and thence by thinner cables to the various lamp points and other fittings. This system is known as the wiring system, and it is the part of the work carried out by the electrician or contractor employed by the house owner.

The source of supply settles the nature of the electric current (i.e. direct current or alternating), and the voltage of the system. The voltage for lamps and fittings must correspond with that of the system Thus a

Electricity. The dial of an electricity meter showing nositions of the dial hands. The correct reading should be 9475 tion of the hands.
lamp that is made for a 110 -volt circuit can only be used on that voltage : if the voltage is less, the lamp will only glow dull red, and if a higher voltage is used the filament will be fused and the lamp destroyed The quantity of current depends on the number and type of lamps used in the house, and this determines the size of the wires and the nature of the safcty devices or fuses.

Measurement of Electricity. The pressure of the electricity is called voltage. measured in volts; the quantity is the current. measured in amperes (amps.): and the power is measured in watts, this being ascertained by multiplying the volts and the amps. Thus a pressure of 200 volts and a quantity of 5 amps . is known as 1,000 watts. 1,000 watte equal I kilowatt ( $k w$. ). The hasis of payment is the Board of Trade "unit" or kilowatt hour (kw.h.), which is equal to the power taken in kw. multiplied by the time of use. Thus a l-kw. fire used for one hour or a $2 \cdot \mathrm{kw}$. fire used for half an hour consumes one unit.

In reading the dials of an electricity meter, start with the right-hand side putting down the figures in order of units, tens, hundrads. thousands. The dial hand should always he read as indicating the figure it has last pisssed and not the one to which it may be nearest. Thus, if a dial linnd is very close to a figure, whether it has passed that figure or not must he determined from the preceding or lower dial If the dial hand of the lower dial has just completed a revolution, the dial hand of the higher dial has passed the tigure. but if the dial hand of the lower dial has not completed a revolution the dial hand of the higher dial has not reached the tigure, even though it may appear to have done so. When one dial hand is on 9, especial care must be taken that the dial hand of the next higher dial is not rad too high, as it will appear to have reached the next number, but it will not have really done so until the dial hand at ! has come to 0 . The dial hands on adjacent dials revolve in opposite directions: therefore, a reading should always be checked after being written down, as it is easy to inistake the dircction of rota-

The small size dial, marked l/10 kw.h., and sometimes coloured red, is usually lor convenience in testing the meters, and in reading the meter consumicrs need not regard anything below the dial divided into units or kw.h.

Wiring Speciflcation. The following specification of wiring suitable for medium size rooms is issued by the Electrical Development Association, 15, Savoy St., London, W.C.2.
fuont Entrance.-One lighting point at front entrance ; switch in suitable position in hall.
Hall.-One ceiling liglating point. In large or lo=g halls, additional ceiling or wall points as required. Two two-way swithes ined ith convencht mostions. for fire und vacuum cleaner.

Diving Room.-One ceiling lighting woint over centre of table; one switch in room near entrance. Wall points as required. Additional switclies to le installed to control wal aslits. One small plus percolator etc Onc laruc plug ind switcli at side percolator. etc. Onc large plug and switchat side of treplace.

Drailina room and hoviae. One ceiling lighting point in centre of roonl ; sivitch near entrance Two simall pluxs fixed "ear window or flreplace or in otlicr convenient position. One larac phug and sivitch on skirtlag at side of tireplace or window.
Kitohen and Scullery.One ceiling lightlng point. Additional ceiling or wall loints may be installed in relling or on wall over cooker, or sink. Ono switeli to
control ceiling light. One sinall earthing plug flxed between 3 ft . earthing plug fixed between ${ }^{3} \mathbf{n}$ it. and ${ }^{4}$ it. from lloor in suitansle
nosition for use of iron, etc. two large earthlng plugs and switches for fire, water heater
or wash tio ler. Hpecian wimwith cooker nall kettle coutrol board if not nrovided by suppay suthority.
LarDfr, Backnoor, and OUTHOUSER.-LIghts to he installed as required. One switch to lie llxed In niost connvenient position for encli light.
Garaok.-One ceillag lighting point: one outside light over karaga door if desired. One suvitch Inside donr to enntrol inside light: one waterpironf earthed owitch to control outaide llaht to be fixed outside. One sinall earthing plug for collvenient connexinn of handlamp, enuine heator. etc.

Notr.-In the kitchen, srullery. Inrder, parage afid wherever there is a concrete, stone. tiled or componition floor, iampholders are to lie made of mavilatint matorlal and switclies nre un be enrtlice or mado of insllinting material Landiva.- (Ine ceiling llahting woint to he flyed sn as to Illuminnte landlng and top of atsirs. Two tun-way swifelice to be fixed one nil the landing nind on ground flonr. One amali
on plus for convenlent connexion HeDroovs. Hedroons. -One ceiling lighting point. Wa\| noints for hracket ighta to be installed if iralred.
Two two-way awitclies to control celling light, one fleed at the donr and the other near the bod. An additional switch to be installed to control wall bracket points. One sniall plug to be fixed preferubly 3 ft. from the floor near the und for table lamp. kettie, ctc. One Inrge plug and suitch to be fived on akirting in a convenient poaltion for lire.
Batirnom.-One ceiling lighting point preferably JVer basin uall bracket over shaving mirror. One inade of insulating ninterial. Sivitches to be earthed or made of Inaulating material. All applianers alich an towel rall. water lieater and llre, to bo sermanently flxed and all exposed metal connected with earth. Portatile clectric appllanecs, such as a fire, alinuld not be taken into thir bathronm.
Water Closets, Attics, loft, Cuplioards.Ceillng or wall liahting pulnta as requlred One switeh for ench light. It in recommended that lights should be installed in all places such ns cupbonrds under stalrs, etc., which are not properly fuminated log general lighting.

The above specification is based on the assumption that electricity will be available under a "Two part" or "All same price for lighting as for heating If this tariff is adopted the wiring is much simplified In arranging for an installation it should be apecified that the work and materiala

Eilectridity. Aooge, switull piag below, interlocking switch-controlled connecsing plur

Wall Plugs and Sockets One of the great advantages of electricity in the house is its cleanliness. and another is its Hexibility With r few yards of tlexible wire a portable electric lamp can be placed exaotly where it is most comfortable to read by, and similarly small electric appliances, auch is irons and toasters, can be used in the position that is most convenient The Hex has attached to one end a bayonet catch adapter which can be inserted in the lampholder of any fixed electric lamp The bulb. however, muat previously have heen removed. and thia means that the fixed lamp and the portable lamp or appliance cannot be used simultanecusly This difficulty can be got over by using a special form of adapter, oue end of which is inserted in the fixed lamp holder. while the other has two branches, one to tako is lamp and the other to take the adapter attached to the Hex of the appliance

A hetter plan. however, is to have sockets and plugs placed on the walls of the rooms The adapter at the end of the tlex then takes a somewhat different form, con sisting of a plug with two prongs or pins which go into two holes in the sooket and establish the circuit. Preferably, the wall sookets should each be provided with a switch, so that the current can be switched off when the appliance is finished with and before the plug is withdrawn from the socket A good type of awitch plug incorporates an interlocking device, *) that the plug cannot be withdrawn from the wocket unless the current is tirst switched off
The nuerits of the various types of electric light fittings are discussed in $a$ subsequent irticle, and the larger conking appliances are Jealt with under the heading Cooker. Apart from these and the various henting appliances, deacribed later. there are the many accessories for the home which sild to comfort ar lighten labour

Most electric appliancos, such as a tosster, coffee percolator, table warming plate, or Hat iron can be safely connecterl to the ordinary lighting circuit. This applies also to the vacuum cleaner or the motor for work ing a sewing machine, but not to the larger appliances. The lighting circuit is not usually designed to carry the heavy currents that are required by Inrge appliances, and if it is asked to do so the result will be blowing of the fuses. If electrical heating, or cooking appliances are to be used on any considerable scale, it is easential to have $\Omega$ separnte circuit. This need not involve an extra meter, as most aupply undertakinge have a system by which a fixed atanding charge is made, and all unita consumed are charged for at a Hat rate, whether used for lighting, heating, or for small mechanical

Electric Heating. Fig. 3. Back view of electrle fire of the type illastrated above, showing the beating elements, wire connerions and foot switch Courtesy of Bellino s Co
cases gas-filled lamps arc used and the walls are light in colour and the cciling white.

Electric Heating. By far the majority of electrio heaters used to-day are of the open wire element tupe. Thic element which provides the heat consists of some varicty of porcelain, fireclay, asbestos or mica bar, on which open coils of resistance wire are wound. These coils end in terminals which are wired up to the switches of the heater, and when the current is turned on the coils glow to incan. descence and thus project hoat out into the room.

Fig 1 shows a period stove, lesigned to heat a coom 18 ft . by 16 ft It tibkes 3 , 2 or 1 unit per hour, according to the switching. A smaller size to heat a room about 16 ft by 14 ft . by 9 ft . high, consumes at the maximum 2 units per hour, but can be reduced by the switch to half power, when it will take I unit per hour. It is generally arranged, in fires of this type, to leave one of the elements permanently connected across the main supply Thus the plug must be renoved from the wall socket, or the wall plug switched off. entirely to switch off the lire, preventing any possibility of a live Hexible lead being left lying about the lloor, where it might be a source of danger.

Fig. 2 shows the standard clement or fircbar emplojed in this make of stove. The face of the bar consists of at number of wells of parabolic shape, in which the heat generating wire is scated in correct focus. The heat rays projected on to the bar from the glowing wire at its focus are thrown out in parallel horizontal beams, and thas the maximum amount of

Electric Heating. Yig. 7. Horjzonta air warmer for a small room Courtesy of Belling de Co
radiant hent is projected. Fig. 3 shows a back view of a lire with the cover removed. The switch used on this type is designed to be operated by means of the foot.

With electric fires there is frectlon from draughts. An existing coal grate need not be displaced, as a portable electric fire may be stood on the hearth in fiont of it. Fig. 4 shows

- fireplace

Fir. 8. Electric convection heater resembling a hot water radiator Courtcsy of belling \& Co. specially designed for electrio hentillg. The lire is shown in process of fixing. 'Ihis type may he placed flat against a wall. lig 5 illus. trates another electric fireplace, in this case one of the Ferranti type In the "Tri city" fire, shown at Fig. $\mathrm{B}_{\text {, }}$ there is a series of metal re flectors.
A figure that is given to decide upon the size of electric fire required to

heat a given room is 1,000 watts, or 1 unit per hour per 1,000 cubic it of space to be heated. 'Thus in an ordinary room, say, 10 ft. high by 14 ft . by 14 ft . (i.e. cubic capacity 1,1960 cubic ft.), a 2,(0)0 watt (2 kw.) fire, consuming at maximum 2 units per hour would be a suitable size.

Other methods of warming by electricity in clude various forms of convection heaters (popularly termed "radiators") and ialso systems wherc the heat is mainly dissipated by actual radiation from the surface of the clement, which is non-
fixed. Fig. 5.
place. Ferranti electric fire-

Electric Eeating. Fir. 4. Bell selfcontalned fireplace, showing how fire is
encrsed in a steel tube 2 in in diameter. The tubo is supported on brackets, the number and length of the units being proportioncd to the size of the room to be warmed. There is $\Omega$ rapid rise of temperature when the current is switched on, nend full heat is available in a few minutes. The temperature may be automatioally controlled by a thermostat. This system is illustrated at Fig. 9.

In a system known as Dulrae panel warming selfcontained electric heating elements are disposed in the heater is the air wirmer of the convection ceilings of the room, and the apartment is It is designed to hent rooms 12 ft . by ceiling areas. This system can be readily in. 10 ft . by 9 ft . high, and consumes 1 unit per stalled when a house is in coursc of erection, and hour. The dimensions are 8 in by 18 in. by may also be npplied to existing buildings. An 4 in high Other convection heaters resemble automatic device regulates the hant, and this in appearance the vertical radiators used in may be set to just the temperature needed to hot water warming systems. The heating lieep the room and its contents well aired (e.g. elemonts are contained within the casings (Fig. 8). There are also hot water indintors, in which the water is warmed by an electric immersion heater fitted in the lower part of the oasing. The convection heaters describel are especially useful for warming halls or passages.
A system well worthy of attention is that known as "Unity" tuhular clectric heating. it works by low temperature radiation, the whole surface of the tube being active. The
heating coil is laced on a nica frame and

Fir. 9. "Unity " Tubular System installed in a nursery achool. Heating tubes ara attached by brackets to the skirting boards and the system operates by low temperature rajiation Courlean of Young. Osmond if Youna. Lid.

# Electric Light : Fititings for The Home 

Suggestions to Suit the Several Styles of Room

The reader is referred to the preceding article on Electricity : and also co Candleshade; Lampshade; Standard Lamp. Bedroom; Hall: Staircase may he further consulted

The effective pussibilitios of room lighting known are the 'opal' ard pearl. The bulb have assumed an important place in schemes for interior decoration sinse electricity has been within the reach of so many pcople and is likely to become still more accessible Eren where any public supply of current is unavailable it is not a matter of great expense or difficulty for a house in the remotest country district to have electric lighting by means of its own generating plant, as for this sole purpose a much smaller plant is sufficient than would be required for heating

When planning the lighting for $n$ mom the practical side will, of course, not be uverlooked for the sate of the decorative. The two necessary considerations on the first side are the adequate placing and strength of lights for their requisite purposes in the partioular room and the economy achieved by choice of the correct type of fittings. It is a much better scheme, for instance, to hare wall plugs conveniently placed for extra lamps than to depend on one central fitting for all purposes, which must either be too dnzzlinz for the

eyes or quite ineffectunl for concentrated light on reading or work It is not cconomy to strain the cyesight or to produce irritntion by a glare when it is unnecessary.

Several new forms of gas filled lamps have been intro duced which overeone tho tendency to a glaring light when used with the type o pendant or wall bracket which discloses the bulb. At the same time these do not in any way interfere with lighting effi oiency. The most commonly
known are the opal and pearl. The bulb
of the former has an inner clear glass and an outer one of thin opalcscent glass, while the latter bulb is frusted on the inside

Modern Ideas on Lighting. The modern lighting expert not only brings out the good features of a room, but also creates fresh heruty by his artistic methods and designs. Wall niohes covered with gold or silver leaf or metallic paint and a framing of mirror glass. metal or contrasted moulding. are rendered even more effective by night than by day with a concenled light placed above and below to show off the china or other ornament in the niche Other niches or small wall cuphoards have glass pancs in the doors, which are in themselves fine pieces of decoration, being tinted, engraved, scmi-transparent with sand-blasted designs, or beautiful with metal work in wrought iron or bronze The light, white or coloured, shines through these glazed doors with a glowing effect. Other decorative ideas for corner lighting are glass statuettes and flower bowls placed on stands

which are lit from inside, the light shining through a top of frosted glass which illuminates the glass object on the stand. Moulded glass panels are also set into walls to give diffused lighting when lit from behind

Strip lighting is effeotive for reccsses, or cupboards, but is too expensive to be practical for most people when employed for the concealed lighting of a whole room ruund the cornice. Strip lights set in tubes of frosted glass are, however, a feature of modern lighting and are very practioal either as wall fixtures arranged vertically with metal plates and bands as shown in Fig. 1 , or set in a single tube horizontally for illunimating mirrors. An illustration of a fitting of this kind can be found in the article on dressing table attached above the mirror in the deaign for constructing a pedestal table.

While modern wall and ceiling fixtures tend to severity of style, beautiful effects are obtained by means of good outline and by the faint stripings and diffused lighting whioh glows from the translucent or opaque glass used by the designers. Such fittings as those illustrated in Figs 2, 3, 4 are obviously suited to the modern type of room and would look out of place in a room furnished in a period atyle. Fig. 2 would be a charmingly decorative wall fixture for a drawing room, while Fig. 3 would be equally appropriate for a dining room, hall, staircese, or lounge fitting and would decorate a corner in the practical fashion of to-dny when things bcautiful are also required to be useful. Other charming wall bracketa for aitting rooms have oxidised silver or gilt mountings with either rimpled or tinted glass.

For a sitting room there is still a general liking for a central fitting using two or thrce 60 -watt lamps, especially where a room is of good size. This fitting is usunlly supplemented by tableand floor atandard lamps and by wall fixtures where theac are necessary. Fig. 4 illustrates a plain ceiling fitting of effective and beautiful outline for dining room or living mom with appropriately severe style of furnishing. Pendants are alao made of imitation vellum in squared or oblong tiered designs with coloured tassels of woollen beads and silk on the corners of the lowest tier Thesc pendants have a somewhat Chinese character, which renders them particularly suitable for a room with pieces of lacquer furniture. A modern lantern form of ceiling fitting for a hall is designed for tubular lamps with an outor friumework of oxidised metal alternating with strips lacquered in a brilliant red or green
Colour in Lighting. Colour is of importance in lighting as it is often possible to improve the aspect of a room by this means. Warm tints should be chosen, whether for the colour of lamps behind translucent glass or for shades Blark lighting; white or bluish, for general effects should be avoided, though for local lights or for reading and working lamps, it may be essential. The suitable colours for shades arc pink, and tones from cream to orange, because these are related to the actual colour of the light itself. They are not only hecoming, but also impart a cosy look to the sitting room, an inviting one to the entrance hall, and an appetising one to the food in the dining mom-all important points in the well-run home.
Lighting the Kitchen. Kitchen lighting is of atill greater imporlance from the practical point of vier. A good kitchen central light is a 100 watt lamp enclosed in a bowl of opal glass fixed close to the ceiling. A light should also be placed over the stove, while onc in the larder and in the kitchen cupboard saves much time and trouble.
Bathroom lighting also is satisfactory with a diffusing central opal globe enclosing a 60 -watt lamp. A small fixture is useful over
the bathroom mirror with a 25 -watt lamp. Should the mirmr he used to shave by, the light may be fixed underneath so that it shines upward on the chin.

Period Fittings. While it is obviously absurd to talk of Tudor or Queen Anne olect ric fittings. the lighting fixtures have to he
 brought into decorative harmony with such perjod styles in furnishing, as expensive forms of concealed lighting are i mpracticable formost people. In a bedroom the most imnor.

Electric Light. Fig. B. Wall brackets and central Atting for a loity room
Courtesy of Wiarino \& Glllow
tant lighting fixture, besides that for the dressing table, is a good reading lamp or bed head light. For a country bedroom wooden wall brackets in oak are designed to hold candle lamps which are in keeping with old-world furniture.
The simple central fitting in tinted glass illustrated in Fig. 5 is suitable for a dining ronm or sitting room, and is pleasing whether used with modern or 18th century style of furnishing. In a dining room such a fitting can be hung rather low over the table. The lofty and good sized panelled room of Georgian style is suitably lighted by grace-

Fig. 7. Lantern fitting in wrought iron suitable for a ball or ataircase
fully shaped wall brackets and a ceiling fitting as ahown in Fig. 6 For a lower room the such anterns may be either suspended on central hitting is of ten a lower room the chains or hung from wall brackets made of the wall lighting heing supplemented by standard lamps in equally harmonious designs.

Lantern fittings in wrought iron look particularly well for panelled halls and staircases or for rooms with oak-beamed ceilings. The one illustrated in Fig. 7 is a good example, and

## Electric Motor: Its Care and Use <br> With Instructions on Building a Model Motor

## In the first part of this article we give hints on the care of fractional horsc-power motors. The second describes a model motor which the amateur can build. See Boat

Small motors-fractional horse-power motors, as they aro termed-are used for many domestio appliances, and the handioraftaman can employ a suitable type to run his lathe or other small machinery.
As a rule, the household appliancesvacuum cleaner, washing machine, refrigerator, etc.-are covered by the maker's guarantee, and the motor or machinery should not be interfered with. It may be an advantage, however, for the handy man to know how to deal with minor defects on other small motors.

The electric motor working under industrial conditions is n prime mover giving the greatest service with the minimum of attention. The essentials are to keep the oil reservoirs for the bearings properly cleaned and filled with good oil: to see that tho lubricating ringe are travelling or carrying oil to the sbalt: to keep the brush gear, commutntor and windings free from dust, dirt and oil; to make sure that the commutator is clean, and that the brushes are properly bedded to the curvature of its oircumference.

To clean an oil lubricated bearing, first remove the drain plug, where this is provided, or the overflow pipe when it is not, and draw off the old oil. Replace the plug and fill the rescruoir with paraffin until it reaches the top of the overflow pipe. After a while this can be drained away again. After refitting the plug fill the reservoir with fresh oil, and replace all oil-hole caps.

A motor fitted with ball bearings need not usually be disturbed more often thinn once every twelve months. The wisest plan is to get an electrical engineer to repack the ball race with grease, since the bearings require properly fitting and adjusting.
Oil must be wiped nway from brush gear, commutator and windings, and all dust and dirt either blown out with a bellows or otherwise removed. Oil, unless removed, may penetrate the insulation of clectrical machinery and prepare it to receive the duat and dirt which so often leads to a breakdown.

A careful inspection of the commutator should be made before this part is touched. If it is of a coppery colour ita condition is hoalthy, and no more should he done than just wipe it with a clean rag. Otherwise, the surface can be polished with fine carborundum clnth wrapped round a piece of wood and held against it while the armature is revolved. Care must be exercised with a commutator that is ventilated or has undercut micas, to ensure that copper dust does not fall between the segments and set up short circuita. A commutator of the latter type should have periodical attention by an elcctrical engincer.

To bed carbon brushes properly to the commutator surface a atrip of carborundum cloth should be inserted between the brush and the commutator (with the eutting face towards the brush) and carefully drawn backivards and forwards until the whole of the carhon face has bcen shaped.

Electric Motor for Toys. The amall electric motors and dynamos used on toys are of two kinds, known as alternating and continuous
ourrent. The former has a two-part commutator; the latter has three or more segments on the commutator, and is the more common. Some small motors are constructed with a permanent magnet instead of a field winding, as. for example; the smaller hoat motor shown in page 114.

The construction of a small motor suitable for driving a toy hoat or for any other amall. power purpose is not difficult, as all the parts can be purchased in the rough. Figs 1-6 show a practical type of motor with horizontal ficld magnets : the winding is at the back, and the whole is low and compact, and adapted for almost any kind of mechanical toy. Castings may be obtained from Whitney's, 129. City Road, London, E.C.I.

The field magnet tunnel should he bored in a lathe, but if this cannot be done it must be carefully cleaned up to shape with a halfround file. Then the various holes are drilled and tapped as shown on the drawings, and the field windinga put on. Each layer must have just the same number of turns of No. 22 D.C.C. wire, and is insulated with a thin slip of waxed paper, and the wire coiled even'y. For the motor in question 38 feet of wire will be needer. Before winding, the cone and side cheeks should receive a covering of several thicknesses of waxed paper. The armature casting is drilled and fitted to the shaft, and the armature poles trimmed up if required so that they just clear the poles of the field magnets The casting is secured to the shaft by a grubscrew, a hole being drilled for this through one section.

The armature windings are No. 24 D.C.C. Ench slot holds two layers with sir turns each, and 13 ft . of wire will be needed. The

Electric Motor for Toys. Figs. 1-6. Planand diagrams of a smallelectric motor suitable for driving a model boat
wire should be given a coat of shellac varnish. All turns of the wires are made around the armature cores in the same direction. Each winding starts on one side of the cores and terminates on the other The starting end of the first coil is attached to the commutator segment iwo places away from the pole pieoe. and the linishing end, twisted up with the starting end of the second coil, goes to the next adjacent regment of the commutator, and so on. The finish of the last coil is joined to the same segment as the beginning of the first coil. The slots in the commutator are sct exactly opposite the centre of the pole pieces The latter should be insulater with cutton tape.

The back bearing (Fig. 4) is attached to the main casting underneath by two screws Fix it temporarily and mark the position of the hole for the armature shaft. The hole for the shaft shoukl not go right through. A small oil hole is masle on top and countersunk a little way with a larger drill. Two holes are drilled in the frame and tapped for the screws. The bearing should be positioned so as to bring the armature in line with the field magnet poles, and the armature must of course turn quite easily and just clear the poles.
'The brushes (Fig. 6) are made from narrow strips of copper ganze rolled up to fit inside the brush holders, and are held against the commutator by coil springs made from steel wire. A hole is drilled through the top of the frame and tapped to take a brass screw which retains the brush holder in place and allows it to be adjusterl. A hole for each brush holder is drilled through the face of the frame, large enough to take a fibre insulating bush, through which the holder passes. The brush holders inay be made from brass tube, a nut being soldered on to the outer edge for the terininal.

The front bearing of the armature shaft is a boss on the bridge piece (Fig. 5), the latter being attached by two screws as shown. The boss is drilled through and an oil hole formed on top. Holes are needed also for the two terininals. The latter require each a fibre bush. A hole is drilled through each of the fixing lugs, to fasten the motor to its bed

The Commutator. The commutator hay six segments. It is formed from brass tubing, driven un to a piece of fibre rod. The position of the segnients being marked out, pins are driven into the fibre through holes drilled in each segmont, and the segments are parted by making slots with a hacksaw. Take the slots clean through the brass ferrule and well into the fibre. The pins prevent the segments frum coming away from the fibre. A hole is drilled through the axis of the fibre, and the commutator is driven on to the armature shaft, to which it must fit tightly. The armature will find its own running position in relation to the field, and the shaft is then pusitioned correctly in the bearings by slipping a short piece of brass tube on the shaft between commutator and front bearing. This forms a washer, and its length must be such as to afford sufficient play between front and back bearing. The latter forms a stop for the back end of the shaft.

The wircs from the field coil go one to the lower brush shown in Fig. 2, and the other to the luwer (neareat) terminal. The other brush and terminal are connected together by a short piece of wire. The accumulator positive is joined up to the upper terminal and the accumulator negative to the lower terminal. The appearance of the finished motor may be seen from the illustration in the article on Boat, where also a suitable propetaw, coupling, and shaft are shown. A 4 to 0 -volt accumulator will energise the motor, and if it is desired to use it in a model boat a special lightweight low built type of accumulator can be employed. Should this or any similar motor not work.
the whole of the eannexions should be examined: if they arc in order the windings should be tested for continuity, anll it should be ascertained if there is a loak to the frame of the motor The commutator segments should be examined, as it is possible that a short circuit is occurring bet ween one segment and another If the motor still refuses to work, then the adjustment of the bruahes will have to be tried.

ELECTRIC SHOCK. A severe electric shook causes a person to cry out, and he may fall to the ground and stop breathing If he remains in contact with a live wire the current should be turned off. If this cannot be done at onoc. his connexion with the wire should be broken: but proper precautions must be taken in doing so. The rescucr should stand on a pile of dry cluthing, if a dry rubber mat is not available, and his hands should be covered with rubber gloves, tubacco pouches or dry woollen clothing. A dry stick, if at hand. may be used to push the wire off the body. It will be notod that emphasis is laid on overything used in connexion with the rescue bcing dry, as moisture conducts eleotricity readily

If the patient has stopped breathing, artificial respiration (q.v.) should be carried out. Smelling salts may be held to the nose, or if the patient can swallow he may be given diluted spirits of sal-volatile He should be kept as warin as puasible -.

ELECTRODE. In a primary cell electrodes are the plates or eleinents. The electrode most vigorously attacked by the electrolyte is known as the anode, and the other plate as the cathode. The poles or terminals of an eleotric battery are known as electiodes also Anode: Battery

ELECTROLYSIS. Tho operation of breaking up chemical compounds by passing an oleotric ourront through them is termod electrolysis, and when skilfully performed it is effective in removing supertluous hairs, birthmarks, moles. and for other purposes. Living tissues are killed by electrolysis. the area of

## Flectro-Plating For the Amateur <br> 

deatruction varying with the strength of the current and the length of time for which it is used A caustic effect is produced, but there should be no scar if electrolyais is performed by a skilled operator. As this method for destroying superfluous hair requires so much time and patience it has to sume extent been superseded by diathermy. Electrolysis is applicable to scaftered hairs ; comparatively few can be removed at one sitting, while by diathermy ay many as 200 can be depilated by. a skilled operator When used to destroy naevi (birthmarks) a general anaesthetic is usually necessary. especially in the case of children undergoing the operation. Electrolysis is sometimes effoctive for the cure of aneurism and hydatid cysts See Depilatory : Hair.

ELJCTRO-MAGNET. The combination of a coil of wire and an iron core is known au an electro-magnet, the wire as conductor carry. ing an electric current round the iron bar in the centre. It has a cominon application in the electric bell. See Bell : Relay.
ELECTRO-PLATE. The wisest thing when purchasing eloctro-plated table forks and spoons is to go to one of the leading firms of silversmiths or gencral stores and to pay the price for a quality that can be reoommended by the retail dealer. Even if the best qualities which are marked A.I, E.P.N.S., are not within the reach of the purse of the prospective purchaser, there are other qualities, known in the trade as B and C , which are reliablo. provided they have the recommendation and guarantee of an old-established retailer. The patterns of table forks and sponns that are most popular are those which are simplest in design. such as the old Einglish and fiddle patterns.

It is best to wash plated ware in hot water to which a few drops of ammonia have been added with enough shredded soap or soap powder to make a good lather. The electroware should be thoroughly washed in this water, a soft mop or piece of tlannel being used It should then be rinsed in very hot, clear water, and immediately dried in a dry, soft towel After drying, rub with chamois-leather.

## How to Coat Small Articles with Silver or Nickel

This articie describes the process of electro-deposition and explaina how to make solutiona for copper, nickel and sllver plating. The work also containg eniries on a number of artcles to which the proceas can be applied, e.g. Bowl: Crumb Scoop

The procoss of elcctrically depositing one metal upon anuther is known as electro-plating. The home-worker can do a great deal with an inexpensive outfit, provided only small articles have to be plated. and the first thing is to clean them

The amateur is counselled to treat all articles of brass or copper as follows First clean and pulish with fine emery-paper, or on a buff in the usual way; then attach a fine wire to the object and immerse it in a solution of potash. The solution is composed of 2 oz . of caustic potash to $1 \frac{1}{2}$ pints of water. This must be brought to boiling point, and the articles immersed until perfectly clean Rinse them in clear hot water, and then place them in a potassium cyanide solution, composed of 4 oz potassiuin cyanide to 6 pints water.

The cyanide is an extremely poisonous substance, and the greatest care should be laken in using it. The hands and arms must be leept well away from these solutions, and the fumes must not be inhaled. The articles muat be wired so that they need not be touched with the hands.
The pmeess of electro-deposition is brietly as follows. When an electric current is allowed to How from one immersed terminal to another through a metallic solution (the electrolyte), and the anode, or terminal at which the curnent. , e.g. Bowl: Crumb Scoop
enters the solution, is of the same kind of metal as that in the solution, the metal will be conducted from the anode and deposited on the cathode. This ultimately results in the cathode becurning heavily coated with the metal and the anode being cither reduced in size or entiroly dispersed If netal articles to be plated are arranged aind connected so as to form the cathode, they will therefore become costed with inctal (see illus.).

Batteries and Bath. Assuming that only small articles are to be dealt with, the following outfit may be suggested. The source of electric current can be a 4 -volt accumulator of, say, 40 ampere capacity ; or a Bunsen battery or Daniell cells may be used. The bath can be a glazed earthenware jar, deep glass bowl, or a wood vat. Some stout brass or copper ruds $\frac{1}{8}$ to $\frac{\text { If }}{} \mathrm{in}$. diameler, and long enough to span across the mouth of the jar, aro needed on which to hang the articles to be plated. These rods are most conveniently provided with binding screws or terminal nuts at one ond for easy attachment of the electric conductor or wire. Copper wire of 24 to 16 gauge is needed, the fine wire for wiring amall articles and the stout 16 gauge for the larger ones.

The next requirements are the motals and solutions. Iron and steel articles must be coated with copper, and a solution for plating is composed of 4 oz of copper sulphat?
dissolved in 12 orz of distilled water Add a strong solution of ammonia until no more green crvstals are precipitated add more ammonia solution, until the green orystals are re-disaslved resulting in an intonse bluecoloured solution Then add slowly a stiong solution of potassium cyanide until the solution is clear Add $f$ as much again of the same potassium olution. and vater to make $2 q u a r t s$ The anode may be a perfectly clean piece of copper plate or bar
Silver Plating For silver the solution may be prepired by dissolving $\}$ uz of silver nitrate in oz. of water, and adding slowly a strong solution of potassium cyanide. Pour of the liquid and wash the white precipitate care fully by putting it in a corked bottle, partly filled with water. Shake it well, stand it aside and allow the precipitate to settle. Pour awny the water, refill, ahake up and illow to settle as before This sloould he done until the precipitate is clean

After this washing, add a solution of potassium cyanide until the precipitate is entirely dissolved Then add about 1 as much again of the same potassium cyanide solution, and make up un ! quart with water This lind of plating requires from 2 to 4 volts, and a pure silver anode innat be used. Iron, steel, zinc. lead, and pewter should be copper-plated immediately before the silver plating is effected

A quickening solntion of 1 oz . of potassium-mercury-cyanide, 1 oz of potnssiuin cyanide, and 1 quart of water should be prepared. Articles thit have been copper plated are first cleaned and pickled, immersed directly into the quickening solution, and left there unti the surfice is unifurmly covered with mercury, when it is rinsed in clean water and placed in the silver-plating bath

This gives better results than direct deposition on the copper, as the silver adheres much better. Iron and steel articles should be kept moving while being plated. The silver will he deposited in from 20 to 30 min , and if all is correct. the article will appear dull or lifeless and nearly white, and must be polished with scratch brushes, rouge, and buffis A small polishing head is very handy for this work Gold can be deposited in the same way
Nickel Plating. Nickel plating is similar to copper plating. and a suitable sulution for it is composed of nickel ammonium sulphate, 1t oz.: ammonium sulphate, it oz. : water, 1 quirt Hot water will hasten the dissolution of the crystals An electric current of 2 voltes and density of $5 \frac{1}{2}$ amperes per sq. ft. of area of the article to be plated, is required for this solution. Pure nickel is used for the anode

Electrical connexions are completed directly the objects are placed in the bath of solution the annde is connected to the carbon of a battery, or the + sign of an accumulator, and the cathore is connected to the zinc of the battery, or to the - sign on an accumulator Do not allow any article being plated to touch the anode or the sides of the vat, or a short circuit will result. Place the objects into the vat and see they are all clear of ench other before switching on the current

Plate as many objects as porsible at one time Prepare the objects by cleaning, etc. immediately hefore plating; do not leave them hanging about, or they will get dirty and the result will he failure. See that all connexions are securely made. Judge the correctness of the work by watching results.

ELEPHANT APPLE. The fruit of an Indian evergreen tree, about the size of an apple and with a hard, woody rind, is known as the elephant apple. The pulp has been used in dysentery and diarrhoea. The gum which exudes from incisions made in the bark is a constituent of Indian gum-arabic

ELIMINATOR. This is an apparatus which replaces the high tension battery in a wireless recciver and in some cases also low simple design. Large battery operated receivers may require considerable modification -e.g. ndditional screening of the high fre quency amplifier from the detector section, etc.- to ensure satis actory working with mains valves, parti cularly to avoid back coupling, the picking up of mains hurn, and interference between transformers, coils and unscreened tun ing condensers. In adequate screening in mains-operated sets also accounts for lack of selectivity, with the consequent fatners of tuning often met with. A suitable high tension eliminator can be employed with practically any receiver, provided the lighting mains are nvailable direct current and there are two types,
The D.C. Type. In the case of D.C. eliminators, it is usial to insert $\pi 10,000$ ohm power type variable resistance in series with mains voltage, and a secondary to give the the positive mains terminal for the principal desired output voltage. The output is applied

Eliminator. A typical example of a battery eliminator for use with alternating current
tension and gridbias batteries The use of an "allmains" unit in conjunction with a recciver primarily designed for battery operation frequently leads to instability and it is better to employ an elimina tor to replace the high tension hattery, and to retain the existing low tension and grid bias batteries unless the set is of
voltage regulation. After pussing through a filter (smoothing) circuit composed of two low frequency chokes in series, and two nuain smoothing condensers, the maximum voltage can be tapped off for the anodes of the screen-grid or power stages of the set. Adjustable voltages are obtained froin tapping points on a potential divider connected across the positive and negative points at the output end of the smoothing circuit.

With the D.C. type there areimportant points to note about the arerial and earthof the sct.

Connect the negalive side of the mains by way of a large condenser to a special earth terminal on the eliminator the earth wire should therefore be remoted from the earth !erminal on the set and joined to this terninal on the mains unit. The aerial should be isolated from the sel.
Isolation is effected by the insertion of a fixed condenser between the aerial terminal on the terminal strip and the wire which is joined to it inside the recciver. This should be of the mica type, value 01 mfd . The earth connexion must be properly made to a water pipe, or efficient earth plate

Eliminator for A.C. Mains. Since alternating current is continuously changing in direction, it is necessary to rectify the current so that it flows in one direction only before it can be applied to the anodes of the valves. Hence, an A.C. climinator must be provided

Eliminator. A theoretical diagram of the eliminator shown in the photograph below. Note the number of smoothing condensers and their positions

There are two types, with some form of rectifier, usually of either
to the rectifier and then passed through a filter or smoothing circuit. The method of tapping off the variour high tension voltages is similar to that used in the D.C. eliminator. If A.C valves are employed an ad. ditional 4 volt winding, for the heater circuit, will be required on the transformer. The removal of the earth wire from the earth terminal of the receiver is not necessary in the case of an A.C. mains unit.

A loud speaker output filter (with two isolating condensers) or an output transformer should be employed in the case of sets operated from eliminators.
In choosing an eliminator care should be taken to ensure an adequate current output. If the receiver comprises one or more stages of screen-grid
high frequency amplification, and a power output stage, the total anode current consumption may be in excess of 30 milliamperes. Therefore a small eliminator designed to give a maximum output of 20 milliamperes will not be suitable, and a larger one should be chosen. Overloading a mains unit can produce only unsatisfactory results, e.g distortion, poor sensitivity and loss of volume
Eliminators are liable to introduce back coupling in a receivcr, which usually takes the form known as "motor boating" and is recognizable by a continuous "pop, pop, pop" The trouble can frequently be remedied by the use of a de-coupling unit consisting of a resistance and by-pass condenser. The resistance, which may have a value of 25,000 ohms, is connected in series with the positive high tension lead to the detector valve A 4 mfd condenser is then joined between high tension negative or earth and the end of the de-coupling resistance remote from the eliminator It is advisable also to de-couple the screening electrodes and priming grids of screen grid and pentode valves respeotively See Alternating Current; Direct Current: Filter: Potential ; Rectifier: Resistance: Smoothing. Transformer

ELM : The Tree. This well-known British tree (ulmus campestris) is handsome and imposing at its best, but owing to its habit of casting large branches, and as the roots travel a long way, it should not be planted near a garden Branch-casting is commonest in hot weather Its proper place is the park, where its fine appearance and bright leaf colour in autumn render it desirable. It may attain a height of 100 ft .

ELM : The Wood. The elm is a hardwood with rather limited uses, though excellent for some purposes. The English variety is a dark brown colour with curly and plaited grain, which does not split easily It is tough and flexible and often takes the place of ash, being cheaper It is very durable under water, and is olten employed in the construction of boats and barges. One of its chief uses is for coffins

Elm is not used for building and very little for furniture, not being durable enough for the first, while its appearance is against it for the second : besides which, it is liable to warp. The bodies of barrows are often of elm, and it is largely used for wheelwright and agricultural purposes See Wood.

EMLACLATION. When there is wasting of the body, the stores of fat under the skin and elsewhere disappear, showing up the angularities of the frame, and there is also a loss of bulk in the tissues generally This will occur in disorders of the digestive apparatus if they are at all severe or last for some time. There is also marked wasting when high fever has lasted for some days, as in the specific fevers, or from long continued low fever. In diabetes wasting is rapid, and it also occurs in tuberculosis. The treatment will depend on the cause. See Diabetes; Diarrhoea; Diet; etc.

EMBEZZLEMENT. This is a form of theft by a servant or clerk from his employer. It differs from larceny in this: a servant commits larceny when he takes money or property of his master out of the master's possession with the felonious intent of depriving the master of his property. He commits embezzlement when, having money paid to him for his master, he appropristes it for himself with the intention of not accounting for it as he ought to do.

A simple illuetration is as follows: A shop assistant sells an article for 18 . and puts the 1 s . in his pocket. This is embezzlement. On another occasion he sells an article for 1s. and puts the money in the till, but subsequently takes it out again and appropriates it. This is larceny; because when the shilling went into
the till, it went constructively into the posses sion of the assistant's master
The punishment for embezzlement is imprisonment up to 2 years with or without hard labour, or penal servitude for not less than 3 and not more than 7 years. The court has also power to deal with a tirst offence under the First Uffenders Act Beoides by clerks and servants, embezzlement may be com mitted by partners as against their co-partners. and also by one joint owner against another. and by publio officers who may not be strictly clerks or servants.
EMBOLISM. When some solid budy is carried along by the blood stream until the narruwing walls of a blond vessel prevent it from going farther, the result is embolism or sth,ppage of the blood vessul. If an artery of the heart is blocked death will pnsue, and the result will be senctas if an imprirtant artery of the train is nffected. In the case of less important blood veasels the only result may be atrophy or degeneration of the part from lack of nourishment.

A common cause is when a stationary clot in an artery becomes detached and moves with the blond stream. If the embulism consists of microbes there will be multiple absoesses : if it consists of tumour cells.
growth will take place at the site of the em. bolism, and in this way a cancerous tumour may form in the brain as a result of cancer of the breast, the cells from the latter having got ints the blood stream. Pending the doctor's arrival the patient must be kept at rest.

EMBROCATION or Liniment. The liquid preparation known as an embrocation or liniment usually contains oil or spirit, to be rubbed in or applied outwardly to the skin in sprains. chronic rheumatism. chronic lumbago, eto Examples are camphor and ammonia liniment. soap liniment, belladonna liniment, etc. Liniments act mainly as counterirritants ( $q \vee$ ) A useful liniment for relievires pain is the following

| Chloral hydrate |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Menthol |  |  |  |  | 1 |  |
| Thymol |  | . |  |  | 1 |  |
| Camphor | . |  |  |  | 3 |  |

The following is a stimulating liniment for sprains, chronic stiff joints, eto

| Oll of turpentine | . | .. | .. | .. | . | 12 oz |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Soft soap | .. | . | .. | .. | .. | . | 11 |
| Camphor | .. | . | . | .. | .. | . | 5 |
| Water | .. | . | .. | . | .. | .. | . |
| W |  |  |  |  |  |  |  |

For chest complaints in young children camphorated oil is a favourite liniment, but care should be taken lest undue irritation of the skin is set up by too vigorous rubbing.

## EMBROIDERY FOR HOME AND DRESS

## Decorated Needlework Described in Detail

For related information see Applique; Canvas: Cross Stitch; Darning; Drawn Thread: Lace; Tapestry; Woolwork. See also Cushion; Table Cloth; Tea Cosy, ete.

The subject of embroidery is here divided into six main classes, namely, embroidery on white materials, linen embroidery, embroidery on silk and velvet, gold embroidery, embroidered laces, and appliqué embroidery These are again subdivided into many kinds of work, and many of the stitches are adapted from one class of work to another. Tapestry work includes such a big section of decorative embroidery worked upon counted threads and in which the stitches entirely cover the material that it is dealt with in a separate article.

Embroidery is usually worked on a background of toile circe (waxed cloth), in an oblong frame specially made for large pieces of work, or in a tambour frame, which consists of two rings, the top one having a spring which causes it to expand as it is pressed down over the bottom ring and material. The latter frame keeps the work quite taut and prevents puckering of the material. Some skilful workers never use a frame. but hold the work smoothly over the forefinger of the left hand or the first two fingers, holding the material firmly with the other fingers and the thumb outside the part being worked. Designs can be bought already traced on material. or a transfer
can be bought. The latter is placed on the
material ink side downwards, and the wrong material ink side downwards, and the wrong side firmly pressed with a moderately hotiron, when the whole design should be clearly seen on the material. The iron should not be rubbed up and down. a firm pressure on each part of the design should be quite sufficient if the transfer is any good. Another method is to trace a design from a drawing, when it is given in the required actual size, or to draw an original design.

Place a piece of semi-carbon paper, inked on one side only, on the material in position where the design is wanted. Put the tracing of design right side upwards over this and secure at corners with drawing-pins to prevent slipping, but first put a tiny piece of paper between the material and the carbon where the drawing. pin goes in, to prevent the material from

Embroidery. Pig. 1. Butterfly worked in broderie Anglaice and above, three stages in mating an eyelet
being marked with carbon ink. Now go firmly over the lines of the design with a blunt knitting needle or sharp learl pencil, and when the carbon is removed the design will be seen
clearly on the material. For transferring clearly on the material. For transferring designs on dark material use a white or red carbon, but as this rubs off with much handling carbon, but as this rubs off with much handling design with running stitches, which can be worked over afterwards.

Embroldery on White Materlals. Madeira work is known by its working thread of greenish blue on a white background, and much of the finest Swiss embroidery is worked with a blue-grey thread. This class of work on

Raised Stem-Stitch. Work this stem-stitch as before, but first lay alons the line you cotton as a found ation and take the stem-stitches over It

Buttonhole-Stitch. Working from left to right, the needle is passed downwards over the tiread

Long and Short
Stitch. One long and oneshort stitch taken alternately

French Knot. Twist the thread round the needlc, holding thread with the left thumb while drawing the needle down close to wherc it first came out

Buttonhole Ring. This is worked in the anme wayas ordinary butonrale ating iro one centre

Feather Stitch.
Bring the ncedle up on the centre line from left to right. and then vice versa. Hold the cotton down with the left thumb so that the ncedle passes ove it each time

Ornamental Blanket-Stitch Work like buttonhole-stitch, rom left to right: but pass he needle two or threc time nto the sinme hole at the top thus making little pyramids

Sloping Satin-Stitch. This is worked from the base upwards from the outside to the centre of
the lear

Fishbone-Stitch. This is like sloping ratin-stitch, but the needely from left to right from the centre to tlic outside, cacl stitch being a little stitch being a hittle
nbove the previous one

Snail-Trail A useiul atitch for stems Bring the needle up to the rold the hread bencith the left thumb. About $\frac{1}{2}$ inch from
he beginning put
n the needre of the the left putting the meedic over the thread which is still under the huinb). Bring the needle up again the other ide of the
hread, and draw
the thread through. A straight stitch and knot will have becn formed. Continue in this way

Satin Stitch. Work the stitches across, placing them close together to cover the fabric without raised effect tiny runningstitches can be put in flrst ior padding. This stitch can be worked from right to left or left to right

Lazy Daisy Stitch. Bring the needle up in the centre of the flower, hold the thread under the left thumb, put the needle back in the same hole as Draw the thread through, keeping it under the point of the needle. Put the needle buck about $\mathrm{i}^{\mathrm{t}}$ inch below to fasten the loop down, bringing it up where the next daisy loop begins

Rose-Stitch. Make a French knot and then work a series of atitches round and round it, beginning In the middle and proceeding outwarda

Loop Stitch. This is aimilar to chainstitch, the necdle passing down the eentre over the cotton, but catching it down with a tiny stitch before going 011 to the next loop

Fly-Stitch. Make a long stitch and catch it down with a tiny one at the cent re

Back-Stitch. Take a running stitch, but with the next stitch the needle passes behind the last stitch bring the needle out. leaving a similar space and proceed as before

Crossed Back-Stitch. This is used on transparent materials; it makes a close ine of cross-stitch on the wrong side, and two rows of back-stitch on the right. It is worked on the right side. Put in the needle as if for ordinary back-stitch, pass it under the material sloping it a little down to the wecond line. Draw it out and makc a back-stitch on the recond line. Bring the ncedle up again under the material, leaving enough space to make a backstitch on the top line as before

Chain-Stitch. Bring the needle through the material, hold the thread down under the left thumb. Put the needie down just Where it came through, then take up one-eighth of an inch of material and draw the thread through. kecping the loop under the thuind till you get to the end. Continue in this way

Fancy Chain-Stitch. For this make alternate large and amall loops. The erh can be varicd by working two small lonjs and then onc large one

Embroidery. Fig. 2. Renaissance work, an eflective form of embroidery tor white materials. such as the tablecloth shown here
nerring-borie, French small scissors so that the cutting may be most knots, eyelet work for carefully done. Venetian embroidery has Madeira and broderie buttonholed edges and bars, the inside of the anglaise, straight and design being filled in with fancy stitches and sloping satin stitch for fillings such as those used in needle-made leaves and solid designs. Initials and monograms can be carried out with the above stitches, with many varieties in fillings for the main stems of the letters
Openwork Embroidery. Real Madeira worl consists of eyelets worked in groups to form a design They are all circular and distinguish this work from broderie anglaise, the
the whole is executed with embroidery cotton, some less twisted than others, to cover the surface quickly and give a smooth finish, such as floss embroidory cotton, flax thread for working on linen, and very fine threads for Swiss embroidery and lace stitches. A coarser cotton is used for padding raised work, while Venetian, Richelieu and Renaissance employ several kinds in one picce of work, the buttonholing being executed in a firm twisted thread and the bars, picots and lace stitches in a softer thread. Hedebo or Danish cut work should he done with linen thread for the main outlincs, and ordinary sewing needles and crewel needles are employed in the process.
latter having ovals as well as circles. Broderie anglaise is not limited to eyelet work but often has solid stitches mixed with it to suit the design. Good materials should be used such as linen, crêpe-de-Chine, lawn and heavy Japanese silk. Either white or coloured thread is uscd and though the embroidery is classed as one on white materials, in this as in other work in this class, coloured materinls are often chosen for its modern expression.

The pattern is transferred to the material, the ovala or circular eyelets are outlined as in Fig. I (see first oval), then these running stitches are whipped, passing the needle through under each stitoh but not through

Fig. 3. Cross-stitch In colour on white linen, suitable for the border of a dachesse cover
Some designs have to the outlined before the material (sec second oval). Now with sharp actual fancy stitches begin, and where this is so it is important to be exact in following the design, as the effect of a piece of work can he spoiled by careless or slovenly outlining. The thread should be fastened on the material by means of a few running stitches, never with a knot, and this also applies when doing the actual embroidery. Only in very special instances is a knot allowed.

When finishing off a thread the end should he taken through some of the stitches at the back, or hidden inside a completed part of the design, so that there are not any untidy ends at the hack of the work. When a raised effect is wanted the spaces inside the outline must be filled with solid stitches, and this is known as padding, for which a soft, thick thread is specially sold. The stitches are piled high towards the centre and shaded off at the sides according to the shape of leaf or flower, and to get good round embroidery it is necessary to make the padding quite firm. The stitches most commonly in use in embroidery are illustrated and details given for working them
The chief stitches used in white embroidery are acalloping, made with buttonhole stitch, stem stitch, crewel stitch (the difference between these last two stitches is that for the former the thread is thrown over to the left, while for orewel stitch it is thrown over to the right), back stitch, crossed back stitch or
embroidery scissors a clean cut is made up the centre of theoval (see third oval) and beginning at the bottom left-hand side the whipped stitches are overcast, completely covering the outline of the design and also taking in part of the material which is folded back from the centre of the oval. Renaissance work has the outlines in buttonholing and the pieces are connected with buttonholed hars, under which the material is cut away at the back. The buttonholing is done over a single tracing thread and of the same width throughout.
The flowers and leaves may be ornamented on the outside edger with picota made by putting the needle half its length ints the last buttonhole stitch, twisting the thread 10 to 12 times round it, pushing the needle through the twists, pulling up the thread so that the spiral forms a semioircle, and then continuing the buttonholed edging. The details of flowers and leaves is often worked out in raised satin and stem stitch and knots are used for centres (Fig. 2). In this illustration of a design for a linen table oloth, the outer edge is of plain buttonholed linen instead of picots. Richelieu work is similar, but the connecting bars are ornamented with picots, while in Renaissance the bara are buttonholed without picots.
Having finished the embroidery the matcrial is cut away underneath the worked bars, leaving these intact, and using a sharp pair of laces, instead of the plain linen spaces teing eft as in Richclieu work
Danish hedebo work has openwork designs overcast and the material cut away at the back. Open spaces are crossed with threads; and these in turn are overcast or rolled. It is combined with open lace stitches worked as a background independently of the material background, as this is afterwands cut away, Satin stitch is often applied between the cut work on the solid portions to embellish the design. Piqué embroidery is work done on a firm background, as the main outlines of design are covered with a cord, sewn along the line, or they are overcast closely, while the centres are filled in with fancy stitches to represent figured materials and damasks, or something of that kind.
Linen Embroldery. Linen embroidery has two varieties, all those done on counted threads, and embroidery done over a design which has been transferred to the niaterial rrespective of lines. Old embroideries of this class were worked on very fine linen, but modern work is done on linen specially woven with rounded thrcads, which arc easily counted and drawn.
Cross-stitch (Fig. 3) is the simplest form of this work, besides numerous geometrical designs which can be carried out by counting the threads. Two-sided line stitches are used in which the needle passes alternatively over and under the threads of the material and in returning covers the threads previously left uncovered. Square stitch is formed in this manner, while chain, long and short stitch, stem stitch, and other ordinary embroidery stitches are used for floral designs. In the cross-stitch design shown in Fig. 3 the curls for the peacocks' tails, and for the fowers on the shrubs are worked in darning atitch. In one variety of linen embroidery the background is darned, leaving the design in the plain material. The background having been filled in, the design is back-stitched to outline it and the centres of flowers are filled with clusters of French knots. Khetha work (Fig. 4) is the reverse of this, having a bold floral deaign outlined in stem atitch and filled with rice stitch or darning stitch (q.v.). The stamens are here suggested in satin stitch. Such work is quiokly done and most effective for cushions or house linen.

Hardanger work (Fig. 5) is a form of openwork on linen and is done on loosely woven canvas, on which the threads can easily be counted. Buttonhole and picot bars aro employed where the material is cut away, or the bars are done in darning stitch and loop stitch and the pattern in straight stitch, which is really satin stitch without padding. the

Fig. 4. Khetha work, in which the effect is chiefly prodaced by the darning stitch
stitches covering in this ease the requisite number of threads.

Punch work produces a drawn thread effect 'Fig. 6) by means of a special punch needle, without the trouble of drawing threads. Various outline stitches may be used for the pattern and satin stitch for flower centrea, the punched holes of the hackground being worked uith tiny hem stitches
Hungarian emhroidery is worked on coarse unbleached linen, the rougher the better, in gay colours and hold designs. By these means beautiful effeots are gained

Distinctive names are also given to other kinds of embroidery, some of which are of a national character. In all work classed as linen embroidery clear spaces of the material are left hetween the designs, the whole ground never being covered as in tapestry work.
Silk and Velvet Embroidery. Embroidery on silk and velvet requires special care. The design cannot be satisfactorily marked on the right side of velvet; it must be lightly traced on the back and the outline followed with white tacking thread, so that the tacking stitches are prominent on the right side of the material. If the work is too big to hold over the finger, an oblong frame must be used, as a pile material cannot be pressed into a round rame. A piece of stout calico should be sewn round the edges of the velvet, and by this it should be laced to the frame with long stitches. the top and the bottom edges first, getting them quite taut, and the sides last. Ordinary embroidery stitches are employed, but in the case of chenille, which cannot be drawn through the material, it must he couched

Embroldery. Fig. 5. Hardanger work. Design for a table runner worked on loosely woven linen or canvas
tion of another kind to forma pattern, giving the effect of patchwork, hut carrying out a definite design It comes under embroidery in its mod ern form, as the designs are sometimes attached by means of huttonhole and fancy em. broidery stitches, while the centres are filled with ornamental stitches and lace fillings instead of the old corded edge or plain fell stitch. It standi out in hold relief, and is quick work in enmparison with ordinary needle emhroidery. Hence its popularity for the decoration of cushions, curtains and bedspreads.

The small pieces that form the design should be tackerl down in position before working, putting the tacking threads near the edge of the top piece and working over them when doing the embroidery. They can be drawn out afterwarda from the back of the work. In the case of floral designs the veinings of leaves and the special outlines of Howers can be worked afterwards through the two materials. By this method the motifs are kept in position with embroidery stitches, which is more popular than the old method of pasting the top material to the foundation.

Embroidered laces come under the same heading as canvas embroideries, where the background is of a loose texture, and all kinds of fancy lace stitches and fillings are used, and others producing a drawnthread effect. Colbert embroidery comes in this class, and includes imitations of 1)resden lace stitches and damask stitches and open fillings. Fancy darning on net is included under the title of embrdidery laces, but work done on filct net comes under a title of its own and is a special clans of work.

EMERALD. These beautiful gems are usually set in combination with tinest dismonds. The stoncs that arc deep green and perfectly transparent down as in laid work ( $q . \nabla$. .). Beautiful work is that arc deep green and perfectly transparent
done by copying Japanese and Chinese designs. irc higher in value than almost any other gem Chain stitch is much employed for bouqueta of Howers, while needle painting is done by means of a flat embroidery stitch and colour shading.

Gold Embroidery. This inoludes all embroidery done with gold and silver threads. It is expensive work, so is only employed where very rioh effects are desired, such as ecclesiastical ornaments and vestments. It requires a strong foundation, such as brocade, velvot, or tlick cloth. The padding for bold designs is done with ordinary white padding cotton, only the surface stitches heing worked with gold thread. The working threads should be handled as little as possible, and a fine stiletto is a great help in making small holes for coarse threads to pass through. This work requires much practice, and in some countries many years' apprenticeship is served in it.
Appliqué embroidery consists of the laying of pieces of one kind of material on a founda-
of the same size or weight. Leas valuable
emeralda arc those in a lighter shade of green in which therc ore white or dark quartz-like markings. These stones when closely exumined have the appearance of being cracked, but notwithatanding these natural Hawlike mark. inga, they command very bigh prices.

Emeralds should always be set in gold claws or in gold hand settings, the latter having the upper edges with milled grain tinish which gives the gold hand the appearance of having had a very fine file drawn across it. Though diamond ornamenta may be set in platinum, emeralds used in combination with brilliants should be set in gold.

The under side of the settings of gems in invariably open, to enable light to be reflecterl through the faceta of the stones. Therefore it is easy to keep cmeralds or similar gems free from dust or soap by brushing the backs of

Fig. 6. Puncn work. Enective design lior linen mats edged with lace, suitable for a luncbeon set

C'ourtesil of Hurrod'x. Ltid
the stones with benzine Another method is to brush them with eau-de-Cologne or sume other spirit which will easily evaporate. A soft toothhrush is best suited for the purpose Care should he taken to prevent emeralds from becoming scratched, as they are much softer than other gems

In recent years the emerald has been so clowely imitated that the stones known as synthetic emeralds are almost indistinguishable from the real gems These copies not only reproduce the clear emerald, but also the stones with quarti markings See Jewelry: Ring, eto

EMERY. Emery is a very hand mineral, a variety of corundum. Owing to this quality, it is used for abrasive purposes. Emery cloth and emery sticks are made, like emery paper by coating the particular material with powdered emery mixed with glac or with some other adhesive sabstance.

Emery Paper. This is invaluable for finishing the surface of netal work. It consists of a paper or linen back coated with an adhe sive and evenly covered with powdered emery The material is available in shects. rolls, or narrow btrips, generally known as emery tape or bands. It is made in many grades, from the tinest, viz. FFFF or SF, to a very coarse gratin. CF, equivalent in cutting power to a socond cut file.

A specially tine grade of emery pisper is much used by jewellers and scientific instrament makiers. and sold as blue back. Fmery

Emery. How to use a strip of emery tape for cleaning up work after it has been brazed
tape is irequently used in lengths of 3 ft. or thereaboute, especially for cleaning up covered work. It is held and manipulated by both hands, one pulling on one end of the tape, the other maintaining an even pressure (see illus.).

Emery Powder. This is an abrasive: its most usual domestic application is in the form of knife powder, sprinkled on a leathercovered board. against which the knives are rubbed and polished There are a number of various grades

Buff sticks, polishing bobs, and similar appliances are coated with emery powder, either by moistening the emery with a drain of oil or by coating the surface of the stick with glue and sprinkling the emery upon it while hot.

Emery Wheels. These are manufactured in a wide range of sizes and grades, from a very small size to large ones requiring $n$ powerful engine to drive them For amateur use a 3 in . or 4 in . wheel is quite large enough to drive by foot-power, or by means of a small bench emery grinder driven by hand. The latter are invaluable for keeping tools in good condition. See Grinding; Polishing.

EMETIC. A number of medicaments are used to induce vomiting, and are termed emetics Examples are: mustard and water, a tablespoonful of mustard in half.glass of cold water; a full glass of warm water, in which a tablespoonful of salt has been dissolved; a tablespoonful of ipecacuanhs wine. This last is a favourite emetio for use with children. A dose of a teaspoonf ul may be given a child of 18 months in bronchitis where the patient is unable to congh vigorously.

An emetic should always be the first trealment in poisoning by irritants or narcotics, but must not be given in poisoning by corrosires, such as sulphuric acid, e'c.
If there is any delay in the action of the emetio, vomiting may be hastened by tickling the baok of the throat with a feather or a paper spill. See Poisoning.

EMINENAGOGUE. This is a remedy for increasing the menstrual How when it is diminished in different diseased conditions. One of the simplest and safest means to be employed for this purpose is a very hot hip bath, to which a teaspoonful of mustard has been added for each gallon of water. There are about a dozen official emmenagogues, the most useful being ergot, potassium permanganate and apiol, the essential extract of parsley. Extracts of certain ductless glands have also been of value. Pron. E-men'a-gogue.

EMPHYSEMA. This is a chronic chest complaint in which the air cells of the lungs become over-distended with air, the resulting pressure leading to destruction of the walls of the air-cells. The diminution in the total lung surface thus produced means deficient aeration of the blood. The disease develops very gradually. In advanced cases the chest becomes rounded or barrel shaped, and the patient is round-shouldered. Cough becomes a marked symptom as the disease continues to advance. The patient should live, if possible, in a dry, equable, sunny climate. The bowels should be kept free. Pron. Em-fy-sē'ma.

EMPIRE STYLE. In furniture this name is given to the style which originated in the years after the Revolution in France. An attempt to copy Greek and Roman forms, its characteristics are classical mouldings and pediments, capitals, wreaths of laurel and of palm. Mahogany, satinwood and rosewood were used; a feature of many pieces is the bronze mounts. Tables, chairs and other pieces are also ornamented with mounts in heavy gilded designs. Much of the furniture was silvered or gilded, while the tripod and the X legs for chairs, etc., were often seen. This style succeeded the Directoire in France and
then passed to England, where Sheraton made pieces in Empire and also in Directoire style. See Dining Room; Directoire; Sheraton.
EMPLOYEE. This word refers to any person who is employed by another, who is called the employer. Most of them must be insured under the national health scheme, and employers are responsible for injuries and accidents that may happen to them while at work See Charwoman: Chauffeur: Groom: Insurance: Servant.
EMPLOYERS' LIABILITY. The liability of an employer for injuries to a servant will in most cases be determined under the Workmen's Compensation Act. In some cases, however, the employer will also be liable either at common law or under the Employers' Liability Aot. The sums then recoverable will be greater than the amount of compensation under the Workmen's Compensation Act. By the common law, an employer is only liable to a servant for accidents which happen to the servant through the employer's fault or negli. gence. He is not liable for injuries sustained by the servant by reason of the negligence of a fellow-servant, even though the fellow-servant is in a position of authority over the one injured.

By the Employers' Liability Act, which does nut apply to domestic servants, nor to any employees except those engaged in manual labour, the employer has been made responsible for injuries to a workman resulting from a negligent order given by a person whose order the workman was bound to obey; the defeo. tive condition of the ways, works, machinery, or plant; the negligence of a person having superintendence of the work; obedience to the rules or by-laws of the employer.

If an accident to a servant liappens by reason of the breach by the employer or anyone for whom he is responsible of any rule or regulation laid down by Act of Parliament for the safety of the workpeople, the employer is liable, quite apart from the Employers' Liability Act. Domestic servants have the rights of any other employee under the Workmen's Compensation Act. See Servant : Work. men's Compensation.

EMPLOYNIENT EXCHANGE. Theee
institutions are found in every populous centre in Great Britain. At them the unemployed in the district register their names, and it is
possible for employers to obtain there domestic servants, charwomen, and others. Application should be made, if possible, in person, to the clerk in charge, who will take down the particulars of the vacant situation and send likely persons along to the address given. No fees are charged. They were established in 1909 and until 1910 were known ns Labour Exchanges.

EMPYEMA. Empyema is a collection of pus in a cavity of the body, particularly the pleural cavity between the lung and the chest wall. It may be a sequel to pleurisy with effusion, or it may occur as a complication in infectious diseases like typhoid and scarlet fever, or in consumption and pneumonia

Empyema may begin suddenly with a chill and sharp pain in the side, made worse by coughing. Then the signs of fluid in the chest make their appearanca In other cases, as in scarlet fever, its onset may be very insidious, with no symptoms pointing to the chest, but it is noticed that the patient shows pallor and declining strength. If after the crisis in pneumonia the patient appears to have fever. the possibility of empyema should be suspected. This is very important in the case of young children in whom the disease, though simulating pneumonia, may be empyema from the start. When a young child supposed to have pneumonia is markedly delirious, empyema should again be kept in mind; also in obscure wasting diseases in children or when the wasting is accompanied by symptoms suggesting tuberculosis of the lungs.

In these cases the doctor diagnoses empyema by drawing pus from the chest, and treatment is to drain the cavity. If the compressed lung expands again the patient may be little, if at all, handicapped thereafter.

EMULSION : In Medicine. An emulsion is a watery mixture with a milky appearance due to its containing oil in tine droplets Examples are emulsions of cod liver oil and of castor oil. Many people who have difficulty in taking plain cod liver or castor oil can take the flavoured emulsions with ease, as being more readily digestible.

EMULSION : In Photography. Whether on glass, film, or paper for the production of negatives or positive prints, photographic enulsion consists of a light-sensitive salt, such as silver nitrate, suspended in gelatine or collodion. See Ferrotype: Film; Plate.

## ENAMEL FOR THE DECORATION OF THE HOME

## Advice on the Treatment of Furniture, 苂oodwork, etc.

## Here are described the correct methods of using enamel paints, how to re-enamel a bath and how to apply quick drying cellulose finishes. The decoration of small wooden objects in enamel is also included.

The householder rightly looks upon enamel as a high-grade paint, used chiefly for the preservation and decoration of interior woodwork. Metal is extensively enamelled, but with essential differences in treatment, and the articles are usually stoved for 24 hours or so, to bake the enamel. Enamel as applied to jewelry, pottery and other articles is quite distinct from that used by the house decorator. The process is described in the article Enamelling (q.v.).

In the use of enamel for woodwork, etc., preparation of the work is of the highest importance. For new interior woodwork proceed as follows: First rub down the wood with glass-paper, unless it is already perfectly smooth, then brush over all knots with a preparation sold as knotting; when this is dry apply a coat of priming to the whole of the woodwork. Brush the priming well into the wood, and when it is dry, clean it down with sandpaper, remove all dust, and fill up all cracks with stopping and putty. Screw and nail heads, which should be below the surface, must be covered with stopping or putty well pressed in until it is level with the surface.

To close up the pores of the wood, the whole must be given one coat of a suitable undercoating. This when quite dry and hard should be smoothed with old fine sandpaper and dusted ; it is followed by a second undercoating of a colour similar to that of the enamel. This second coating must be allowed to dry thoroughly and quite hard; it should present a perfectly even colour and a good surface, but will be matt or semi-glossy in appearance. It must not be soiled, or touched with greasy hands. When quite hard give one good flowing coat of the enamel. Interior wall surfaces of plaster or cement must first be primed or filled with a good coat of reliable priming solution; this is needed to stop the suction of the plaster, as otherwise the unequal porosity of the ground work will affect the colouring, the enamel drying with a patchy effect.

New exterior woodwork should be treated in the same way as inside work, except that outside quality material should be used for the undercoats. Exterior white enamel work should be finished with two coats instead of one, the second applied after the first is thoroughly hard and dry. The amateur will
probably more often be called upon to deal with cxisting woodwork that has already heen painted If in good condition, and when the new colour is the same as the old, it will suffice to rub down and wash the paint with sodawater, stop up holes and give one cont of matt enamel or second undercoating, finishing with the glossy enamel. When the old paint is in bad condition it can be well rubbed down, given one coat of stopping, again rubbed down when dry, all cracks filled and then treated as for new work.

Interior wall surfaces, previously painted and in good condition, can be given one coat of undcrcoating and one of glossy enamel. Walls in bad condition are enamelled as for new work. Distempered walls to be converted to the modern flat cnamel finish can be treated as for new work, but finished with underconting and a final coat of flat enamel

## Application of Enamel to Metal

Exterior ironwork should be cleaned of rust, given n coat of anti-rust priming, followed by two coats of glossy enamel, flatting the first coat of enamel by sandpapering and dusting prior to applying the final cont of glossy enamel. Bicycles and similar vehicles made of inetal are preferably baked or stove enamelled. If they have to be done at home without an enamelling oven, treat then as for exterior work, taking care to olean thoroughly every part hefore commencing the work. Special enamels are sold for this work.

The illustrations show the right and wrong ways of manipulating the brush A useful type is a Hat bristle brush ready ground, or worn in by previous use, cleaned and washed. When using proprietary enamels always uso undercoatings made by the same manufacturers. Do not add anything to the enamel ; simply stir it and apply it in broad, generous strokes of the brush. Do not apply too much enamel, or it will run and show ridges, nor must it be brushed out too thin, or hare places will appear, with unequal gloss. The thing to bear in inind is that a gool coat of enamel should be of equal thickness everywhere on the enamelled surface, and just as thick as it can he without sliding downwards. When enainelling a room do the prominent parta, like the donr, cupboards, and windows, first, and finish with the skirting. Begin with the panels of a door: then do the muntins, top, iniddle and bottom rails or crose-pieces, and finally the stiles.

Enamel sets very quickly, and in half an hour from application it cannot be touched up without showing. Endeavour to apply the enamel so that the finished work is always behind the brush. Thus in covering a large area work up and down or across from side to side, sn keeping the edge of the enamel always alive or workable. In dealing with windows, cut in all the sinall rails first, and then finish on the broad areas.

Enamelling a Bath. To clanse the bath scruls it with hot water and suap extract. This will usually remove all the grease and dirt, but should these be obstinate the application of some gritty scouring powder may be nccessary. When the scrubbing has been completed, two or three good scourings with cold water should follow. 'The next step is to wipe the bath dry and to smooth the surface by rubbing with glass paper of nedium texture. Special care should be taken to rub down the parts around the exit pipe and wherever the old paint has been chipped a way from the surface.

The bath must then be allowed to dry thoroughly. From now onwards until the last coat of enamel has dried no water must be permitted to fall into the bath. It is well to tie up the taps so that they cannot he turned on. Also, as taps often drip, it is a
good plan to suspend an old empty paint can under each tap, or to stop the mouths with a cork. Just prior to the application of the first cont, the bath must be wiped iree of dust and grit. If smuts have blown in from an open window, it may be advisable to rub them off with a rag dipped in turpentine.

Many good enamels are specially sold for bath work. The one selected should be purchased in two grades: (a) to dry with a matt or dull surface, and (b) to dry glossy. Twice as much of (a) is needed as of (b).

The lirst and second coats should be made with the dull-drying medium. They should be applied sparingly. Do not try to hide all the marks of discoloration with the lirst coat. The aim should be to obliterate a little of the discoloration as each coat goes on until none is left when the final painting has bcen carricd out. If a non-glossy enamel be used for the two preliminary coats, each will be dry after the lapse of two days, and then the glossy enamel may be applied; this should be left for a week. As paint hardens quicker in dry weather, it is best to do the work in spring or summer If on placing the hand lirmly on the new surface there is the slightest disposition to adhere, it may be considered as atill insufficiently hard.

When, however, the paint is dry, the bath should be lilled with cold water, the plug should then be removed and the hot tap allowed to run In this way, the cold water should gradually give place to warm and then hot water The latter should be allowed to

remain overnight, when the job may be considered at an end. If the plug be made of metal, it will be advisable to replace it with a rubber one, so that it will not chip the new surface.
Cellulose Finishes. Cellulose enamels are on an entirely different basis from oil paints, and thus possess different properties. In the manufacture nitrocellulose is dissolved in specially prepared solvents to which plasticisers, gums and resins are added. Special pigments are incorporated to give the deaired colours and tints. The drving takes place by evaporation of the liquid solvent content, and the action is very rapid.

In their first stages of development cellulose cnamels were only suitable for application by spray, a method used extensively in industrial work. It has been found possible, however, to produce cellulose finishao which do not dry too rapidly in the early stages to make then inpossible to brush These modified finishes arc, in fact, very suitable for application by brush, and the technique differs only slightly from that with oil paints The products are characterised by many desirable properties such as quick-drying, good gloss and great durability. They are generally suitable both for indoor and outdoor work

## Special Methods for Cellulose Enamels

When using a cellulose enamel stir the paint well up from the bottom and apply with a clean rubher-set brush having soft bristles. The lirush should be well charged with the paint and handled so as to diatribute it evenly over the surface. The second charge of the brush should he applicd at some little distance away from the first and the material laid off towards the previously painted area By linishing the stroke with the tip of the brush lightly in a wet portion, brush marks and "drags" will be avoiderl. The material should not be brished out in the manner of an oil paint, but only sutticiently to give complete and even cover. Only a small aren at a time should be covered. At roum temperature, the first cont should be left a minimum of 2 hours before the second is applied. The shades are mixed tugether to obtaill any particular colour

Brushing cellulose enamels can he applied over alinost all types of surfaces, but these should, of course, always be clean and dry. tll traces of polish, wax, grease and cil should first be removed with turpen. tine. Rust on metal should be removed by sandpaper and good quality petiol until no trace of it reınains. On bare wool. plaster or wallboard a speci. ally made undercoat is usually recommended, as this helps in building up to a good tinish.

Enamel Fig. 1. Applying putty to all holes and cracks. Fig. 2. Sandpapering hightly to produce a level suriace. Fir. 3. Applying the undercoating. Fig. 4. Laying of vertically. Fir. 5. Flowing on the enamel : note grip on brush and absence of brush marks. Fig. 6. Cutting-in edge of moulding

Such undercoats are usually on an oil base. The undercsat should generally be given a drying period of cight hours or more before the finishing coat is applied

Before applying cellulose enamels to finished surfaces these should be sandpapered nmooth, and the rame applies to all rough places or parts where the old paint film is broken through, when the edges should be " fcathered " down. All traces of varnish must be romoved Cellulose enamels should not be brushed over a surface that has been recently painted with varnish or enamel, or lifting may occur When applied over surfaces which are already painted, the life of the cellulose finish will only be that of the old paint film beneath

Clear Cellulose Varnishes. These are particularly suitable for use by amatours on stained furniture, such as sidebuards and dining tablew, where french polish would ordinarily be employed It is necessary to remove every trace of grease or was polish from the surface before the clear cellulose is applied. The varnishes are not intended to be employed over a cellulose enamel to increase the gloss, as a better method is to rub the surface with a cloth moistened with a little polish suppliod by the manufacturer of the enamel. An occasional rub over with this polish will ensure that the gloss is retained Clear cellulose varnishes are only suitable for indoor work.

The solvents in cellulose finishes arc inflamnable, and the material should noi be used near a fire or any open flame. It can be used on geysers and fireplaces without fear so long as no flame is present while the material is being applied, or within a few hours after application. When used indoors the noom should be well ventilated.
ENAMEL: Flower Designs on Wood. A modern note for small artioles is struck by staining white woorl brown or grey and using enamely only to paint the decorative pattern than by dolng all the work in the latter material. White wooll door plates, trays, blotters, hoxes and book ends can be quickly tranaformed into charming sets by this means. The contrast of the matt background and shining flowers is attractive
The set of powder jar (or it would do equally well for oigarettes), trinket box and pin tray here illuatrated could be stained grey, using a water stain that is ohtainable in amall bottles.

Enamel: Trinket boz. pin tray and powder jar in stained grey wood with fower design in brightly coloured enamels See key diagram above

The surface of each white wood article is turst rubbed dow $n$ with a piece of glass paper and then, having diluted the staill to about half its strength with water, each piece is painted. When dry the stain is rubbed down with glass paper and polished with a stiff brush in order to give a satisfactory surface on which to enamel the pattern

## ENAMELLING AN <br> Method: vistal

Having told how a pendant ant on to describe the use of non-firiu $u_{\mathrm{b}}$, miplets,
In most cases enumelling is used in conjunction with metalwork. In cloisonné enamols, or instance, it is inseparable, fine wires being tirst soldered to $n$ base. The muffic furnace is of great importance to the cnameller: This can be heated by gas or electricity. For quite small articles the jeweller's enamelling furnace shown in the photograph on page 426 could be employed. It is worked with a draught burner and does not require air blast The following tools are noeded: a sinall hench, a pair of furnace tongs, a porcelain peatle and mortar, a pair o! small shears, an otching point, or scriber, and a set of enameller's

# NRATIVE ART 

 brush, acid bowl, and a sinall vice standard silver wire. saw round the engraved line.on the pin tray the on the pin tray the leaves are done first, then the two half-open Howers are coloured, then the white one and last the blue, allowing each part of the design to dry in turn. The design on the trinket box only is outlined in the diagram above, but this is reproduced in actual size and can be easily adapted to suit the sevenal pieces.

The chosen design is traced on traoing paper and transferred to each article, using red carbon paper, a small piece of which is placed between the design and the wooden surface. Take oare not to lent the wood.

The colours are then filled in according to the chart. using small tins of enamel supplied from an arts and crafts department or studio. Outfits of 10 colours can be obtained for 4 s . 6 d with medium A boxwood stick is used to apply the enamel in a oircular motion, spreading it evenly over the surface ; where one part of the design intersects another, allow the underneath part to dry before colouring the before colouring the
tyeydecigrated by fired enamel, this article goes igns for a trinket hox in imftation cloisonne

Enamel Pendant. A simple pendant would form an easy joh for the beginner. The design having been ohosen, the following materials will be nceded: A picce of fine silver shcet, gauge 10 , aizo $2 \frac{1}{2} \mathrm{in}$ by $2 \frac{1}{2} \mathrm{in}$. Fine silver, i.e. unalloyed, should always be used for best colour results, as standard silver, i.e. alloyed, blackens when heated and dulls the enamel Besides this there arc required a sheet of silver foil, gold shell, loz. gum tragacanth, a small bnttle of purc sulphuric acid. and a pioce of

Take the piecc of silver and trace upon it the shape of the pendant. Carbon paper will give a good impression on the inetal. Then. with the scriber, or etching point, engrave the traced linc, so that it is plainly seen when the oarbon rubs away The next operation is to

Fix a saw in the suw frame, being careful that the teeth are pointing outwards and downivards towards the handle. Screw up, so that the saw is absolutely taut (Fig. 1). Saw a small hole in the bench peg, the small projecting part of the bench (Fig. 2). Place the silvor on the peg, just above the hole. Hold it firmly with the first and second fingers of the left hand. Placo the saw in the hole against the edge of the silver, moving it up and down in even strokes. It is the down stroke that outs, and must, therefore, have slightly more pressure. Kcep the saw perpendicular. When coming round a curve, move the metal gradually mund, not the suw. See that it is kept flat
all the time (lige 3) It it is allowed to tip up it may break the saiv

Drilling the hole for the insertion of the ring necds n little practice Place the drill in the chuck Keep the drill-stock perpendicular placing two fingers on the cross-bar See that the cord is not caught at the top (Fig 4) Rovolve the spindle until the cord is twisted down it. Very gently press the cross-har down. and it will come up agnin without a second movement (Fig. j). When spinning, no furthes pressure is ncocssary. The metal must now be annealed or suftened. If the bench is not litted with a burner for the hlow pipe the furnace can be used

Having in the tirst instance obtamed a good heat in the muffle, put the silver on the firing plate. With the furnace tong plact it in the mufle for a few scconds until the silves reaches red-heat. Great care inust be taken to withdraw it immedintely, as it will melt if left ionger The silver may be plunged into water to cool. It will now be soft and pliahle, and is ready for doming Holding the silver by the pelges, place it on the stecl stake and tap it with the planishing liammer, inaking even pits in circles until it heconics the required dome (Fig (i). Should the metal become stiff and springy. the annenling process must be. repeated Enamel applied in Hat metal drawa up, eracks and tlakes off Hence the reason or doming

The pendant iy now seady for cleaning The jresence of any grease or disculoration may ruin a colour: therefore too much attention cannot be given to the following: Pickle is tho tochnical name given to the weak solution of acid used for cleaning metals

Particular sare must be laten in the mixing, and these instructions failhfully followed, or a serious accident may resull. The quantilies are one part sulphuric acid (eitriol) to 20 parts water (abone 10 fluid oz of venter to ! oz. of acid). Alyays noser it? reater ints ihe bowl first;
velphuric acid gently, a few drois
civering the entire surface of the te
Even so, the bowl will be found iveir. Wuch Should this process be revers unid poured in quickly or carelessly, the su" mixiug would eneat- tenat enningh is calua an explusion.

After leaving it a few seconds the pickle is ready for use. Place the bowl upon a gas ring with a small fame. Put the silver in, and heat until it is just on the boil Renove the silver from the howl with n mateh end or piece of wood. It is not advisable to put the hands in the pickle more than is necessary. Never use iron tweezers. Iron in pickle leaves a pink deposit on the silver. Next talie the silver to a tap, and with the wire brush, under running water, brush the surface briskly. When back and front are absolutely bright and free from srease it is ready for the enamel.

The grinding must now lie done. Clean the mortar thoroughly. In it place, with a little clean water, a small piecc of enamel of the desired colour. Jxperience only will teach the amount necessary to cover a surface. Take the pestle, which must also be cleaned, and tap it gently with the wooden mallet, reducing the enamel to small Hakes (Fig. 7). Then grind with the pestle until it becomes a fine, even powder (Fig. 8). The water will now be milky This milkiness must be washed away under running water until the water is perfectly clear Care inust be taken not to wash the enamel away. This can he avoided bo giving it time to aink at each rinsing. Put the enamel in one of the saucers with a littic water, and cover it with the lid Repent this operation with each colour that is requirad

Where a thin motal is employed, $\pi$ counterenamel will have to he used. 'This menns that the hack is covered with enamel. It is done to prevent cracking, ao the metal and enamel

contract at different tutes during cooling. the edges gently to disperse it over the surface Take tion Hakes of gum tragacanth and soak Then smooth it over, using a slight preasure in a sancer with water. When the liquid is until the whole surface is evenlyand thoroughly sticky to the touch, cover the back of the pen- covered. Care should be talien that the enamel dant with it, using a clean sable paint brush. is not too thick. The moisture should be The pendant or piece of silver to he denlt with sonked up with clean, white blotting paper or should he held on the tips of the fingers by linen rag. To apply the enamel to the front the the edges. bacle upwards, to avoid marks on pendant must be turned, but atill held in the the nilver he milver.
This having been done, the next step is to shaded as required, but no gum tragacanth is take a small spatula or penknife, and with it necessary on this side of the article The surconvey the enamel to the back (Fig. 9). Tap facc ahould then be sinonthed over with a
palette knife (Fig 10), and the moisture absorbed by the method

## just explained.

The firing plate (Fig. 11) is now required This is made of nickel-sheet, and must be cut in such a way as to clear the sides of the muffie, and short enough to allow the door to close. Turn the end up, so as to give a grip for the tongs. The muffle should now be an even cherry red, with no dull black spots. This is essential for gond results Place the enamel on the firing plate, lifting it carefully with a palette knife. Remove the door from the muffle and rest the plate in front and leave it there (Fig. 12). When all traces of mois ture have evaporated it is ready for fring. At this stage the powdered enamel is dry and easily shaken off, so care must be taken in placing in the muffle (Fig. 13).
The difference in the melting points of various colours make it impossible to say exactly how long an enamel should remain in the muffle The onameller inust watch carefully and see the changing as the enamel melts. door out ant it is not good to have the frames ap. ime, as it chills the muffle. When the enamel is nearing the molten state, hold the tongs over it, and when they are reflected in it, the enamel is fired and must be removed quickly. Overfiring is disastrous, and neglect at this stage may easily spoil the pendant or other object being fired. Do not remove the pendant or other object from the plate, but put it near the muffle to cool gradıally. The enamel has now had ite first firing. It may happen that there aro holes in the surface, or that part of the counter-enamel has dropped off. This must be patched when cold, and refired before proceeding.

Silver and gold foils are used for still brighter effects. In this pendant, silver foil might underlie the small spots of the design to give a jewelled appearance. Take the sheet of silver foil and. holling it between the packing papers, cut smallcirclesto thenumberre. quired. These are applied to the surface of the enamel by means of a spot of gum tragacanth solution. Fire again, but this time it is only nocessary to reach red heat. When cold, cover the foil with spots of enamel. A small sable brush is best for this purpose. Spots of white or other light oolourarealso
done in thisoperation. Again only a slight
firing is given, so that these spots are ulazed but do not sink to the surface level. There remains the heightening of salient features of the design with gold. For this take the gold shell and a fine sable brush. Using a littlc water, paint the design with s strong, clcan line, and fire again.

The pendant is now linished except for the jump-ring for hanging. This may be made from a piece of standard silver wire, cankerl to slip easily thruagh the hole already dirillerl.

Cigarette Box. The panels of the cigarette hox illustrated in Fig. 14 nre simple examples of painted enamel. They are held by means of copper
 In addition to the tools and materials already mentioned, a ground glass slab and glass muller are required, also a small bottle of oil of spike laverder, a bottle of fat oil of turps, and one gramme of iridium black. The plaques are enamelled on copper shcet. gauge 5 or 6 .
Mark off, with the scriber, the five pancls (i.e. four for the sides and one for top), seeing that they are parallel and true. They should measure about $f$ in. each way above the actual size when finished. The doming pulls the edges inwards, and thus the design would le hidden under the frame if it were not slightly smaller than the metal. With the shcars cut on the etched line and round off the corners with a file. Anneal the metal as indicated in the making of the pendlant.

Dome each plaque (Fig. 6) It is important that all the odges and corners lie flat on the bench and do not rock. Next pickle and brusli the plaques, making then very bright.
Coloured ensmels ap plied directly on to copper look dark and heary. therefore the plaques art first covered with a cleas crystal enamel, called cop. per Hlux. To cover the five plaques, about $\frac{1}{\mathrm{l}} \mathrm{lb}$. of copper flux will be required.

Cover the back and front of the panels, not forgetting the gum tragacanth on the back. Remember to press the counter-enamel down well, and smooth the domed
sidc. Enamel will not find its own level when it is molten, so if caro is not taken at this point, a bumpy sarface will result. Dry the plaque in front of the muffle and fire it until the flux is quite clear. While it is cooling. trace the design on tracing paper. Place over the plaque a piece of carbon paper and the tracing above it, fixing it down with four drawing pins.
lun over the tracing with a hard pencil to produce a clear carbon line on the flux. Take the ground glass slab and on it put a small quantity of iridium black, one drop of fat oil of turps, and a few drops of oil of spike lavender. Grind together with the muller. With a fine sable brush paint over the carbon line. It nust be strong and distinct. If too much oil is used it will be blurred, especially after firing. Fvaporate the oil in the front of the muffle, then fire until the line is glazed. The greatest heat is at the back of the muffle, therefore that end of the enamel will be fired first. The enameller must not wait for the other end to fire, but take the plaque out and turn it. so that the other end gets the sanie temperature. This must be olserved in every firing to a void overfiring at one end.
Cut the silver foil into the required shapes between two pieces of paper. Cover the back of the foil with gum tragacanth and place it in position on the plaque, pressing it down firmly. This must also be dried before tiring, as if moisture is left under the foil it will bubble. While it is cooling, grind the colours, wash each carefully, and place them in clean saucers. In applying, with an end of a palette knife or pen-knife, care must be taken not to merge one into the other. To avoil this, clean up any enamel which has gone over the outline with a sable brush. Dry and fire as before.

Finishing Touches with Gold Shell
Possibly the work will look blotchy and uneven in colour. l'articles may have flown off when it approached the heat, leaving here and there patches of the flux exposed. These must be covered with colour and fired again. When the colour is satisfactory it is morked on with gold shell, which is used in line and dots. Where the drawing needs improvement, e.g. on the rigging of the ship, line work is expressivc, and dots are effective on the crest of the waves. After firing the gold, this panel (Fig. 15) is finished. The side and end panels are shown in Figs. 16 and 17. As regards colour and manipulation, they are repetitions of the lid panel just described.
The numbers of the enamels used in the panels may be useful. They are as follows: sky-blue, 167; Ship-ruby, 115 ; Sailsyellow, 105; Sea-blue, 136. For the lish, ruby and yellow ase employed, the sea boing of the same shade (136) as in the top panel.

Enamelling. Fig. 14. Cigarette boz in polished copper, riveted on cedar wood, with enamollod deajgns on inget domed plaques

The live panels having been completed, they arc applied to the box in the following way. Sheet copper, gauge 10. is used: Cut separate pieces to cover the lid, sides, and end of the box. In the centre of each of the picces measure the space to be cut for the panel. making il a quarter of an inch smaller each way,

Enamolling. Fig. 15 (above). Deagn for an onamelled plague in the lid of a cigarette bor. Figa, 16-17 (below). Designs for side and epd panels

shown in outline at Fig. 19, is suitable for \& trinket box. Choose a picce of copper 12 in wide, and measure it on the box. Make a tracing of the design and fit it on the box before tracing it on the metal. Make sure that the design fits the article, and, if necessary, alter it to fit so giving it $\frac{1}{\text { b }}$ in. all round to hold it when To trace on the metal, go over the whole fixed. Drill a small hole to insert the saw, of the deaign with a steel tracer, working and saw along the line, keeping well on the from the under side of the metal, and inside. File up the frame until it is true and fits the enamel. Berel the back to follow the shape of the dome sides.
Dome tho copper frame, so that while the enamel is held in place the outside edges lie flat on the box. Bevel the edges round the enamel. Measure off the holes and drill, gauging the drill by the diameter of the pins. Fix the frame to the box with $\frac{f}{2}$ in. copper pins. If the wood is thin the pins must be cut to the required length before being driven. Cover the sides and the ends in the same way.

In cloisonné enamel, fine wires or cloisonnés are soldered to a metal plate. Finely ground cnamel is filled in between the wires and fired. The surface is then ground evenly to the height of the cloisonnés. Opaque enamels are usually employed in this type of work. The fish design would be quite suitable for an experimental piece.
Non-firing Enamel. There is no comparison between the two kinds of enamel, but for many purposes liquid enamel is more practical, and it is much more quickly applied. The materials required are 8 colours in bottles, 1 bottle medium, No. 0 , or 00 round sable brush, and 1 small stick with pointed end. Enamel of this kind can be used with equal success on wood, leather, glass, and metal, and its application is a simple matter.
One class of enamelling is an excellent reproduction of cloisonné work, and is not difficult, but accuracy is essential. The Lespece of copper, cut the various pieces out. design illustrated in Fig. 18, with lid and side at least $\frac{1}{\mathrm{~A}} \mathrm{in}$. on the end of each side, is in.

Enameling. Fig. 18. A copper covered bor embossed and treated with brilliant coloured enamels. For design 500 Fig. 19
being left all round the top. Fit the two short sides first, turning over the in in., and nail along the bottom of the box. Glue the rest of the metal on to the wood, using metal glue. Fit the back, turning the $\frac{1}{15} \mathrm{in}$. over as before, and nailing down, then glue the rest. The front is treated in the same way. The ends of the front and back must be made neat by hammering over the edges of the side pieces.

Round the lid glue slips of copper which have been punched. The top edge can be hammerod over the top of
the box to about in lix the top panel over this, get it into its right place and nail it down, using $\frac{2}{6}$ copper nails. Prick a hole before inserting the nail, using n metal pricker, then insert the nail and hammer in place, using a nail-driver. This tool is employed so that the marks of the hammerhead do not show on the copper When the whole of the box has been oovered with copper, give it a hard mib with a leather, and it will be ready for enamelling.

Consult the key (Fig. 19) for the colours. Work in the enamels with the small stick sold for the purpose. Work all the colours from the centre to the cdge, which is raised, and beyond which the enamel should not go. Mauve is ohtained by mixing a little lapis blue with red. Mis it in a small oontainer made out of a piece of sorap copper. Do not finger the ennmel, as the marks of the akin show, and cndeavour to work cleanly.

Key to colouring: 1, green ; 2, buff ; 3, mauve: 4, lapis: 5, cerulean bluc: 6, pale mauve; 7, turyuoise.

The enamel spreads, so ieave it well inside the design, ns it does not look well if the colours join up. In all enamel designs there is a division left between the different parts, so following out the idea ol cloisonne, where the outlines are formed by the wire divisions. When the brushes are finished with they can be cleaned with methylated spirit. The bottles should be corked well when they are put away, and the liquid stirred before it. is

Enamelling. Fig. 19. Design for working liquid enamel without firing on copper. saitable for ud and side of boz
used. If the colours become thick, pour a little of the special medium into the bottle and stir it thoroughly.

ENCEPRALITIS. Inflammation of the brain substance, especially of the grey matiter, which is known as encephalitis, may be due to an injury to the skull, to inflammation extending from disease of the skull bones, as in middle-car disewes, when an abscess is likely to result, or may be due to poisoning, as in acute alcoholism. It often accompanies meningitis, and may also occur as a separate disease, which is commonest in young children, although occasionally adults are affected by it. Encephalitis is said to be microbic in origin.

In children it may follow measles, scarlet fever, pneumonia, and other infectious diseases, but more frequently the previous health lias been good. The onset may be marked by druwsiness and irritability, and perhaps vomiting. Then convulsions ensue, the child going from one fit into another The tcmperature rises perhaps to as bigh as $105^{\circ}$. The convulsions cease and are succeeded by deep unconsciousnces or coma. which lasts for a variable time. When the patient begins to wakc up it may be noticed that there is paralysis of one side of the body and face. This, after lasting for somo weeks, may gradually disappear, while in other cases a certain

the water should be changed twice so that the natural bitterness of the plant will be reduced, and, when tencler, the leaves should be put into cold water, left for several minutes. and then squec\%ed dry Endive cooked in this way may then be chopped and rewed like spinach. After a preliminary boiling in slightly salted water, endive heads may be stewed in a pan containing a small lump of butter, seasoning to laste, and a little crean See Salad

ENDIVE : Use on Furniture. This decoration found on certain pieces of furniture is modelled on the curled leaves of the endive It is used on Ionis XV rococo
annount may be permanent. Mental entectilement may also result

Enceplatitis lethargica, popularly known as sleepy sickness, is also a disease due to a microbe and is infectious, though apparently not strongly so, It is likely that some people are carriers of the disense It is characterised by persistent drowsiness. the patient always dropping off to sleep, from which however he may be roused to answer questions. Squint is common, and a notable sympton sometimes present is persistent hiccough

If the patient recovers he may do so completely. On the other hand there may be serious sequelic. Frequently this state resembles that of the discase known as Parkinson's, or paralysis agitans. In other cases there is a tendenoy to jerky movements suggestive of St. Vitus's dance. Still other cases exhibit mental and moral defects, such as lying, uncleanliness, etc. The disease which may occurat any age, is notifiable, and in any form requires the prompt attendance of as doctor. Pron. En-sel-a-li'tis.

ENDIVE. This salad plant is of value in late summer, autumin and winter. The chic sowings are made in June, July and August. Seeds sown in June and July will furnish endive in autumn, and an August sowing will provide winter supplies. The rows should be 16 inches apart and the seedlings thinned to 12 inches from each other If the supertluous seedlings are planted on a fresh site they will provide a later supply than those that are left to grow where sown. Seedlings raised in August should be planted in a garden frame in October to ensure winter produce. Endive needs well manured and deeply dug soil, which must be kept moist in hot, dry weather

The blanching process, which is essential to the production of succulent endive, takes about 4 wecks. and should be started when the plants have well developed centres. A simple method is to cover each plant with an inverted flower pot and to obscure all light by covering the hole in the pot. Plates or tiles may be used. Blanching can also be carried out by tying the leaves together to exclude light from the middle of the plants. The round-leaf viricties of the Batavian condive are excellent, and the various forms of the moss or curled endive are also to be recommended

Cooking. Although principally used in salad-making, endive may also be cooked like any other green vegetable. When it is boiled,
decorration, and was utilized by Chippendale in his renderings of French detail.
Endocarditis. See Heart
ENEMA: Its Uses. An enema is an injection of Huid into the rectum or lower howel and is also resorted to in supplying nourishment to the body when this cannot be given in the ordinary way.
An enema for constipation may consist of water alone or with soapsuds, olive oil, castor oil, turpentine, etc. A soapy-water enema is made by pouring a pint of boiling water over l oz of soft soap and stirring well till the soap)

Nost model steam ellgines function on one of two principles, either with the simple oscillating cylinder or with a double-action slide-valve cylinder. In the former case the cylinder itself turns about the pivot pin, and as the end of the oylinder moves from side to side, so it automatically covers and uncovers the steam port.

The stean enters the first port, forces the piston down to the bottom of its stroke, by which time the cylinder has moved over and closed the steam jort, and as the piston ascends the cylinder it uncovers the cxhanst port and allows the steam to escape. A small spring and adjusting nut are fitted to the pivot pin to kecp the cylinder and valve face in contact.

The double-action cylinder is a fixture, and is provided with a slide valve, like a miniature box without a lid; this noves up and down by the action of the cccentric, and alternately covers and uncovers the steam ports, admitting steam first to one end of the cylinder and then to the other. At the same time it connects the steam passage in the cylinder with the exhaust port, which communicates with the exhaust pipe, and allows the used steam to eacape to the open air.

Timing the Valve. For anything more than a toy, this type of cylinder should be adopted In important item is the correct timing of the valve; this is accomplished by first setting the crank at its dead centre, that is, at the end of its stroke, with the piston almost touching the end or cover of the cylinder. The eccentric is set at right angles to the crank; when in this position the valve should
is dissolved It is allowed to cool sufficiently. Two tablespoonfuls of castor oil, 6 oz of olive oil, or a tablespoonful of rectified oil of turpentine may be made up to a pint with warin soupy water; or $\frac{1}{2}$ to 1 oz of Epsom salts may be dissolved in the same quantity ol warin water. Instead of giving a large watery enema glycerin may be used and 2 or 3 teaspoonfuls will proliably suffice. In obstinato cases the injection of $\frac{1}{2}$ to 1 pint of warm olive oil will be helprul
The cnema may be administered by an ordinary douche bag or can, to which is attached a couple of yards of narrow tubing ending in a vulcanite nozzle which should be smeared with vaseline. The patient is placed on the side with the thighs bent up on the abdomen. When the bag and tube have been lilled with the lluid, the nozzle should be gently inserted into the rectum. The bag sliould then be slowly elevated some two lect above the patient, so that the lluid may flow in. An enema may also be given by using a Higginson syringo, a rubber tuhe with a bulh in the middle.

ENGAGEMENT. $\Lambda n$ engagement or hetrotlal is the formal recognition of the lact that a man and woman intend to marry. The perind lasts from then until the wedding day. Almost invariably the man gives to his fiancee, as the lady is called, a ring known as the engagement ring, and sometimes one is given by her in return. Sometimes a public announcement of the engagement is made through the newspapers.

If the parents of the two are unknown to each other, steps are usually taken to bring them together. Sometimes the engagement is celebrated by a dinner jarty or other social function. An engagement is regarded in English law as a contract, and if either party breaks it an action for breach of pronsise of marriage can be begun. See Agreement ; Breach of l'romise: Marriage: Ring; Wedding.

## Engines and Boilers for the Model Maker

## Small Power Plants Constructed with Simple Tools

Useful hints are here given on the care and running of model steam plants. Reference should he made to the associated articles Boat; Electric Motor ; Locomotive; Railway
cover both steam ports. The eccentric is sligstly advanced or rotated until one of the steam ports is just about to be uncovered. Steam is therefore admitted to the back of the piston, and the engine will function correctly. This principle is applied to model locomotives, and many other types of steam engines, but in various sizes and proportions according to the models.

All small steam engines should have regular attention in the way of lubrication and cleaning. The boiler should not bo left standing alter a run, but emptied of water; any surplus spirit should be emptied from the container, the body of the machine wiped dry with a cloth and all working parts lubricated. 'The safety valve requires to be inspected from time to time. All methylated spirit should be kept securely corked up in a can, and away from the engine The container must be wiped dry on every occasion when it is filled.
The water in the boiler should never be allowed to get too low. Its lerel can be seen in the water-gauge glass, but as a rule the spirit lamp will burn out before the boiler water is all boiled away. When the spirit lamp is retilled the boiler should always be replenished at the same time. Should the pressure of steam risc to an alarming extent, turn of steam to the engine and run it at fyll speed; also either remove the spirit lamp or clse blow it out.
Simple Steam Engine. The diagrams given in Fig. 1 show the parts needed for the construction of a small horizontal boiler with oscillating engine, together with a suitable lanip.

Engine. Fig. 1. Diagrams ol parts which are required to construct a simple engine A. Side eleration and sections of complete model. B. Details for the spirit burner. Fig. 2. Parts arranged to drive a aimple toy locomotive

It is suitable for driving a model boat, but by engine may be built quitc arranging the boiler and engine in a different casily by the least experimanner, and making the other parts to suit, enced beginner Cylinder they can be adapted to drive a toy steam and standard are of gun. locomotive of the simple type shown in metal, the crankshaft, disk l'ig. 2. In this model the boiler casing is and crank-pin being in one made from tin, the cylinder is disposed piece of steel. The boiler illustrated, which between the main frames, and drives the wheels has a working pressurc of 20 lb ., is suld com-
through simple spur gears The boiler can be plete with lamp and funnel.

Boilers. A simple horizontal or vertical boiler for a stationary engine is readily unade by utilising scamless copper tube of $2 \frac{1}{2}$ to 3 in. diamcter for the barrel, the ends being closed with gunmetal castings or flanged copper disks which just fit inside the barrel. The ends are silver soldered or brazed to the barrel. A casing and firebox of tinplate or other sheet metal may be made for a horizontal type In the case of a central flue upright boiler the lower part of the barrel may serve as a firebox, suitable air holes being made and an opening for the entrance of the lamp-tube and
Engine. Fig. 8. A usefal engine buitt rom parts supplied by Stuart Turner, Ltd., suitable for working amall models

made from thin brass tubing, closed with brass
ends that must be securely soldered.
The cylinder can be purchased ready for use from most of the dealers in model engine supplies, and a simple form of standard may readily be made from sheet metal. The valve face of the cylinder is soldered to the standard, and holes are made in the latter for pivot pin and main bearing. The crank is bent up to shape from a piece of steel wire. Wheels for the toy locomotive can be bought from the model shops, where also a suitable flywheel can be obtained. The locomotive wheels are simply driven on to their axles, remembering to fix the gear wheel before putting the second wheel on to the axle. By setting the boiler in a vertical position and making a circular spirit lamp, these parts can be converted into a vertical engine.

Fig. 3 shows a robust doublc-acting oscillating engine suitable for a small boat, or for running Meccano models or similar toys It is larger and more powerful than the simple type just described, the borc and stroke being i's in. The set of paits is sold by the makers, Stuart Turner, Ltd., Henley-on-Thames, at a trifling cost, and the
burner. The lower boiler end is fixed inside the barrel at the appropriate height, convex side uppermost, and is bored for the brass tube which serves as the flue. This latter passes up through the top end, and is carefully silver soldered or brazed to both boiler

Engine. Pis. 4. Babcock \& Wilcox type model boiler in part section. Fig. 5. A Stuart mill engine with cylinder in section
ends. A good boiler for larger stationary engines is the Babcock and Wilcox type shown in Fig 4 The boiler is made in two sizes the smaller for engines up to $\frac{1}{2} \mathrm{in}$. bore and $I$ in. stroke, the larger for engines up to in bore and If in stroke. The boiler of the latter is composed of seamless copper tube, $8 \frac{1}{d} \mathrm{in}$. long and 3 in in diameter, the ends closed with gun-metal castings silver soldered to the barrel. 'Through the bottom of the barrel five water tubes, $t$ in in diameter, also of seamless copper, are fitted by silver soldering them to the barrel, one end being lower than the other to ensure rapid circulation. The

stcam is taken from the top of the boiler, through a screw-down needle valve, inside the boiler casing, coiled over the top of the burner to act as a simple type of superheater, and connected to the engines by a union nut.
The casing is made from lour iron castings The castings for the casings, and the gunmetal builer ends, tubing and fittings, are all supplied by Bassett-Lowke, Ltd., Northampton. The boiler is quiet easily assembled by the amateur. All that is necessary is to drill holes

for the fixing screws through each of the end castings, tapping the holes drilled in the side plates, any roughness on the castings being smoothed off with a file. The boiler sits in the circular recess cast in the front plate and rests upon pad pieces on the back plate, castings: it is held by sel screws thruagh the upper purtion of the back plate. The boiler fittings comprise a screw $\cdot$ down steam valve, a safcty valve, pressure gauge and water gauge, all of which can be parchseed with the castings. They are fitted by brazing thc bushes, which are supplied with the fittings, into the boiler

Engine. Fig. 6. Component parts of the Stuart mill engine
main bearings, remem. bering to place the eccentric sheave in place before doing so The Hywheel is fitted to the outer end of the crankshaft, and secured with a sct screw. The crankshaft has a shouldered screw to act as a crank-pin, which has simply to be passed through the big-end bearing of the connecting rod and screwed in place.
The cylinder. piston, and slide valve are barrel, and then screwing the fittings into assembled and screwed in place with threc place, seating them on to a thin lead washer. screws passed through from the underside of The glands for the water-gauge glass are packed with fine cotton soaked in tallow. The holes for the gauge glass must be directly in line to avoid risk of fracture.
Two separate castings are provided in the shape of a lire door; these fit into holes corod in the front of tho boiler casing, and are held in place by a ${ }^{\frac{3}{2}} \mathrm{in}$. diameter steel pin. These are simply pushed into place, and may be removed to inspect the flames from the burner. This boiler can be heated by a gas ring or by a vaporising spirit lamp.
The chimney, $7 \frac{1}{2} \mathrm{in}$. long, is made from stout brass tube $1 \frac{1}{\text { in }}$ in diameter, which presses into a hole cored into the top of the

Engine. Fig. 7. 8ingle fue launcth boiler, with blow lamp. Fig. 8. Another type ol marine boiler, made fig. 7. courlesy ol Bassett-Lowlie of Whitnelys
the back plate casting. The chimney is belled over at the top, and at a distance of $\frac{5}{8}$ in. from the bottom is provided with a brass ferrule $\frac{1}{4}$ in. thick and $1 \frac{1}{2}$ in. in diameter. The tube may be polished and lacquered, or painted in any colour. The best finish for the boiler is Brunswick black, and for the castings a brick red to represent brickwork.

Horizontal Engine. An excellent hurizontal steam engine for amateur construction is illustrated in Fig. 5, and is known as the Stuart mill engine ; the castings and machined parts may be obtained from Stuart Turner, Ltd., Henley-on-Thames, or most model supply shops. It can be purchased in the form of fully machined castings, shown in Fig. 6, thus obviating the necessity for lnthe work and enabling tho engine to be constructed with the aid of simple hand tools. In Fig. 5 the cylinder is shown partly sectioned, to illustrate the construction.
The method of erecting this engine consists in taking the bed-plate casting, cleaning up the surface, and fitting the crankshaft to the the bed-plate casting, care being taken to see that the piston rod is in perfect alinement with the guides These are composed of two rectangular bars of steel bolted in place, with distance pieces between them and the machined surface of the bed-plate casting. The crosshead hns to be tested to soe that it slides
$\qquad$

[^2]
frecly without shake in the guides: any roughness in the casting should be removed with $n$ fine file or by scraping The little end of the connecting rod should turn freely in the jaws of the orosshead, and is secured with a steel pin. The piston rod sorews into the end of the crossliead, and is secured with n lock nut. The piston and glands should be packed with linen thread soaked in tallow to ensure a proper steam-tight sliding fit when the engine is working. Tho eccentric strap is fitted to the shcare, and the eccentric rod placed in position and scoured with a lock nut. The knuckle joint at the end of the valve rod is then serewed in place, and the two connected together by a litle bolt and nut.

The slide valve is timed as described earliet in this article, all bearings carefully lubricated, the remaining loolts and nuts placed in position, and the engino is ready for use. It might be inounted upon a hardwood base and connected to the boiler previously described by fitting the stenm pipe to $\Omega$ union screwed to the valve-cbest cover. the exhaust pipe being taken to the climney or disposed of in any con. venient manner. This little plant would then drive a number of work ing models, or even a omall-sized dynamo.

Marine Eng!nes. Re. quirements for the power plant used in a model liner, destroyer, or speed boat are light-
ness, compactness, economy in steam consuinption, and a low centre of gravity. A good boiler is one of the single-flue type (Fig. 7) with a number of water tubes across the llue. Since the liue is surrounded by water no outer casing is needed, and the boiler fits snugly in the bull. the weight. being disposed low down.

Fig. 8 shows a marine boiler made from sheet copper shaped up and riveted together This has a dome, from which dry steam is taken off for the engine. In the absence of a dome, the steani pipe is usually made to traverse tho flame before going to the engine.

Boilers of the above type are best lired with a parafin or petrol blow lamp. preferably the former. Special lamps are made for the purpose by the leading model engineering firms (see Fig. 7), but it may be practicable to use one of the tubular commercial liumps made to heat a soldering iron.

The engine shown in l'ig. 8 tnas be built up from the machined set of castings and parte supplied, with the requisite bolts, nuts and screws, by Stuart Turner, Lid., already referred to. If the worker anticipates any difficulty in driiling and tapping the holes. this work will also be clone by the manufacturers for an additional charge. The engine is enclosed in an almminium casing has hall bearings, and weighs, with fly-whecl, 21 oz Other particulars are : bore $\frac{3}{} \mathrm{in}$., stroke of in. and height from bottom of crank case, $4 \frac{1}{2}$ in The crankshaft is balanced. A displacement lubricator would be a desirable addition.

Another enyine for which a set of machined parts is sold by the nbove inentiuned firm is that illustrated in Fig. 10. This is an enclosed twin-cylinder engine with $\frac{3}{3} \mathrm{in}$. bore and $\frac{3}{4}$ in. stroke. The heipht is 4 in .; width 3 in . ; and
 and the gear whecls, with other working parts, run in an oil bath. This set is supplied with all holes drilled and tapped. The engine will propel a 4 ft . 6 in. boat.

ENGLISH TERRIER. This lively, in telligent and companionable dog is very similar to the black and tan or Manchester terrier, but his colour is pure white without any markings save his black nose. Any others are blemishes, according to show regulations, though the presence of a spot or two might not be considered as such by the family to which he is attaohed.

An ndmirable ratter, he does not always shine as a house guardian, his sense of hearing not being so acute as in other breeds, and often he is distinctly deaf. He has a long, narmow, llat head with fox-like muzzle; small black cyes and upright ears. The tapering tail is carried fairly level with the back. The coat is close, hard and glossy. and the weight from $12-20 \mathrm{lb}$. The English terrier is rarely seen to-day, having become alinost extinct. See Dog.

Engine. Figs. 9 and 10. Two examples of Stuart marine engines which can be built ap from sets of macnined parts

# ENLARGING METHODS FOR AMATEURS 

## How to Make and Use Photographic Enlargers

The following article covers the whole field in a fascinating department of phorography, being thus one of a group that includes Developing; Exposure; Photography ; Printing

A properly expused and developed vest. pocket negative can well be enlarged iroin $2 \frac{1}{3}$ in by 15 in. to a really large picture 12 in . by 10 in ., or 15 in by 12 in. With the finest anastigmatio lenses enlargements on much greater scale than this are made.
Apart from the obvious use of getting large pictures from small negatives, the amateur will find that he can often greatly improve his photograph in enlarging it by getting rid of unnecessary or disfiguring detail, as seen in the examples in Figs. I and 2. The original snapshot (Fig. !) of a harbour contains much irrelevant detail that destroys the interest of the photograph. By enlarging the centre portion of the photograph (Fig 2), a really interesting and well-balanced picture is obtained.

1'hotographs may be enlarged either by the use of daylight or by artificial light, but more reliable results are obtained with artificial light. The simplest form of daylight enlarger is scen in Fig. 3, which consists of a box, small enough at one end to take the negrative that is being enlarged, and large enough at the other end to take the sheet of bromide paper on which the enlargement is made. Near the negative end a small lens is placed controlled by the shutter; the focus in fixed, and only one size of enlargement can be made with the particu. larenlarger. Exposure is marle by placing the enlarger out of doors, with the negative towards a clear sky, the time necessary being found by test. An cxposure meter will help in judging times.

Artificial light enlargers are of different types. They may be grouped in two olusses : (a) Those that use large and somewhat expensive condensing lenses, and (b) those that use reflected light in some form. A standard form of condensing enlarger is scen in Fig. 4, where A is the lantern house, B metal collars containing the condenser, which open and close to vary the distance between the light in the lantern house and the condensing lens, the latter being fixed to C , the carrier stage, in which D , the slide carrier holding the negative to be enlarged, is placed. Bellows E, permit the focussing of the lens $\mathbf{F}$. The focussing of both lens and condenser is effected by sprockets and chains, worked by milled headed screws, G. It is nccessary to be able to focus the condenser itself, since the inore the enlarging lens F is racked out, the siorter inust be the distance between the light source and the condensing lens
With apparatus of this nature it is easy to make colargements of every size from any negative, the only limitation being the size of condensing lens. The rule is that its diameter must be equal at least to the diagonal of the negative to be enlarged.

In using an enlarging lantern it is essential to see that the light is accurately centred and focussed. This is because the condensing lens only makes use of a point of light from the source of illumination, as will be seen in tip diagram, Fig. 5, which shows the complete
optical syatem used in an enlarging lantern. This also illustrates the necessity for accurate centring, for if the line AB does not pass through the centres of the light-condensing and enlarging lenses, it is impossible to get even illumination.

An enlarging lantern arranged in the vertical position ofiers distinct advantages. Adjustments are made rapidly, and in some types automatically, while no separate casel or table to take the whole apparatus is required, An efficient form, the Kodak, "Autofocus " enlarger, is illustrated in Fig. 6. The lamp-house A contains a reflector with a shcet of opal glass to diffuse the light; be ow are the negative carricr $B$, the bellows $C$ and an anastigmat lens $D$. No condenser is re. quired A gas-lilled lamp of 150 watts is recommenderl. An automatic focussing device, E, gives a sharp image whatever size enlarge. ment is chosen. The apparatus is designed to be clamped to a table. If a V.P.K. negative be used ( $2!$ in. $\times 1 \% \mathrm{in}$.) enlargements up to

$8 \frac{1}{4}$ in $\times 5 \frac{i n}{}$. can we made ; the largest negative which the carrier will take permits an enlargement up to $21 \mathrm{in} \times 14 \mathrm{in}$., other size negatives giving proportionate enlargements.

A slightly more elaborate iwechanism employing a condenser, the Ensign "Magnaprint " is shown in Fig. 7. Its characteristic is tho speed with which enlargements are produced, a $1 / 1$ plate enlargement from a $\ddagger$ plate negative being prepared in 3 seconds. The focussing is semi-automatic, the whole instru ment moving on the pillar and locking into position for the required degree of enlarge ment. The maximum is $20 \mathrm{in} . \times 16 \mathrm{in}$. from a $\ddagger$ plate negative. This enlarger is also avail. able for copying or photographing prints or sinall objects using the lamp-house as a source of light.

Various light sources may be used in enlarging lanterns so long as provision is made, where a condenser is used, for raising and lowering the light and for forward and sidewarl movements The ideal form, from some: points of view, is the electric are, but this is somewhat expensive and extravagant of current. The gas-filled type of electric lamp is quite satisfactory, particularly if a lamp with a projection type filament is obtained. A 60. watt or 100 -watt lamp should be used to get a strong enough light.

Where the ordinary electric supply current is not available, one of the smull (i.volt gas. filled bulbs, which are used in motor headlights, iun off an accumulator can be successfully adopted.

When it is proposed to take a photograph with a view to enlanging a negative afterwards, care should bo taken to soe that the negative is fully exposed and developed for a somewhat shorter time than usual, in order to obtain a thin negative, which gives the best results in an enlarging lantern. A thin negative of this kind should bo one in which, while every detail can be clearly seen, the densest parts will allow type to be scen through them when the negative is placed upon a printed page.

The Making of Enlargements. The process of making actual enlargements from small negatives requires very little practice, though it needs the cultivation of an eye for picture

Enlarging. Figs. 1 and 2. Above, small snapshot same size as orlginal negative. Balow, enlargement of portion of negative showing the greatly improved picture obtained by getting rid of irrolevant detail such as the barrel, roof, and figure cut in half, and useless foreground and ninteresting sky Photo by P. J. Morlimer
making, i.e. the selection of the best portion of the negative to enlarge, the suppression of irrelevant detail

To make an enargement, place the ncgative in the negative holder. with the top end ol the negative nearest the photographer's hand and the film side towards the enlarging easel. It the negative is an oblong one, place it in the holder upside down with the film outwards By noting these points the enlarged picture thrown on to the easel will not only be the right way up. but will also be the right way round

Next, turn on the light and, with the nega tire in the slide holder, focus the front lens sharply on the cnlarging easel according to the size of enlargement required Then take out the negative and inove the light backwaril and forward by racking the lantern housf until the disk of light thrown on the enlarging easel is perfectly even If the centre of the disk is more lirightly illuminated than the rest, the light must be pushed forward: it. on the other hand, the centre is dark the light is too near the condenser and must be racked back a little. Minor incqualities of light on the easel can usually be rectified by placing a sheet of ground glass between the light and the condenser This diffusion of the light will help to render less conspicuous in the enlarge ment scratches and other minor defects in the film ol the negative

Placing the orange cap over the lens, pin or otherwise insten n piece of bromide paper on the easel in position so that the required portion of the picture falls on to it Removing the orange cap, an exposure is made while three parts of the bromide paper are covered with a piece ol card; then expose successively the three remaining parts of the bromide paper, giving each portion an equal exposure. Thus fonr exposures will be made on one piece of paper ranging from one to four times, and it will be easy to decide, after development, which of the four exposures was nost nearly right

No detailed guide lor exposure in enlarging can be given, since the strengths of artificial light vary so greatly and the density of negatives differs so considerably. When the time of exposure for the particular negative has been lound, a careful note of it should be made, either on the envelope containing the negative or in a negative record book. For details of developing and printing the reader should consult these beadings.

One of the best developers for bromide enlargements is amidol With prints that are

Fig. 4. Standard torm of artiffial light enlarging lantern with condensing lenses Courtesy of Ension, Led

Enlarging. Fig. 3. Simplest form of daylight enlarger consisting of a boz and a fired focus lens
correctly and not paintod underneath with dull black in order over exposed de. to reduce light reflecting. velopment with amiaol stops when the image is fully developed

Many difleren types ol bromide papery are avail able for enlarging purposes, varying from the ordinary glossy surface, used in press photo graphy, and matt surfaces of different grades of smoothness, to very rough-surlaced papers, some heing tinted crean to give warmer effects In general smooth matt surface paper is more suitable to enlargements with much tine detail, while broad effects are olstained with the rougher papers $A_{n}$ en arged print which is a little dull in colour. particularly in the shadows, may often be inproved considerably by rubbing te surlace with encaustic paste.

On the baseboard are fitted the tubes and sliding platform for the lamp-house. Dimensions are given in Fig .10 The long tubes are fastened at each end to blucks of wood by straps of tin bent over and screwed to the blocks. The latter are kept in position by nails or brads round them (not through them) knocked into the baseboard. They are thus independent of the baseboard, and the whole of this portion is casily removed. On the long tubes are placed two shorter pieces of slightly larger tubing, which slide frcely and are connected by a stout plate of copper or other metal, soldered at each end. A slot is cut in the centre. Pieces of an old tubular brass camera tripod serve this purposc, ol brass curtain rods of two sizes can be used

On the centre plate the lamp-house propet is lixed; it consists essentially of a cigar box with an adjustable lamp carrier (Fig. 11). It is fastened to the plate by a bolt and nut, which passes through the slot on the plate (Fig. 10), thus permitting a sideways move ment of the lamp house to allow for the adjustment of the light. Backward and forward movement is supplied by the sliding tubes on which the plate is supported; upward and downward movement by the adjustable lamp carrier. In this case an old focussing pro

Maklng an Enlarging Lantern. A home. macie enlarging lantern using a condensing tens, with the amatcur's camera for projection, and having all neccssary adjustments can be made for little more than the cost of the lens.

The body consists of 3 -ply wood taken from n tea chest, the dimensions of which are shown in the sectional diagram (Fig. 9). It is built up on a stout hasehoaird 16 in long $7 \frac{1}{9}$ in wide, and \% m
thickiFig
10). 'Гo this baseboard the two sides of the box which consti. tutes the lantern are screwod They are 2 in shorter than the liase board; a re. movable end piece. A, car ties a black velvetcurtain to cover the end of the box and prevent light leaking
 out The end piece lits loosely to perinit the withirawal of the lamp. house and its fittings. Its dimensions are seen in Fig. 9 : the two sides are screwed at the top to a piece of wood it in. long, $2 . \frac{1}{2}$ in. wide and about $\frac{1}{5}$. thick, and braced at the bottom by a piece $7 \frac{1}{f}$ in. by ${ }_{8}^{3}$ in., by $\{$ in It is shown partly withdrawn in Fig. 8

The box has practically no top. At the lront a cover, B , about $3!\mathrm{in}$. or 4 in . deep, is ! movided (Fig. 9). Along the top of both sides strips of tin, C, $12 \frac{1}{2} \mathrm{in}$. long, $1 \frac{5}{8} \mathrm{in}$. wide. bent along their length at right angles, are nailed and screwed. These angle strips are bent so that one side is at least ! in. wide, the other being ${ }_{8}^{3} \mathrm{in}$. or less, and this wider side is
jection picce trom a disused magic lantern was made use of, the lenses having been removed. Such pieces of scrap optical apparatus can be easily picked up from optical dealers or on second-hand stalls. An alternative arrangement for raising and lowering the light is shown in Fig. 12, where an ordinary electric bell or wireless terminal, A, slides up and down a rod, the tlex of the electric lamp being gripped, not too tightly, between two nuts on the shank of the terminal. Similat forms o. light holders can be improvised.

The lamp-house is completed by tivo pieces of wood (Fig. 13), screwed on to the top of the cigar box with a circular hole cut in the centie to allow the focussing piece used as the lamp carrier to pass through.

The purpose of these pieces is tn provide a covering for the light when in the lantern.

Einlarging. Fig. 6. Showing the very efficient Kodak Auto-focos" enlarger. Fig. 7. A more elaborate mechanism, the Ensign "Magnaprint"enlarger Courleny of Kodali, I.Id., and Easiun. Llil
[he covering moves with the tight, and pre box with pieces of wood out to tit, or it may vents direct rays escaping from the lantern, he properly mounted.
since it moves underneath the overlapping The condenser box is made a light-tight fit strips of blackened tin. If lurther means of light exclusion are required, pieces of 3 -ply wood $7 \frac{1}{2} \mathrm{in}$. by 3 in . or 4 in . can be placed on top of the box at either end, according to the position of the lamp-louse. At the front end of the lantern a slot is cut with a keyhole saw to take a frame bolding a sheet of ground glass for diffusion of light, if necessary. The slot is cut at the height of the condenser, and a strip of wood is fastened inside to provide a ledge for the diffusing glass.

The condenser box is seen in the photograph (Fig. 14) and the diagram (Fig. 15). For a $5 \frac{1}{2}$ in condenser such as is necessary for an-
in the front of the lantern in the manner shown in the photo (Fig. 8) and in the diagram (Fig. 9). A solid piece of wood, D, a bout $\frac{1}{2}$ in. thick and 63 in . wide, supplies a platform for the condenser box. It is screwed on to an
 both sides uprights, $F$, of $\ddagger \mathrm{in}$. 3 -ply wood are screwed, with a cross-piece at the top, of the depth required to make the condenser box a reasonably tight fit. When the condenser box is in position light leakages are stopped by stuffing strips of black cloth all round; these are nailed down with narrow strins of 3-ply wood (see photo Fig. 8).

To avoid moving the lantern backward and lorward in enlarging different sizes the easel is arranged to slide along a plank 1 in . by 7 in . Details of its construction are seen in Fig. 17. The easel consists of an ordinary large-sized drawing board fastened to a sliding saddle. piece by means ol two copper brackets, which are cut out of a piece of 2 in . square metal and folded up as shown in the dotted lines in the sinaller diagrams in Fig. 17. A thumbscrew passes through the saddle, gripping the edge of the plank to keep the easel fixed in the desired position.

Enteric. See Typhoid.
Enteritis. The meaning of enteritis is inflammation of the intestine. See Colitis : )iarrhoca: Intestine.

ENTREE. This name s given to made-up dishes such as chicken cutlets, quenelles, fricassées, ris. soles, ragoats, soufflés, etc., and may be either hot or cold. If more than one entréc is served. the hot should procede the cold. The remains of tish, poul try, gaine, and meat can be used, and kidneys, sweetbreads, and livers are employed. The entrdo course at dinner follows the fish, and precedes the joint.
Entrée Dish. These aro made in silver, Sheffield

larging $\frac{1}{4}$-plate negatives, a bis cuit tin $6 \frac{1}{\frac{1}{2}} \mathrm{in}$. square and about $2 \frac{1}{2} \mathrm{in}$. deep is required, or a larger one can be cut down to fit, the cut ends being turned over and soldered. An aperture is cut in the bottom of the tin $4 \frac{1}{2} \mathrm{in}$. wide and $3 z \mathrm{in}$. deep, i.e. a little larger than a $\frac{1}{2}$-plate. A strip of copper the length of the condenser box and $2 \frac{1}{4} \mathrm{in}$. wide is taken and bent over at right angles, one side of the bend being if in. wide, the other 1 in . A second strip of the same length $2!\mathrm{in}$. wide is bent over at right angles, each bend in this case being $1 \frac{1}{2}$ in. wide. These strips are bolted on to the top and bottom of the con denser.box to allow the negative carrier to be pushed in between the strips and the box, gripping it but permitting free movement. On the copper strip which is bolted on to the top of the condenser box a hooked piece is soldered on to support the camera, as shown at A (Fig. 15) Its dimensions are given in the smaller diagram (Fig. 16). This hook fits into the slot at the back of the camera in which the focussing screen slides. The condenser is wedged into the tin

Top cover for lamp-house and base for lamp carrier. Fig. 14. Condenser boz made trom biscuit tin, showing arrangement for holding negative carrier and camera. Fig. 15. Sectional diagram for construction of condenser box. Fig. 13. Metal for strip holding camera soldered on front of condenser box. Fig. 17. Details of easel with method of attachment to sliding saddle
plate and electro-plato, and may be purchased singly or in pairs Such dishes are often found with a detachable handle, which enables the cover to be turned upside down and aach dish made into a pair. Sometimes they have fixed liners with a space between the two parts for hot water. The entrée dish lends itself to rather elaborato ornament, and good 18 th century specimens fetob high prices. See Sheflield Plate; Silver.
ENTREMET. This term is applied to all dishes of dressed vegetables, such as caulillower su gratin, cassolcttes of cuoumber, etc., as well ns to hot and cold sweets and afterdinner savourics.
ENURESIS. In young children enuresis or bed wetting is sometimes a very troublesome complaint It is not wise to malic a fuss about it, and in an ordinary case there should be no threat of punishment. The bedclothes should not be too heavy, and the child should not be allowed to bury himself beneath them, nor to sleep on his back. An old method of preventing this is to tie $n$ cotton-reel on the small of the back.
The diet should be simple, avoiding spiced food and condiments, and the last meal should not be heavy nor too near bedtime. No fluid should be allowed within an hour or two of going to bed. The bladder should be emptied just before getting into bed, and the child should be awakened in an hour or so to empty it again. A mackintosh shcet and draw sheet should be used. If constipation is present it must be corrected, and the motions should be observed for the presence of threadworms. In boys circumcision is sometimes necessary. Adenoids and enlarged tonsils are a common cause. When no obvious cause is present suggestion may be a valuable help.

EPACRIS. This evergreen heathet like shrub is suilable only for cultivation in $a$ hented greenlinuse where the various kinds bloom in autumn, winter and spring. It belongs to the group known as hard wooded plants and is not an casy plant to grow well. In spring when the Howering season is over the plante should be pruned; any repotting that may be necessary is done then A suitable compost consists of peat (or peat twothirds and loam one-third) with sand added frcely. The pots must be well drained. Grent care in watering is necessary to ensure that the soil becomes neither sodden nor dry. Propagation is by cuttings insertod in pots filled with sandy peat and placed in a propagating casc under glass in summer.
EPIDEMIC. The name opidemic is given to a disease when it affects a large number of people at one time. Tho discase is usually one due to a microbe. but other canses may operate and affect large numbers of perple. e.g. a poison contained in some article of food or lead poisoning from pollution of water by lead pipes These epidemics of poisoning and of dericiency diseases, when once their nature and causation are apparent, can be casily brought to an end

Notification and isolation bave helped to limit the spread of most infectious discases. In the case of small-pox, vaccination has been invaluable; and in the case of what are known ns the water-borne discases, c.g. enterig fever and cholera. The same may be said of control and, if necessary, the steriliza. tion of water and milk supplies. Much may be done to limit the extension of diseascs in which insects, such as the mosquito, flea, house-fly, etc., are the agents of infection, by measures of exterminating the insects or for affording protection from their bites or contamination Protective inoculations with serums and vaccines, by increasing the resistance of the body, have proved suocessful.
It is not clenr why some epidemics occur at more or less regular intervals. In the case
ol diseages which may affect the some person is by cuttings in summer in a frame Another repeatedly, there will be a certain period of immunity after the illness and, as in the case of induenza, the epidemic may sweep over the community in a series of waves separated by varying intervals of time Widespread minteorological conditions may be factors. and lowered resistance affecting large comnunities because of food shortage See Inoculation.

## Epidermis. See Skin

EPILEPSY or Falling Sickness (Gir epilēpsis, عeizure). Disease of the uervous system characterised by periods of unconscious ness. Epilepsy most commonly begins in childhond, before the fifth year The fundamental cause is unknown, though fright, injury alcoholism, and an attack of illness appear to be exciting causes. The offspring of those parents who suffer from insanity of ueurasthenia are mire prone to exhibit epilepsy than are other childrens

The incidence of epilepsy would be much diminished if epileplics refrained from marrying and having children, every child of an epileptic need not have the taint, bu in a family some members are almast surt to have it.
Two forms are recognized. In petit mal the attacks of unconsciouisness often last no longer than a few seconds and there are no convulsions. Grand mal is characterised by the occurrence of convulsive fits The subject may have a preliminary sensation or nura, which warns him of what is going to happen Sometimes the beginning of the sit is marked by a loud cry: At first the muscles are rigid. and suspension of respiration catuses blueness of the face After a fow scconds, violent convulsions occur, and the tongue may be severcly bitten. After one or two minutes the patient passes into a state of somnolence which may be succeeded by prolonged sleep.

During an actual fit all that can be done is to prevent the patient from hurting himself. He should be allowed to remain in the recumbent poature, the clothes should be loosened round the nock, and a roll of cloth should be introduced between the teeth to prevent the tongue from being bitten. The most useful drugs are the bromides of sodium and potassium. These should be given for a long period. Careful attention must be given to the general health of the sufferer
Epispastic. See Cantharides: Counter Irritant.
EPSOM SALTS. Sulphate of magnesium in the form of Epsom salts is much used for purgative action, the best time for taking it being immediately on waling in the morning. A moderate dose for a grown person is a tesspoonful in a tumbler of hot wnter For stronger action 2 grains of calomel may be taken at bedtime and Epsom salts first thing in the moming. Some people find it easier to take the effervescing magnesium sulphate, of which of to 1 oz . may bo taken in a glass of water and drunk while effervescing.

In certain cascs of heart disease or Bright's disease, where the tissues are becoming waterlogged through the fluids in the blood escaping through the vessel walls. morning doses of Ejpsom salts sometimes give good results by removing from the system any excess of fluid. In this case the dose is clissolved in the smallest quantity of water which will take it up, in order to encourage a frec escape of Huid from the walls of the bowel. See Aperient: Constipation.
ERCILLA. This is a self-clinging evergreen creeper, with leathery leaves and racenues of purplish flowerd, which spring from the axils of the leaves. It is suitable only for walls, for it is not very hardy Any ordinary anil suits it, but sandy loani is best. Propagation

EREMURUS (Giant Asphodel or King's Spear) These remarkable plants produce a large tuft of long strap-shaped leaves and in early summer send up tall strong epilica, the upper parts of which are covered with closely mas 9 ed llowers. The large floshy roots are of extra ordinary formation they radiate from a central bud like the spokes of : cart theel.
Planting is best done in carly nutumn and $n$ shelter ed place, e.g among shrubs, must be chosen, for the plants start into growth early. There should be $a$ (i-in. onvering of soil nbove the roots. which must be handled carefully because they are brittle. Well. drained lonmy soil suits them best: clayey land must be made suitable by adding old turf, sand and some leaf-mould or decayed inanure. It is advisable to protect the mots in winter by placing ashes or leaves on the soil nbove them. The best method of propagation is by sceds sown in a frame as soon as they are ripe Ereuurus robustus bears pale mosecoloured llowers on a stem up to 10 fect high; himalaious, with white flowers, grows 6 to 8 feet; Warei, reddish bronze, is 0 feet or more high Bungei, 4 to 5 fect, with yellow flowere. is one of the best for small gardens.
ERGOT. The ergot, a fungus which sometimes appcars among grasses and weeds, is very fatal to the plants aftacked. The ergotted seed becomes black and elongated like the spur of a cock, from whence it derives its name. The remedy is to gather and burn all infected plants
Poisoning by Ergot. Ergot is used in inedicine, but should only be taken under the doctor's direction. In acute ergot poisoning following on an overdose of the drug, the chief symptoms are violent sickness and diarrhoca, licadache and dizziness. These symptoms may gradually pass or may increase in severity, the patient falling into rapid convulsions, leading to loss of consciousness and death While ivaiting for the doctor, an emetic, e.g a tablespoonful of mustard in half a tumbler of water, may be given, and when the patient has vomited thornughly, 2 tablespoonfuls of castor oil. Strong hot tea should also be given freely.

Symptorns of poisoning may also appear through eating bread containing rye which has been attacked by the fungus.

ERIGERON. (Summer Starwort.) This is $n$ most valuable plant for the herbaceous border: in summer it bears numerous large daisy-like flowers on stems up to 2 ft . high, in shades of lavender, purple and other colours.

The piant thrives in ordiriary well cultivated dirty yellow or leadish-white soil and enn be increased by division in tho autumn or by sowing seeds in a bos of soil in a frame in spring.

The commonest kind is Erigeron speciosus, 2 ft. high with mauve-purple flowers; opeciosus superbua with more richly coloured

Erigeron. The Summer Starwort, a beantiful hardv border flower
blooms is finer. Quakeress, lavender, is one of the best of all; other finc modern varieties are B. Ladhams, mse-pink; Pink Pearl, blush-pink; Asa Gray, apricot-buff; Amos Perry, lifac; and Fontainebleau, lavender. blue. Alpinus, 9 in., purplish blue, and aurantiacus, 6-8 in., orange yellow shado, are suitable for planting in tho rock garden.
ERINUS. Erinus alpinus is a pretty Little plant of trailing growth suitable for crevices in tho rock garden; it flourishes best in well-dirained gritty soil. It is not as a rule long lived, but can casily be increased by seods sown in spring in the rock garden where the plants are to flower the following year. Erinus alpinus is only 4 or 5 inches high, and bears rose purple flowers in early summer.
ERMINE: For Wear. Ermine, which is the fur of the stoat, is mostly obtained from Canada and Russia, tho coat of the British stoat not clianging colour to pure white in the winter to the same extent as it does in northern regions. The skins are narrow and about 10 in . long, the tail being white with a black tip, and the fur short and close. What is known as summer erinine is the beige colour fur of the stoat's coat in summer.
Ermine loses its whiteness, and becomes yellow with age : it can be cleaned, but once the yellow tinge appears, bleaching will not restore its pristine purity. This yellow colour may be kept from appearing for a considerable time if the fur is stored away in darkness when not in usc.
Ermine is trying to the complexion, and looks best in the evening for coat, collar, or wrap. Being easily soiled, ermine needs to be treated with great care. After use it should be wiped over lightly with a fine white cloth and wrapped between layers of tissue paper. When badly soiled, ermine is best sent to the cleaners; but if it is to be treated at home, cornflour should be rubbed in with the tips of the fingers, and afterwards brushed out with a soft, white-bristled clothes brush See Fur:
ERMINE MOTH. The small ermine moth is found in nearly every orchaid and garden, and the caterpilars are very destructive to trees and shrubs. The moth itself may be identified by its upper pair of wings, usually of a leaden whitencss, with small black spots on the edges of the wings, which also are fringed with livid-coloured hairs. The caterpillar is about $\frac{1}{2}$ in. in length, the body being a
and the head brownish.
The moth often selects apple, pear, plum, or almost any fruit tree on which to deposit eggs in masscs near leaf:bud and blossonl. The caterpillars archatched during autumn, but rest under a protective scalc until trees are coming into leaf, and then spin a thick web of threads round a young slioot, enclosing foliage, within which they live, feeding upon the leaves.

When each caterpillar is full grown it encloses itself in a cocoon of white silk, in which it pupates until the month of July, when it emerges as a moth. Remedies are to kill the moths before they deposit eggs, and burning or crushing of the caterpillars while in their webs.
According to Leallet No. 65, issued by the Ministry of Agriculture, the most antisfactory trentment for affected trees and hedges is to spray them soon after the blossom is over with lead arsenato (l lb. of lead arsenate pacte to 20 gallons of water).
ERYSIMUM (Fairy WallHower). Free Howering annual and perennial plants with small wallflower-like blooms in yellow, orange and other colours. The two most popular annuals are arkansanum, yellow, and peroff. skianum, orange. They do best when sown out of doors in carly autumn to bloom in spring and early summer. Seeds may, how. ever, be sowll in spring to provide plants in bloom from July onwards. They flourish in ordinary soil, preferably that which is not

Erysimum. One of the fairy wallilowers (Erysimum arkansanam), a bardy annual
clayey: Erysimum rupestre is a rock garden plant, 3 or 4 inches high, which bears yellow flowers in summer. It is easily grown in sandy soil.

ERYSIPELAS. Erysipelas, or St. Anthony's fire, is an acute, rapidly spreading inflammation of the skin, and sometimes of the
underlying tissues, accompanied by heat,

Ermine Motk, an orchard pest. 1. Mature nsect. 2. Egg mass. 3. Caterpillar. 4. Cocoons. 5. Apple shoot with web Miniotry of Aurculture and Fisheries and
swelling, rednoss and pain of the affected part, together with high fever and general prostration. The teinperature may run up to $103^{\prime \prime}$ or $104^{\circ} \mathrm{F}$., and the patient will vary likely become delirious.

The skin of the face is the most common site, and large or small blisters may be present. The patch spreads rapidly, the parts first attacked getting paler and perhaps.scaling. If the eyelids or scrotum are involved, there may be much swelling owing to the laxity of the tissues in these situations.
The disease is due to " germ, a streptococcus, like those which cause suppuration, finding its way into the skin. Infection may take place through an open wound of any kind, even a slight scratch. Debilitating diseascs, such as diabetes and Bright's disease, and alcoholism, by weakening the resistrnce of the tissues, predispose to the disease. Erysipelas is a discase notiliable to the authorities, and treatment should be in the hands of the dootor. See Infectious Diseases

ERYTHEMA. This is a blush or reddening of the skin occurring in patches of various sizes which temporarily disappear upon pressure. It is due to many causes, such as emotional disturbances which produce blush. ing; external irritation in the case of chilblains; effects of heal and sunlight; friction of the skin by ill-fitting clothes, etc. ; counterirritants like mustard; nervous influences, e.g. neuralgia; and poisonous substances in the blood, eg. belladonna; poisons derived from the bowel, etc. Whero therc are no symptoms other than redness of the skin, with perhaps slight itching and burning, the application, of a lotion such as the following usually gives immediate relief

Water to
0 minima
4 oz.
The lotion should be mixed with equal parts cold water and sopped on to the skin. In erythema due to chafing, the irritable parts may be dusted several times a day with a powder composed of zinc oxide 1 part, magnesium carbonate I part, starch powder 2 parts. The part should be washed before applying the powder.
Erythemr multiforme is an reute inHamma. tory skin disease characterised by papules. lumps, red patches and sometimes blisters on tho skin. Erythema nodosum is characterised by pinkish-red round or oval swellings chietly over the slin boncs. The treatment should be supervised by the doctor, unless it is slight. If the digestion is poor or the patient is of a constipated habit these matters sbould be put right.

ESCALLONIA.
Thesc aro beautiful summer-Howering shrubs, most of them being evergreen. They are not very hardy, and in all except the mildest districts must be grown on a sunny wall. Escallonia macrantha, with attractive evergreen leaves and rose-coloured Howers, makes an admirable hedge in seaside gardens in mild localities, but clsewherc it needs the shelter of a wall. One of the hardiest is Escallonia langleyensis, a vigorous shrub 6 fect or more high, which may be grown in-the open garden in southern counties and

Escallonia macrantha，a crimson－flowared bedge shrub which thrives in seaside gardens
bears rose－red llowers Exoniensis and philip－ piana，both with white flowers，are two fairly hardy sorts Escallonias thrive in ordinary soil and are propagated by cuttings set in sandy compost in a frame in summer．

Eschscholtzia．This is the botanical name of a showy hardy annual，the Californian poppy（q．v．）

ESKIMO DOG．Most of the Arctio and sub－Arctic dogs share certain features in com－ inon，being of a wolfish appearance．The head of the Eskimo particularly takes after that of the wild animal，but the dog differs in one respect by carrying its tail tightly curled over thic back．The colour may be whito，black， black and white，silver grey，etc．Opinions vary about their disposition．Some say they arc uncertain in temper，others give them excellent characters．See Dog．

Eskimo Dor．Specimen of the breed，which in appearance is closely akin to the woll

ESPAGNOLE SAUCE．From this rich brown foundation sauce many other varieties are preplared．It can be made by melting 2 oz ．of butter in a stewpan，and adding to it 3 oz ．of ham or bacon cut into dice，a bunch of paraley and herbs，tied together，an onion and a carrot（sliced）， 1 tableajoonful of chopped mushrooms， 3 peppercorns，and a clove．Fry all these a light lirown．then add 2 oz ．of Hour．

When this is also brown，pour in 1 pint ol brown stock，add 3 sliced tomatocs，and let the sauce simmer gently for $\frac{1}{2}$ hour，stirring it occasionally and keeping it well skimmed． Add a wineglassful of sherry，with seasoning to taste，and then rub the sauce through a
sieve or tammy cloth，adding a little more stock if it is too thick．The wine and mush－ rooms may be omitted．

ESPALIER：For Fruit Trees．The norizontal eapalier tree is a convenient type for planting alongside the paths in the fruit and bitchen garden，the branches being trained on wires stretched between posts Such trees，if correctly managed，produce exceptionally fine fruits They are suitable also for planting against a wall．Apple，pear and plum are usually grown in this form The trees may have one tier or，as is shown in the illustration，several tiers of branches．A f́resh tier is formed by allowing a shoot at the top of the main stem to grow until it is 12－14 in． high；the top is then cut off，and when side shoots develop one on each side is sclected and trained horizontally at about 12 in．above the tier bencath．Other shoots are rubbed off

At the winter pruning the new branches should be cut back to within 12 in ．of the base of the previous summer＇s growth；thus they will extend every year by about 12 in．The summer pruning consists of shortening all side shoots late in July to within 6 in or so of the base；in winter these arc cut back to within about threc buds of the base． See Apple；Cherry；Fruit：Pear：Plum，etc

ESSENCE．Es－ sences are the essential oils from aromatic plants，obtained by a process of distillation and made into solution with purc alcohol． They are much used in the preparation of sweet and savoury dishes The commonest used are essences ol vanilla，lemon，almond， cloves，leppermint and ginger．These are very strong and one or two drops are sufficient to provide the Havour required

To make essence ol lemon， $1 \frac{1}{2}$ cupfuls dis－ tilled water should be mixed with 1 cupful pure alcohol and $\frac{7}{2} \mathrm{O}$ oil of lemon．Saffron should be used to colour． Orance essence is made from 6 oz．alcohol mixed with $\frac{1}{2}$ oz．sweet oil of orange，and coloured with cochineal．Almond essence is made from $\frac{1}{\mathrm{oz}}$ ．oil of bitter alnionds， 1 table． spoonful distilled water and $1 \frac{1}{2}$ cups alcohol．

Essence of cloves is prepared by infusing 1 oz．cloves in 2 oz．proof spirit for the period of a fortnight，straining it and then bottling the essence for use．

To make ginger essence，$\frac{1}{2}$ oz treshly powdered ginger，$\frac{3}{}$ oz lemon rind，and $\frac{1}{2}$ pint brandy or spirits of wine are needed．Let the rind and ginger soak into the liquid for a fortnight．Shake the whole daily，and then strain and bottle it，when it will be ready for use．See Almond：Lemon：Vanilla．
ESSENTIAL OII．The chief tlavouring part of vegetable substances is known as the essential oil That of lemon，for example， has the complete odour of the lemon，essential oils being diatinguished from lixed oils by this characteristic property．Almond yields both an essential and a fixed oil，but it is only the former that smells of almonds．Essential oils differ from fixed oils in not leaving ar greasy stain on paper．

ESTATE DUTY．This term is used fot the duty payable in the United Kingdom on death from the eatates of persons who lenve property．It was first imposed in 1894 and is graduated according to the value of the estate． The value of all property left，real or personal．
settled or unsettled，is added together and duty charged thercon at the rates noted below
In the case of amall estates，i．e．those under £500，the executors can pay，if they prefer， a sum of 30 s．if the value is not more than $£ 300$ ． and of 50 s ．if it is between $£ 300$ and $£ 500$ ． This frees them from all other charges．
The payment of the duty on estates of high value may be made in the form of real or leaschold property which is part of the deceased＇s estate．Certain classes of war loans are taken in payment at their face value， provided the doceased had held the stock for a certain period

Other provisions of the law about estate duties deal with gifts made during lifc（inter vivos）．If auch were made within three years of death they are regarded as jart of the estate and duty is charged thereon．If the gifts were for charitable or public purposes the period allowed is onc year．Exceptions to this are gifts less than $£ 100$ in valuc，settle－ ments made on marriage and those which were part of the deceased＇s normal expendi－ ture，e．g．an annual allowance to a daughter

Personal estate and real estate are valued separately for death duties．On personal property interest at the rate of 4 per cent is charged from the day of death until the

Espalier．Example of an apple tree，the branctes of whicu bave been
settlement of the account．On real property the duty may be paid by instalments over a period of eight years．In this case interest of 3 per cent．is charged，but only from 12 months after death．See Executor；Legacy Uuty；Probate；Will．

Estate Duties．Table showing the scale of duties in lorce after the Budget of 1830 ，in which the rates
on fortunes of 8120,000 and over were increased

ESTMMATE．An estimate is a statement giving the probable cost of an undertaking by one who is prepared to do the work．Before building，repairing，or decorating a house， laying out a garden，removing furniture，it is advisable to ask builders and others for is advisable to ask builders and others for
obtained from two or more firms and the it is wiser to err on the side of formality, and prices compared. The lowest estimate, however, is not always the most economical.
The success of any estimate depends to a large extent on the care and accuracy with which the inquiry is expressed; no one can quote a price for a piece of work unless the requirements are set out in sufficient detail. There should be a clear, precise, and definite statement of the work to be done, when and low it is to le done, the materials to be used, terms of payment, and a penalty clause for failure on either side. Often when an inquiry is made the terms are ambiguous or indefinite, with the result that some misunderstanding arises later.
When a house is to be built, it often prys: to engage an architect or quantity surveyor to prepare a bill of quantities. This includes a list of everything to be used in the work, and is the snfest method to adopt, as the surveyor will see that the work has been done and the materials used in the right way and without waste. On the other hand, if a profcssional is called on to advise or quote for a piece of work, it is assumed that ho will perform the task in a "orknan-like manner, and failure to do so is justifiable cause for complaint by the employer.

Estimates for building need to be examined with even greater carc. An estininte becomes a contract when it is accepted, but it may contain a clause providing for an increase in the figure in the event of any change in the, rate of wages or prices of materials, and adjustments of this kind must be nllowed for or the contractor can withdraw. See Architecture; Bungalow; Cottage; House.

ETHER: Use in Medicine. 'I'lie purified iorm of ether is employed for producing anacsthesia. It may be sprayed on the skin to Iree\%e it, and diminish the pain of an incision or puncture, or on tender points in neuralgia. As a general anaesthetic ether is preferable to chloroform in many cascs, because it acts as n heart stimulant. It may also be used as a rapid stimulant in fainting, collapse and cardiac weakness generally, as a carminative in Hatulent dyspepsia, and as an antispasinodic in asthmatic conditions. Ether should not be administered by an unauthorised person. The drug is very intlammable, and should never lee handled near lamps, fires, etc.
ETIQUETTE: Some General Rules The rules of etiquette which obtain in a social, business or professional environment forin a safeguard in dealing with other people correctly. This is particularly the case when the sur roundings are new and formality has to be observed with strangers, without any sliffness.

For instance, in the case of a family settling in a country district after living in a large town, certain differences of etiquette should be studied. Of these the two most important are that the new arrival should not call on anyone first, and should be careful to distinguish between calls and card leaving, hy returning the sane form of civility in each case. 'l'o call on someone of $\Omega$ higher social position who had only left cards would be to appear pushing. and perhaps cause a prejudice against the newly arrived family. On the other hand, to return cards where a friendly call has been made would be frigid, and be talien to mean that the acquaintance was not cared for.

Another instance where a knowledge ol etiquette may be of importance ie in the case of women whose husbands' profession stations them abioad. By observing the strictly correct procedure they avoid getting into a wrong set, because, by being polite but not intimate, they gain time to form a cool judgement without giviny offence. The best plan is to follow the advice of someone who is already well established in the locality. A general rule which may be followed when in doubt is that
that possible when confronted with a is well to observe how other people ancet it.

Appointments should be punctually liept, whether jusiness or private. Letters should be answered as soon as possible. Invitations should be clearly and cordially expressed, and replied to in the same vein. A lettor of introduction should alwilys be given to the person it is intended to benefil open and delivered open. If not used the giver should be notified and the reason explained, with thanks for the kind intention It is not neccsary to introduce people to each other unlesy they are likely to have something in common, but where there are only one or two persons present it is better to introduce them than to allow anyone to fcel awkwarl. Whatever the respective rank. age, or position, the man is always introduced to the woinan, and unmarried women to the married, unless the former is of superior rank. The onus of future recognition rests upon the person to whom the other is introduced.

Mer and Women. The rules of etiquette between men and women have been somewhat modified. In social life a man would rise when his hostesy or other women entered the room or stood: he would open the door for them and follow their lead. In business this would be absurd. Some years ago it would have been hard and fast rule for a man to give up his seat to a woman standing in a train or public conveyance. Now a business girl realizes that an older man may be more tired than herself. but anyone on beng offered a seat should accept it graciously without argument.

When walking with a woman a man should be on the kerb side of the pavenient, and should never greet or leave her out of doors without raising his hat. The rule for a man about paying fares for a woman is one which udmits of variation. Many independent women think it unfair to allow a man to pay. Whatever the reason they should not argue and a woman should always be prepared to pay for herself quickly to save any awkwardness

As far as the ballroom is concerned, it is worth while cultivating certain little courtesies, which go hand in hand with good manners. Always avoid dancing steps which draw attention to yourself, and never show off unless you happen to be an exhibition dancer. Introduction, though n simple matter, is one very fow people take the trouble to perform gracefully. At a dance, or anywhere else, the man should be taken up to the girl, and the person who performs the introduction, with a slight inclination of the head towards her, should say : "Miss _ inay I introduce Mr. " and then, inclining the head towards the man, say : "Mr. -., Niss-_."
Never hurry over an introduotion, and pronounce the names very distinctly.

The etiquette which governs dress is not altogether founded on fashion, and its rules are best interpreted by suitability. The most elaborate clothes inight be worn at a wedding which would look out of place elsewhere in the daytime. A greater laxity obtains now in these matters.

At many informal partics evening clothes are not expected, though when in doubt it is best to be formally correct. When staying in country houses people are expected to have the right clothes for any outhloor sports in which they take part, and to wear the correct evening dress for dinner. See At Home: Call: Cards, etc.

EUCAINE. Substitute for cocaine as $\Omega$ local anaesthetic. Solutions of the drug may be dropped into the eye or injected into the skin for operations on these parts, or injected into the gums for tooth extraction. In an ointment eucaine may prove useful in cases of intolerable itching.

EUCALYPTUS : Medicinal Uses. Euca lyptus oil is obtained by distillation from the fresh leaves of the Australian blue gum-tree 'The dose is one-half $t_{1} 3$ minims, and it may be taken on lump sugar. It has been given in aguc, in septic fevers, and in oonsumption and chronic bronchitis when the sputurn is foul smelling. It is a strong antiseptic and disin. fectant. The following makes a useful inhala tion or spray in diseases of the air passages

## Eucalyptus oil <br> Light carbonate in umsiosiii <br> Water to make

Add one teaspoontul of the above to a pint of hot water and breathe in the resulting vapour.

Encalyptus ointment smeared on boracio lint is a good application for abrasions and burns. Tincture of eucalyptus is efficient in arresting bleeding.

EUCHARIDIUM. This is a pretty, harly annual, belonging to the evening primrose family. It may be sown out of doors in nutumn to provide spring flowers, and in spring to yield summer flowers lt likes well drained soil in a sunny position. The favourite is Eucharidiun Breweri, 6 inches Ligh, with pale rose-columed flowers which are slightly scented.

EUCHRE. This is a chrd game for two, three, or four players. Here the game is described for four players, who play ns partners, two against two. Three varieties of packs aro used. A 32-card prok, the ordinary full pack, from which all cards firm the six to the two inclusive are omitted, a 28 -card pack, in which the sevens are also omitted, or a 24 . card pack, on which all cards from the eight to the two are omitted.

The carils rank according to trumps. In the trump suit the jack, known as the right bower, is the highest card. The second highest card is the jack of the suit the same colour as trumps. This jack is known as the left bower. The order of the cards is then the ace, king, queen, ten, etc., of trumps, followed by ace, king, queen, ten, eto.r of the suit the same colour as trumps. In the tiwo suits of opposite colour to trumps the order is as at whist. If a joker is used it becomes the highest trump.

The deal is by cutting, low dealing, nce being low, and for cutting all other cards counting as at whist. Five cards are dealt to caoh player, in one round of three at a time and one round of two. The next card is turned up for trumps. The game is to take at least three tricks by the player or partners who make the trump. If the players who call trumps fail to make the three tricks they are said to bo euchred.

The eldest hand begins play by ordering up the trumps or passing. If he orders up the trump, then the dealer must take up the exposed trump card and discard one from his hand. But he does not take up the exposed trump until his turn comes to play, though he must discard immediately. If eldest hand passes, then dealer's partner may say, "I assist," thus ordering the dealer to take up the trump, or ho may also pass, and so with the third player. Finally the dealer himself may take up the trump or pass. If he passes he turns the trump card face downwards on the top of the pack. If all have passed, the eldest hand has the right to name a fresh trump, suit or pass, and each player in turn will have the privilege as long as the plaver before has not named the trumps. If all players again pass there is a fresh deal by the next player, eldest hand.

If a new trump) is named of the same colour as the one rejected, it is cailed making it next, but if of the opposite colour it is called crossing the suit. If joker is played it is customary to say before a dea! what suit the joker shall represent if turned up. When the
trump is made, eldest hand leads and cach player in turn follows suit if possible. If not, he may trump or discard. The winner of each trick leads for the next trick. As each trick is made it is tumed face downwards, and is not allowed then to be examined. A player who has named a trump may elect to play alone against his opponent, in which case his partner places his hand face downwards on the table and takes no further part in the play of that hand The ordering up of the trump, the taking up of the trump by the dealer, or the making of a fresh trump, all come under this rule

Rules on Revoking. If a player revokes and it is not discovered till the trick is turned over, the hand is abandoned as soon as the revoke is claimed and proved. Players must allow tricks to be examined at the end of the game when a claim for revoke is made, or they suffer the penalty of a revoke. If the revoke is discovered before the trick is turned the player's adversaries may take back their cards and play fresh ones if they wish, but the player's partner cannot. Exposed or cards dropped face upwards nust be played at the tirst opportunity. A player who holds the incorrect number of cards cannot claim a misdeal after the first trick has been played, nor can lie or his partner score that hand.

The players or partners who macie the trump and win threc tricks score one point. If they win five tricks they score 2 points. Failure to take threc tricks is euchre, and the opponents score 2 points. A lone hand scores 4 points for five tricks; one point lor three or four tricks; and his opponents 2 points if he is euchred. Two points are scored by a player's opponents for a revoke, and 4 points by lone hand if his adversaries revoke. The game is 5,7 or 10 points up as may be agreed upon by the players. In three-handed euchre the maker of the trump plays against the other two players. He scores 3 points for a fivetrick win, and one point for three or four tricks, and loses 2 points to each of his opponents for euchre.

EUGENOL. This is a colourless oily liquid smelling like oil of cloves, of which it is the chief constituent. It is strongly antiseptic and is not poisonous. When applied to mucous membranes it diminishes sensation. Eugenol makes a useful application in neuralgia and toothache, and is much used in dentistry. Eugenol may also be used to relicve itching, 10 grains in 1 oz . of lanoline.

EUONYMUS. This is a group of hardy evergreen and leaf losing shrubs, suitable for various purposes in the garden. Euonymus japonious is a well known hedge shrub, which is particularly useful in seaside gardens, where it is less liable to be attacked by the magpie moth, which often disfigures euonymus hedges in inland gardens. Euonymus radicans and its variegated leaved variety are trailing shrubs which will thrive beneath trees and provide a uscful evergreen ground covering. The common spindle tree (Euonymus europaeus) is very handsome in autumn when its brightly coloured fruits are at their best. Ali chrive in ordinary soil and are increased by cuttings set in a frame in late suminer, or by seeds sown out of doors. Euonymus radicans is increased by division in autumn. From the bark of this shrub a dried extract. known as euonymin, is made, and frequently employed in medicine as a purgative.

Euonymus. The trailing Veronica zaulicans which can be grown suc-
cessfully beneath large trees

EUPHORBIA or Spurge. The genus of plants of this name includes annuals found in gardens and hedgerows, e.g. E. peplus and the common sun spurge, some shrubs, and plants which resemble cactus. When cut they exude a milky juice. The Euphorbia peplus, also known as petty spurge or devil's milk, is useful in asthma. Pilulifera, found in Australia and S. America, also known as Australian snakc weed or cat's hair, is also used for asthma and for hay fever and coryza. Euphorbia obtained from an American species is a remedy for bronchitis.
In poisoning by a species of euphorbia there is vomiting and purging, the face becoming dusky. Give an emetic of mustard and water and a dose of castor oil, or, if the patient is voniting, encourage by draughts of tepid water. Thereaiter give demulcent drinks, thin arrowroot, etc. Keep the patient warni and if breathing cesses resort to artificial respiration. See Poisoning.

EUSOL. The compound solution of hydrochlorous acid known as Eusol is an antiseptic Gluid made by mixing bleaching powder and boracic acid together in water. It loses its strength fairly rapidly, especially in hot weather. It will be found useful in most conditions where an antiseptio lotion is necessary. It is too irritating for the eyes, though it may be sprayed on the thront.
Dakin's solution is a similar preparation and keeps better. It is prepared in two strengths. The stronger will keep for a month and should be diluted with six parts of water before used; the weaker is not suitable for use after a wcek. All these solutions can be obtained freshly made up from a chemist. See Antiseptic.

Eustac̃blan Tube. Diagram showing anatomy of passnges running from anatomy of passages running
ear to
nose and throat

EUSTACHIAN TUBE
tubes are narrow passages about 1 l in. long, leading from the back of the throat near the posterior opening of the nose into the cavity of the middle ear. Each tube is lined with a delicate mucous membrane, and in health is always opened in swallowing, allowing the free passage of air into the middle ear cavity. The importance of this is that it allows the air pressure in the middle ear cavity to keep the same as that outside the car drum, and thus a free movement of the latter is kept.

Sometimes in catarrh of the nose and throat the catarrh spreads along the Eustachian tubes, blocking it up and so preventing the frec entrance of air to the middle ear. Partial deafness and buzzing sounds in the car are frequently due to this cause. See Ear.

EVENING DRESS. Setting aside court dress, which is a matter of uniform or regulation costume, evening dress for men resolves itself into a well-cut dress suit and a dinner jacket suit. The swallowtail coat and white tie arc worn for the formal house or restaurant dinner, theatre or evening party. Either a white or black waistcoat is permissible, though the former gives a smarter, brighter appearance to the wearer. Tlie dinner jacket, always with black bow tie, is worn for informal dress at home or out. It frequently makes its appearance now at smaller dances,
is usual in the country house when a dinner party is not being given, at bridge partics, and for quiet theatre-going occasions.

When dining with formal acquaintances it is best to wear full evening dress if in doubt as to what is expected. Where the invitation is received through the post well in advance of the date of the party it is usually a sign that it will be a formal one, and require the regulation swallow-tails. For outdoor wear in large towns a black overcont, crush hat, and white silk scarf are correct with evening dress.

EVENING PARTY. The formal evening party is often merely a reception, begiming about 9.30 and going on till after midnight. It may follow a dinner party to enable a larger circle of the hostess's acquaintances to meet some distinguished person in whose honour the evening's entertainment is given. In this case, those who are invited arrive at any moment within the time limits and stay as long as they wish, in just the same way as at an afternoon At Home. On the other hand, should there be a special fenture, such as music, bridgc, roulette, cinema sliow or lecture, it is usual to put this on the invitation so that the guests may arrive at the hour stated. Dancing also, if intended to form the staple attraction, would be mentioned. Eyening dress is the rulc.

For a mixed party includ. ing children, which might be given at Christmas or for a birthday, games are often introduced, card and conjuring tricks are popular if well donc, charades are a never-failing attraction when thought out beforehand and dressing facilities are arranged, while suoh games as clumps and musical chairs have a perennial appeal. In the country the parties of such a descrip tion often start early in the evening.

For light refreshments or suppers at all these entertainments selections from the saine kinds of food are served; sandwiches in all their varietics, meat jellies, mayonnaises, eggs or prawns in aspic, every sort of galantine, terrine, pie, cold sweet, savoury and ice. In the winter hot soups, served in cups, and in the summer iced drinks are in special demand. Iced drinks and ices should be available throughout the evening, and where there is no staff to distribute them the guests should be asked to help themselves to refreshments.

Informal Partics. Some hostesses specialise in small Sunday evening parties, only inviting those who are likely to enjoy each other's society, and without any formality. It is usual to serve a sit-down or help-yourself supper about eight o'clock at this type of party, and evening dress would be optional.

Informal after-dinner parties are useful methods of entertainment where accommodation is limited, and give opportunity for introducing people whom one is anxious should meet each other: In such cases the invitation may be by telephone or sont in a friendly note, asking the prospective gucst to come in after dinner on such and such an evening.

Nothing elaborate in the way of refreshments is needed. Usually coffee is hancled round as soon as the company is assembled, and liqueurs may be offered at the same time. Fruit. cakes and cocktails or other drinks may be offered during the course of the ovening.

Entertainment during such an evening can take the form of cards, music, or merely conversation, according to the tastes and talents of the guests. If any of the guests can contribute items, a cabaret performance is devised, the room for dancing can be oleared
except for chairs, small tables set round the walls, and the necessary piano.

For $n$ more important musical evening a concert may be arranged either to introduce talent or for a charity. If for the latter purpose, the preliminary work involved in getting up a concert includes some advertisement of the forthcoming event in the local newspapers, by the distribution of handbills among residents and for exhibition in shopwindows, arranging and numbering the seats, and providing tickets and programmes. See Bridge Party: Cocktail Party; Dinner; Thentricals.

EVENING PRIMROSE. Some of the evening primroses are perennial, but others are biennial. The latter perish after they have flowered, and must be raised from seed every year to ensure an annual display of bloom ; the perennials live on from year to year. The common evening primrose, Oenothera biennis, of which the flowers do not open during the daytime, soon becomes a weed in gardens, for it sows itself freely. It is not noarly so attractive as some of the perennial kinds, although useful for odd comers and in the shrubbery

The best of the peremnials is Oenothera Iruticosa or Fraseri; this is a splendid border plant, 18 inches to 24 inches high, which bears bright yellow flowers that are open during the daytime. Speciosa, 2 feet, has beautiful white flowers, and missouriensis, $\AA$ trailing plant for the rock garden, has large yellow blooms. The new Oenothera trichocalyx, " feet high, with

Evening Primrose, the fowers of which are closed during the day and open in the evening white flowers, blooms in summer from seeds sown in spring under glass.

The even. ing primroses suitable for planting in bord ers
flourish in ordinary soil; missouriensis thrives best in well-drained sandy loam. The perennials can be propagated by division of the clumps in autumn or spring, or by sowing seeds out of doors or in boxes of soil in a frame in April-May.

There are several annual evening primroses, of which the most striking arc taraxacifolia, blush, 6 to 8 inches high; rosea, rose colour, 0 to 8 inches; and bistorta Veitchii, yellow and crimson, 12 inches. The two firat named are hardy anmmals to sow out of doors in April; the last should he sown under glass in March.

EVERGREEN. The term is applied to the innumerable trees, shrubs and flowers which retain their leaves all the year round, instead of shedding them in the autumn, as deciduous or summer leafing shrubs do. With the exception of the holly, box, and some varieties of the oak, there are few evergreen native treos, but notable instances of other popular cvergreens are to be found in the laurel, privet, ivy, and rhododendron See Andromeda; Aspidistra; Bouvardia; Box; Butcher's Broum ; Ceanothus; Ivy, etc.

EVERLASTING FLOWER. The socalled everlasting flowers are uscful in the garden during the suminer months and for room decoration in the autumn and winter. If they are required for use in winter they should be cut during dry weather before the blooms are fully expanded; after having been set out in a cool room to dry they should

Evarlasting Flower. One of the everlasting fowers, Eelichrysum, which flowers in summer and may be dried for winter decoration
be bunched and hung, Howers downwards, indoors until required for vases.
Those chiefly groun are hardy and half hardy annuals-helichrysum, acroclinium and rhodanthe. Helichrysum is a hardy annual, and should be sown out of doors in early April where the plants are to grow; it reaches a height of 2 feet or more and bears large blooms in crimson, orange, yellow and other colours. Rhodanthe and acroclinium, with rose or white flowers, are of slender growth and reach a height of about 12 inches; they mnay be raised from szeds sown out of doors in April-May or under glass in March: they are often grown in pots for the summer decoration of the greenhousc.
EVERLASTING PEA. This is a useful climbing summer-Howering plant for covering a trellis, porch or other support. They are hardy, thrive in ordinary soil and reach a height of 6 to 8 feet. The hest way of raising a stock is to sow seeds in a box of soil in a frame in spring or out of doors in April. The commonest kind, Lathyrus latifolius, bears rose-red flowers; the variety White Pearl is more attractive. Lathyrus grandiflorus has rose crimson flowers.

EWER. This name is given to a wide spouted jug made in earthenware and glass The early ewers were used for holding water to pour over the hands after meals. These werc usually of silver or other metal, and some were made with a basin to match. See Crockery; Cream Jug; Jug.

EXCHANGE: Of Goods. Many persons wish, instead of selling and buying, to exchange one article for which they have no use for one which they want. Furniture dealers, especially those who sell antique and second-hand goods, frequently take one article in payment or part payment for another. I popular way of bringing about an exchange is to advertise in one of the newspapers, say the "Daily Telegraph" The articles to be exchanged should be described as clearly as possible in the limited space available, and it should be stated when they can be seen.
EXECUTOR: His Duties. An executor is a person who is appointed by a will to see that it is carried out; on him devolves the duties of seeing that the testator's debts are paid, and his property disposed of as he has directed. It is well to appoint two executors in a will, for one may die before the testator or immediately after him, and before the duties have been completely carried out. If the estate is a small one, and can be wound up quickly, it is bctter to appoint two in the alternative, thus: "I appoint as executor of this my will John Simith, or if he dies before me or refuses to act then I appoint

William Jones." It is best for a testator to nominate as executors penple who are younger than himself.

An executor's first duty is to prove the will, either at Somerset House or at one of the local Probate Registries. It is wise to employ a solicitor to do this The next duty is to collect the property. All dehts should be got in and all stocks and shares transferred to the executor's name, at any rate so far as may be necessary for him to realize enough to piay the debts and legacies. The first debts to be paid are the funeral and testamentary expenses incurred by the exccutor, and next the debts owing by the accused in his lifetime; and after that, when all debts are discharged, the executor begins to pay legacies, and to distrihute the property.
An executor should be diligent in collecting debts-that is, he should not delay so long that the debt becomea statute barred. Debts should be paid in the folloiving order
(1) Funcral expenses and expenses of proving will and getting in property
(2) Debts preferred by special statutes
(3) Rates and taxes and wages to certain servants ; compensatlon due under Workmen's Compensation Act. contributiony to msurance Acts.
Next. the ordinary debts must be paid, but cerfain debts are deferred until all others have been met, e.g. money lent to wife by husband, or vice on terna that hender should receive a inte of interest on ternis wiat lender showlile receive a rate of
If the deceased left plenty of assets to pay all his debts, it does not matter in what order the executor pays them; but if there is not enough to go round, the executor should adhere strictly to the order given above.

As between the people to whom money or property has been left by the will, the executor often has to make a choice; he has to take some of the property to pay debts, thus leaving not cnough to pay all the legatees. He must apply thic assets towards payment of debts in this order
(1) Pronerty not disposed of by will, sublect o a fund ior pecuniary legacios
(2) Property included in a residuary gift, subject (3) Pronerty specifcally appropriatel for pay. nent of debts.
(4) Property disposed of subject to a charge for payment of debts.
(5) Any fund for necuniary legacies
(6) Property specillcally disposed of in will.
(7) Property uppointed by will under a general nower of appointment.

An exccutor is liable personally to the estate if he wilfully neglects to collect or realize the property. He is personally liable to a creditor if he admits assets by paying a debtor of an inferior class when that creditor is of a superior class. He may be liable if he personally promises a creditor to pay his debt; but the promise cannot be enforced unless it is in writing signed by the executor or his agent.

If the executor gives notice to creditors by means of advertisement in certain newspapers calling for claims, he is not liable for debts notified after that time.

Occasionally a legacy is bequeathed to someone who cannot he found, e.g. a melative who has emigrated, address unknown. In such a case the executor would be well advised to pay the money into the chancery division of the high court, and then await the claim. See Death; Estate Duty ; Legacy ; Will.

EXERCISE. I healthy child rejoices in exercising its muscles, and the more vigorously the better. Children who are cooped up in cramped and badly ventilated rooms are prone to develop rickets. Their bones become soft, bend easily, giving rise to mis-shapen chests, bandy legs and other bony deformities. A large number of girls, mostly amongst the poorer classes, show a faulty development, the reason being that they are very frequently kept indoors for household duties.

Games, therefore, are the natural right of the young, being necessary to their growth.

It a child is indispused for games by lack of bodily vigour, attention should be given to its health, and suitable gentle cxercise should be selected, to lead yradually to something more strenuous In adolescence games provide a safe means whereby a superabundance of energy may be expended. Apart from their uselulnces in developing the body, games should be encouraged as a means of developing character and of enabling the child to come into casy relationship with his fellows

Nor is exercise less necessary for those whose hodily development is complete. The sedentary worker who neglects exercise becomes stale, his vigour is diminished, he suffers from a lack of elasticity, and his digestion is apt to be sluggish. If he also lives well in the way of food and drink, these evils will be intensified and he may become obese or gouty, suffering from arterial disease or a combination of these, and break up comparatively early in life. Exercise improves the tone, the size, and the firmness of the muscles, strengthens the heart and lessens its work, increases the excretion of waste products by the lungs, the skin, the kidneys and the bowels, and so makes possible a free, untrammelled activitv of all the hodv tissues
Nothing call compensate Wholly lor the lack of exercise in the open air, but in the case of town dwellers whose opportunities in this respect are limited, an hour once or twice a week in a well-appointed gymnasium will be of the utmost value, or carefully chosen exercises may be done regularly at home in a well-ventilated bedroom Exercises involving much strain should not be undertaken by those whose hearts are weat, or who are much older than 30

Walking provides good (excrise it one walks sufficiently fast, and more particularly if the wall: is uphill; but as the value of exercise is largely enhanced by the extent to which interest is excited, the superior claims of golf are apparent, apart from the additional exercise to the arms For the same reason any ot her suitable game should be pla yed whenever it is at all possible to do so. See Beauty Culture; Breathing: Diet; Drill: Figure

EXHAUST : From the Engine. This word is used for the waste steam or burn gases ejected from an engine, and also for the exhaust piping. In internal combuation engines the waste gases anc expelled through the exhaust valves and the exhaust port into the exhaust pipe. Most motor cycles are provided with a device known as an exhaust lifter, usually controlled from the left-hand side of the handlebars. This raises the exhaust valve when required, releases the compression of the engine and prevents firing

The fumes from the exhaust of a petrol engine may contain the highly poisonous gas known as carbon monoxide, produced by imperfect combustion of petrol in the cylinders.

If the engine is allowed to run while the ar is standing in the garage, the extaust pipe must be connected to the outer air, and the buikl iny ventilated by opening doors and windows
EXOPHTHALMIC GOITRE. Over action of the thyroid gland, which is situated in the neck just below the Adam's apple, is the cause of a clisease to which the name exophthalnic goitre has been given. It may be contiasted with myxoedema, which is due to under-action of the same gland. Its ohief characteristics are prominence of the eyeballs, enlargement of the thyroid gland, rapid heart action, and a continuous tine tremor. The disease is more common among women, and it is possible that worry or excitement may help to bring it on

The symptoms are very gradual The heart brat is quickened and may range between 100 and 120 instead of the normal 65 to 75. The action is abnormally forcible and the
vessels in the neck, the pulses at the wrists and in front of the ears, eto., become readily visible. As a rule thr patient loses ilesh and becomes anaemic.

Everything should be done to secuie mental as well as physical rest, and in the case of a town-dweller slie should be sent if possible to live in the country for a time, avoiding excitement and getting plenty of fresh air and plain food. Ten hours' sleep is not ton much in suoh cases. The drugs mostly given are iodine, arsenic, digitalis, belladonna, and the bromides. Attacks of diarrhoen and vomiting should at once be brought to the notice of the physician. The application of X-rays has proved a successful cure in many cases of exophthalmic goitre In severe cases an operation is undertaken

EXPECTORANT. A ding used to piremote rasier expulsion of expectoration fion, the air passages in disease by altering the character of the secretion or otherwise is termed an expectorant. Among these are sodium or potassinm bicarbonate, a mmonium chloride, ammonium carbonate, iodide ol potassium, ipecacuanha, squills, volatile oils (e.g. camphor), balsams (c.g. compound tincture of benzoin), and a variety of others Some expectorants are depressant to the heart, e.g. pecacuanha and antimony, and care has to be talien in giving them to the aged and debilitated, for whoni stimulating substances like ammoniun carbonate, ammoniacum, and camphor arc preferable

The following is a typica. expectorant mixture such as might be prescribed in a case of chronic bronclitis. The dose is 2 tablespoonfuls cvery $\&$ loours

EXPECTORATION or Sputum. Material coughed up or got rid of by spitting may come from the mouth, nosc, throat, air passages, or lungs A clear, sticky sputum, like white of eos, occurs in the carly stages of bronchitis, pharyngitis, and of lung conditions such as phthisis and pneumonia. In chronic catarrhal conditions of the nose and throat greenish. grey, sticky material is hawked up in "clearing the throat," frequently stippled with black specis due to inhaled dust. A brownish or yellowish-red sticky aputum constitutes the rusty sputum of developed preumonia
Streaks of blood in the aputum may come from the mouth in sjongy conditions of the gums, etc., the throat from adenoids, etc., or the air passages generally when inllamed When in larger or sinaller quantities of pure or ahmost pure blood, it is termed hamoptysis Thic commonest cause is consumption. Theblood is coughed up, it is bright red and is mixed with air these circumstances dis. tinguishing it from haema. temesis, or blood from the stomach, which is vomited and is usually dark in colon' and intermixed with food.
In disenses in which there is expectoration this should not be received in a hand kerchief, otherwise it dries and is shaken off into the air, carrying with it the disease microbes. In cascs of consumption a pocket spittoon or spitting bottle. is always insisted on for this reason, but there are othere than consumptives whose expectoration is dangerous, and it is their duty also to use a bottle and protect their neighbours IVithilu

doors the sputum may be received in pieces of paper, which are immediately burnt, or if they are received in a receptacle this should contain some antiseptic solution, e.g. of lysol See Bronchitis; Pneumonia, etc.

EXPOSURE : In Photography. Corred exposure is the key to success in all forms of photography and without it цood results cannot possibly be obtained The camera cannot be treated as an instrument in which only a button has to be pressed and the machine does the rest. The simple roll film camera with a lens of an aperture of 18 ol 111 (U.S numbers 4 or 8 or Kodak No. 1 fol V.P.K.) will give satisfactory results for most subjects on sunny days in midsummer without. any special consideration of exposure times, for it is designed to do this, but at other times of the year or on dull days and with certain kinds of subjects a knowledge of the conditions to be observed is absolutely essential.

There are four conditions which govern the exposure: The actinic, or photographic, value of the light; the sensitiveness, or speed, of the plate or film used; the lind of subject being photographed; the aperture, or speed, at which the lens works. Taking the last condition first, it will be assumed in this article that a lens worling at an aperture of 18 (as explained under F Numbers) is used For a lens of $f 11$, such as is found on the ordinary V.I'K and other eheap roll film cameras. all the calculations must be doubled
The actinic value of the light varics very considerably according to weather conditions, time of day and time of year. It does not necessarily follow that because the light. appears to be bright it is good in the photographic sense; for what has to be considered is not the appearance of the light to the eye, but its chenical action on the sensitive film Nome forms of light which are hardly perceptible to the eyc have very definite action on the photograjhic plate. Again, winter sunshine, which may appenr to be atrong. is photographically weak, and even on an August day the light is not quite so stiong in the alternoon as it is in the morning.
Small variations in the chemical strengtl, of the light do not matter, because the latitude allowed by modern filns peimits exposuras which inay be two or three times the thenretically correct figure without impairing the result. In fact, for the amateur working with a roll filn camera it may be broadly atated that the one thing he has to guard against is under-exposure; he is hardly likely in taking snapshots to over expose.

The second consideration, the speed of the plate or tilm used, is one that will give the amateur very little trouble if he will adopt the plan of finding the plate or film that suits his purpose best and sticking to it Deternining the speed of a plate is a very complex matter. Not only do different plates vary in speed or sensitiveness in ways which are not comparative in spite of the so-calledspecd numbers marked on the hoxes, but even different batches of the same plate will vary. Experienced workers in photography. therefore, find that the best results are ohtained if they conline themselves, as far as possible, to one brand of plates or films whose speed they know.

As to the third consider. ation, the kind of subject that is photographed, the novice soon learns that a white object requires n
shorter exposure than a dark ona He does not always reoognize that darkneas of colour is not the same as darkness in lighting, and that a white object poorly lighted may pactually require a longer exposure than a dark objeot well lighted.

Guides to the exposure required for various objects under different conditions may be found in elaborate tables in photographic handbooks calculated according to time of year, olimatio conditions and speed of plates or films.

The most sure and satisfactory method of calculating exposure is probably to use an exposure meter, such as Watkin's Bee Meter. These exposure meters depend upon the time taken for a piece of sensitive paper to become coloured. This is seen in the half-circle A at the bottom of the illustration, alongside of which is a standard tint $B$. The time taken by the sensitive paper to acquire the colour of the standard tint varies with the photographic strength of the light. Instructions for its use are given with the meter.

It provides an accurate method of determining the strength of the light under the conditions actually met with at the time of making the exposure.

A simple form is supplied for purely snap. shot work which shows whether the light is good enough for an ordinary snapshot, i.e. the exposure of about $1 / 25$ th of a second, which the shutters in the cheaper cameras give. If the sensitive paper in the meter docs not darken properly in the minimum time stated it indicates that it is practically useless to attempt to take a snapshot.

Cameras with single speed shutters marked as working at $1 / 25$ th sec. usually give an exposure of about $1 / 1 \mathrm{j}$ th to $1 / 20$ th sec., which is about the longest exposure that can safely be given with the camera held in the hand if mevement is not to show itself in the picture. Cheaper shutters marked as giving an exposure of 100 th of a second generally give about $1 / 50$ th. These variations are all to the good, as they result in longer and better exposures.
Longer exposures can easily be given. Rest the camera on a fence, a gate post or the top of a chair, and by setting the shutter to "bulb" give short-time exposures. Thus, with the shutter set at bulb the release is pressed and let go again instantly. If this is done as quickly as possible without shaking the camera an exposure of about a $t \mathrm{sec}$. will have been given. For 1 sec. do the same with a perceptible pause between pressing the release and letting it go, or by pressing the release while the words "one, two" are said sharply. Doing the same while saying sharply "one, two, three, four" will give a 1 sec. exposure. See Developing; Film: Plate: Snapshot.

EXPRESS DELIVERY. Packages and letters can be sent from most post offices for express delivery by special messenger. The charge is 6 d . for each mile or part of a mile, and a ld. for each package in addition to the first up to a maximum of ten. Packages over 1 lb. in weight pay a further 3d. By this service live animals, liquids, and loose cash can be sent and persons conducted to and from any given place. The messenger can take back an inland telegram without extra charge.

Packages may also be posted and then sent by special messenger at the charges mentioned from the post office to the address thereon, instead of waiting for the ordinary postal delivery. Additional fees are charged if messengers are kept waiting for more than 10 min . These range from 2 d . upwards.

On payment of 3d. to a servant of any of the olief railways, in addition to postage at the ordinary rate, letters not exceeding 2 oz . will be forwarded, and paseed on from one
company to another at a junction, by the next available train or steamship, to be called for at the station to which the letter is addressed, or to be tranaferred to the neareat. letter bux for postal delivery. The letter may be taken to a passenger atation of the railway company, or sent there by express delivery on week days. It may also be forwarded after conveyance by train by express service.

ESTIRACT. Meat extracts are obtained from lean meat by various processes, which include the use of heat. They contain a very small amount of nutritive material, their chief constituents being extractives, substances which result from the breaking down of proteids, and mineral salts. They act as
stimulanta and help to remove fatigue. They also improve the appetite and digestion, so that other food which is taken at the same time proves of more use to the body. Meat extracts are useful flavouring agenta. Extract is sold in bottles of various sizes, and with a little hot water, soup or broth may be quickly prepared.

Malt extracts contain a large percentage of carbohydrates, which are readily dissolved and digested, and one also finds in them active diastase, the ferment which converts starch into sugar. Thus they provide an additional and suitable supply of carbohydrate, and also assist in the digestion of starchy food. See Beef Tea; Food, eta

## The Eyes and Their Care <br> Hints on the Preservation of the Eyesight

The subject of sight is dealt with in this Encyclopedia under a number of headings, e.g. Eyeglass; Sight
Teating ; Spectacles. See also the entries on Astigmatism; Blind; Cataract and other eye afiections
Of all the organs of the human body the is ushered in with intense pain in the eyeeye is the most delicate in structure, the most ball, frequently radiating around the eye, and susceptible of injury by disease, accident or sometimes accompanied by headache and overstrain, and any affliction of this organ calls for expert treatment at the earliest possible moment. In no case is this more essential than in ophthalmia of the newly-born, a disease whioh makes its appearanco within a day or two after birth and is the cause of the great majority of cases of blindness. It is characterised by the discharge of pus from the eyes; any such discharge calls at once for skilled attention if total blindness is to be provented.
Visual Defects in Children. During child. hood various faults of vision, such as shortsight, long-sight, squint and astigmatism, may make their appearance, and parents and guardians should be on the alert to have the cyes of children examined at once if they observe any signs of visual defect. The child suffering from short-sight will hold objects which he wishes to see nearer to his eyes than is normal and cannot identify objects that are at a distance. The child who is long-sighted will complain of pains in the eyes and of headache when read. ing or writing, due to over strain of those muscles by which the eyes are focuseed on near objeota. In all sucl cases glassos are essential.

Squint is most frequently due to over-atrain of the fooussing muscles, and is a sign either of weakness of these muscles or of long. sightedness. Astigmatism is generally caused by irregularity in the curvature of the front of the eyeball, and demands the provision of speoially ground glasses. Its presence may be suspected where the subject complains of eye strain or of headache, especially after a visit to a kinema, theatre, etc.

Eye Changes in the Elderly. After middlo age difficulty niay be experienced in viewing objeots clearly which are near at hand. This is due to hardening of the internal structures of the eyc and weakness of the muscles of focussing, and assistance inust be rendered by glasses, which will require to be strengthened as the disability increases with advancing years. If it is found necessary to obtain stronger glasses more frequently than every five years, and especially if at night-time street lights or candles are seen surrounded by rainbow-coloured rings, it is possible that the subject is suffering from a dangerous disease known as glaucoma, which, even in its chronic form, demands immediate surgical treatment. When acute, glaucoma
 vomiting. Its onset, therefore, is liable to be mistaken for a bilious attack, and valu. able time wasted in securing treatment. In all cases where glasses are required, they should only be obtained on the prescription of a qualified oculist.

In order to a void the occurrence or aggravation of visual defects, it is of importance that all close work should be done in a good light. Excessive light is equally harmful. In reading or writing, a prosition should be adopted in which the source of light is, if possible, behind and from the left. This is particularly inportant at the school age. Undue stooping when writing should be avoided as tending to increase tension within the eyeballs, and therefore to aggravate any existing predisposition towards short sight. For the same reason tight neckwear and excessive physical exercises may be harmful. Reading in bed is injurious, and children should never indulge in it.

Diseases and Injuries. A stye is a small abscess which forms at the root of an eyelash. It should be treated by pulling out the eyelash involved, and by bathing the eye frequently with a hot lotion made by dissolving a teaspoonful of common salt in a pint of water which has been boiled. This lotion is also useful for all simple intlam. matory diseases of the eyelids. Chronic inflamniation, however, demands drastic treatment by an oculist, as the condition may be due to trachoma, a condition which is dangerous alike to the patient, owing to the possibility of blindness supervening, as well as to others who may become infected.

Soiled towels in public lavatories should never be used to dry the eyes, as the infection of trachonue, as well as of many other conlagious diseases. nay readily be conveyed by such means.
To prevent the sealing of the lids which is so frequent in inflamed eyes, and does harm by imprisoning the discharges, the eyes should be well smeared at bedtime with a salve or ointment. Useful ointments are 10 grains of boracic acid powder in 1 oz . of soft paraffin or vaseline, and equal parts of yellow oxide of mercury ointment and vaseline. A little glass rod with a rounded end is a convenient instrument to use for applying. The lower eyelid is drawn down and some ointment, picked up on the end of the rod, is put on its
inner surface. The patient closes his eye, part of the day For such persons eyeglasses and by gently rubbing over the surface of the lids the ointment is spread over the eyeball.
A lotion or collyrium (q.v.) should always be used comfortably warm. It may be applied by soaking a piece of cotton wool in the lotion and squeezing this out into the eye, or by means of an eyebath (see below).

Foreign bodies in the eyes may usually be removed by brushing with a camel-hair pencil, or the moistened corner of a pocket handkerchief. Il simple measures fail, instil a drop of castor oil into the eyc, place a soft pad, as of cotton wool, over the closed eyelids and secure this in position by applying a bandage lightly. A doctor sliould be consulted without delay.

Wounds of the eyeball are extremely dangerous, no matter how trivial they may appear, as they may be productive of blindness. A blow on the eye, as in boxing, may cause serious internal injury even though no external signs aro visible. It is of importance $\hat{\omega}$ remember that failing vision may be the first symptom of grave diseases, such, for example, as Bright's disease or diabetes.

Hygienic Measures. When in perfect health, the whites of the eyes should be of a clear bluish-white. Redness shows that the eye is suffering from a slight cold or a strain. Give the cyes a warm boric lotion bath three or four times a day, using a teaspoonful of boric acid powder to every $\frac{1}{2}$ pint of hot water. To remove a yellowish tint from the whites of the cyes, drink a glass of hot water to which the unsweetened juice of a lemon has been added. In all treatment with bandages and pads, medicated cotton wool and butter muslin are the most hygienic materials to use, since they can be thrown away. Spongen should never be used unless they are certain to be deatruyed immediately afterwards.

Pcople who write or read a great deal often suffer from eye strain This may be relieved by bathing the eyes in a solution of salt and water, a taasponnful of salt and a quart of water. Pure cold water is in itself a good eye wash, or a woak solution of zinc sulphate will be made up by any chemist and is very good for tired eyea After extra fatigue a strip of lint, nuistened with water and laid on each eye and kept in place by a bandage for about ten minutes, is very helpful.

An eyebath is a convenient appliance for washing the eyes. This is a little vessel of glass or some other matcrial, with its edge shaped to tit into the socket of the eyo. It is filled with the lotion and the patient bends forward the head and applies the edge of the bath firmly round the cye. He then throws his head back and opens the eye widely. The lotion is kept in contact with the eye for a minute or two. The cleansing may be facilitated by opening and closing the eye several times while the bath is in position.
EYEBROW. If eyebrows aro too thin a little red vaseline or cocoa-butter can be applied nightly with a small eyebrow brush, which is like a minute toothbrush in form.
In applying any strengthening lotion care must be taken not to encourage the growth of hairs between the eyebrows. Some eyebrows have a tendency to meet over the nose. The use of tweezers keeps the line of the brows in good trim, unless the hairs are abnormally coarse, when electrolysis may be employed by a good operator. Brushing the eycbrows with a clean brush lightly smeared with a little brilliantine each morning tends to darken thom and give them a silky appearance. It is possible to have the cyebrows and lashes tinted in any desired shade of brown or black See Beauty Culture; Face.
EYEGLASS. Eyeglasses are usually worn by persons who do not require glasses constantly, but only for a particular purpose or for
are perhnps more suitable than spectacles.
Excluding the single eyeglass, or monocle. there is not a great dcal of variety in the eyeglasses worn by men and women in ordinary life. There are slight variations in tho nature and strongth of the spring that keeps the glasses in position on the nose and in the shape of the bridge that unites the two glasses: there are glasses with rims and glasses without, and there are glasses that fold up and glasses that do not, but that is practically all. The frames, however, vary in quality and material, ranging from the cheaper ones of nickel or steel to the expensive ones of solid gold. Silver is rarely used for these frames, but rolled gold is frequently seen. Some persons have eyeglasses with horn or tortoiseshell frames. Some wear a cord to attach the eyeglass to some part of the person: others prefer to carry them in a case.

The eyoglass has usually a rim of metal round the glass proper, but many persons wear glasses without rims, and for these certain advantages are claimed. Their weight, it is said, is about one half that of ordinary eyeglasecs: they are, when properly fitted, almost invisible, and they have no rims to interfere with the vision if they get slightly out of place.
The Frames. The frames of eyeglasses are often inade in other inaterial than metal, and those fashioned of tortoiseshell or horn are not easily repaired. When the nature of the damage permits, the fracture can be mended with Canada balsam, using this as a cement. The parts are held together with finc bindling wire, or with a strong paper-clip of the John Bull type, and left for 24 hours to set hard.

A common fault with eyeglasses is for the frames to become distortod and forced out of they will not be admired if blemished by surface defects. Correct diet and exercise are essential factors, but local treatments are also integral to the preservation of a fine skin. It is quite easy to call to mind inany healthy women and girls who do not prossess beautiful complexions for the simple reason that they take no care of them.
On the other hand, the athletio movement of the past twenty years has undoubtedly improved the akin, eyes and hair of the sex in general. The sports girl breat hes more deeply, and so possesses a bigger supply of oxygen in her blood, expressed in greater physical beauty, owing to her better circulation. This combined with saner views on diet and fresh air has also lessened digestive troubles and constipation which have a directly adverse effect on the facial appearance.

A frequent cause of a sallow, wilted look is sinıply the neglect of drinking sufficient water. The normal body requires three or four pints a day, some of which is taken in food. A glassful should be drunk at night and in the morning. A free use of water combined with plenty of fruit, green vegetables, a nourishing diet, fresh air and the regular performance of breathing exercises will remove premature hollows under the eyes and round any unbeconning facial angles.

Facial Contour. Superfluous flesh in a youthful face will often respond quickly to correct diet and massage, when the desire to reduce is strong enough to make certain sacrifices, such as cutting down sweets, pastries,
line. In bending the parts and bringing them into place, keep the fingers of each hand close together with the bent part of the frame between them, thus localizing the strain. If a small pair of pliers is used, remember not to exert ton much pressure and smash the glasses. When viewed in plan the lenses should be in lino. and likewise when viewed from the front. The plaquets, or nose grips, are often faced with cork, and this can be cleaned with petrol, or new pieces cut from a good quality bottle cork and cemented in place. See that the plaquets are in line and at equal angles to a vertical centro line.

Eyeglasses with astigmatic clips, or those in which a spring draws the two parts together, will benefit by cleansing with petrol, and the spring be retensioned by drawing it through the fingers and thus increasing its length. Replacement parts are generally obtainable from manufacturing opticians See Sight; Spectacles

EYELASH. The beauty of the eye depends to a great extent upon the oyelashes. They should be as dark or a sharle or two darker than the hair. They can be printed at night with castor oil applied with a camel's hair brush. If tho eyelashes are inclined to be very straight they should be gently brushed upwarl over an orange stick laid along the erlge of the upper cyelid. The use of a slightly astringent eyc lotion containing witch hazel tightens the eyclids and prevents fall of the lashes.

EYELET. An eyelet is a small round hole in cloth, sailcloth, etc., which is worked like a buttonhole for the passage of a lace, ring or rope. In needlowork it is best known as the open hole which is used in various forms of einbroidery for working berries and similar small round parts of the design. See Embroidery : Stilctto.

## Face: Contour and Skin Treatment

## The Use of Simple Cosmetics and Massage

## For related information see the articles Beauty Culture: Diet; Hair; Neck; Skin. Consult also the entries Powder; Soap, etc.

A good facial contour ranks next to a fine and not giving way to laziness. The muscles complexion in creating a general impression which preserve the contour of the face must of beauty. The skin is of first importance, be kept healthy because on their vitality because no matter how handsome the features mature good looks depend.

The upright carriage of the head has a good iffect on these muscles. Exercises to assist in preserving the contour of the jaw are
given in the entry on Neck. The pursing of the lips as if for whistling, when exhaling during breathing exercises, smoothes out lines from nostrils to the corners of the mouth and helps to correct a sagging tendency towards the points of the jaw. A simple little exercise which wards off a double chin is to protrude the lower lip and blow as if trying to blow away something from the tip of the nose.

The following hints are also useful for the preservation of the contour of the chin, the most important line of the facc. After applying a skin cream, smartly pat along under the chin with the back of the hand (or a rubber patter) for about two minutes to stimulate the muscles. After washing dab an astringent lotion coniposed of one part of toilet vinegar to two of rosewater, under the chin. A daily treatment which is raid to remove a double chin is to use an emollient cream and an astringent on alternate days with a chin strap which is worn for fifteen minutes. Soak a pad of cotton wool in the astringent and after kneading and patting the muscles, place this under the chin and keep it in position with the strap. The next day massage with a skin cream and wear the strap for the rame length of time.
Astringents and Creams. The face shoukd always be thoroughly cleansed before apply. ing an astringent or massage. A good method is to sifuceze a pad of cotton wool out of cold
water. sprinkle it with a lotion composed of 2 oz . extract of witch hazel and 10 oz . rose water, and then spread over it a cleansing cream, and with upward strokes of the pad thoroughly wash the face and neck. A pleasant cream for this purpose is made as follows :
Take $\frac{1}{2}$ oz each of white wax and sperma ceti and 4 oz white vaseline; melt together and pour into a heated bowl. Very gradually add 3 oz orange flower water and 1 oz . witch hazel, stirring all the time, and continue stirring until the emulsion is cold.

This way of cleansing the face is satisfactory during the day, after a journey, or exposura to wind and sun, or when the complexion is intolerant of soap and water. It may be used at night before an astringent or if any makeup has been applied to the skin during the day. The value of an astringent is that it braces the skin by closing relaxed pores, and it is essential that any foreign surface matter should be first removed. Nearly every skin benefits by washing daily with soap and water, massaging the lather over the face with both hands. A good rubbing with a turkish towel across the back of the neck and behind the ears stimulates the circulation after the final cold sponge in the morning.
There are many degrees of astringents, and discretion must be used in choice for the individual skin. (See Complexion.) Sponging in the morning with cold water to which a few drops of simple tincture of benzoin have been added is sufficient for the fresh complexion. The use of a complexion milk, after washing, containing benzoin and cucumber is suitable to most skins. It is not worth the trouble of procuring the many ingredients which go to the making up of these milks, when excellent preparations are on the market at a small cost

## For a Relaxed Skin

If $\frac{1}{2} \mathrm{oz}$. simple tincture benzoin is added to the 2 oz . witch hazel extract and the 10 oz . rosewater this makes an excellent mild astringent for dabbing on the face with cotton wool, and also for tired eyelids if a pad of cotton wool is squeezed out of cold water, soaked in the astringent, and laid on each eyelid for 20 minutes during a short rest. Should the facial condition be really flabby a stronger astringent is composed of 2 oz . toilet vinegar to 4 oz . rosewater. This can be used at night and an emollient applied afterwards to prevent undue dryness of the skin The patting movements with the pad of cotton wool moistened with an astringent stimulate the circulation and help the removal of waste matter before closing the pores. This process'toncs up the skin.
Lanolin is the basis of many so-called "skin foods." An inexpensive but satisfactory crearn is made by melting 2 oz hydrous lanolin with 2 oz . white vaseline and stirring in 1 oz . each of olive and almond oils, and 2 dr each boracic powder and zinc oleate. For anyone afraid that lanolin will encourage superfluous hair (used in such proportion it is quite unlikely to do so) a cream with a casein basis may be used. Casein is prepared from the albuminoid matter of milk, and a simple emollient is composed of 3 oz casein, 6 dr . buracic acid, 3 dr. cocoa butter. Occasional massage with olive oil may also be necessary to counteract dryness. This ail is soothing for treating temporary conditions of dry skin caused by exposure to wind and sun

For a sunburnt skin relief can be obtained by a piece of lint saturated in warm water to which a few drops of cloudy ammonia have been added, care being taken to keep the eyes closed while holding the lint to the scorched skin. To remove tan a mixture made of two parts peroxide of hydrogen, one part lemon juice, and one part rosewater can be applied to the face, after using the cleansing
cream, and allowed to dry on. If this treatmen should be too drastic at first, dilute the mixture with more rosewater. Freckles, which are pigmentary discolorations of the skin, are not unsightly unless they are ton numerous and deep in colour. They may be hidden, and to some extent the rays of the sun may be counteracted by the use of a calamine lotion and face powder.
The formula for calamine lotion is as follows : Prepared calamin, 6 dr . ; powdered oxide of zinc, 2 dr ; glycerin, $1 \frac{1}{2}$ or. ; rectified spirit of wine, $1 \frac{1}{2} \mathrm{oz}$.; elderflower water to make the lotion, up to 8 oz . This lotion deposits a fine powder. To keep it on the face of a child a soft muslin musk is necessary

The following ointment may be rubbed sparingly in at night, but should not he used for children. It produces a peeling of the skin which usually leads to the disappearance of the freckles. Mercury perchloride, 1 gr . powdered starch, 2 dr. ; powdered oxide of zinc, 2 dr . ; soft paraffin, 4 dr

The treatment for blackheads is described under that heading. The application of calamine lotion, after sponging the affected area with hot water, is useful for both this unhealthy state of the pores and for a spotty condition of the face.
Facial Packs. From earliest days of heauty culture, facial masks or packs have been used. These are said to embody cleansing and astringent properties Special mud and clay packs are variously recommended for clearing the skin and eliminating acidity. A simple and efficacious pack is made by placing a tablespoonful of fuller's earth in a cup and mixing with it sufficient rosewater and witch hazel lotion to make a thin paste. Oatmeal may be used as a pack mixed with buttermilk, which possesses whitening properties when it is applied to the skin. A facial mask which bleaches is made with almond meal mixed to a paste with the sunburn lotion containing peroxide, lemon juice and rosewater. Another pack is of half a cupful of cooked oatmeal into which 2 tablespoonfuls of milk and one of glycerin have been thoroughly stirred Yet another is of egg. The beaten white is first applied with a camel-hair brush and allowed to dry on the face. A second painting with the white is followed, when this is thoroughly dry, with the application of the beaten yolk. This egg mask and

Face Plate Contrivance invalumounting work to be turned across the forehead Toothache.
more cream is applied, and the chin and checlis arc lightly pinched with the cushions of the finger-tips. Then, with fingers placed on the cheekbones, the thumbs meeting under the chin should stroke upwards to meet the fingers with a firm pressure, returning lightly under the chin. Repeat this movement for two minutes. Next, stroke the finger tips from the point of the jaw past the corners of the mouth to the nose and very lightly across the closed eyelids to the roots of the hair and

Lines should be followed and not rubberd across. Should there be a vertical furrow between the brows, it may be stroked gently upwards. The cream must be very lightly patted in round the eyes with the third finget, as the slightest rubbing will stretch the sensitive skin there. After this the massage cream may be wiped off. If the massage is performed at night a little emollient may be left on round the eyes and along any deep lines; if during the daytime, the skin may be toned with a mild astringent before powdering.

FACEACHE. Pain occurs in the face in inflammatory and suppurative conditions, e.g. dermatitis, gumboil, mumps, etc., and the cause of the pain is indicated by the redness and swelling which are also present. In the absence of such plain indications, un explana tion for the pain should be sought for in clisease affecting the teeth, eyes, nose and the cavities leading from it, the car, etc., and in the general state of health of the patient, as anaemia, constipation, gout, hysteria, Heumatism, and other disorders frequently underlie the occurrence of pain. See Neuralgia

FACE PLATE. A face plate is a contrivance used on a turning lathe as a means of mounting work to be turned. It comprises a circular disk, generally of cast iron, with a projecting boss at the back. A hole is drilled through the centre and screwed to correspond with the size of the screw thread on the mandrel. The plate is, as a rule, provided with holes or slots through which bolts are passed, which, in conjunction with clamp plates, bolts, and nuts, are used to fasten the work to the face plate. See Chuck: Lathe.

FACING: In Dressmaking. This is the name given to a strip of material laid along the edge of a garment, either on the wrong side, for neatening and strengthening, when it is the other packs described are left on for an sometimes termed a "false hem," or else hour and then washed off with pure soap and on the right side, as an ornamentation, this warm water. Afterwards, a light facial mas- often being of a contrasting material. The sage with an emollient should be given. A name is also applied to the top layer of such thin muslin mask cut to the shape of the face portions of a garment as are made of double with eye-holes and tied on with ribbons is often used to keep these applications on theskin.
Helpful Massage. Some women are afraid of facial massage as they think it stretclics the skin. This is only the case if wrongly or too hurriedly applied. All four movements, atroking, friction, pétrissage and tapotement can be used with advantage. The first starts the treatment with firm upward strokes when using the cleansing cream. Then, having wiped this off with an absorbent tissue, an emollient cream is applied and light friction given with the cushion part of the finger-tips, working the cream with circular spiral movements over the face. Facial massage should have an upward and outward tendency to correct the droop of the muscles. Then with the wrist held loosely the peroussing novement already described is performed with the back of the hand under the chin. Next
material, i.e. the collar and cuffs

As regards the cutting of facings, the rule for the lirst mentioned type is that the strip can be cut on the straight if the edge to which it is to be applicd is straight. A curled or rounded edge, however, is either faced with a strip cut on the cross, which can be pulled to shape, or else with a strip cut to the exact shape of the garment, and of the same way of the grain, these shaped pieces always being used for the facings laid inside the front edges of a coat, and also for the top layers of collars and cuffs, etc. One way of attaching a facing of the strip type is to set it over the garment, with the right side downwards, and to stitch it on just within the top edge; then to turn the strip over to the wrong side, and to hem the unattached edge down.
Another plan employed is to turn in the edges of the garment, set the facing over it,
turn in the lacing edges and hem or slipstitclı down When attaching a coat frons facing, the inner edge is left detached.

FAGGOT: In Cooking. This is the name given to a preparation made from calf's liver, or the inferinr parts of a sheep, such as the liver, lights, pluck, and heart.

To make faggots from the intestines of a sheep, procure the liver, lights, pluck, heart and swectbread and some of the skin. These must be well washed, put in a saucepan with cold water poured over them, brought to the loil and simmered gently for about 15 min Add salt and pepper and pour off the liquid Boil an onion in a little water and chop it Cliop the liver, lights, etc., and pound them well with the onion. Then add a sprinkling of nixed herbs and a pinch of nutmeg, and stir in sufficient breadcrumbs ti) make a firn paste.

Mould the mixture into squares and wrap each square in a piece of skin. Place them in a baking-tin that has been well greased, and lrave it in a moderate oven until they are n pale brown Make a gravy to serve with the laggots from the liquid in which they are boiled. Add pepper and salt, and thichen with a tablespoonful of flour made into a paste with a little of the cold liquid. Bring it to the boil and add a little caramel or gravy colouring if necessary
FAGGOTING: The Trimming. This is wimetimes used for beading to make an open seam for a dress or underwear. A slightly different variety of faggot stitch is used in drawn-thread work. The two edges to be goined should be sewn to stiff paper or toile circe, about $f$ in apart. The tacking threads should he about $\frac{1}{4} \mathrm{in}$. in from the edge of the hems to allow room for working the stitch isnder them.

The following plan will keep the stitches even. Place a ruler along the edge of one hem, and at cuery $\hat{i} \mathrm{in}$. mark put a dot on the material with a lead pencil. Repent this operation on the opposite hem, but let the first dot come half-way between the first and second dot of the opposite edge, then the other dots will follow in order. To work the faggoting, join the thread on the wrong side of the hem at the top left-hand corner, holding the worl so that the seam is in a perpendicular line before you, the stitching proceeding downwards. Bring the needle

Fargoting. An example of this useful trimmlag up from the underside of the hem on the opposite
side, through the first dot.

Now put the needle under the stitch just made. which lies across the opening between the two hems; put the needlc under the opposite hem and bring it through at the dot. It is important that the needle should be put down behind the thread last made so that the stitch comes under it. The illust ration shows this position. Repeat this operation down the whole seam, then cut the tackings and take away the paper. See Drawn Thread Work.

FAHRENHEIT. This is onc of the two chief ways of measuring heat by a thermometer. On a Fahrenheit thermometer the distance from the freezing-point of water to the boiling-point is $180^{\circ}$. The freezing. joint is marked $32^{\circ}$ and the boiling-point $212^{\circ}$. See Centigrade; Thermometer
FAIENCE. This nanc is applied to various kinds of earthenware pottery and tiles having a highly glazed or enamelled surface. The

Falence. Persian bas-relief in polychrome faience brick $\begin{gathered}\text { the period of Darius ( } 500 \text { B.C.) }\end{gathered}$
word comes from the name of the Italian town Facnza, which made a speciality of this pottery from the time of the Renaissance. The alt of the Moorish potters who eatablished themselves in Spain and left, among other examples of their skill, the tiles of the palace at Seville, spread to Sicily, and from there prepared the way for the Italian masters of majolica faience. Luca della Robbia is the best known of these. In the 15 th century he created the most beautiful examples of this tin-glazed ware.
Damascus comamelled earthenware also is believed to have helped to inspire ceramic art in Europe, as it was largely imported during the 15 th century. Holland made the delft ware which was a compromise between majolica and Chinese porcelain, its methods being taken from the former and its designs from the latter. In 1676 a Dutch potter settled at Lambeth and started delft faience ware in England Some varieties of Josiah Wedgwood's ware are styled English faience.
Germany developed faience methods for stove tiles and beer tankards, while in France the best known faience was the blue Roucn ware developed afterwards at Moustiers in a variety of colours. Enamelled brickwork was used in the days of Darius, and was the forerunner of the splendid glazed tile decoration which is extensively enployed in Persian architecture.
Modern fabrics of Doulton, Minton and Ault are among those classed as faience, also some makes of Japanese pottery. The decorative effect may be in form, the beauty of monochrome glaze as seen in certain tiles, or through polychrome designs heightened by applied reliefs. Many modern reproductions of majolica are good, but others tend to be crude in ornament and colour.
For this reason picces which bear the sign manual of creative artists, or, as in the case of Della Robbia reproductions, aim at preserving the best traditions of the past, may be sought for as satisfactory notes of decoration in a sitting room. Sometimes one may rejoice in the possession of pieces that ought to be safeguarded, such as a fine Satsuma vase, a Rhineland tankard, a Leeds bowl, and even a piece of Valencia lustreware or Urbino majolica. See Delft; Lambeth Ware; Majolica; Pottery ; Terra Cotta; Tiles

FAILLE. Heavy taffeta woven with a pronounced rib is sold as faille. It also makes the most serviceable of ribbons, and is more hard-wearing than ordinary taffeta.

FAINTING: How to Treat. The cause of fainting is a deficiency of blood in the brain, which produces a temporary loss of consciousness. The fainting fit lasts usually
lor less than 1 min. but may be prolonged when it follows severe losy of blood or disease of the heart. In people predisposed to fainting any sudden strong emotion may tend to bring on a fit. A blow on the abdomen or on the head, intense internal pain, standing up quickly from a sitting posture, or getting suddenly out of a hot bath may cause fainting, especially if the heart is weak.
When one feels laint one should get into the fresh air or close to an open window and lie down or sit with the had bent forward between the kners A fewsips of cold water or a little spirits or sal volutile in water will assiat recovery. If a person faints, lay him on his back with the head low, loosen the clothing about the neck, chest and waist, and let him lie still until he recovers. He should have as much fresh air as possible, and when necessary may be carried into the open air, the head being kept low.

Recovery can be belped by the following measurcs: Sprintle the bands and face freely with cold water. Gently slap the face and hands with a soft, wet cloth. Put a bottle of smelling-salts or eau-de-Cologne to the nose. After recovery the person should rest lying down for a few minutes. In severe cases the legs should be raised well above the body and massaged in the direction of the heart. If breathing is not resumed, artificial respiration ( $q$ v.) should be carried out. See Dizziness.
FAIRY RING. This popular and superstitious name is given to rings of toadstool-like fungi which establish themselves in grass, and sometimes assume considerable dimensions. The grass in and around the rings is generally of luxuriant growth, because it benetits by the nitrogenous matter in the decaying fungi. A fairy ring can be exterminated by watering it with a solution of sulphate of iron or copper, 1 lb . in 3 gallons of water Afterwards a little fresh soil may be applied and grass seed sown in spring or September to cover the bare spot See Fungicide
FAIRY ROSE. This is a dainty dwart form of the Polyantha type of rose, compact in habit, with elegant leaves, and bearing bunches of pretty blossoms. It is suitable for pot culture, as it does nut grow more than 1 ft . high. Plants raised from seed generally llowev three months after sowing. If grown outdooms they demand well-drained soil in a sunny position See Rose.
FALSE ACACIA. The name of lalse acacia is given to Robinia pseudacacia, a familiar tree with pinnate leaves and drooping clusters of white, pealike tlowers. It does well in town gardens.
FALSE HEM. This is a strip of material sewn at the extreme edge of the part which requires additional length, turncd over to the wrong side and hemmed at the required depth. In cases where there is not enough material to allow for a deep hem to be turned up, a false: hem can be added of sateen or any material the same colour as the garinent itself, taking care that the facing does not show on the right side.

A double hem can be made by folding a piece of the same material over and attaching it to the edge of the garment, covcring the join with a trimming or fancy stitching. In
the case of a thin material the false liem can be joined to the garment by means of faggol stitching. See Faggoting; Hem

FAMILY COACR. Family coach-is an old-fashioned game which is popular among small children. The players sit round the room, and each chooses some part of the coach to represent Thus one will be the box, another the lamps, another the wheels, and so on II there are a great many players, each part may be taken by two or three children.

Somebody tells a story about the journeyings of the coach and its adventures on the road, mentioning the various parts in the course of the narrative. As each part is mentioned, the child who represents it has to get up and turn round, and when the coach itscli is mentioned the whole party has to do the same. Any player failing to respond to his or her name in the story has to pay a forfeit, which is redeemed at the end of this amusing game in the usual manner

FAN : Uses and Ornament. Fans are of two distinct types, the folding and the nonfolding. The non-folding kind, in use with evening dresses, consists of one or more plumes. The stick or handle may be of tortoiseshell or mother-of-pearl, or of compnsition to imitate either of these, of jade, amber or coral.

The folding fan was invented by the Japanese, and is said to have heen suggested by a bat's wing. From Japan it sprend to China and thence to Italy, and was introduced into France by Catherine de Medici in the 16th century. The non-folding fan was inspired by the palm leaf, and dried palm leaves are still used for the cheapest kind of oriental fan. The earliest known fans were of this straight shape, and are recorded in stone on the walls of an Egyptian tomb at Thebes, where a Pharaoh of the 18th dynasty is surrounded by fan bearers.

Spaniah fans have the advantage of expanding from right or left, and are most usual in black lace with black bog oak carved mounta. Beautiful fans, painted, feather, or lace, still come from France. Interesting Chinese and Japanese fans can sometimes be picked up in curio shops. They may be made entirely of carved ivory, tortoiseshell or wood, the blades being strung together with coloured ribbons, or of folded, painted silk
The principle of Japanesc fan painting is worth noting, because it has inspired the most successful designers of all nations. As the fan is invented for cooling purposes, patterns should be light and airy. The Japanesc carry out this ides often by suggesting flowers, rushes, or branches of shrubs waving in the brecze, with birds, butterflies or fish introduced to balance the design. These Japanese designs can be copied successfully by an amateur on a plain silk or gauze fan. Quite a success has been achieved by a strnight Japanese fan, shield-like in shape, gold designed and varnished with red lacquer, hand-

ornamentation is a favourite design in fan painting. they can be placed to suit the arc of the fan, and filled with landscapes, classical figures or heads after the style of cameos.

If the fan is to tir painted, the fabric must he painted before it is made up It must ion cut to the desired size, leaving a good margin for turning in. Stencil colours suitable for painting on silk, georgette or gauze ahould be used If a pale some tassels depending from its stick; this is colourod silk is chosen, the design looks very carried by the wearer of a black cevening dress well in liquid Mandarin inks applied with a A charming idea from an old French fan is fine brush. The design must be carefully a centre medallion of pansies bordered with a drawn on the silk before painting. Further ribbon knotted at the top and festooning to border a smaller medallion on either side containing the monograms of giver and receiver. Unig monograms of giver and receiver. beautiful 18th century fans, to be seen a "Th the centre medallion the words South Kensington Museum Designs painted menoughts of you are painted. The three on these fans were the work of Watteau and medallions connected by some kind of light other genre painters. See Stencilling

## FANCY DRESS FOR JUVENILES AND ADULTS

## Suggestions which Improve Attractive Costumes

## In this Encyclopedia related information will he found under the headings Children's Party <br> Dance; Dancing. Sec also Making-up: Theatricals

A costume which is out of the common, basket of mixed llowers, the straw hat full that does not cost too much, and is comfort- of pink roses, or the ribboned lamb, one of able to dance in is what most people desire in the way of a fnncy dress. English or French costumes of the powder periods are always dignified and becoming, and though they can hardly be said to be uncommon are required for a ' Powder Ball,' and are often favoured by men and older women who do not care for the exnggerated typo of costume seen at any fancy dress dance. Adapted by modern designers, dresses that are suitable for wear with powder and patches may be quitc original.

Whatever the style, if a white wig is to be worn, care should be taken not to hire one with a woolly, wispy appearance. It ought to be well dressed, with that crisp formality in each curl which marks the finest designs, and is better, especially if it is to be worn with a strictly period 'square cut' 18th century costume such as is shown in Fig. 1, when it is not made of pure white hair, but with a slight mixture of grey. Patches placed on the cheek and chin should not be forgotten. These cost 1 s . 3 d . for a box of assorted sizes. Women require $a$ dainty pink and white make-up with accentuated cyebrous and lashes for wear with a powdered or white wig.

Shepherd and shepherdess or other rustic china figures furnish models, copies of which can be carried out by the clever amateur dressmaker. Such picturesque ideas are more charining for children than grownup persons, and can be carried out inex. pensively in printed and plain sateens. Success lies in matching the delicate colouring and approximating the various patterns of the painted materials; also in copying the details of the oblong birdcage with stuffed bird
Fan of cream coloured lace, monnted on an amber frame Courtesy of Selfridge a Co., i.td emerging, the oval which typical objects should be carricd. except when dancing.

Very small girls look attractive as Christmas. tree fairics A pretty design is shown in Fig. 2. Small boys may favour a pierrot or harlequin costume (Fig. 3), unless they set their hearts on a wooden soldicr, pirate or Red Indian design. Patterns for many good fancy dresses are obtainable from the best pattern services.
The topical costume often finds favour with men: a clever idea from a newspaper cartoon or caricature, a popular play or book title travestied. These are necessarily whims of the moment, and their value lies in being apt and well done Other inspirations may come from studying the posters on the hoard ings, either of plays or advertised goonds Characters out of fiction and drama of present and bygone times always make their appearance, more or less effectively, at fancy dress dances, nnd this class opens up a wide ficld. Sometimes a dance is arranged when all the dresses have to be of a period or out of a book -as, for instance, a Victorian, or an Arabian Nights' ball. The Victorian jockey (Fig. 4) is a suggestion for a man's costume for the former

National dresses offer a variety of diatinc tive designs, of which many beautiful examples are illustrated in such n work us "Peoples of All Nations." Such costumes look wel! in pairs, and attract the cye to both partners

Oriental Make-up. Oriental costumes open up a wide ficld of choice and can be dignified. beautiful, piquant, mysterious or comic accord ing to design and suitability. A beautiful Chinese princess dress is shown in Fig. 5 Such costumes need a special make-up for the skin and eycs to render them effectively in keeping with the character represented. This is not a difficult task according to the following directions.

Having cleansed the face thoroughly with cold cream and wiped it with an absorbent tissue or soft towel, apply grease paints Nos. 5 ) 2 and 6 for a dark foundstion, blending the colours evenly over the face: $\Omega$ few strokes
from each stick of paint will suffice, then with a batik dyed design which is outlined working them in with the finger-tips. If the effect is too dark a little No. 2 grease paint well worked in will remedy this. Having They may be in pierrot style for a boy thoroughly smoothed the foundation tint or a white sleeveless blouse and a short apply a grease rouge (or a little grease paint striped skirt may be worn as the foundation

Nu. 9) and smooth carefully. Now soften a piece of white soap and place it over the eyebrows. When this is dry, smooth the grease paint very gently up to it and the hairs will be invisible. Apply an eyebrow pencil, drawing the ends of the eyebrows in all upward slanting curve, slightly or exaggeratedly according to the requirements and character of the costume.
To give the oriental effect to the eyes a line is drawn from the outer corners upwards, about half an inch long, with a black lining pencil, and after powdering the tace with a dark shade of powder, a woman should make up her lashes heavily with black mascara, and a man lightly, just sufficiently in his case to reinove any powder from them. To give a dark-eyed effect the for a girl. upper eyelids should be shaded with a deep The object is blue lining pencil. A brilliant but rather dark red shade of lipstick should add the finishing louch for a woman.
Some Quaint Costumes. Many variations of black and white fancy costumes are seen at a big dance. A chimney sweep design, with a stove-pipe hat made of cardboard and covered with black paper, the bodice of white sateen with bricks marked on it in black stencil paint, trousers of black velveteen fringed in long strips below the knees, black gloves and a sweep's brush in place of a fan, supplies an idea for a quickly made costume. A chessboard design is also striking for either a man or a girl. The long trousers are made in black and white check sateen with braces to match over a white silk shirt. The headdress or cap is ornamented with chessmen in black and white.
Polka dots of black on white sateen make up into an attractive pierrot costuine with ruffles half-black and half-white. A silk wig can be worn with such a costume, which is made of black silk knitting yarn on one side of the parting and of white silk yarn on the other. Another beautiful black and white dress is shown in Fig. 6. The body part of this butterfly and the skull cap can be made of black velveteen, while the wings can be of white silk

Strange wigs may form an important part in quaint designs. They are best and coolest made on a foundation of embroidery canvas shapel to the head. Wigs are effective in wool or linitting silk left in loops or the loops cut and frayed to form a fringe; another way is to make them of tiny blossoms and !eaves. Small roses, jcssamine, violets, and lilies of the valley are suitable with leaves skilfully introduced to soften the face line, and each dress carrying out the colour and petal shapes of the llower chosen. Other wigs are made completely of coloured feathers.

In wool and silk these wigs give a touch of originality to the many variations of the pierrot and pierrette, and all the harlequinade characters. Such costumes and many flower costumes can be effectively made up in crîpe paper for children's fancy dress dances, when the object is to have bright and original designs with a small outlay.

FANLIGHT. Originally this term meant a glazed sash filling the arched head of a door or window opening, and was so called from the fact of its having bars radiating upward like a fan. Nowadays it denotes any sort of small uindow at the top of a door or larger window.

Most fanlights are bottom hung, on stout butt linges, the casement opening inwards from the top. A simple quadrant of iron, with double cords, pulleys and a cleat, is cheap to buy and ersy to install.

FARAD. An electro-magnetio unit of capacity. It is the capacity of an electrical condenser charged to a potential of one volt by one coulomb of electricity. A microfarad $(\mu \mathrm{F})$ is one millionth of a fared.

The application of electricity produced by an induction coil is known as faradism or faradization. It is more stimulating than the constant current, and may be applied to the whole body or to any part. See Capacity; Condenser ; Electricity.

## Farcy. See Glanders.

FARIIACEOUS FOOD. Farinaceous foods consist very largely of staich: bread, 50 per cent. ; oatmeal, 63 per cent. ; maize, 64 per cent. ; macaroni, 77 per cent. ; and rice, 84 per cent.; and in the last-named the amount of proteid is small. Wholemeal and standard bread contain the fat soluble vitamin $\mathbf{A}$, and are richer in organio phosphorus compounds than white bread, and possess obvious advantages for children unless white

Fancy Dress. 1. Powdered wig and period constume. 2. Christmas Tree qairy. 3. Barlequin pierrot. 4. Victorima jockey, for a "character" dance. 5. Chinese princess design saitable for an oriental ball; it is carried oat in Chinese embroidery. 6. Butterfy, a beautiful design for a black and white costame. 7. Feathers, consisting of a softly draped silver gauze bodica with skirt of white feathers and georgette 1. Claude Harris; 2 and 3, Bassano 7. Henri Manuel
bread is sulpplemented by milk, butter or animal or fish fats. Margarine of the vegetable variety does nothing to improve the food value of white bread in respect of vitamin, though it supplies fat. Wholemeal bread is less easily digeated than white bread, however, and may give rise to syinptoms of indigestion. Maize in the form of cakes or porridge is a good food, but the flavour is too coarse to make it a food of choice. Its derivatives, hominy, oswego and cornflour, have not this disadvantagc and are often used in this way.

Farinaceous foods provide the starch which is a necessary constituent of diet, and some provide proteid also. and to a less extent fat ; but, to balance all these constituents to our requirements, their use must be supplemented by other things. See Diet; Flour ; Food: Maize ; Oatmeal ; Rice, etc.

FARTHINGALE CHAIR. Chairs of this kind were made for women in the days when farthingales were worn. The specimens in existence date mainly from the 17th century, and am valued by collectors. They are without arms, and arc much higher in the seat than ordinary chairs. Most are upholstered, and some have a squat, padded back, with a horizontal top rail See Chair.
FASTCOLOUR. Colours should not be called fast if they are liable to change seriously upon ex. posure to sunlight, but clotb so dyed or printed that its colour is substantially unaltered after a fortnight's exposure to sun and air can reasonably be ao described Colours are not fast unless they will bear washing, and a test in this respect is to boil a sample for 10 min . in soap and water, with a handful of conmon weshing soda to the pint.

The crucial test of fastness is the readiness of the seller to give the money back should the colour fade, and certain cloths can be guaranteed in this way lacking definite guarantees, the assumption nust he that fast colour does not mean unalterable fast ness under all con ditions of wear and laundering. The matter is really important, for in sorne circumstances the garment is useless when the colour has gone. Articles made in mixed colours cannot invariably be redyed, and as a general rule redyeing, whether done at home or at the dyers' and cleaners' works, is less fast in colour than a good dye applied while the cloth is being made. See Colour; Dyeing; Laundry.

FASTING. Properly speaking, fasting means complete abstention from nutritious food for a shorter or longer time. It is sometimes a useful remedy when carried out under the supervision of a doctor, but for the great majority of people a prolonged fast is exccedingly risky and nearly always injurious. The temporary deprivation of food will frequently lower the resistance to infection by the germs of disease. After a long fast the digestive organs are in a debilitated state, so food should at first be liquid, and taken in very simall quantities.

In cases of acute gastritis fasting for at least 24 hours is required to give the stomach a rest ; and a short fast will also be useful when, from over-indulgence in rich food, the liver is overloaded and biliousness has been induced. Abstinence from certain kinds of food, or a large reduction in the quantity taken, is beneficial in many conditions. Thus, in diabetes and in obesity, starchy and sugary foorls are much curtailed, and in certain toms
of rheumatism and in other diseases marked benefit may accrue by omitting butcher meat from the diet. See Dict: Obesity, etc.

FAT : Its Food Value. Fat is found in the body in adipose tissue, bone marrow, and clsewhere. Adipose tissue is widely distributed amongst the tissues and, with the exception of a fell situations, e.g. the eyelids, exists as a layer of varying thickness beneath the skin. The stored-up fat forms an important fuel reserve for the use of the body
Fat is made up of carbon, oxygen and hydrogen. No nitrogen leeing present, it cannot take part in the building-up of the muscles or organs, but it supplies heat and energy to the body, an ounce of fat giving more than twice as much as an ounce of starchy food

Fat alone cannot support life, but it is a necessary ingredient of any diet. Fats that are derived from vegetable substances and sold as margarine do not provide a suitable source of fat for growing children, on account of their not containing fat soluble vitamin. This is present in mother's milk and is derived from the cow's milk and animal fat included in the mother's food. Fish oils also contain it. Infants require a larger proportion of fat than adults. When a child is fed on cow's milk, the whole of the natural fat ahould be present. On skimmed condensed milk a child will starve.
The standard proportion of fat in the diet of an adult is as follows

## Protein

Carbohydratc
12
50
While proteins and carbohydrates (sugar and starch) are digested by the juices of the stomach and pancreas and absorbed into the blood emulsified into a soapy tluid vessels, fat is emnlaid in the intestine and is absorbed into the
The following table shows the percentage of
fat in various articles of food

FATHER: His Legal Position. By fathor, in law, is meant the father of a legitimate child, as the father of an illegitimate child has no rights or duties towards it, save is so far as he may be ordered to contrilute by an affiliation order. While father and mother arc living together the father is the sole guardian of the children. If they are separated and any question arises, the court will decide.
A father is responsible for supplying his children with food, clothing, lodging and medical attendance up to the age of 16 . If he is too poor to do this, he must see that they are attended to, e.g. by the poor-law authorities. A father is not responsible for thic consequences of any wrong done by the child, nor is he liable for its debts unless they were incurred with his authority. In certain cases of offences committed by his child, the father may be ordered to pay the fine. A father has the right to choose in what religion his child shall be brought up. See Affiliation; Child: Guardian: Illegitimacy: Mother.

FATIGUE. Alter a hard day's work, mental or physical, the vigour of the whole body is lowered. Waste matters linve accumuInted in the system, and until they are carried off by the circulating blood a greater or less sense of fatigue reminins.
It is a mistake, when in this state, to eat a full meal, even if food has not been taken for some hours. A tiued person should lie down for half an hour, or longer, before taking a meal. Recovery will be all the quicker if one neither talks nor reads. Massage, when obtainable, is the best of all restoratives when one's muscles are tired and clogged with waste matter. Alcoliol only disguises fatigue, in no way removing it. See Brain Fag.
FATSIA. This is an excellent room plant with large, handsome, indented evergreen leaves. In warm showery weather the plant may be placed out of doors
Tall growth may he remedied by the process known as stem-rooting, by which the top of the plant is converted into a dwarf. Repotting, when necessary, is done in March using a compost made of two parts loam, one part leafmould, and one of silves sand. This plant is hardy in the southern and ot her mild counties.

FAUCET. This is a term usually applied to the socket of a cast-iron pipe It is also used to describe a spout with a plug or spigot used for drawing liquor from a cask. The name is also, in some districts, used as a description for any kind of tap from which water can be drawn, for a hot or a cold water syatem See Stop-cock; Tap. Pron. Faw-set

FAVUS. In human beings favus or honeycomh ringworm is a contagious disease which may apicar anywhere on the skin, but oftenest on the scalp. Its chief characteristic is the formation of bright sulphur-yellow, irregular, cup-shaped crusts, pierced on the scalp by the hairs. They are easily broken off, and when renoved a reddish sulface is seen, which leaves a scar on healing The canse of the disease is a vegetable parasite or fungus

In treatment, the hairs piercing the crusta must he pulled out, and the rest of the hair should he cut close. The crusts are softened by applying lint wet with olive oil, and covered with gutta-percha tissue, and removed by washing with soap and water A germicidal application should be applied morning and evening, composed of precipitated sulphur, 4 drams, and purified lard, 2 oz. Treatment must be continued for many months where the scalp is attacked X-ray treatment sometimes gives excellent results See Ringworm

In Poultry. The disease favus or white comb in poultry is due to a parasitic fungus, Iophophyton gallinoe, which is distinct from that causing favus in mammals. This fungus attacks the comb and wattles of birds, and spreads from the naked parts of the head to parts covered by feathers. The breast and more often the rump may be attacked. One side only of the neck may be quite denuded of feathers, whilst the other shows no signs of the disease. As a rule, however, it is the comb that suffers first and most from the attack

The first signs of an attack are small, pale, irregular, cup-like spots on the comb or wattles, generally appearing on the comb first. These spots grow together, and sooner or later form a crust of a dirty yellowish-grey substance, which is often arranged in concentric layers. When the feathered areas become invaded the disease is more persistent and may end fatally. The feathers may become erect, dry, and somewhat brittle, and fall off, the naked skin being covered with crusts. The affected birds exhale a mouldy odour.

The treatment consists in bathing the infected parts with warm water and soft soap, and then applying some ointment to destroy the parasite. An ointment made of sulphui and lard, mixed in equal proportions, is a
simple remedy. Another more eltective but more expensive remedy is nitrate of silver, which, when rubbed into the comb and wattles, has been found of great benefit. An
ointment of 5 p.c. of nitrate of silver in soft paraffin (vaseline) is recommended for the purpose in Leaflet No. 67 issued by the Ministry of Agriculture-from which these particulars of the disease and its treatment are taken. Red oxide of mercury 1 part, to lard 8 parts, is an excellent remedy if persistently used for several days. Before applying the ointment the diseased parts should be carefully fomented, and all the crusts removed as far as possible with a blunt knife.

FEATHER BED. When feather beds are made, care should be taken to see that the feathers are thoroughly stoved and sterilized in the first instance; they may then be enclosed in a case of ticking, the inside of which is rubbed with beeswax to prevent feathers from pushing through.

The dressing may be done at home or by the firm responsible for the manufacture of the bed. The process consists of separating the light feathers from the quills, and returning the cleared or loosened bulk to the case. See Bedding: Bedstead; Mattress.

FEATHER EDGING. In furniture this is a method of using marquetry so as to give a frame of special character round a central panel. It is found especially on walnut pieces of the reign of Queen Anne. It is made by cutting two thick strips of wood so that, when they are placed side by side and glued down, the grain of each piece meets in a feather-like formation. It is also known as herringbone. See Marquetry : Queen Anne Style.
FEATEDRED JOINT. A feathered joint is one in which the joint between two pieces of wood is secured by means of a narrow strip of relatively thin wood known as a feather. To a large extent it is similar to the groove and tongue joint, except that the latter is formed from the solid.

Featheredge boards, such as wrather-boarding, where one edge is thinner than the other, are laid overlapping, and the joint is sometimes known as a feathered joint. See Joint.

FEATRER GRASS. This is the English name of Stipa pennata, an ornamental hardy perennial grass worth growing in a border for the sake of its graceful, nodding plumes. Propagation is by seed, sown in a frame in spring or by division in autumn. Stipa gigantea, the giant feather grass, grows 3 feet high.
FEATRERS: Their Care and Cleansing. The feathers of poultry, when they have been properly cleansed and preserved, provide the household with material for stuffing cushions, beds, bolsters, and pillows. They are also useful to make good deficiencies when remaking such articles.
To achieve the best results, care in plucking the birds is essential. There must be no skin or flesh adhering to the feathers, and in the case of geese the coarse feathers should be removed first, so that the fine inner down may be kept separate. This down forms the most valuable kind of feather. Chickens are sometimes plucked too young for their feathers to be of any value, and only those of mature fowls should be used. The same applies to pigeons. Game feathers, too, are seldom worth preserving, as they are apt to be tainted, and likely to remain so indefinitely.
There are two methods of preserving feathers, viz., wet and dry, the former being adapted to small feathers and quills, and the latter to small feathers only. To prepare by the wet process, place the feathers in water heated to a temperature of $100^{\circ} \mathrm{F}$. into which sufficient white curd soap has been dissolved to form a milk-like emulsion. Then stir and let soak for an hour, after which stir again,
and then collect on a sieve to drain off. After and resume their soft, fluffy appearance if con similar treatment in a second warm bath, stantly shaken during the drying process using Castile soap instead of white curd soap, Swansdown trimming can be washed in the rinse the feathers in two baths of tepid water, same way, and dried before a fire, with con made slightly alkaline with a little ammonia, and finally in a bath of clear cold water. The feathers should then be placed in paper bags and dried in a mildly heated oven.

Preserving by the dry process is effected by sprinkling the feathers slightly with a dilute non-corrosive disinfectant, and packing them loosely in paper bags. The bags should then be placed in an oven sufficiently
 hot to scorch paper in 5 or 6 min ., and left there until the bags begin to brown. In both processes the feathers must be subsequently beaten lightly to get rid of dust, after which ready for use. After five years the feathers usually require re-dressing.

Feather stich. Lett to right: single,
double and treble forms of this docoration stant shaking. When not in actual use, valuable feathers should be wrapped in tissue paper and stored in boxes with either camphor or naph. thaline balls as a protection against moth.

FEATHER STITCE. This is a useful trimming, as it can be executed with coarse cotton, fine silk, or any other medium in order to suit the foundation. There are three forms of feather stitch, single, double, and treble, formed with one, two, and three stitches in succession to the left, and the same order to the right, of a centre line.
The beauty of this work depends on its regularity, and this can be ensured by dots or by running a centre line. For ordinary purposes the stitches should be about $\frac{1}{8}$ in. apart

Ornamental Feathers. Ostrich feathers that are dirty and straight can be washed and recurled. The feathers are dipped in and out of a warm lather of soapy water. They are then well rinsed, shaken out, and dried in front of the fire. They burn very easily, so, although heat is essential, it must not be too great. The feathers should be shaken constantly and when dry recurled by drawing a blunt penknife or ivory paper knife along each strand. Great care must be taken not to cut the feather : the point of the knife can be used if blunt, otherwise it is better to use the back of the blade. This is held obliquely, and drawn across the strand until it curls.

Feathers that may have got damp and straight through exposure to rain can be curled in the same way. In the case of a feather ruching, it is enough to shake the trimming before the fire immediately after exposure to damp. The feathers must not be allowed to dry straight. If they do, the process of recurling becomes much more difficult.

Feathers are bleached by washing them in warm soapy water, and then exposing them to fumes of sulphur. To dye feat hers, first put them into hot water. and allow them to drain. When they are lifted out of the dye, they should be rinsed at least twice in clean, cold water, and then dried before the fire. If red, however, one rinsing will be sufficient.

Marabout trim. mings are washable in warm soapy water,

FEE : Of Professiona! Men. This word is chictly used for payments made for services rendered by professional men. e.g. doctome. solicitors and architects

Fees of Doctors. Doctors usnally charge a certain amount per visit, which sometimes includes medicine, hut sometimes does not. It varies with the size of the house visited and the standing of the patient. An ordinary middle-class family will be charged anything from 5s. to 10 s . fd. per visit. Double feew are charged for night visits, but much less when the patient visits the doctor. The class of patient recustomed to do this is, however, dealt with under the National Health Insurance scheme.

There are various special fees. For instance. in cases of childbirth it is usual to charge an inclusive fee of perhaps $£ 55$-5., which includes attendance at the time of delivery and until the patient is well again, unless unexpected developments occur. The fers of specialists, both for consultation and for operations, depend almost entirely on the standing of the man employed. In the ordinary way a first visit to a London specialist will cost £3 3s., and subsequent visits one or two guineas each. Larger fees are charged if the patient is visited. and still larger if an operation is perforined.

Doctors do not usually give any details of their visits when they render their accounts, usually half yearly, so in most cases the householder can only surmise whether or not the total is approximate, in his opinion, to the services rendered. Nursing and maternity homes charge fees, but these vary yery much indeed.

Solicitors' Charges. The fers charged by solicitors are laid down in a scale whioh was drawn up under an Aot of Parliament. This scale chiefly relates to sales, purchases and mortgages, and is based upon the value of the projerty or the amount of money involved. The fees charged are intencled to cover the services of the solicitor and his clerlis, but not anv outlay for stamps, duties, etc. Very few solioitors charge on the full scale, but on the other hand it is almost impossible for a layman to check his solicitor's bill. He can, however, make a bargain for a fixed sum when he commissions the work, or if dissatisfied be can have the bill of costs taxed. This, however, may involve him in considerable expense.

Fees of Archltects. Architects charge usually on the amount of the contract. A charge of 10 p.c. on the cost of a house of moderate size is generally regarded as rensonable. Fees or commissions are also charged by house agents and auctioneers. For selling furniture by auction a usual charge is 5 p.c. on the amount realized. For selling property a smaller percentage is usually charged, especially if the amount involved is considerable. A oharge of 5 p.c. is also made for letting houses and furnished flats, the amount being paid on the first year's rental. These fees are paid by the seller or owner, the buyer or tenant usually paying nothing. Valuations of furniture, etc., are also charged on a percentage besis, which varies from $2 \frac{1}{2}$ to 5. There is usually a minimum fee of five guineas.

FEEBLE-MINDED : Care of. Children who are mentally weak may be greatly improved as a rule by intelligent careful training and attention to their health. On the other hand, if neglected or otherwise improperly treated, they may remain permanently backward, and find it very hard to earn a living or go through life with ordinary success. There are innumerable grades of inental weakness

From the earliest age the inother must try to arouse the child's interest in his surroundings. Little things that healthy children notice and learn about for themselves the feeble-minded ohild must be taught. is he becomes old enough to understand, habits of cleanliness and self-control must be impressed upon him.

Threats and scolding and punishment are worse than useless. The child must not be ridiculed or cowed. but encouraged. Bad habits must be corrected. In this matter it are objectionable If he stenls, explain that he will not be trusted, and that things will be locked up: if he is untruthful, tell him that no one will believe what he says in future, and that people will dislike him. This is better than punishing or threatening or scolding.

The weak-minded child must be taught regular liabits. He sloould go to hed and get up much about the same time every day, and have meals at fixed hours. He should be tanght to make full use of all his senses-sight, hearing, touch, smell, and taste. Physical exercises, when supervised, and massage, will help ill developing and training in the proper use of the muscles.

In many cases it is hetter not to send the feeble-minded child to school until he is at least six years old. If a special school or institution for children of feeble mind is available, he will be muoh better there than at an ordinary school. Nuch has been done by legislation to asfeguard the interests of the mentally deficient.
FEEDER: For the Baby. This serves the same purpose as a bib, hut is larger. It usually takes the form of a square or oblong piece of material, from one side of which a semicircular picce is cut out for the neck, tapes being secured to the shoulders to fasten it round the back of the neck, while often tapes arc sewn to the base of the sidea, to pass round the waist and tic at back, so that the fecder does not move out of position. Sometimes, however, the back is made exactly like the front, so that the feeder can be reversed as neerled.

Feeders are made of good white washable materials, and the favourite trimming consists of animals, such es bunnies or chicks, done in appliqué work. Feeders are generally made of single material, hemmed at the edges, or buttonholed. Pretty designs can be worked in cross-stitch, the feeder bound with a contrasting colour, which matches the emhroidery.

Making a Pattern. A pattern for a feeder may be drafted thus: Cut a piece of paper to measure 13 in . long and 5 in . wide. Mark one of the shorter calges with the word top. Measure from this top edge down one of the longer edges some 2 in., nad make a mark there; then measure from the first point across the top edge some 2 in ., and make another mark. From the mark in the longer edge now cut through in a nicely curved line to the mark in the tope edge, and so hollow out the neok part. The pattern, when drafted, consista of half the feeder, and the shorter of the two long edges is the centre front. When cutting it in material, this front edge should be put to a fold in a piece of doubled fabric, so that a whole feeder can be cut out. The neck should be faced in with a strip of material. See Eimbroidery.

FEEDING BOTTLE. On account of the difficulty in keeping the narrow glass and rubber tubing clean and free from germs, the old type feeding bottle should never be used. The stale inilk which is certain to accumulate in the tubing-no matter how carefully it is washed-invariably becomes a breeding-place for disense germs, which may set up diarrhoea or even worse ailments.

The best form of feeding bottle is that in which the rubber teat fits directly on to the end of the bottle. The teat should be of good rubber, so that it can be readily turned wrong side out and thoroughly cleaned after each feed. At the other end of the boatshaped type there is a rubber valve to allow the admission of air to take the place of the milk the baby sucks out. The hole in the
nipple ahould be large enough to nllow the infant to draw out the milk without too much difficulty, but it should not be too large, or the milk is holted, with subsequent vomiting or indigestion (See illus. p. 50.)
It is best to have two bottles, one of which can be kept in a cleansing solution while the other is in use. Immediately after each feed the teat and the rubber valve should hoth be renoved, and, together with the hottle itself, be well washed, a clean hrush being used if necessary dipped in scalding water for a few moments. The hottle, teat, and valve should then be soaked until next required in a solution containing half a teaspoonful of sodium bicarbonate to each pint of wnter. On no account should the mother or nurse put the nipple in her oun mouth in order to start the flow, as by this means infection may be conveycd to the baby. See Baby.

## Feet. See Foot.

FELLOE. A felloc, or felly, is the outer rim of a wooden wheel, or the curved pieces of whioh it is composed. A simple example is the wooden wheel of a garden wheelbarrow, which generally has four separate pieces or fellies forming the rim. These pieces are separately an wn from suitable timber, and when made up in this way the grain of the wood is more nearly concentrio with the wheel, which is much stronger than if the rim was saun from a solid piece of board.
Should a small wheel be broken at the felly, the damaged part may be sawn out, the joint faces of the remaining parts cleaned up true, and a new felly cut to shape from timber of a corresponding thickness, the joint faces being carefully fitted to the old work and secured with short dowels rounded at the end. The steel rim will have to be removed and replaced in the usual way.

FELT: Varieties and Uses. There are many uses for the various kinds of felt in house furnishings and in the manufacture of hats. In the latter the two chief kinds of felt are fur and wool, the former being the more expensive. Rabbit hair obtained by paring away the skin from the fur is the chief material used in making fur felts, and hare fur is employed for velours felt. Specially fine surfaces are put upon hat felts by using a little of such fine hair as nutria.

Felts proper have no thread atructure, hut are made by matting together fibres which exhibit peculiar powers of cohesion. Goods, however, arc sold as felts, notably for carpet or mattress underlays, in which there is an upper and a lower surface of hairy felt and an intermediate woven layer. Felts of this type are practically stretchless and retain their original dimensions, where other kinds may tread out larger, or run up in size. Felt is not designed to take much pulling strain. but if necessary to stretch it tight the pull should he in the direction of the length rather than the width. Fine felts closely compacted from soft wool are made into bedroom slippers with a thicker, coarser felt for the soles.

Roofing felt, whioh is the coarsest kind, is composed of hair, wool, jute waste, and other rough fibre. Used under corrugated iron roofing it tends towards coolness in summer and warmth in winter. Nailed upon wood and treated with tar and shingle, it makes an inexpensive non-conducting weatherproof roof. Odd lengths make excellent packing material, and strips serve for draught-excluders. Refrigerators can be improvised with felt as a covering. Felt is useful to protect pipes of a house from frcezing.

Felt Appliqué. This decoration is effective for Hoor cushions, work bags, coverlets, nursery cushions and mats. Bundles containing a number of good-sized pieces of different coloured felt are obtainable at liandicraft shops, or it may be bought by the
yard. As it costs 4/- the yard and $\frac{1}{1}$ will If a thick wool is used it can be conched on cut out quite a number of flowers, animals, etc., it is sometimes better to buy it in this way if several articles are to be made or decorated
Motifs are cut from the picces of coloured felt and applied to hessian, cloth, canvas, crash or to a groundwork of the felt itself. Designs and translers are easily obtainable from a needlework department, or can be originated to form motifs without much difficulty. Wool or matching silk is used to stitch the appliqué. Sometimes flowers are worked in the wools, while leaves and a jar or vase containing the bouquet are cut out in the felt and applied with coarse buttonhole stitch.

If a thick wool is used it can be conched on
the edge of the felt with small stitches in a matching silk (see Laid Work). This method looks particularly well for conventional flower or geometrical designs. Ciroular holes are usually cut in the centres of flowers and filled in by darning across, using a colour contrast for the horizontal and vertical stitches. See Appliqué ; Embroidery ; Woolwork.
FENBERRY. The name is sometimes given to the cranberry, a hardy evergreen trailing plant bearing deep red globular fruit of sour Havour. It requires an open position on marshy peat, and may be propagated by cuttings, layering, or by division of the plants. See Cranberry.

# Fences and Fencing Methods 

## Efficient Varieties and How to Erect Them

## This article, which concludes with a section on the low about fencing, is supplemented by other entries on Gate; Post; Wire Netting, etc.

The object of a fence is to define a boundary and to serve ns a protection against intruders. It should be strong, efficient, and pleasing in appearance, and can be made ornamental in character. Oak is by far the best wood to use for a fence, not only on account of its long life, hut on the score of appearance, and the very small cost of upkeep, an occasional cont of wood preservative heing all that is necessary. The construction should be simple, and preferably the posts should stand abuve the top line of the fence. It is a wise precaution to put such fences together with galvanized iron nails, as an ordinary nail quickly rusts and so will cause unsightly stains.
Oak pales nailed to triangular section cross hars let into strong onk uprights make an effective fencing if the pales are overlapped by a $\frac{1}{2}$ in., 4 pales being usually reckoned to cover 1 ft . of length. Fig. 1 shows an onk pale fence in process of repair, with new gravel boards being fixed.

Chestnut Pale Fence. A cheap and effective type of fence is made of cleft chestnut pales, fastened together by galvanized wire. This fencing, which is supplied in 10 yd . lengths and can he rolled up into a bundle, is excellent for enclosing woodlands and for small gardens. The chestnut fencing is made up in a variety of styles with the pales of uniform height ; or, alightly more ornamental in appearance, with adjacent pales of unequal length. Stock heights vary fmm 2 ft . to G ft., with 2 or 3 row's of wire. This fence can bo rapidly fixed in any position, even over rough and undulating ground. The stinining or end posts should have butt ends and be properly hedded into the ground. Intermediate posts can bave pointed ends, and he driven into the ground by means of a wooden bectle or mallet.

Fence. Tig. 1. Repairing a cleft oak pale fence with new gravel boards

Before fixing the fencing the straining post and gate posts should be securely strutted, to prevent them being pulled over. One end of a length of fencing is then fnatened to the first post, and the whole picce strained tightly with a simple block and tackle, or with thic nid of a 6 ft . pole used as a lever in the manner indicated in Fig. 2. The wires are then secured to the posts with galvanized iron staples, drivon in tight. The assistance of $n$

Fence. Fix. 2. Fence of cleft pales, showing use of lever for straining the wire when securing the leacing to the straining post
ron clip which passes through a hole in the dropper and is closed on to the wire by a special hand tool. This type of fence is especially adapted for undulating ground. Fig. 4 shows a strong fence inade of conencte straining posts and standards. to which are attached six horizontal wires. The posts could be cast in a simple mould, the holes for the wires being made at the same time.
The shape of the posts may vary, but a pattern which tapers on two sides will be found satisfactory, and is more economical in coneretc. Inmedintely before the concrete is placed in the mould the reinforcementa should be fixed in place. For ordinary sized posts, steel rod $\ddagger$ in. in diameter, placed one at each corner of the post, within about 1 in. of the outer surface, is suitable. The ends may be bent over at right angles, and if bound together in the middle with a piece of stout wire, the reinforcing strength will be greatly increased. The mods should first be wined together in the form required, and the concrete then placed around them in the mould.
After the concrete has been properly cured, Which will take n month or so, the fence may be erected in the ordinary way. A post a bout 7 ft . long should be sunk in the ground to a depth of about 2 ft .0 in . to 2 ft .9 in or so, according to the nature of the soil and the strain to which it is likely to be subjected.

The corner posts will be rendered stronger than the ordinary line posts by making them of larger dimensions, and reinforcing them with larger rods, say, of \& or $t \mathrm{in}$. rod, placed on each of the four sides, ns well as in the corners. These corner posts should be securely braced up hy struts, in order to withstand the constant strain to which they will be subjected hy the wire.

Points of Law. Except in certain special circumstances there is no legal obligation on the ouner or occupier of land to erect a fence. At the same time everybody is bound to keep his own animals from sccond person is necesaary for this. To join up treapnssing on his neighbour's premises, and the lengths, wire theun trgether with the ends of the galvanized wire, which are left protruding.

A simple type of fence is made by using prepared timher framed together and completed by nailing slats of wood on to two or morc longitudinal rails (Fig. 3).

Wire Fences. An extremely durable fence is made of galvanized hard steel wire woven together to form n network. The horizontal and vertical wires are secured in the process of manufacture by an immovable knot. It is available in rolls of 55,110 , and 220 yd The horizontal wires are at unequal intervals, varying from 7 to 10 in . at the top to 3 to $6 \frac{1}{2} \mathrm{in}$. at the bottom, according to the type of fence and its purpose. The vertical wires are spaced 11 in . to 22 in . apart. The type with smaller meah makes $n$ strong pig fence. In erecting such a fence it is absolutely necessary that it should be tightly stretched, for which purgose it is desirable to obtain the regulation straining tools supplied hy the manufacturers. The posts may be of iron, wood, or reinforced ooncrete, and all corner. gate, and end posts should be properly strutted.

I similar fence made with horizontal wires only is suitahte for cattle, and can be erected without trouble by straining and fixing it to posts by otaples. Besides the straining posts and intermediates there are iron spacers ("droppers") which do not enter the ground. The wires am secured to these by a form of
trespnssing on his neighbour's premises, nnd
is liable for the consequences if he does not. If n fence is put up, there is not any right in anybody to have it kept up, npart from contract. But a contract of tenancy usually implies a legal obligation on the tenant to mnintain existing fences. Somctimes a duty is cast on the owner of a fence to maintain it ns between hin. eclf and his neighbour.

Where land adjoins a highway, if the owner chooses not to fence it, hecannot complain if damage is done by straying cattle which are being driven adong the highway, but if cattile stray about the highway and damage property the owner can claim

Fig. 3. Simple fence made from prepared timbers

Fence. Fig. 4. Example of a concrete post and wire fence, showing the method of bracing the straining post with a strut
damnges. The owner of land adjoining a high- copicd in modern way must fence off anything dangenousand likely to cause damage to travellers. Thus it is negligent to leare unfenced a hole or pit near a dark country road. A wall or fence adjoining the highway is a nuisance if it is in a dangerous condition, and the owner is liable not only to pay damages to anyone who may be injured in consequence of his neglect, but also to be indicted for a public nuisnnce.

It is dangerous to use barbed wire for external fences. If one erects a barbed wire fence as a boundary between his own field and a neighbour's, and any of his neighbour's cattle are injured by it, he will be liable. So also if he places a barbed wire fence next to a public road, and if such a fence is blown down by a sudden gust of wind, he will be liable to any member of the publio who sustains damage. It haseven been held that the owner of such a fence adjoining a public footpath is liable to pay daninges to a person whose coat is blown by a gust of wind against the fence and torn.

The local authority, if satisfied that $n$ barbed wire fence adjoining a road is a nuisance to the highway, may give notice requiring the wire to be removed; and if it is not removed they may summon the owner before the magistrutes. The latter may make an order for the owner to remove the wire, or, if he does not, the local council may remove it and recover the expenses from him. A barbed wire fence includes a fence on which any barbed wire is placed.

FENDER. This piece of houschold furniture came into use when the open fireplace was abandoned. Fenders are made of brass, steel, or iron, and are cither solid or pierced, often with fire irons to match. Some are freely decorated, the Adam style being used as well as other artistic patterns. Apart from these is the familiar kitchen fender.

Of antique fenders the hest date from the 18th century, some being beautiful examples of crafts. manship. Of the four illustrated, No. 1 is of polished steel, pierced with ovals showing roses and thistles, with a pplied brass ornaments of conventional tulipa It stands on brass ball feet, and dates from the middle of the 18th century. Nos. 2 and 3 are of pierced brass. The former has a middle

## place, etc.

FENNEL. This is a tall, vigorous, hardy and herbaoeous perennial. With finely out ornamental leaves and yellow flowers in summer, it thrives in ordinarg soil and takea up a good deal of room Ferula communis, 5 ft . high, is one of the most decorative: it is increased by seeds or division. Ferula assafoctida and other species supply the assafoctida of commerce. The fennel used for garnishing and other purposes in cookery is foeniculum valgare, a hardy perennial which can be raised from seeds making of liqueurs.
band of fine tracery and upper and lower bands of seroll work: the latter shows plain moulded bands top and bottom, the centre being pierced in rosette patterns with applied circular bosses. Both stand on paw feet, and are middle 18th century work. No. 4, which is later lyth century, is also of pierced brass. It has a serpentine front, the piercing being in two tiers of interlaoed archos with a central cmbossed band of roping

These designs are in keeping with a panelled and are more room than are the various kind of metal, marbled or tiled Hat ourbs. With electric and gas fires the tendency is to do away with the fender as a superfluous piece of furniture. See Chimney Piece; Curb; Firc-
sown out of doors in early summer. The seed are employed for Havouring and also in the

Fennel Sauce. This rauce will give an added flavour to mackenel. Prepare it by picking some fennel leaves from the stalks,
washing them thomughly, and then putting them into a pan of boiling water over the fire. When tender, drain and chop them as finely as possible. Melt 2-3 $0 \%$ of butter in another pan. mix in 19 tablespoonfuls of flour. and blend the two for a minute or so over a gentle heat.

Take the pan from the fire before adding $1 \frac{1}{2}$ pints of milk, then boil up the whole again, stirring all the time. Put in 3 tablespoonfuls of the chopped fennel, together with seasoning to taste, continue boiling for a few minutes. and the sauce is then ready to be served.

FERN: The Varieties. Ferns embrace many species of stove, greenhouse, and hardy kinds, ranging from the wild bracken of woods and common, to the eaquisite varieties grown in stovehouse and greenhouse. They are propagated by division of roots, by young buds on the fronds, and by spores. The fronds are wonderfully varicd in size, texture and colour, and some ides of their wide diversity of shape may be gathered from the diagram, which shows the following ferns

1. Maidenbair
2. Niphobolus nugustatus Splecnwart
Apline hare's foot . Australian spleen wort

Fern. Examples of fern follage showing some of the many varieties of frond. A key to the drawlag will be found in the tert
7. Tunbridge flay fern 8. Bird's foot 9. New Z.enland fern 10. Actinlopteris radlata 12 Hart's tonkue
12. Elk horn © Silvery brake

Hardy ferns are admirable plants for a shady border providing the soil is moist; they do not flourish in dry ground. There arc many crested and tasselled varieties of the male fern, lady fern, hait's tongue and others which are very beautiful in summer and should be planted in preference to the commoner forms. Planting is best done in autumn though it may be carried out in spring. If the soil is clayey, leaf-mould and sand should be dug in freely and an annual top dressing of leaf-mould or decayed manure in March will do good.
Some ferns do well in room windows, for instance the holly fern (cyrtomium falcatum). pteris oretica and its varieties, asplenium bulbiferun and the ladder forn (nephrolepis). Some of the less vigorous hardy fenns also make good window plants. A suitable compost consists of half leaf-mould or peat with sand added.

Therc are many charming ferns suitable for cultivation in a bested greenhouse having is minimum winter temperature of about 55 degrecs. The ferns must be shaded from hot sunshine in-summer and the soil kept moist. The maidenhair ferns (adiantum) are great favourites : some of the most attractive are ouncatum, gracillimum and pacotti. Other suitable ferns are the bird's nest fern (aspleniuin nidus). lace fern (cheilanthes),
squirrel's foot fern (davallia bullata), gold and silver ferns of which the fronds are covered with gold and silver powder, and the ladder fern or nephrolepis. The stag's horn fern (platycerium) is of remarkable appearance, with fronds like the antlers of a atag ; it is grown in peaty soil fastened on a block of wood or boand which is suspended against the greenhouse wall.
The Fernery. An indoor fernery requirew comparatively little labour and skill to provide a source of constant attraction. A position where other plants will fail can be utilised, and there is such great variety that it is not difficult to find a large number of the loveliest ferns which will flourish. Give them plenty of root room and avoid any accumulation of stagnant water.

An outdoor fernery built of rockwork is always attractive. Sandstone is preferable for construction. Use the pieces as sparingly and as naturally as is possible, endeavouring to convey the idea that they are cropping out of the ground. Loam, leaf-mould or peat and sand form a suitable compost.

Fern Case. Filmy ferns, whioh have thin, almost transparent fronds, are very beautiful and can be grown in a closed case in a cool shady greenhouse or in a shady room window. They need very moist conditions, though moisture must not be provided by watering from above. The ferns should be planted in a drained soil compost of sandy peat and loam : it is wise to oover the compost with moss, for this remains moist and thus helps to maintain suitable conditions. The chief filmy ferns are hymenophyllum, trichomanes radicans (Killarney fern) and others. See Aquarium; Asparagus Fern.

FBRN ROOT. The liquid extract of the root of tho male fern is very frequently prescribed for tapeworm, as it destroys the worm and leads to its expulsion from the intestines. The dose of the liquid extract of male fern is 45 to 90 minims : but the drug should only be used under the supervision of a doctor.

Before taking the fern extract the bowels should first be thoroughly emptied by the use of some purgative suoh as one to two tablespoonfuls of castor oil or a dose of Epsom salts taken overnight. The next morning the dose of malc fern is taken on an empty stomach. About four hours later this is followed by a second dose of the purgative, if necessary. The patient shquld make certain that the head of the worm (and not only portions of the body) has come away, and to help in determining this it has been suggested that the receptacle used should be lined with crape. The head is about the size of a pin's head, and is at the end of a tapering neck. The diet should be light for two or three days preceding the treatment, and it may be advisable to keep the patient in bed. See Worms.

Ferric Salts. The name is given to compounds of iron, like perchloride of iron and citrate of iron and ammonium.

FERRIER'S SNUFR. This is an old remedy sometimes used for cold in the head. It consists of subnitrate of bismuth, powdered gum acacia and morphia. A pinch sniffed into the nose allays pain and greatly diminishes the discharge. As this preparation contains morphia, it can only be obtained on a doctor's prescription, and Ferrier's snuff should not be used indiscriminately or too often, or a morphia habit may be developed.

FERRO-CONCRETE. In modern building ferro-concrete consists of a framework or skeleton of steel encased in walls of concrete. The term is applied generally to any structure made of concrete with internal steel strength. ening members. Ferro-concrete is extensively used in all classes of building. See Concreta.

FERROTYPE. Ferrotype is a method of obtaining direct positive photographio images very rapidly on thin iron plates or cards
'Though principally used by itinerant photographers on seapide beaches and elsewhere, it can be employed to provide entertainment in the home.
The thin iron or cardboard plates are coated with collodion emulsion. A special form of camera is used with a magazine holding 50 or 100 plates. It is so arranged that by working a lever the plate is brought into position for exposure. and after exposure carried into a combined developing and fixing bath. At ordinary temperatures the plate is developed and fixed in about 1 min or $1 \frac{1}{\frac{1}{2}} \mathrm{~min}$. It is then rinsed in water and allowed to dry: the result is a positive image (not a negative as in an ordinary camera), with a not unplessing appesrance. With a reasonably good lens the detail is perfectly sharp and the image clear, although, owing to the iron or cardboard baoking, a pure white ground is not possible. Only one copy of each picture is possible, but as it can be produced complete within 2 min . of the moment of making the exposure it is quite feasible to make a series of exposures if a number of oopies of the picture is required.
An improved apparatus of this nature is the Prismotype camera. With tho ordinary ferrotype camera the image is reversed, so that any lettering that may appear is unreadable. This camera overoomes this disadvantage by the provision of a prism over the lens. Combined fixing and developing salts are sold by the makers of the camera, the formula being a proprietary one.

Insufficient exposure of ferrotype plates gives dark pictures, and too long an exposure gives light ones. If white streaks appear on the photograph development is incomplete, and the plate should be returned to the tank. After the plate has been in the developer-fixing solution for 30 or 40 seconds it is comparatively insensitive to light See Developing.

FERTILIZER. This name is commonly employed for artificial or chemical manures, which are largely used in gardening. The main elements of plant food are nitrogen, phosphates, and potash; and these are present in artificial manures suitable for gencral use in the garden.

Fertilizers containing nitrogen are sulphatc of ammonia, guano, and nitrate of soda. Phosphat ic manures are basic slag, bonemeal, and superphosphate. Potash fertilizers include wood-ashes, kainit, nitrate, muriate, and sulphate of potash. Green manures, dead lish, weeds, garden refuse, and animal matter are very rich in plant food essentials, but they need proper proparation by being placed in a heap and turned over occasionally.

Lime and soot are valuable agents; the former is of special value in improving and sweetening soil as well as unlocking inert fertility. Slow-ncting fertilizers, such as bonemeal, basic slag, and kainit, are best applied during autumn; and soluble manures as sulphate of ammonia, nitrate of soda, sulphate of potash, superphosphate, and guano, during the spring.

Never apply these fertilizers to sickly plants, as benefit can only be derived during healthy growth. Moderation should govern the use of any fertilizer, as excess encourages rank growth rather than fine crops, and if a proprietary compound is being used careful regard should be given to the instructions supplied by the maker. See Basic Slag; Lime: Manure ; Potash.

FESCUE. The fescue grasses (Festuca) are often present in the mixtures sold by seedsmen for pastures and sports grounds, and are especially useful for sowing on light land. Festuca glauca, which has blue-grey leares, is a pretty edging plant

FESTOON. As used in architecture and on furniture a festoon is an ornament made to resemble a wreath of flowers. The festoon
was used by the Adam brothers, and a similar decoration is sonietimes found on silver. See Adam Style: Anaglypta. Christmas: Swag.

FEVIR: Its Occurrence. The normal temperature of the human body is $98^{\circ}-09^{\circ} \mathrm{F}$., and anything above that means that fever is present. It is elight. if the temperature does not rise above $101 \cdot 5^{\circ}$; when it rises above $106^{\circ}$ there is a state of hyperpyrexia, which may prove dangerous. In cases of fever the temperaturo usually reaches its highest point in the evening.

Fever nccurs in infectious diseases, and is due to the poisons produced by microbes: in inflammatory disorders, e.g. pleurisy ; in some digestive disorders, in heat stroke, etc. There are certain symptoms which are found in association with a rise of temperature, whatever its cause. The patient feels out of sorts, and there may be a general soreness or aching, headache and backache. Children frequently have convulsions at the beginning. Sleepless ness is common, and delirium may be present. The mouth feels dry, there is thirst and usually constipation. The appetite is impaired, and there may be nausea and sickneas. The pulse rate and the brcathing rate are increased.

Unless the fever is slight the patient should be put to bed in a quiet room. The diet must be liquid only, diluted milk, etc., and water or fresh lemonade may be drunk freely. The following remedy will help to keep a mild attack of fever in check. The dose for a child is 1-2 teaspoonfuls every 3-4 hours, for an adult 2 tablespoonfuls every 3 hours. In the case of children half the mixture only should be given at a time.

Sweet spirits of nitre
Solution of acetate of animonia
Syrup
$\begin{array}{llll}\therefore & \because & 2^{102} \\ \therefore & \because & 11 \\ 0 & \because & 4 & \ddot{1}\end{array}$
When the temperature tends to be high, or the patient is restless or delirious, the body should be sponged with tepid water, a part only being exposed at a time; or a cold pack (q.v.) may be employed. Tho treatment should be superrised by the doctor, and until it is clear that there is no infection the patient should be isolated. See Infectious Disease; Scarlet Fever; Thermometer: Typhoid Fever, etc

FEVERFEW. The popular name of chry. santhemum parthenium (known also as matricaria or pyrethrum). of which the double

Feverfow. Golden feather, or feverlow, popular summer bedding plant with yellow leaves

Howered variety is a useful garden plant, $\boldsymbol{2}$ feet ligh, bearing a profusion of small double white Hlowers. It will thrive in shade and sow itself freely. The name feverfew is also applied to that popular bedding plant, golden feather.

FIBROID. Fibroids of the uterus are tumours composed of murcle and fibrous tissue which may arise in any part of that organ, but are most common in the body of the uterus.

The commonest symptom is excessive loss of blood at the periods, and it is of great
importance that advice should be sought done in summer chiefly, is early. The tumours enlarge just before the menstrual periods, and the occurrence of difficulty in passing water for 2 or 3 days before a period should incite suspicion of their presence.

The period of maximum frequency is be$t$ ween the ages of 35 and 45 . Although the presence of a fibroid or fibroids may not prevent conception, it nearly always renders dangerous, and sometimes inprossible, the birth of the child, or even its development to full time. If the growth becomes infected by germs, general blood poisoning and the death of the patient will ensue. The only treatment of any avail in the great majority of cases is the removal of the uterus.

## Fibroma. See Tumour.

FIBROSITIS. This term is applied in medicine to swelling of fibrous tissue from inflammation and is the condition present in muscular rheumatism, where the fibrous sheaths and intersections of the muscles are affected. Where the swellings occur nerves may be compressed or dragged upon, and this is especially so when movements are made. hence the rcute pain associated with this complaint. The lumps can sometimes be felt.

Fibrositis may follow exposure to cold and clamp, injury or poisoning from sepsis in the mouth, intestine or elsewhere. In some caspa rest in bed is necessary. Aspirin may be useful in relieving the pain, and the bowels should be cleared with a dose of Epsom or Rochelle salts. A course of sulphur may also be beneficial. Heat, either in the form of a hot water bag or of poultices or fomentations will be found comforting. Massage is an all-important part of the treatment, and after the rubbing the patient should make such movements of the part as are possible without pain, and in most cases he rapidly gains freedom in doing this. To prevent recurrences he should keep a clean mouth, pay attention to the regularity of the bowels, and by extra clothing, etc., take precautions against exposure. See Lumbago ; Massage, etc.

## Fibula. See Leg.

FIDDLE PATTERN. Tablespcons and forks are very often made in this pattern, which came in vogue in the l9th century. Its main features are the round end and straight side, the handle having sharp corners where it rounds away into the stem. See Fork; Spoon.

FIDGETS. Elderly peoplo frequently suffer from sleeplessness and troublesome fidgets. This is probably due to a general failing of all the organs, which hinders the purifying processes of the blood. The patient should eat very modcrately and be kept a good deal in the open air, even when unable to take much active exercise. An occasional warm (but not hot) bath before going to bed will soothe the nerves.

A form of fidgets to which other than elderly people are prone is due to muscle fatigue, the limbs feeling nerveless and out of control. The treatment noted above may give relief, but if not. a doctor should be consulted.

FIG : Growing and Cooking. The edible fig is borne upon hardy trees of varying sizes belonging to the genus Ficus, of which the indiarubber plant is a member. Except in mild districts, figs are best grown under glass, or on a sunny wall. They strike readily from cuttings of ripe wood placed in sandy soil, in bottom heat in late autumn. When rooted, the young plants should be given separate pots, and then either repotted as required if they are to be fruited under glass, or planted out against a wall. As the habit of the tree is naturally gross, rich soil must be avoided. If the soil is deficient in lime, mortar rubbish or chalk may be added liberally, and the soil rammed well down. Propagation may also be effected by drawing suckers away from the base of establishing plants. Pruning, which is
done in summer chiefly, is
directed towards prevent. ing overcrowding. Suckers (shoots that grow from the base) should be pulled up. The best variety for general oultivation is Brown Turkey.

How to Cook. The frealt fruit of the fig-tree is useful for dessert. These are always called "green figs," and are sometimes made into jam, or a compôte cooked as follows: To about $\frac{7}{3} \mathrm{pt}$. of water add $\frac{1}{2} \mathrm{lb}$. of sugar, and let them boil together for about 10 min . Add $1 \cdot-1 \frac{1}{2} \mathrm{lb}$. of figs, and simmer them slowly until they are tender. Then take them out, and let the syrup boil briskly until reduced to about $\frac{1}{2} \mathrm{pt}$. Pour it over the figs, and leave them to get cold. Lemon peel added to the water, and a little lemon juice or wine added when the fruit is soft, will improve the Havour.

In stewing, use the small figs, and soak them overnight in cold water. Then put into an enamelled saucepan 4 oz . of sugar, $1 \$$ pint of cold water, and the thinly peeled rind of a lemon. When the sugar is dissolved, add $1 \frac{1}{2} \mathrm{lb}$. of figs, and stew them slowly for about $1 f$ hours. They are usually served with a milk or custard pudding. If liked, the juice of a lemon may be used as flavouring for the figs instead of the peel.
The fruit for eating as dessert should be quite ripe, and must not be kept too long or it loses its delicate flavour and bloom. The finer kinds of dried or Turkey figs serve also as a dessert dish. In appearance they should be slightly moist, and have a whitish tint outside and a rich yellowish brown inside. The smaller figs are drier in appearance, but should be clean and without black patches. They are mostly used for stewing, and are useful for various kinds of puddings. They may take the place of raisins in a cake, and in that case should not be soaked in water.

Fig Cake. A rich cake can be made by sifting $\frac{1}{2} \mathrm{lb}$. of Hour with a pinch of salt, $\frac{1}{}$ teaspoonful of ground ginger, and $\frac{1}{2}$ teaspoonful of baking powder. In a separate basin cream 3 oz . of lard and 2 oz . of butter with 5 oz . of brown sugar, adding the rind of $\frac{1}{2}$ a lemon. When these ingredients have been well worked, add 3 eggs one by one, and beat them well in. Clean and cut up into small dice $\frac{1}{2} \mathrm{lb}$. of tigs, add them to the flour and then mix them with the butter and eggs, taking care to work the dry ingredients in lightly. Lastly, add $\frac{1}{2}$ gill of sour milk, turn the mixture into a lined cake-tin, and bake it for about it hours.

Fig Jam. To make fig jam, weigh some small green tigs, which should not be quite ripe, wipe them, and score them across the top. Lay them in a brine of salt and water for 10 days, then wash them and boil them in fresh boiling water till a skewer will easily pierce them. Put the figs into cold water and leave them for 4 days,

Fig Pudding. Another variety can be made by using equal quantitios of chopped ags and raisins
changing the water each day. For every lb. of figs take l lb. of granulated sugar and make it into a syrup, allowing one gill of water to every lb. of singar. Cool the syrup after straining it, pour it over the figs, and leave them all night. The next day boil the jam till the fruit is quite clear, put it into jars and tie it down securely. (See Jam.)
Fig Pudding. Chop $\frac{1}{2} \mathrm{lb}$. of dried figs very finely, and add to them $\frac{1 \mathrm{lb} \text {. of }}{}$ breadcrumbs, 4 oz . of finely chopped suet or dripping, and 4 oz . of sugar. Beat up 2 eggs, pour them, with a good breakfastcupful of milk, over the dry ingredients, and mix well. A little grated nutmeg or powdered allspice might also be added. Turn the nixture into a well-greased pudding basin, twist some greased paper over the top, and steam it for about 4 hours.
FIG MARIGOLD. Few of the mesembryanthemums or fig marigolds are hardy in Great Britain except in specially favoured places. One of the hardiest is the ice plant, Mesembryanthemum crystallinum, an annual which is raised from seeds under glass in spring; it has succulent stems and leaves and white or red Howers in summer and should be planted in a sumbaked spot. One named Mesembryanthemum cordifolium variegatum, with green and

Fir Marigold, annual suitable tor as sunny garden yellow leaves, is often used in carpct bedding; it is raised from cuttings in a frame in August. In spring and summer the points of the shoots must be pinched off several times to kecp the plants dwarf.

FIGURE : How to Improve. The founda. tions of a good figure are laid in early youth. With ordinary health, if hygienic rules have been observed, a strong, graceful body may be developed which with a little care will retain correct lines.
Diet, fresh air, proper breathing, sufficient relaxation and eaercise all contribute toward moulding a good figure. Outdoor games should be encouraged for normal children to develop healthy growth of bone and muscle. Swimming and classical dancing, particularly in the open air, are especially beneficial, as they exercise every muscle with rhythmic perfection. Skipping improves breathing, balance and carriage. Tennis, when played vigorously, is a good form of exercise.
While perfectly controlled muscles are essential, over-development of these to some extent destroys elasticity and coarsens the limbs. To acquire symmetry and to preserve the good lines of the body a short course of exercises, which flatten and strengthen the back and abdomen, deepen the chest and keep the body supple, should be performed daily. Suppleness and symmetry are the keynotes of beauty. They mean fluent grace of line and movement.

Suitable Exercises. In addition to the exercises given under Beauty Culture and

Breathing, the following three would make up the daily dozen of an excellent course suitable for either sex.
(1) A lunge exercise is good for all the muscles of limbs and trunk. Stand erect with hands on hipe. Take a step forward with the right leg, bending the right knee. At the same time lunge forward and upwards with the right arm to the full extent, following the arm with the eyes. The left arm is simultaneously carried backwards and downwards. Spring back to the original position, then lunge with left arm, bringing the left leg forward. Spring back and repeat the exercise, lunging with right and left -arms alternately.
(2) This exercise should be practised gradually. Lie flat on floor, face downwards. Support the weight of the body on the toes and hands, palms flat on the ground at the side of the body, fingers pointing forwards. Raise the body by atraightening the arms and keeping the trunk rigid without bending at the waist. Slowly lower the body and try to touch the floor with the chin. Raise and lower the body alternately, touching the floor only with the toes, the palms of the hands and the chin. This is a splendid exercise for the arm. thigh and abdominal muscles.
(3) Stand with feet apart, arms extended to the sides at shoulder height, palms downwards. Bend the body forward from the hips until at right angles, keeping the knees stiff. Then bend down and touch the ground between the feet with the right hand, left arm raised to a vertical position above head, keeping the body bent the whole time. Repeat ten successive movements each side. Digestion is stimulated by this exercise, the liver and kidneys toned up by using the back muscles, and, in addition, the abdominal muscles strengthencd.

Do not hold the breath during the exercises, but breathe deeply and evenly throughout. The murements should be repeated until there is a slight feeling of fatigue. It is surprising how speedily strength is improved by persistent practice. See Beauty Culture; Breathing Exercises; Diet; Obesity.

FIGURE OF EIGHT MOTE. Although this moth is exceedingly common and fairly large, it rarely comes under the notice of the gardener; but the caterpillar is often evident to him. The perfect insect is less than $1 \frac{1}{2} \mathrm{in}$. in the spread of its greyish-brown forewings, which bear the distinctive mark from which the moth takes its name. There are two whitish blobs on each wing, and the one nearer to the base of the wing takes the shape of a crudely formed 8 . Flying by night, it is rarely seen, except occasionally by watch. ing the street lamps which attract it. The cggs, laid in September, hatch about April, and the caterpillars which out in the open feed upon hawthorn, blackthorn and crab, in the garden attack apple, plum and other fruit trees. They often appear in great numbers, and may be recognized easily by their characteristic blue backs which have a yellow line down the middle. Each segment of the body of this moth bears four black warts on the back, and the warts bear bristles.

By late June the larvae are full grownabout if in. long; but they are large enouyh to be noticeable early in May. When fullfed they descend the trunk to spin a cocoon near the ground, attached to the bark or sticks or stones. As soon as their presence is detected, a large sheet of somie sort should be spread under the tree where they are thickest, and the branches should bo jarred by rapping them sharply with a stout stick, bringing the caterpillars down in a shower.

FILAMENT: In Wireless Apparatus. In a wireless receiving valve of the battery operated type the filament is a metal wire enclosed by the grid and anode. Upon being heated by the How of current from a low tension accumulator the filament emits electrons from its surface. In this type of valve the filament constitutes the cathode, in contrast to an indirectly heated mains valve, in which the filament (i.e. heater), and cathode are separate.
The filament of a modern battery operated valve is usually connected direct to a low tension accumulator of suitable voltage, the current supply being controlled by an "onoff" switch inserted in either the positive or negative leads. A mains valve derives its heater current from a mains unit, which is controlled by a switch on the mains side of the equipment. A variable resistance is sometimes inserted in series with the filament of a screen.grid battery operated valve as a means of controlling volume. Suitable values are 15 ohms for a 2 volt valve, and 30 or 50 ohms for 4 or 6 volt valves. See Cathode; Valve.

FILBERT, Belonging to the genus Corylus, the tilbert will flourish in ordinary well drained soil. On the chalky soil of Kent the filbert flourishes excellently, and it may be used as a hedge, instead of privet or thorn, or as a scrcen, or in groups. The tree may be raised from nuts planted in the autumn, or from layers or suckers. Popular varieties are whito-skinned, redskinned, Webb's prize, and Cosford. The best crops are obtained from trees that are closely pruned to the shape of a vase. Pruning must not be done until after the catkins have faded: side shoots, other than those bearing the small red-tipped female flowers, are then shortened. They are best freshly gathered, and will then peel easily when removed from the shell. To blanch the nuts for cooking, or any other purpose boil the shelled nuts for a second or two, then tu into a clean rough cloth, and by kerncls remove the brown skins. See Nut.

FILE: Its Uses. A file is provided with a spike called a tang at one end, to which a wooden file handle can easily be fitted. When in use, the file is grasped by the handle in

Fisare of Eight Moth, an orohard peat. 1, male : 2, fomale ; 8, catorpillar the right hand, with the length of the file pointing forward across the top of the work to be tiled; the finger tips of the left hand are laid down on the top of the file close to the point end. Vertical downward pressure is applicd equally with both hands, and at the same time the file is driven forward in the direction of its
length by force exerted principally by the right hand. On therrecovery stroke the downward pressure is entirely relaxed, or the file may be lifted off the work.

Excrt the downward pressure principally with the left hand at the commencement of the stroke, transferring it gradually during the stroke, so that at the finish of the stroke the

File. Correct position in ase: thumb on handle, weight on both arms, file horizontal
principal pressure is exerted by the right hand. This must not be overdone, or rounding instead of flatness will appear; properly done, the gradual transferring of the duty of pressing down from the left to the right hand just keeps the file dead level, and level work is the result.

It is essential for the work to be held in a vice or otherwise rendered absolutely as firm as possible. The above description applies particularly to the use of a flat file on a flat surface (see illustration).

Files are classified according to size, shape, and roughness of surface. The only shapes which are required for daily use are known as hand, half round, square, round, and three square. The grades of roughness are known as rough, middle, bastard, second cut, smooth and dead smooth. The amateur will find the following assortment of files useful: a 10 in . bas. tard, an 8 in. second cut, and a 6 in . smooth hand file, an 8 in . second cut halfround, an 8 in . and a 6 in . second cut square, an 8 in . and a 0 in . second cut round, and a 6 in . second cut threesquare file.
FIIET LACE WORE. This lace derives its name from the French filet or net which forms the background on which the pattern is darned. It is a square mesh varying in size from is to $\ddagger$ in. for the atandard filet nets, although larger meshes have become fashionable for window curtains, table centres, cushions, chairbacks,
Filbert. Leaves and frait of a tree
useful to the gardener for hodges and other articles of the kind.

Real filet lace has a hand-made background made with the ordinary netting stitch used by fishermen, but with a much finer ncedle and mesh, a round ateel knitting needle being used for the latter where a mesh of less than $\frac{1}{8}$ in. is required. Many English filet laces are worked on a machine-made background, the designs being darned on the net by hand.

Fig. 1 shows a square of hand-made net lashed firmly to a square filet frame of thick wire, bound with green silk. With a small piece of work, the ground net should bo sewn to strong calico, and the latter sewn or lashed to an ordinary frame bound with strong calico. A round embroidery frame could be used for small motifs, by sewing the latter to a piece of material each side so that the net in the middle is quite free.

The stitch employed is the ordinary darning stitch, passing the needle under and over the
meshes of the net in an up-and-down direction until the space is filled A specimen of this is shown in the lower part of Fig. 1. The working thread should be of the same thickness as the netted threads, and the number of times the darning must be done in one space depends on the thickness of the thread. Embroidery cotton, flax thread and flourishing thread form suitable mediums for this, as they are only slightly twisted; hard, round threads and tight twists should he avoided. Coloured embroidery silks might be darned on dress net, with a judicious blending of the colours.
The most expensive filct laces nie worked in cloth darning, shown in the top left corner of Fig. 1. To do this, darn up and down as described above, but work only half the number of threads required to fill the space, then darn in the opposite direction, going under and over every thread in turn, including the net background
Making a Lace Border. Fig. 2 shows how a lace border can he made and a corner formed in the same deaign. The darning passea over three threads of the mesh on the leaves, and over two threads for single spaces For the heading of the lace-the straight cdge by which it is sewn to the material to be trimmed -a straight line of three rows of threads is darned right along. To make a firm edge the net should be cut away to its proper depths allowing for a small hem to be turned, and the border darned through the two thicknesses of net, so that there is not a raw cdge. The lower or outside edge of the lace is buttonholed, and this must be worked before the net is cut.

Fig. 2 shows the direction the stitches should take to form pointed scallops, and the buttonholing is worked from left to right. They are worked on two sides of a mesh up to the top or deepest point of a scallop, then on threc sides of the mesh at the dip, and down the side of next point, one mesh at a time. To furm the corner the direction can be followed from the illustration. In the latter the net is cut away on one side, and the portion after the corner is left ready for cutting. Geometrical or conventional flower designs can be copied from cross-stitch hooks and from filet crochet patterns. See Crochet.
FILIGREE. Filigrec ornaments, such as brooclies, pendants, necklets, earrings, etc., are made of very thin flat wire, the upper surface of which has fine mille. griffe markings, like the milled cdges of silver or gold coins, but somewhat deeper. The designs are formed by a series of hand-twisted wire loops or circles frequently ornamented with cabochonshape stones, such as turquoises, sapphires, corals, etc. White or grey oxidized silver or gold wire is used.
The fincst silver filigree is made in Italy, and. in addition to articles of jewelry, there are heautiful specimens to be seen in the form of sweet dishes, jewel cases, etc. See Brooch; Earring.

FILLET: Of Meat and Fish. Strictly speaking this is the fleshy part of the thigh or therl Museum. S Kiensington name undercut of a sirloin of heef, but the Kodat comnany have abandoncd the manuname is usually applied to small boneless por- facture of ginss plates, whether for amateur tions of ment or fish, dressed in various ways and shaped, if meat, like cutlets, or, if fish, in strips or neat pieces. See Beef; Fish; Mutton; Veal, etc.
FILLET: In Furniture. This is a small flat face that separates round or oval members in a moulding. The fillet helow an ogee
moulding is sometimes known as a keel fillet. The one above it, which projects beyond the curved member, is known as the wing fillet. See Moulding.
FILM : In Photography. Celluloid films have many advantages as compared with glass plates. They are lighter, not liable to breakage, and less liable to halation than unbacked glass plates. In the roll form as cartridges for daylight loading they arc extremely convenient for snapshot work. The tendency to curl up when dry has been overcome by coating both sides with gelatine. Roll films suffer from a liability to longitudinal scratches, probably caused by rolling too tightly ; care should be taken when

Filet Lace. Fig. 1. Showing hand-made net attached to wire frame, and method of making darning stitch. Fig. 2. Design adapted to a border and corner, suitable for edging a tray or table clotb
the film is in the camera to sce that both top and bottom spools revolve easily.

Roll films are a little more awkward to handle in developing and fixing than plates (see Developing). They are partly sensitive to colours, being orthochromatic but not panchromatic, or equally sensitive to all colours. They are obtainable in fairly high speeds

Filins are also available in Hat form, six or a dozen exposures being carried in a film pack. Thesc arc exactly similar in characteristics to roll films, hut are designed for use with plate cameras. For more advanced photo. graphers flat films of n stouter kind are made which have all the advantages of plates and none of their disadrantages.

They are to be obtained both orthochromatic and panchromatic, and in the higher speeds. These flat or cut filnis arc carried separ. ately in plate holders or dark slides, and are treated as if they were plates. Films are so convenient that the or professional use.

As films are more liable than plates to surface danage by scratches and finger marks, it is $n$ sound plan to harden them by immersion for $\ddagger$ hour in a solution of one part of formalin in 25 parts of water. After removing the surface water with fluffless blotting paper

the film can the dried before a fire. If dried thus without hardening it would melt.
The Clearing Bath. Stains on a film caused during development, both on the front and sensitive side and on the gelatine back, can usually be removed by a clearing bath. The film should he thoroughly washed to get rid of the slightest trace of hypo, and then immersed in the following solution
Alum
$\underset{\text { Water }}{\text { Citric }}$
Water
If chrome alum is used the quan tity should be 1 oz . instead of 2 oz . This solution can be uscd two or thre times, and it brightens the negative considerably. To remove the film from useless glass or gelatine negatives, soak them for several hours in strong soda water and place them in water which is nearly boiling; they should then come off quite casily.
To strip the film from a cracked or broken negative, place the negative in a bath made of 1 dram of potassium fluoride in 1 pint of water, with 10 or 12 drops of strong hydrochloric or sulphuric acid The film will float off, and after rinsing in cold water can be lloated on to another piece of glass, and when perfectly Hat squeezed on and allowed to dry slowly, surface water being drained off. This process enlarges the film considerably, and the new glass should be at least if
times the size of the original negative. If this enlargement is not required it may be prevented by soaking the film in methylated spirit immediately it is detached by the acid aolution. See Cinematngraphy; Developing : Fixing; Negative.
FILM PACK. This is a means of using flat films in a plate camera with the advantage of daylight loading. Six or 12 films are placed together in a cardboard holder, each film being backed with black paper, the end of which projects at the top of the pack and carrics a number. The whole pack is placed in a film-pack adapter fitted to the particular camera, taking the place of the ordinary dark slide or plate holder. When a film is exposed it is changed by pulling out the numbered tab ateadily and without excessive force; this pulls the exposed filin round a roller nt the hottom of the pack so that it is changed from the front to the back of the pack, and the next film is rearly.

When the last paper tab is pulled out a shield is brought in position in front of the last exposed film, protecting it from light and nllowing the whole pack to be removed from the adapter in daylight. If it is desired to develop single exposures the adapter containing the pack can be taken into the dark room and the iequired filma removed, care being taken to close the pack pioperly before replacing. See Devcloping; Film; Fixing; Photography.

FILTER : For Drinking Water. When drinking water is suspected of being contaminated it should be carefully filtered before use. As an extra precnution, it is well to hoil it firat. Water loses its confained air by boiling and becomes flat, but the process of filtration restores more or less air. The water supplied to city people is thoroughly filtered, but in country districts, where the
supply comes from wells and streams, the process must be carried out in the home Where disease germs are present, however, reliance should not be plaoed on filters; the best safeguard is to boil drinking water.
Several filters suitable for use in the home are on the market. The Pasteur-Chamberland is made in several types, the largest being pressure filters for attaching to the main water supply. A smaller one, of the nonpressure type, made to stand in the house, is of earthenware or enamelled iron. Its size varies, the largest being able to deal with 16 gallons of water a day and the smallest with three. A filter of this kind is illustrated in Fig. 1.
Another useful type is the silicated carbon filter (Fig. 2), made in various sizes and styles. For ordinary domestic use there is a stoneware article, the largest size of which has a capacity of 12 gallons. These need from time to time extra charges of the silicated carbon, which is the purifying agent. Filters on the same

Filter. Fis. 1. Mon-prespure fliter in enamelled iron. frequency stages
It protects the loud speaker or telephone windings, sinoe the insertion of these delicate windings direotly in the anode circuit of a low impedance valve might result in a breakdown.
The filter is, moreover, an aid to stability in a receiver or amplifier with two low frequency stages. Employed in conjunction with a de-coupling resistance and by-pass condenser conneoted in the anode circuit of the detector valve, an output filter is particularly useful in cases where the high tension supply is derived from a mains eliminator liable to produce " motor-boating" and other troubles. The filter also permits the use of a single long lead from the set to a distant loud speaker, so avoiding induction effects. The socond terminal on the loud speaker is connected to any nearby earth point.

A common value for an output filter choke is but a general one is three of sand to one of lime-putty. It can be allowed to stand, .fter it has been thoroughly mixed, till nearly hard but not dry, and can be made to the required consistency with water or lime water for immediate use. It is less likely to shrink or crack if prepared in this way, and may be mixed with colouring matter to give any required tint. One part of sand may be omitted, and one part of crushed marble, sla baster, or spar substituted in order to give a different type of surface. See Plaster.
Finger. See Hand.
FINGER AND TOE. Finger and toe, anbury, and club root are all names for the
 same troublesome disesso attacking the roots of turnipe and cabbages. See Club Root. FINGER BOWL. Finger bowls may be of plain or cut glass, those of the former type being often coloured.

Fingar Bowl. 1. Barly moulded Irith finger bowlo c. 1780. 2. Bowl of Bristol Blue glase with gilded dige, a 1800. \& Lrish out glas Fork, 0.1800. 4. Finger bowl decorated withinate ontting, c . $1820-80$ Courteay of Cecll Davia
they should harmonise with the dessert service and the table decorations generally.
Finger bowls of old glass can occasionally be purchased, and are usually of greater beauty than modern ones. Some are of the double. lipped type, and are found in a variety of patterns, cut and engraved. More rare are the barrel-shaped ones, the charm of which lies in the beautiful steel-blue quality of the old crystal glass, austerely deoorated with groups of raised lines. See Glass ; Table Laying.
FINGER STALL. A finger stall is used to protect broken nails, cracks at the top of the finger, or any small wound which needs to be covered, but it should never be used on an open wound without some kind of bandage or dressing, as it is not aseptic.

Rubber finger stalls may be bought from any chemist, but ordinary ones can be made from an old pair of gloves. Cut of the glove finger corresponding to the finger for which the dressing is required, leaving a triangular piece of material extending from the base. This is then pierced and a piece of tape inserted. The tape should be long enough to cross over the back of the hand and take a turn round the wrist, being then fastened. See Bandage: Dressing.

FINIAL : In Furniture. This word is used for the top finish of a vertical member of a piece of furniture. Examples are the ting acorn tops found on the supports of Queen Anne looking-glasees, and the terminal ornament at the top of a pole fire-screen.

FINING: In Cookery. Fining is the process by which thick or cloudy liquids are made to appear clear. Home-made wine. jellies, and soups are frequently fined. The wines are treated with isinglass, and jellies and soups with white of egg and eggshells boiled with the liquids and afterwards strained. For clear soups raw beef is minced and substi. tuted for the white of egg.
FINNAN RADDOCK. The name is given to the cured and dried haddock procurable all the year round. The fish is of a creamy yellow colour. See Fish; Haddock.

FIR. This name is commonly used in refer ence to various conifers, e.g. abies, picea, pinus and others
Fir Cone. Fir cones make excellent fuel for an open grate. They should be collected and dried, and then stored in a $\log$ basket. When the fire has bumed up well and is bright and clear, put on the cones. They burn briskly and give out a pleasantly fragrant smoke.
A large fir cone makes a reliable weather glass. It should be hung up in the porch or liall. When wet weather is to be expected the cone will close up tightly, owing to the moisture in the air. When a spell of dry weather is coming the cone will open and spread out. See Deal: Fire; Fuel; Wood.

FIRE: How to Lay. Much depends upon the corrcet laying of a fire, but no difficulty whould be experienced if a sufficient supply of dry wood is kept ready for use.
The kitchen fire is generally the first to be lighted in the morning, by raking out the dead cinclers and ashes from the grate, placing crumpled paper in the bottom, with the finest kindling on top of it. Upon this is placed slightly larger wood, with a fairly large piece, and a few knobs of coal on the top. The top of the range should then be replaced or the kettle placed over the opening, the dampers adjusted correctly for draught, and a match applied to the paper. The paper inay be saturated with paraffin oil before it is placed in the grate ; to tip paraffin over the whole fire is risky.

In the case of an anthracite stove, the same procedure may be followed, except that, instead of the damper, the small door at the bottom of the stove should be opened when the fire bas been lit, in order to provide more draught, and a fairly large quantity of anthracite placed on the wood. For open grates no damper is provided, but the grate is generally larger, and more wood can be laid on it. Open grates are more common in the country, and a wood fire is easily made up before coal is placed upon it. The same procedure may Ise followed in the case of barless stoves and fireplaces, although in the latter case it is generally wood that is burnt.

Where the fire is open, that is, not enclosed, as in a range or slow combustion stove-care should be taken to see that the register is opened before the fire is lit, or the room will be filled with smoke. Essentials are that there shall be room for the flames from the paper and kindling and a sufficiency of air for proper combustion, for which reason there must be a space for the air to get through. It is useless trying to light any fire if the kindling be so tightly packed that the air cannot pass all through it, a good draught being a great help to speedy and effective fire lighting.

Fire Lighter. Special compositions, gener ally of pitch and sawdust, are sold for fire lighting. In some cases the composition is placed on kindling wood all ready for use, and in others it is sold in blocks, divided up into squares, one of which is used at a time They are very useful when the kindling wood is damp, but care should be taken that they are stored in a place that is not greatly exposed to heat, as they are liable to catch alight.

Pine cones are converted into fire lighters by soaking them in a mixture of 8 parts of resin to I part of tallow. This is done while the mix ture is hot ; the cones are improved by sprinkling them with sawdust. As they are very inflammable they should be stored in a safe place, preferably out of doors, but protected from the elements. See Anthracite; Coal; Gas; Grate, etc.

FIRE : Precautionary Measures. One of the first duties of the householder is to ensure that proper precautions are taken against fire, and while much has been done by legis
lation so far as the building of the house is concerned, the interior arrangements must be carried out by the inmates themselves. Various safeguards and emergency measures to be adopted in case of fire are outlined in this article, together with a brief description of some of the fire appliances on the market. Such measures include the provision of extinguishers and ladders, the immedinte closing of doors and windows, and the application of water, sand, or a chemical extinguisher.
Open fireplaces ought to be protected by an efficient fireguard at night, or on occasions when the house is left unattended for any length of time. The storage of inflammable oils should be in an outbuilding, and not in the house itself. Oil used for lamps should be kept in a safe place away from any heat, and the lamps themselves wiped dry at the time of refilling. Candles and nightlights should never be left burning unless properly protected by a holder of adequate size or housed in a candlestick with a glass shade. Never put a lighted lamp in any position where the heat from it may be a source of danger. A lamp is usually alight for a considerable time, and while the heat at the start may not amount to much, the cumulative effect may be enough to scorch, and finally to fire, adjacent woodwork. The airing of clothes at an open fire should only take place under supervision, as a cat or a dog may easily overthrow a clothes-horse and cause a fire. Another wise precaution is the provision of metal ash-trays : many fires have started from a dropped cigarette-end

## Importance of Instant Action

The greatest safeguards against fire are those which can be quickly a pplied. Speed is everything; the biggest fire starts as a tiny one, and therefore if a fire occurs act at once. A tumblerful of water applied at the instant of the outbreak may suffice, or the prompt application of a thick rug or mat
If the hedroom curtains catch fire, seize a pillow and beat out the flames, and if assistance be at hand, let the doors and windows be at once closed, and apply the water from the toilet jugs thrown forcibly into the heart of the fire. An outbreak can sometimes be suppressed by the prompt application of a wet blanket.

When it is necessary to enter a burning building it is better for two persons to go in company, so that if the first is overcome by the smoke the other may be able to effect a rescue. If the snooke is very dense the entrance should be made on the hands and knees. A wet handkerchief, towel, or a damp sponge gripped in the teeth is an aid to breathing, as it acts as a sort of filter for the air

Many excellent fire-fighting appliances are on the market, and their purchase should be looked on as an investment. The chemical extinguishers are probably the most effective for domestic use. They are made in many sizes and types, but those of two or three gallons capacity are as good as any in an ordinary house. They work in various ways. In some there is a handle to be turned; in others the appliance is turned upside down, struck a blow on the floor, and the liquid at once directed into the heart of the fire. Whatever the type adopted, its method of use should be demonstrated in the presence of all those normally resident in the house, so that all may be familiar with it. The appliance should be kept in a well-known and accessible position.
Insurance Against Fire. A policy insuring a house and its furniture against fire should be taken out by every householder. The rates vary, but lis. Gd. for each $£ 100$ insured is a fair average. It is more economical in most cases to take out a policy that covers other risks, e.g. burglary and employers' liability as well.

A fire insurance nolicy is essentially an
agreement in good faith. A failure to disclose any material fact necessary to estimate the risk properly vitiates the policy, and the same is true if anything is done without permission of the insurer whereby the risk of fire is increased after the contract has been made. The risk of fire as a result of invasion, riot, strikes, or civil commotion is not covered by an ordinary fire policy.

Fire insurance policies are issued either subject to average or without average, and those who take one out should make inquiries on this point. In the former case, if the full value is not insured, the insurer must bear a proportion of the loss. For instance, A insures his house for $£ 1,000$, but its total value is $£ 2,000$. A fire damages it to the extent of $£ 800$, but the insurance company will only pay him $£ 400$, or half the amount of his loss, as his house was only insured for half its value. If, however, property is insured without average, the full amount of the damage is payable up to the limit of the amount insured. See Insurance.
Fire Alarm. Fire alarms are of two classes. Thosc installed in the public streets are set going by breaking the glass and pulling a handle or knob; an electric circuit is completed, and a bell rings in the firo station. Those installed in the building to be protected are of two kinds, those which merely indicate that an excessive temperature has been reached in some part of the building, and those which release a jet of water about the place where the fire is.

The first kind generally consist of mercurial thermometers. When the mercury reaches a predetermined limit it will touch a wire fixed in the glass and thus complete an electric circuit which causes a bell to ring or a steam whistle or "syren" to go off. The sccond consists of fusible metal disks which are fixed generally in the ceiling, and melt when a dangerous temperature is reached in their neighbourhood, letting down a spray of water : an audible alarm is usually conbined with the disk apparatus.

FIREBRICK. Firebricks are manufactured from various kinds of earth and treated to render them lire resisting. Moreover, they have the property of radiating heat, and arc an excellent non-conductor of heat. For this reason it is an ideal material for the back of a fireplace, or any other location where great heat has to he resisted.

Firebricks are obtained in a wide range of sizes and shapes. Modern grates which are made on the barless principle often havo a fircbrick back extending the full height of the grate. See Grate.

FIREBUSH. This is the common name of Cratacgus pyracantha, a type of evergreen hawthorn, bearing white tlowers in May, followed by bright scarlet berrios in autumn. Ordinary soil is suitable for the firebush, but a sunny aspect away from the shade of other trees is desirable. There is a superior variety called Lelandi, of more compact growth, and bearing dark-green leaves with clusters of white Howers, followed by bright orangescarlet berries.

FIRECLAY. A variety of clay that will withstand extreme heat is used in making firebricks, for setting parts of a grate or stove, and for other purposes where resistance to great heat is essential. The best qualities come from the neighbourhood of Stourbridge. It is obtained in powder form, has to be moistened with water, and applied in a plastio state with the aid of a trowel, or pressed into place with the fingers, according o circumstances.
Many excellent compositions are on the market that have fireclay as a base. They are sold under different trade names, and have much to rccommend them for amateur

Fire Guard in wire, essential in the nursery Courlesy of Selfridges
use as, being purchasable in small tins, they are economical in use and of a proper consistency for such work as the repair of a damaged fireplace. Fireclay is very useful for luting the joints around a stove-pipe, for making good any defective places in an anthracite stove, or in fact any place which is subjected to the heat of a fire. See Firebrick; Grate.

FIRE GUARD. An essential picce of hearth furniture where there are children, a fire guarel is also useful as a protection against flying sparks which might cause damage during absence from a room after a fire has been lighted. A useful form which will save many anxious moments in the nursery is of wire netting and shaped so that it eompletely masks the grate opening. By the Childron Act, 1908, any person over the age of 16 years who has the custody, charge or care of any child
under the age of 7 years is liable to a fine of $£ 10$ if he allows that child to be in any room containing an open fire grate that is not suffi-

against the risk of being burnt or scaldedthat is, if the child actually suffers serious injury or is killed. It is a defence that the adult person in charge took reasonable precautions against the risk; as, for example, by having sonseone else in the room to look after the child. It may even amourt to manslaughter to lcave a child in a roons with an open firc grate left unguarded.
FIRE IRONS. These articles, used for tending a fire, consist of poker, tongs and shovel. They are usually sold in sets to match the fender or other fittings, and sone sets include a hearth brush. They are made of brass, iron and steel; also of copper and oxidized silver. The older types of fire irons rest on two fire dogs, a development of the old andirons or dogs, but a modern faslion is to bang them from a stand made to match. Newer than a stand with the imple.
ments clustered round it is the wrought iron frame, with tongs, pokicr, hearth brush and bellous all to match the log irons, as shown in the illustration.
These oldest existing examples, known as log irons, were implements used for inoving logs from the fire. consisting of a fork and a roller. Smaller oncs of sinilar type came later into use. Afterwards fire irons were designed in the Adam style, and a beautiful set is shown here. These are of polished steel with engraved urns on the top of the handles. The panel of the shovel with its honeysuckle decoration is in keeping with the remarkable grace of this set.

The methods of cleaning and caring for fire ironsvary to some extent with the metal. Polishing is necessary from time to time, and those in unoccupied roomsshould be guarded from damp. See Andirons; Coal Box; Poker; Tongs, etc.

## Fireplaces, Homely and Beautiful

## Principles of Design and the Best Styles Described

For related information see Anthracite Stove; Chimney Piece; Grate; Range. See also Cottage : House; and the entries on Coal; Coal Box ; Curb; Fender; Fucl

Fireplaces are so linked up with traditions of British home comfort that, whatever the methods of heating used to supplement them, there is little likelihood of their going out of fashion in living-rooms. This is particularly the case with forms of fireplaces which are atructurally good and designed in fabrics eminently suitable for their purpose.

Brick fireplaces endure for several reasons. They are right in many stylcs of moms and different periods of architectural decoration ; they suggeat complete comfort and plense the eye. The warm tones and harmonious colours of good bricks, combined with their delightful texture, render them a particularly suitable material when built up in simple but effective designs. British brickwork has had a gool revival in this century, and for fireplaces mixtures of old English 2 in. handmade l,ricks are often chosen, which are well burned to a pleasing variety of tints. In many of the newer houses the bricklayer has put his craft to $n$ specially artistic use in carrying out excellently designed fireplaces.

Where coal lires are not desirable, gas stoves of architectural character to resemhle a coal fire, or one marle of imitation loge, and burning in $n$ dog grate can be reasonably associated with a brick fireplace of the less heary type. An anthracite stove may also the auitably framed by the simplo treatment for a hall fireplace shown in p. 240, though such a design would he equally pleasing for a small sitting room or country bedroom, with either a gas or coal fire.

Attractive Examples. Many larger modern livingroom fireplaces are baserl on designs taken from genuinely old examples such as that scen in Fig. 1. This beautiful fireplace with its massive oak shelf, heam, square tiled hearth and stone curb is many centuries old. Interesting detaila are the fireback, dog grate and fire dogs or andirons which support the antique fire irons. Firebacks look their hest in such a setting. Modern adaptations of these are copied in cast iron or can be made from sheet metal with applied ornament. The deaign call be carved in wood

or modelled in plaster on a ennvas backing, and the finished casting obtained from an iron founder. Various sizes of cast iron firebacks were commonly in use in the fireplaces of the 17th, 18th and 19th centurics, and were made in Sussex during the 15th century. The earliest designs were very simple, but those of the 17th century reproduced to day are decorated with flowers, fruit, figures and rarious heraldic emblems.

Brick and tilework fireplaces in bold simple designs are an excellent choice for oak panelled or half panelled rooms, and are quitc suitable in the country type of drawing room, where the keynote is comfort and the furnish. ing of a somewhat solid character. Brick lonks particularly well with carpets and rugs in mellow oriental colourings and with curtains and covers of linen printed in a Jacobean design or in conjunction with chintz hangings. Such a fireplace may provide cosy nooks on either side for winter evenings, and immediately produces a feeling of velconic and homeliness with $n$ wide hearth and curb in one with the chimney piece and with brass accessories to enhance the glowing warinth.
In modern adaptations of Tudor style the stone arch, open hearth with its herring bone
brickwork and simple treatment of the the chimney breast and setting the gas fire mantelpiece are seen Nothing is more easy direct against the wall. Electric fires, which to keep clean than the hearth of this period, need no flue, can be placed anywhere in the either during the day when the fire is burn- room, hut as a rule they are decoratively best ing, or when relaying. The fircbrick interior in a modern fireplace setting, though when of with canted forward back is very cfficient: the kind which simulates an ordinary fire, they burning little coal and throwing out a good are seen in various period settings. heat, but by its size admitting of a big fire on a cold day, while rough logs can he burnt instcad of the specially cut ones necessary for sone types of grates. The beauty of copper or brass wall and hearth fitments add to the attraction of such a fireplace. Fig. 3 shows an adaptation of Tudor style in Bath stone and old English bricks l'liles surround the sent out into the room. The brick fircplace outer part of the hearth finished by a solid seen in Fig 5 possesses a barless slow combus. tion grate Various othe, forms of fire or fireplace interior will be described in the article on Grate.

Structural Details. In designing a house, it is im. portant to locate the fireplaces as far as possible on the internal walls. Every fireplace in an outside wall involves a separate chimney and stack to itself, and the multiplication of stacks is an cxtravagance.

Fireplacce are formed by building projections, generally of brick, either into the room or outward into an external chimney stack. Theso projections are known as jambs. The usual size of a fireplace opening is about 3 ft . so . when intended to be fitted with the usual registerstove or grate. A charming oak curb. Even in these days of electric fires alfect can be obtained by removing the montel most people really prefer a genuine coal fire, register-stove and builifing a fireplace with especially the down firc in the modern render- bricks. These can be sct in front of the walls ing of a Tudor room either wood panelled or of the jambs, and the work can be carried out oak-heamed.
While a Tudor stone or a brick fireplaco seems ideal for the dining room or lounge hall the being some bullnose bricks with which to form Georgion the dining room or lounge hall, the the face of the jambs, and some nicely coloured he of shown in Fig. 4 is perfect for stock or facing bricks. These must be set in with painted panelled walls. The curved steel femler, steel hasket grate and fire irons, pale green tiles, white marble surround and ornamented shelf are beautiful features of the whole.
Modern fireplaces of small type abandon such architectural treatments and adopt rectangular designs and receding planes usually without ornamental moulding. Such a design is shown in Fig. 2, with a dovegrey marble surround and black marble curb. This fireplace is particularly suitable for a small llat. The coalbox is in the lower part of a built-in bookcase, the companion cupboard containing wood. In this example the mantelshelf is very narrow ; often in such a fireplace it is absent.

In many modern fireplaces slow combustion grates are found, or they are merely settings for gas and electric fires. A gas tire neerls a flue only a quarter of the area necessary to that for a coal fire, and it is possible to use llue blocks built into the partition wall. Space can thus be saved by doing away with

Fireplace. Fig 3 (left). Adaptation of Todor style in Bath stone and old English bricks. Fig. 4. Drawing room fireplace in Georgian atyle in panelled setting

The tireplace opening should be small in relation to the size of the room, as a small opening and a large room accord well, while a large opening in a small room is never a success. The width of a fireplace depends so much on

Fireplace. Fig. 6. Diagram sbowlag section throagb a \& imple brick-built Areplace
the room that any definite rules are impossible, but 12 in . will suit most rooms up to 12 ft . sq. The opening is governed, of course, by the size of the stove. A 16 in . or 18 in . stove will be suitable for a room about 16 ft . long by 12 ft . wide, but muoh will depend on the geographi. cal position, number and size of windows, and number of outside walls.

FIREPROOFING. There are various methods of treating an artiole or piece of material so as to render it partially or wholly non-inflammable. In the case of fabrics the treatment consists in immersing the articles in a liquid, or of spraying them, and is obviously limited to those inaterials which are not liable to damage by being so treated.

For example, fancy dreases made from muslin and other common materials may well be fireproofed, but a rich evening frock would sustain damage if immersed in chemicala Various formulne have heen published from time to time for the fireproofing of fabrics, and these vary very much as regards their efficnoy. The follnwing are applicable to materiala of the olasses mentioned:
a. A strong solutinn of tungstato of soda.
b. Ammonium borate, 1 nart.

Potassium carbinato, 3 marts.
Water, 33 parts.
Wood is rendered fire-resistant by the use of any of the recognized fireproof paints, these being applied in much the same way as ordi nary paint. Fireproofing compositions may also be brushed into the wood, or the articles may be entirely immersed, cither plan being adopted according to the nature of the work. In addition to the use of fireproof paint, whitewash is a good protective for woodwork. It is made by dissolving lime in water with the addition of a little whiting, and is simply brushed over the work. Two or three conts will act as an efficient fire-retarding medium The following are effective fireproofing compositions for wood :
a. A strong solution of tungstate of soda.
. Anmonium borate, 2 parts.
Potassium carbonate, 6 parts.
Water, 80 parts.
FIREPROOF WARE. Cooking utensils made of fireproof china, earthenware and glass have now largely replaced metal pans and pots, especially for braising, stewing and soup making. Casseroles can bo bought in all sizes, from the large type capable of holding a family stew, to the smaller ones used in the preparation of ragoûts, salmis and hot pots. Ramequin cases in brown or green fireproof china are also
sold for making small soufflés, creams, etc. also white china shells for holding scallope of meat, fish, game or vegetables

Au gratin and other baking dishes are obtanable in the same wares, and are invaluable in houses where menls have to be kept waiting, for they can be left in a hot oven without fear of breakage. Groen china entrée dishes, also fireproof, are equally useful, while even more attractive are the ones in glass Brown earthenware casserules and square baking dishes look well on an oak table. All fireproof ware can be kept clean by washing it in warm, soapy water, and burn marks may be removed with fine sand. Stains caused by fruit or vegetables are best trented with soap and water. The dish should be soaked in this solution and then washed in the usual way. See Casserole
FIRE SCREEN. Of the two types of small screens known as fire screens one only, the shield on a stand, which can be fixed into position to protect the face from the fire, is true to its name. The other is rcally an empty grate screen with a purely decorative value.
The first is rarely seen except in the genuine or reproduced styles of the eighteenth and tho finst half of the ninetcenth century. The second type should be carefully chosen. A well-blacked grate is preferable to the chenper and less artistic forms of bought screens.
The mahogany Chippendale style fire screen, with glazed brocade, or needlework panels, is always correct with furniture of the same character, and so is the Louis XV type of ornate gilt panels, and the Empire model with ormolu decoration Screens in decorative leather work are suitable for a living-room, while furnishing jaspé and linen are quickly and effectively embroidered in coloured wools to make panels for wooden frames. A piece of Chinese embroidery, glazed and framed in narrow black, looks well if nicely fitted to the grate opening of a small fireplace.

A pretty screen for a sitting room grate is made by ferns or flowering plants arranged in a simple two-tier flower box to suit the size of the fireplace, but it is often impossible to exclude the down draught from the ohimney without $\Omega$ slieet of glass fitted to the opening

Fire Screen. Left, early 18th century screen in coloas print on silk with a carved and gill limewood frame and stand : late 18 th century

behind the flowers. Another idea of the same type is an arrangement of cut flowering shrubs or foliage in a pottery vase Metal screens, chromium plated or in rustless steel or oxidized silver or copper, have the merit of not tarnishing. These usually match the ourb or fender and fire irons, and are sold in a suite or separately. See Flowers; Lenther Work.

FIREWOOD. Firewood can be bought ready for use in bundles, but is cheaper when bought as rough wood from a grocer and chopped up as required. In country districts local supplies can be obtained. If the wood is cut when green it will hare to be dried and stored for some months.
If the oven has been used during the day. wood may be left in it all night, and will thus dry quickly and thoroughly. Logs of wood are useful to supplement coal and to burn with slack. Sometimes opportunities occur of buying discarded blocks of wood paving. These are an excellent form of fuel for the house on account of the tar with which they are soaked. See Coal: Fuel, etc.
FIRMER. A firmer chisel is an ordinary carpenter's chisel, having a blade of normal proportions, neither thin, as in paring chisels, nor of exaggerated thickness, as in mortiso chisels : the blade has $\Omega$ tang and shoulder to take a wooden handle.
The firmer gouge is the ordinary form of gouge as used by carpenters and joiners; the blade is more or less curved, and may vary from practically flat to a semicircle in cross section. It is sharpened on the back by grinding on a grindstone, and whetting on an oil stone, in the usual way. Firmer gouges are employed for all olasses of curved work and, in addition, for some forms of carving, such as hollowing and shaping a model boat hull. See Chisel; Gouge.
FIRST AID : How to Render. Everyone should know how to give some aid in cases of accident and sudden illness. A few simple mensures promptly carried out will often prevent serious developments, and may save life-
It is a common incident to see would-be helpers lifting a fainting person into a sitting posture. The fainting is due to insuffioiency of blood in the brain, and this manoeuvre still further reduces the supply, thus prolonging the fainting fit. Indeed, when the heart is very weak or the patient has lost a great deal of blood death may be caused by lifting him.

In cases of unconsciousness the first essential is to loosen all the patient's tight clothing and provide for a frce current of air. To assist this other people should not be allowed to crowd around him. When the face is pale, the patient should be laid flat on the ground and the legs slightly raised: when flushed, the head should be raised. In both cases the head should be turned to one side. Nothing of any description should be given by the mouth until consciousness is restored.

On no account should those rendering first aid make any attempt to force brandy or other slimulant down the throat of an unconscious person, as this may result in choking him.
It should be the rule not to move a person who has been hurt or becomes suddenly ill, except so muoh as is necessary to permit of his breathing easily, until some opinion has been formed as to what is the matter with him. Urgent conditions like bleeding and shock should be attended to first, the former by taking the necessary steps to arrest haemorrhage, and the latter by applying warmth. In cases of severe burns, especially in children, a shock-like condition may be present. By putting a child in a warn bath not only is the shock treated, but the removal of clothing is made easier.

Before beginning artificial respiration, in all cases where it is necessary, the mouth and the back of the throat should be examined to
make sure that they are clear. Clothing should not be removed unnecessarily in the case of accidents out of doors. In the case of hleeding, the wound may be exposed by slitting a seam with a knife, but while this is being done pressure should be put on the main artery. If a person's clothes are on fire, some heavy fabric, a rug, a blanket, or cont, should be thrown round, and he should be rolled on the floor in this.

In sending for the doctor, it may save valuable time if he is told, preferably in writing, the general nature of the emergency, e.g. bleeding, broken bone, poisoning, etc., and details, as to the part injured, the poison suspected, and so on
First Aid Cabinets. First-aid cabinets for servicc in the home in plain deal, fumed oak, and white enamel are sold in various sizes. They contain all the dressings and bandages necessary in case of accident, while some of them, finished with nickel-plated fittings and plate-

## Fish : Choice, Cooking, Food Value, Etc.

## Some Facts of Daily Interest to Every Housewife

## This article describes the several ways of cooking fish, gives information ahout various fish dishes and contains other facts of value in the home. See the entries on fish ordinarily eaten, c.g. Cod; Haddock: Halibut; Salmon ; also Diet ; Food

Next to meat we must rank fish ns one o the most valuable sources of the proteid, or body-building material, and fat. This food may be used, with benefit to health, by persons who do not require a full meat diet for the repair of bodily waste. Even those workers whose occupation requires a liberal diet can thrive upon a little meat and a moderate allowance of fish. For townspeople of sedentary employment or for those engaged in light manual work, fish constitutes one of the best proteid foods.

Cod, haddock, smelts, and flounders are among the lean fish, and very little fat can be derived from them. But cod has a high percentage of proteid, and is therefore nutritive.

For energy, as well as the restoration of tisasue, we need a varied fish dietary, and fat fish should be chosen by persons whose labour demands muscular exertion. One of the virtues of a fish diet is its full absorption in the body. Only about five per cent of the solid matter of fish is lost in digestion. All the lean fish are readily digested, and are therefore recommended to invalids ; and any fairly normal digestive system can absorb salmon or the more oily kinds.

Cost and Food Value. It must not be sup posed that the cost of some kinds of fish has any relation to their nutritive value. A dozen oysters yield only a small amount of fat, and about as much nourishment as a single herring. A sole may please the palate more than a plaice, but it contains considerably less fat; halibut is almost as nourishing as turbot. Mackerel have much less fat than eels, but more proteid. Tunny, sold in tins, has over 30 per cent. of fat.

One great advantage in a fish diet is its digestibility as compared with meat. Cod is perhaps the least digestible fish and mackerel the most digestible. Lean fish, such as whiting, can be digested readily by many invalids When a food is cheap it is often refused on the
ground that cheapncss and a lack of nourishment go together. This is not the case with any of the fat fish-herrings, blonters, sardines. sprats, and eels.

Some kinds of fresh fish may contain as much as 70 per cent. of winter. Oysters have over 77 per cent. of water and about 22 of nutriment. In a salt herring there is 53 per cent. of nutrients. The difference between the amount of fat in fish is shown by comparing a hake with a mackerel. In the former the fat is only about 5 per cent. and in the latter 25 per cent. But the lean fish are by no means devoid of nourishing matter. Cod contgins 91 per cent. of body-building material but very little fat. Turbot yields rather over 84 per cent. of proteid, and halibut contains 79 per cent.

Varieties of Fish. There are unreasonable prejudices against eating several kinds of valuable fish. One of the blennics, known as the cat-fish or wolf-fish, is often despised as a table fish, but it is very good eating. Some of the British sharks and dogfish are quite edible. They are rejected because of their unattractive appenrance. One of the tastiest fishes that swim is the gurnet or gurnard.
The handsome lythe or pollack is not a good fish for kecping. and must be eaten soon after it is caught. The edible quality of this fish is not sufficiently known, and the same may be said for the coal-fish or saithe and sea bream.

The choice of fish may be largely determined by its appearance. Fresh fish is stiff, plump and firm, has bright, firmly attached scales. clear eyes, and red-coloured gills. When the freshness wears off the fish becomes flabby, the Hesh is easily indented with the finger, the eycs are dull and glazed, while the scales fall off ensily. Growths about the head or fins, unsightly blotches and scaleless pintches re well-known signs of disease
In stale fish the gills change to a dark red or a whitish colour ; but this test is not
infullible, for trawl-caught fish are suffocated often in the process of hauling in the nets, and the gills become congested and dull-looking. Oysters should be firmly closed, but if slightly open, the shells should meet instantly and tightly on the blade of a knife heing inserted between them. If the shells gape, the fish are unwholesome.

Tinned Fish. Tinned fish should be turned out of the tin as soon as the latter is opened, and consumed as quickly as possible. Lobster, in particular, keeps hadly. Tins which show signs of rust, of being soldered in many places, or which give a hollow drum-like sound when tapped or shaken, should be rejected. Sardincs, smnll herrings and tunny which are preserved in oil should he taken out of their tins and kept in a covered china or glass dish. When air reaches the open tin. chemical action is sct up, and the oil becomes impregnated with the metal. A wholesome smell characterizes cured fish which is in good condition. In case of doubt, make a small incision with a knife near the backbone and test the odour

Fish should be kept in a cool, dark place, and whenever possible in prepared paper bags placed in ice. If the bags are fastened down the fish should keep fresh.

Cooking Directions. Fish are usually fried or boiled, hut there are other methods, such as steaming and grilling and baking. Boiled fish lose some of their nutritive value in water. but steamed fish retain the nutrients, and are more agreeable to the palate. Most fish that can he boiled can be steamed

The general rule in boiling all kinds of tish is the avoidance of haste. The water should be heated until it is near the hoiling point, and the fish, wrapped in muslin, placed in it and boiled quickly for 2 or 3 min . only. The heat must then be reduced, and the fish allowed to simmer; 3 lh . of fish will require 20 min . for boiling, and 35 for steaming: 1 lb . of tish will require about 12 min . boiling. Casserole cooking is a good method with large fish. which should be placed in the casserole in fillets with a little butter. An onion, pepper. and any kind of spice that is approved, such as cloves, should be added. After stewing for 5 min , a glass of white wine will give an additional flavour, or a teaspoonful of Worcester snuce, and some slices of lemon. Take the fish up on to a hot dish and allow it to drain well still wrapped in muslin. Remove muslin and pour away the liquid that has collected before serving.

Two or thrce of the coarse freshwater fish are scarcely worth cooking. Barbel is an exnmple, though in Spain this fish is conked with onions and spices, and eaten by the peasantry. Chub arc insipid and very bony. liream from fresh water are edible, but cannot be considered luxuries, and the same may be said for roach. Carp and tench have slightly more flavour, and may be stewed or fried in olive oil, butter, or beef dripping. Pike may he cut into collops and fried, or stuffed and baked. Perch should be skinned to remove the rough scales. Gudgeon are rather morc Ilavoured than many river fish, and may be fried like perch. Trout of over 1 lb . should be filleted and fried or grilled. Large lake trout and sea trout are best boiled. Kedgerecs, curries, and rissoles can be minde with almost any kind of fish as the main ingredient.

The flat fish-skate, soles, plaice, and dabs -are best cooked by frying, either whole or in fillets. Cod, large haddock, and pollack should be cut into steaks before frying. Fish are often stuffed with forcemeat and baked.

In the preparation of fish it is essential that each cloth or cookery utensil should be thoroughly cleansed after use, or the next article of food which comes in contact with it will contract a fishy flavour. A saucepan or kettle in which fish has been boiled, or
one used in making fish soup inust be washed separately from other pans. After touching fish it is sufficient to wash the hands in the ordinary way to remove all odour
Curing Fish. Fish cured in the following way will keep for a long time. Clean and carefully wash and scale the fish, and, if large split it down the back. Rub it thoroughly inside and out with finely powdered common salt, and bang it in a cool, draughty place for 24 hours. Next rub into it a mixture of 1 oz of bay-salt and $\frac{1}{2}$ oz each of coarse brown sugar and saltpetre.
Lay the fish on a dish, cover it with more salt and leave it for at least 48 hours. Then turn it, cover it again with fresh salt, and leavo it for a further period of 24 hours. Drain off the brinc after this time, dry the fish, fix it on thin sticks, and hang it in a cool. dry, airy place. If kept for long soak the fish in cold water for 24 hours before cooking it.
Filleting Fish. Large fishare seldom filleted unless a portion is purchased that can with advantage be boned and cut into strips or pieces Flat fish, such as soles and plaice, niake the best fillets, although haddock and whiting are frequently used for this purpose. To fillet flat fish, lay it down upon a board and with a sharp-pointed cook's knife cut off the head and fins: also cut the tail across. Score a line down the spine and, pressing the knife against the bones and taking long, even cuts, take off one side of the tish. Then turn it round and remove the other side. Turn it over, and repeat the process.
Hadduck and whiting are treated in the same manner, but in these cases there are only two fillets, instead of four, to be removed. It is economical to fillet fish, for the bones can be used to make fish stuck for the sauce.

Frying Fish. Frying is the quickest way of cooking most fish. Small lish are usually fried in the frying basket, and fillets and steaks of fish are fried either in deep fat or in just sufficient fat to cover. In all cases the fat must be very hot when the fish is inmersed ; su hot that it has ceased to bubble and a blue smoke is rising from the pan. All fish before lieing fried must be well dried, and this is best accomplished by rolling it in flour seasoned with salt and pepper

Fillets and steaks of fish are usually dipped into beaten egg and conted with breadcrumibs hefore being fried, or dipped into batter. When the outside is of a pale brown colour the fish is cooked The fish is lifted out of the pan with a fish slice to prevent the flesh from breaking. Fried fish must he well drained before being served. This is cone by p!acing it on a sheet of kitchen paper or on a cluth It is served up on a dish paper, and the usual garnish for fried fish consists of pieces of cut lemon and sprigs of fried parsley.
The fat most commonly used in Great Britain fur frying fish is land or dripping, Hlthough some prefer the continental custom of frying in olive oil. Frying oi! can be bought at provision shops, and is not so expensive as pure olive oil but equally efficacious.
Fish Stock. This atuck forms a good basis for fish soups or sances. Make it by putting 1 lb . of bones, heads, and trimmings of any fresh fish into a saucepan containing 1 quart of cold water a blade of mace, a small peeled onion, 4 cloves, 6 peppercorns, and a pinch of salt. Bring it to the boil, let it simmer for 10 min ., then strain it. If the stock is allowed to boil too long it will become bitter. Fish stock must not be kept from day to day as it soon turns sour.

Using Cold Fish. There are many ways in which the remains of cold cooked fish can be made into appetising breakfast, luncheon, and supper dishes. Any cold, left-over sauce should be used for mixing these dishes, and they should always be well seasoned. The following five recipes will be found useful.

Fish Cake. Any cooked white fish and some cold cooked potatoes, in the proportion of 1 lh . of fish to $\frac{1}{2} \mathrm{lb}$. of potatoes, are needed to make these cakes. Skin, bone and flake the fish, rub the potatoes through a sieve, and in the ineantime melt 1 oz . of butter in a pan over the fire and add to it a tablespoonful of milk. When these are hot, put in the lish and potato, the beaten yolk of an egg and seasoning to tastc, and stir the whole over a low heat for a few minutes. Spread the mix ture evenly on a plate, mark it with a linife into a dozen even-sized divisions, and form each into a neat, round cake about ${ }^{\prime}$ in. thick Brush these over with beaten egg, coat then with breadcrumbs, and fry till brown in a pan of amoking hot fat. The mixture may also be formed into balls and fried

Fish Galantine. Take the skin and hone from 1 lb . of any cooked white fish, break it into flakes, and mix them with two teaspoonfuls of chopped parsley, the beaten yolk of an egg, seasoning to taste, and enough egg. anchovy, or shrimp sauce to bind the whole. Make the inixture into a ro!!, place this on a greased baking sheet, brush it over with the white of egg, then sprinkle it with breadcruinbs or maize meal, and bake it in a fairly hut oven till brown. This galantine can be served hot with the same kind of sauce as is userl for mixing, or cold with salad
Fish Moley. Chutney and grated coconut should be served with this Indian dish. To prepare it, cover $\ddagger \mathrm{lb}$. of desiccated coconut with boiling water, and leave it to soak. In the meantime, fry 2 oz of sliced onion in the same quantity of dripping. Add $\frac{1}{3}$ teaspoonful of powdered tumeric or saffron, the strained coconut water, a sma!! piece of green ginger, 1 teaspoonful of sliced chillies, 1 lb . of cooked fish, cut up into small pieces, a tablespoonful of vinegar, and a little salt. Simmer the whole till it thickens, and then heap it on to the centre of a dish, arranging round it a border of boiled rice.
Fish Mould. These moulds can be made from the remains of any cold tish. Remove all skin and hone from about 3 heaped table. spoonfuls of fish, put the flesh in a mortar, add 1 tablespoonful of fresh crumbs, 1 teaspoonful of chopped parsley, 1 oz . of warmed butter, a beaten egg, 4 tablespoonfuls of milk, and seasoning, and pound all well
Well butter some sniall dariole monlds, fill them with the inixture, cover them with pieces of greased paper, and steam them gently for $\frac{1}{2}$ hour in a pan containing enough boiling water to reach half- way up the moulds. Turn the moulds on to a hot dish, pouring round them $\ddagger$ pint of parsley sauce.

Fish Pie. Any kind of cooked tish can be used for making this pie. Prepare it by rubbing 2 heaped breakfastcupfuls of masherl potatoes through a sieve. and adding to them 1 or. of melted butter, a tablespoonfu! of nilk, and salt and pepper to taste. Then mix all well together. Renove the skin and bone from one heajed breakfastcupful of cooked fish, chop it up coarsely, and place it in a pie dish.

Melt loz. of butter in a saucepan, stir in the same quantity of flour, and then add 1 pint of tish stock. Stir this sauce over the fire until it boils and thickens, add 1 hard-boiled egg

Fish Kettle of blue enamel fitted with wire strainer.
Courtesy of Staines Kitchen Eluipnient Co.
chopped in large picces and reasoning to taste Add sufficient of this sauce to the fish to moisten it well, and cover the dish with the potato mixture, amoothing it evenly over the top, and marking it with a fork Scatter small lumps of butter over the whole, and bake the pie in a moderately hot oven until it is biown. Salt cod may be used after soaking and preparing.
Uses of Fish Bones. Fish boncs provide valuable manure for the garden if placed in the ground immediately before or at thic time of seed sowing. They are usually mixed with 0 other manure before use, and succeed best in dry soil. Bones left over from meals may be used in this way, but uncoolied bones are better.

Bones in the Throat. In most cascs where a fish-hone is caught in the gullet, it is rither spat out or swallowed later on with a holus of food. A scratch inay then remain and gire the mistalien idea that the bone is still there. When the hone effects a lodginent it is a good plan to swallow large monthfuls of bread not much masticated. Small bones may sometimes be gradually dissolied by taking occasional sips of lemon juice or lemon juice and water. If the bone is not removed by these mensures $n$ doctor should be consulted, or the results may be serious.

Poisoning by Fish. Several varicties of fish are poisonous by reason of substances that are manufactured by certain of their glands, e.g. liver, ovary, etc. Some are always poisonous, some at certain periods, and some only to persons who are peculiarly susceptible.

In Great Britain mussels, mackerel, and sometimes oysters, as well as tinned salmon, crab, lobster, eels, elc., occasionally produce severe svmptoms of poisoning. This is usually due to their having heen invaded by microbes, e.g. that of botulism. Oysters have been responsible for carrying enteric fever and allied disorders Mussels, especially those taken from docks, harbours, and the mouths of rivers, where the water is contaminated with sewage, are frequently poisonous.

FISHER FUR. Inng-haired and dark brown in colour, fisher fur, or fisher marten. as it is also called, is obtained from the largest of the marten tribe, an animal ineasuring 2 to 3 ft . in length. Fisher fur, like all other darkcoloured pelts, may be cleaned with silver sand. Put the sand into a dish in the oven, and when it is thoroughly warmed rub it into the fur. It may then be shalien or, if neccssary, brushed out. See Fur

FISH KETTLE. This is a utensil for cooking fish. It is generally oval and fitted with a strainer or drainer, and is made of block tin or aluminium, while some of the better kind are lined with copper. The drainer is essential for several reasons. It enablea the fish to he lowered gently into the kettle, and to be taken out again without breaking, and may also be used to keep fish warm when it is not to be served immediately. The Urainer is placed across the kettle and the fish, which should be covered with a clean cloth, is put upon it and is thus kept warm by the steam. Fish kettles may be cleaned in the same way as other aluminium or tin pans. See Aluminium: Tin.

FISH KNIFE. The blades of these knives are of silver or electro-plate, not of stcel, and are therefore blunter than the ordinary table knives Fish knives and forks are made either in two pieces, the hinndles being of ivory, mother of pearl, or silver, or they are made in one piece entirely of metal
Plated fish knives and forks or fish servers should be washed immediately after use, with hot soap suds, to which a small lump of whitening should be added. If there has heen any delay, after washing, rub the surface of the knives and forks lightly and quickly with cut !emon, then rinse in the suds again and wipe the articles dry.
FISH SLICE or Server. This article of table use, now represented by fish carvers, was introduced into Fngland in the 18th century and is valued by collectors It has t.wo inain shapes, one in the form of a trowe!, i. - having a triangular blade, and the other with $n$ curved edge on the working side. They were madc in ailver and Sheffield plate

A somewhat similar slice, suited to kitchen use, is made of tinplate or sheet aluminium, and the handle formed in one with the blade. This is used for lifting and turning fish when frying it. It has holes for draining the fat.
FISH STRAINER. This is a perforated metal plate with handles, upon which fish is placed when it is boiled in a fish kettle. The handles are perpendicular to the plate and reach to the top oi the pan, so that the fish can be lifted out of the water and drained without fear of its breaking. See Fish Ketele.
Fit. See Apoplexy; Convulsions; Epilepsy : Fainting: Hysteria.
FITCH. Fitch fur, obtained from a small animal of the marten species known hoth as fitch and pole-cat, has long black top hair and yellow underwool. It is used as n trimining and is of ten dyed satisfactorily to imitnte sable.
The word fitch is somewhat loosely used in connexion with artists' brushes made of ox hair and used for painting in oils.

FIXATIVE. Any materinl used to make anmething permanent or fixed is a fixative, as, for exnmple, that used in the form of a spray in fix the crayon or pencil lines on a drawing. This is perhaps the most usual npplication in a domestic sense, and such a fixative may be composed of dry white shellac dissolved in purc alcohol, sufficient of the shellac heing used lo form a thin film when it is sprayed on to the paper that is used for the drawing.

The fixative can be obtained at any artists colour shop and is put up in a convenient forin in a small hottle. The sprayer is an L-shaperl tubular device sometimes known is an atomizer. One end is inserted into the hottle of fixative and the other end used as a mouthpiece, and as the wind is hlown into it. the fixative is drawn out and deposited on the paper in the form of $a$ fine spray.

FIXING: Photographic. The photographic negative or print is fixed when those portions of the sensitive chenicals in the film which have not heen acted upon by light and the developer are dissolved out. This is usually effected by a solution of hyposulphite, or thiosulphate, of sodium, commonly called hypo. in water

For fixing negatives and films a solution should he made of 4 oz . or 6 oz . of hypo in 1 pint or 20 o7. of water. It should not he weaker than 4 oz . to the pint for negntives, hut may be stronger. In making up the solution warm or hot water should he used; hypo in dissolving reduces the temperature of the water considerably, and if cold water is used it will take an inconveniently long time to dissolve. The solution should he cold before it is used.

It is not possible to sny at what precise point
certain that the process is not complete when the creamy emulsion has been dissolved away;
negatives must bc left in the fixing solution for double the time that it takes to remove this creamy appearance from the back of the negative Stains, dark patches and other markings which cannot he removed from negatives are the result of incomplete fixing.

When the fixing aolution has been used two or three times it is likely to become discoloured and stain negatives. It is therefore desirable to use only fairly fresh solutions. A pint of the solution given above will fix efficiently about a dozen 4 plate negatives An acid fixing so!ution is particularly desirable for bromide prints. It is made up in the following proportions :

The potassium salt should not be added to the hypo solution while it is hot, or sulphurous acid may be given off and the solution thereby weakened This bath gives clear and brilliant negatives ; it can he used for all fixing purposes, except for P.O.P or daylight printing papers.

It is essential after fixing negatives and prints to remove every trace of the hypo, or the print will gradually fade. Washing mny he done in running water or by frequent changes of water. More than 90 per cent. of hypo is washed away in the first 10 min ., but considerably longer is required to remove the remainder, and for this purpose it is essential that the negative or print should be in perfectly fresh water. It is uscless to expect to wash a negative effectively by placing it at the hottom of a basin under the tap with water overflowing at the top; what happens is that while the larger portion of the hypo is dissolved and washed away, the negative lies in a weak solution at the hottom of the bisin.
Various forms of washing apparatus for both negatives and printa can be ohtained. In freely-running water negatives and hromide prints should he washed for at least 30 min . ; prints on thick paper or card and P.O.P prints should be washed for an hour. See Bromide Paper: Developing: Gaslight Paper.
FIXTURES: The Law About. Legally fixtures and fittings are those articles affixed or joined to property in such a manner that while so nttached they become part of it, e.g. gas or electric: light fittings, tapestry on the walls, etc They may belong either to the Iandlord or the tenant. In the ordinary case a tenant is not allowed to remove fixtures even though he has himself put them up. Where, however, they are fixed for ornament, or for the convonience or pleasure of the tenant, or for the purposes of his trade or business he may remove them so long ns he does not injure the landlord's property in doing so.
After a tenant is in occupation he may put up over a doorway a wood or plaster ornament, panel, or frieze. These may he removed by the tenant if by so doing it will not damage the landlord's property. Otherwise they remain in the house and hecome the landlord's, although the tenant paid for their erection. Blind rollers, towel rails, fireplace accessories which were in a house when the tenint entered into possession remain the landlord's property. Blind rollers are often removed by an outgoing tenant under the mistaken idea they are his perquisites. To take nway fixtures unlawfully is larceny at law. Trees, shrubs, etc., which were in the garden when the tenant entered into possession remain the landlord's fixtures.

In another sense a tenant can remove certain Gxtures from their places, but must not take them from the house when giving up possession. Hangings, blinds, grates, stoves, may be taken down or removed to make room for similar
articles of the tenant's own, hut here again no damage must be caused to the landlord's property, and on leaving, all such fittings must be replaced, or the substituted ones left.

It should be particularly noted that a cupboard built into a house is the landlord's fixture, as distinct from a movable one provided by the tenant.

A tenant should remove any fixtures he is entitled to take at the time of quitting the premises, as he cannot re-enter the house for the purpose of removing them.

Trade fixtures are removable by the tenant, unless there is any stipulation to the contrary in the lease or agreement. In agricultural tenancies, such as farms, small holdings, allotments, the tenant is entitled to compensation for any improvements. For example, if he walls off part of his garden and plants fruittrecs, so that in the course of a few years there is a valuable orchard, he will demand and receive compenantion, as he cannot take the orchard with him on removing. On the other hand a town tenant must lenve all fruit trees in his garden as fixtures of the landloril.

Much trouble is anved if the tenant aske for and receives from the landlord a complete list of fixtures, as it often happens that these get Inst or destroyed, and the landlord demands payment or damages in respcct of thein For exainple, he finds a kitchen raker is missing, and accuses the tenant of removing it. Probably it was missing when the latter entered upon the tenancy, having heen taken by a previous tenant. A list in duplicate agreed upon by landlord and tenant at the commencement of a tenancy would avoid much misunderstanding. See Blinds; Bracket: Cuphoard Curtains.

FLAG. This is the popular name given to some varietics of the family of iris. It is also known as the poor man's orchid. The word flag is generally intended to refer to the wild yellow iris, or to the purple iris, which blooms in such a prolific fashion in June in suburban gardens. It is not, strictly speaking, a hulhous plant, hut has rhizomous mots, which may be separated in the autumn if increase of stock is desirable. Its botonical name is Iris germanicus. See Iris.
flageolet : In Cookery. The sinal green beans of French or kidney heans, known as llageolets, are cooked in several ways. In Great Britain they are gencrally sold in a dried state, though they are also excellent when fresh and cooked in the same manner ns green pens. Dried Ilageolets need to be washed and soakicd overnight before heing put into a saucepan containing just enough cold water to cover them A small quantity of mixed herbs and an onion should be added to give flavouring, and the whole hrought to the boil.

The heans require about 2 hours' cooking before they are tender, when they should be drained and tossed over the fire in a pan containing a littlc butter. They arc then ready to be sensoned and served. Fingeolets may also he served in egg, or paraley. or any ot lier suitable sauce, in which case they should be cooked until tender according to the directions already given, drained. and then rehcated in the sance.

FLAGON. This word is employed for a versel used for holding liquid, one somewhat taller than the tankard and fitted with a lid. In England flagons are found in the 16 th century or earlier. The lid was hinged at a point well back on the handle, and was provided with $\Omega$ thumb-piece, so that when drinking, the drinker could keep the lid quite clear of his mouth.

Flagons were minde of silver, as well as of pewter and cheaper metals. One example, illustrated in the next page, dating from 1663, is of silver gilt. It is cylindrical in shape. with a

Flagon. Left, flagon of serpentine marble mounted in silver-gilt ; about 1830. Right, flagon ol silver-gilt, repoussé with tulip flowers, leaves and animals; 1003 Courtesy of the Director, Victoria \& Albert Museum, S Eensington
fat cover and a scroll handle. The thumb piece represents a pierced heart, and is beautifully chased and embossed It stands $15 \frac{1}{2}$ in. high. To-day the word is used for the glass bottle in which certain kinds of wine are sold See Silver: Tankard.

FLAGS: The Game. Also known as French and English, this is an excellent game for large parties of ohildren, such as picnics, school treats. and the like. It is played out of doors or in a large schoolroom, as a good deal of space is required The players are divided into two sides, which are chosen in the ordinary way.

A line is marked across the middle of the ground: one side occupics onc half of the ground and the other side the other half. At each end of the ground are laid handker-chiefs-stones, caps, or any other portable objects do equally well-which represent the flags of the side, and are to be defended agninst the enemy. The sides then take up their position in their own camp, and the game hegins
It is the object of each side to capture the Hags of the other, but the moment a player uteps across the dividing line he can be caught by any member of the opposing side. If caught he is a prisoner, and must stand hehind the Hags with outstretched hand awaiting rescue If he succeeds in reaching a flag without being caught, he can carry it hack in safety. No Hag may be taken while there are prisoners to be rescued. The game continues until one side has captured all the flags of the opposing side.

FLAME FLOWER. This is the popular name of Tropaeolum speciosum, one of the most beautiful of hardy climbing planta It has pretty light green leaves and in late summer hears a profusion of scarlet flowers. It flourishics hest in the cool, moist, northern counties and is often difficult to establish in nouthern districts. The roots should he planted in March or April in well dug soil to which leaf-mould has been added freely, and the position must he a shady one. It is often planted on the north side of an evergrcen tree or hedge.

FLAN. This is a fruit pie or tart made by lining a flan ring or mould with Han pastry, and filling this, after baking, with tinned or stewed fruit and covering the fruit with a thickened syrup. Flans are usually eaten cold.

Flan Pastry. To make this, take 6 oz . flour, 3 oz . butter, $\frac{1}{2}$ oz. castor sugar, $\frac{1}{2}$ teaspoonful baking powder, 1 yolk of egg, and a little cold water. Sieve the flour, add baking powder, sugar and a good pinch of salt, rub in the butter, add the yolk of egg and a little water to
air to escape Cover thic bottoin of the patry with crusts of bread so that it will keep straight while baking. Bake in a fairly hot oven 30 to 45 minutes or until a nice golden brown. Remove the crusts when donc, and fill the flan case as required.

Almost any kind of tinned, bottled or stewed fruit can be used for flans. Apples should not be allowed to stew to a mash. but are better cut in very thin slices and arranged in the tlan case in circles, the slices overlapping each other slightly. Other large fruits, such as peaches, pears and plums, may be cut in slices, but they are often used whole. Tinned pineapple slices give a prettier effect than the chunks, and cherries or other small fruits of a contrasting colour can be arranged in the holes in the centres of the slices. Slices of orange, cut crosswise through the sections, with the pith and pips removed, make a delicious flan. In this case use the juice from other tinned or stewed fruit to mako the syrup. Small fruits, such as cherries, strawberrics, raspberries, gooseberrics, red or black currants, aro always used whole.
To fill the flan case, drain the juice from the tinned or stewed fruit, and arrange the fruit in the flan case. Put the juice in a saucepan and bring to the boil. For each gill of the juice allow a teaspoonful of corntlour, blend this with a little water and add to the juice when boiling. Stir until boiling again and simmer for about eight minutes or until it thickens a little. Then add a teaspoonful of castor sugar to the gill, boil up again and let it simmer until thickened and reduced a little. Allow this syrup to cool, then pour it over the fruit in the flan case to just cover it, and leave it to get cold and set before serving. The top can be decorated just before sending to the table with little mounds of whipped cream.

FLANK : Of Bacon and Beef. The side of an animal from the ribs to the thigh is termed the flank. It is used mainly in connexion with beef or bacon. Thick flank of beef, though coarser in fibre than some other parts of the animal, is well flavoured and generally tender. It has no bone and little fat, is reasonable in price, and is therefore one of the most cconomica! parts to buy for puddings, pies. etc. Thin flank is rather fat, but is low'priced and suitable for stews. It is excellent pickled and eaten cold. See Bacon ; Becf.

FLANNEL : Its Treatment. Fabric, not made from all wool cannot legally be sold as flannel unless qualified by some other word. Ceylon flannel, for example, is an accepted name for a wool and cotton mixture, and Canton Hannel for an all-cotton cloth. Various district flannels have a celebrity of their own.
bind stiffly. Roll out Welsh Hannel, apparently the original one, is the pastry about of a slightly different character from York$t$ inch thick. Well shire, Lancashire, and Irish Hannel.

The difference lies largely in the sort of raw wool used in the several localities, as some are softer than others, and hence warmer nnd more soothing when worn next the skin. White flannels which are used for underwear arc sulphur-bleached tike blankets. Natural llannels are of a greyish or brownish mirture colouring, and this sliade originated by the intermixture of wool from brown and black sheep with white fleeces. A similar colouring is now often the outcome of mixing wool dyed for the purpose. Grey flannels arc made in several shades by blending white, blue, and black wool.

Flannels are also woven with stripes and checks in light and dark colours for men's shirts, but not all wool shirtings are strictly entitled to the name flannel.

White tlannels are made for cricket and tennis trousers in a heavier material than for shirts and underwear, and West of England flannels arc espeoially to be recommended.

The fancy flannels sold by tailors for summer suits in striped and other patterns with threads in several colours are of no constant character, although generally light, soft, and warm. They vary considerably in their capaoity to keep their shape when made into garments. Good tailors allow carefully for the shrinking propensities of the flannels they sell.
More or less all tlannels shrink upon washing, and the disposition to shrink is greatest in those made of the softest and finest wool. In dealing with baby flannels it is well to dry them by hand before the fire, counteracting the shrinkage by gently pulling out the fabric in each direction as drying proceeds. Harsh flannels shrink less because of the nature of the wool from which they are made. There are chemical processes, requiring very careful control, by which woollens can be rendeted unslirinkable, but these are not invariably efficacious or beneficial to the finished effect.
The heavy West of England flannels mode for trouserings, and for blue blazer conts, are treated slowly and laboriously in course of making, and this, while addine appreciably to the cost, adds also to the satisfaction in wear. Cheap flannels can be quickly produced which are exceedingly difficult to distinguish at first sight from the superior qualities, and dissatisfaction with them accounts in part for the superseding of tlannel by other fabrics.
The easiest method of making a llannel seam is to join the two edges of dannel with a running stitch a little more than in. from the top of the material. The right sides of the two pieces must face inwards. Ncaten the edges with sharp seissors, open and press the seam flat and turn down the edges of the Hannel on to thôir own pieces of material. Then commence from the left side, and catch the extreme edges down to tho materials by a herring-bone stitch. Flannel seanssused in the making of babies clothes, flanncl blazers, etc., are finisned with a binding of narrow silk ribbon pressed to give a nent, Hat appearance. See Blanket; Bleaching; Laundry.

FLANNELETTE. An all - cotton cheap imitation of flannel, flannelette is made in a variety of qualities, and can be had white, dyed in plain colours, and with either woven or printed designs. Some лre twilled, others plain. Countless burning accidents have occurred from leaving flannelette-clad children near an open tire, and the inflammability of the material is its greatest drawback. Almost any fabric will burn if kept in sustained contact with flame, and the objection to cheap flannelette is not that it can be burnt, but that flame leaps along its hairy surface, quickly enveloping the wearer. To guard against this risk, the first essential is a tire-
guard, and care in keeping matches out of burnt in an open tray of some kird. The which can be made at home The framework the way of young pople. The second is to simplest form is a flat lid a biscuit tin is wire or bamboo covered with trate buy a good quality of flannelette with not too much fluff on the surface.

FLASHING : Brick and Stone. This a nail, as shown in Fig. 2. This gives a噱 slope to the rpparatus, so that the is turned up into the joints of brickwork, or light of the flash is thrown well to the front into a groove or raglet, about 1 in . deep, cut in stonework. It is intended to prevent injury to the brickwork by rain splash. ing from the roof, and in addlition to form a watertight connexion between the tiling or roof covering and the adjacent brickwork. The best material for this work is sheet lead of a thickness known as 5 lb .

The flashings shown in Fig. 1 are fitted by cutting a strip of ihe lead to a suitable length, with one side cut into a series of steps equal in depth to the distance between the brick courscs. The upper edges are then bent over and ingerted into the joints between the brickwork, for which purpose the mortar has to be raked out, the metal secured with wedges, and the joint pointed in cement. The other part of the flashing is turned under the tiles or roofing material, and in good work is wurked over a board with a V-shaped fillet or tilt, upon whioh
 of the operator. A strip of touch-paper with the flash powder heaped on it provides ignition.
Two satisfactory forms of flashlight lamp are shown in Figs. 3 and 4 In the first the powder is on a tray, elevated on a cane or long stick; it is the tiles are eet. There is
 Simble cover tuashing. Fig. 3. Examples of horizontal cover fashings whioh assists in resisting thus oxtra covering fired by bringing a lighted taper into contact The stepped side known as a cover flashing is employed in a similar manner, but rests upon the top of the tiles (Fig. 2). Various arrangements of horizontal cover flashings are given in Fig. 3. The householder will do well to see that flashings against exposed brickwork are in sound oondition. See Gutter ; Rool.
FLASHLIGHT : In Photography. For photography at night, both incloors and outdoors, flashlight in the form of magnesium powder, or the mixture sold as flashlight powder, offers great possibilities. Magnesium ribbon burns too slowly; the casiest and safest form is magnesium powder, burnt by being threwn through a flame.
The apparatus consists of a narrow cup in which methylated spirit is burnt, and an inner cup in which the magnesium powder is placed. The spirit is lighted, and when the photograph is to be taken the rubber bulb is pressed firmly, blowing the powder through the Hame and giving a brilliant flash An easily contrived nome-made alternative is shown in Fig. 1, consisting of a long-stemmed clay pine, round the bowl of which is fastened a piece of wick or cotton wool with wire. This is soaked with methylated spirit. The bowl is filled with magnesium powder, the cotton wool lighted, and air blown sharply through the mouthpiece, by means of a piece of rubber tu'bing with a bulb.

Be sure that only nagnesium powder is used; if any of the flashlight mix. tures are put into this type of lamp a dangerous explosion is likely to follow.
Flashlight mixtures are perfectly safe when used correctly, but the amateur should not make them himself. Flashlight powdurs give a much more powerful light than magnesium powder. They should be

For ordinary purposes in a room with light. coloured walls to reflect the light, a heaped teaspoonful of flashlight powder will give good results with a subject not more than 10 ft . from the camera, and $a$ lens of not less than $f 8$ aperture and a fast plate. For larger rooms with lenses of fll apcrture or !ess, and ordinary films, a heaped tablespoonful should be used.

In all flashlight work indoors the utmost care must be taken to see that the flame does not come anywhere near curlains or other inflamnable material.
One great disadvantage is the smoke. The only way of getting rill of the trouble is to use an apparatus in which the smokcis traplued. Fig. 5 shows a form

## Flats: Some Hints on Furnishing

Making an Attractive Home for the Town Dweller
See the entries Bachelor Flat: Basement; also those on the various rooms, e.p. Bathroom; Bedroom; Dining Room; Kitchen. Consult too Carpet: Colour; Cooker; Cuphoard; Necoration; Electricity; Fireplace, etc.

In the future anyone who has to live can grow flowers and, plants, and, if space in the central districts of a big city seems permits, fruit trees and vegetaljes. The destined to dwell in n flat, as this type of residence appears to be on the rapid increase owing to the high cost of land and the consequent necessity for more people to live under the same roof. Specinl furniture, heating and cookery equipments are being designed for flats, with a view to increasing comfort and convenience and at the same time taking into consideration the necessity of space saving.
Advantages and Disadvantages. From the family point of view flats have certain advantages and disadvantages. The rent of a flat usually includes rates and taxes, and sometimes lighting, an arrangement which simplifies the estimating of expenditure. The initial outlay of starting housekeeping in a flat is considerably lower, as less furniture is required. The fact that all the rooms are on one floor minimises the labour of housework, compared with houses with one or more floors

Where the family are out a great deal and no regular maid is kept, the porter can rcceive parcels and take charge of the flat, thus giving a greater sense of security. Flats are particularly convenient for those who have a house or cottage in the country where they spend week-ends or holidays. A flat has a!so a distinct advantage over a house in that the latter cannot be left for long periods without getting damp, while the former, having occupied rooms either above or below, or both, remains comparatively dry

The disadvantages of flats render them less suitable residences for families where there are young children The entire lack of garden with its playing space within sight and call is a serious drawback. Nany men also dislike this absence of a garden, and the cooper-up feeling of a small flat is ol,jectionable to them. They like their oun front door and their own back garden where they

Flat. Fir. 1. Sitting room in a small flat, where comfort is allied with an effect of spaciousness llumplires \& Vera Joel
it is to keep it spotlessly clean, free of any thing likely to collect dust, and to have a place for everything, rather after the manner of a well-designed caravan. Ideas for such arrangement and equipnent will be found in the article on Kitchen.

The decoration and furnishing of larger Hats presents no particular problen It is in the case of small rooms where every inch of space has to be utilised without being overcrowded that ingenuity and good selection are required. When buying furniture it should be chosen for its practical value as well as for its decorative appearance. If it takes up too much space it will not look decorative.

A writing.desk is best selected that can give the maximum amount of drawer accomnodation, and therefore the merely beautiful writing table with cabriole legs but little storage capacity for papers will be eschewed in favour of a practical burcau or desk. The book table, the divan, the wardrobe compactuin, the sectional bookcnse, the fitted corner cupboard and dresser and the drop-end table arc all suitable pieces for flats. In very small dining rooms and dining recesses metal furniture looks well because it is suitable. A step-shaped wall bookcase, the top of one "step" at a convenient level for a reading. lamp, and that of the lowest for an occasional table, is another useful piece of furniture Rounded corners, sunken handles and flush edges are all excellent points in space-saving pieces.

The Illustrations Described. Fig. 1 shows an interesting example of a sitting room in a small flat. Comfort is ensured by the big easy chairs, with their pleasing upholstery, while the plainer surfaces of floor and painted walls give an effect of space increased by the facts that there is neither fricze nor cornice and that the ceiling is in one colour with the walls. The window and fireplace treatments are particularly good. The architrave designed for the former successfully obviates a curtain fabric pelmet, while the fireplace treatment has effectively disguised the usual ugly small mantelpiecc found in many flats of this size. Just indicated on the left of the photograph is a convenient recess fitted with shelves for books and glass.
The other illustrations are of an ordinary London flat which has been treated in a style specially designed to do all ny with superfluity and yet achieve decorative value by means of goud line and colour. The dining room end of the living-room is furnished with chairs having frames of metal tubing, red canvas being used for the backs and sents. The table and small sideboard are topped with heavy opaque glass and framed in metal. The window treatment at the other end of the room is particularly attractive, aluminium strips being substituted for pelmets, while the outer curtains are brown and the glass curtains of pale yellow voile. The walls, distempered in light buff, are left bare of pictures. The writing table is a beautifully designed but simple piece of furniture in natural oak.

Cupboards play an important part in flat comfort, and many practical suggestions will be found in the article on them (p. 324). Wherever there is avaitable space in hall, passage or bathroom it should be utilised for a cupboard in which to store linen, plate, glass and china. If the hall and passage are dark and narrow, light-coloured walls are essential to create an illusion of space; if there is an angle turn in the passage a lighting fitting placed there will illuminc both hall and passage.

Legal Points. The law governing flate is, in the main, similar to that for ordinary dwelling houses, as for legal purposes a flat is a separate house. Dealing firat with unfurnished flats, the tenant who is about to
take a flat must de. termine what his tenancy will beyearly, quarterly, or monthly. He can take a lease of a flat for a number of years or for a shorter period.

The chief thing is to have a proper agreement in which nre set forth the term of tenancy, rent, stipulations as to repairs, etc. Careful study of the agrecment before signing will prevent trouble later. Particularly should the tenant note his position in regard to repairs, the amount of rent, and period of notice required to terminate the tenancy on either side. A schedule of fix.

Flat. Fig. 3. The window treatment in the living-room of a London flat, the dining recess being shown in the illustration below ture should te provided by the landlord. Occupiers of flats e.g. bicycles, prams. All these matters are usually pay an inclusive rent, the landlorl usually dealt with in the tenancy agreement. paying all rates and taxes. Gas and electric light are usually not included in rent.
In the case of flate where a number of tenants use a common stair and eutrance, the precisc obligation of each tenant in the matter of cleaning and lighting should be clearly defined. Where there are only two or three flats in a building the tenants usually come to an arrangement as to their respective share in cleaning and lighting.
l'articular attention must he paid by tenants of Hats in the matter of nuisances. Mats should not be shaken from a window so as to canse annoyance to the tenant in the flat below. Any noise, also, that disturbs the rest of the tenants, above or below, beyond what is reasonable, constitutes a muisance, as also are late singing or playing on a musical instrument. If carried to excess and con tinued to a late hour a tenant or tenants can get a court injunction to have it stopped. A professional singer would he entitled to practise in a flat, but not at a late hour. The occupier of a flat must not leave objects on a landing so as to annoy the other tenants,

Flat. Fig. 2. Dining recess in the living-room of a
London flat. The frames of chairs and table are of chromium-plated metal tubing

In the matter of sub-letting care shou!d be taken to see whether the agrecment requires that the consent of the landlord should first be obtained. A tenant within the lient Acts who sub-lets all the premises coses the benefit of the Act, i.e. he can be turned out.

Furnished flats are preferred by many persons, and these are governed by much the same conditions as regards tenancy as unfurnished. The rent is higher, and they do not come under the Rent Act. The chief precaution here is to see that the owner or superior tenant furnishes a complete inventory of all furniture and fixtures. Household and table linen are not as a rule included thercin.
In a case where a tenant having a lease of a Hat sub-lets it to another party he is still himself liahle to the landlord for the proper upkeep and conduct of the premises. If the sub-tenant proves undesirahle he must he given notice to quit, and, failing that, a court summons must be taken out. Nost landlords will stipulate for no sulb-letting, or they will want to he satisfied as to the desirability of the sub)-tenant.

A house may not be structurally converted into flats without the permission of the local authority, though a man can let his house to two or three tenants if he wishes, provided no change is made in the structure, and call these sets of rooms flats. For rating purposes he must acquaint his local collector of his action. This conversion into flats is highly technical, and legal advice should be obtained.

FLAT FOOT: Its Treatment. This is a deformity in which the normal arch of the foot sinks and the sole tends to turn outwards, so that the person walks more on the inner border of the foot. Most frequently it is due to a gradual weakening and strctching of the ligaments and muscles which maintain the arch, from much standing. \cute cases are treated by putting the foot into plaster of Paris, thus ensuring rest for the overstretched structures.

From the outset in ordinary cases, the patient must be supplied with proper boots. These should be roony enough, and the inner side of the boot should be raised $\frac{1}{3}$ in. This is done by putting a leather wedge on the heel, the base of the wedge being on the inner side. The heel is also prolonged forwards on the inner side for 3 in. A similar wedge is put on the sole of the boot. The result is that the patient walks more on the outer side of the
foot and the ligaments-are saved from stretching. Even when his boots are off, the patient should be scrupulously careful that his weight is taken mainly on the outer side of the sole. The leg muscles should also be strengthened by tiptoe exercises, massage and electricity. A cold foot-bath at bedtime, followed by dipping the feet alternately in basins of hot and cold water, are helpful. See Foot.

FLAT IRON. In the ordinary household a flat iron is the most usual implement for ironing linen, etc., though in towns it has been largely replaced by the electric iron. Flat irons are sold by weight, and 4 lb . is a good nedium size, though the professional laundress uses hoth heavier and lighter ones. See Ironing; Laundry

FLATTING. In painting, a flat or lustreless surface is produced by the use of flatting paints. These are so prepared that they dry up with a dead surface like distemper, but with the lasting qualities of good oil paint, and when thoroughly dry and hard can be washed with soap and water. Such surfaces lend themselves to stencilled designs and similar ornamentation. Flat colours are obtainalile from any oil and colour shop. See Paint.

FLATULENCE: Its Relief. The accumu lation of gas in the stomach or intestines is a very common and troublesome affection. In the stomach it may be duc to dilation of that organ, the narrowing of the opening through which the digested food passes into the intestine, or to any other cause which allows fermentation to occur. People who cat in a hurry or do not chew their food properly, and those who allow bad teeth to remain unattended to, are frequent sufferers, and the affection is common in hysteria. Flatulence in the intestine is mostly due to fermenta. tion of food caused by bacteria in cascs of constipation.

For temporary relief any one of the following carminatives may be taken: $\frac{1}{2}$ teaspoonful of tincture of ginger in a wineglassful of warm water; 2 or 3 drops of oil of cajuput on a piecc of sugar ; $\frac{1}{2}$ to 1 teaspoonful of compound tincture of cardamoms in water; 10 to 20 grains of compound cinnamon powder.

For intestinal flatulence measures must be taken to prevent constipation (q.v.). In this form, which usually becomes troublesome tivo or three hours after a meal, intestinal antiseptics should be used. Useful drugs here are salol in five-grain cachets twice daily between meals. A pill which gives good results is made up thus, one being taken when the Hatulence is troublesome and the dose being repeated next day if necessary :

## Menthol <br> Powdered ginge <br> Glucose to make <br> . .2 grains $.26 \ddot{1}$ .8 pilis

## See Diet; Indigestion.

FLAVOURING: In Cookery. One of the most important processes in preparing a successful dish is the Havouring, which is generally added last. No hard-and-fast rule can be laid down as to quantities: the safest way is to use all flavourings sparingly, and for the cook to taste as she adds.

Where sweet dishes are concerned, the most common flavourings are vanilla, almond, and lemon. Vanilla can be procured either as an essence, of which one or two drops only are required, or in the form of a pod. The latter is boiled with the milk or other substance, and removed when the preparation is cooked. Almond easence is used in the same way as vanilla. These essences are added as the preparation is removed from the stove.
Almond flavouring is given to a custard or similar mixture by dropping a laurel leaf into the milk and bringing it to the boil. The leaf should then be taken out. Lemon rind, boiled up in the milk to be used for a custard or milk
pudding, etc., will give a delicate lemon flavouring; but care nust be taken to pare the lemon 'rind very thinly, so that none of the white pith adheres, or a bitter flavour will result. A bay leaf gives a much-liked flavour to savoury dishes, minced meat, etc., and is also used for pickled herrings.

For soups and other savoury dishes a favourite Havouring is a bouquet gami. This consists of sprigs of parsley, mint, thyme, blade of mace and a bay leaf, which are tied in muslin and put into the dish, being taken out before the dish is served. Other flavourings that are much used are nutmeg, ginger, cinnamon, allspice, mixed spice, and cloves. Celery seeds, parsley, chervil, and taragon are used as flavourings for soups and sauces, and a few drops of essence of anchovies, tomato ketchup, and mushroom ketchup are also much favoured in savoury dishes. To give a delicate onion Havour to a salad, ruo the inside of the bowl with piece of onion or garlic. See Almond; Clove: Essence; Onion: Spice, etc.
FLAX. There are some lovely garden flowers among the flaxes, suitable for the Hower garden and rockery. They tlourish

Flax. The yellow fax (Linnm favum), a charming ock garcen fower
best in well drained or rather light soil. The best two for the average garden are Linum perenne and Linum narbonense, which grow about 18 in . high and vear blue flowers in summer. Linum flavum and Linum arboreum, 10 to 12 in , high, with ycllow flowers in summer, thrive best in the rock garden. Linum grandifforum rubrum is a hardy annual with bright red flowers; from seeds sown out of doors in March-April, it blooms in July. The perennial kinds are easily propagated from seeds sown out of doors in April.
FLEA. The flea is a carrier of plague from rats to human beings. To get rid of fleas, dust the sheets with insect powder or sprinkle them with essence of peppermint. The underclothing should also be sprinkled with peppermint essence or a few drops of chloroform here and there. Dogs and cats should be washed every week or two and dusted with an insect powder. For the irritation of a flea-bite apply a dilute solution of carbolic acid or of ammonia. See Insecticide.

## Fleabane. See Erigeron.

FLEA BEETLE, This insect, also known as the turnip flea, is a minute beetle, of which there are many allied specimens. They vary in length from \& to $\frac{1}{12} \mathrm{in}$. ; the thigh joints of the hindermost legs are strongly developed, which gives them power of leaping like fleas. The most familiar and most destructive of these has a longitudinal stripe of yellow on each wing-case. The mature beetles pass the winter in hiding under any rubbish left on the

Flon Beetle. Left, matury spocimen of the curnip pest. Right, larval form also deposit white eggs in batches on the lower surface of the leaves, which hatch about ten days later. The young grubs of the flea bectle bury themselves in the tissues of the leaves upon which they feed.

The pest should be dealt with first by clearing the seed ground of all débris which will shelter the beetles in winter. If, however, the seedlings are already attacked, they should be sprayed with a solution of soft-soap, quassia, and paraffin in water. To give the seedlings a chance of surviving the attack, the sceds should have been sown thinly, a course producing more sturdy plants. A scattering of nitrate of soda, 1 oz . per yard run of row, is helpful because it encourages the seedlings to grow quickly. Many of the beetles may be captured and destroved by sweeping the seedlings with a buttertly net. Applications of lime and of soot arc beneficial. See Insecticide
FLEECE. Fleece is the coat of wool shorn from a sheep, but the word is also used to describe any soft, woolly material of a fleecy nature. The kind generally employed in dressmaking consists of a thin, machine-knitted woollen web, made specially with a view to being wire-brushed and having a fuzz of fibre teased to the surface. It is used for lining gloves, house slippers, and children's winter coats. The lining should fit the article exactly, and should be put in while the garinent is in the making, not after it is finished. See Wool.

## FIEX: In

 Electric Fittings. This word is an abbreviation for a flexible insulated wire, generally used to connect movable olectric fittings to convonio each separately insulated from the other; they are usually braided on the outside and then twisted together. Bell flex should not on any account be used for eletric lighting appliances.

Flex. Construction of flexible wire cads : above, for push-in terminals; below, for terminal auts
ground, and in spring when the seedlings of turnips appear they swarm on the young leaves, nibbling small holes in them until they become useless whicl weate or dies. The female beetles

Lighting Hex is similar, but comprises more fine strands, each of them larger in diameter than those in the bell flex, and the insulation is more robust. The heaviest form of flex wire is that known as workshop flex, and is again more substantial than ordinary lighting flex. It is usually braided on the outside over both of the wires, or may have an outer covering of a rubber compound. Such flex should be used for electric lieaters, small motors, the vacuunl cleaner, etc.

Flex should never be used if it is in a damaged condition, since, if the insulation is worn or cut, there is great likelihood of its breaking down and causing a short circuit. If the covering of the wire shows signs of wear or damage (e.g. where it enters a plug or lainp), new connexions should be made, the wire being cut back till a sound portion is reached. If the rubber insulation has perished a new length of flex should be substituted. The connexion of flex wires to electric light fittings should be done with great care. The insulating material must be removed to leave exposed the two separate bundles of stranded wires. These should be wiped with a piece of emery paper, and each bundle twisted together. The ends aro turned over at right angles and doubled back upon themselves. The wires can then be inscrted in their place in the fittings, and secured with a set screw in the usual way.

Where the flex is to be attached to a binding screw or terminal contact post, and secured by means of a nut, the wires are twisted round into the form of an eye. In either case it is essential to prevent any single strand of wire becoming separated from the rest, as this might cause a short circuit.

FLOAT: In Plastering. This tool is used by plasterers to lay on plastet and to bring it to a smooth or fine surface. It can be made from ordinary deal or other wood, but must

The ordinary fars of supply of current. drawbacks are its liability to attacks of moth is ardinary flex, as found in domestio use, and its tendency to harden into lumps. s of three types. The common bell flex Cotton flock, although neither so light nor consists of two separate stranded wires, each springy as wool flock, is said to be free from composed of a number of very fine wires, and the danger of moth, and is extensively used for be perfectly smooth in the face and very slightly rounded on the edges. The back should have a con veniently shaped handle set length ways, as Figs. 1 and 2. See Plastering.

FLOCK. The material known as flock is manufac tured from the refuse of wool or cotton, or from old cloth or rags that have been broken up by a machine called the devil Wool llock is unsed for cheaper uphol stery and mattress tery but its
 upholstery in spite of its tendency to become popular flock is that made from rags, but its employment need not now be feared, since under the Rag Flock Act (1911), the sale or manufacture of unclean flock is prohibited and rag-flock must be sterilised and purified to a standard of cleanliness laid down by the various local authorities. See Bedding; Mattress; Upholstery.

FLOCK PAPER. This name is given to a variety of wallpaper covered with Hock, or fine powder obtained from cloth and similar material. The use of flock paper for special decorative panels or miniature carpets in a doll's nouse, or to represent a lawn or grass on a model of a house, is effective. See Wallpaper.

## Floors and Floor Coverings

## Methods of Construction and Repair

Garious constructional and other articles in this work deal with the subicct of hoors and mooring, c.g. Archliecture; Board; Bungalow; Cottage: House; Joint; Wood. Sce also Amateur Carpentry; Carpet: Damp Course; Linoleum; Rubber, etc.

The importance ol a good sound Hoor to any dwelling cannot be over estimated. Health and comfort alike demand a floor that is even and level, free from draughts and immune from damp

The simplest floor is laid directly upon the earth, and many old country cottages atill have lloors of rammed earth, generally covered with bricks, stone slabs, or flooring tiles. Picturesque as they may be, such Honrs are always cold, prone to dampness, and generally very uneven. The best treatment is to remove the old tiles or bricks, excavate the earth for a depth of about 6 in., lay a good sound hed of concrete lloated off level, and re-Iny the bricks upon this foundation, after having treated the surface to a generous application of hot tar or asphalt. The bricks or tiles will be set in mortar and well grouted. Those badly worm can be laid upaide down if the under side is in gond condition. This saves buying new bricks.

Most dwelling-houses are flonred with timher, consisting of Hooring hoards averaging 1 in . in thicliness and 5 to 6 in . in width. These may have plain edges or be tongued and grooved, the latter being more rigid and draught-proof. Any wooden floor laid near the ground must be well insulated from dampness and thoroughly well ventilated. This is accomplished by first covering the whole site with a bed of concrete at least 4 in ., and preferably 6 in., thick. The appearance of such a bed ready prepared is illustrated in Fig. 1.

Two courses nre now open; one is to insulate dampness by treating the surface of the concrete with a thick coating of tar or mastic, and to lay the flooring direct upon it, having previously conted the under side of the floorboards witli some wood preservative. This method has disadvantages, including the absence of ventilation, and it resulta in a hard and unyielding surface. If the site is sloping, much making up is necessary. A damp course is needed, and adds to the expense.

Wood Floors. Taking everything into consideration, a wood lloor is best if laid on joists in the usual way. Particular attention is directed to the following points: the sleeper walls which support the plates upon which the floor-joists themselves are supported, the presence of air-bricks heneath the floorboards, and the double course of damp-course slates Figs 2, 3, and 7 show the relative arrangement of the parta

In such constructions, when the joists span the opening hetween the sleeper walls, they are known as bridging joists and the floor as a single lloor ; it is the simplest and the strongest construction. The joists are usually spaced from 12 to 15 in . apart, their size depending upon the length to be spanned without support. Sizes of timber usually adopted are 4 in . by 2 in . for the ground-floor joists of small houses with rooms a bout 12 ft . wide, provided they are supported at intervals of 4 ft . or so by a sleeper plate and a honcycomb wall or supporting piers of brickwork, topped with damp-course slates, somewhat as in Fig. 3.

The upper floors are constructed in a simila manner A wall plate of timber is set into the brickwork, and upon this are set the flooring joists, which have to be of such st rength that they can safely carry the load. Usual dimensions are 4 in. deep by 2 in thick for an opening 5 ft . wide, but when the opening or span is, say, 10 ft . wide the joists should be 6 in deep by $2 \frac{1}{2} \mathrm{in}$. wide. A 12 ft . opening requires a joist 7 in by 3 in or 9 in . by 2 in . In the latter case light diagonal struts are used in order to prevent the joists twisting sidewaye.

First-Hoor joists should be spaced 14 in apart, centre to centre, and when the joists are more than 8 ft. long they should be stiffened by herringbone strutting, made from $1 \frac{f}{2}$ in. square deal nailed hetween the inner faces of the joists. The under sides of the lloor joists are lathed and plastered or covered with heaver or other building board
The upper surface of the joists is lloored by laying the first plank against the wall and nailing it to the joista a second plank is then fitted up to the lirat and securely cramperl with flooring cramps (see Dog). and nailed to the joists, continuing until the loor is covered.
If the nails are driven through the llooring into the joists, use the regular flooring brads, 2 in. or $2 \ell$ in. long, and punch each one well down below the surface. This must be done when T. and G. (tongued and grooved) floorhoards are used, but plain edge (P.E) boards, especially when narrow, should be nailed through the edge, driving a nail at an angle of about $45^{\circ}$, as indicated in Fig. 9. This results in a snooth floor without any visible nail heads. The floor is finished by means of a plane
Trimmer Joists. When the lloor is not solid, but has an opening for a staircase, or has to be built around a fireplace or hearth, a some-

what different treatment of the joista becomen neccssary As the model by-laws prohibit the fixing of any woodwork nearer than 9 in. to any Hue, it is necessary to provide a trimmer. or brislging piece, into which the ends of the joists are fitted and secured by a joint known as a tusk-tenon Such trimmers are set securely upon wall plates, or firmly built into the brickwork, and should be at least $\frac{1}{2}$ in thicker, and of equal or greater depth. than the joists they support. Fig. 5 shows a trimming joist with trimmers tusk-tenoned.

The lloorhoards should not be terininated directly agninat a hearth or staircase opening. but should rest against n narrower board neatly mitred at the corners, and fitting around the opening. In some cases a trimmer is itself tusk-tenoned between two joists. which should be thicker than normal to carry the extra load inmposed by the trimmer. A diagonal fireplace set in the corner of a room may have a trimnier tenoned into one joist and aupported at the other end on the brick. work. Fig. 8 shows various customary arrangements of trimmers and joists and the names given.

Floorbuards should be laid in long lengths, spanning the full width of the roon, but whenever a joint lias to be made it should invariably come over a joist. ns shown in Fig. 9. The woods chietly used for house floors are onk, teak, pitch pine and deal. It is usuai to lay the boards in narrow widths, say, 4 in . to 5 in ., instend of the 6,7 , or 8 in boards of carlier days, and the finish is generally good enough to permit of polishing
Wood block floors are employed in lecterclass houses, particularly for passages, etc

Floor. Fig. 1. Concrete foor-covering befors laying joists and foorboards. Fig 2, Sleener walls, showing damp course slates, upon which foor plate and joists are laid. Fig. 3. Floor joists and sleeper walls for a ground floor. Fig. 4. Joists built into brickwork. Fig. 5. Trimmers and trimming jolst, showing tusk-tenon joint. Fig. 6. Flooring and joist around a staircase well or odening

They aresome times used in kitchons. They need a concrete foundation, and there must be some kind of bituminous shecting interposed between foundation and hlocks. Usually the under sides of the blocks are dipped in a bituminous mixture before being placed on the concrote. The wood blocks can be had in from $1 \frac{1}{2}$ to $2 \frac{1}{2}$ in. thickness. Parquet floors ( $\mathrm{Y} \cdot \mathrm{\nabla}$. ) are laid with wooden blocks, usually $t$ in. thick, some 9 in. long and 3 in . wide

Composition Flooring. For kitchen, scullery. bathroom and other rooms of these kinds, it is possible to employ a jointless composition flooring by using a plastic material which sets in 24 to 48 hours. Various colours are available, and simple designs can be worked into the material. Stone and concrete floors are used in kitchens, larders. yards, and verandas. For ordinary paving purposes natural York stone is one of the best. There are also various artificial stones made with granite chippings and Portland cement, or clinker and cement. Outhouses and sculleries are generally laid with concrete or cement.
Floor Repairs. The repair of existing floors is a frequent problem. Cement floors do not present much difficulty. The bad places should be further broken away. and deepened. all dast and dirt washed away, and the doficieney made good with strong coment mortar. If the whole surface has worn badly it will be better to hack it all over with a chisel and hammer. Then bruah the surface clean, wet it thoroughly and recoat to a thickness of at leat $\frac{1}{1}$ in. with strong coment mortar (ganged cement 1, and sharp sand 2). A hard burface, fres from dust, is obtained by using cement and fine washed granite chips, adding some reliable waterproofing composition.
To repair wood flooring cut out the bad boards and replace by now, making all joints in the length of the timber over a joist or other firm support. To cut out a tongued and grooved board without damage to the remaining boards, saw through the tongues, using a keyhole or pad saw with as fine a blade as possible. The board can be sawn across by prizing it up at one end, slipping a piece of batten underneath, and outting across the board with a tenon saw.

Decorative Floorings. The simplest mothod of deooration for a wood floor is by staining it. This may be done with one of the branded floor stains or an excellent stain can be homemade with vandyle crystals, which can be purchased cheaply from a chemist. These are melted in hot water: the amount of dilution depends on the colour required for the floor. Having thoroughly cleansed this with a strong soda washing and allowed it to dry, the stain is painted on with a good brush. The polish is not obtained until the floor has had several subscquent rubbings with a wax polish.

Bright colourings of considerable durability are obtained by the use of the floor paints sold for this purpose by most oil and colour merchants. Such paints are chiefly suitable for bedrooms. Tiles are a decorative flooring for certain types of halls, for bathrooms, kitchens and sculleries, but as they are expensive, substitutes are used, one of the most successful being tile designs in rubber fooring. Such floorings are durable, easily laid. comparatively low priced and hygionic.

Floor. Fig. 7. Diagram of prinoipa parts of a ground looz

They also lessen noise, which is a boon in many homes. Obtain. able in different qualities, these floorings are also designed in marbled and plain effects.

Besides parquet floorings, dealt with under that head ing, linoleum in its varions qualities, makes and designs provides useful floor cuvering and surrounds for carpets.
Cleaning Floors. A painted, waxed, or varnished floor should be wiped free of dust and dirt with a soft rag, and then treated to an application of crude oil and benzine. one part of oil being used to three parts of benzine. This is a good cleaning mixture which obviates the use of water, but only a small quantity should be used at a time. It should not be allowed to remain on long and should be wiped off with a woollon rag If the floor has a waxed surface, any good wax pasto can be applied, and the polishing done with a rag, brush, or polishing mop.

Grease spilt on unfinished wood such as a kitchen or pantry floor is best treated with cold water. The latter should be poured on at once. so as to harden the grease and

Fig. 8. Diagram of first floor, giving the names of the timber parts Hoor as dry as possible. See Mayonnaise. preferred. See Embroidery : Silk. fried parsley.
wet patch vigorously, working the brush the same way as the grain of the wood Then wring the cloth out of the water and wipe the

Floor Polish. Beeswax (q.v.) asually forms the main ingredient of floor polishes, but a cheap and effective substitute is to be found in tallow candle ends. To make a polish of these, melt down $\frac{1}{\frac{1}{2}}$ domen or more ends, according to size, and mix the tallow with $\frac{1}{2}$ pint each of paraffin oil and turpentine.
Horence Cream. This is a name given to a salad dressing of the mayonnaise type.

FLOSS SIIRE. Used in needlework, floss silk consists of silk fibres so lightly twisted together that the thread spreads out and gives a glossy appearance. The stitches must be short, for the silk frays easily. A 2-ply or 3-ply floss is the beat, and embroidery floss should be asked for by name, as there are many varieties of twist. Boiling colours are to be

FLOUNDER. One of the commonest of the flat fish found in English waters is the flounder. Its flesh is nutritious, and is easily digested. It should be well washed and rubbed over with salt an hour before it is to be cooked. Dry the fish well and dip it into beaten egg and then into breadcrumbe before frying it in hot fat. Serve it garaished with some

To boil a flounder put it in a fish-kettle with just sufficient water to cover. Add salt and a little vinegar to taste, then bring it to the boil and simmer gently for about ten minutes. It should be served with anchovy or parsley sauce. Flounders can also be grilled. See Grilling.

FLOUR. Fine soft powder prepared from grain, e.g. cornflour rice flour, maizo flour, wheat flour, etc. If Hour is montioned without any indication as to source, wheat Hour is implied.

Flour is described as soft or hard. Soft flour is made from wheat that has a low percentage of gluten, and that of an inelastio kind. A hard or strong prevent it from spreading. The grease may flour has a high proportion of gluten, and that then be scraped off with a knife, and the of a tough kind, which becomes elastic under affected part scrubbed with warm water and certain influences when made into dough.
washing soda. If the spot appears dark after this treatment, spread over it a pasto made from fuller's earth and water, leaving it overnight.

All floors should be well swept in the morning, and if of the polished type, rubbed with a sort duster or mop. For scrubbing purposes, a bucket of hot water, a floor-cloth, a scrubbing-brush, a mat for kneeling, and some good household or soft soap are essential. Commence is that portion of the room farthest away from the door, and with the cloth wet the arrounding boarda. Dip the scrubbingbrush into the water, rub some soep on the brietles, and scrub the

Iis. 9. Diagram illastratiog the rarious methods of fointing onds of foor boards, and of aaling them to the jolite
property of softening gluten and making it elastic. If hard flour is used it should be sifted first. If bread, or something fermented by yeast, is to be made, then only hard or strong lour may be used. The yeast possesses the property of making tough gluten very elastic, and as the yeast produces gas from the sugar of the flour, so the elastic gluten retains it, and bread of large volume is thus made possible.
The colour of tlour is in some respects dependent on the wheat used, on the method of milling, or on the grade. White wheats make white flour, and red wheats produce a yellowish tinge. If the flour has been made in a stone-grinding mill-a method very nearly extinct now-it will be darker than if made in a roller mill and, as a rule, will not keep so long sound.

For some years there has been a growing practice of bleaching flour, generally with nitrous oxide gases, but also with chlorine. This takes away the yellowish colour, but the quantity used is so minute, and there is so little left in the flour, that no deleterious effects can be discovered in the baked articles. Certain other substances, called persalts, are also used to effect a slight bleaching action, while calcium and other phosphates are sometimes added to make soft flour somewhat stronger.
Flour Hutch. Regarded now as an antique piece of furniture, this was originally used to bold flour end bread. The hutch is a form of cupboard standing on four legs and strengthaned by stretchers. The lid is on the top, and inside are usually two divisions, one for bread and the other for Hour. Most of the existing pieces are of oak. With a little ingenuity a hutch can be converted into a modern piece of furniture; for instance, a dresser. In this case a back is necessary, the hutch itself serving for the cupboard.

Flour Sifter. This term usually implies either a flour dredger, used for small quantities, or a wire sieve for langer amounts. The object is to aerate and thus lighten the flour, and to remove lumps or any foreign matter. An ordinary sifter requires shaking before the flour will pass through, but mechanical oncs are obtainable inside which, by turning a handle, wire rings are made to revolve, thus forcing out the flour. See Baking; Bread.

FLOWER BASKET. Hanging flower baskets as shown in Fig. 1 are intended to hold a potted plant, and are very useful in the garden, conservatory, or hall. They are easy to make, and provide a means of putting any waste strips of wood to a useful purpose. If deal is used, it would be best to finish with paint, leaf green being suitable. Any hardwoods could be left plain, or stained and polished with linseed oil.

Fig. 2 shows an elevation, and Fig. 3 a plan of a basket of useful size, in the making of which 20 strips similar to Fig. 4 and four strips similar to Fig. 5 will be required. The strips are intended to be $\frac{3}{} \mathrm{in}$. square, but sizes may be altered as required. The baskets are wired together, holes being bored through the long strips for the purpose. Two wires are used, one at each side, and each runs through the bottom strip and up through the corners, as shown by the dotted lines in Fig. 2. Galvanized or copper wire is most suitable, each piece being some 6 ft . long. In building up, thread the wire through two strips, and

across these thread two other strips, as shown in Fig. 6. The bottom is formed by nailing the short strips over the bottom strips, and the basket is completed by threading the remaining strips over the wires. Care must be taken to have the ends of the wire which project above of equal length; they are twisted over a stout ring, which is used for hanging (Fig. 1). See Basket Plants.

FLOWER BED. Flower beds, preferably of simple design, are made on the lawn and in other parts of the garden and filled with massed flowering plants for the purpose of ensuring a brilliant show of spring and summer bloom. They are planted in October with bulbs and spring flowering plants and late in May or early in June with others which will bloom throughout summer and autumn. See Bedding Out.

FLOWER GARDEN. The chief features of a modern flower garden are the herbaceous border, formal flower beds, rock garden, shrubbery planted chiefly with flowering shrubs, lawn, and water lily pool, with perhaps an adjacent bog garden. The little formal garden, its beds and borders intersected by paved paths, is fashionable and is generally represented even in plots of restricted size.

The principal needs of most hardy flowering plants are a sunny position and deeply dug and manured soil, and if those are provided there is every likelihood of a successful issue. The herbaceous border of hardy perennial plants is perhaps the most important feature of all, for, if planted with a representative selection, it will remain gay throughout the summer and autumn months.

Any kind of land can be made suitable for a flower garden by correct cultivation. Olayey ground is improved by autumn and winter digging and by adding such materials as lime, finely sifted coal ashes, old potting soil, sand, grit from garden paths, leaf-mould, decayed garden rubbish and wood ashes from the bonfire. Light land is improved by digging in leaf-mould, decayed garden rubbish, pieces of turf, hop manure, and stable or farmyard manure. It is better to apply the manure in spring and to fork it in lightly than to dig it in during the autumn or winter.

Planting may be done in autumn or spring or in mild weather in winter. Some of the chief hardy herbaceous perennials are lupin, delphinium, phlox, Michaelmas daisy, erigeron or summer starwort, geum, peony, pyrethrum, bellflower, columbine, sea holly or' eryngium, globe thistle or echinops, evening primrose, purple sage, mauve catmint, sliasta daisy, coneflower or rudbeckia, and perennial sunflower. The spaces between the perennial or permanent plants are fillod with gladiolus. lily, montbretia, and dahlia, and with hardy annuals, of which seeds are sown in spring. Swcet william and Canterbury bell may also be planted in autumn to bloom the following summer.
Formal flower beds on the lawn or elsewhere should be of simple design ; those of elaboratc shape cause a good deal of labour and they are not so pleasing as circular, rectangular or oval beds. It is usual to fill them with spring bulbs, wallfowers, polyanthus, forget-me-not and other early flowers by planting in October. In late May or early June these are taken up and are replaced by summer flowering plants, e.g. zonal geranium, marguerite, lobelia, tuberous begonia, snapdragon, dahlia, etc.
The rock garden must be in a sunny place, and the site must be well drained; if theso conditions are provided, and if leaf-mould, sand, grit and stone chips are added freely to the mound of soil, most of the rock garden plants will flourish.
There are so many beautiful flowering shrubs which are hardy in Great Britain that there is no longer any excuse for a shrubbery planted with uninteresting evergreens. By making a suitable selection one or another of them will be in bloom throughout the spring and summer months. Some of the chief kinds are early spring heath (Erica carnea), Forsythia spectabilis or golden bell, broom, Pyrus floribunda (flowering crab), Japanese cherries, rhododendron, azalea, laburnum, mock orange, lilac, guelder rose, bush honeysuckle or weigela, hydrangea, ceanothus and witch hazel or hamamelis.

## How to Make a Lily Pool

A water lily pool can be made a delightful featurc even of a small garden. It must be in a sunny place, for water lilies will not bloom well in the shade. Some of the small water lilies will flourish in water 18 inches or so deep, so an elaborate excavation is not necessary. By lining the sides and bottom with stones and covering thesc with oement, it is not difficult to make a watertight pool The water-lily plants should be put in mounds of soil at the bottom of the pool in early May ; the use of a few large stones will keep the plants at the bottom of the water. The moist soil at the margin. of the pool provides an ideal home for bog plants such as monkey musk, Iris siberica, Japanese primrose, and many more.

A delightful formal garden can be made by filling the beds with some of the old-fashioned flowers such as columbine, poppies, peony, mauve catmint, lavender, rosemary, pansies, snapdragons, and so on, and paving the paths with stone or brick. A sundial or bird bath might well mark the centre of the garden. If flower beds are made on the lawn they should be few in number and near the edge.

Arches covered with climbing and rambling roses and clematis add to the beauty of the Hower garden, and a trellis so placed as to provide a background to a garden seat or ornament could be covered with climbing plants. Sce Arch; Border; Carnation; Cleınatis; Climb. ing Plants; Daffodil; Dahlia; Digging; Garden ; Herbaceous Border ; Hydrangea: Lily : Pansy ; Rose, ctc.

FLOWERING CURRANT. This is the popular name of ribes, a genus which includes the gooseberry and red, white, and black currants and some useful hardy flowering shrubs. Ribes sanguineum, the common Howering currant, will thrive in shady places; it bears reddish flowers in spring. See Ribes.

FLOWERING RUSE. The common name of Butomus umbellatus, a British wild plant suitable for planting by the waterside in gardens. It grows 2 to 3 feet high, with rose-coloured flowers in summer. See Rush.

FLOWERING TREES. These are well suited to planting in small gardens, and might be used with advantage to screell unsightly surroundings. They provide shelter without casting too much shade. Autumn is the best time to plant, though the trees may be put in the ground in spring and in mild weather in winter. Some of the most orna mental are the flowering crabs (Pyrus spectabilis, Horibunda, Eleyi, and others), thorn, laburnum, Magnolin conspicua, the purple. leaved plum (Prunus pisserdi), Japanese cherries, and lilac

## Flowers and Their Arrangement

## How to Make the Most of Floral Decoration

The reader is referred to the entries on the various howers mentioned in the article, e.g. Carnation; Rose: Tulip; as well as to Bouquet; Bulb: Colour; Table; Vase, etc.

Uniess a pantry and sink are avnilable when arranging flowers, it is best to place a tray with vases and bowls on a table, the bunches of Howers on a newspaper, with another one spread at hand for rubbish : a big jug of water, scissors and a knife complete the preparations. To obviate the use of newspapers and afford complete protection to a sitting-room table, the American cloth tidy illustrated is a useful accessory to flower arrangement, and one which is quickly made. It requires a yard of brightly coloured American cloth, a cotton galon to tone, a pair of scissors attached to thic latter, and a motif of Horal cretonne applied to a corncr of the tidy by means of buttonhole stitch. (See Appliqué.)
If not arranging the flowers in a flat bowl the lower leaves should be removed, as they choke up a vase. All woody stemmed Howers, such as lilac, roses, chrysanthemums, will last better if the stalks are peeled at the ends so that they are free to absorb water.
Should flowers not seem very fresh they may be revived by being placed in quite warm water. The water should be changed at least every second day, and when flowers suddenly become limp the stalks should be cut again. If cut Howers have to be bought, it is worth remembering that they last much longer when they are just coming into their natural growing season than when they are forced or when the species are practically over for the year. Flowers also last longer in well aired rooms than in stuffy ones
Japanese Ideas. Japancse intluenoe has affected the arrangement of flowers. It is nn longer thought sufficient just to stick a bunch into a vase, but rather to make each arrangement a piece of decoration, taking into consideration the relative characters of the Howers, their supports and containers, the colour of the walls, etc., and the shape required to make a pleasing effect. Thus an arrangement

Flower Tidy made from a gard of brightly coloured American oloth, a motif \& floral cretonne being applied to a corner, as shown above on the right. The soimers are attached to the cotton galon edging

FLOWER POT. Flower pots of burnt clay are too familiar to nced description, but as nurserymen usually refer to them by name or number. tlieir sizes in inches, taken from the diameter at the top of pots, are given to prevent confusion. Thimbles, 2 in.: thumbs, $2 \downarrow$ in. : small sixties, 3 in . : large sixties $3 \frac{1}{2} \mathrm{in}$. fifty-fours, 4 in . ; forty-eights, 5 in . : forties, sometimes called small thirty-twos, $5 \frac{1}{2}$ in.: large thirty-twos, 6 in . ; twenty-fours. 8 in . sixteens, 9 in ; twelves, 10 in . The sizes may possibly vary slightly according to different. makea See Potting
off. Sweet williams also require to be massed in a wide vase or bowl, and certain other Howers, such as primroses, wallflowers, and pinks, whose great charm is in scent and colour rather than in form. Tulips are an example of Howers which require a background of wall to look their best. owing to their beauty of line.

Carnations are essentially Howers which look best with a detached treatment of bloom. In a cut-glass vase, as seen in Fig 4, they are perfectly suited. The asparagus fern softens the slightly hard effect of the stalks supported by a wire holder. Geraniums require a formal treatment and look well in a square glass with maidenhair fern. Violets also are a joy in a low crystal vase.
The decorative note is stressed in Fig. 5, an arrangement of Fire King snapdragons in a pale green jug, set on an oak window-sill and harmonising with the printed linen of the curtains. Such long-stalked summer flowers require depth of water and aro better placed in a tall jug or vase. Stocks are beautiful in a pewter tankard, as seen in Fig. 6, the pink, inauve and plum-coloured tones of the flowers and their delicate greenery contrasting exquisitely with the grey metal.

For Heavier Flowers. Where it is desired to get a beautiful effect with heary flowers or sprays of flowering shrubs, an easy method of support is the following: Choose a big, wide vase of some metal or strong pottery. Measure the top opening across and cut two strips of thin wood to fit. Lay these about $\frac{1}{\frac{1}{2}} \mathrm{in}$. apart and nail some crossway pieces about 1 in . from the end; this forms a slot. After soaking in water to make the wood swell a little, place this rough framework about 1 in . from the top of the vase, wedging it in. Because of the wedging, this method is not suitable for glass or china vases. The flowers will rest in the slot, apparently growing from the centre of the vase. Such a support could be used to assist an arrangement of mock orange blossom by the possessor of a Somerset cider jug or other large suitable receptacle, such as a big copper vase, to form the delightful empty grate screen shown in Fig. 8. Through the summer bold arrangements of foliage and tall flowers such as foxgloves, gladioli, dahlias, and Michaelmas daisies can be used in this nay to decorate a country sitting.room.

High graceful flower arrangements form entirely satisfactory corner furnishings, and particularly decorative in a dark corner are tall white flowers in \& white vase. White lilac. chrysanthemums and madonna or Harrisii lilies are all suitable for this purpose. The last named are shown in Fig. 9, brightening a dull hall. Another charming scheme for a hall window-sill is seen in Fig. 3. Here oriental poppies make a brilliant show of colour in a hammered brass vase. Nothing could give a more inviting welcome to an oak furnished interior unless it was a square tall vase of amber glass containing bronze chrysanthemums. It is a point worth noting that these flowers must be placed in deep water as, unlike certain others, do not last well in bowls.
Mixed flowers can be used to create beautiful effects for the table or to be set against a wall. Colour and shape must be well considered. Such mixtures as pink tulips, mauve irises and various kinds of the narcissus family can be well arranged together. Short stalked cottage garden flowers are delightful mixed with apparent carelessness in a green pottery bowl. Another scheme for the country room would be marigolds, cornflowers, big white daisies and field grasses in a pewter jug. Mauve lilac and pink peonies will make a handsome corner decoration. Later in the year dahlias in a pinky mauve shade will look beautiful with mauve scabious, and if arranged
a black Wedgwood bow, Fig. 2, has been achieved with the aid of such a block. and so has that of thesweet peas in Fig- 7. Again, both these flower arrangements are for a position at a table level, and the pottery bowls are well chosen to set them

flowers in the home : SUGgestions for the arrangement of many beautiful varieties. See text
in a big jar spikes of pink gladiolus may be added with excellent effect.

Winter Decoration In the winter months tall spreading arrangements of foliage and berries, such as spindle, the various barberries. cotoneasters and rowans will brighten rooms when flowers are scarce. Another floral decoration which pleases the thrifty housewife is achieved with honesty. Beautiful effects can be obtained by using the flat silvery seed pods of this old-fashioned plant in their natural state combincd with those dyed in shades of pink and mauve against a background of dark evergreens. Baskets of dried everlasting flowers are liked by some people and can be made attractive combined with statice in mauve and yellow and the introduction of sprays of conifer foliage.
The seed heads of candytuft also remain fresh for a long time in water and look charming in a silver or pewter mug against a dark background. Physalis, with its orange scarlet Japanese lanterns. will look beautiful with pine foliage and branches of larch, the stems and cones of the latter dusted with silver frost powder after the fashion of Swiss Christmas bouquets.

Packing. When it is desired to forward Howers by post it is best to cut them in theocol of the day and put in water some time before packing in a cardboard box. Layers of thin wadding between each layer of flowers help to keep then fresh, and it is a mistake not to pack as closely as possible without crushing the blooms.

Flowers for funerals should be sent to the house early on the day fixed. The old custom of using only white flowers has been modified and there is nothing to forbid the use of coloured oncs for this purpose. Roses, carnations, tulips, in fact flowers of all colours, made up into wreaths, crosses, etc., may be sent. If in the announcement of the denth it is also mentioned that no flowers are desired, such wishes naturally will be respecterd.

Pressing. Some people like to press botani. cal specimens while they are away on a holiday or at. other times, while children sometimes do this as a bobby. Such specimens are best carried in a metal case when they are picked and should be pressed shortly afterwards in a botanical press. Sheets of white blotting paper, cotton wool, photographic paste and a small paint brush are needed. For mounting the dried flowers either an album is required or the specimens may be mounted on loose sheets of thick drawing paper and stored in a cabinet obtained quite cheaply for this purpose.

FLOWER SHOW. In Great Britain July and August are the chief months for flower shows. The following suggestions are offered to those gardeners who may desire to enter the lists at the local horticultural society's show, but who do not know the way in which exhibits may be prepared and staged to the best advantage. Those interested should secure the society's schedule as soon as issued, study its various classes, and select those in which it is desired to compete. They should study the rules and send the entry form carefully filled in to the secretary well in advance of the advertised date for closing.

The next matter of importance is consentration upon the cultivation and management of those plants from which exhibits will be drawn. If cut bloom is the object in view, thesc generally will be taken from the hardy plant border. Plants selected should have lairly frequent doses of weak liquid manure, alternately with watering. Cut out all weakly flower spikes and use them for indoor decora. tion, and stimulate strong growths in order to reach perfection.

Flowers for a show are best gathered during very carly inorning. and after they have been
placed in clean, soft water should be sheltered in a cool, dark space until ready for packing. If the show is n long distance awray they should be sent in an exhibitor's hox, which will allow them to travel in good order. If the show is near at hand simply place damp moss round the stems and pack them in boxes lined with clean tissue paper.
Roses and Sweet Peas. Roses that are grown for exhibition purposes require attention not only for stimu. lating cultivation, but also for intelligent disbudding. The best blooms will need shading from bright sunshine when they are opening, bearing in mind that on the morning of the show it will be the opening bud that will be the right one to cut, as its expansion will have developed just about the time when judging is taking place. Tie a band of soft wool round the bud before cutting and do not remove it until the bloomsare staged. Always cut with long stems, and see that flowers are sprayed with clean water from a very fine sprayer.

When arranging sweet peas see that the spikes are so placed that each is clearly visible, and be careful to put only the exact number in each vase, as called for in

FLUE : In Chimney and Range. Flues are internal passage ways or channels to discharge the sinoke and fumes from a fire, foul or hot air from a room, or to supply fresh air. In a cooking range the flues are the internal channels by which the hot gases are conducted past the oven or boiler, as desired.

A brickwork construction with one or more vertical Hues is generally known as a chimney stack. A typical stack is shown in the accompanying diagram. In domestic architecture a flue is usually carried out in brickwork, and is part of the fabric of the building. Flues for gas fires may be formed in the wall itself.

In a dwelling-house a Hue deals with the smoke, conducts the heated and foul air from the room, and acts as a ventilator. Consequently it should never be closed up, unless other means of ventila. tion are provided. Most Hues have been designed for open fireplaces, intended for the use of ordinary coal, and in these cases the grate should be deeply recessed. The back should slope towards the front, so that the smoke has to curl over before ascending the fluc proper. The cross sectiona: area of the flue should be as small the show schedule. Each variety must be as possible and the sides as smooth as praccolour colour, perfect freshness is absolutely essential.
Pot specimens of such plants as fuchsias, zonal pelargoniums, tuberous begonias, etc., will require stopping or disbudding well before the show, and a safe rule is to remove all Hower stems appearing above the leaves at least a month in advance.

Most exhibitions have classes for table decoration. Points towards success are light. ness and grace combined with simplicity of colour and daintiness. Overcrowding is a fat al mistake, and it is too often forgotten that ample space should be left for diners.

Make sure that exhibita are strictly according to schedule, otherwise disqualification may follow. If a class calls for six blooms do not include seven. Cut all blooms before the sun gets on them, and they will retain their fresh. ness until the crucial moment of judging.

Do not st retch time too fine on the morning of the show, and remember that whether your exhibit is finished or not nobody will be allowed in the tent while the judging takes place. Clear up all rubbish from the neigh. bourhood of your stand, and, after putting everything in proper order, leave the tent and await results. If in doubt or difficulty go to the secretary, but do not worry this busy official unnecessarily. See Carnation; Chrys. anthemum : Rose, etc.

FLOWERS OF SULPHUR. This is another name for sublimed sulphur, which occurs as a gritty yellow powder. It is used internally as a laxative, and is especially useful in chronic constipation, piles, and chronic rheumatism. The dose is 20 to $\mathbf{6 0}$ grains, and it inay be taken with marmalade or in milk or treacle. Externally, in an ointment, it is used in scabies or itch, and in other skin complaints. In chronic rheumatism benefit may be derived from sprinkling the affected part with flowers of sulphur in fine powder and wrapping flannel bandages round. See Laxative: Sulphur
ticable, in order to present the minimum of resistance to the ascending air.
To retard down draughts and to stop the passage of rain in wet weather, all Hucs should have at least one bend with an easy slope. The height of the flue opening above the roof should be at least 3 ft . above the ridge or adjacent roofs, and in restricted areas the height can with advantage be much greater.

Ventilating flues are constructed in brickwork in much the same way as a smoke flue, but the opening is often long and narrow, as such an arrangement can be built into the cavity between two walls. Such flues terminate on the exterior in a special elbow or bent box having an opening and flap valve. Indoors the flue openings may terminate in the form of a cast-iron grating with a movable cover, permitting the flue to be opened or closed at will.
Portable coppers, central heating boilers, and fittings of a like character are usually provided with a flue pipe made of cast iron. All such flues must be kept well away from any woodwork, and, where they pass through a wall, should have a proper cast-iron wallbox or plate built in. This type of flue can economically be combined with a simple brick chimney stack, several of the iron flue pipes being conducted into the brick stack.
The Kitchen Range. A regular kitchen range, when built into brickwork, has a rather elaborate arrangement of flues. The provision of two or more flues is for the purpose of changing the direction of flow of the flames and hot air, dampers or controlling valves being provided to check or stop the passage of air through one flue, and to vary the crosssectional area of a flue. Constricting the area of the flue will, up to a certain point, increase the speed at which the hot air ascends ; hence the faster the heated air ascends the more fierce will be the fire, as more air is consumed. Further closing of the damper so far restricts
the: Hue opening that it can no longer pass sufficient air, and the fire is damped down or checked and burns more slowly. By these controlling devices the lieat from the fire can be concentrated on the oven when the oven Hue is open and the other closed, or concentrated on the hot-water hoiler, etc.

The thues need to be cleaned weekly. 'To do this, open the damper and top flues, insert the flue bruslr in each, in turn, and $t$ wist it well in every direction. Next open the rounds on the top of the hot-plate and, with the scraper and brush, gather the soot and scrape it into the dustpan. Tlie lower flues should be cleaned in the same way See Anthracite Stove; Bricklaving: Chimney: Grate Range; Stove Ventilation, ctc.

Flue Brush. A brush with a long, annealed wire handle is best for cleaning a tlue. Four strands of atout wire are tightly tivisted to grip small knots of the inaterial which makes the brush, the remaining length of twisted wire forming the handle. For everyday use a brush is made of black China bristle, and the stiffer the quality the better. A wire brush used occasionally will remove hard carbon or soot deposits and slight corrosions. Long chimney flues can bo swept out with a circular brush screwed to the top of a rod of hickory or other suitable wood; joints are made by screwed sockets, and any number of extra rods can be attached as the brush is forced up the chimney See Brush.

FLUFF. The short fibre which shakes out of beddings and is swept out of carpets is collected with the dust, and is best burnt, unless, of use for the garden. It has a value as manure and may be mixed with garden soil. The fibre assists a light soil to hold moisture and contains plant food. Woollen fluff is bought by hop farmers, being specially useful in growing hops.

Fluff from the woollen cloth mills and shoddy factories is used for stuffing cheap mattresses and furniture. A kind which makes the best stufting for pin-cushions is blanket cardings.
FLUMMERY. This makes a delicious and wholesome cold sweet. Wipe 3 lemons, chip off their rinds very thinly and lay them in a basin with $\frac{1}{2}$ pint of boiling water and $\frac{1}{2} \mathrm{lb}$. of white sugar for $\frac{1}{2}$ an hour. Then dissolve $\frac{1}{2} \mathrm{oz}$. good weight of gelatine in 2 or 3 tablespoons of hot water. Strain this to the water, and add the juice of the lemons and the yolks of 4 egis. Put this mixture into a jug, which stand in a pan of boiling water. Stir gently over the fire till the mixture thickens likic a custard. On no account overheat it. Strain it, and when cool add a glass of sherry. Serve in custard glasses

FLUSH BOX. This is a metal or wooden box or cistern used to supply a sudden rush of water to a closet. A common form comprises a galvanized iron cistern with a siphon arrangement : as the water rises in the tank the nir is expelled from the siphon box, and the contents of the tank are discharged with considerable flushing force.

The device may be used in connexion with a rain-water tank; it will then collect the rain-water as it trickles from the rain-water pipe, and store it until a sufficient quantity has been accumulated to dispel the air from the siphon box, when the contents are forcibly discharged, thus cleansing the drains. In fixing such tlush tanks there must be frce ventilation to the siphon outlet, and the pipe line must be free from a trap; if such a fitting exists it must be removed, or be provided with i ventilating pipe. See Sanitation: Water Closet.

FLUSHING. This affection is apt to be troublesome to many women at the change of life. It may be produced at other times by indigestion, eating hastily, drinking alcohol, tight lacing, and the use of tight neckwear The remedy is to avoid the nccasion of the trouble. Bromides and ichthyol are useful.

FLUSE PANELLING. In furniture this is a method of joining up stilcs, panels, eto., of wooden doors so that all are on the same plane, no part projecting in front of any other. The tops of tall pieces of furniture are often treated in this way to prevent the formation of a hollow well that tends to harbour dust behind the cornice See Door: Panelling

FLUTE : How to Play. The transverse. concert, or, ns it was formerly called, the German, flute is an instrument made cither of ebonite, cocus, or inetal. Of these matcrials,
chluride, otherwise known ns killed spirits, when it has been prepared for use by dissolv: ing in hydrochloric acid as much rinc in the form of odd little picces or cuttings as the acid can attack. Rosin and sal-ammoniac are other useful fluxes

Fluxes for brass and copper include aminonium chloride, rosin, zinc chloride Tallow or mosin are good tlu xes for lead. Zinc is soldered with hydrochloric acid as the flux, and the same acid may be used as a flux on galvanized steel. Chloride of ammonin is a good flux for soldering steel and rrought iron. The soldering of aluminium presents some litt!e difficulty, as the lluxes mentioned are ineffective. Various

Flute. Boobm concert flute, cylindrical, 28 in. Ty cocus the deleterious effects of the moist breath. The silver flute requires a less strong embouchure than the others, which recom mends it to amateurs, but on the other band its tone is not so good.
The instrument has a chromatic compass of about threc octaves divisible into three registers:
The quality of the lowest register is rather recdy The middle register, produced by increasing the air pressure, is fuller and more mellow, while the highest. produced by stil greater nir pressure, and by cross fingering, is pure and brilliant, exccpt in the extreme notes. On the whole, however, the scale is fairly even

After using, the instrument must be thoroughly wiped inside and out, especially near the joints where mointure is apt to collect. and, if not removed, to cause inevitable mischief. An oily rag passed through it now and again will help to keep it in good order, especially in hot weather, and all aprings and moving parts should be periodically cleaned and made to work freely, oiling if necessary, but with a very sparing hand. Should the holes becomo dirty, cleanse them with a soft rag or brush, but never usc anything which may in time enlarge the holes, or faulty intonation will be the result. The flute in its casc should be kept in a dry but not too warm a place.
FLUTLNG. As applied to work done on wood, stone and on silver and similar nietala Huting is the regular semicylindrical ornament with which many pieces ale decorated. Examples are often found on the pillars of candle-sticks and tho hases of teapots, and in stone, plaster or wooden pilasters and pillars. In small ivoodwork, fluting can be obtained by the use of a reeding plane, or hand beader, an inplement in the form of a spokeshave; when applied to plaster work or cement construc. tion it may be either moulded or run in with a templet or horse.

FLUX: In Metal Work. Fluxes are used in uniting metala during welding, brazing, and soldering, to prevent oxidation, to clcan the surfaces, and ensure a sound joint. A flux in common use is zinc

Fly. Above, adult house fly. Below
proprietary solders are sold for the purpose. In addition to the fluxes enumerated there are several preparations on the market. including one, in the form of a paste, that combines the properties of a flux and a solder.
The flux commonly used for silver soldering s borax, prepared by rubbing a lump on a clenn piece of slate, slightly moistened with water ; the creamy paste so produced is then applied to the parts to he jointed, and is an efficient Hux for small work. Borax may be applied in powder form. and in some cases mixed with small pieces of solder. The same flux is in extensive use for all classes of hrase brazing where spelter, or brazing wire, is employed See l3razing. Soldering: Welding.
FLY: The House Pest. The fact that, Hics arc active agents in spreading infectious diseascs is now generally recognized. In a count made of the microbes on the bodies and legs of a number of house-flies the avarage wrs found to be over a million. The diseases of which Hies are the most active carriers include typhoid fever, dysentery. tuberculosis, cholcra, and the epirlcınic diarrhoen from which lange numbers of children die in summer and early autumn.

Flies lay enormous num. bers of egge, and in hot

Foot of house-fly weather female tlies developed from the eggs may themselves be laying eggs within so short a period as threc wecks. The eggs are laid in manure. human excreta, garbage: etc.

War on the house-fly should be carried out relentlcssly by every prudent householder.

The most necessary mensures are to remove manure and garbage heaps to a distance from the house, to keep dust-bins constantly covered and to burn all vegetable and other foad waste. The dust-bin should be thoroughly washed from time to time, and then dried before using it again. In hot weather it should be disinfected once n week with some dry disinfectant. Manure or garbage herps should he sprinkled with chloride of lime.

In the larder all food must be kept in a ventiInted safe or covered with ganze. lood which must be exposed on the table or elsewhere should be protected by wire or muslin covers. Care nust he taken to keep the baby's milk frec from contamination.

Fly. Effective screen made from fine wire mesh fitted Into a frame and inserted beiow the raised sash of a window

It a dead Hy is found in the milk, the milk should not he given to the baby. Fly-papers should be placed about the larder, kitchen, and dining room, nnd other parts of the house if necessary. One device for keeping flies away is a tly screen of the type illustrated This is an adjustable screen of fine wire mesh fixed on a wooden frame, and its purpose is to prevent flies from entering
smearing the inside al a plate, a saucer, or a small ornament with a mixture containing pepper, and in verting it over two sticks or pieces of wood, leaving just room enough for the Hies to cravpl in undernenth An effective mixture for this purpose is composed of $\frac{1}{2}$ teaspoonful of ground hlack pepper with a little brown sugar and either cream or margarine, a little water being used to dissolve the sugar and make a paste Quassia chips are also em ployed, and a recipe for them is to hoil $\ddagger$ oz. of quassia chips for 10 min . in ahout a pint of water and add 4 oz of treacle or syrup. The trap should be cleaned and reset every moming. the result fully justifying the trouble taken.

Beer is frequently used in fly-traps. A recije of this kind contains a tablespoonful of beer, 2 drams of forinaldehyde, and a table. spoonful of sugar, the mixture being put into saucers with some small pieces of bread dipped in for the lies to settle on. Formalin is generally effective for the same purpose, a teaspoonful being added to a little milk in a saucer.
A useful instrument for killing flies comprises a straight handle, on which is fitted a flap made either of wire or leather. It is used by striking at the insects with the flap, which is more or less hinged. Several types are shown through an open window. In this way a free in the illustrations. The construction can current of nir can enter the room, but Hies be carried out in wire or wood. A short cannot get through the wire

Fly Papers and Repellents. A fly paper can mixture of powdered resin of paper with 』 proportion of three perts of the rain, in the of colza. It will suffice if the resin is melted over a slow fire, and the colza stirred into it to form a sticky substance, which is then applied while hot to the paper.

A somewhat different system is to repel the flies by the use of blotting paper soaked in equal quantities of oil of pennyroyal and eucalyptus oil, the pieces heing placed on the window sill or any place where the flies are likelv to enter. Another method is to sonk a sponge or some. crumpled hotting paper in hot water, and pour a little_oil of Lavender upon it.

An effective method of catching flies is to cover the top of a jam jar with a twisted piece of paper in the form of a cone, with the smaller end downwards. The flies will easily find their way in, but cannot escape, as they seem unable to get through the small end of the cone from the inside of the jar.
Another simple form of fly trap can be made by

Fly. Attracted by bait, flies enter the inner cone of the trap from beneath the overhanging metal band at base alterwards emarging through a hole the the fine wire mesh globe

F/Number. Lens front of a band mera with usual series of /numbers marked at bottom
size of the aperture of the lens, the lowest figure being the full aperture when the diaphragm is fully open They govern the speed at which the lens works, and consequently the length of the exposure. A fast and expensive lens will work at $\mathrm{f} / 45, \mathrm{f} / 3, \mathrm{f} / 2$, or even lower, while the lenses on the cheaper snapshot roll film cameras generally work at $\mathrm{f} / 8$ or $\mathrm{f} / 11$. The $\mathrm{f} /$ number of a lens represents the number of times that its diameter is contained in its focal length; thus, if the focal length of a lens is 6 in . and its diameter is 3 in., the latter divided into the former gives 8, which is the $1 /$ number The more the diaphragm or stop of a lens is closed and therefore the higher the $f /$ number, the greater the sharpness of cletail in the picture, both in foreground and distance This is called increasing the depth of focus, as explaincd under the heading Focus. The speed of the lens is directly indicated by its f/number at full aperture, one working at 1/4.5 requiring only a fraction more than a quarter of the length of exposure required by a lens working at $f / 8$; that is, the second lens, which is one often found on tilin cameras, requires an exposure 4 times longer than the first lens to give a good negative.

The usual series of $f / n u m b e r s$ or stops is in the sequence $5.6,8,11.3,16,22.6,32$, each of which requires an exposure twice that of the stop immediately preceding it. For instance, if the exposure time for $f / 8$ is known and it is necessary to stop down to $\mathrm{f} / 11$, the time of exposure is doubled: if $1 / 16$ is used it is multiplied 4 times. These are the numbers usually marked on lenses, but there is also another system, called the Uniform System, or U.S. stops. Some foreign-made lenses have numbers marked on them which are not the ordinary series, such as 6.3, 9, 12.6.
In general, the rule for the calculation of exposure for any unusual $f /$ numbers is that the time of exposure for the lowest number having been found, exposures for the other numbers in a particular serics are proportional to their squares. To do this, take the square of each ot the numbers on the lens mount, and then, taking the lowest as the unit, make a table showing the proportions of each of the other squared numbers to it. See Focus; Iens; Stop.

FOAM FLOWER. The botanical name of this hardy plant is Tiarella cordifolis. It is hardy, 10 to 12 inches high, and bears white flowers in April. It is easily grown in soil with which sand and leaf-mould have been mixed and is suitable for the rock garden or shady border. It is propagated by seeds sown in a frame in spring.

FOCAL PLANE SHUTTER. A form of shutter used in cameras, particularly reflex and press cameras, for objects moving at high speed. It consists essentially of a hlind wound on spring rollers and having transverse slits of different widths. It passes up and down immediately in front of the plate, i.e. it is at the point or plane at which the lens throws an image sharply in focus, hence the name.

The blind is arranged to work at various speeds by increasing or decreasing the tension on the spring in the roller. By varying the tension and the width of the slit used, a great variety of times of exposure may be obtained, exposures as short as $1 / 1000$ th of a second being possible.

A certain amount of practice is required for the successful use of a camera with a focal plane shutter, when snapahotting fast-moving
ohjccts, as, for instance, a cricket ball leaving a bowler's hand, or a football entering the goal. When looking at the screen of a reflex camora the tendency is always to make the exposure a fraction of a second too late, inasmuch as there is an appreciable time lietween the release of the mirror and the actual exposure. It is therefore necessary to anticipate very slightly the action to be snapped, and if the camera is properly focussed beforehand, it is best to watch the subject directly. A quick eye and a sure hand are essential; fnst plates are best See Cainera
FOCUS : In the Camera. Points to be considered with a camera lens are its focus, or focal length, and its depth of focus. The focus of a lens is that point at which, when the camera front is racked out, a clear image, sharp in detail, of the object being photographed
pin-point sharpness. Such a lens is said to have maximum depth of focus.

This is by no means an advantage, as in landscape photographs it destroys all sense of distance, and in portraits gives unpleasing resulta, making the background, for instance, as prominent as the sittor. With a long focus wide aperturc lens, working at about $1 / 4 \cdot 5$, the sharpness of focus quickly falls off, and more distant detail is greatly softened. When the maximum depth of focus is required with such a wide aperture lens, it is obtained by the simple process of stopping it down to f/ll or more.

In cheaper cameras lenses are sometimes described as being of fixed focus. This simply means that the distance between the lens and tho film cannut be varied, and when the camera is opened it will be always in focus.

is thrown on to the ground glass focussing screen or the plate. In the case of a simple lens, or a simple double lens (notananastiginat), this point is roughly Fig. 4 following way. The Foldink Table. Fir. 1. Table standing rigid : lens is racked out central not in use the top is remaed. uns is racked out wark folded upon itself. Figs. 2-4. Details until clouds, orsome far-distant object, are scen sharply on the focussing screen. The distance then found between the ground glass screen and the front surface of the lens, in the case of a single lens, and midway between the two lenses in the casc of a doublet, gives roughly the focus, or focal length of the lens.
For various purposes very difierent focal lengths are required. In the cheap folding camera a very short focus lens is generally used, which has a wide angle, and covers a large field of view, giving a picture with relatively small detail. The other extreme is scen in the telephoto lens, which has a very long focus with a particularly narrow angle. It covers a small field of view, but gives objects on the plate in relatively large scale. For ordinary purposes the amateur is best served by a medium long focus lens. Photographs taken with a long focus lens have a more natural appearance than those taken with a short one. For a camera of $\frac{1}{4}$ plate size a lens of about 0 to $\overline{7} \mathrm{in}$. focus will give satisfactory results; a 5 in . or shorter lens will give the widle angle effect referred to.
The length of focus of an anastigmatic lens cannot be measured in the fashion described above for simple lenses, because difficult optical questions arise
The depth of focus varies with the class of work which tho lens is designed to carry out, and according to its aperture as indicated by its $\mathrm{f} / \mathrm{number}$. By depth of focus is meant the distance at which all objects in the field of view are seen sharply in focus on a ground glass screen. Thus with a short focus, small aperture lens working at $f / 11$, practically everything from a point about 4 ft . away from the camera to infinity, or the farthest distance, will be rendered on the film with

Errors in Focussing. Many photorraples an spoilt by being out of focus through inaccurate judging of distance, particularly in the case of more or less hasty snapshots. The only remedy is practice. This is easily obtained if a camera with a focussing screen can be acquired, or a temporary screen of ground glass fitted to the back of a film camera in place of the film holder, care being taken to see that the ground glass is at the same distance from the lens as the surface of the film. It is necessary to see not only that the principal object is in sharp focus, but that the range of sharpness is properly distributed. A photograph will be quite spoilt if, while the principal object is sharply in focus, the foreground is fuzzy.

If it is found that photographs are obtained which are out of focus in spite of careful estimation, it is well to look to the focussing scale as a possible source of the failure. Photograph an object at an accurately measured distance with two or threc others at shoit distances in front and behind it ; a print will show the amount of error in the scale, this process being repeated for one or two other distances, and the scale corrected as necessary. Etrors in focussing are
often due to careless adjustment of the moving pointer; the pointer should be as close to the scale as possible withont rubbing, and should be viewed from immediately above and not looked at from the sidc.
The Focussing Screen. A focussing screen of a camera should be of ground glass with a very fine grain, and not tho ordinary ground glass obtained from the glazier, which is too coarse for accurate focussing. For a tem porary substitute if the ground-glass screen be brolien. use a piece of plain glass daubed with putty or conted with a thin paste of flour and water ; a fine cambric handlierchief or a sheet of tissue paper stretched tlat may be used in emergency. Sec Camera Enlarging; F/Number; Lens; Photography.

FOIE GRAS. This is the French term for the fat liver of the goose. Madc up into pâté de foic gras, it is regarded as a great delicacy. See Pâté de Foie Gras.

FOIL: In Architecture. This term is used in ornamental tracery to denote one of several almost circular lobes tangent to the inner side of an arc, and mecting each other at points called cusps. Sce Trefoil.

## Folding Chair. See Deck Clıair

FOLDING TABLE. The structural necessities of a folding table are that it shall be perfectly rigid when open, and fold away into the smallest possible conipass when not required for use ; if possible it should also have no loose parts to get lost, but this is not always practical. In Fig. I, the only loose part is the centre bar running through and between the diagonal rails To put the table away, the top is taken off and the loose bar withidrawn; this leaves the framework free to fold up, the top folding either inward or outward, and the lower part autornatically folding in tho opposite direction, forming a quite flat arrangement. The two ends are made first. These consist each of two $1 \frac{1}{2}$ in. legs with 1 in . cross rails screwed to them, as in Fig. 3; at the top is screwed another rail, which equals in width the thickness of the leg and the cross rail together. Tho diagonal rails arc rounded at the ends so as to clear the side rails when leing folded. They arc secured to the legs by nuts and bolts. with a washer

Folding Table. Fig. 5. Circular gate-ler table. Fir. 6. Top hinged over and lers foldink across each other. Fik. 7. Side view, showing by dotted lines in centre leg the position of rails of movable rate. Fin. 8. Table top, showing two stops to limit extent to which table opens
between. It will be noticed that the rails are fixed to the inside of the logs except at one of the corners, in this case at the bottom right corner (Fig. 2) : this is necessary to allow them to clear themselves.

When the whole frame has been assembled. the hole for the centre bar is bored; this may be a narrow brass rod with a knob sorewed on at each end. The top is of 1 in . stuff glued up to width cnd strengthened with battens slotscrewed to the under side; three will be sufficient for a 4 ft .6 in . table. To keep it rigid and in position four small buttons are screwed to the cross battens, as in Fig. 4, these being simply turned to release the top. Allow the top to project to the extent shown.

Folding Occaslonal Table. A small table very useful for occasional use and folding into a still smaller space is depicted in Fig. 5. The top hinges over, the legs folding across each other from the centre (Fig. 6). The legs are cut off 2 ft .4 in ., 1 in . being allowed for the top, turned according to the pattern, and then mortised to take the rails. It should be noticed that the gates fit one inside the other, so that the rails of the one will be closer together to the cxtent of tho width of the two rails. Fig. 7 shows the table open, and the position of the rails of the movable gate are shown in section in the centre leg. Having glued them together, the gates may be fixed at the centres with dowels.

A 1 in. top piece is now screwed to the one gate, as in Fig. 8, being slightly wider than the two gates when folded. and occupying in length just the space between the projection of the legs at the top To this piece the main top is hinged with three hinges. The whole job should now be opened till the gates are at a right angle and two stops fixed to the top as in Fig. 8, this being the extent to which the table should open. The contours of the turnings are most suitable for oak, but apart from this the table can be made in any wood. See Gate-leg Table ; Table.

FOMENTATION: How to Apply. A fomentation consists of a piece of Hannel or other absorbent material wrung out of boiling water. It is a very oonvenient method of applying moist heat, produces the same effects as a hot poultice, and is more easy to renew as it becomes cool. Fomentations relieve tension, pain, and spasm. They form valuable measures in intestinal colic and the intense pain attending the passage of a stone from the kidney to the bladder, or of a gall-stonc. A hot fomentation may give much relief from the pain due to a sprain. Applied to a bruise, it not only gives relief, but diminishes the subsequent discoloration.

Place a thick roller towel over a deep basin and pass a stick through each end. In the centre of the towel lay a piece of coarse flannel or a piece of blanket, folded into two or more thicknesses. Your the boiling water over the Hannel, and let it soak for a few seconds. Then twist the sticks in opposite directions, so as to wring all the water out of the flannel. The fomentation must be wrung as dry as possible and shaken out lightly. Apply it quickly to the painful part and cover it with a piece of jaconet or thin mackintosh. This should overlap the flannel by 1 in . or more all round, otherwise the fomentation will cool too quickly. Over all place a sheet of thick cotton wool. Bandage to prevent displacement. When the ohject is the relief of pain it should be changed every 20 min . The skin should be dried before applying the fresh fomentation.

A turpentine fomentation used to produce counter-irritation, as in lumbago, is made by adding 1 or 2 teaspoonfuls of oil of turpentine to a pint of boiling water, and applying as before; or the turpentine may be sprinkled on the fomentation just before it is applied. In cellulitis, whitlow, or any other aoute
suppurative condition, a fomentation prepared by adding one teasponful of glycerin of boracic acid to a pint of boiling water often gives great relief. See Bandage ; Poultice.
FONDANT, Largely used in the making of confectionery, the fondant forms the basis of many different kinds of sweets. To make it, melt 4 lb . of granulated or loaf sugar in about 4 pint of cold water placed in a saucepan over a low fire. Stir the syrup gently until the sugar is completely dissolved; then pour in 2 tablespoonfuls of liquid glucose. Cover the pan, and boil its contents rapidly for a few minutes, removing any scum. Let the syrup boil to $240^{\circ} \mathrm{F}$., continue skimming without stirring, and brush the sides of the pan occasionally with cold water. This will prevent the fondant from beooming granulated.
When $240^{\circ}$ has been reached, pour the whole on to a marble slab, which has been rinsed with cold water, sprinkle a little water on top of the fondant, and allow the latter to cool slightly before working it with a wooden spoon. When it has cooled sufficiently, it may be kneaded with the hands until it is white and smooth, and then flavoured and coloured to taste. Store it in an airtight box.
Fondant required for coating purposes should be boiled to a temperature $\bar{j}^{-}$higher.

It should be kneaded and stored in the same way, and when required for use placed in a saucepan, together with a little sugar syrup, colouring and Havouring, and melted over a low fire The fondant should be beaten all the time with a woorlen spoon, and must not be overheated. Occasionally it should be removed from the fire and beaten vigorously. Enough sugar syrup is added to make the fondant of a thick, cream-like consistency. When lukewarm, the centres for swects or small cakes which are to be coated are dipped into it and left to dry.
The sugar syrup is prepared by dissolving $1 \frac{\mathrm{lb}}{} \mathrm{l}$ of granulated sugar in 1 pint of water, then bringing it to the boil and boiling it for 5 min . in a covered pan. The lid is removed and boiling continued for 25 min . This syrup may be bottled when not required for immediate use. Fondants may be crystallized by leaving them to stand in cold crystallizing syrup for about 9 hours, and then drying them upon trays.
Fondant Icing. A quick fondant icing can be made by mixing in a pan $\frac{1}{2}$ a gill of cold water, the juice of $\frac{1}{8}$ a lemon and 1 lb . of icing sugar. Warm until a creamy liquid is formed and pour over the cake as required. See Cake; Chocolate ; Sweets.

## Food: Its Value and Preservation

## A General Survey of this Vital Domestic Subject

This article may well serve as an introduction to those on the various items of food and drink that
are found in thls work, e.g. Bacon: Beef: Bread ; Butter; Cake: Cheese; Flah; Fruit; Jam ; are found in thls work, e.g. Bacon; Beef; Bread ; Butter; Cake: Chease; Fish; Fruit: Jam ; Mutton' Pork, etc. See also Break'ast ; Diet; Digeation; Dinner

The principles regulating the proper ration. Diet. The claims of the palate must give way to soundness in dieting, and difficulty, on the score of expense, in providing a proper diet can be overcome quite well by a judicious choice of food-stuffs, as many of the cheap foods are intrinsically as valuable as the more expensive. Skilful cookery can do much to give attractiveness to food-stuffs which are not in themselves very inviting, and this is perhaps the most important factor in solving the dietetic problems of households with very limited resources.

Meat may be (1) home-fed and killed ; (2) fed abroad but killed at home ; (3) refrig. erated, or chilled ; or (4) frozen ; the last is generally mutton. The second class is that of prime animals but has probably lost fat during the voyage. The third class can be recognized by its pink fat and by the outside of the meat lacking the lustre of fresh meat. The fourth class, if unthawed, will be stiff, and, if thawed, the outside will have a faded or perhaps even a parboiled appearance, while fluid will drip or ooze from the meat, which has not the nottled appearance of fresh meat; the fat has a dull, white colour.

It should be understood, however, that chilled and frozen meat are quite as nutritious as fresh meat, and that the inferior cuts of any meat are from this point of view quite as good as the better. As regards digestibility, mutton is more digestible than beef, and beef than veal. Pork, because of its large content of fat, is difficult to digest. Tripe and sweet. breads are easily digested.
Rabbits are in season from September to February; a young animal is distinguished by its smooth, sharp claws and soft ears. The meat is easily digested. Game derives its Havour by being hung for from five to ten days, until, in fact, decomposition has begun ; this, however, has no ill consequences because the meat is dry.
In choosing a fowl an old one will be recog. nized by its stiff, horny feet, long spurs and dark-coloured thighs. The skin of a fowl should not be discoloured and the flesh should be firm. The meat of duck or grouse contains a
considerable amount of fat and is correspondingly harder to digest. The breast of a chicken is the most easily digested kind of meat. Only fresh fish should be accepted. A fresh fish is stiff, the eyes are prominent and bright and the gills are bright red. Salmon and eel contain a considerable proportion of fat, and so require good digestive powers. Owing to their cheapness, herring are one of the most valuable foods. Oysters, if raw, are vcry easily digested. Crab and lobster are difficult to digest.
The qualitics of bread are discuseed under its own heading. Macaroni and vermicelli are preparations of wheat flour and are rich in gluten. Barley has a composition like that of wheat, but it docs not form gluten. It is a good food, though barley cakes are less palatable than, and not as easily digested as, bread. To make pearl barley, the grains are deprived of the husk, rounded and polished. Barley meal consists of the whole grain ground; in Scotch, mulled or pot barley, the grains are husked and roughly ground; patent barley is merely flour formed from pearl barley. Rye makes a dark, somewhat heavy and acid loaf, not so easily digested as wheat bread.

Oatmeal contains relativcly large amounts of protein and fat and, apart from greater difficulty of digestion, is a better food than white bread. It might with advantage form a part of every dietary. Maize resembles oats in composition but is rather harsh in Havour. From it cornflour and hominy are prepared. Rice is deficient in protein, fat and salts, and therefore is mainly a starchy food. Polish. ing the rice deprives it of vitamin.

Arrowroot, tapioca and sago consist of starch simply. There are various kinds of arrowroot on the market, Bermiudan arrowroot being the best. Tapioca is got from casuava root, sago from the sago palm. When these are used as milk puddings, protein and fat are supplied by the milk. The pulses, namely peas, beans and lentils, are rich in protein, but peas and beans are rather difficult of digestion and much of the protein is not assimilated.

Potatoes contain a large proportion of starch with a little protein. Experimentally, vigorous health has been maintained on a diet
of potatoes and vegetable margarine with a flavouring of onion. But the water in which the potatoes were boiled was also taken, the potatoes being very thinly peeled before cooking. The water contains valuable salts and vitarnins taken out of the potatoes. The loss of these salts can be prevented, or lessencd. by boiling potatoes in their skins.
For convenience vegetables and fruits arc grouped in five classes according to their content of carbohydrate, which is their principal constituent as regards caloric value. Their vitamins, salts and acids are of great importance, in many cases of most importance. The carbohydrate content of each group is shown in the table of foods given below. The vege table and fruit yroups are as follows: A Cabbage, lettuce, caulitiower, sprouts, spinach, tomatoes, watercress and radishes. B French beans, onions, carrots, turnips and beets C. Strawberyies, gooseberries, oranges, peaches, pineapples and melons. D. Pears, apples, currants, raspberries, cherries, apricots, peas, parsnips and artichokes. E. Bananas, plums, prunes and potatoes.

## Constituents of some common articlea of food

By reference to this table and to the particulars given under the heading Diet as to the relatíve proportions of proteins, carbohydrates and fats in a diet, and the number of calories needed by various people, it should be possible to construct correct dietaries. These can be varied very largely to suit the family purse.
Storage and Preservation. In the storage of food cleanliness and coolness are essential. On no account should milk, fish, meat or similar fond-stuffs be kept on the floor of the larder, and they should always be covered or screened to protect them from dust and from the visits of Hies. A gauze screen is not sufficient protection against the blue-bottle, as the female deposits her eggs on the gauze and they drop down on to the meat; a piece of muslin should be placed over the meat or on the top of the gauze cover. Weighted gauze covers should be put over jugs or other receptacles containing milk, jam, etc. It is advisable that root and green vegetables should be stored separately.

Coolness may be secured by free ventilation of the larder through n gauze-screened window; by having a moistened canvas cover over a food container; by placing ice on fish, meat etc, or by placing food in an ice-chest.
Much of the food used nowadays is canned or bottled, and a considerable nmount of bottling is done in the homic. To make such food keep it is subjected to heat in the tin, in the lid of which an opening is left to nllow the escape of vapour. This opening is then soldered up, and the contraction which occurs when the tin and its contents cool usually causes the ends of the tin to bulge inwards

If the end of a lin bulges outwards it should be rejected, as the bulging is due to gasess formed by putrefaction. Such a tin is said to be blown.
Unscrupulous traders may perforate the tin, allowing the escape of the gases, then reheat and reseal. The presence of two soldered openings should therefore be viewed with suspicion. Bottled fruit and vegetables are treated similarly. Jam is usually covered after it is cold, and the surface may be sprinkled with some chemical preservative; indeed, something of this kind may be found in any kind of preserved food.

When a tin has been opened the food should be used at once; it is dangerous to allow it to stand in the tin or even, having once healed the food emplied from the lin, 10 allow it to sland.
The use of chemical preservatives for food can hardly be dispensed with, as so much food is imported, and both this and home-produced food require to be stored, sometimes for considerable periods. Some chemicals used for preserving are harmful if taken in the amounta which might well be ingested in the course of ordinary diets containing a fair proportion of preserved food. Boracic acid is an example.
The Public Health (Prescrvatives, etc., in Food) Regulations, 1925, prescribe the articles which may contain chemical preservatives and the appropriate preservative and amount of it for each. The only preservatives allowed are sulphurous acid and benzoic acid

Poisoning by Food. Food poisoning may be due to metallic poisons, copper, tin, or lead, from containers or cooking utensils, but is relatively infrequent. Strict care, however, is necessary to keep such utensils clean and not to allow foods containing acids, fatty or otherwise, to remain long in a copper utensil. Defects in the lining of a tin may cause chemical contamination of food.

Most cases of food poisoning are due to the activitics of what are called the salmonella group of bacilli, for example, bacillus aertrycke and bacillus enteritidis. The symptoms may be caused by the poisons produced by the bacilli, poisons which remain active even if the food is raised a bove the boiling point of water ; or by the living bacilli themselves.
There is vomiting, diarrboea, abdominal pain, cramps in the limbs and some fever. Vomiting and diarrhoca are usually sufficiently severe to clear the bowel, but it will be useful to aid cleansing of the stomach by giving large draughts of tepid water and, if the bowels are not acting freely, a dose of salts or of castor oil. The patient must be kept lying down and be kept warn; stimulants also may be needed. Pain and cramps should be treated by hot applications.

Another lind of bacterial food poisoning is known as botulism (q.v.).

Formerly much importance was attributed to ptomaines, alknloidal products of putrefactive organisms, but it is now clear that such poisons are destroyed in the stomach and are extremely unlikely to give rise to symptoms.

It must be borne in mind that food capable of causing poisoning is rarely offensive or in fact noticeably altered in any way.

FOOL. This is a popular variety of English sweet. The name is taken from the French word fouler, meaning to crush or bruise, and is given to stewed or crushed fruit mixed with cream or custard, and sugar. See Gooseberry; Rhubarb; Strawberry

FOOLSCAP. This word is used lot paper of a size frequently used for writing, though too large for correspondence, and for drawing. A sheet of it measures 17 in . by $13 \frac{2}{2} \mathrm{in}$. A sheet of double foolscap measures 27 in by 17 in See Drawing.

FOOL'S PARSLEY. Also known as the iesser hemlock, the botanical name of this plant is Acthusa cynapium. The leaver have beon eaten in mistake for parsley, though, as they give off a nauseous odour when rubbed together, such a mistake should not occur it is said that the roots have been eaten in mistake for young turnips. The drug bas narcotic properties, and possibly poisoning may occur from eating it. The treatment is to einpty the stomach by an emetic such as a tablespoonful of mustard in half a glass of water: Give a dose of castor oil, and then draughts of strong. hot tea, and kerp the patient warm See Poisoning.

FOOT. The bones of the foot compose threc groups: the tarsus, comprising seven bones, which form the lieel and instep; the metatarsal bones, five in number, on the fore part of the foot; and the pbalanges, of which there are two in the great toe and three in each of the others. The inner border of the great toe is in line with the inner border of the heel, and the axis of the foot is a line from the centre of the heel through the mid point of the end of the great toe

A number of deformities of the foot are caused by wearing badly-shaped boots, the usual fault being too pointed toes; but sometimes, and perbaps in addition to the first, the boots are too short. The toes tend to be crowded together, the great toe being displaced outwards (hallux valgus), and perhaps one or more of the other toes actually overriding the others Hallux valgus is likely to be accompanied by a bunion on the inner side of the joint connecting the great toc with the foot, and this joint may be inflamed and enlarged.

A short boot or one with a too high beel may give rise to hammer tocs, a condition in which the toe is bent upward at its junction with the font and bent sharply towards the sole at the joint in front of this. One or all of the smaller toes may be affected Corns form readily on these toes, and form on the toes apart from deformities when the boots are too tight. Soft corns between the toes are due to the latter being crowded together and to the spaces between not being kept clean and dry. It is obvious that the first thing in the treatment of all these conditions is to have properly fitted boots.

There are two arches in the fout, one from before backward and the other from side to side. The maintenance of the former is largely due to the long plantar ligament, the action of which resembles that of a bow-string. When the arch sinks down in flat foot (q.v.), this ligament and other structures which assist its action are stretched.

The foot is liable to several varieties of deformity besides llat foot, for example, claw foot and club foot and drop foot. Trench foot is a condition resembling frostbite, occurring in those who bave to remain for long periods with wet and cold feet, without the opportunity to remove their bonts frequently.

Ingrowing Toe Nails. The toe nails need a good deal of attention in order to keep them in good condition. Both in the case of children and of adults they should be cut regularly.
Some persons suffer from an ingrowing toe nail, a very painful condition. It is often causid
by a badly fitting boot or one with a very narrow toc The best preventive is to wear square cut boots, raised or blocked at the toes. Cut the nails straight across, never cutting the outer edges, as this only encourages the sides to grow deeper into the skin

To cure an ingrowing toe nail, insert a small pledget of cotton wool sprinkled with boracic acid under the ingrowing part. The pledget should be renewed every morning and the toc anointed with boric ointinent every night.

Care of the Feet. If the feet get very quickly tircd, and the ankles are weak, one of the best remerlies is to bathe the feet night and morning in warm water to which has been added a tablespoonful of brown vinegar or a handful of Tidman's sea salt. The feet must then be dried and well rutbed with methylated spirit or toilet vinegar.

In cases of excessive perspiration the feet should be bathed three times a day at least. and directly after exercise, in warm water to which a little disinfectant lotion has been added. After drying, a change of stockings must be made, and fine woollen stockings should the worn. It is advisable to put on clean stock ings every day until the trouble disappears. A little boric powder may be dusted into the feet of the stoci:ings before putting them on.

To prevent blisters the feet should be bathed in warm water to which either a little powdered alum, permanganate of potash or toilet vinegar has been added. In excellent powder for the purpose is made by mixing together 1 oz each of alum, rock salt and borax. A tablespoonful of this mirture can be added to the bathing water. The feet should be thoroughly dried and rubbed with methy lated spirit or toilet vinegar, particular at tention being given to the heels and the sides of the foot. A little fuller's earth dusted into the inside of the foot of the stocking is useful. If, in spite of all precautions, a blister makes its appearance, it must be carefully dressed to prevent it from sticking to the stocking or being irritated by further friction. A useful preventive is to rub the feet over with witch hazel, and dust them with talcum powder

For rhcumatic and gouty feet relief may often be obtained by means of a footbath of water as hot as can be borne, with a table spoonful or more of bicarbonate of soda added T'he feet should be soaked in it for a period varying from $\frac{1}{4}$ to $\frac{1}{2}$ hour, hot water being added to maintain or increase the heat.

Treatment of Cold Feet. Amongst infants and children indigestion and colic may result from cold feet, while in the case of adults sleeplessness is very often brought about in the same way. The underlying cause, which should be treated, may be anaemia, chronic digestive trouble, neurasthenia, etc. As a palliative thicl: woollen atockings and roomy boots (not low shoes) should be worn in winter A pair of fibre or loofah soles in the boots is an excellent preventive of cold feet. No one should go to bed with cold feet. Warming them at the fire is not free from the risk of aggravating the condition. Exercise is a better method, and has more lasting effects. Another plan is to dip the fect for one or two seconds in cold water and then rub them briskly with a warm towe
FOOT. This measure of length, one of the commonest in use, consists of 12 inches. Three feet make a yard, and there are 5,280 feet in a mile. A square foot consists of 144 square inches, and 9 square feet make a square yard A cubic foot consists of 1,728 square inches, and 27 cubic feet make one cubic yard. The usual abbreviation for both singular and plural is ft., which is used throughout this work. See Long Measure; Square Measure.
FOOT AND MOUTH DISEASE. This is the nopular name for Aphthous fever of animals. It occurs in epidemics which may be widespread. Large and small blisters appear
on the lining of the nouth and on the feet. Cattle, sheep and pigs are chiefly affected, but it may extend to other domestic animals From thein it may be conveyed to huinan beings by milk, hutter, cheese, through wounds, and by other means. It is generally a mild disease in huinan beings, usually lasting 6 or 7 days, but fatal cases do occur. Milk should be boiled when the malady prevails.

FOOTBALL. There are two kinds of foot ball, a round one used in the Assuciation game and an oval one used in the Rugby game. In both the inflated inner ball is protected by a leather covering. When the outer covering gets torn or worn through in a particular spot it can be easily repaired by sewing on a freah piece of leather. Damage to the blailder involves a little more trouble. A usual method of re pairing a puncture is to cut out a circular piece of shect rubber large enough to cover the damaged part completely and leave a nargin over. This piece is applied to the bladder with a solution of india-rubber and napbtha.
A tire repair outfit generally includes patches and solution which are suitable for repairing a football, but the solution may be purchased separately and old pieces of bicycle tire can be used to cover up the puncture. For an effective repair it is essential that pressure should be maintained until the solution has dried thoroughly, and the football should not be used for at least a day afterwards.

A practical method is to lay the bladder on a hard, Hat surface, press the patch in its place, then put a book or other flat object over the pratch, and cover the whole with an iron weight from a kitchen weighing machine, or any other available weight

Football Boots. Since the first essential of the football boot is strength, care should he taken when purchasing to examine the atitching and to sec whether there are any Haws. The best boots have several rows of stitching at each seam, and those showing any signs of broken threads, or stitches so near the edge of the leather that they fail to catch it up, should always be rejected.

Next to strength it is most important that the boots should be waterproof. To ensure this the soles of the best boots are made of first quality chome-tanned leather. There are many qualities, and it should be remem bered that the mere fact of tanning with chrome salts will not turn a poor quality hide into first-class chrome leather.

There are good makes of chrome that are not stamped, and the grain should be exam. ined for imperfections. In good leather this will be firm and even over the whole surface, and should feel firm and hard to the touch. The grain side should be entirely free from surface cracks however minute, as these indicate that the leather has probably bcen tanned from what are termed drysalted hides. A boot made from leather of this sort will quickly become cracked and perished. Chrome-tanned leather is considered to be absolutely waterproof, and is recognizable in general by its clark green oolour. football boot made of sound vegetable-tanned leather will be found almost equally serviceable, provided it is kept well greased to render it waterproof.

A good pair of boots should last several seasons, provided that they receivc proper treatinent. The leather studs on the sole should be renewed as soon as they show signs of wear, and the services of the shoe repairer
ot harness maker immediately requisitioned to make good any burst stitches After play the boots should be thoroughly dried away from the fire, all mud removed, and codd or other fish oil well worked into the leather Failing fish oil, Russian tallow or mutton fat may be used with good effect. This will keep the boots supple and waterproof, and prolong their life much beyond the average. They should be well cleansed and greased hefore: they are laid aside between seasons.
FOOT BATH. When a foot bath is talien to check a cold, or for any reason to draw blood from other parts, it should be as hot as can be borne. An ounce of mustard or a cupful of salt added to the hot water increases the heneficial effects. The legs should be covered with a blanket during the process, the fect sloould be quickly dried with a warm towel, and then coveral with a piece of warmed llannel or a pair of thicli woollen shockings.

A warm foot bath promotes sleep) and removes the feeling of tiredncss after a day's "alking. When a full bath is not talien every clay, a cold foot bath in the morning is very refreshing and keeps the feet warm in winter. Alom, or enough permanganate of potash just to tinge the water, will help to diminish the tendency to sore fect when inuch walking has to be undertaken See Bath.
FOOTMAN: The Manservant. The ndoor duties of a footinan are in some respects those of a parlourmaid, and include laying and waiting at table, answering bells, looking after the fires and lighting, cleaning the silver, and opening the door to visitors. During the earlier part of the day he will be expected to clean windows and knives, fill coal-scuttles, and clean boots. He will also be expected to valet when required and to carry micssages or letters. In large establishments several footmen divide these dutics and are under the butler.

A footman wears a livery provided by the employer. As a male servant, a footman in Great Britain requires a licence, costing 15 s . a year, and must be insured under the National Health Insurance scheme His employer is also liable for him under the Employers' Liability Acts. See Insurance; Servant.

FOOTMAN: The Piece of Furniture. The name of footman is given to an antique metal stand used for keeping plates and dishes hot in front of the firc in the dining room, and usually made of polished brass or steel. They are still used as a decorative and practical accessory on the oldfashioned hearth.

FOOT RULE. Foot rules are made of boxwood, with folding joints, or of steel, either in a single piece or jointed. They inay be from 1 to 3 ft . in length; the average is 1 ft . sub. divided into fractions of an inch, $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}$, or even as small as $\frac{1}{64}$. More accurate measurements should be taken with sucto instruments of precision as a caliper gauge or a micrometer. Boxvood rules should be kept in a dry place, and the metal joints occasionally oiled to Steel ines require oiling from time to time to prevent rusting, or they
can be nickel-plated. A folding rule with a Gimm joint can be used as a hevel square in cases of emergency.

FOOTSTOOL. This stool is made in many shapes and sizes. It may be low and circular, octagonal or square, and covered in
bead work or needlework, or in such materials as tapestry, leather, imitation leather, velvet, and carpet. It may be an oblong stool with fect and a wooden frame upon which cane or rushwork is stretched. It may extend the width of the hearth and be known as a fender stool. The modern footstool may also be amplified into a high stool to serve the double purpose of a support for the feet or a low seat. See Pouffe; Tapestry.

FORBDDDEN FRUIT. This is the popular name given to Citrus decumara. It is a good greenhouse pot-plant for decorative pur poses, flourishing in a mixture of loam and silver sand. If given an annual dressing of animal manure it does not need repotting for years. The plants may be stood out of doors during the summer months
FORCEMEAT. Forcencat is a savoury mixture, the foundation of which is breadcrumbs mixed with eggs and scasoning. It is used to stuff boned joints, veal, fowls and other birds, hares, freah haddocks. and other baked fish. Forcemeat balls are sometimes used in addition as a garnish
The following is a simple recipe for a force meat that can be used with veal. Add 4 oz of very finely-chopped suet to $\mathbf{G} \mathbf{~ o z}$. of bread. crumbs, and the grated rind and juice of hal a lemon. Season it with salt and pepper, and add a dessertspoonful of mixed herbs. Bind the forcemeat with a braten egg, and, if more moisture is necessary, add a little milk
Forcemeat Balls. To make forcemeat balla form the mixture into balls, using a little Hour if too moist, dip in beaten egg and fry golden brown. Or they can be baked in the dish with the meat with which they will be served.
Brain cakes or balls are made from calves' or sheep's brains, and are used for garnishing a calf's or sheep's head. See Brains; Breast Chestnut; Hare; Liver; Oyster; Pigeon Sausage; Veal
FORCING: In Cookery. liorcing is the process by which ornamentation of sweet or savoury dishes by cream, butter, or sugar mixtures is carried 0 ut Forcing pipes are of many varieties, and they determine the pat tern or design of the decora tion. A syringe or bag to which funnels of different shapes are attached is used. Forcing sets can be bought for a few shillings and, although the process is not easy to a novice, prac ticesoon brings mas. tery of the forcing syringe. The icing, which should be of a firm, creamy consistency, should be placed inside the syringe, about half flling it. The handle, with the pump pulled out as far as possible, is screwed on and then gently pressed downward, the icing being forced out through the funnel. See Decoration: Icing
FORCING : In Gardening. The art of bringing crops to maturity in advance of their natural season by means of artificial beat is known as forcing. In large gardens the process is usually carried out in forcing houses, scientifically heated; but it is quitc
practicable under less elaborate conditions, and out - of - scason crops niay be obtained by means of a small, warm grecnhouse, a hotbed in the open, oreven in the cellat of a dwelling-house.
Fig. 1 shows how mushrooms can be forced beneath green. house staging in soil liept in position by boards, and sceluded from light by sacks or draping tacked to the edge of the stag. ing. Seakalc, thuharb, chicory, etc. nay be foreed in this manner Other methods are shown in Figs. 2 and 6 , the former being merely a llower-pot inverted

Forcing. Examples of methoda of forcing in gardening. Explanatory details ar erot cor cork plugging the top drainage hole (a), the latter displays a box holding roots, with another turned upside down and placed on top. These three incthods arc equally useful in the greenhouse, or sheltered in a cool, dry cellar or shed.

Methods of forcing in the open air are shown in Figs 3 and 5, the former being a sectional drawing of a good type of forcing. pit, by means of which many crops may be raised with success It consists of a hotbed sunk 2 ft . deep, resting on a layer of brickbats, and boarded round the sides. A frame, some 9 in . narrower than the pit, is placed on top, with about 9 in . of soil inside. Such a pit must always be situated in well-drained land, where the manure will not get water-logged during wet periods, and during frost it should be banked round with leaves or litter, as at a.

Fig. 5 shows how rhubarb, sealiale, etc., may be forced by means of a box placed over the plant, this in turn being covered with leaves or stable litter. A hole is cut in the hottom of the box, so that growth progress may be observed at times, the hole being covered with a removable slab, as shown. Old baths, llower-pots, and other cast-off receptacles, may be used.
Fig. 4 shows how early potatocs may be secured in pots ploced in a light, warm greenhouse. A tuber is planted with a single sprout in a pot, with about the quantity of soil slown in the sketch, the pot being filled up with rich soil as sonn as the plant has grown to a height of about 6 in. See Asparagus: Frame ; Frost; Greenhouse ; Hot bed; Manure

Forcing. Figs. 1-3. Method al folding a square of greasedroof paper to forin an eflective bar fo making cream decorations. Below, bow to cu the tip of the bag, $A$, for plain piping, $B$ for leave. and C , for making stars

FORFEITS. In many children's games failure to accomplish a task set, such as guessing something, or breaking a rule, c.g. answer ing out of turn, or failing to escape from a pursuer, is punished by the offender forfeiting something, e.g. a trinket or handkerchief. At the end of the games these forfeits are called and redeemed, and the process often affords considerable amusement

One player is chosen to act as judge He may kneel or sit, but it is essential that he does not see the forfeits. These are held, one by one, over his head, and a jargon which talies vatious forms is gone through. The judge may be asked: "What is this 1 hold over your head?" or words to that effect. He in return asks whether its owner is a lady or a gentleman He is told and is then asked what the lady or gentleman who owns the forfeit must do to redeen it. Ignorant of the identity of his victim, he then pronounces sentence, and the victim must endea vour to do what he or she is ordered.

The humour of the game lics in these sentences, for they consist of silly and apparently impossible tasks, or actions likely to make the performer look foolish. Such are. bite 2 in . off the end of the poker, which is done by biting with the poker 2 in away; leave the roon with two legs and return with six, which is done by returning carrying a chair; pile two or three chairs upon each other, take off your shoes and jump over them, them referring to the shoes. The player may he told to pay a complinent to every verson in the room; to crawl under the table and hark like a dog; to answer "No" to questions put to him by each member of thecompany in turn ; to rejest a verse, stating the number of the word after saying each one; or to hold one foot in his hand and hop round the rooin.

A popular forfeit is for a person to be asked to spell the word Constantinople a syllable at a time. As soon as he gets to the letter i, all the other players shout "No," which is the following syllable. The speller, however, nalurally thinks that he has made a mistake, and begins again, only to meet with the same disconcerting shout when he reaches it the second time. Another forfeit invariably affording amusement is to require the person to langh in one corner of the room, to sing in another, to cry in another, and to whistle in the fourth. See Children's Party.

A knowiedge of elementary smith's work is of value to the amateur worker. Much can be done with a few simple tools and a homemade forge. The materials mostly used are wrought iron and mild steel. The latter may have a blue-coloured surface, when it is known as Bessemer. A cold-drawn mild steel is preferable for many purposes, as it has a clean bright surface and is better for cold working, since it avoids the necessity for much cleaning and filing.
Practically speaking, the methods here described for the hot working of the metal can be applied to cold bending, except that the metal cannot be bent to such a sharp angle when cold without risk of cracking at the bend. Wrought iron should seldom be bent cold, except when the bends are in the nature of a long ourve, and free from any suggestion of a right-angle bend. The essentials are a forge, an anvil, some hammers, and a few simple forge tools, such as tongs, which the amateur can make, one or two chisels for cutting metal, and some sets and swages, as well as a strong leg vice.
Making a Forge. The simple forge shown in Fig. 3 can be made as follows, and deals with metal up to 1 in . or so thick. The pan (Fig. 1) is made of a piece of stout sheet iron about No. 18 gauge and cut to the shape shown (Fig. 2) with a cold chisel, the sides bent up at right angles and the corners riveted together. The stand is made from four pieces of angle iron about $1 \frac{1}{2} \mathrm{in}$. by ${ }^{2} \mathrm{in}$. thick, riveted to the comers of the pan at the top, and braced together at the back and two sides with diagonal struts of flat iron strip about 1 in . wide and $t$ in. thick, riveted at the top and bottom to the angle pieces.
The bellows should be of the double action type. The outlet pipe is connected by an iron pipe to the back part of the pan, using standard iron gas fittings for this purpose, and taking care to make an airtight connexion by the use of red lead paint smeared on all joints before screwing them together. The tuyere can be purchased if desired, but an efficient substitute can be made from a short length of iron pipe screwed to the air pipe in the manner shown in the diagram (Fig. 4), and fitted with a reducing bush at the outlet end, or nozzle. The nozzleshould beabout 6 to 8 in . from the back of the pan, and nearly at the bottom.

The fire can be lighted with paper and pieces of wood in the usual way. and the bellows worked gently to draw up the fire as soon as it has taken hold. The fuel should be coke or fine slack coal, the former for preference, as there is less smoke. It must fill the pan and be heaped up in the form of a mound, and as the bellows are worked the air will escape through the fire and form a crater of intense heat. It is then known as a clear fire. and is in the required condition for working.
The iron is placed inside and covered with more fuel to exclude the cold

## Forges and Forging Processes

## Equipment and Instructions for the Amateur Metal Worker

This contribution may be usefully supplemented by reference to such entries as Bent Iron Work; Brazing; Soldering; Welding: Wrought Iron Work. See further the articles on Boring; Hardening ; Metal Work, etc.

Forge. Figg. 1 and \& Pan for a homo-made forge. Fig. 3. Pan and framowork complete. Fig. 4. 8eotion of tajdre and pipe connexions. Fig. 8. Parts
should be rounded off slightly so as not to mark the hot metal, and to assist in preventing the face of the hammer breaking away at the corners. The front edge of the face is known as the toe of the hammer, and the back or face nearest to the worker as the heel. A 3 lb cross peine hammer, or a hand sledge of about the same weight, will answer practically all requirements. A sledge hammer is only needed when a helper or striker is available, and one who is capable of handling the tool in the proper manner, otherwise the amateur had better be con. tent with the hand hammer.
A pair of flat-jawed or open-mouthed tongs, and a pair of hollow-jawed tonge can be made or purchased. Their form is shown in Fig. 7. To hold the work properly the tongs should be fitted to the thickness of the job by heating the jaws to a red heat and hammering them together while a piece of the metal to be held is gripped between the jaws, as in Fig. 6. The tongs should not be left in the fire.
Other tools that may be purchased as occasion demands are a flatter, one or two fullers, and one or two rounding tools or swages. The appearance of these can be judged from the illustrations (Fig. 8). The flatter (not shown) re-

Forge. Fig. 7. Above, round or hollow-jawed tonga below open-month tong. Fis. 8. Above, top and bottom fullers ; bolow, top and botiom, rounding tools passage of stock metal while making bolt heads sembles the top fuller, but has a large square
 The hardie hole is used to hold the shanks of the tools, and the pritchel hole to permit the and the like. The two side cdges of the face head. Flatters, fullers and swages require an are often rounded off for a short distance assistant to hold the tools. The shank of the from the horn in order to facilitate the bottom tool rests in the hardie hole of the anvil, bending of rod metal.

The best hammer for all round use is a ball peine one weighing $1 \frac{1}{2} \mathrm{lb}$. to $2 \underset{2}{\mathrm{lb}}$. The face
as shown in Fig. 11 on the next page. The vice must be a good strong one of the regular blacksmith's or leg type, as shown in Fig. 9, and in addition it must be firmly fixed to a strong bench.
Simple Manipulation. As a first attempt an angle bracket can be made, measuring 6 in . long, 4 in . wide, and from stock 1 in. wide and $t$ in. thick. Take a piece of metal of this size and at a distance of 4 in . from the end make two heavy centre punch marks, one at each side of the bar. Place the metal into the fire with these marks in the centre of the fire, and blow it to a cherry-red heat. Do not use more air than is needed to get a hot fire, as an excess of air causes scale or hard deposit on the surface of the metal. When the metal is red-hot remove it from the fire and place it on the anvil with the centre punch marks on the edge of the face, the bulk of the bar resting on the face of the anvil and the 4 in. part projecting. Hammer it over by hitting the extreme end until the metal is nearly close up to the body of the anvil, then hammer the corner to make it square and true.
It will probably be found that the bar has been knocked over so that the two legs of the angle are not in line, and this has to be corrected by placing the metal on the face of the anvil and beating it flat. Do not work on the metal after it has cooled to a black heat; it must be reheated and the work may then proceed. To flatten the angle faces, they are laid flat on the face of the anvil, and the flatter held by an assistant, while the worker
strikes the top of the Hatter with the heavy hand hammer.

The same result is obtained by careful use of the hand hammer. The metal can then be cut off to length, either with a chisel and hammer or by the use of the backsaw. While the work is being heated the greatest care must be taken not to burn the metal, this being apparent by the appearance of bright star-like sparks, or it will be useless.

All man. ner of flat bends are made in the same way. As an example of curved work, assume that it is deaired to make an S hook from meta」 about $\frac{3}{8}$ in. diameter. The first step is to cut the bar to length
 nd true up the ends by means of a file. Heat about half of the metal and, holding it in a pair of tongs, lay it on the horn of the anvil and hammer on the far side of tho horn in such a way as to bend the bar downward. Draw the bar back and forward and continue the hammering until the bar is bent nearly into a circle. Heat the other end and hammer it over as before, using the end of the horn as guide to the shaping. Then lay the hook on the face of the anvil and flatten it with a blow here and there as requisite to cause it to lie flat. If necessary, reheat the metal and lay it flat on the face, and with a few well. directed taps complete the shaping.

Both the foregoing are examples of simple bending which could be accomplished cold. The use of a forge is more apparent when the sectional area or shape of the bar is to be altered, as, for instance, when converting a round to a square. An example of this is found in a simple bolt which can be made by taking a piece of square stuff equal to the size of the head, and drawing down the bar to a round shape, This is done by hammering it over the base of the horn with the hand hammer, as shown in Fig. 10, thus increasing its length without widening it very much The bar is drawn out square, hammered on the sides and made octagonal, then rounded and finally finished with the rounding tools or swages in the manner shown in Fig. 11

Increasing the Diameter of a Bar
The process of increasing the diameter of a bar is known as upsetting, and is accomplished by holding the heated bar upright on the anvil and striking it on the end, thus reducing its length. If the heat is located at the end of the bar, and that end dropped vertically on the anvil, and then struck a blow, it will bulge out at the bottom. By localizing the heat, that is, by heating as nearly as possible at the desired spot, and cooling the adjacent parts with water, the bar will bulge at the hot part and nowhere else when it is struck on the end as shown in Fig. 12. Local swellings, as for example the eye around a bolt hole, are formed by driving a punch through the hot metal and then inserting a mandrel, or tapered piece of steel, and hammering the edges of the metal while the bar is in the hole, at the same time keeping the bar driven up into the hole (Fig. 13).
Some very effective work is accomplished by twisting a bar of hot metal. This is done by gripping the bar in the vice and twisting the other end with a strong spanner or with two pairs of strong tongs, as in Fig. 14, of a size to suit the bar being twisted. Instead of doing all the bending on the anvil, the
amateur will find that good results are given by grasping the work in the vice and then knocking over the part to be bent; but this must be done quickly (Fig. 15)

FORGET-ME-NOT. The popular name of myosotis, of which several kinds are grown in gardens. Some of them are suitable for the rockery, while others are used for tilling spring flower beds in association with bulbs The common early spring forget-me-not is Myosotis dissitiflora; it is a mistake to grow the ordinary kind, for there are modern varieties with rich blue flowers which provide a finer display. Royal Blue is one of the best.
Seeds are sown out of doors on a prepared seed bed in May, and the seedlings, once transplanted, are finally planted in autumn where they are to bloom in spring. The easiest way to raise a fresh stock of forget-menots is to lift a few old plants when the blooms have faded and replant them on a reserve border where the seeds will fall and produce numerous self-sown seedlings. Myosotis palustris, the water forget-me-not, is a beautiful Howering plant very cffective for the bog garden and water side.

One of the best rock garden forget-me-nots is alpestris; it fourishes in well-drained gritty soil and is raised from seeds sown in. a pot of light sandy soil placed in a frame in spring. The so-called New Zealand forget-me-not is Myositidium nobile, a vigorous plant 15 in . or more high, with large evergreen leaves and blue forget-me-not like flowers in summer. It is a difficult plant in many gardens and is usually happy only in the mild western maritime counties.

FORK : For the Table. Some forks are entirely made of silver or plated metal, but fruit and fish forks may have handles of ivory, mother of pearl, bone, or their substitutes. Silver forks will last a very long

Forge. Fig. 10. Drawing down a piece of metal. Fig. 11. Using the swife tools. Fig. 12. Increasing the diameter ol a Dar. Fig. 13. Forming the eye around a bolt hole. Fig. 14. Twisting a hot bar with tongs. Fig. 15. Making an angle bend in the vice
time, but electro-plated ones tend to become tarnished as time goes on.

Pickle forks are obtainable with telescopic handles, which enable them to be extended to reach to the bottom of a tall jar and obviate soiling the fingers. In choosing carving forks attention should be paid to the safety claw. In the best makes of stainless steel, the claw ensures perfect control over the joint or poultry which is being carved.

An implement exists for cleaning betwcen the prongs of a fork. It consists of a number of snall spiral brushes mounted in a wooden surface, the brushes being so placed that they just fit in between the prongs.

The table fork seldom cells for more in the way of repair than a re-shaping of bent prongs, which are easilystraightened out with a small hammer and a hardwood block. At the same time, the points may be re-sharpened, or re-shaped, with the aid of a small file. In both operations care should be exercised to avoid damage to the plate, should the fork be electro-plated, by hammering cautiously and lightly, and by only using the file in order to take off any roughness on the prong.
Carving forks, and others, such as those used for table condiments, are often made with ivory, horn, or bone handles, and these become loose and require refixing. Many of the modern forks are made with a serrated tang which is claimed to be immovable, whereas the earlier forks were nearly al ways secured by rivets passed through the handle and the tang of the fork. If the tang has been riveted and the rivet be broken, it merely requires a new rivet, and to load the hole in the handle with liquid cement-immediately prior to inserting the tang in its place. If the tang is broken off at the rivet hole, as is often the case, the amuteur will do well simply to refix the fork on to the handle by filling the hole in the handle, then pushing the fork into place, allowing it to set hard, and then drilling a small hole through the handle and the tang and securing it with a rivet.

The cement used may be composed of resin and white sand, or 6 parts of resin, $1 \frac{1}{2}$ parts of beeswax, and ith parts of plaster of Paris, dissolving this by first heating the beeswax
and resin, and then stirring in the plaster until a thin, soft paste is formed. The tang should be warmed prior to inserting it into the cement-filled hole in the handle.

Broken Guards. Carving forks frequently suffer from a broken guard. Their repair depends upon the design. Generally a flat spring sunk into a recess formed in the fork keeps the guard in place. Should this break, punch out the old pin, while holding the fork over a suitable hole in an anvil or on a block of wood or lead. Then clean out the slot and remove the old piece of spring ; obtain a new one to pattern, insert it, replace the guard, and grasp it in a vice or strong pair of pliers, using a picce of leather to prevent the fork from being scratched.

Then with the assistance of a piece of steel wire of appropriate thickness, previously prepared and pointed at one end, feel for the holes, drive the pin through, test the guard to see that it works properly, finally cut the wire off close to the fork at each side and slightly rivet up. Take care not to rivet the guard too tightly, or it will be prevented from working. See Carvers; Cutlery; Knife ; Pickle Fork; Silver; Toasting Fork

FORK : For the Garden. A garden fork is usuaily a three-pronged implement, the fork part being of iron and the shaft or handle of wood. It is used for turning up the soil, digging up potatoes, and for other work where it is more suitable than the spade. A good fork should have the handle well fastened to the prongs. It should not be left exposed to damp, as the wood may rot. See Digging; Spade.
FORM. This simple design of seat has its domestic uses Fig. 1 represents a type suitable to be made in deal. The necessary dimensions are indicated in Figs. 2 and 3. The end uprights are cut from $1 \ddagger$ in. stuff to the size given, allowing $1 \frac{1}{4} \mathrm{in}$. for the thickness of the top. At the top edges, corner notches are cut away to take the side rails (Fig. 2), which are screwed in, and a mortise cut lower down in the centre for the lower rail.
A small shoulder is cut on both edges of this rail, so that allowance must be made for this in the mortise; aiso for the wedges (Fig. 4). Having made the joints, the shapings may be cut on the ends and the three rails prepared. It will be noticed that the top rails project beyond the ends, this giving greater strength to the screws, which would otherwise be apt to break away at the ends.

When putting the job together glue the lower rail in first and wedge it, and screw the other rails on afterwards. The top may be secured by screwing from underneath, or may be nailed on if desired, in which case the nails should be punched in. For a hall the form might be stained

FORMALIN. A watery solution of formaidehyde, formalin is a powerful antiseptic. It is much used as a disinfectant, as it has the advantage of not alfecting coloured materials. Sec Disinfectant; Fumigation.

FORSYTHIA (Golden bell shrub). This is one of the finest of all early flowering hardy shrubs. In March and April the leatless branches become wreathed in yellow bell-shaped blooms. The best for the average garden is Forsythia spectabilis $6-8$ ft. high. Forsythia suspensa, which is of slender, rather drooping growth, may be planted in the open but it is better on wall ; it thrives fairly well on a shady wall but better on a sunny one. The pruning of forsythia is carried out as soon as the flowers arc over; old branches may then be cut out and others shortened. The object is to force the shrub to make fresh shoots which will bloom well the following spring. Forsythia flourishes in ordinary soil and is easily propagated by bending down the tips of branches and pegging them in the soil When firmly rooted the ends of the branches should be transplanted.

Forsythia. Spray of the brilliantly coloured flowering shrub known as the goldon bell tree

FOWL: Choosing and Trussing. In selecting a fow for roasting, ohoose one that is young and plump. Male birds are superior to hen birds for roasting; they should have big feet and knee-joints, and the claws and beak should be easily broken, while the hreastbone should be supple. If the neck and feet are very thin and a purple tinge is visible through the skin of the thigh, the bird is old. Old birds may be used for boiling or in the preparation of many made dishes, and the carcasses are excellent for improving the strength and Havour of stock for gravies and soups. An old fowl which would be tough if roasted in the ordinary way can be rendered eatahle if boiled gently for an hour and then roasted for half an hour in a moderate oven
When the hird is prepared at home, commence plucking from under the wings, then gradually work all the feathers off the bird, clearing the breast first. Care must he taken not to break the skin by dragging off the feathers roughly. Pick out the stumps remaining in the wings and legs, and singe off the hairs with a lighted piece of white paper. Lay
FOULARD. Foulards are often, but not invariably, woven with a fine twill, and are firm without being stiff or heavy. The name is given rather to the design than to the fabric itself, which may be woven of silk or mercerized cotton.
The commonest type is blue with a white bird's-eye spot. llack and brown are other favourite colourings with a white spot, which is obtained by discharging the colour, so showing the white of the original silk bencath. Oriental and conventional floral designs are also frequently used.
Cotton foulards have not the good appearance of silk, soil more quickly, and when creased do not lose their folds readily. See Silk

Foundations. See Brick; Conorete.
FOUR-STROKE or Otto Cycle. This is the term given for the cycle of operations in the most common type of internal combustion engine. The full oycle occupies two revolutions of the engine crankshaft; a cornplete operation is performed by a half-revolution of the crank, it being understood that a halfrevolution completes the full distance travelled by the piston. The sequence of the oycle is
(1) induction : the gases are drawn in by the descending piston ; (2) comnression : the gases are compressed by the rising piston; (3) explosion: the gases are fired, and force the piston down (power stroke); (4) exhaust: burnt gases are expelled by the rising piston. See Internal Combustion Engine; Motor Car; Two-Stroke.

being decorated with suitable stencils.
m. Fig. 1. Simple design for a deal form. Fig. 2. End upright, showing notches for side rails. Fig. 3. Part of side elevation. Fig. 4. Lower rail, showing wedges
the fowl on its back on a table and sever the nock where it joins the body. Remove it with the head. but leave suflicient skin in front to turn neatly underneath and cover the opening. Draw out the crop and loosen the entrails, cut across the vent and insert the fingers in the bird to find the gizzard. Pull this out, together with the remainder of the inside, and wash the neck, lieart, liver. and gizzard, cutting open the last-named and removing the bag of stones inside it. It is important that the gall-bag should be taken away unbroken, otherwise anything it touches will be bitter.
How to Truss. Before trussing the fowl, scald and scrape the fect and scaly part of the legs. Cut off the feet and throw them into the stookpot, then wipe the bird inside and out with a cloth dipped in hot water. The bird may now be stuffed at both ends with veal forcemeat, if desired. To truss the bird for roasting, twist back the wings so that they form triangles at the back; then thread a trussing needle with string and make a knot at the end. Pierce the nearest pinion, taking the needle out at the back and catching in the skin of the neck, which should be folded neatly over. Draw the needle through the pinion on the other side, then return, piercing the wing lower down and catching in the top of the thigh on each side. The needle should come out through the lower portion of the pinion. Unthread the needle, tie the two ends of the string securely, and the wings should be in slape.

To truss the logs, pass a threaded needle through the end of the thigh-bone at the back and arrange the legs nently, folding the skin of the lower portion of the bieast under them. Draw the needle back, catching in the legs, passing through the flesh and come out through the wings; then tie the string securely. If fowls are trissed without skewers they are more easily dished up, and all that is necessary to untruss them is to cut the string and pull the knotted end. To truss for boiling, loosen the skin of the legs by working it free with the fingers. Cut the bones of the feet right up to the flesh, and push the legs up into the body until they have disappeared under the thigh. The trussing
may now be completed as for roast fowl except that the stumps of the legs nust be so arranged as to be invisible. All the methods of cooking chickens can be applied to fowls. See Boning; Carving; Casserole: Chicken; Curry; Duck; Egg; Forcemeat : Giblet; Goose; Poultry; Stuffing; Turkey.

Fowl Manure. This is of great value in the garden, but it is potent and must be used with care. The best plan is to keep it under cover and to mix it with twice its bulk of soil before use. The mixture may be applied to fruit bushes, vegctables and flowering plants in spring at the rate of 3 oz . per square yard or yard run of row.

FOX: The Fur. This fur ranges in value from that of the Japanese, Kitt, Turkish, and Patagonian foxes to the more expensive white, blue, and silver. The chenper kinds are almost invariably dyed, and may be obtained in a variety of colours. The fur sold as black fox is almost always a red or white skin dyed, as the genuine black fox is rare and extremely expensive. Silver fox is also rare, and for firmness and softness it has no equal. Blue fox fur is brownish grey in colour, or, in the best specimens, a deep slate.

Arctic or white fox is considered the hest kind for dyeing purposes, as its skin is less likely than others to change colour after the process. As a white fur, however, it necds frequent cleaning, and should not be worn in a smoky atmosphere. Hot bran, rubhed into the fur and hrushed or beaten out again, is the best cleaning anedium.

Cross fox is of the same species as red fox, but its coat is marked with yellow streaks and a dark line runs down the centre of the back. Grey fox is used largely for making rugs and foothags. Fox furs generally, hecause of their softness and tendency to mat, are not recom. mended for durahility. See Fur.

FOX AND GEESE. This is an excellent game for a children's party, either indoors or out. One person, usually an adult or one of the older children, is the mother goose, while a second is the fox. The remainder form a long chain behind thie mother, with arms round each other's waists. It is then the business of the fox to catch the geese.

The mother attempts to stop him doing so by holding out her arms as widely as possible and turning him back whenever he tries to get past her. As he may only take the last member of the chain, and may not force his way past the mother, it requires considerahle agility for him to circumvent her. As the chain grows shorter the difficulty increases. The game continues until all the geese have been captured by the fox.

FOXGLOVE. The common foxglove is Digitalis purpurea, a well known plant suitable for the shady horder, and for open spaces in the woodland garden. It sows itself freely and there is usually no difficulty in maintaining a supply. Often the seedlings are so numerous as to be a nuisance. The old reddish-purple varieties are far inferior to the modern ones, and these ought to be grown. The Shirley strain of foxglove provides tall plants with fine flowers in many showy colours. The yellow foxglove also is beautiful. See Dig talis.

FOX TERRIER. This dog has quick intelligence and most of the virtues that recommend a dog for companionship in the home or on a ramble. It is true, he is properly a sporting dog, bred definitely with the object of entering a fox's earth and driving out the recluse for whom both hounds and hunters are waiting; but he adapts hinself quite easily to a domestic rôle, contenting hinself with an occasional rat-hunt or the discomfiture of tramps.

For his legitimate business he should be rather small, though the show standard
 the legs straight, the fect round and compact, the hind legs strong and muscular, with lone and powertul White should he the predominating thighs and the inarkings should be in either brindle, red, or liver colour.
There are two breeds of fox terrier: the smooth and the wire-haired. The former has a short, smooth and dense coat, of which the individual hairs are scarcely apparent. The wire-haired terrier has a similar coat, but it is overlaid by longer and harder hairs which break up the smoothness of the surface and give an entirely different appearance and feeling. See Dog.

FOX TROT. The slow fox trot, most difficult of modern dances, is of great assistance in acquiring good style and balance. Long gliding steps are employed, some taking two beats, counted "Slow" (S.), others one beat, counted "Quick" (Q.), and these, together with the correct use of contrary body movement (C.B.M.) make this dance one of graceful curves, not mercly a scries of straight steps.

The fundamental steps aro the walk and the three-step. For the walk forward, take a ong gliding step (S.) st raight from the hips, beats of music, counted Q Q.S. When moving forward, go on to heel first, rising on to ball of foot. Take second step on ball of foot, and lower as the third step forward is taken on to heel first. When moving backward, take first step on ball of foot, rising up as the second step is taken on to ball of foot and lowering the heel of this foot as the third step is taken back on to hall
Standardized figures are the feather step, natural turn (Figs 1 and 2) and reverse turn (Figs. 3 and 4)
The gentleman's feather step (S.Q.Q.S.) consists of a long step forward with right foot (R.F.), and a three-step taken as follows. Forward with left foot (L.F.), preparing to pass outside partner, forward R.F., outside partner, forward I.F., in front of partner. C.B.M. is used on the first and fourth steps. A rise is taken at the end of the first step. retained for the second and third, and dropped as the fourth step is taken. The lady's feather step commences with a long step hack with L.F. followed by a three-step, hack with R.F.,

Fox Trot. Figs. 1 and 2. Steps of the natural turn for both partners. Figs. 3 and 4. Those of the reverse turn
back with R.F. C.B.M. and rise and drop are the same as for gentleman.

The gentleman's step in the natural turn (Fig. 1) counted S.Q.Q.S.S.S., is as follows: Forward with R.F., turning on it to R to side with L.F. (commencement of three-step), still turning, back with R.F., back with L.F., turning on it to R. ; pull R.F. back to L.F., turning from $L$. heel on to $R$. heel, forward with L.F. The lady (see Fig. 2) steps back with L.F., turning on it to R., closes R.F. back to L.F., turning from $L$. heel on to $R$. heel, steps forward with L.F., forward with R.F., turning on it to R., to side with L.F., and brushes R.F. through (close to L.F.) and steps back with it. Both dancers use C.B.M. on first, fourth and sixth steps. The figure makes just over three-quarters of a turn.

The reverse turn (Figs. 3 and 4) is counted S., Q.Q.S., Q.Q.S. The genticman steps forward with L.F., turning on it to L., then takes two threesteps, the first consisting of a step to side with R.F., still turning L, back with L.F., back with R.F., turning on it to L The second three-step is taken to side with L.F., forward with R.F. outside partner, forward L.F. in front of partner. The lady steps back with R.F., turning on it to L., closes L.F. back to R.F., tuming from R. heel on to L. heel, steps forward with R.F., and again forward with L.F., turning on it to L. ; steps to side with R.F., back with L.F., and back with R.F. Both dancers rise and drop as in the ordinary three-step on the second, third and fourth steps, rise again at end of fourth and remain up for the fifth and sixth, dropping as the seventh step is taken. C.B.M. is employed on the first, fourth and seventh steps. The complete step makes just over three-quarters of a turn.

The diagrams show R.F. shaded; L.F. in outline; position of foot after turning on it, in dotted outline. To follow them faco direction of toes, turning diagrams at same time. See Dancing ; Quick Step; Waltz.

FRACTURE. The usual cause of fracture is external violence. It may bc direct. as when a cartwheel runs over a limb, or indirect, as where the jolt caused by a fall on the shoulder or elbow breaks the collar bone.

There will be sweiling over a fracture, and a shortening may occur. In the course of a few days the broken ends are connected and surrounded by a mass of soft tissue known as callus, which is later converted into bone. Strong bony union usually takes place, but, instead of bone, gristle or cartilage or simply fibrous tissue may be forined, allowing of more or less bending of the bone, and in this way constituting an un-united fracture.

First aid consists in checking dangerous bleeding by pressure on the main artery, and in the application of an antiseptic or clean dressing to the wound in the case of a compound fracture. In all fractures the ends of the broken bone must be kept at rest to prevent further damage, and if the doctor can be on the spot early, or the accident occurs indoors, this may be accomplished by

Frames for the Garden. Fig. 1. Brick frame: $a$, cement foundations b, toplight ; c compost ; d, botbed. Fig. 2. Same extended for outside heat $a$, outside walls ; $b$, hotbeds ; $c$, compost. using piliows, cushions, bricks, etc., to support and restrain the limbs. If the patient requires to be moved at once, splints should be applied, und any material may be used for the purpose if it is sufficiently rigid, e.g. sticks, umbrellas, folded newspapers, etc. When there is difficuite in obtaining splints, an upper limb may be fixed against
some sort are applied to keep the bones in their correct position. After a few days the limb is massaged each day, and the doctor makes passive movements at the joints to prevent stifiness. After some weeks the patient will make movements for himself. liefore putting the full weight of the body on a broken lower limb he should use for sone time a crutch, and later a stout stick.
The term extension for fractures means the mechanical stretching of a limb or part of a limb, and is required most often in fractures Fir. 11

Frame. Fig. 9. Poriabin garden grame with sliding lights. Figs. 10 and 11. Details ol gaides elevation. Fig. 13. Front elevation
the trunk, or the lower limbs can be tied of the shafts of the bones. One way of doing together until splints are available. The this is to fix long strips of adhesive plaster to splints should be padded with clothing or the sides of a limb, say, the leg. The ends of other soft material and should be applied the strips are attached to a horizontal piece of on the inner and outer sides of the limb.

In removing persons suffering from fractures of the thigh or leg the stretcher should be a rigid one. A door taken off its hinges would be very suitable if a stretcher has to be improvised. If a person suffering from broken thigh has to be carried uphill he should be carried feet first, and the reversc on going downhill, so that the weight of the trunk may not press down on the injured limb.

The first thing done in the treatment of a fracture by a doctor is to set or reduce it, that is, to bring the broken ends as nearly opposite to each other as is possible. Then splinis of

wood, or stirrup, a few inches below the sole of the foot. A stout cord is attached to the centre of the stirrup by drilling a hole through the latter, and is then led over a pulley and made taut by having a weight attached to its lower end. See Anklc ; Arm ; Bandage ; Colles' Frecturc; Dislocation: First Aid; Shoulder: Splint.
FRAME : For the Garden. Every gatdener realizes that a frame removes many of the restrictions which hamper his operations all the year round. It is indispensable for the raising and growing of flowers and vegetables in spring and summer, whilst during autumn and winter it is a means of rearing and preserving plints that would otherwise succumb to the first hard frost. Various types of frames are here illustrated.

It is an advantage to set the framo on a hotbed of manure or of manure and leaves; the hotbed, which can be made up in March, should project 12 inches beyond the frame.

A suitable compost, which should be 1 ft . deep in most cases, is composed of three paris loam and one part leaf-soil. Protection is necessary during sovere weather, and this may consist of sacking, mats, bracken fern, etc.

Ventilation lights should always be raised on the opposite side from which the wind blows, using wedged or stepped blocks for the purpose, similar to those shown. Watering should be done early in the day, so that foliage may be dry before night. Plants are more easily cut down by frost while their leaves ne damp). Amongst plants and seedlings for raising, growing, forcing, or bringing-on, in frames possessing a mild hotbed, are the following:
Prussels spronts, cauliflowers, celery, lettuce, mushrooms, parsley, strawberries, rhubarb, onions, tomatoes, cucumbers, early notatoes, leeks, melons, marrows, begonins, violets, pansies, hali-hurdy annuals, etc.
A handy type of emiergency frame is shown in Fig. 4. This will be found useful, as a
protection for hardening-off tender scedlings, for the growing of early salad vegetables, and for sheltering plants that will not withstand the rigour of winter.
In gardens of ample accommodation a plain brick example may be devised according to Fig 1, and if necessary by extension as in Fig. 2, in order to obtain incressed licat from hotbeds placed outside. Such a frame should be erected in a position with a south aspect. A good average size is 6 ft . wide, $2 \frac{1}{2} \mathrm{ft}$. deep at the back. and 18 in . high at the front. If a wooden frame is preferred, the dimensions may be the same.

Where the garden is small a movable frame, similar to that shown in liig. 3, is recommended. A structure of this kind, during early spring, autumn, or winter, may easily be removed to a position facing south. In summer it can be situnted in a spot screened from hot sunshine. The fourth type figured is one built of turves, with a glazed wooden top-light. Another style of turf frame is displayed in Fig. 5, a type often used for the growing of early potatoes.
A Portable Frame. Fig $\boldsymbol{y}$ shows a useful frame of convenient size which the amateur can easily construct for himself. The glazed tops are made to slide. Suggested dimensions are indicated in Figs 12 and 13 . The lower portion can be made in 1 in . matchboarding. nailed together, and with corner blocks screwed inside. At each end, and projecting just the thickness of the top, ie. 2 in., a guide is screwed from the inside, as in Figs 11 and 13. A centre slide and guide is made as in Fig. 10, and fixed to the back and front, the slide being cut into these to bring them to the same level. The water grooves formed in the slides should be carcfully noted.
The front rail of the top glazing frame is thinner than the other rails, and the glass runs right over it ; this is necessary in order to allow the water automatically to run off at the front. The frame is rebated on the inner edge and mortised together, the joints being dowelled to fix them : they should be put together with white lead paint, as glue is unsuitable. The cross-bars may be cut in the solid and rebated, or they can instead be of two pieces screwed together; in either case they are mortised into the main frame. A water gronve is cut at the under sido about $\frac{1}{2}$ in from the front to prevent the water from creeping back into the frame. If several small panes of glass be used, the upper square should overlap the lower one a hout $\frac{3}{3} \mathrm{in}$, and a tack be put at the bottom of each glass to prevent it from slipping; putty is used to secure it in the rebate. All the woodwork should receive at least two coats of paint See Forcing; Garden; Hotbed; Kitchen Garden.

FRAME AERIAL. This is a portable form of wireless receiving aerial comprising one or more turns of wire wound upon a framework which acts as a support. The received signals are strongest when the frame is rotated so that its plane lies in the direction of the transmitting station, this property being utilized commercially for direction finding. In the case of a broadcast receiver, however, the presence of metal objects, neighbouring aerials, eto., may produce large errors in the directional properties of a frame aerial.

Frame aerials are essential for portable or self-contained receivers, and they are valuable generally on account of their sharp tuning and high selectivity. The chief disadvantage of this kind of serial is its poor sensitivity, and for this reason the receiver utilizing a frame aerial should possess at least one stage of screen-grid high frequency amplifioation, and one or more stages of low frequency magnification.

Making an Aerial. A simple acrial suitable for wave lengths from about 200-550 metres, in conjunction with a 0005 condenser, can be wound upon a wooden framework having two
cross supports each 2 ft . long (see diagram) The turns are wound in saw-cuts made in ebnonite strips placed one at each extremity of the framework and secured by wood screws. The winding may consist of 14 turns of No. 22 D.S.C. copper wire (aeven turns each side and one turn per slot), all turns being continuous and in the same direction. The two ends of the winding are taken to the terminals on the vertical support. For the long waves (1,0002,000 metres) 50 turns are required. four turns being wound in each slot.

To connect the frame to an existing receiver, remove the acrial coil (also the sccondary coil if used) and the aerial and earth leads. Con-

nect the frame terminals to the grid and filament of the first valve, so that the winding is then tuned by the aerial tuning condenser See Aerial.

FRAME SAWT. A frame saw is a large flexible saw blade carried in a wooden frame which has a certain amount of "give," so that the saw blade can be tightened by turning a bottle screw. The teeth of a frame saw are coarse, as the tool is intenued for rough work, such as firewood. See Bow Saw; Saw.

FRANC:OA. These graceful plants, popularly known as bridal wreath, are not quite hardy, and are generally grown in pots for greenhouse, conservatory, and window decoration, or they are planted out in conservatories. In mild districts they may be grown out of doors all the year round; in other places they should be kept in a frame during winter. They are propagated by seeds sown under glass in spring or by cuttings. Francoa ramosa, with white flowers, is the favourite kind ; it is a perennial, 2-2! feet high.

FRANGIPANE. This perfume was intended to combine all the chief odours; it has the reputation of being the most lasting perfume made. The recipe is as follows, the ingredients being mixed and allowed to stand for a month, then filtered through absorbent paper :

FRANGIPANE CREAM FILLING. Thi is the recognized term for a filling for pastries, tarta, etc., although often other flavourings, such as vanilla, almond, and so forth, are substituted. It is made in the following way :

Melt 3 oz . of butter in a stervpan, add I pint of milk, and when nearly at boiling-point beat in $\frac{1}{2} \mathrm{lb}$. of dry sieved flour. Beat this well together until smooth. Stir and cook it over a gent le heat for a few ininutes, or until it leaves the sides of the pan without sticking. Cool it for a few minutes, then beat in scparately 2 whole eggs and 2 extra yolks. When well blended add 4 oz of castor sugar, and some flavouring essence. When cold it may be used as desired for filling tartlets, cakes, eto.

FRAUD. Fraud is sometimes a criminal offence. For instance, obtaining goods or money by fraud is a crime. It is also a civil wrong, giving rise to an action for damages.

Fraud consists in making a statement of fact knowing it to be untrue, or with wilful or reckless disregard as to whether it is true or not. If such a statement is made with intent that it shall be acted upon, and the person acting upon it suffers loss, it is an actionable fraud. If the person making a false statement honestly believes it true, he is not guilty of fraud.

There is ono excoption, namely, a falsc statement made in a company prospectus. In such a case, when the state ment is proved to be false, every director, promoter, or other person responsible for the prospectus is liable in damages unless he proves that he had an honest-and reasonable belief in the truth of the statement.

Any contract in duced by fraud may be avoided by the innocent party. He
Frame Aerial. Left, simple aerial which can be made by the wireless enthusiast. The dimensions of the framework are shown in the diagram above can resist any claim made against him on the contract or can have the transaction set aside, and claim the return of anything paid or transferred under it. But he must be careful to take steps to set it aside as soon as he knows of the fraud. If he does not, or if it is im possible to put the parties back into the original position, the transaction will not be set aside, but the innocent party will be left to his remedy in damages

FRECKLES: Their Treatment. For freckles the following remedy is for outward application only, to be applicd at night.
 Glycerin
Sort parallu
A lotion which is intended to be applied to the exposed parts of the face, neck, hands, and arms before going out into the strong sun light, and which speedily dries, leaving little trace of grease, is made up as follows :
Zinc oxide
dra!n!
Pow dered calamine
Olive oil
Solution
Solition of ammonla

The following bleaching lotion applied daily with a camel-hair hrush has the effect of lightening the colour of the freckles. It should be kept tightly corked

See Beanty Culture; Face; Skin.

FREEHOLD. In old English law this is the latter being a combinaone of the ways in which land is held, others tion of free whoel and back being copyhold and leasehold. Frcehold land is the nearest approach to absolute ownership that is recognized by the law. Such land cannot be held by a definite term of years as leasehold can, but must be for an indefinite term or in perpetuity. The owner of it is sub. ject, therefore, to no dues except the ordinary rates and taxes. If he huilds a house upon it he is the absolute owner of house and land.

In 1925 an Act was passed which provided for the abolition of copyhold and other antique tenures in England at the end of three years, and therefore for the establishment only of frechold and leaschold land-holding. See Houre; Land; Leasehold.

FREESIA. These greenhouse winter and spring-flowering bulbs are much admired for their delicate flowers and sweet scent. As they may be grown in small pots, they are suitable for small greenhouses and also for windows. Many people purchase fresh bulbs every year, but this is unneccssary if ripening and drying the bulbe is properly carried out. The bulb should be potted in July or early August, putting about six in a 5 in pot. One pot of freesias is enough for a room. The best soil is a compost of 3 loam and of each of sand and well-decayed cow manure. Cover the bulbs with $\frac{1}{2} \mathrm{in}$. of this mixture. Place them in a cold frame and growth will he evident in a few wecks. Keep the plants close to the light and water very lightly, increasing the quantity as growth develops Hard forcing is not desirable. After Howering, water frcely until the leaves turn yellow, decreasing the

Fresis. Flowers and leaves of one of the new coloured varieties supply as the leaves die down. They are easily increased by off. sets in August.

In recent years many charming new varieties in a wide range of colour have been raised. There are now mauve, heliotrope, crim. son, rose and orange colour. ed freesias. Most of these later varieties are less fragrant than the old white and yellow ones.
FREESTONE : For Building. Any building stone that can be dressed easily or freely is called frecstone; it is generally taken to be the most easily worked stone in a given district. The surface finish can be varied according to the tools employed, and the beds or joints are left rough to prevent slipping, and to provide gtip for the mortar.
The principal varietics of freestonc in common use are termed the quarry-faced, which is the natural face of the stone as it comes from the quarry; hammer-faced, with the lumps knocked off with a hammer; and chiselled, wherc the surface is rough and the marks of the tool irregular. When the surface is smoothed and finished it is known as toolcd. Rusticated freestone is worked over with chisels in imitation of old and decayed stone, and is capable of producing a very pleasing surface if treated on broad lines and on large areas. See Stone.

FREE WHEEL. This is a device on a cycle by which a rider is enabled to keep the pedals stationary, thus allowing the machine to coast while at the same time a restful position is maintained on the saddle. Differing types are the ratchet, the roller, and the coaster hub perdalling brake.

In the first mentioned type of free wheel; ratchet teeth are cut on the inner circumference of the chain ring, and a number of pawls are mounted flush on the outer circumference of the inner member, which latter is serewed on to the hub of the wheel. These pawla engage the faces of the ratchet teeth, thereby transmitting the drive from the chain ring of the wheel.

In the roller or wedge type of free wheel, the inner circumference of the chaill ring is ground quite smooth. The rollera, usually five, are
on the onter circumference of the inner mem thereby driving the wheel. faces. As a general rule the chain ring runs on a double ring of balls, the races for which arc formed on the inner faces of the cover plates and the faces of the chain ring.

The chief essential with all types is to cnsure freedoin of movement of the paits, and to this end the free wheel should be lubricated at in. tervals, say every 250 miles or so. It is advisable to wah out the free wheel oceasionally with paraffin. To do this properly, lay the machine on its side and apply the paraftin while at the same time rotating the whecl, and keeping

the pedals sitationary. Leave the machine to drain, then oil the free wheel. See Bicycle; Coaster Hub.

FREEZER: For Ice Cream. There are many good makes of freezers. A "Half Minute" freczer requiring 5 lb . of ice to freezc a gallon of ice cream is reputed to be the quickest. By its usc ice cream can be preplared in the home, garden, or at a picnic at the last moment.

Vacuum freezers are also obtainable in which ice cream is made by two operations. The ice and freczing salt. in the proportion of thirec cups of crushed ice to onc of salt, лге inserted in the outer container after the freezer

Freezer. The Gardner Hall-Minute freezer, bandy For use at a picnic. Abova, rikht. Rapid vacuum treezer. The ice cream compartment opens from the top and the salt and ice container from the bottom her in recesses cut with an inclined facc When frce wheeling the firiction between the inner face of the chain ring and the rollers tends to push the latter towards the hottom of the inclined recesses, but when pedalling it tends to push the rollers up, and thus wedges the chain ring and the inner member as solid,

This result is attained because the distance between the inclined face and the inner face of the chain ring at its narrowest part is alightly lcas than the diameter of the rollers. It is usual to lit light springs hehind the rollers to keep them in contact with both

French Bulldog. Champion of a favourite breed of house dog
lias been invertel When this container is half full, pack the ice and salt well down, finish filling and then pour in a cup of cold water, clamp down the lid and reverse the container.
Ice cream is prepared according to instructions given with the freezer and poured into the smaller inner container and covered with a lid. The freezer is again inverted so that the ice and salt compartinent is uppermost. Such vacuum freezers arc ohtainable in various sizes. See Ices.
FRENCH BEAN : How to Cook. French beans should be used when very young, for they become tough and stringy when old. Wash the beans and top and tail them, then cut them lengthwise into thin stripy resembling grass blades. Small ones need not be cut. Leave them in cold salted water till ready to conk. Put the heans in a saucepan of boiling salted water and boil very quickly with the lid off for at least 20 min . Drain, and ahake them over the lire to dry them, add a small lump of butter and a little pepper and salt, and serve them very hot.

French beans can also he stewed. Put $1 \frac{1}{3}$ 102 lb . into a greased casserole, leaving them whole if they are sufficiently tender, or slicing and stringing them if there are any signs of toughness. Cover them with 1 pint of white sessoned stock, then put the lid on the casserole and cook until tender. Drain the henns, taking them and the stock out of the casserole. In the cosserole melt a lump of butter about the size of a hen's egh, afterwards mixing in a tablespoonful of flour. Then pour on tho stock, stir the whole until it boils, and put in the heans. Heat thoroughly and serve in casserole. The cultivation of the beans is described in the article Bean (q.v.). See Bran

FRENCH BULLDOG. A French bulldog difiers so much from the British that one is unable to see the relationship between the two. The bat or upright eary, for instance, are the antithesis of those that are seen on the British national dog; the under-jaw does not project in the saine manner, therc is less wrinkle about the head, and in addition the chest is not so wide.

Whatever may have been the case originally, the French breed is now distinct in build and temperament. He is quick and active, instcad of being slow and lethargic, and he makes an
excellent house pet, his average weight being from 20 lb to 24 lb , though some are a trifle heavier. The favourite colour is brindle The coat is short and smooth, the tail short and carried downward in bulldog fashion See Bulldog; Dog.

FRENCE CEALK. This powder has a smooth soapy feel, and is used for sprinkling inside boots or gloves to muke them slip on frecly. In Hat cake form it is used by tailors and dressmakers for making marks on dark cloth or other fabric.
The powder is also emploved for absorbing grease from silk or other material, for which purpose it is sprinkled upon the grease apot and then ironed with a warm llat iron. It is used as an ingredient in dusting powders and for clearing turbid liquids. For the lastnamed purpose powdered French chalk is shaken up with the liquid, and the powder, in settling down, lenves it bright and clear. French chalk, alone or mixed with paraffin wax, is sprinkled over a floor to make it smooth for dancing.

FRENCH COOKERY. Genuine French cookery does not consist entirely of highly sauced and decorated dishes. It cmbraces the knowledge of combining finvours so that one does not unduly predominate. Garlic, for instance, should merely accentuate other flavours, and its actual presence should not be detected.

No waste is permitted and no portion from the boiling or stewing of the ment is thrown away. The liquor portion appears as a good brown soup, well Havoured with vegetable and thickened with sago, macaroni or some other similar substance, while the meat is thoroughly impregnated with the taste of vegetable, a little bacon, and a suspicion of spice and red pepper.

In French cookery the sauce always reccives due consideration, containing in the stock from which it is made the essence of meat or fish whioh it is intended to accompany, and flavoured with herbs such as tarragon and chervil.

Dressed vegetables are a distinct fenture of French cookery, and make a course by themselves. Cold vegetables are formed into salads, and with a mayonnaise sauce or salad dressing make relishes for cold meat. Salads of all kinds are popular with the French, but great stress is laid on the dressing. Almost any kind of salad berb is used in anlads, with portions of meat or fish chopped up, and covered with mayonnaise sauce. See Casserole; Silad; Sauce.

FRENCH CRICKET. This is a game well adapted to small gardens. It is played by any number, without sides, and there is no scoring. Fach batsman plays until he is out, and is then succeeded by the next.

The wicket is represented by the lontsman's feet and lega uj, to the knee. He stands with his feet together, the hat held vertically in front of him, and the first ball is bowled from a spot some fell paces olf. The batsman must not allow the ball to hit his feet, neither must he move them, or he is out. Any memher of the field who stops the ball then bowls it from the apot at which he stopped it, but the batsman must not alter his josition except in so much as he can without moving his fect. If the ball is caught by any player he is out.

FRENCR CURVE. The French curve is used in drawing and design work, and consists of a thin piece of pear wood, celluloid, vulcanite, or similar matetial, cut to a series of scientifically designed curved forms. Its use is of the utmost assistance to those who are unable to depend upon a free-hand drawing. The method of use, illustrated above, consists of laying the curve flat on the paper and marking around the cdge with a peneil. French curves are sold separately or can be obtained

French Curve. Device used by the draughtsman
to enable him to dispense with free-hand drawing
in scts, and are made in a wide range of shapes. Almost any curve can be drawn by combining the various elements from different-shaped curves, but when doing this it is necessary to note if one curve flows freely into the other As a guide, it is preferable to draw around a greater distance than that actually required for the operation, and then by trying the other curves it is possible to judge whioh of them is most suitable. The juncture of two curves should be indicated with a pencil-mark, so that when inking in the drawing the distance which should be drawn by the use of one curve wilt be apparent and the commencement of the other will be clearly defined. By these means the component curves may be prevented from having any suggeation of a sudden change of form or an ungraceful bulge. See 1)rawing.
FRENCH FOLD. Raw edges may be finished by what is known as a French fold. This is a wide fold or bind enclosing the elge, turned over to the wrong side and slipstitched down. The strip for the fold may either he cut on the cross or on the straight, according to the shape of the edge to be bound A French fold may be used to renovate worn or fraved hems, cuffs, ctc., or to finish the sleeves ind hem of a child's frock.

A French fold may he 3 or 4 in . wide or a very narrow fold may be used, but if a marmow one is required a smiall rolled fold of material called a roulean may be made. A strip whould be cut on the omss about I in. wide and placed on the outer side of the material, edge to edge. 13 un a thread $t$ in. from the edges. turn over to the wrong side, leaving $f \mathrm{in}$. on the right sidc. Fold the remaining $\frac{1}{} \mathrm{in}$., 1 urning it inside, and hem it nently down. The four thicknesses of fold placed tound the edge in this manner produce a good round edge, which is most useful in tinishing off the edges

of brocade, yatin, crêpede-Chine, and other similar materials, when it is inpossible to use an ordinary bem.

Another type of French fold which is useful for the same purpose, and is employed to finish the cdges of tunies, frills, eto., is called a French hem, and is made as follows: Run a small tuck on the wrong side of the material as far within the edge ay is desired, then roll the tuok downward, turn the raw edge of the tunic up to meet it, and hem or slipstitch down to this

FRENCH HONEYSUCKLE. This is a family of hardy perennial herhaceous plants bnown botaniaally as Hedysarum The only species much grown is coronarium. or French honeysuckle. It has divided leavos with oval leaflets, downy leneath, and spikes of crimson pea-like flowers in sumnier ; height 3 to 4 ft.
The seed may be sown outside in April or May, and the plants put out in autum where they are to hloom. They will thrive in almost any soil, but require a sunny position Another specics much used is unultijugum, a shrub or sub-8hrub growing 3 to 4 ft high It flowers in July, bearing tlowers purplish red in colour.

FRENCH MARIGOLD. A showy half hardy annual (Tagetes patula) which is raised from seeds sown under glass in slight warnith in February and March: the secdlings are planted out of doors in May. The dwarf varieties, 9 in., ure popular edging plants. There are double and single Fronch marigolda with yellow, orange, and reddish flowers. Legion of Honour, yellow and brown, is one of the ohief favourites for edging. The tall varietice reach a height of 2 ft .

FRENCH NAIL. This type of wire nail is in general use for rough work. It is circular in section, with a fint head, and is procurable in a wide range of lengths and in many different thicknesses. Sizes in common use range from ? in. to G in. long. The 1 in size is particularly handy for fixing beaver and other building boards to the studding. The 3 in . size has many uses in the garden, such as nailing up fencing, while the larger sizes are of valuc in building construction. See Nail.

FRENCH POLISHING. This is a process by which a polish is produced on wood. The polish is a solution of gum resins or gums, and its composition varics. Shellac is always the main ingredient and alcohol the solvent. The simplest form of french polish consists of a solution of $\mathbf{6} \mathrm{oz}$. of shellac in a pint of spirit.

The surface to be treated must first be well coated with polish, and time must be allowed between the rubbings for the polish to settle and dry. At first the main object is to put $n$ shell or covering of polish over the surface, whilst later n glaze is put on the surface thus obtained. It is useless to try and obtain a good polish on a surface insufticiently covered.

Make a polisher's jad by taking a piecc of cotton wool and folding it into a firm pad the shape of an egg, with a point at one end Cover this with a piece of old linen, not too fine, folding over the pad and gathering the ends up into the palm of the hand. Pull the point well out. Open the pad and pour in the jolish from the back; it should never be used on the front. Press lightly on $n$ board or palm
of the hand in order to bring the polish through to the front of the pad.

On New Work. If the wood is rather porous, give it a coat of wood-filler before polishing. See that the surface to be polished is entirely free from dust. Cover the surface with polish by rubbing gently with the pad, using a circular motion. When the surface is covered, leave a little while to harden.

Should the surface be at all rough, it can bc rubbed down with fine powdered pumice used on a rag, but no powder must be left on the surface when polishing is resumed. The pad is replenished with polish from time to time, always putting it in from the back. Continue working in a circular motion until the surface is well covered. If possible, leave it to harden for a short time after each rubuing

It is usually necessary to budy-in, as this process is called, three or four times, leaving a day between each coat. As soon as the work is lacky, leave it until dry: otherwise the shell may be pulled off. Never stop in the middle of the work, as that may result in pulling up the polish. Rub down with pumice between ench coat.

In finishing off, rub carefully with fine pumice and a drop of oil, working with grain of wond. Give a final coat of polish, using rather a dry prd, and leave to harden for several hours. Talie a new piece of cotton wool, and on this puur a very littlee crystal glaze. Rub all over the object, using a circular motion, and when the pad is almost dry, rub hard until a very bright surface is obtained.

Repolishing Old Wurk. The instructions given above apply to the production of polish on new articles. An old piece of furniture such as the top of a dining.room table is repolished on somewhat similar lines. First mix a cupful of vinegar in a quart of boiling water. Dip a piece of flannel into this and quickly wash over the whole surface of the table to remove any grease Rub dry and polish it well, using a soft cloth; then rub it down with a piece of sandpaper No. 0 or a rag dipped in pumice powder. If there arc any holes or deep marks, fill them with stopping and leave it to dry. Rub down to make it even with the rest of the work, and colour with stain to match the wood.

Brown polish known as button polish is the best to use, as it works well and dries quickly and hard. It can be bought at any oil-shop. Make a pad as explained above, and fill it with the polish. Press on the palm of the hand and work in large circles until the whole surface is covered with figure 8 marks. Keep on going over and over the surface.
Should it feel tacky or inolined to pull up the polish, stop at once and put the job on one side. From time to time continue to body-in until there is a thick coat of polish all over the surface. For table-tops a thin cont is useless, as it will orack at once. Rub the surface over with pumice, but do not scratch it. If it requires more polish, go on bodying-in. Take care to remove all dust or grit.
Spiriting On. This is one of the most difficult jobs for an amateur. It must be done gradually. In working in the polish sometimes a little oil is useful, but a void using too muoh, as it sinears, and is difficult to get rid of. As the pad needs replenishing, use methylated spirit instead of polish, alwnys putting it in from the back, and employing 1 or 2 drops at a time. Rub a little harder than before, but always in circles or figure 8 . When only spirit remains in the pad, if the surface is not sticky. lake a clean pad, put a drop of methylated spirit or crystal glaze into it, and rub hard up and down until all smears disappear and the result is a brilliant polish.

Work should be done as far as possible in a narm room. Leave it for 24 hours, and if it Las pone dull rub it well again. See Furniture; Sideboard: Table, etc.

FRENCH SEAM. As it ensurcs absolute neatness on both the outer and inner sides of a garment, a Frenoin seam is widely used, generally on lighter weight materials, in making lingerie, ohildren's frocks, blouses, etc. It may vary from \& to $\ddagger \mathrm{in}$. in width, according to the material.

A French seam is made by taking the two edges of material to be joined and running a thread on the right side as near the edges as possible, avoiding any chance of fraying. Nenten the edges with a sharp pair of scissurs, and turn over to the wrong side. Take the join firmaly between the thumb and first finger of both hands and press it uuwn. Kuna tacking thread through the pieces of material, far enough from the join to enclose the edges left on the right side, before finally finishing the seam by a machine stitch or running thread.
FRENCH WINDOW For a drawing room, or any other room looking on to a garden or a conservatory, French casement windows extending to the floor level are sometimes preferred. It is essential that they should be exceptionally well-fitting, ot herwise the room will be draughty and cold, and they should never be fitted to rooms with a north or north-east aspect. None but thoroughly seasoned wood should be used for the frames of a French window.
It is advisable to make the two casements to open outward. They should be hinged to solid frames, and fitted with rebates in the
frames, at the top and bottom as well as the sides, so that they can close tight against each other and against the surrounding framework. To prevent rain or wind from entering it may be necessary to run a strip of rubber down the centre where the casements meet, on the inside. The problem of ventilation can be solved when the room is fairly lofty by an upper casement hinged horizontally to the top of the main framework and working independently of the vertical casements enclosed by their own frame. Thero should be bolts at the top and bottom of one cascment and a solid sashfastening on the other in order to secure it thoroughly. See Bolt; Casement; Curtains; Window.

FRET, This name is given to any geometrical ornament cut or painted on a flat surface in or on a building. Its most familiar form is the key pattern, derived fron the Greeks, which consists of a series of narrow bands set at right angles to one another, so as to form a consecutire geometrical design. There are several variations of this pattern, such as the diamond fret, in which the lines are set diagonally to the top and bottom boundary lines of the decorated space. Fretwork is frequently employed on the outer stonework of buildings where it is desired to relieve the harshness of $n$ bare flat surface. The name fret is also used for the metal plate which closes the opening below a grate. It is often pierced.

## FRETWORK: A Decorative Handicrafit <br> Practical Advice on Tools, Materials and Designs

The reader may further be referred to the entrics Antofret; Cabinet Making; Chippendale, etc.; also to those on the various woods used, e.g. Oak; Sycamore; 'Walnut
The term fretwork now has a meaning rather used for coarser work, where speed in cutting different from that current a few years ago. is desired rather than a fine finish. Smaller In place of the elaborate models that were saws come in for very thin wood, but are not then popular, we have a simpler atyle in which recommended for ordinary use as they are utility has first consideration. In addition, rather more difficult to control. fretwork has a wider and more important application, owing to the growing popularity of the fret in furniture, and the development of wireless receivers and gramophones, both of which use a fret. Thus the fret has become a decorative motif rather than an end in itself.
The Tools Required. The most important tool is the fretsaw frame (Fig. 1). The 16-in. size is recommended, as it is sufficiently large to saw wide pieces of wood without being too heavy. Some form of tension device is an advantage, such as that shown. In regard to the saw blade itself, the No. 2 is suitable for general purposes. Thicker saws than this are

Fretwork. Fig. 1. How the tretsaw should be held. Right, tension device tor tighteniag the blade
has a flat face covered with a piece of flexible material, to enable it to give to any small inequality in the surface. A set of files is needed to enable the work to be trued up after cutting These tools are the essential ones. There are others, such as the rule, light hammer, plane, and so forth, which can be obtained as the necessity for them arises.

Materials. The wood used in fretwork should be obtained ready planed and glass papered. Such wood has already been brought to even thickners, an important point, because it is essential that joints should fit accurately. Designs are prepared specially to suit standard thicknesses of wood, so that only standard material should be purchased, for preference. Satin walnut is largely used, since it is comparatively cheap, is obtainable in wide widths, and is close in the grain. Oak and mahogany are also employed for better-class designs.

A material which has come to the front in recent years is plywood. This is made up of three or more layers, the centre one running at right angles with those at each side. Owing to this feature plywood is practically as atrong in its width as it is in its length, a particular advantage in certain frets because of the rigidity it gives. One drawback is that plywood shows the layers at the edge, but for certain types of work this does not matter. Wireless and gramophone frets should as a rule be cut in plywood; a thickness of $\frac{3}{16} \mathrm{in}$. is usually convenient. Decorative frets as applied to furniture can be cut in $x_{12}^{x}$ in. or 18 in. plywood. As these are stained and polished the layers at the edge do not show.
Designs. For ordinary fretwork models finished designs are obtainable from various supplicrs. These are printed full size and require simply to be stuck down on to the wood and the outline cut. In some cases, the home worker may like to prepare his own designs, particularly for frets to be applied to furniture, etc. A convenient method is to use squared paper. A portion of the design (perhapa a quarter, or, in some cases, one-half), can be drawn full size, and the position of the other parts mapped with the nssistance of the squares. Tracing paper may be used for copying designs or motifs.
Pasting Down. The design, however ob tained, has to be applied to the wood to enable the cutting to be done. For this purpose paste should be used in preference to glue, since the latter grips the paper too strongly, making it difficult afterwards to peel off the design. The wood should be pasted rather than the design, because in the latter case the moisture is apt to stretch the paper and so distort the design. A clean cloth rubber should be used to make the design lie flat, working it from centre outwards so that any air buhbles are pushed towards the edges. Fig. 2 shows the process.
Large designs are sometimes a little difficult to handle. In this case the method shown in Fig. 3 can be adopted. Here the design is rolled mound a piece of dowel, and the fretwood pasted. By placing the dowel at the top it can be rolled forward and the design unrolled. The latter will then lie flat on the wood. This method prevents distortion Allow the paper to dry thoroungly before beginning the cutting.
Drilling. This operation is closely connected with the actual cutting, for the latter depends in a great measure on where the holes are drilled. As a general rule it can be taken that holes should be made near to some projecting piece of ornament, as the saw is usually started at such places. It is not advisable to start the saw at the mid.point of a curve, as when later on the join is made a disconnected appearance usually results. In some cases such a start is unavoidable, for instance, in a circle; the hole in this case is

Fretwork. Fig. 2 Use of rubter In laying a design. Fig. 3. Laying a large desugn with the netp of a
dowel rod. held when cleaning up the filshed work
made near the line and the saw carefully taken into the circle in a continuous sweep Small imperfections of outline can be corrected with the file.

Fig. 4 shows the Archimedean drill in use. Note that the wood lies on a flat hoard; when so supported the drill is not liable to split out the grain when it emerges at the underside. If laid on a table with a rough and uneven top, a small depression in the latter might cause the grain to break away as the drill comes through.
The drill shown has flyweights, which keep the tool rotating whilst the upward stroke with the bobbin is made.

Using the Fretsaw. It is most important to hold the raw upright, a facility which comes only with practice. The work should be examined after it has been cut and any inaccuracies carefully noted. Never attempt to force the saw into the wood; it only reaults in a broken hlade. Keep it working steadily up and down hy its own weight. It will then cut quite quickly enough and truly.
When a corner has to be turned the saw should be moved up and down without the alightest forward movement, and should be turned gradually whilst in this position. It will be found that the blade will gradually

Fretwork. Fir. B. A. result of turning saw at corvers. B, better method, corners being left sharpand clean
turn in the required direction. It is better however, to avoid turning in the corner, because it is liable to rob the design of its sharpness (see Fig. 6, A). The illustration shows the unsightly gap at the corner made by the turn. A similar thing has occurred at the point of the leaf, where the outline has become dull and rounded. A better method is shown at Fig. 8, B, where the saw is taken into the corner first along one side and then along the other. In this method the two cuts meet and leave a perfectly sharp corner. At the external corner the saw is taken along one side past the corner. It then describes a little loop and comes back along the other side.

A point to bear in mind in all designs is the continuity of line. Where two members of a pattern cross onc another, they should appear actually to do so. The eye automatically puts in the joining lines between them. In the same way where one member branches out from another in a continuous curve, the line should be sweeping and continuous. This should be noter especially by fretworkers who prepare their own designs.

Finishing Off. If the paste has heen used sparingly, it is usually a simple matter to peel off the design. If it shows some resistance, however, it can be damperl slightly, using the water sparingly. On no account allow the edges of the work to become wet, as this is liable to raise the grain, which is difficult to smooth afterwards. After the paper has been pecled off as cleanly as possible the whole surface should he cleaned up with glasspaper, using the glasspaper block (Fig. 5). The work should bo held down on a flat board during the process. If laid on the bench, any incquality in the surface of the latter might cause part of the design to stand up, and so catch the block, resulting possibly in a breakage. Quite small pieces of design can be treated in a different manner. The glasspaper itself can be laid on a flat board and the design rubbed upon it.

No finish such as polish or paint should be applied to ordinary fretwork models. It only chokes up the edges. Certain designs
are somewhat different because they have no elabor. ate internal fret. They are comparativoly plain, and are intended to be lacquered or painted. Frets to be applied to furniture are also in a different category. These are polished with the rest of the job after they have been applied.

Sometimes a file has to be used for fretwork. Filing, however, should be regarded as a last resource, and on no account should the fretting be done carelessly, with the idea of cleaning it up afterwards with the file. This is simply a circle, square, and so on. The eyo readily waste of time. A legitimate use of the tile detects any defects in regular shapes, and the is in fitting joints. It happens frequently s that the design stretches slightly when boing laid, with the result that the joints do not fit properly. A few rubs of the file noticad The soon put this right.

Assembling Fretwork. In a largo number of cases glue is used, the most convenient form bcing the liquid kind in tubes. The nozzle is applied to the join and a little glue squeezed out. When the fret is to bo applied to furniture care must be taken not to allow the gluc to exude at the edges, hecause it is difficult to remove cleanly and looks unsightly. A good method is to squeeze out the glue on to a flat board, rubbing it with the fingers to spread it evenly. The fret is placed on this and rubbed up and down so that the back is covered with glue. It can then bc placed in position and held down by a llat. weighted board. When necessary to use nails in fretwork it is advisable to drill holes first, unless the nails are very small.

Types of Designs. It does not follow that because a design is elaborate it is therefore difficult to cut. In fact, the reverse is often the case, the very intricacy of the pattern hiding any small inaccuracies. The most difficult type of design is that which is built up on a geometrical formation, such as the

Fretwork. Flg. 7. Designs for irets particularly suitable lor loudspeakers or gramophone cabinets
lacing straps certain of the members can be made to appear as if they wore bencath others, by just sinking such parts where others cross. The grain of the applied fret must run in the zane direction as that of the groundwork.

Erinoid and Xylonite. These substances are somowhat tougher than wood, and a special metal-cutting saw should be used for them. One great advantage of using this type of material is that the surface can be modelled to a certain extent nifer the cutting has been completed. The job is finished off with glasspaper and a file, and the surface polished with fine pumice powder. Such things as paper knives and small frames can be made from erinoid or ebonite.
FRIAR'S BALSAM. This is another name for the compound tincture of benzoin. The dose is $\Omega \frac{1}{d}$ to 1 Huid dram. Friar's balsam is much used in lung discnses, especially consmallest inaccuracy is at once apparent in a much used in lung discnscs, especially con-
circle, for example, whereas in intricate floral sumption and chronic bronchitis, for its dis-
or leaf work small errors would pass un- infecting action. It has a stimulating effect smallest inaccuracy is at once apparent in a much used in lung discnscs, especially con-
circle, for example, whereas in intricate floral sumption and chronic bronchitis, for its dis-
or leaf work small errors would pass un- infecting action. It has a stimulating effect

Fig. 9. Designs showing how
comparatively simple designs which are not geometrical in form, and which have no very thin members. Some suggestions for loud. speaker or gramophone frets are given in Fig. 7. As a rule the simpler these are the better. There should be plenty of openings to allow the sound to emergc. Such frets should be cut in ${ }^{5}$. in . plywood.

An imitation of carved work can be olbtained by the use of fret work (Fig. 9). Suitable patterns are those often seen on Jacobean furniture, consisting inostly of interlacing strapivork designs. The design is drawn out in the usual way on paper, and pasted on the wood. The thickness of the wood used depends upon the relief required for the imitaticn carving. Usually $\frac{1}{8}$ in. or ${ }_{16} \mathrm{in}$. is about right. The outline being cut. the whole is glued down to the background of the work: To make the effect still more renlistic the background in the internal spaces of the frets is given $n$ roughened finish by means of a punch. This does away to a great extent with the appearance of an overlay, and miakes the work simulate renl carving. The applied fret itself can be carved here and there. For instance, in dealing with inter
ion, a teaspoonful of the balsam is added to a pint of very hot, but not boiling, water, and the resulting vapour is inhalcd. It is a useful dressing for wounds, as it is an officient antiseptic and also tends to check bleeding. Used in the proportion of one part of balsam to ten parts of water, it also forms a soothing application for cracked lips and rough skin.

Fricandeau. A popular dish made from fillet of veal is known by this mme. See Veal.

FRICASSEE. This is a type of stew, generally white, consisting of meat, game or fish cut into piccos and cooked in sauce.

Chicken Fricassée. A fricassce can be made with half a cold boiled chicken. Take the meat from the boncs, and put the latter, together with a small onion, into a pan with the liquor in which the ohicken was cooked. Cook them woll for an hour or more, then strain off the stock. Melt 1 oz . butter in a pan and stir in 1 oz. flour. Add enough stock to make a thick sauce, put in the pioces of chicken and simmer them gently for 30 min . Mix the yolk of an egg with $n$ gill of milk or 3 tablespoonfuls of cream, and add this gradually to the contents of the saucepan. Stir in a teaspoonful of chopped parsloy, n little lemon juice, and seasoning to taste. Serve on a hot dish garnished with sprigs of parsley and slices of lemon.

Fish Fricassee. Any white fish, cooked or uncooked, may be employed in making a fricassée. To do this, break lb . fish into Hakes and prepare a sauce with $1 \frac{1}{\underline{t}}$ gills milk, a lump of butter slightly larger than a hen's egg, $1 \frac{1}{2}$ oz. flour, nend 4 pint fish stock. Senson this to taste, then add the fish and heat the wholo thoroughly, allowing it to cook for a few minutes if the fish is raw. A squecze of lomon juice may be added just before serving, and a bordor of potato, together with a little chopped parsley, used as a garnish. Sec illus. p. 493.

Rabbit Fricassée. A brown fricassée of rabbit can be made thus: Take out the inside, cut off the head, and remove the eyes. Wash
the head, liver, and heart in cold water, soak them in cold salted water for 15 $\min$, and then put them into a saucepan with a pecled onion and a quart or more of water or stock. Bring them to the hoil, remove the scum, add seasoning to taste, and then simmer for 2-3 hours.

Cut the rabbit into joints, wash and dry Fricassée. Brealdast dish made from any white fish an meantime put six rashers of out a policy from a friendly society should careatrealiy bacon into a saucepan and fry them fully examine the conditions and not sign until gently until the fat looks transparent. Then they are satisfied. If they are unable, for any put them on a plate, and to the pan in which reason. to maintain their paymente, they are they were cooked add $\& \mathrm{lb}$ dripping. When this is smoking hot, cont the joints of rabbit with Hour, and put them in two or three at a time, frying them until golden brown Then take them out and keep then hot with the bacon, fry a sliced onion in the fat, atir in one or two dessertsponnfuls of flour, and let it brown. Skim and strain off about $1 \frac{1}{2}$ pints of the stock, add this to the flour, and bring the whole to the boil, keeping it well stirred.

Add a few drops of browning and mure scasoning if necessary, put back the rabbit, together with the head, liver, and heart, and cook all gently for $1 \frac{1}{2}$ to 2 hours Add the hacon about 15 min . before serving The rabbit should be piled in the centre of a hot dish, with the bacon on top and the gravy poured round Dice of cooked carrots may be used as a garnish. See Oyster; Sweethread.

FRIENDLY SOCIETY. These societies exist for the purpose of enabling persons to insure their lives, to provide funeral expenses or endowments, and to make provision for sickness, unemployment, old age, and various other contingencies
Two Types of Society. Their original con stitution and scope have been greatly altered by law and claanging industrial conditions, and they now may be classified into two groups, the fraternal orders, such as the Manchester Unity of Oddfellows, and the collecting societies, such as the Liverpool Victoria. The organization of the fraternal orders is to a large extent dependent upon voluntary labour. On the other hand, collecting societies employ paid collectors, who usually call every weck upon members for their contributions.
The conditions of membership vary according to the rules of the particular society. Members can insure death hencfits for any sum not exceeding $£ 300$, but the sum assured in respect of children is limited by statute to $£ 6 \mathrm{in}$ case of children under 3 years of age, to $£ 10$ for children under 6 yenrs of age, and to $£ 15$ for children up to 10 .

One advantage of memberahip is the ability to dispose of any sum payable at death, not exceeding $£ 100$, by means of a written nomination, which must he registered at the head office of the society. Other benefits obtainable from friendly societies include relief or maintenance during widowhood or distressed circumstances; when travelling in search of employment; or in such circumstances as shipwreck or damage to boats or fishing nets.

Members can also provide, again by weekly payments, for the old age, i.e. any age after 50 , and for the sickness, widowhood, orphanage, and old age of their dependentr. Other forms of insurance secure the member against loss by fire up to the value of $£ 15$, or of the tools used by him at his work

A momber, in addition to his own life assurance, may insure funeral expenses for hushand, wife, or child, and in respect of a parent, grandparent, grandchild, brother or
sister Endowments the room, such as the fireplace tiles or the and endownent ground of the carpet.

Before distempering the frieze care should be taken to see that the underlying plaster surface is good; any holes should be stopped with plaster of Paris, finished off with a trowel, and, if necessary, with pumice stone On a really smooth surface one coat of the distemper will suffice for a plain frieze in any colour that may he desired. Such colour usually matches the ceiling. In certain cottage rooms nothing looks better than a simple frieze washed with deep cream colour. If the plaster work is roughed up before being coloured the frieze is more effective for an oak beamed roon.

Stencilled Friezes. These are often seen in nursery decoration With this type of frieze,

Frieze. Fig. 1. Frieze for hall or dining room. It is in relief plaster work, distempered pale buff, and surmounts oak panelling
having chosen the design of nursery rhyme, fairy tale characters or attractive animals, the amateur decorator proceeds to trace it with a blue or red pencil on a sheet of stiff oil paper. This is then affixed to a smooth board and the traced pattern cut out with a sharp modelled by an artist or from his drawing, a mould is taken, and the result is reproduced as often as may be desired. The slabs or lengths of frieze are transferred from the place of manufacture to the room, and lixed in prosition on the wall by the same method as ceiling sections.
Imitation plaster friezes in fairly high relief, made of woodpulp, papier mâchć, or asbestos, are also made in sections or panels, and can be ohtained from paper manufacturera. They are applied like wallpapers. Relief motifs are obtainable separately, which can be placed on a plain surface as desired. (See Hall.) In heraldic designs these are particularly suitable for oak panelled rooms. It is necessary to bear in mind that small roons will not stand too higha relief.

An effective frieze for an ordinary room can be made with any good washable distemper. A frieze banding may be used to separate this plain frieze from the wallpaper. Bandings should repeat a defi. nite colour note in

Frieze. Fig. 2. Frieze of colour prints for a nursery. It is very deep so that the detail is easily seen by children, and surmounts a blackboard dado
penkinife. If the pattern is so intricate that first introduced into England in the roign of the sheet after this operation will not hold together, parts of it can be left uncut, these being subsequently filled in with a brush on the wall surface. The oil paper pattern is fastened in position on the wall with drawing pins and the colour, either distemper or oil, brushed over it. The pattern is moved on to the next space to be decorated, and the process repeated until the entire frieze is finished. Unless this is only partially to be decorated at detinitely appointed places, the design selected should be one that fits the spaces to be covered on each wall, and careful preliminary measurements should be made.
 The design itself should be easily contained in the centre of the oil paper, so that its repetition will be practically mechanical, without the necessity of any further measuring. Stencil designs can be obtained which can be traced and adjusted on to the oil paper. Charming nursery friezes are also designed by good wallpaper firms. The frieze illustrated in Fig. 2 is made very deep so that its details are easily scen by small children. Surmounting a dado of "black board" it has an added charm for the day nursery. In the modern room decoration is often cut out and applied on a frieze where interest is required and not necessarily all round the room. For instance, a group of tigures or a flight of birds will be placed over the fireplace, and perhaps at two comers of the room only. The designs of these groups vary according to the decorative shape required by the space. See Anaglypta; Colour; Cornice: Stencilling; Wallpaper.

FRIEZE: The Material. As originally made centuries ago friezes were coarse woollen oloths rendered blanket-like by roughening the surface with wire brushes. A rough face is still a feature of most friczes, which are cloths too heavy for suits, but oxcellent for overcoats for motoring.
Irish friezes are appreciated for their thickness. The cloth is heavily fulled after being woven, and it becomes so dense that wind dues not blow through.
FRILL. This is made of a strip of material out any width, single or double, the upper odge gathered or pleated on to a garment or band, and the lower ellge finished in some way and left to hang loosc. Frills in heavier inaterials ars usually cut on the cross and finislied with a picot cdge or with a bind.
Lace, net, georgette, ninon or any silk or light cotton material may be used for friliing. The lower edge of the frill may be trimmed in many different ways; a hemstitehed border is sometines used, or a tiny rolled hem or scalloped bind may neaten the edge. Frilling -both plain and pleated-in various colours and materials can be purchased by the yard. The pleated kind is the least practical because the plenta lose their shape when washed.
FRINGE : Uses in Furnishing. While fringes for dress are a matter of scasonal fashion, these trimmings have a definite place in decorative furnishing As period trimmings they belong to the 16 th and 17 th centuries and the first decade of the 18th century and were greatly used until the reign of Queen Anne for enriching cushions, hangings and upholstery. During the Georgian periods they were not much employed, but appeared aysin in Victorian times, and are extensively used to-day both as correct period and as modern trimmings for cushions, ourtains and pelmets, bedspreads, stools, pouffes and lampshades.

Fringes look particularly well with Jacobean style chairs, upholstered in greer, brown or marvon velvet and further embellished with heavy cords and tassels. Metal fringes were
and turned legs, but seldom for the later 18th century pieces with cabriole legs, when fringe would have detracted from the embroidered seats then in vogue. Tufted fringe was used on William and Mary chairs. It was secured
Charles II, but straight silk fringes were much employed in the Tudor period and raricgated fringes were seen in early Stuart days. Such trimmings are thorefore correct for the settee and chair with twisted oak frame, or for stools and chairs with $X$ legs reproduced from the Tudor stvle, for William and Mary stools and armchairs with stretchers by small buttons edged with

Fringe. Delow, fringe made by fraying exds of ribbon, linen, etc. Above, left, beaded fringe
silver wire and trimmed velvet upholstery. As trimmings for candle-shades for use with electric light sconoes silk fringes are often employed, and lampshades may be compoaed of silk fringe shading from pale yellow to orange or from flesh pink to deep rose, sewn in wavy lines on a silk foundation.

Fringes can be bought by the yard in various colours and widths from all drapery stores, and are applied by means of a band which confines the top ends of the fringe. Fringing may also be made on the material itself. When this is done the depth of the fringe must first be decided, and a line of machinestitching run at that distance from the edge. All the threads parallel with this line must then be pulled out with a needle or pin until the actual stitching is reached. The machinestitching is not essential, but it helps to prevent the material from fraying. A beaded fringe can be made by cutting a number of threads of even length and threading each of them with the same number of bcads. Fasten off the bottom end securely, knotting it so that the beads cannot fall off. The lengths should then be applied at regular intervals to the edge of a lampshade, or other article to be so adorned, or may be sewn to a narrow braid first and then applied. See Bead; Curtain:

## Lampshade.

FRITILLARY. The most striking of these is Fritillaria imperialis, the crown imperial, which in spring bears drooping yellow or reddish Howers on stout stems 2 feet or so high. The bulbs should be planted 6 inches deep in autumn and left undisturbed for years. The snake's head fritillary (meleagris) 8-12 inches, has beautifully chequered blooms in purple, white and other shades of colour in spring: it flourishes in grass or in the rock garden. Aurea and citrina, with yellow llowers, are two pretty fritillaries for sandy loamy soil in the rock garden. Propagation is by seeds sown as soon as they are ripe or by offsets. See illus. p. 159.
FRITTER. Fruit, meat, fish, cheese, eggs, or bread can all be employed to make fritters. Fresh fruit can be userl, but meat or fish should be already cooked. Remains of cold meat or fish can be successfully reheated in this wray. Hard-boiled eggs should
be sliced rather thickly. A good frying batter should be made, and slices of the fruit, meat, eggs, etc., dipped into it, then dropped into a pan of very hot, deep fat and fried a golden brown. See Apple Fritters; Batter; Bread Fritters; Cheese Fritter; Cold Meat : Frying; Orange Fritter.

FROG: Its Garden Utility The frog should always be welcomed in the garden, and introduced there if he does not come of his own accord. He never touches leaf or flower in the way of food: but in addition to a prodigious consumption of insects of all kinds, he also destroys slugs and earthworms. His soft skin of yellow and brown must be kept moist, and to keep him in a healthy condition and active it is worth while providing for his comfort by having a patch of long grass in a shady corner of the garden, with a sunk pan of water near by, in which he can soak at intervals.
The frog and the toad are quite easily distinguished. In addition to its brighter and varied colour, the frog is more angular, has longer legs, and the moist skin is perfectly smooth. The toad has a rounded outline, is more portly, and the dry, warty skin is of one dark tint, without spots or bands.

FROGROPPER. Under this popular name are included a number of insects allied to the plant-bugs and aphis, and, like them, subsisting by suoking the juices of plants. The familiar and conspicuous cuckoo spit is formed of surplus fluid, exuded by the immature froghopper and whipped into a froth to protect its tender body. If the froth is blown aside the yellow insect will be seen. In the mature stage it uses its hinder pair of legs for making prodigious leaps, and as a rule escapes capture.
In the earlier stages the insect inflicts great damage on many plants, partioularly noticeable on carnations and pinks. Washing with insecticides, such as a solution of nicotine and soft soap in water, is recommended; but the most certain method is to look for the cuckoospit and then destroy the insect by pressure of finger and thumb. See Insecticide.
FRONT AXLE : Of a Motor Car. The front wheels of a car rotate on stub axles which are connected by more or less vertical pivots to the ends of a fixed or dead-i.e. non-rotating-axle secured to the springs. The axle, in addition to transmitting the weight of the vehicle from the springs to the wheiels, has to resist the torque or turning

Front Azle of a Motor Car. Diagram showing a front axle of the dropped type
effort imparted to it when the brakes are applied. This torque tends to twist the end parts of the axle, and the circular section now generally adopted for the ends between the spring pad and the stub axle is best adapted to resist such forces. The diagram shows a front axle of the dropped type.

FROST. During the winter months the householder has to guard against the action of frost. Should no precaution be taken water is liable to freeze in the pipes, especially during the night, the water supply may be cut off, and burst pipes will add to the inconvenience. Except when the frost is unusually severe these troubles can generally be prevented by wrapping straw, felt, sacking, or some other
material round the pipes, and kecping an oilstove or other heating apparatus in any room where pipes are exposed to the cold.

Protecting a Pipe. External water pipes should be protected with a generous wrapping of straw or felt An effective method is to hox them in with a wooden ensing and pack it with straw or hay An important part to watch is the overflow pipe, which protrudes a few inches from the wall and is very often forgotten. Should it freeze, surplus water cannot get awny and flooding may result.

In frosty weather it is as well to shut off the main water supply each evening and to drain the system. The drinking water should come off the rising main, and the supply for the bath, w.o.'s and hot water apparatus is from a storage tank in the roof, fed by the rising main. Usually in addition to the pipe from tank to hath, lavatory basin, etc., there is a scparate pipe running to the hot water tank, each having a stop-cock near the cold tank. It may be well temporarily to shut off the bath and w.c. supply when a had frost is expected, draining the pipes by opening a tap at bath or lavatory basin. The w.e. should he flushed last thing at night, when the Hushing cistern will remain empty till the stop-cock at the storage tank is opened again the following morning If the w.c. water comes from the rising main the supply will have been cut off when the main stop-cuck was turned off.

## The Hot Water System

The lire in the kitchener or independent hot water boiler should be banked up at night. Since the cold supply to hot water system has not been shut off, the circulation in the latter will not be interfered with unless the cold water tank frcezes The rising main having been shut off, the cold tank cannot refill, of course, so little or no water should be drawn from the hot supply taps in the circumstances

If the pipes of the hot water aystem freeze, as evidenced by the water ceasing to flow from the hot taps, the fire in range or boiler must on no account be lighted until the thaw comes. The water must run quite freely and continuously before it is safe to use the boiler.

The householder should make himself familiar in advance with the run of the pipes and the position of the stop-cooks, so that in emergency he can shut off the main supply at the hydrant box usually situated in the forecourt, or at the additional stop-cock which should be provided inside the house. The latter is a great convenience when fitting a new washer to a leaky tap, eto. A long-handled key will be needed for the outside stop-cock, which is on the pipe usually some two or three feet underground. This should be obtained and placed in a readily accessible position. When shutting of the main supply in frosty weather it is preferable to use the outside stop-cock, as then the whole of the service pipe can be emptied, and there is no water left in the pipe to fireeze. Reference should be made to the diagram given in the article Water Supply.

Should it be impracticable to shut of the main supply to a storage tank or flushing cistern it is desired to empty, the ball-cock may be tied up with string, the latter being faytened to a rafter or to a stick laid across the open top of the tank or cistern. Should there be no stopcock on the distributing pipe from a tank, it may be possible to plug the outlet with a piece of broomstick having a tapered end.
Dealing with a Burst Pipe. When pipes freeze there is always a likelihood of a burst somewhere in the system, and this may not show itself until the thaw. If the hurst pipe forms part of the distributing system from the storage tank the appropriate stop-cock near the tank must he turned of. Failing this the taps on the system should be opened to empty the tank as quickly ay possible, and the stopcock on the rising main must be turned off, of
course In emergency the prpe at the burst (on the supply side) may be hammered llat. but this makes subsequent repair more difficult and expensive, as a section of the pipe will have to be cut out and replaced However, to prevent a flood this measure may be justified. When the pipe has been Hattened it should he cut through and the end bent over and hammered tight at the end.

During a spell of severe frosty weather, if the hedrooms of the house are culd or the habit is to sleep with the windows open, a goorl plan is to remove the water from the hasins, jugs or water bottles for the nigbt, as if these freeze they are liable to crack

Frost in the Garden. One of the greatest benefits of frost from the gardener's point of view is the purification and pulverisation of land which follows the freezing of the soil where nutumn digging has not been shirked. Frost penetrates and disintegrates the close particles of heavy olods, reducing them to that friable condition so much desired when sowing and planting time comes round, and destroying the pupae of pests which lurk beneath the surface. To ensure the quicker germination of the seeds of alpine plants it is usual to expose the pots of soil in which they are sown to frost and snow by placing them out of doors. During sevcre frosty weather plants in cold frames should be well protected hy niats. See Apricot;

## Frame; Fruit.

FROST BITE. This most commonly affeots the fingers, the toes, the ears, and the tip of the nose. Children, old people, and alcohol drinkers arc the most likely viotims.
In the mildest form the skin turns to n dusky red, a soft swelling occurs, and pain may be acute. This is the common chilblain In a further stage the chilblain hecomes a blister, which may break and leave a small ulcer. In still severer degrees gangrene results.
When any part is actually frozen, the circuIation must be restored very slowly. The patient must on no account be taken near a fire nor even into a warm room. Put him in a cool room, and gently rub the frozen part with snow, or with a piece of flannel wet with cold water. As the blood beging to circulate, tingling and pain may be felt. Wheir this occurs the rubhing may be carried out more briskly, the hands of the nurse may be applied to restorc warmth, and the patient may be taken into a warmer room.
The sufferer may now be given a small
quantity of warm liquid, such as hot milk or tea If the fingers or the tocs become much congested, raise the limb. As soon as the circulation is fairly restored, wrap the part in cotton wool or Hanncl See Chilblain

FROSTED GLASS. Frosted or ground glass is produced by tivo cssentially different methods. By the first an acid is used to etch away the surface of the glass, and thus render it partially or wholly obscure. The second process consists of grinding the surface with emery and water. thus producing the familiar appearance of frosted or ground glass. A similar result is also ohtained by sand-blasting See Glass

FROZEN FOOD. Many kinds of lood are frozen for purposes of keeping. If frozen meat is properly cooked and of good quality, it almost equals the home killed variety.

Meat should never be cooked while the frost remains in it ; it must he melted out in cold water before the meat is exposed to the firc Frozen meat requires longer and slower cooking than home-killed meat.

Freczing has a more deteriorating effect un beef than on mutton and lamb, C'anterbury lamb in particular suffering little by the pro cess. All frozen meat shrinks while cooking. and allowance for this should be made when it is bought.
All kinds of game arc now preserved by chilling and freczing, which enables this favourite food to be served at table long after the gamc season is over. Rabbits which have been frozen should be converted into entrées or stews. They should be cooked longer than fresh rabbits, and be made savoury with plenty of vegetables. It is not advisable to roast frozen rabbits Most poultry makes an excellent food when frozen. The birds, if of really first rate quality when preserved, may be cooked by almost any method employed for fresh poultry.

Fish which is frozen can be kept for weeks and will be quite fit for table, but it should be soaked for some hours in cold water before being cooked.

Milk is sometimes frozen in blocks, especially if intended for use during a long voyage. When thawed it more closely resembles fresh milk, and is invaluable where invalids or young children are concerned. Fruit also can be kept for a considerable time in cold storage. See Beef; Ice; Mutton; Refrigerator, etc.

## Fruit: Its Food Value and Its Culture

## With Details about the Planting of an Orchard

Further information will be found under the headings Apple; Pear; Plum; Strawberry, etc. See further Grafting; Pruning; also Diet; Food; Jam
When obtainable in good condition, fruit and raisins, contain about three-fourths of should be eaten as regularly as any other their weight of sugar, and also from 2 to 4 per article of food. The great niajority of fruits contain scarcely any tissue-building or energyproducing substances, but they are rich in salts and vegetable acids. The latter undergo changes in the course of digestion and appear ultimately as alkaline carbonates.

Fruit as Food. While not contributing material for growth and repair, some fruits are rich, however, in the vitamin which is necessary to a healthy development and existence, and the absence of which from the diet leads to the occurrence of scurvy. Lemons, oranges, and grapes are fruits that may be mentioned in this connexion.

With some exceptions fruits contain from 80 to 90 per cent of water. Fruits containing over 80 per cent of water are practically useless from the nutritive standpoint alone, but they are nevertheless invaluable for the salts that they contain. Their solid contents consist of sugar, salts, chiefly of potash, and cellulose. The nutritive qualities of a fruit depend chiefly on its content of sugar. Dates and figs, prunes
cent of protein. Bananas contain more than 20 per cent of sugar, grapes and plums about 15 , apples and apricots a bout $10-12$ per cent. The slight percentage of fond material in fresh fruit is reduced by cooking.

For children fruit is particularly wholesome, and, as is shown by their craving, it is a really necessary article of diet. The best varietics for children are apples, oranges, grapes, and bananas. Fruit alone cannot nourish a child, but fresh fruit should be a part of a mixed dietary of milk, cereals, eggs, and meat suit. able for young children.

Ripe fruits act as a regulator of the system, and provide some of the extra Huid required in hot weather. Livery people may eat stewed fruit with advantage. Grapes are valuable in cases of ailments arising from a too generous diet, and the juice is a wholesome laxative. All íruit is more or less laxative, and good for constipated people, when eaten fasting.

Oranges have been recommended in certain cases to persons of a diabetic tendency; but

Fruit. Table showing the average food content of ihe principal varieties of fruit
patients should consult an expert physician before experimenting with swect fruits.
Watery fruits, such as melons, limes, oranges, and apples, are wholesome thirst quenchers, partly through the water they contain and partly by stimulating the flow of saliva.

Fruit should be eaten only when fully ripe, but not when beginning to decompose. In cities fruit is frequently sold in a very underripe condition. It is then indigestible, and lacks the sugar which forms its chief nutritive matter. In strawberrics is found the same acid that is contained in apples. Lemons and oranges contain citric acid. These acids undergo a change in the bodily chemistry, and do not increase the acidity of the blood
The best time to eat fruit is about two or three hours after a meal. Immediately after food it very often interferes with digest ion.

A person suffering from gastritis or diarrhoca would aggravate his malady by eating fruit. In some people, too, many fruits produce Hatulence. Fruit containing many seeds, including strawberries, raspberries, black: berries, figa, and currants, often cause great irritation of the inteatine in children and elderly people.
Plums, peaches, and apricots are rather tough, and unsuitable for people of weak digestion. The most digestible linds are oranges, grapes, grape-fruit, raspherries, and fully ripe apples and pears.
The Growing of Fruit. The growing of fruit is a matter of considerable interest, and there are many who wish to have, not merely a few apple, plum, pear, or cherry trees, but a garden or orchard in which a variety of fruit can be grown on scientific and economical lines. Such a garden should include what are known as top trees, i.e. apples, cherries, plums, etc., be tween which trecs bearing soft fruit, as it is called, i.e. currants, gooseberries, raspberries, as well as straw. berries, should be planted.
The varieties chosen must be suited for the particular soil; the manner in which the trees are to be trained must be settled beforehand and the plantation must be arranged so
 planted in the corners of each square, with
lillers and soft fruits in het ween.

In plantations of this kind thinning is effected in the following manner: The small fruita are grubbed as soon as the permanent tices or fillers require more space, and later on $\times$ the alternate fillers themselves are reinoved, thus leaving a tree in the centre of each square formed by the jermanent trees Finally, when the permanent trees are nearly full grown, the remaining fillers nust also be grubbed.

The quincunx method of planting is very like the square system. The plantation is arranged in a similar series of squares and the perinanent trees are

Fruit plantation with two varieties of apple -Lane's Prince Albert and James Grieva ( 1 a planted alternately at distances or 14 square leet. Between them, soft frwits $X$ such as raspherries and strawbarries should be olantel
way, except that a tree is planted in the centre of each square As a rule. the trees planted in the centre of the aquare are fillers, but if they are to be retained permanently, an upright variety must be sclected so that all chance of overcrowding is avoided Interplanting with fillers and soft fruit can be carricd out quite as easily as with the square

In the case of triangular or hexagonal plantations the trees are planted at the comers of a serics of equilateral triangles, and are, therefore, equidistant. Such plantations cannot be thinned satisfactorily, and the system is only suitable for plantations consisting entirely of permanent trees. In the cordon system the trees are planted in rows 6 ft . нpart and 2 ft .6 in . apart in the rows. The direction of the rows should be north and south, and the trees trained at an angle of 45 degrees to the ground inciining to
the south
The following are suggestions for plantations of fruit : Bush apples, for example Lane's Prince Alhert and Jaines Grieve, may be planted on the square system, lif ft apart. They should be inter. planted with red or black currants or gooseberries at 7 ft . Alternatively Newton Wonder and Lord Derby can be planted at 20 ft. syuare apart, also on the square, and bet ween them soft fruits at 5 ft . square. A third scheme for bush apples is Worcester l'earmain and Allington Pippin at 18 ft., interplanted with soft fruits at Gft. If half-standard trees are preferred Newton Wonder and Four Systems of Planting. There are in all Allington Pippin should be planted on a 24 ft . four systems of planting top fruit trees: square system. In this case bushapples, pears, square, quincunx, triangular, and cordon. For plunis, or cob nuts can be planted in the the square system the land is marked out in a centre of each square, and the intermediate land can then he interplanted with soft fruits at 6 ft . square.
Turning to plums and pears bush plums of the Victoria and Czar variety planted at 14 ft . square make a good plantation. Soft fruits can be planted between them at 7 ft . square. Bush pears of the Conference and Durondenu variety can be planted at 12 ft . square with soft fruit at 6 ft . between them. A more claborate scheme is for a mixed plantation of standard trees. Apples of the Bramley Seedling and Lord Derby variety should be planted at 40 ft . on the quincunx plan. Between them bush Czar plums should be interplanted at 20 ft . The intermediate land can be planted with Stirling Castle or Lane's Prince Albert apples as fillers at 10 ft . square or witli soft fruits at 5 ft .

Fruit trees may ho planted at any time during their dormant period. provided the land is in a dry, friable condition so that the soil can be worked well in amongst the roots and the land can be firmly trodden without puddling it. The best time to plant is in November
system
that the trecs have suflicient space to grow without overcrowding. Top trees take about 30 years to reach their prime : soft fruit trees take a much shorter time.
The land selected for a fruit plantation, if at all exposed to high winds, must he protected by a windbreak. Iombardy poplars are generally used for this purpose Cuttings a bout 1 ft or 1 ft .6 im . long and 3 ft apart should be planted along the boundarics of the plantation the saine year as the top fruit is planted, and hey will have grown into a high hedge by the time the fruit trees begin to bear. If a shelter or hedge of poplar is not considered sufficient, the lirst row of fruit trees should consist of damsons or plums of the Monarch or Kentish bush variety, which will serve as a rcond shelter.
Fruit plantations nust be properly fenced to prevent damage from hares and rabbits when the trees are young, and pilfering whel yegin to bear. varieties is always difficult. Success is fairly certain if only standard varictics are planted, but it is desirable to makic careful inquirics as to which are the most successful in neighbouring plan tations, so that the selection can be based upon local knowledge of the soi and its capacities.

Caremust he aken that each tre s allowed suflicient space for growth It is a great mistake to plant trees so closely that when half-grownthey have to be pruned very severely, as this leads to a great decrease in the ecreare in the
 Newton Wonder 11 and Allington Pippin (©) varieties are planted at distances of 24 square leet. In the centre of each square is a nut or bush plum a and between the apples, at a distance of 6 square feet. is soft fruit $\mathbf{x}$

Put them into a preserving pan, allowing a quart of water to every pound of fruit. Heat it up, then strain it carefully through a jelly bag and add the juice of 1 lemon and \} lb. of sugar to every quart of syrup. Stir the whole until the sugar has dissolved nnd, when cold, add is little ice and serve.
Various kinds of sytups uscful for flavouring purposes are made in much the same way, except that less water is used The juice of the fruit is either squeezed out, ns in the case of orangea, and then boiled with a little sugar, or extracted by stewing with sugar and a little water, and then position of each tree should be clearly marked hoiled up with more sugar. See Loganberry with a packing stick, stake, or white.

Bush Fruit Trees. Fruit trees may also he grown in pots, and although such cultivation is thoroughly practicable, it is not a profitable proposition without glass. Good specimens should be obtained during the autumn from a nurseryman specialising in cstablished pottrees. Repotting is a most important factor, heing necessary every few years to keep the trees healthy and fruitful. Roots should always be freed of old exhansted soil previous to potting, and clean pots with ample drainage jrepared to receive the plants. A layer of broken turf is then placed on top of the crocks and the roots placed in position. Soil must he well distributed, and made very firm with a potting stick. Pots of about twelve inches in diameter are a suitable size. Leave an inch or so between soil and pot-rim for watering Alter potting give a thorough soaking.

Early in the year the trees are placed under glass; a temperature of 40 to 45 degrees is high enough for the first few weeks; this mas be increased to 50 to 55 degrees later on. When the trees are in blossom the greenhouse must he ventilated freely

Pot fruit trees are placed out of doors when the crops have heen gathered: they must be in a sunny position, the pots plunged to the rims in ashes. Careful watering is necessary to ensure that the soil does not become dry. Pruning is done chielly by dishudding to pre vent the growth of superlluous shoots. Apples, plums, cherries, and figs are suitable for this form of culture.

Removing Fruit Stains. Bcfore it has time to dry the alfected part sliould be covered with salt and then washed without soap, the nikali in the latter tending to fix a stain rather than to remove it If the stain is dry, the material should be stretched over a basin and water which is almost boiling poured over the mark. Very delicate fabrics may he treated by spreading them over a piece of blotting. paper and then sponging on the wrong side with hot water. If the mark still remains, moisten it with a little lemon juice and then rinse it with hot water

Fruit stains on the hands can be removed with olive oil and castor sugar. Mix a little of the sugar and oil to a paste, and then rub this well into the skin. Let it remain for a few minutes before washing the hands in warm soapy water. Obstinate stains may need two or three applications. See Stain.

FRUITADE. Black or red currants, whortleherries, and raspberries are probably the most suitable fruits for making this drink.

Mulberry ; Orange; etc

FRUIT SALAD. This attractive dish is a favourite swect for parties and also for the dinner table in summer Fruit salad is made from uncooked fruits, either fresh, canned, or hottled. The more varieties of fruit contained in the salad the better it is. Pineapple chunks form a good foundation. The salad can be served plain or with cream, ice cream, or custard, with chopped nuts or desiccated coconut as a garnish. Tinned fruit salad can be obtained ready mixed for use
To make the salad of oranges, bananas, and apples, or other comparatively dry fruits, a syrup must be made from sugar and wnter boiled together and coloured pink with cochineal. The fruit should he sliced, sprinkled with castor sugar, covered over. and put aside for an hour or so, and the syrup poured over when cold. A wineglassful of sherry added to the syrup is an improvement. liruit salad can be scrved in separate small glasses or in a bowl.

FRUIT SAUCE. This snuce can be made from either fresh or bottled fruits. To prepare it, boil tngether 2 gills of water, 2 breakfastcupfuls of red or black cuirants, raspberries, or any similar fruit, and sugar to taste. Skim the sauce frequently, and when it thickens strain and serve it with any swect pudding.

FRUIT SLICE. This labour saving device consists of a special knife which preels and also slices fruit quickly and neatly. Such a knife

Fruit. Below, seedling Japanese qulnce and, above, single-stemmed red currant tree, grown in pots
mny also be used for peeling and slicing ur chopping vegetahles.

FRUIT TART. Various kinds of fresh or hottled fruit, used either separately or in conjunction with others, are employed in the making of fruit tarts. Blackherries and apples, raspherries and red currants, and apples and rhubarb are suitable combinations, though any one may be used alone. See Pastry.

FRUIT TRAY: How to Make. A useful article, frequently in demand, is a fruit storage tray. Convenient sizes are 24 in . by 16 in ., 27 in . by 18 in ., and for a fairly large size 30 in . by 20 in Imerican
whitewood is very suitable for making one, but birch, beech, white pine, ash, satin walnut, and common deal can be pressed into service, allowing a shade extra for thickness for the ast-named kind of sood.
Fig. 1 shows a useful type of tray. The sides can be 4 in wide, and are cut to shape to allow a frec flow of air to the fruit, at the same time giving hand clearance. Kidncy-shaped hand holes are also indicated in the ends. The sides can be nailed together, and are stiffened in the angles by blocks. These can finish $1 \frac{1}{4}$ in. by $1 \frac{1}{4}$ in. by if in. long, and when in position will recess $\frac{3}{3}$ in. below the top edge of the frame and project $1 \frac{1}{2} \mathrm{in}$. below it to form toes. The recessing of the blocks will permit of similar trays standing firmly above one another when being stacked.
Close up to the blocks, and in the centre, three cross rails, about $1 \frac{7}{7} \mathrm{in}$. by $\ddagger$ in., and with the upper edges rounded away, are let in llush with the hottom edge of the frame and screwed. The lath bottom of $1 / \mathrm{in}$. by $\frac{1}{8} \mathrm{in}$. lengths is screwed or nailed to these and to the framing (Fig. 2). The stretcher can be cut in right through, as at $A$, but is hest masked by setting the ends $\& \mathrm{in}$. in front face of the framing

Racks for Trays. In stacking, the difh. culty is always that to get at the lower trays, all the upper ones have to be lifted off. Some form of rack, therefore, has its uses, and that sketched at Fig. 3 is easily put together. Four 5 ft . lengths of 2 in . by 2 in . mnterial will serve for the uprights, with the rails top and bottom of the same material cut to the necessary widths and depths. These are mortised and tenoned together, and an additional rail, 3 in. by 1 in., dovetailed in or screwed at bnok, can be added for fixing to
the wall. The main feature of this design Wash and dry it well, removing any unis that each tray will draw out, bearing being eatable parts. Lay it in a saucepan with cold obtained by glueing and screwing a $1 \ddagger$ in. by water to cover it, and a little salt, and dry $\frac{1}{2}$ in fillet to the sides of the dravers, so that it and cut it into thin slices, dipping each these can travel on similar fillets of the same piece into flour seasoned with salt and pepper. width and thickness, screwed horizontally, and Heat about 2 oz of good dripping in a frying at equal heights to the inside of the front and back uprights to serve as slides. The corner blooks of trays must not in this case project below the bottom If properly spaced a

tray ean be insorted between cach pair of pan, lay in the fry and cook it a rich brown. sliding trays, so that it travels on the edges Take out the pieces and keep them hot of the tray immediately below it Fig. 3 should malie these points clear.

FRUIT TRIFLE. This makes an excellent party sweet. Prepare it by splitting a sponge ring into halves, spreading it with apricot jam, and placing the bottom half in a dish. Drain the syrup from a small tin of fruit ralad, heat it, and then pour some of it over

Fruit Trifle. Popular dish for a children's party
the aponge in the dish. Put on the top half of the cake, soak it with the remainder of the syrup, and, if liked, also pour over it $\frac{1}{2}$ gill of sherry. Beat together one whole egg and the yolks of two others, and add to them 1 pint of milk and 1 dessertspoonful of sugar. Pour the custard into a jug, and stand the latter in a saucepan of water over the fire, stirring its contents until they thicken

Add a little vanilla Havouring, and when the custard hegins to thicken take it out and leave it to cool. Then pour it round the outside of the sponge ring until it is not quite level with the top of the cake, and leave it to get cold. Heap the fruit salad in the centre of the ring: add a pinch of salt to the whites of the two eggs, and whisk them to a stiff froth Fold into them a dessertspoonful of eastor sugar and shake them all round the top of the sponge cake, leaving some of the fruit in the centre uncovered If sufficient, shake the remainder over the custard and sprinkle the whole with chopped pistachio nuts

FRY. Such parts of lamb and pork as the liver, heart, etc, are known as fry, and, in the case of pork, also as haslet or liarslet. The sweetbread is also included, and in lamb this is considered a great delicacy. The most usual way of preparing such a fry is as follows:
while the gravy is made. Into the fat in the jan sprinkle a level tablespoonful of flour, fry this a nut-brown colour, taking care that it does not burn. Pour in $1 \frac{1}{2}$ gills of stocli and stir the whole over the fire until it boils Season carefully, arrange the fry in a hot dish, and strain round the gravy. If liked, a small chopped onion can be fried with the meat. If liver alone is served, garnish with bacon. See Bacon; Liver; Sweetbrcad

FRYING. Frying consists of cooking food in smoking hot fat or oil As it is the quickest method of cooking, it is especially useful in an emergency when dishes have to be prepared at a few minutes' notice. Cheap pieces of meat with tough fibres should never be fried, the rapid cooking only serving to make them more tough, hard and indigestible. Fat must reach a far higher degree of heat than does boiling water before food can he successfully fried in it, and should give off a faint blue smoke before the actual frying commences.
There are two methods of frying, the shallow or English method, and the deep or French method. In shallow frying only a small quantity of fat is used, and when one side of the food is cooked it is turned over so that the other side will cook. Deep or French frying requires a deep pan containing enough fat to cover well the food to be fried. French frying is used for rissoles, filleted fish, fish-cakes, etc., and the artiole to be so cooked is coated with batter, egg, and breadcrumbs or pastry. With both methods the fat must be beated until a blue smoke arises before the fond is put in.
Of the two methods, deep frying is the more economical, for though it requires a large amount of fat,

Fuchsia. Method of propagation. 1. Unsaitable cutting. 2. Sturdy shoot with heel (a). 3. Potted shoot with sand round heel. 4. Several cuttings in single dot ; A, sand. 5. Cuttunga in glass-covered boy. 6. Old plant praned
to lurnish side shoots

them on until they are big enough to occupy a good-sized tub.
Ordinary loamy soil, with a little leaf-mould, decayed manure, and some sand will suit the plants. During the flowering season they should be well watered In the winter they should be dried off. Cool-house treatment will suit them all through. Before they start into growth in the spring they should be repotted and cut back.

Propagation is simply effected by putting young shonts in sandy soil under glass in August. These cuttings root very freely, especially in a propagator.

In spring the shape of the plant must be decided on. If a standard fuchsia is wanted the plant is allowed to reach the desired height of stem before it is stopped. If a pyramid is wanted the top of the plant should be cut off to ensure the development of side shoots. Magnificent, tall, pyramid-shaped fuchsias can be obtained by carefully stopping and training and by repotting as becomes necessary

Hedges and large bushes of hardy fuchsias are familiar to all visitors to the south-west and other mild districts of the British Isles. These shrubs will also Hourish in colder districts, though there they are often cut to the ground by frost in winter. If a covering of old ashes is placed over the roots in autumn the shrubs will usually start into fresh growth in spring. The best of the hardy fuchsias are macrostemma, Riccartoni, and gracilis. See Bedding; Greenhouse. Pron. Fow-shah.

FUDGE. A sweetmeat that hails from America, fudge is made from white or brown sugnr, milk, cream or condensed inilk, butter, and Havoured with chocolnte, coffee, and vanilla cessence.
The ingredients required for chocolate fudge are $\frac{1}{2} \mathrm{lb}$. brown sugar, 2 tablesponnfuls of butter, 4 tablespoonfula of chocolate powder, a small tin of unswectened evaporated milk or a teacupful of milk, or $\frac{1}{2}$ teacupful each of cream and water, and a little vanilla easence, Mix the chocolate powder with the milk, cream, or evaporated milk to a smooth paste. Melt the butter in an enamel or aluminium sancepan. Add the sugar and chocolate by degrces and boil up gently until a little of the mixture dropped into a cup of cold water hardens when rubbed between the fingers. Remove from the stove and add the vanilla fla vouring. Pour the mixture on to a shallow buttered tin and mark it out into squares with a knife before it sets.
Another and cheaper way of inaking chocolate fudge is by using 4 tablespoonfuls of cocoa powder instead of chocolate.

Coffee Fudge. To make this use a teacupful of golden syrup, a breakfastcupful of brown sugar, a small tin of unsweetened, condensed milk, a tablespoonful of butter, and 2 table
ordinary or bituminous kind Other fuels are anthracite and coke, used for special slow combustion stoves and for boilers. In country districts a good deal of wood is used, while in some parts of the country peat is burned. Oil. too, is employed as fuel, while electricity and cosl-gns, though not strictly fuels, can be used for warming rooms, heating water, melting metal, and similar purposes. Peat is only found in certain parts of Grest Britain, Cleshire. for instance, and owing to its smouldering propensities is only suitable for fires that are not intended to brighten as well ns warm n room. There are also pntent fuels on the market, but the valucof these varies

Gas fires and cookers and electric henters and conkers arc installed in many homes. In others a system of central heating is arranged, but in all these a certain place is usually left for coal fires, which. although somewhnt waste ful, have attractions for so many persons

Special coke grates are procurable which coin bine the cheerful glow of the open firo with some of the advantages of the gas firc. The coke is ignited by gas jets at the hottom of the grate, which are turned out after about 20 min. the coke then being well alight. In an ordinary grate, with: coal as the main fucl, logs of wood can be burned, and if oak or any other good hardwood is bought it is not unduly expensive. See Anthracite; Coal : Coke; Electricity ; Gas; Oil ; Peat; Wood.

FULHAM WARE. The stoneware produced by John Dwight at Fulham in the last quarter of the 17 th century is highly prized because it marks the beginning of great art in English pottery. Examples of the fine statuettes which he moulded are not often net with.

There was a Iarge output of Fulham ware of morc useful types, readily distinguished from the Cologne ware on which it was founded, and this may be collected to advantage. Besides greybeards it includes brown mugs and

Fudge. American sweetmeat resembling soft toffee, made in various flavourings
lankards, sometince with hunting scenes and Hogarth designs in applied reliefs. There are also Hasks and jugs with horizontal ribbing round the neck, simple noggins with little or no decoration, and the like

This domestic pottery successfully displaced the Flemish Grès ware of the time, and was the forerunner of Staffordshire salt-glaze. Modern Fulham ware is represented by normal types of brown stoneware and other domestic designs See Pottery

FULLER'S EARTH. This mineral is used as a dusting and cleansing powder, both for clothing and for the skin. In the former case it is efficacious in removing greaso from woollen and other fabrics, and enters into the composition of some makes of cloth ball.

Fuller's earth is used on the skin, especially when a bland, inert covering is required for an irritated or chafed surface, and is therefore an ingredient in certain soaps and face creams It is sometimes used for powlering the skins of babies, but when applied as a dressing for the navel or inflamed buttocks of infants it appears to have been followed by tetanus or lockjaw. A powder containing boracic acid is always thercfore to be preferred for this purpose. Fuller's earth can also be employed for clenning lloors and other wooden surfaces. See Boracic Acid: Cloth Ball: Clothes Face ; Stain, etc.
FUMED OAK. Oak can be darkened by subjecting it to the fumes of ammonia. This gives an appearance of age and enriches the

British afuseun
24 hours in a case, cupboard, or small room, with one or more open saucers of liquid a mmonia. A packing-case should have strips of paper pasted over joints that are at all open If one or more panes of glass can be fitted as windows the work can be cxamined without opening the case and letting fresh air in. A quick test of the effect ammonia will have on the wood can be made by placing a piece on the open mouth of the aminonia bottle. A trial for a few minutes will show whether the wood can be fumed or not.

Fuming is usually done after the construction of the article is finisher.. but before the application of varnish or polish.

FUMIGATION. The idea that houses require fumigation after illness from some infectious disease is being rapidly dispelled. It is now generally recognized that in the majority of cases infection is spread by contact with a patient suffering with, or recovering from, the infectious disease. Fumigation of rooms after
such cases has heen discontinucd in many large towns and boroughs without any increase of infectious cases, though spraying with disinfectant is carried out instead
Fumigation of rooms for the purpose of getting rid of houschold pests is still common, but here again the advent of the modern form of penetrating spray, together with the discovery of suitable insecticides, has largely superseded the use of a gascous disinfectant as a means of exterminating insects. The flumigation of tooks, gloves, hoots, fancy leather work and dresses and all fabrics which are likely to be ruined by steam disinfection is still carricd on Ronms or othor spaces to be fumigated must first be sealed hermetically, and can then be treated aclequately by funigation if desired

Sulphur or formalin are most often used. Sulphur may te used in the form of crushed rolled sulphur or as sulphur candles. These arc ohtainable in varying sizes from chemists, and are provided with instructions as to the number required ior a given space. Liquid sulphur eas in cylinders may also be used. The room should be liopt, sealed for at least 24 hours.

Formalin is usually employed in a special apparatus which heats the liquid, causing the gas contained in it to be given off. From 10 to 15 oz . of formalin are required for every 1,000 cubic ft of space. Another method is to pour $10-15 \mathrm{oz}$. of formalin on to $\overline{\mathrm{oz}}$. ol potassium jermanganate crystals contained in r deep dish. Enough gas is produced to treat 1,000 cubic ft . of space. Formalin may alsin be used in the solid form of paraform tahlets. These heated in a special lamp give off formalin gas, 30 tablets heing used for 1,000 cubic ft . of space.
In all methods of formalin funigation the room should he kept warm and moist, and remain sealed for at least six hours. After fumigation the room slould be well aired and thoroughly cleaned.
Other Uses of Fumigation. Fumigation is also practised for protecting plants, frinit trces, and the like from the ravages of garden pests. Imong those used in this connexion are carbon bisulphide, formalin, and hydrocyanic acid gas. Carbon bisulphide is recommended for use against the apple sawtly, as injections of it will destroy the pupae of the sawfly in the soil. As it is poisonous care should be taken not to inhale it freely.

Fumigation may be used also to destroy rats, but this is inadvisable where they are in dwelling-houses, and it must be employed with great care wherever food is stored. For burrows in the open earbon hisulphide may be used. A large wad of cotton wool, rags, or similar material should he soaked with the liquid; this should be at once inserted in one of the main burrows, and its outlets and inlets closed up. The liquid evaporates, permeates through the burrows, and asphyxiates the rats. This fumigant is not only poisonous but inHammable. No light, therefore, should be brought near it. Fumigation is also one of the mathods employed for destroying "asps, and in a different way for protecting furniture. See Disinfection; Furniture; Rat; Spray; Wasp.

## Fumitory. See Corydalis

FUNERAL: The Arrangements. When n death takes place, the nearest relative, or someone acting for him or her, must make arrangements for the funeral, which should take place not later than the fourth day from the death of the person.

The first duty is to sec that the body is properly laid out, this task being usually performed by a woman. If $n u$ one is known, an undertaker will supply one.

The next urgent matters are to notify the death to the registrar, to choose the grave,
and to fix a time for the funeral. If a doctor has been in attendance he will give a cortificate of death, which should be taken to the registrar for the district, at whose offices the necessary particulars about the deceased, age, etc, are entered If no doctor has been in attendance, the coroner must he told, and he will arrange for an inquest, if necossary.

In undertaker should he sent for, or visited, and terms arranged with him. Usually, on knowing how many persons be must convey, the place of the burial, and other such matters, he will fix an inclusive fee for carrying out the funeral, including not only the hire of cars and hearers and the purchase of the coffin, but the payments at the cemetery and the fees to the clergyman or minister and others He must he given the death certificate which has been supplied by the registrar, and which he must show to the officiating clergyman.
The grave should then be chosen by visiting the cemetery or churchvard where the deceased is to be buried. The undertaker will also make this arrangement if requested. In some cases the ground for the grave must be bought outright; in others only an interment fee is charged. Where there is a family vault, notice must be given that it is to be opened. In parish churchyards there is usually some difference made as to fee between parishioners and non-parishioners. The time for the funeral must be fixed, in conjunotion with the undertaker, and the invitations sent out

The service will be conducted by the clergyman or minister attached to the graveyard unless the mourners wish for their oun clergyman, in which case they should acquaint the one in charge with their wishes. It is usual also to put a notice of the death in The Times, The Daily Telegraph or the local paper. This may give the time and place of the funeral, and if no llowers are required it should state that fact. Relatives only may bo invited, but in other cases invitations are extended to friends. In the case of persons having a large circle of friends it is not uncommon to hold a service, to which all friends arc invited, quite apart from the funeral ceremony proper
The Funeral Ceremony. On the day of the funeral the guests arrive at the house just hefore the time appointed for the procession to leave it. After the coffin has been carried out they will be escorted to the cars, the nearest relatives taking precedence over the morc distant ones and over friends. In nost cases friends go to the church, but only near rela. tives to the house.

On reaching the cemetery a service will be held in the church or ohapel, and then the mourners will follow the hody to the grave, where the burial sentences are recited. The guests may return to the house, where perhaps light refreshments are served. On returning to the house the blinds which were drawn down during the ceremony should be pulled up.

For hodies that are cremated a somewhat different procedure is followed. An undertaker is secured and he will make many of the arrangements, hut two doctors must view the body and give their certilicates heforc the ceremony can be carried out. See Cremation; Death; Flowers; Mourning; Vreath.

FUNGICIDE. A fungicide is a preparation for billing fungus on trees and plants. Two that are recommended for fungus on fruit trees by the Ministry of . Igriculture are Bordeaux mixture and lime sulphur at summer strength. Fungicides should always be ap. plied as preventives rather than as remedies, as attacks by fungi develop very rapidly. The best way of preventing an attack is to cover the vulnerable parts of the tree, i.e. leaves, fruit, and young wood, with a fungicide, applied as a very fine spray.

Fruit trees should be sprayed with lime sulphur in February-March before the huds
arc advanced in growth. Amateurs arc advised to purchase lime-sulphur concentrate from horticultural dealers rather than to attempt to make the mixturc themselves, and to dilute it according to the directions. Bordeaux mixture is used just before the blossoms open and again as soon as they have fallen. If lime sulphur is used when the trees are in leaf a weaker solution is required or the leaves will be damaged. Spraying black currant bushes with lime sulphur from midMarch to mid-May at fortnightly intervals is the best way to get rid of hig bud or black currant mite. Bordeaux mixture can be obtained in concentrated form, and then needs merely to be mixed with water

Black spot and mildew on rose trees can be controlled by spraying the trees in mid-winter with sulphate of copper, one ounce in threc gallons of water, by using Bordeaux mixture in March, and liver of sulphur, one ounce in threc gallons of water, occasionally in summer. See Bordeaux Mixture ; Fruit; Lime Sulphur; Spraying.

FUNGUS. This name is applied indiscriminately to parasitic plant diseases that are caused by spores. Fungous diseases such as apple canker, finger and toc disease, are dealt with under their respective headings.

Sometimes poisonous fungi are mistaken for edible mushrooms, with serious consequences. Some varieties are poisonous to all who eat them ; others may be harmless to the majority of people and poisonons to a few, owing to some idiosyncrasy. Even edible mushrooms are indigestible, and may cause diarrhoea in delicate persons and children. They decompose rapidly and should always be eaten fresh. When mushrooms are cooked, set aside, and then warmed up again, they may be harmful owing to the development of poison.

It is not easy to distinguish the harmful from the harmless kinds. A Ministry of Igriculture pamphlet points out that certain tests are quite fallacious. For instance, it is widely believed that the contact of poisonous fungi tarnishes a silver spuon, that all fungi which grow on wood are dangerous, and that an edible mushroom may he known by the fact that the skin is easily peeled off. These heliefs are not to be relied upon.

Poisoning by Fungus. The symptoms of fungus poisoning may not come on for 10 or 12 hours, or even later; then there may be severe pain in the abdomen, followed by vomiting and diarrhoea. The muscles twitch, the skin becomes cold and clammy, the breathing rapid, the pupils of the eyes dilated and the face pale. In some cases nervous symptoms, headache, giddiness, etc., precede or take the place of those indicating irritation of the stomach and howels. The heart gradually fails and the patient collapses. The case inay run on to coma and end in death.

The doctor must be sent for al once, and meantime give an emelic. Use whalever is at hand, rather than have any delay.
A tahlespoonful of inustard or two of salt in a large tumbler of tepid water answers admirably. If these arc not available, give large clraughts of lukcwarm water, and tickle the hack of the throat with a feather. Follow the emetic with a good dose of castor oil ( 1 oz . for an adult).

Kecp the patient lying down in a warm room, and well covered with hlankets. Apply cloths wrung out of hot water, or hot poultices, to the abdomen. Rub the arms and legs vigorously to promote warmth and prevent cramp. Give suitable stimulants, such as hot coffee, hot milk, hot brandy or whisky and water, or a teaspoonful of sal volatile. See Ipple Canker; Brown Rot; Canker; Emetic; Mildew; Mushroom; Poisoning ; Toadstool.

## Furs: Their Varieties and Uses

## The Choice and Care of these Valuable Garments

In this work our readers will find entries on all the popular furs, e.g. Chinchilla: Ermine Musquash, etc. The articie on Rabbit is also of interest. See further Clothes Moth; Rug, etc.

The term furs includes tur coats of various kinds, neckilets, animal ties, wraps, cloaks, capes and muffs Fur is also used for making collars and cuffs and for lining coats, gloves, and motoring rugs : another use is for trimmings and edgings, while felt hats are also made of it. Fur rugs, made chiefly from racoon, goatskin, sheepskin and white bear are used on Hoors and as hearthrugs More costly furs may be used for travelling rugs, and leopard, gazclle and wild cat skins are sometimes employed for upholstery
While the retail price of furs varies somewhat according to fashion, and bargains can be acquired at special and summer sales, certain skins are always highly priced. The value of a fur skin depends upon the colour, texture and durability of the fibres of the underfur, and also upon the pelt. The coats of fur-bearing animals are at their hest towards the end of the winter. The sea otter is ranked as a standard for the seven most precious furs taking the wearing quality of this fur as 100 the other furs compare as follows : Seal, 75 ; sable, 60 ; silver or black fox, 40 ; ermine, 25 white fox, 20 ; chinchilla, 15 .

If the best value is to be obtained, furs should be purchased from a reliable furrier. Imitation skins, so treated as to render them almost indistinguishable from the genuine article, are sold under a variety of names Some of these skins are hard-wearing and, therefore, economical to huy, but others are apt to develop a worn and shahby appearance with undue rapidity.
Rabbit is used extensively as a substitute for seal, erinine, dyed musquash, sable, beaver, chinchilla, and nutria; goat is frequently made to represent monkey and hear; and marmot to represent sable and inink. Hare replaces sable and various kinds of fox; lamb is treated to look like nutria; nutria is used instead of beaver; while dyed musquash often imitates seal and opossum skunk. Sometimes, too, furs are skilfully topped as a means of disguising their real origin, or to enhance their appearance, as, for instance, when light sable is topped to give it the Russian sable colour. This process consists of brushing the top bair with a colour which imparts richness to the fur, while another device is to insert white hairs in the skin of a cheap fox to give it the appearance of silver fox. Badger hairs are used for " pointing" purposes

## Wide Choice of Furs

Furs of the hard-wearing order include astraklian, badger, beaver, mink, goat, bear. seal, musquash, and skunk, but if grace is desired, then mole, sable, chinchilla, marten, fisher, broadtail, fox, and ermine may bc selected. Where cheapness is the main consideration, rabbit, racoon, opossum, fitch, hamster, hare, marmot, Thibet, wallaby, and the smaller wolves are to be recommended.

For women of limited means fur coats are not a wise investment. In mink or other expensive furs they are outsice the usual range of price, and even in cheap furs such garinents are not relatively low priced There are still the considerations of the work of the sorter who matches the skins and of the skilled cutter. At a good furrier's both sorter and cutter command high salaries and have acquired their art through long years of training and experience. A satisfactory fur coat cannot be cheaply priced if it is to preserve a good shape and appearance Poorly sorted skins and badly cut garments of this type look ostentatious and clumsy

The ideal lur coat is warm without being unduly heavy. Hudson seal, which is merely musquash deprived of the top hair, is a skin which makes up into comparatively light coats. It tends to split, however, and is therefore not so bard-wearing as might be desired When a split occurs, the two edges of the eather should be brought together and oversewn at the back, while if the leather itself has perished a new piece of fur will be required. To carry out these renovations it will be necessary first of all to remove the lining. Where a cheaper coat is required, dyed coney or sheared lamb is chosen. Moleskin coats, while not suited to rough wear, are liked by some wonien on account of the colour and their supple quality when well made

Fur buttons to match a fur coat can be made from odd pieces of the pelt scwn over ordinary large huttons and, if necessary, padded with cotton wool. The buttons should be attached to fur coats in this way Sew a piece of black tape, just wide enough to pass through the shank of the button, along the leather for about 2 in . ahove where the first hutton is to he placed A hole should be pierced for each hutton, and the shanks slipped through. Then push the tape through each shank and sew it firmly along between each button, finally stitching it for about 2 in ns at the commencement.

In the choice of furs the discerning woman will realize that fur should he chosen to suit her complexion and hair. A costly chinchilla or ermine scarf may not hecome her nearly so well as a marten tie Fox, too, is particularly becoming, but it is not durable.

Besides being made up into separate furs and into garments, fur is also used for trimming purposes. On winter coats or wraps of velour cloth and sitnilar materials long-haired furs such as lynx or wolf may be used. Lighter

Fur. Moth-proot wardrobe for storing furs, adapted from a cedarwood cigar cabinet
lurs, such as the various dyed conies, sheared lamb, foxaline and also sable, ermine and white or grey dyed fox are used to trim summer coats and evening wraps. Fur sets of collar and cuffs can be purchased unlined, and also trimming in various widths by the yard It is in such sets and trimmings that the retail prices of furs vary nost, according to the current fashion, as often thesc furs are of the cheaper kinds, dyed or shaped to suit the requirements of a particular season and of no lasting value.

While valuable furs which have become old-fashioned in shape are best re-modelled by a furrier, cheaper furs or odd pieces, if care is talien, may be cut at home. If a furrier's knife is not ohtainahle, a strong, sharp penknife should be used. The fur must be laid on a board with the skin uppermost, and the place where the incision is to he made marked with chalk. While the cutting is being done, the fur should he held down firmly at each side. To join two pieces, place them together with the fur inside and oversew the edges. Do not draw the stitches too tightly or the fur will pucker.

Care and Storage. The care of furs is important, for proper treatment adds considerably to the length of time during which they will remain wearable. Natural furs wear best, because dye has a deleterious effect on the pelt or leather, though in some cases it is so slight as to he almost negligible. On the other hand, dyed furs are practically immune from the ravages of moth Furs should be kept in the dark and hung up whenever possible. The fur should fall in the natural way, skins such as fox being hung from the head Before putting on furs shake them vigorously, excepti in the case of such delicate skins as chinchilla After wear, repent the shaking process and go through the fur gently with a metal comb Fiur coats which have been rubhed on the under-slecves or collars should also he combed after use

Wet furs should never be dried betore a fire. Hang them up, preferably in a draught, and when the moisture has evaporated shake and comb them with care. In addition to occasional shakings, the furs should also lee beaten with a light cane and suhsequently combed in order to keep them free from inoth. The presence of the latter can be detected by patches of loose hair. Should these appear the furs are best sent to a furrier, for, though moth is not difficult to keep at bay when proper precautions are taken, it is not casily eradicated once it has actually started its destructive work.
The cleaning of furs may be done either by a professional cleaner or at home, though the former method is to he recommended in the case of valuable skins. Both hran and silver sand, when heated in a dish in the oven, make a good cleaning agent for almost any kind of fur, though sand should not he used on white peltry. Either of these should he rubbed into the fur with the fingers, and afterwards brushed or heaten out. White and other light-coloured furs may be treated in the same way with warm powdered magnesia. Frequent cleaning can be avoided by wiping the furs with a damp towel after wear

Fur hearthrugs require equally careful treatment, for they are quickly attacked by moth. In the summer they tend to make a room look too hot, and should therefore be removed in favour of cooler floor-coverings.

Cold storage facilitates the care of expensive furs during the summer months, and ensures immunity from moth. Furs bought at that time of year from a good furrier are usually stored free of charge till they are required. Special moth-proof bags are sold in which skins may be hung up while not in use, and are particularly useful in this connexion when
the owner is travelling or away from home for a long period.

For home storage of furs a useful moth. pronf wardrobe can be ohtained. The illustration shows a cedarwond cabinet adapted for this purpose, but which was originally made for packing cigar-boxes when exported to this country. Such cabinets are sold by a cigar merchant at prices varying from $\mathfrak{f} 2$ as to $£ 55 \mathrm{~s}$. Cedarwond, especially when perineated with the smell of the cigars, possesses moth-preventing properties and is of decorative valuc, for a piece of furniture of this kind either stained to darken it or preferably, if in accord with the room, in its natural state. When required for storage of smaller furs, the shelves which originally furnish such cahinets can be retained. If these have been removed, as in the one illustrated, a wardrohe rail can be ensily fixed or hooks for fur articles placed in hags to keep them free from dust.
Furlong. This measure of length contains 220 yards and is the eighth part of a mile
FURMENTY. This is prepared by boiling I quart of milk in a large sauccpan over the tire, and putting 2 oz. of stoned raisins and the arame quantity of cleaned currants in another pan containing just enough boiling water to cover them Boil them for 5 min . until they feel solt and are well swollen, then drain off the water and add the fruit to the boiling milk.
Add 1 teacupful of prepared wheat grains, 2 oz. of loaf sugar, and a little nutmeg, and boil all these ingredients for about 20 min . Then take the pan from the fire and let the mixture cool slightly, afterwards straining in 2 well-beaten eggs. Stir the whole againover the fire until it thickens, but do not let it rehoil. add a little hrandy or home-made wine, and pour the whole into a deep bowl, serving it cold
In some districts prepared wheat can be bought by the pint at any confectioner's, hut when it is not pussible to purchase it in this way it can he made at home. Do this by soaking a pint of husked whent in cold water for 24 hours, then put it, with a pint of clean cold water, in a covered jar in the oven Bake it slowly till the grains are quite soft, and it is then ready for use.

FURNACE : How to Construct. A furnace is used to melt metal for casting, and in the article Casting are given diagrams and instructions for building $\boldsymbol{n}$ useful brick furnace suitable for cast irnn or brass. The same article describes a furnace made up from standard fireclay bricks and heated by a gas blow plpe A gas-fired crucible furnace, working on the injector principle, is shown at lig. 1 on this page. In conjunction with the furnace a font blower of the type shown in Fig. 2 is employed to furniah the necessary air pressure

Furnace. Fig. 1. Gas-fired crucible furnace working on the Injector principle. Fig. 2. Foot blower used in conjunction with the furnace to give the necessary gir pressure

Mufle Furnace. A muffle furnace for the enameller is readily made from fireclay bricks, built up as shown in Fig. 3 The furnace body is strengthened with iron bands, and a loug chimney is provided to dispose of the fumes, and to create sufficient draught to cause the fire to burn well and fiercely. All oints must he luted with fireclay. and the whole well baked with the gas burner
In this style of furnace the door is usually at the end and the flue pipe at the top. The burner is locnted beneath the furnace, the latter standing on short legs resting on a substantial base of some fireprool material, such as a fire hrick or a sheet of ashestos on an iron plate A hole is cut in the botton of the furnace to admit the llames of the burner, and a simple damper regulates the amount of air admitted

Fireclay bricks can be obtained flom the ironmonger, who will also the able to procure the clay muffle to go inside furnace, the appropriate type of gas hurner (Fletcher Russell \& Co.'s) with gas and air regu!ators. and if desired a chimney with cast iron foot. The gas sup. ply tap and pipe must be large enough to allow full pressure at the noz. zle. and for the size indicated a half. inch supply is re. quired It is advisable to procure the clay muffle first and to make the furnace to suit it. Dimensions inside inufflefor the furnace in question might be 4 in. long by 2 in. high by 2 in . wide.
For a larger size a ${ }^{6}$ in. supply pipe would be needed, when mufle might be, say, 9 in . by $4 \frac{1}{2}$ in. by $5 \frac{3}{8}$ in. See Boiler; Casting; Enamclling: Fireclay, etc

FURNISHED HOUSE. In London the hest letting seasons are in the winter and during the late spring; at holiday resorts, unless also winter resorts, during the summer months. The houscs are let furnished from month to month. or for three months or ceen

longer, as the case may be. In July and August, when most people take their holidays, the highest prices are ohtained at holiday resorts, but June and September are busy months, while early lets are arranged for May ; in some sheltered spots the season lasts into Octuber.
There are two ways of letting a house. The tenant may carry out the business himself either by advertising or by private

Heaty. thus saving an sgent's commission and other incidental expenses. In most cases. how ever, it is usual to entrust it to an established firm of house agents The agents charge a small commission on the whole tranyaction that is to say, on the tutal a mount eventually realized by the let. They undertake no responsibility for default on the part of the visitor, but any risk is minimized by the stipulation for payment of half the various instalments of rent, in advance.

Thic first step is to enter in the ugent's register of houses to let, the rent required, and particulars of the accommodation available. This is intended for the information of visitors on the look-out for houses, who call on the agents and are invited to see if there is anything in the register that will suit their requirements In this manner the tenant gets in touch with prospective clients, and after that it reats inainly with the principals to come to terms when the premise have been inspected The final step is the signing of an agreoment drawn up by the agents, the cost of which is shared by the partics Under this agrecment the visitor binds himself to take the house for the term and at the rent agreed upon. the tenant paying all rates aud taxes,
If any rooms are unfurnished or partly furnished, which are occupied or used as store rooms, care must be taken to see that they are not included in the number of hedrooms and sitting rooms entered in the agent's book. This is important because if any mistake is made in this respect the tenant may be called upon to furnish the room or make $\Omega$ ieduction in the rent.

Preparing the House. One of the lirst considerations in getting a house at a seaside resort ready for a fainily with children is to arrange it so that it can be easily kept clean From this point of view linoleum is to lie preferred to carpets and rush mats to carpet mats. In case of accident it is always advisable to put away the things that are most valued amongst the household roods, especinlly silver, china and other valuable ornaments. Unless by apecial arrangement plate and linen are never included, and they should be carefully put away. Glass, china and blankets are counted ns necessaries, and reasonable supplies of these should be provided, together with all that is necessary in tlo way of kitchen utensils. Gas or electric fittings must be in good working order. and the same remark applies to blinds, curtains and door locks and any labour*rving devices.
Where the meter is not on the slot system, the gas company ought to be notified of the change, so that the incter can be read, and the tenant pays for the gas he has consumed up to the date of his departure

If the garden is any size, and has been well cultivated, the tenant may undertake to see that it is kept in onder, and make a charge for his trouble, unless the upkeep of the garclen has been included in the rent. It is more usual for the visitor to make his own terms with the gardener, but he is not under any obligation to $10 \cdot s 0$, and the tenant should bo careful to stipulate for the upkeep of his garden upon making the agreement. The latter document should also contain a clause forbidding the newcomer to take in lodgers or to sublet the house or any portion of it Sec Agreement: Cottage; Holidays.

## FURNITURE AND FURNISHING

## Good Taste and Economy in the Equipment of the Home

Other peneral information on this subject will be found under the headings Colour: Decoration. Sce also Antique Furniture and articles on the various styles, e.R. Chippendale; Tudor; and those on the rooms and pieces of the home, e.g. Burcau; Chair; Kitchen; Nursery
While modern furniture is undoubtedly have a late 17 th century dreaser as a sidea good choice for amall rooms in the average hoard, and the dining table, for the sake of flat that is to be newly equipped throughout, there is still a strong feeling for antique styles in furnishing perind houses. The great thing is to choose auch styles with a nicc apprecia. lion of their suitability to their surroundings. In old days no one worricd about period As new pieces of furniture to meet the ourrent modern nced were designed, so they were gratefully acquired by the rich and comfortably settled in the same room with the pieces of former years

Each acquisition was an event as important as the entire redecoration and refurnishing of a house to day. It is still really far more importont to acquire pieces to suit individual needs and to blend colours, shapes, woods and metals harmoniously. than to try to live in the unoomfortable replica of a room only anited to the life of many generations ago On the other hand there are reasons for selecting certain periods to inspire furnishing schemes, the chief of which is the type of the house. One may possess antique pieces and good reproductions, but while there are so many modern decorative schemes in which such picces can be pleasantly set. it is far more difficult to reconcile furniture having metal tubing frames and table surfaces of glossy enamel or glass to a Tudor setting, than to utilize successfully a refectory tahle and oak stools in a morlern dining room with painted walls and a rubber tiled foor.

The Oak Period. As many small houses of to-day are based on the 16 th and 17th century cottage and farmhouse type, it is useful to rememiner that the oak period in antique furniture coincides roughly with the Tudor and Jacobean periods in architecture, and therefore oak is in harmony with lowpitched ceilings and visible heams, brick fireplaces and casement windows. Those who wish to furnish after the style of the 17th century have to day two special conditions with which to contend. They cannot own much gennine old furniture of the period, and are likely to feel tied when trying to equip the whole house to correspond, as they cannot he limited to furniture which was aufficient for a household of 300 years ago. They have to remember that in early Jacoliean timea there was no electricity available, no gas, no sanitary arrangements, and very few carpets.
Some people solve the problem rather wisely by confining one period, such as the Jacobean, to one or two rooms of the house. For instance, a Jacobean hall and even a dining room, in spite of the limited space of to-day, are pursible to furnish with some degree of success. A carved oak cheat is perfectly at home, and forms a very useful receptacle for rugs and other articles. The Jacobean chair, with its hard wooden seat, almost upright back, and straight legs, is right in the hall, and, when cushioned, quite suitable at the table, but scarcely in a living-room where comfort and ease are demanded. The court cupboard or buffet-both terms are correct-makes a picturesque feature

The small gate leg table is more appropriate in the hall than in the dining room, because of its limited top accommodation and inconvenient underframe, which renders it awkward for the legs and feet of diners. An excellent cascment window trentment for either Tudor or Stuart period style hall is given in the article on Curtains.
If the dining room is to be furnished in this style, some liberties must be taken. It may
hoard, and the dining table, for the sake o one with centre rail henenth, but built on the lines of the old draw-table. This table, of which there are many made to day, is quite in keeping with the Jacohean tradition, while being more comfortable and convenient for a small room It was common in the 16th and early part of the 17 th century for diners to sit upon stools placed down the sides of the table. This fashion appears to day in small dining rooms (q.v.). In larger momis tall cane backed chairs namally ansociated with the period of the Restoration are often seen, up holstered in velvet or tapestry and often with fringe to trim the chair aeats The dining roon (and hall) may have a atone flagged floor to all appearances In reality it will be made of composition which is quiet to the tread and warm to the feet. Rugs of old Persian designs may enrich this flooring. Parquet is mure ordinary with a carpet of Oriental type. In this room no mahogany should be used, for it was not employed in the 17th century.

There is something to he said for the use in auch a dining room of definitely modern armchairs and settee upholstered in brown velvet and leather, as they do not clash with any. thing. Leather was a common material for the finishing of chairs in the 17 th century. A piece of furniture that well may be included in an oak room is the burean; though still existent, specimens are very rare of earlier date than the end of the Stuart period, but the bureaus was made of oak in Cromwellian times, and good reproductions are easily obtainable.

The Walnut Period. A drawing room furnished in the Jacobean style is not correct, as such a room was unknown at this period With the arrival of William III and Dutch domestic ideas after the changes of 1688, furniture undoubtedly took upon itself a more comfortable and pleasing aspect Tall sash windows were used more generally, houses became formal in plan and elevation, rooms squarer, and chairs and tables were made frequently of walnut, and showing graceful curves in their structure The William and Mary period saw the arrival of the parlour, and the alteration in social habits, particularly the introduction of tea as a popular beverage, influenced furnishing in the direction of leisured grace and comfort. Upholstered chairs, showing very little wood, began to appear, and the grand. father chair and clock are typical of the time. The picture of a room in the William and Mary or Queen Anne period is one of quiet restfulness and homely charm. The walls had broad panela, often of walnutwith gilt
enrichments, conferring greater dignity than was usually seen with the smaller panels found in Jacobean and Tudor interiors.
Inasmuch as the old parlonr suggests genetal social functions, and not specific use like the dining room. it is the model for the furnishing of the diawing room, or the more gracious type of living-room of today. The Queen Anue parlour was eminently service. able, comfortable, and homely, yet it hall a sense of style, and syinmetry, which appesls to-day as much as it did then.

The articles suitable for rooms furnished in accordance with the walnut period include a mund tea-table, chairs with and without arms, having seats covered in needlework or brucade and concave splat backs, a china cabinet, or a niche with fitterl shelves each side of the fireplace, a bureau, one or two tabourets or footstools, a chest of drawers, a dresser which is without cupboris, a folding card-table, and a sinall settee which was practically a double chair, with two splats divided by a smaller one. outwardly flaring arms and six cabriole legs. known as a courting-seat. The whole of this furniture may he in walnut, and a suitable colour for the hanginge of a room in which it is placed rould be green, though maruon. blue or yellow were often used
The beds of this perionl had very tall posts, and they were fitted with voluminous curtains, with shaped lambrequins (festooned drapery) above the bed itself was low, within a fuot or eighteen inches of the ground, and the posts were not highly decorated. Furniture made in cheaper woods was often painted and lacyuered. Gilding and inlay were also used. Lacquered leather screens, with six folding panels, were a decorative feature

Modern versions of such pieces and accessories are often seen to day. Fig. 1 shows a group of charming painted furniture. The Ledside table and chest of drawers show the earlier influence of Queen Inne designs, while the chair, though reminiscent of the ater and inore classical Adam period, blends happily The walnut period extended in the main fiom ahout 1685 to 1713.

The Mahogany Period. Through the discovery of the value of mahogany for furniture making, the 18th century may be said to be dominated by mahogany as far as furniture is

Furniture. Fig. 1. Group of modern painted furniture showing inspiration from both Queen Anne and Georgian styles, but blended by colour for use in the same room

Furniture. Fig 2. Space-saping bureau wall tirture. The flap folds up and the thickness of the piece is then 31 in. The flap below conceals space for magazines Courtesy of Rowley Galler,
concerned. With the commencement of the age of Chippendale, which can fairly be placed between the end of the first quarter of the 18th century and the commencement of the wars with France (1793), furniture followed in the main the French tradition, becoming lighter and more elaborate in ornamentation.
To possess a home which shows almost throughout inspiration from the mid-Georgian period is simple, for furnishing houses liave reproduced Chippendale, Hepplewhite, and Sheraton furniture in vast quantities. On the whole, these reproductions are good in design, and constructed on simple lines, a voiding overelaboration of carving, and usually selecting the plainer examples as models Bedrooms, hased on those of the late 18th century, often show inspiration from the work of Hepplewhite, and the four-post bed itself, with its lluted columns, is copied. Sanitation, indeed, had not yet arrived at a constant supply of hot and cold water, and the bathroom had yet to make its nppearance. But there were small washstands and dressing tables which combined picturesqueness with that utility and convenience of which to-day we avail ourselves. This bedroom furniture gradually became the Victorian suite, made up of a wardrobe, dressing chest or dressing-table, with or without a washstand, and one or more single chairs.

A bedroom equipped with furniture of the Hepplewhite or Sheraton period, roughly the last quarter of the 18 th century, should avoid the suite, and may pmperly include, beside the bed itself, a tall-loy, or double chest of drawers, a man's wardrobe, hasin stand, fold-ing-topped dressing-table, separate mirror, wing easy chairs, and oddments such as screens and hanging shelves. Until the 19th century it was the custom not to hang dresses, but to lay them flat in drawers. Hence the tall-boy, which gave extensive drawer accommodation, and the wardrobe fitted with trays.
It has taken more than a century to bring the sideboard, in structural essentials, back to

What it was originally
In early Georgian days a side-table, it became a complete sideboard with Hanking cupboards and centre drawers during the last quarter of the 18th century, and gradually developed in size and impertance until in the Victorian age it was almost a domestic altar, and occupied much room. The high back was practically unknown before the reign of William IV, but all through the 19 th century it was part of the conventional sideboard

Today, in conformity with English period furnishing and also with the best motlern ideas, it has shrunk to relatively sensible proportions for the size of rooms.

The Modern Period. A great advance has been made in the structure of upholstered chairs and settees, which are more comfortable now than ever helore The principal reason for this is the development of the use of wire springs and mesh and the consequent increase of durability and resilience. These circumstances have also affected the production of the modern mattress, which has made the bed of today much more comfortable than before.

Divan beds are lavoured because they look decorative in the daytime if attractively covered and cushioned Heads are constructed with fittings which serve as bedside tables and bookshelves in accordance with practical ideas of dual purpose furniture for smaller moms. For furnishing the modern small house various pieces of "double duty" furniture can be obitained, such as a compact sideboard with a writing slab which can be pulled out and is stowed away when not in use, in place of the usual drawers a bove the cupboards; there is also a dining table with a sliding top beneath which is accommorlation for cutlery in baize-lined partitions. The illustration of ${ }^{n}$ amall burenu wall lix. ture (Fig. 2) depicts a particularly useful and space-saving idea The chair and mirroralsu shown are examples of good taste in modern furnishing for small rooms

Very practical built-in furniture is a great feature of modern furnishing Fig. 3 shows a dining room with a built-in sideboard and a glass cupboard. The table in this illustration cannot be appreciated without the colouring. The glass top could be carried out in various beautiful shades-a seagreen, for instance, with table glass in amethyst and the beautifully de signed candlesticks in crystal with a purple line and mauve or silvered candles. The corners of the table are chromium plated, this finish is repeated in the handles of the fixtures and doors. The chairs unexpectedly hark hack to a Regency style, but seem quite at home in company with the lace trimmed mats, the china, cutlery and lustre central lighting fixture.
Modern style is essential in the kitchen. In many of the newest abodes it is small, yet replete with

Furniture. Fig. 3. Modern dining room furniture designed for a small flat. The austerity of the fxtures and glass-topped table is softened by beauty of colour and accessories
seen when not in use, the children's big toys are placed, instead of being cupboard-bound in an untidy mass. Wardrobes are provided with hooks low enough for the small child to reach, so that the virtue of putting thinge a way directly after use can be inculcated early in life. Little low chairs and tables are addec, and that invaluable item the play pen.
Another particularly well plenished apart ment is the modern bathroom, with real or closely initated washable tiled walls, tables with glass tops, and a floor of rubber tiling or cork parquet.

The Care oi Furniture. The beautiful ap. pearance which distinguishes really well-kept old furniture is due, in the main, to two circunistances. It has been shielded from rough usage, and it has been regularly cleaned with the familiar preparation called elbow-grease.

The kind of polish used for any wooden furniture is of comparatively small importance, for none of them is effectual without regular use and vigorous application. None of them will achieve its purpose by a liberal allowance and little rubbing. Beeswax and turpentine is a mixture which, though very old-fashioned, is perfectly safe to use on any wood, and in this connexion it should be remembered that it was the only proparation used by scores of housemaids who, through years of labour, produced that delightful patina we admire so much to-day on old furniture. On the other hand, preparations under various names are reliable, provided they are not taken as substilutes for regular rubbing with a linen cloth.

One of the worst marks and most difficult to remove is the circular stain left by carelessly used glasses in which hot liquid has been served, and it is worth remembering that the more brilliant the polish of the table top the more permanent appears to be the mark. The reason for this is that a fine polish is really a very attenuated film or gloss over the surface of the wood. This film is only obtained after an immense a mount of labour. Alcohol or hot liquid will destroy it, and in the case of french polish only one method will put the matter right. This is to have the whole of that portion of the table-top glass-papered down and to repolish it afresh. The colour niay be restored to varnished or wax-polished surfaces by treating them with linseed oil (q.v.). Ash and deal topped tables, such as those used in kitchens, can always be well scrubbed with soap, sand, and hot water, and the harder they are rubbed the better.

Blistering of Furniture. Occasionally inlaid furniture will cockle. That is to say, the thin veneer will come up here and there in a blister, and it cannot be remedied except by a cabinet maker, who may remove the veneer and re-glue it under pressure. This blistering is caused often by furniture standing too near a radiator, or sometimes damp will swell the wood and cause the trouble. It is curiously true that houses heated by radiators are more likely to damage furniture than those heated by the open fire, notwithstanding the variability in temperature arising from the older system. The explanation appears to be that heat from radiators draws the moisture from the wood, causing it to warp and split. Furniture reyuires fresh air in England, for the wood is not dried to stand great heat as is the case in hot countries.
A weak solution of oxalic acid will clean leather coverings, but all preparations should be very sparingly used, and leather should not often have anything applied to it, or it is liable to become sticky. Horsehair seats should never be re-covered over the old cover, which should be removed and the stuffing taken out and cleaned before stretching a new covering over.

FURNITURE BEETLE. Several species of bectle that in a state of nature reduce to powder the dead, dry branches of trees have taken to the destruction of woodwork in the house -rafters, floorboards, and furniture. They are all very small, longer than broad; their

Furniture Bectle indicated by a fin
wder eseaping from the holes in the wood.
Remedies are very difficult in application Dry heat of about $130^{\circ} \mathrm{F}$. is perhaps the most certain way to destroy the grubs, and if the article affected is sufficiently small the ordinary gas-cooking oven will serve for the purpose. In the case of fixed woodwork and large furniture the apartment must be made absolutely airtight, when it may he lilled
with the va. pour of car. bon disul. phideol hydrocyanic
acid. The. atter is a deadly poi. son and the former, though less dangerous a poison, will contact with a light. Naph.

Worm-holes in cieal flooring (natural size) made by the furniture beetlo
British Museum of Nalural Historu
thaline in liquid form may be injected into the holes, but it is a tedious operation if there are many of them; or corrosive sublinate dissolved in methylated spirits may be substituted where the odour of naphthaline is an objection. See Antique; Sideboard: Wood Worm.
FURNITURE CREAM AND POLISH.
Beeswax and turpentine together form an excellent polish for furniture. Shred the beeswax and add as nuch turpentine as will dissolve the wax to a moderately thick solution, or, as an alternative, add $\frac{1}{2} \mathrm{oz}$. camphor to a bottle containing a pint of turpentine. Let the latter mixture stand for 24 hours before adding 2 oz. finely shredded bceswax. When this is dissolved the polish is ready for use. Neither of these polishes should be made on a stove or close to a fire. Paraffin and turpentine or linseed oil, turpentine and methylated spirit mixed in equal quantities, provide other satisfactory polishes.

A good reviver for furniture which has been some. what neglected is made from $\frac{1}{2}$ pint each turpentine and linseed oil, and $\ddagger$ pint each brown vinegar and methy. lated spirit. Put these ingredients into a bottle, shake them well, and let them form an emulsion before using See Antique Furniture Spring Cleaning.

FURRING: In Building, Furring is the process of nailing small strips of wood to joists, rafters, wall surfaces, or any other part of a building, to form a level surface whereon to fix laths or building boards. The same expression is applied t" packing pieces of timber which are employed to bring uneven pieces of carpentry work to a regular surface, as, for exaniple, the packings under joists, to bring the top surfaces level. Short pieces of timber attached to the ends of the rafters of a roof for carrying the eaves beyond the surface of the wall are also known as furrings. Usually
 fuse bolders
urrings are of quite small section, often about 2 in . wide and $\frac{3}{8}$ in. thick, and in the case of preparing a wall surface for covering with building board it may be necessary to pack out the furring strips so that their faces should be level.

FUSE : How to Replace. An electric fuse is a short length of thin wire of an easily fusible metal which is inserted in the electric circuit as a protection against fire. The current causes heating of the lamps or apparatus and also of the wires and cables, but there is no danger under normal circumstances. If, however, an excessive amount of current llows the heating may approach the limit, when danger from fire will result. Being of an easily fusible metal, the fuse reaches melting point earlier than the other parts of the circuit, and thus breaks the circuit, so that no current can How.

Where the cables enter a housc two scaled luse boxes with glass fronts, one for each cable, will be found situated or: the company's side of the meter. These fuses are not to be touched by the consumer If they happen to fail, he should ring up the company to send and replace thent Next to the meter on the consumer's side comes the main doublepole awitch, consisting of two large tumbler switches connected by a wooden bar so that both work together After the switch comes a pair of consumer's main fuses, through which the whole house supply passes; next comes a batch of threc or niore pairs of fuses, each pair carrying the current for a section of the house; and finally there may be a number of amaller fuscs, which are often away from the other fuse-gear, and control single rooms.

In the event of the sudden extinction of a group of lights, the first thing to be done is to find and examine the fuse which has gone. If the fuse shows signs of heating and appears simply to have melted, one may suspect the cause to le gradual deterioration of the wire through long use, and a new piece of fuse may he substituted Should the wire have disappeared, except for some blobs of melted metal, a delinite fault on the affected circuit must be looked for before attempting to insert a new fuse. The cause may be a short circuit due to a mistake made in wiring some fitting which has been receiving attention, or perhaps the insulation on a hanging flexible has become frayed, thus allowing the bare wires of the two leads to touch and form a short circuit. After the cause of the trouble has been removed, the house inust be entirely isolated by opening the main double-pole switch, when the melted fuse can be replaced by a new one. The ends of the burnt fuse will afford a guide to the proper size
It is important to use the same size fuse-wire as beforo when replacing a fuse, as a larger size may be an infringement of the wiring rules approved by the fire insurance company, and thus may even invalidate the fire policy. The operation consists in cutting off a suitable length of fuse-wire and laying it in place with the ends wrapped round the terminal screws, finally securing the ends by screwing down the terminals, but not hard enough to cut the soft fuse-wirc. See Electricity.
FUSTIAN. Although the name is applied to the whole class of heavy corduroys and molcskins, fustian means nore specifically the dense, heavy cotton cloth with a smooth, leathery face that is much employed for making labourers' trousers. Drabs and browns are the colours most commonly in use, although others can be obtained. Fustian also makes an excellent material for covering chairs and stools.

ABARDINE. Raincoat cloths of various kinds are known as gabardines. Chiefly twill-woven, some of them ar plain-weave, and are of cotton, a mixture of wool and cotton or all-wool. Those which are close-textured are best. Fawns, drabs, greys, slate, smoke, and similar self and mix ture shades are the predominant colours.
Certain wool cloths of a twill or whipcord character and designed initially for raincoats are employed for dresses and tailor-made costumes.
Gabardine is made chiefly in 54 in . width. White or cream gabardine in heavy weight, either in all wool or with a cotton weft, makes an alternative to flannel for cricket and tennis trousers, and is less liable to shrink.
Before being made into raincoats gabardine is submitted to a process which causes rain to run off the surface without wetting the cloth. Rainproof gabardine, unlike mackintosh, is not spoiled, but actually improved, by being dried in moderate heat before a fire. Grease and soap are very destructive of this rainproof property. Cotton rainproof gabardine in the best quality, and made from supercombed Sea Island cotton, wears well, but soon becomes dirty in towns.
GABLE. Properly speaking, the gable is that part of the outside wall, having a triangular form, which risesabove the level of the roof line. The gabled roof istheonly alternative in an ordinary house to the hipped roof, thelatter meaninga roof that is returned round the end of a building. Sce Bargeboard; Bungalow; House ; Roof. GADROON : For Ornament. This is a fluted ornament. It consists of a flowing reeded form, short for its width and rather oval or egg-shaped. It is often seen on the cdges of tables, and is frequent on picces made by Chippendale. It is also found on articles of silver and Sheffield plate.
GAILLARDIA. These are very showy annual and perennial plants with large double or single blooms, ohiefly in shades of yellow and crimson. The perennial varieties are liable to perish in winter on heavy, clayey land, and it is usual to treat them as biennials by sowing sceds every year in June, either out of doors or in boxes of soil in a frame. Cuttings may also be insert ed in a frame in August. Excepton light or well drained soil it is rise to winter butb seedlings and outtings under glass and to

plant thein out in May. Somc of the finest up-to-date varieties are Mrs. Bateman Brown, Tangerine and Mrs. McKellar. The Howers are long-stemmed and useful for cutting. The annual gaillardias are raised from seeds sown under glass in March, the seedlings being planted out of doors in May. These plants are useless after heving Howered. Pron. Gä̀-lar-di-a.

GAITERS : How to Knit. Gaiters can be had in various materials, as, for example, in cather, black oilskin, and waterproof cloth, but they may also be knitted in wool. Leather gaiters may be cleaned with boot polish, and those of oilskin washed with a cloth dipped in warm sonpy water.

A knitted pair, designed for a child of 2-4 years, can be made according to the following directions. Width is given by means of the expansive rib in which they are worked, and extra length can be added to make them suitable for an older child of 4 to 6 years. The materials required are 3 oz . of 4 -ply Beehive Scotch fingering wool, and two No. 10 bone knitting ncedles. Half a yard of elastic about $\frac{1}{2} \mathrm{in}$. wide will be required for the straps which go under the instep to keep the gaiters in position. Fora larger size use 5-ply fingering and No. 8 bone needles, and knitextra length before shaping for the ankle.
Beginning at the top of the gaiter, cast on 48 stitches 1st row : Knit 4, "purl 2, knit 2 ; repeat from * to the end of the row. Repeat this row for $1 \frac{1}{2}$ in. for the welt which comes above the knee. Now begin the knee shaping. Knit plain up to the last 12 stitches, then turn and knit back 24 stitches ; turn again and knit 23 stitches; turn and knit 22 ; turn and knit 21. Continue in this way, knitting one stitch less each time until only 12 stitches remain on the last short row. Now turn and knit all the stitches on the ncedle; turn again and knit first 2 stitches, then purl to within the last 2 stitches, which knit. This completes the knee gusset.

The pattern for the leg begins as follows. lst row: Knit plain. 2nd row: *Knit 2, purl 2 ; repeat from * to the end of the row. Repeat the last two rows until this fancy rib pattern measures 4 in. long. Here extra length can be knitted for a taller child before shaping the ankle
Shapo the leg by decreasing one stitch at each end of every second row until there are only 40 stitches left. To decrease at the beginning of the row, slip the second stitch, knit the third, then pass the slipped stitch over the third stitch. At the end of the needle knit until within three stitches of the end, then knit two stitches together, knit the last stitch. Continue without any further shaping until the gaiter is long enough to reach the ankle (in the gaiter illustrated 43 in.), then work the instep. Knit 12 stitches in the rib pattern, then on the next 16 stitches only, knit for lit in. ; this makes the instep tab. Fasten off the wool very securely but still keeping the stitches on the needle.

Now go back to the point where the last 12 stitches were knitted before the instep tal was begun, and after the 12 stitohes piok up and knit 9 stitches along the side of the instep tab, knit across the 16 instep stitches, pick up 9 stitchies on the opposite side of the tab, and knit the remaining 12 ankle stitches. Work six rows on all these stitches in plain knitting, and cast off rather loosely. Press the gaiters
on the wrong side, putting a thin clamp cloth over the knitting, then sew up the back seam and sew elastic at each side in position so that it will just fit under the instep of the shoe. See Knitting; Sock; Stocking.

GALANTINE. This cold, glazed dish is prepared from boned meat, poultry, or gainc.
A good breakfast galantine can ve made by removing the skin and gristle from 1 lb . of raw topside of beef and the rind from 6 oz . of raw. streaky bacon. Chop both finely or put thein through a mincing machine; then place them in a basin with 6 oz. fresh white breadcrumbs, 2 beaten eggs, and 1 gill of good stock. Season, then pound the mixture gently, either in a mortar or with the end of a rolling. pin. Turn the whole on to a pastry-board, shape it into a roll, tie it up in a floured cloth, and boil it gently for two hours in stock or water flavoured with onions, turnips, carrots, or other root vegetables.

When cooked, lift, and after removing the cloth reroll it and press it between tins until it is cold. Brush over the top and sides with 2 coatings of glaze, letting the first dry before applying the second. Trim the ends, lay the galantine on a dish, and garnish it with aspic jelly. See illustration below.
Chicken Galantine. To prepare this, bone one large chicken (see Boning) and remove the skins from 6 pork sausages, seasoning the latter with salt, pepper, and grated nutmeg. Cut $\frac{1}{2} \mathrm{lb}$. ham and 2 hard-boiled eggs into strips, place the boned fowl on a table, and spread a layer of sausage meat all over the Hesh. On this lay alternate strips of ham and egg. Cover the whole with more sausage-meat, then roll up the bird from side to side like a roly-poly pudding. Tic it up in a clean pudding cloth, and then put it, together with the bones, in a stockpot half-filled with water. Let tho whole simmer for about $1 \frac{1}{2}$ hours, and when it is cooked, re-roll it tightly in the cloth, placing it between two tins or dishes. A good plan is to put heavy weights on the upper one in order to press the meat
Leave the bird to get cold, and in the meantime prepare a sauce by melting 1 oz . butter, stirring into it 1 oz . flour, and cooking the two over a gentle heat for 5 min . Add $\frac{1}{2}$ gill milk and $\frac{1}{2}$ pint of the chicken stock, stir the whole until it boils, and then let it simmer gently for 5 min . Season the sauce carefully with salt and pepper, strain into it 2 teaspoonfuls lemon-juice, and let it cool slightly beforc adding 4 sheets of gelatine previously dissolved in 1 gill of hot water. Reheat the sauce carofully, put it through a hair sicve, and when it has cooled stir in l gill of cream. Then pour it evenly all over the chicken, and leave the whole to set, afterwards placing it on a dish with a borler of chopped aspic arranged round the

Galantinc of boned meat, an appetising breakfast dis
edges. If a cheaper dish is preferred, all milk may be used in place of the cream
Veal galantine is made in the same way, using the same stuffing, but it is glazed in the same manner as the heef galantinc after pressing.
Nut Galantine. A vegetarian breakfast dish is made by shelling and blanching 3 oz . of nuts, skinning them and putting them through the mincing machine. Add $\frac{1}{2} \mathrm{lb}$. breadorumbs, or potatoes, a finely minced onion, and a teaspoonful each of chopped parsley and mixed herbs Season well and bind with white or tomato sauce, and the beaten yolks of tiwn eggs. Make into sausage shape, put into a scalded Houred cloth and tie securely, before placing it in boiling water and letting it simmer for ithours. When done, press and glaze as for beef galantine.
GALATEA. Made for nurses' uniforms and house dresses, galateas are strong twill cottons generally striped in blue and white and sometimes in red and white. Hardtwisted yarn and fast colours are omployed in the manufacture, and they mny be recomniended for very hard weir. Pron Gal-la-tee-a.

GALBANUM. This is a gum resin. grecnish yellow in colour and with a disagreeable odour. It niay be used as an expectorant. in doses of 5 to 15 gr . The compound galbanum pill, also known as the compound pill of assafoetida, as it contains botb drugs, is used in hysteria.
GALEGA (Gont's Ruc). This is $n$ vigorous, hardy, herbaccous perennial which
 bears bunches of pea-shaped flowers in summer It Hourishes in ordinary soil and is inoreased by division or by sceds in spring. Officinalis and Hartlandii, pale lilac and officinalis alba, white, are the chief sorts; they reach a hcight of about 3 ft These plants take up a lot of room and thercfore are Galega or Goat's Rue, which bears scarcely suit-
lilac-coloured, pea-shaped flowers lilac-coloured, pea-shaped flowers in sammer able for small gardens.
GALL. This is another name for the bile, the excretion of the liver (q.v.). The name is also used for the excrescences on the oak, Quercus infectoria, which is produced by the eggs of an insect.

Gall Ointment. This is an astringent ointinent made by rubbing up powdered galls with benzoated lard, and is chiefly used for haemorrhoids or piles. When there is pain in this disorder the gall and opium ointment is better. See Piles: Tannic Acid.

GALLIC ACID. This substance is found in tea and other vegetable products. It is an astringent and acts like tannic acid. from which it niay be obtained by boiling the latter with dilute acids, eg. sulphuric acid. The dose is $5-15 \mathrm{gr}$. It has been used for arresting internal bleeding. and is uscful for the night. sweats of phthisis, and in chronic diarrhoea, etc. See Tannio Acid.

GALLON. This measure of weight is used for beer, milh and other liquids, and for corn. It contains four quarta, and the
standard imperial gallon contains 277274 cubic in Its weight equals 10 lb of distilled wator.

Stock Sizes of Cisterns. The usual stock sizes of galvanized iron cisterns. roctangular in form and open at the top, intended na receptacles for water are as follows

| Gs). | Length | Width | Depth | Gal. | Lengtli | W\|chth | Depth |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

GALL STONE. The hard, stony mass to which the name of gall stone is given consists of bile pigment, lime salts and cholesterin. It may be the size of an egg or no larger than sand, and the numbers vary from one or two large oncs to hundreds of smaller ones. Gall stones, which may occur in the gall bladder or in the bile ducts, are much more common in women than in men. and are rare before middle age Over-cating, lack of exercise, and abusc of alcohol are common predisposing canscs. The active cause is germ infection from the intestine or by way of the blood which sets up chronic catarrh in the gall bladder.

Gall stone colic, or biliary colic, is the intense spasmodic pain occurring when a stone, leaving the gall bladder, passes along the bile prassages on its way towards the intestine.
Preventive treatment consists ill restricting the diet, insisting on sufficient exercisc and keeping the bowcls regular with salines, such as Epsom or Glauber's salte, etc. Alkaline mineral water or plain water should be drunk frecly. Tight clothing should not be worn.

When an attack of gall stone colic occurs the doctor should be urgently summoned Hot fomentations over the whole liver region sometimes relieve the pain. and should be tried until the doctor arrives. See Jaundice.

GALL WEEVIL. Attacks of the little gall weevil are very common to turnips Damage is in the form of small whitish swellings, from the size of peas to that of marbles. The eggs of the weevil hatch into small, grey, wrinkled mag gots, which feed on thic tissues, making a hollow cavity in whioh theylie.

Thopest is worst on light soil and may become serious on any land ir

Gall Weevil. Young turnipg galled by the peat. Top right, the weevil, much enlarged

Galtonia candicans. the bardy Cape Byacinth, which bears white bell-shaped flowers in August article below
proper motations are not adopted. Change of site may not nvert it entirely, but will liecp) it within bounds Should it threaten to become a chronic nuisance, evcry old stem of green and every old unused part of the turnip crop should be charred over the garden fire before being dug intos the soil

The piece of ground for next year's crop should be dressed with fresh lime at the rate of two stones per square rod, the substance being left on the surface for a few weeks and then turned into the top spit. As a further precaution, all transplanted greens should bc well puddled with wet clay and soes the following year before planting See Cabbage ; Club Ront; Turnip

GALOP. This dance consists of gliding steps executed with much rapidity. Slide the left foot into the second position and chassé to the left, making a half turn on tho ball of the left foot and drawing the right foot up behind. The movement is then repeated with the right foot The girl's steps arc the same, but she begins with the opposite foot to the man's This is usually taught with 8 chassé, 4 and 2 danced smoothly
GALTONIA. This is a handsone hardy bulb plant which forms a tuft of large leaves and in August bears drooping bell-shaped white flowers on a stem about 3 fect high. It is known also as the cape hyacinth and as Hyacinthus candicans. The bulbs are hardy, thrive in ordinary well tilled and manurer soil, and are planted in March, 4 inches deep and 12 inches apart. Sand should he scattered round about the bulbs when planting on heavy land. In cold districts ashes should be placed on the soil above the bulbs in winter. See illus above.
GALVANIZED IRON. Shcets of ordinary iron are treated by galvanizing to resist. corrosion, common forms including the corrugated shects used for covering roofs. Flat or Italian roof shecta are made of galvanized imn with one of the sides 4urned up to form a weather-tight joint.

Galvanized iron is handled in a similar way to ordinary black iron, except that for soft soldering the flux should be hydrochloric acid. The soldering iron should not be worked too hot, and the surface of the metal must be thoroughly clezned with a file or scraper
hefore attempting to solder. It may be welded with the oxy-acetylene blow pipe if the film of zinc on the surface is removed by filing

Galvanized Wire. As a rule, galvanized wire consists of soft iron wire coated with a protective film of zinc, applied by one of the recognized galvanizing processes. Being soft and pliable it can be used for binding metal parts to woodwork. It is made in many sizes, from fine to a rod of substantial thickness
liencing wire is generally made of galvanized iron, and No 8 is the usual size for a singleztrand wire. Stranded galvanized wire is used for clothes-lines and fencing, the common size having seven strands and ranging from Nos. 3 to 6 wire gauge. A cwt. of No. 6 contains about 450 yd., a cwt. of No. 3 about 260 yd ., and other sizes in proportion. Gal. vanized barbed wire is generally made of steel, and sold in reels of $\frac{1}{2}$ cwt. or more. Galvanized wire netting in various gauges and meshes is sold in rolls of 50 yd ., from 12 in . to 72 in wide, and from $\frac{1}{2}$ in. to 4 in. mesh the inesh being the size of the spaces between the wires See Fence: Gauge; Wire: Wire Netting.

GALVANIZING. The object of galvanzing is to preserve from corrosion articles made of iron and steel. It consists in applying a protective coating of zinc to the surface of the metal, and requires the use of special machinery. For hot galvanizing, the article to be treated is immersed in a bath of molten netal at a temperature of about $1000^{\circ} \mathrm{F}$.

Electro-galvanizing is carried on in much the same way as the electro-deposition of copper and other metals. Another method is the dry process, sometimes known as sheradizing. The articles have to be properly cleaned, and are then placed in a frame or barrel and heated to about $600^{\circ} \mathrm{F}$. The barrel contains a quantity of zinc dust, and as the articles move about in it the dust is deposited upon them and forms a protective conting. The sheradized surface is rather brighter and more silvery than that produced by the ordinary hot galvanizing. Should the amateur worker desire to have his products galvanized, this can be done by sending them to a galvanizing firm through the local builders or ironmongers.
