Melon Marmalade. Canteloupe, citron, or musk melons may be used for miarmalnde. Quarter the melons, hut do not peel them. Take out the seeds, weigh the fruit and allow a pound of sugar to every pound. Grate the melons on a suet grater, discarding the rinds. To every three pounds of pulp allow the grated rinds of two lemons and a teaspoonful of ground ginger. Put all (including sugar) into a preserving pan, and let it boil gently until it thickens and sets well. Stir steadily from time to time to make it amooth, and remove scum as it rises When it is done pour into pots and cover while hot.

Ginger and Marrow. An excellent but cheaper marinalade of the ame type as the one descrilied is made by allowing

I lb sugar to each lb. vegetable niarrow To 6 lb . marrow should be added $\mathbf{6} \mathrm{lb}$. sugar, i lemons, 6 oz. green ginger, 2 oz root ginger, and if teaspoonful cayenne. The marrow is pared, pips removed, and cut into square pieces of roughly 1 in. Peel lemons, slired the rinds, cut up the root ginger, and put the juice, slireds and marrow into a large pan with the ginger and sugar. Let them stand until the juice covers them. This takes about 24 hours. Boil until the marrow is quite Iransparent. No water is ndded

Pineapple Marmalade. Remove the peel and eyes from the pineapple: pass the fruit through the mincer, weigh and allow is lb sugar to every lb. fruit. Mix the sugar and fruit well and leave in a bowl overnight Next day put into a preserving pan and simmer gently for an hour or until it sets. The large quantity of juice in pineapple makea it unnecessary to add water. Pour the marmalade off into warm jars and tie down while hot

Quince Marmalade. Quince marmalarle is prepared by peeling and quartering the frnit, removing the cores, and then putting the latter, together with the peelings, into a pan con taining just enough cold water to cover them Boil them over a slow fire until their llavour las been well extracted. Thes strain the liquid through a fine sieve and let it cool. After weighing the quinces, put them into a pan, pour the strained liquid over them and then cook them until they are a pulp, pounding them with a spoon if necessary For every pound of fruit add $\mathcal{I} \mathrm{lb}$ preserving sugar, stirring carefully until the Intter has dissolved Boil up the marmalade and continue hoiling until it sets, when it may be potted.

MARMALADE PUDDING. To make a boiled marmalade pudding, chop finely 5 oz . suet and put it into a basin with 5 oz . fine hreadcrumbs, 2 oz flour, the grated rind of a lemon, 3 oz . brown augar, and a pinch of salt. Into a small basin put 5 o7. orange marmalade, a tablespoonful of golden syrup which has been warmerl, and 2 egga. Heat all well together, then add nearly 1 gill milk. Mix the dry ingredienta, make a well in the centre and work in the eggs and marmalade. It must then be turned into a well-greased pudding. hasin or mould and steamed for $2 \frac{1}{2}$ hours. It should he served with marmalade sauce.
MARMALADE SAUCE. Mix a small deasertspconful of arrowroot into a thin paste with cold $u$ ater, then add $\frac{1}{2}$ pint boiling water, stirring it into the arrowroot by degrees. Turn all into a saucepan, and boil for 2 or 3 min add the juice of $\frac{f}{2}$ a lemon, 1 dessertspoonfui white sugar, and 2 talilcspoonfuls marmalade. Simmer ior 2 min . before serving, but stir all the time.

MARMOT. A somewhat harsh fur marmot is usually of a greyish black colour in the ground, becoming lighter and more yellowial. red at the top. The hair is reddish, stiff, and often speckled with black. It is usially dyed to imitate the more costly mink, and in this torm is used for making wraps and coats.

MAROCAIN. A soft lustrous material of silk or mixturc of silk and wool, or of all wool, marocain can be obtained in various qualities This material, bcing heavicr than crêpe-deChine, drapes well for dresses, and is also used for light-weight wraps and conts. It is ohtainable in plain colours or patterned.

MARQUEE, A large tent or marquee is constructed with two upright poles with the canvas formed in a ridge between them. It is generally oval in shape, or rounded at the ends with straight sidos. A marquee is often erected on a lawn for refreshment service accommodation and for sheltering the guests at social functions or during sports. See Tent.

## Marquetry and its Processes <br> A Decorative Handicraft Explained and Illustrated

In addition to Inlaying and Veneer, our readers are referred to the entries on the various woods used, e.g. Ebony; Satinwood: and to the articles that can be decorated with marquetry, such as Cabinet; Grandfather Clock: Knifc Box: Screen. Sec also Buhl: Louis Style

Marquetry is a form of inlaying in which the effect is obtained by the use of vencers applied to a gmundwork. The inlavs and the background are cut at once, the process affording scope for many artistic and elaborate effects

In Italy niarquetry was used to decorate caskets during the 1 हैth century. Ivory and natural woods were emploved. The form known as intarsia was first executed there in the ligth century. Geometrical designs were used, but later floral and pictorin decoration was applied in this manner. By the end of the 17th century marquetry was lavishly emplaped on Continental furniture, and by the 18th the great English designers, with the exception of Chippendale, used it frecly to decorate cabinetg, bureaux and amnller pieces. The secretaire shown in the first illustration gives an idea of the delicate and beautiful design and workmanship of the hest French marquetry in the 18 th century

Modern English marquetry work in the form of panels chiefly used for decorating side boirds, cabinets. screens, and mirrors, shows fine design and craftsmanship. The floral panel of the fire screen illustrated is beautifully executed in woods of contrasting colours, and the panel whioh decorates the sectional mirror is suggestive of the charming work that can be carried out in a simpler design
Fig 1 illustrates the principle of marquetry work Two shects of peneer of different wood or colour are fastened together and a saw out

Marquetry. Secretaire in marquetry with inlay of flowers marble top, ormoln monnts. The upper part has a falling front enclosing two dramers, the lower is a cupboard. French ; period of Louis XV Bu Dermission of the Director, Victoria \& Alberl Museum, South Kensington
made through the two, as irr Fig. I A. They are then aeparaterl and the pieces interchanged, as in lig 1 B , thus ohtaining the required inlay. The remaining parts (Fig. I C) would form another inlay. though it is seldom possible to use then for the same joh, as the hackground usually has to match the wood of which the piece is made. In commercial work the cutting is done with a power or treadle sulw, but an ordinary fretsaw frame with a very fine blade will serve the purpose quite well
Fig. 2 shows the type of donkey used by the trade when the mar quetry is still cut by hand, and is quite a simple structure to make. The worker sits astride the form and places the work between the $t w o$ thicknesses of wood at the head. A firm grip is obtained by placing the foot on the treadle, which being connected to the outer thickness of wood by a mpe, draws it inward toward the other. The advantage of the donkey is that the work is easily removed or altered to another position. leaving both hands fiee. and is fixed at an easy height.

A similar type is shown in Fig. 3, and is fixed in an ordinnry bench vice, the two thick. nesses being gripped with a thumb-screw. The front and main thick ness should be of 1 in. stuff and the back $\frac{1}{2}$ in

The wide range of materiel for inlaying is not confined to wood Tortoiseshell, ivory brass, and other metala have all been userl, hesides stained wood. The direction of the grain in the inlay plays a great part. Where the inlay occupies a small space in a large panel, it is only necessary to put a small portion of veneer sufficient for the inlay in the required position, but in a panel such as is seen in Fig. 4, where the inlays are distributerl faitly evenly over the whole panel, the inlay and background venecrs should be of the same size. In this care two different woods are used for the inlays, so that three thicknesses of veneer will be used. If two panels are required six thickneases nre cut, two of each lind of wood. The cross-banded edge and the inlaid line would not be cut in the marquetry, but would be applied after it had been laid.

Either knife or saw cut veneers may be usell, though if only a few thicknesses are to be cut it is advisable to use saw-cut; being thicker, it is not so liable to split during the culting process. If knife-cut is used, even though only one panel is required, it is generally a better plan to cut an extra panel and so get extra thickness to cut. as the firmer the substance the easier the outting will be All the veneers for a single panel must be either knifc or saw cut, as it is impossible succerafully to lay marquetry cut from veneers of different thicknesses.
A Simplo Pattern. Fig. 5 is an example of marquetry using only two woods, oak and ebony, the right-hand side showing the
finished panel with oak background and the left vicc versa. As the design fnitly covers the whole background, both sheets of veneer will be of the same size. First prepare a carcful drawing of the design on paper, with the woods to be used marked (though where only one inlay is used this is bardly necessary) and make a tracing of it.

Prepare the two sheets of veneer and glue them together with thin glue, and with $n$ sheet of paper between, so that they can be separated later If two panels are to be cut, place the oak and ebony sheets alternately, and when they are cut and separated, interchange the adjacent alieets It is of vital importance that the thicknesses should be as close together as possible, otherwise they will be apt to split during cutting. When glueing they should be placed between two llat boards and cramped to. gether Paper should be put between the veneer and the boards, to prevent them from sticking une to the other
When dry, paste the tracing on one side, and, fastening the work in the vice, cut round the design carefully right on the line with a very linc frctsaw. It is necessary to hore holes in which to start thesaw, and these should be as finc as possible and in such n position as not to bc noticeable; this is usually where two curves meet The saw must be held quite square to the work, so that the parts will interchange perfectly, and should be procected with in such a way that the panel is not unduly weakened. Do not cut away thic centre poition first, яs

Marquetry. Above, fifa screen in mojern marquetry. the panel being in woods of contrasting colours Below, mirror with pictorial panel in marguetry Courlenl" of A. J Rowlell. Kenainglon
this would render the veneer liable to split, especially when afterwards cutting the outer shape across the grain at the top and bottom. When any part is cut completely out, like the small pieces in each corner and the centre, mark on it the part finm which it was cut and its position, so that it can he replaced afterwards.
Having cut the complete design, the nex step is to separate the thicknesses. This is done by easing the parts away with the thin blade of a knife, so that the paper splits. If any difficulty is found from the glue having been too thick it is advisable to weaken it by
placing the veneers between two sheets of yellow pine is also good This latter should damp blotting paper and laying a weight on be givell a coating of size after toothing to top The moisture will then percolate through fill in the grain, and left to dry, as otherwise the wood, when the pieces niay be separated when the marquetry is a pplied the pine would easily. The various portions of the adjacent soak up more than its fair share of the glue sheets are interchanged and the whole glued and leave the marquetry liahle to peel of. on to a sheet of paper, using thin glue. Apply the glue sparingly, or the veneers anay buckle. See that the various parts lie together fat: t may be necessary to put them under a the caul methorl is used. Figs. 7, 8, and ? weighted boand for this purpose, though glueing down on to the paper is usually sufficient. When dry the veneer may be glued on to the ground work
Using Two Inlays. Fig. 6 is a nother exnmple of mar quetry, embodying the use of two inlays (satinwood and a green stained wood) on a mahogany liack ground. In this case the inlays secupy a relatively small space in the panel, the flower and the base only being in satinwood and the stalk and leaves in green wood, so that it will he necessary only to cut pieces sufficiently large to cover the local inlays. The dotted lines show the position in which these are placed, the green piece being put on the mahogany hackground first and thic two pieces of watinwood on the green wood after. wards. The tracing is pasterl to the flat mahogany side, care being taken to see that the various parta of the design come opposite to theit correspouling veneers. The cutting is then proceeded with in the usual way
The lines forming the divisions to the petals in the flower are formed by saw cuts. As the whole of the llower is intended to he in satin. whod only, it is advisable not to let the division lines run guite down to the juncture with the atalk, so that the llower will remain in one picce, thus asving the unnecessary labour of putting them together again. The lines are shown running right through in the sketch, since it might he desired as all alternative to form the flower with petals of alternate satin and grcen wood, instead of all satin, in which casc the cutes will run right through.
The necessity for good workmanship in marquetry is seen when cutting small panels. The practised fretworker will lind little difliculty in cutting out the shapes, but the beginner should have some preliminary practice in making even saw cuts hefore attempting any claborate work. It is a good plan to glue odd pieces of thin fretwood of contrasting colours toget her with a sheet of paper loctwenn them. A suitable but simple design should be drawn on one piece, and thell cut out.
The use of colour in marquetry is a valuable help in working out suitable designs. White woods, especially sycamore, can be stained by aniline dyes to almost any required shade, and brightly stained woods contrasted with dark roorls will give some tine effects.
The groundivork must he of a suitable wood to hold the glue well, frec from knots, and able to stand well without shrinking or twisting It must he prepared perfectly true and Hat, and must be toothed. Hunduras mahogany is the ideal wood to use for a ground, though

Fig. 3
give an idea of the kind of appraratus which is wanted The canl is a piece of woorl slightly larger than the ground and about I in. thick, ind quite Hat; this is to lay on the veneer and press it equally all over. The crosspieves are slightly longer than the width of the givund, those for the hottom being square. The top pieces are straight on the top edge but are curved slightly on the underside ( Hig .7 ), so that when pressure is applied to the ends the glue will be forced fiom the centre outwitrd (rig. 8). The shaping is rather exaggeratel in the diagram, hut alout $\frac{i n}{}$. will be sullicient in a length of 2 it. The lower conspieces must be wider than the top ones, so that the preasure bends the top pieces straight. Two cramps or handscrews are required to each crosspiece

The ground being ready, marl: centre lines in the length and hreadth of loth the marquetry and the ground ; this will give the cxact position for it to he fixed. The lines should he marked on the paper-covered side of the marquetry. Glue both the giound and the marquetry; place the latter in position and drive in two tine reneer pins to fix it temporarily. The marquetry should be paper side upivaril, so that the glue gripe the wood. Now lay a sheet of paper over the whole.

Heat the caul thoroughly on one side, place it on the paper and apply the centre crosspiece, tightening each cramp a little at a time so that pressure is applied gradually from the centre outwarl. Fix on the other crosspieces and give all the cramps in extra screw, and leave it to set. The whole process of applying the caul should be gone thmugh as quickly as prossible, hcause if the glue once chilla it will he impossible to aqueeze it out, and a repetition of the process will be required

Cleaning Up. To clean up the work when set, n steel scraper is used, and care must be taken to work this so that it dnes not tear the grain up. eapecially where the grain of an inlay mins counter to that of the backgiound. The joh is tinished off with line glasspaper, and the two pins used temporarily to sccure the veneer should be removed before cleaning

## MARRIAGE IN ITS LEGAL ASPECT

## The Responsibilities of Husband and Wife Outlined

## For the cercmony of marriage our readers are referied to the articles W'edding and its subsidiary cntries, c.e. Bride; Trousscau. Sce also Divorce; Husband

Marriage was defined according to the law district This official is not allowed to perform of Engiand to mean the union for life of one man and one woman to the exclusion of all ot hers, or the union of two people who promised to go thmugh life alone with one another. Consequently English law does not recognize polygainous marriages. In order that a marringe may be legal the following requisites must be conplied with :

Husband and wife must be of marriage able age, ie. 16 years of age. They must bo of such a mental condition as enables loth of them to know and appreciate the fact of the marriage If it can he provel that one of the partics to a marriage ceremony was incapable of knowing or appreciating what he or she was doing the ceremony is null and void.

The parties must consent to the marriage, and this involves the proposition that each of them knows what the ceremony means Instances have occuried where both boys and girls have been entrapped into marriage, being told it was something else, particularly in out-of-the-way colonies and other countries wherc people can go hefore a magistrate or other person and by signing a paper are declared to be married. Anyone who was married in this way can obtain a declaration of nullity.

There must he no legal impediment. A table containing the list of marriages pmobibiter will be found in the prayer book. Since that list was compiled it has become lawful for a man to mariy his deceased wife's sister. and for a woman to marry her deceased husband's brother. The marriage must hic performed in a legal mode. According to the rites of the Church of England, thesc arc either by the special licence of the archlishop of Canter bury, by licence granted hy a bishop or his surrogate, after the publication of banns or after due notice in lieu of banns given to the superintendent registrar of the district

The archbishop of Canterhury's licences miny lic given entirely at his grace's discretion, and may anthorize the marriage in any place and at any hour. The bishops mny only authorize the marriage in a church or chape in which banns inight have been laufully publisherd, and the marriage must be between $8 \mathrm{a} . \mathrm{m}$. and $3 \mathrm{p} . \mathrm{m}$. Banns are to be published in the chureh, and the clergyman is entitled to seven days' notice in writing.

Publishing the Banns. Where the purtien live in different parishes the incumbent of one parish shall not solemnize the marriage with out a certificste from the incumlient of the other parish that the banns have heen called there also. The parties must be married within three months after the publication of the banns, which are to be pulilished in an andible manner during three succeeding morning services, or, if there is no morning service during the evening service, and it must le on a Sunday. Pcople who do not desire banns to be called may be married according to the rites of the Church of England after having given notice to the superintendent registrar, who pulilishes the notice in the proper inamner for at least three weeks. In all marriages in the Chureh of England the ceremony wust be perforined by a clerk in holy orders. It is doubtful whether a deacon can perform the ceremony, though it has once been decided that he may

Marriages inay be solemnized according to the rites of other religious Imdies in cortain registered buildings and by registered persons, or in the presence of the civil registrar. A marriage in a register office can take place before the superintendent registrar of the

The Marriage Licence. In England annl Wales marriage licences are of two kinds, those issued by the officials of the Church of England and Wales for marriage in a building belonging to that form of faith, and those issued by a registrar for marriage in a church or chapel belonging to Nonconformists and registcred for marriages, or for marriage in a district register office.
As regards the Church of England marriage, licences can be obtained in London by applica. tion at the faculty oftice, at the vicar-general's office, and at the bishop of London's registry, hy one of the parties about to he married. Eilsewhere they may be obtained at the oflices of the bishopsi registrars, but licences obtnined at a diocesan registry only enable the parties to be married in the diocesc in which they are issued. Those procured at the faculty ollice, 2:3, Kinightrider Street, Doctors' Commons, London, E.C, are available for Iondon and all England and Wales; those pmoured at the vicar-general's oflice, 1. The Sanctuary, Westminster, Iondon, S.IV.I, are available for London and all England and Wales, excent the province of Yurk
No instructions, either verbal or in writing, can lic reccived except from one of the parties. Iffidnvits are prepared from the personal instructions of one of the parties about to le married, and the licence is delirered to the party upon payment of fees amounting to 31 s. in addition to the cost of stamp, los. No previous notice is required, and the licence is available as soon as it is issued. The cost of licences in the country varies, according to the diocese, from $£ 115 \mathrm{~s}$. to $£ 212 \mathrm{~s}$. Gd
To secure a licence for a marriage in a Nonconformist piace of worship or a register olfice, notice must he given persunally to the superintendent registrar of births, deaths, and marriages, or the deputy of such oflicer. One notice only is necessary, whether the parties live in the same or in different registration districts. and either party may give the notice. If both live in the same district, one of them must have lived there for 15 days before notice can be given.

If the parties are living in different districts, and both have fulfilled the necemsary residential qualification, notice may be given in either district. If one only had fulfilled the qualification, the notice must le given in the district in which the residence has been fulfilled, and the other party must be resillent in England or II ales when the notice is given The notice contains particulars as to names, ages, residence, length of residence, and the building in which the marriage is to take place.

After the lapse of one weekday, not Christmas Day or Guod Friday, from the date of the entry of the notice, the superintendent registrar may, provided no impediment is shown, issue his certificate and licence for the marriage, which can then take place on any day within three months from the date of the entry of the notice. For a marriage hy licence of this kind the total fees are $£ 2$ 10s. (kl. For marriages in Scotland no licences are necessury, hanns or notice by a registrar being substituted. They can talic place in a private houso or in a hotel.
Consent of Parents. The conscut of parents is only necessary where one of the parties is under the age of 21 . If, however, a young person under ago makes a rumaway match and marries without the parenta' consent, and even in spite of the parents prohibition, the marriage is lawful. Any minister or registrar, however,
who marrics an infant alter having been prohibited to do so by the parents or guardians and also the infant himself is linble to sevore penalties.

Marriages with Foreigners. In the case of marriage with a man who is a foreigner an linglishwoman may find herself awkwardly situated unless she takes care to find out how far he is at liberty to marry her, and whether or not any consents are required according to the law of his domicile. For instance, the French law is very atrict, and even though a man may lie an adult it reguires that licfore he can be lawfully married he shall obtain the consent of his parents.
An Englishwoman who marties in this country a domiciled Frenchman who has not obtained the proper consents is recognized as married by the linglish courts, but in France her marriage is not valid. It is wise, therefore. for an Englishwoman who intends to marry a foreigner in England to make previous inquiries at the oflice of the consul for that country, so as to ascertain whether or not it is essential to prncure anybody's consent to the marriage

Under the Marriage With Foreigners Act. I! Mif, nrangements may be made with foreign states for the issuc by the proper ofticer of those states of a certificate that duc notices have been givell. The foreigner may be required to give notice to the persons by ol in whose presence the marriage is to he solem. nized of the fact that he is subject to the marriage law of the country He inust get his government's official to issue a certificate that the notice reyuired has heen given, and that no impediment exists or that proper consents have been given. Anyone who celebrates a marriage where such a certificate is repuired without that certificate having been given is liable to a penalty not exceeding floin, or to imprisonment not exceeding a year. This Inw docs not apply to marriages hetwcen two .Jews solemnized accorling to Jewish law

Valid and Invalid Unions. In England it is an offence punishable liy fine and imprison. ment to give wilfully a false name on leing married, but the marriage is not rendered void. A marriage is apparently void where it is celebrated according to the rites of the Church of England after publication of banns if false names are given and both partica know that the names that have been given are false.

An Anglican marriage is void unless it is celebrated by a person in holy orders. It is also void if not celebrated in a lawful place, i.e. a chureh or chapel of the Church of England, a registered place of worship of any other denominalion, a place authorized hy the archbishop ly a special licence, or a register office. As to marringes which take place abroad, the foreign law applies, save that the marriage must be of such a kind that it comes within the linglish detinition of marriage, e. it must not hie a polygamous union.

Sometimes foreigners living in England attempt to celebrate marriages in places of their own which are not registered for the purpose. Such alleged marriages are void according to English law except, it may be, where both parties are subjects of a foreign state and they go through the ceremony of marringe within the precincts of the cmbassy of that particular state.

A nother point to be noticed is that, although as to the form of a marriage celehrated a hinad the courts in England will recognize that form, they will not recognize the validity of a marringe between Einglish people who could not have married in Grent Britain. Thus, hefore the pussing of the Deceased Wife's Sister Act, the Einglish courts did not recog nize a martiage abroad between an English man and his deceased wife's sister.

Marriage at sea on a British ship is a marringe in Britain and can be celebrated by all
episcopally ordained clergyman or minister There is authority for saying that a marriage celebrated by the captain is not valid.

The law as to what constitutes a valid marriage between British subjects abroad is not altogother olear. A marriage cclebrated anywhere according to the law of that country in the presence of an Anglican, Roman Catholio, or Greek olergyman is valid ; but cases arise where no clergyman can be found, as, for example, in remote parts of India or Australia. It has been held in some cases that where the parties intending to go through a ceremony of marriage bound themselves by words reprcsenting the fact that they are taking each other in marriage, the marriage is lawful. On the other hand, it has been held that where two pcople went to the British consulate in Smyrna and were married without the presence of a clergyman it was void.
In the case of public vessels, commanding officers of a certain rank are authorized under Admiralty instruotions to act as marriage olficers. They can, it appears, lawfully perform the ceremony of marriage on such vessels while at foreign stations, but only if one party to the marriage is a British subject, and if the ship is not at a port or place where there are facilitics for martiage in the ordinary way.

The Mestica! Side. A medical man is rarely consulted by persons about to marry, and in the vast majority of cases there is no need for median advice ; but, on the other hand, there are many cases uhere marriage should be delayed, and more than a fow where it ought to be avoided altogether.

A very early marriage is usually undesirable, though there arc exceptions to this rule, because the development of the body does not always correspond with age. So far as the wife is concerned a late marriage has also its risks. From the age of 30 to 35 onward the pelvis (or bony cavity at the lower part of the body) grows more solid and rigid. When a child is born, the bone-encircled outlet through which it passes does not yield so readily as it does in a younger woman, and hence labour may be slow and painful. Apart from rickets or other disease, this is not the case in a woman who marries earlier in life, has her first ohild before she is 30 , and continues to bear children thereafter.
Probably the best time for a woman to marry is between the ages of 23 and 27 . But in most cases there is no reason why she should not marry a year or two earlier or three or four years later. A woman with very narrow hips would, therefore, do well to consult a doctor before marrying, or at any rate some time before the birth of her first child is due. Sometimes the pelvis is not alone small, but misshapen, perhaps as a consequence of rickets. This, again, is a case for medical advice. Whether such a woman should marry at all is a question that will depend on the nature of the deformity.
There are certain diseases which should prevent the marriage of prudent people. Thus, serious heart dilsease (either in a man or a woman), Bright's disease, consumption, epilepsy, or any mental affection, makes marriage very undesirable. It is often a difficult question to answer whether an apparently normal-minded person in whose family inwanity has appeared should marry. A good deal depends on the cause and type of the insanity; but medical advice should always be sought.

A woman should never marry a man who is a confirmed drunkard. Very many women make the great mistake of believing that they can reform such a man. If a man habitually drinks to excess before marriage, he will almost inevitably continue his bad habit after it. And not only will the wife suffer, but the children are very likely to turn to drink also, or ton suffer from some nervous disease.

As to the marringe of cousins, it may be said that in the children of such parents any peculiarity of constitution common to both father and mother is very likely to be intensified. Cousins may, therefore, marry with safety if both are healthy and if there is no such disease as opilepsy, insanity, pronounced hysteria, etc., in their families. The danger of cousin marriages is that both may have the same kind of constitution, and, if any family disease exists, both may combine to transmit a tendency to the devclopment of this diseaso in an intensified form to their children

It was said above that both very early and late marriages are inadvisable. The same applies to the marriage of a young woman to an elderly man, or vice versa. Precisely what disparity of age is allowablo it is impossible to say. Many young women can be happy with husbands considerably older than theinselves, while to others life will be a continuous round of discontent. As a general rule, it is best that the wife should not be muoh older than the husband, and that the husband should not be more than 10 -at the most 15-years older than the wife.

The Marriage Settlement. When people of means are about to marry, it is usual for them to set aside a certain amount of property to make provision both for themselves and for the offspring of the marriage. This specially applies to people with landed property which has been in a family for some time.

The form of such settlements is as follows : Two or more trustees are appointed, one by the intended wife and one by the intended husband. A deed is drawn up to which the intended husband and wife and the trustees are parties. The intended husband conveys to the trustees or transfers to them whatever property ho intends to put in settlement, and the intended wife does the like. The deed directs the trustees to hold this property, until the marriage has been celebratel, for the intended husband and wife respectively ; and, after the marriage, to pay the income as directerl.

A Typical Example. Where the major part of the property is settled by the husband, it is usual for the income of it to be paid to him during his life, and, after his death, should he die before the wife, to pay part of the income to the wife. As to the capital, the husband is generally given a power to appoint it amongst the ohildren of the marriage in such proportions as he thinks fit, and if he does not do so, then his wife may, if she survives him; and if neither of them does so, then the ohildren of the marriage are to take cqually. The wife's property is settled on her in the same way, herself for life, then her husband for life, and then the ohildren as appointed.
The above describes an ordinary settlement of stocks, shares, and other invcsted moneys. In the case of land, however, it is different. The family estate is settled to be held by the trustees in trust for the husband for life, with an allowance to the wife; and, after the husband's death, a certain income or jointure is to be paid to the wife, a certain sum is to be paid to younger sons and to daughters when they attain the age of 21 or marry, and the land is to be held by the trustees in trust for the eldest son of the marriage in tail. This deed is called a family settlement.
A genuine marriage settlement, i.e. one made beforc and in contemplation of marriage, is a contract and conveyance for valuable consideration, because marriage is the most valuable of all considerations. Consequently, it cannot be attacked as fraudulent, i.e. as, putting property out of the reach of creditors, unless tho marriage itself was part of a scheme to defeat creditors.

If the husband who has made the marriage set tlement should go bankrupt, his trustee in
bankruptcy can seize lor the creditors his life interest in tho scttled lands or funds, but he cannot seize the land itself or upset the settlement on the ground that when the busband made it he was heavily in debt To this rule there is an exception. If a man and a woman get married on purpose so that the man can make a settlement of his property on the woman so as to put it out of their creditors' reach, the settlement can be upset as a fraudu lent conveyance. But this can only happen if both the man and the woman werc parties to the fraud.
The person who is to receive the rents and profits of the land through the trustees for his life is called the tenant for life, and has very extensive powers of management of the estate. Put briefly, he has power to deal with the cstate almost as if he were the absolute owner of it. He can grant leases of the property, he can sell it, all except the principal manor house and any heirlooms, and even these he can sell by leavo of the Court; but any capital moneys rcceived must always be paid over to tho trustces, who will invest them and only pay the income derived from them to the tenant for life.

MARRIAGE: The Card Game. This card game is suitable for two players. It is played with the piquet pack of 32 cards, i.e. all from the seven upwards, and is won by a game of 66 points. The values of the cards are as follows. The acc counts 11 points, the ten 10 points, the king 4 points. the queen 3, and the knave 2; the other three have no scoring value. Trumps are played in this game.

As in piquet and similar games, scoring is from cards in hand and from cards played. The scores for cards in hand are, for a marriage, i.e. king and queen of an ordinary suit, 2 points; and for a love, i.c. ace and ten of an ordinary suit, 30 points. For marriage and love in the trump suit these scores are doubled, i.e. 40 points and 60 points. In the outplay the counting cards played and taken give the score. Sixteen points arc added for the last trick taken, and 20 points if the last six tricks have been won by one hand alone.

The players cut for deal and the lower cut deals. He gives 6 cards to ench player and turns up the 13 th card to show the trump) suit. The remaining cards form a stock fron which the players draw. The play begins by the nondealer leading. The dealer can then, if he so wishes, play a card of another suit, as he nced neither follow suit nor trump. These two cards form a trick, and the winner of this trick leads in the following one.

The winner of a trick can now declare any marriage or love he may hold; if it is good it is scored at once. Each love and marriage must always be shown before scoring for them, and one card of the proved love or marriage cannot be played at once. The winner of the trick next draws the top card from the stock and the loser draws the one below it. This occurs after every trick until the stock is exhausted, so that during the earlier part of the outplay each player has six cards in hand.

Marriages and loves aan be made whenever convenient, but only by the winner of the trick immediately preceding. A declaration cannot be made after the stock is closed, nor after the first card of the eleventh trick is played. That is to say, during the last six trioks no declarations are valid. With equal loves or marriages the non-dealer or elder hand scores on declaration ; the other player does not.

A player holding the seven of trumps may exchange it for the turned-up card when it is his turn to draw, and as long as the stock remains unclosed or unexhausted. When a seven or the last card from the stock is drawn, it cannot be exchanged. After draving either player may declare the stock closed, and after that no player can draw a card from it. The one who closes it must thus win the game in
the outplay by completing if points; if he Drain them and remove the skins. Boil up steamer, add salt to taste, and cook them ails to do so hig opponent
even if he has not reached (i6 points and has a score lower than than of the closer.

MARRON GLACE. This aweetmeat consists of chestnuts preserved in sugar. To make them, procure some large chestnuts and remove the shells. Boil the chestnuts, putting them into boiling water, for about 15 min . ender but do not break them. Put them to cool, and make a syrup of 1 lb . sugar to pint water and boil to the temperature. of $290^{\circ} \mathrm{F}$. Take up the chestnuts with a pair of sweetmeat tongs and plunge them in the syrup, one at a time. Place the chestnuts on

## MarRow in Garden and Kitchen

## Its Cultivation and Some Attractive Recipes

After describing the growing of the marrow, our article gocs on to deal with various ways of cooking it. Sec also the article on Marmalade. For further information see Frame; Greenhouse; Hotbcd; Kitchen Garden: Manure; Pumpkin

The vegetable marrow, although regarderl serve vegetable marrow plain: Prepare it as a vegetable in cookery, is a fruit, like the tomato and the cucumber. It is a half-hardy annual trailing plant, with edible fruit.
There are numerous varieties of the vegetable marrow Of those with large fruits Long Green and Long White are favourites. Moore's Cream. Peny byd, Rotherside Orange, and Table Dainty are excellent small marrows. The bush and custard marrows are less vigorous in growth than the trailing varieties.
How to Cultivate. To grow good early marrows, the seeds should be sown under glass early in April in pots of light soil, in a greenhouse in which a temsperature of $50^{\circ}$ to $55^{\circ}$ inay be safely maintained. As soon as the plants are large enough to handle, they should be slifted into 6 in. pots. l lefore heing planted out of doors in May they should be hardened off. Marrows may be grown on turf heaps, even on a heap of garden rubbish, or on the

Marrow. Well-grown specimen of a green marrow. Top, right, a round marrow
ground level in manured soil. Three or four successional plantings may be made at intervals of a fortnight until the end of June, or seeds can be sown out of doors in May.

As soon as the leading shoots reach length of 18 in. to $2 . f \mathrm{ft}$. they should be pinched out, and case should be taken that the runners are trained evenly over the ground.

Feitilization should be carried out when the first of the femate hlooms make their appearance. This is done by stripping male Howers of their petals and applying the pollen to the centre of the female flowers.

If the marrows are wanted for preserving, they should be cut before they are ripe, and hung up in a dry room by the bases of their stenis. Marrows should alwnys be cut before they are fully ripe, for they are then of superior Havour. The young shoots of marrow plants, when thinning is desirable, form an excellent substitute for spinach.

How to Cook. When prepared as a vege table for table the marrow should be cut in halves or quartered, pared, and the seeds and pulp removed; but if intended for a made dish it is sometimes boiled whole, and after it is cold it is pared and sliced, as it remains firmer when treated in this manner. To
put in boiling salted water to cover it, and boil from $20-25 \mathrm{~min}$. Serve on pieces of toast with melted butter sauce poured over or handed round in a sauce boat
Marrows can also be baked. Prepare a good-sized marrow and cut it in two lengthwise, remove the seeds and parboil it for about 10 min . It should now be stuffed with a good veal forccmeat, Houred, and the two halves fastened together round the stuffing
 with white tape. Bake in a moderate oven about 20 min., basting it with plenty of good dripping and letting the marrow brown at the last Just before it is done strew brown crumbs over the top and baste them well. Serve with a good thick brown gravy poured round the base. Minced meat or ham may be added to the forcemeat.

Marrow can be added to fruit in pies and puddings or mixed with various ingredients and made into sweet dishes. In addition, marrows also make excellent preserve.

Cold cooked or parboiled marrow can be fried in butter or bacon fat and makes a good breakfast dish scrved with bacon.

Marrow au Gratin. Marrow aut gratin is prepared by peeling a marrow, splitting it into four, then removing the seeds and washing it. Put it into a saucepan of boiling water to which a little salt and soda have been added, and boil it gently for about 15 min ., or until it is tender. Nix $1 \frac{1}{2}$ oz. flour to a smooth paste with $\frac{1}{2}$ gill cold water, and put $-\frac{1}{2}$ gills milk to heat in a pan with 18 oz. butter, and pepper and salt to taste. When the latter are hot, pour on the llour and water, bring the whole to the boil, and then simmer it for 6 min., kecping it well stirred in the meantinie. Add 1 oz. grated checse. pile the marrow on a slice of toast placed in a gratin dish and pour the sallce over it. Sprinkle another ounce of grated cheesc on top, then put the whole under the grill and brown it slightly.

## Steamed Marrow

 Steamed marrow is served on toast and covered with egg sauce. Put the prepared pieces in a

Marrow Culture. 1. How to prepare a mound. 2. Seed sown in pot. 3. Seedling potted-on and ready for planting out. 4. Fruiting and non-fruiting blooms $a$, male : $b_{1}$ female. ${ }^{2}$. sherry and Madeirn, and is pale amber in served with soup or fish in place of sherry. and as a dessert wine. Sce Wine.

MARSH MALLOW : The Plant. This hardy biennial plant (Malva sylvestris), which grows wild in Britain, renches a height of nbout 2 ft . and hears reddish flowers in summer. The roots are thick, long and tapering They hend easily, are whitish. yellow outside, white and tibrous inside and a bound in mucilaginous juice. They are some. times used medicinally. The lenves of the herh should be picked and dried in August. See Hollyhock; Malva.
MARSH MALLOW: The Sweet. To malen lhis, dissolve 2 or. gum arabic in a $\}$ pint water. thell strain it. P'ut it into a small saucepan and add 4 oz. loaf sugar ; stir till melted, then hoil until a firm ball is obtained fron the syrup. To test it drop a little into cold water, rub it between the fingets, and if it forms a ball it is ready.

Remove it from the fire, Havour it with orange flower water, and work in the stiflly beaten whites of 1 large or 2 small eggs Spread this mixture out in a layer on a thick bed of confectioner's starch, which can be purchased at any large store. Cover it over with another layer of starch and leave it till next day. It should then be ready to cut into squares. Well dust the picces with starch and pack them away in airtight boxes

MARSH MARIGOLD. This decorative, water-loving plant grows about 1 ft . high, and bears yellow flowers in spring. The marsh marigolds arc useful plants for the sides of lakes, streams, and pools. Water may be allowed to llow on the roots, or may simply permeate the surrounding soil. The best month in which to plant them is October. Caltha palustris, 12 in., is the common yellow marsh inarigold, of which there arc several

Marsb Marigold. Clump of the rolden water plant which will grow in a damp corner of the garden
varieties. The finest of all is Caltha polypetala, 18 in., with rich yellow blooms. Marsh marigolds have creeping root-stocks and are increased by division in spring. See Marigold.
MARTEN: The Fur. Of the various kinds of fur obtained from the marten tribe, haun marten and atone marten are the best known. The finest of the baum marten skins are obtained from Norway, and are dark brown in colour. The tails, which are sometimes made to resemble sable tails, wear well, but in texture they nre coarser than sable.

Stone marten wears and looks almost as well
as banm marten, hut the tails are not ao good, and the skins have to be arranged in a special manner to obviate the marks caused by joins.

Fisher fur is obtained from another species of marten and, like baum and stone marten, is employral for making stoles, wraps, muffs, etc See Fisher Fur: Fur; Sable.

MARVEL OF PERU. This is the common name of Mirabilis jalapa. This herbaceons prennial is hardy only in well-drained soil in

mild districts ; in cold places, or heasy soil. the roots should he lifted in antumn and stored in boxes of soil under glass for the winter. It forms a busli about 2 ft . high and bears flowers of different colours on the saine plant. If seeds are sowll in a heated greenhouse in spring the seedlings will bloom in the summer of the same year.

MARZIPAN : The Sweetmeat. Marzipan is made from almond paste, coloured, shaperl, and llavoured in a variety of ways. Marzipan potatoes are made hy forming the almond paste, slightly Havoured, if liked, with vanilla, into the sliape of very small new potatoes. Mark a few cyes on each, and roll them in a little powdered chocolate.
To make cherries, colour the pastc with cochineal and roll it in the hands into little balls. Very thin strips of angelica will make the stalks. With careful sliaping, half-open pods of peas can he made with almond paste coloured with spinach green: apricots, with ralfron-coloured paste. Pastes coloured with cochineal and with saffron ate joined to make an rpple.

To make fruit marzipan, add, when making the nlmond paste, a tablespoonful of thick pulped fruit or jam to every lh. of sugar. Colour and flavour it as desired. When the paste is cool, roll it out to a thickness of ahout $f$ in., and ice it very thinly with royal icing. Cut it into any small shapes hefore the icing has quite set, and decorate each swect with a tiny silver ball, scrap of angelica, or small piece of blanched nut.
Dried French plums or good prunes and good quality dates can be aplit in half and stulfed with coloured, Invoured marzipan. Attractive sweets are also made by moulding a ball of coloured marzipan, and pressing on to ench sille of it a blanched almond, or half a walnut that has heen toasted for a minute or two in a moderately hot oven See Almond Paste : Chocolate: Icing

MASCARON Also known as a macaroon, this is the name of a raised ornament found on Venctian
glass and glass made in that style. It is a little bloh of glass on which the impression of a mask or face is stamped while loot The term is sometimes used when the design is a lloral or ot her ornament.

In furniture the mascaron is the figure of a face, either of man or animal, used as a centre feature in clecoration It is found in pieces of the time of William and Mary, and frequently on those made in the Louin XIS style. See Venetian Glass.

MASCOT. Anything given or acquired as a huck-bringer may be included under this term, from a tiny charm to the biass effigy on the front of a car. Copies in various materials of certain animals, such as a black cat, n pig (in bog oak the luck is supposed to be attracted when a leg of the mascot is broken off), or a blue bird; in gold or silver, the swastika (a (areck cross with each arm continued at right angles, the name meaning fortunnte), the sign of the zodiac or special setting of the stone for the birth month, the numbers 7,9 and 13 , various clarms in New Zealand greenstone and ligyptian scarals, are all favourite mascots.

Mascots for motor cars are made in Llass, or in brass or nickel, according to the inctal work of the car for which they are destined. 'fhose in glass ate designed so that they can he illuminated from within by means of a bulb and an electric switch. These mascots arc usually fitted to the homnet, and frequently screwed on to the top of the petrol tank. the actual method of fixing them varving with the make of the car.
The jacinth and amethyst are considered particularly lucky gems, while a black opal is said to bring fortune to an aitist if hought or found personallp, but not if reccived. A gold-mounted hare's foot or monkey's paw, a four-leaved shamrock, white heather, or a coin with a hole in it, onay be treasured as a talisman. The horseshoe "hen nailed up as a mascot must be turned with ends upward or the luck runs out. Grotesque animals or dolls come and go as fashionable mascots.

MASDEVALLIA. This orchid is suitable for cultivation in a glasshouse having a minimum temperature of 55 degrees. The plants must be potted in a compost of peat, orchid libre and splagimm moss, with sand and ernshed charcoal added. The compost must he kept reasonably moist throughout the year. When repoting hecomes necessary it should be done in February. I few of the hest kinds are Veitchiana, vermilion; ignea, reddish; and covarensis, white. Thare are many hybrids raised by crosy-hreeding between these and other suecies.
MASK. Any covering disguisc for the face, or upper part of the face, ivith openings for the cyea and, if necessary, for the mouth, is called in mask. These have been used from the carliest times of the theatre on the stage
Silk or satin half masks are worn at a masked ball, while the men and animal faces sold for the $3 t / 1$ of November and at Christmas time are bought by children for disguise and for fairy plays. Beautiful or grotesgue masks are

Mascaron. Left, cup with blue and white stripes, and gill bosses of lions' heads Right, bowl with spiral threadg, gilt masks, and small bosses $\mathrm{H}_{4}$ permission of the Director. Dictoria \& Alluert Museum. S. Kensinglon
executed in a great variety of innterials for wall decoration by oriental and other artists. The mask used in fencing is of iron netting with a padded frame fitting over the head and round the face to protect it from foil thrusts. See Fancy Dress.

MASK FLOWER. These lialf-hardy per ennials (Alonsoa) bear small, snapdragon-like flow rs in the summer time. They may be grown in pots under glass or be planted out for the summer. Propagation is by cuttings in a frame in August. The rose-red Alonson Warscewiczii is one of the slowiest. Tho plants nust be kept in a slightly heated greenlouse in winter.

MASONRY. The whole art and craft of working in stonc, from the rough shaping of the block to the completion of the finished product, is known as masonry. The term is also used to describe those prits of a structure which are built in stone. Stone being expensive material to build with, only the facing stones are generally squared up and worked to a fair face. The interior of the wall is made up with rough material, and the inner face lined with the faced stone, or with brickwork.
Masonry differs from brickwork in that generally the stones vary greatly in dimensions, and call for greater skill on the part of the operatives to get $n$ perfect bund. Walls made of stonc have to be considerably thicker than those of a similar height in brickwork. Exceptions are when the walls are built with conrsed stones properly squared and pointed, in which case the wallis may be thinner than in brickwork.

MASSAGE. Method of curing varions nuscular, nervous, and vascular maladics by rubbing, stroking, bnending, and otherwise treating the muscles with the hand. The four principal actions in massage are termed pétrissage, effleurage, friction, and tapotenient. Petrissage or kneading is done by pressing the palm of the hand into the museles, and grasping, kneading, rolling, and snueczing them by the thumb and fingers Fimeurage, or stroking, should be done with the pralm of the hand, which at the end of a stroke should glide back to the starting point. Friction is a circular movement done with the finger tips ol palm of tho hand. Tapotement is done by: the hands swinging from the wrists, and this movement should lie light, sharp, s!ninge, and vely rapid.

Anotlier livision of the movements in mats sage is asscciated with the Sivede, Peter Henry Ling He divided them into three: active, passive, and resistive. Passive movementsare done ly the operator, active movements by the patient himself Resistive muvements are done while the patient resists, or by the patient while resistance is supplied by the operator. These movements increase circulation.
The National Hospital, Quicen's Squars, London, W.C., gives a recognized certiticate. Students from other hospitals and achools must satisfy the examiners of the Chartered Socicty of Massage and Medical Gymmastics at Tavistock House (North), Tavistock Square, London, W.C.I.

MASTER : His Duties. The relation of master and scrvant is entered into by agrecnient. This need not be in writing unless the agreement is to be for more than a year from the day on which it is made. In agreement of service which does not state how long the service is to continue is supposed in English Inw to he for a year, but subject in practically every case to tensonahle or customary notice

In very many occupations there has grown up a customary period of notice. Thus, a domestic servant is entitled to give or receive a month's notice. The cditor of a newspaper by custom is entitlect to six montlis' notice. But most cases depend not on custom, but on
what is reasonable And what is reasumable depends upon the kind of service and the kind of engageinent.
Length of Notice. It may be stated, as a general principle, that the higher the class of service the longer notice has to he given on either side, and this is hecause it is always more difficult for a man in a higher grade of employment to get a job than it is tor a man in a lower grade, and it is also more difficult for the employer to procure a new servant of a higher grade than of a lower grade. Thus, an office boy would be entitled to $n$ week; $\Omega$ managing clerk to nt least a month. But as iudges and juries may take different views of what is reasonable, it is always wise in a contract of service to stipulate for n particular length of notice.

It is the servant's duty to serve faithfully. This implics an obligation not to disclose his master's secrets A servant who does this inay be restrained by injunction from continuing to disclose such recrets, and is also liable for damages. It is also a servant's duty to obey orders, so long as those orders are not unrensonable. It is the master's duty to pay his servant's wages punctually and without deduction; though in a few cases, by special ngreement, a master will be allowed to deduct penalties in the nature of fines for spoiled work, etc. A servant must be punctual; he must also he diligent, that is to say, he must work his hest and not be guilty of slacliness. If a servant, in carrying out his master's ortlers, incurs any liability, the master is bound to indeninify the servant against such liability.

A master is liable to outsiders for any act done by his servant within the scope of the employinent. This is a very wide phirase. It does not mean that the servant must have heen acting in obedience to express orders: in fact, the master may be liable under this doctrine although the servant was acting contrary to orders Suppose, for example, a tradesman employs a motor lorry in his busincss. and he tells the driver that whenever he is Iriving down the High Strect he is not to exceed a suced of 8 iniles an hour hecause of the traftic. In disregard of thesc orders, the man drives at twice that speed and negligently damages another vehicle The employer is. neverthciess, liable.
Liability for Wrong-doing. A minster may even he liable for his servant's fraul. This was held in a case where the manager of a bank stated in answer to an inquiry that X Y was a person of good substance to whom credit night be allowed, although at the time he knew that X Y was in very low water and could not mect his obligations. The bank was held liable for the fraud, because the statement was minde by their servant acting within the scope of his employment.
In the same way, a servant who is cmploved to make contracts binds his master within the scope of his employment. For instance, if 1 has a shop and he employs a man to manage it, and to do those things which manayers generally do, and he makes a contract such as a manager in the ordinary way would be entitled to nalie, A must corry out that contract or pray damages if it is broken. although he expressly told his manager not to make contracts of that particular kind

But if the person with whom the manager was dealing had notice that the mannger was not entitled to make that particular kind of contract, then A will not be linhle. It is for this reason that some firms print upon their Ietter pajer and other business documents, slich as invoices, a warning that no orders are to he accepted on bchalf of the lirm unless countersigned by one of the directors, or something of that sort Others give warning that no verbal orders for goods nic recognized.

The servant who is guilty of a wrongful act may himself be liable as well as his innster.

And where the servant, acting on his mnster's behalf, makes a contract in his own name or without disclosing that he is a servant, the person with whom he contracts may, on discovering that he made the contract as a servant, sue the master, or may elect to sue the servant personally. If so, then the servant has a right to be indemnified by the master

A inaster is not liable for any criminal offence committed by his servant unless he expressly authorized it or was in some way a party to it, in which case he can be convicted, sometimes as a principal and sometimes as aidling and abctting or as being an accessory before or after the fact. If the driver of a horse, being i . servant, is guilty of cruelt y to the horse, he alone is liable; hut if the cruclty consists in driving a liorse which was unfit to be out on the road or unfit to be employed to pull a load of such n weight, the inaster will also be linble if the horse was sent out with $h$ is knowledge or approval.
There are some statutes which make a master liable for offences committed by his servant. e.g. under the Licensing Acts. There are others which make the master liable in the tirst place, but with liberty to him to prove that the servant was really responsible and acted against orders; as, for example, certain ndulteration of fond prosccutions.
The Right to Dismiss. A servant who is dismissed without due notice may bring an action. The only ansiver to such on retion is that the servant has been guilty of misconduct. Disohedience to proper orders is good ground; in the case of domestic service, immorality is a good ground; dishonesty is sufficient; so is impudent hehaviour; so is persistent and gross neglect and inattention to work which is likely to cause serious loss to the employer; so is systematic unpunctuality. A slight breach of contract will not entitle the master to dismiss a servant without notice. The misconduct must he something which amounts to a repudiation by the servant of the proper relationship between them: that is to say, something like a fundamental breach of contract. Unless the contract of service says so, a servant cannot be dismised merely for being ill; but if the illness is of such a protracted nature or of such a kind ns to render the servant permanently unfit or unfit for a long perind to carry out his duties, the master may dismiss him.

If a servant has becn guilty of an offence which entitles the master to dismiss him instantly, the master must either do so or forfeit his right. For example, if the servant is guilty of impudence to his master on Wednesday, and the master says nothing ahout it until Saturday, which is pay-lay, and then on prying the wages tells the servant to go without notice because of the impudence of Werlnesday, the master is wrong. He ought on the Wednesday to say, "You are dismissed now, but if you like to renain to complete your week I will allow you to do so."
It sometimes happens that a master dismisses a servant sunmarily without justification, and after he had dismissed him discovers that the servant has bcen guilty of something which would have justified dismissal. If the servant brings an action for wrongful dismissal the master is entitled to rely for his defence ulon the second ground, of which he was not hware when he dismissed the servant. Sce Character: Employers' Liability ; Insurance ; Wortimen's Compensation.
MASTICATION. Unless food is thoroughly masticated, unnccessarily hard work is thrown on the digestive organs, and sooner or later indigestion results. Each mouthful should be chewed until it is Huid and frec from lumps. Eating solid food dry ensures more thorough mastication. Stareliy foods, such as hread and potatocs, should be well chewed. These
nie partly digested by the saliva in the mouth, and the more thoroughly the anliva is mixed with them the more easily will their digestion he completed in the intestine. Particular care should be taken with fat, cheese, hard-boiled egge, nuts, and other aubstances.

Children should be taught to masticate their fond thoroughly. Old people whose teeth are decayed should get artificial teeth, 0 ', as an alternative, they should have all food cut up very finely with a mincing machine; otherwisc digestive troubles, headaches, etc., will result See Diet; Food; Indigestion; Teeth.

MASTIC CEMENT. Brick, burnt clay, or limestone powdered and mixed with litharge, oil, or some similar substance makc what is known as mastic cement. It is used in constructional work for such details as bedding an iron casement into masonry, or the laying of a floor on a concrete or similar foundation. In making this cement care must be taken thoroughly to pulverize or grind the materials. If good resulta are required on fine work, the crushed material should be thoroughly sifted through a fine sieve. See Cement.

MASTIFF. Almost the oldest of British breeds is the mastiff, which is a most faithful custodian of home or person, and so powerful

Mastiff. A prizewinner of this lormidable English
breed of bouse dog
that no one dares to risk a fall with him. When carefully trained, he is not savage, but he should not be chained Mastiffs of tiro colours are bred, brindle and fawn.

The body is massive, broad, and deep, with strong lega set wide apart, giving the dog a square appearance. He should be of great size and weight, yet aetive when properly proportioned. The legs, both front and back, should be straight, that is to say, the hind legs should be parallel, but the hocks fairly well bent back. Back and loins should be wide and muscular. The head is broad between the ears; the muzzle short and broad under the eyes, and nearly parallel in width to the end of the nose. The mastiff is somewhat expensive to keep, needing plenty of meat and ample room. See Dog; Kennel.
MASTINE. This is a mixture used for staining wood. It is inade to imitate mahogany, rosewood, light oak, weathered oak, fumed oak, and antique nak. Of the nature of an oil stain, it may, if required, be thinned with turpentine. It can be obtained in tina (1 lb., 2 lb. , or 7 lb .) through any colourman. See Stain; Turpentine.
MASTITIS. In. flammation of the breast. or mastitis, is nisually due to the entrance of a microbe through an abrasion of thic nipple. The nipples should be kep scrupulously clean with soap and water, and may then be daubed

mat. Oval-sbaped mat made of rusnes, suitable for kitcnen or baturoom
with the following: Compound tincture of lavender, $1 \frac{1}{2}$ oz.: glycerin, l dram. If the nipple becomes fissured or abraded it should be washed with boracic acid lotion after nursing and then anointed with a paste consisting of equal parts of bismuth carbonate and castor oil.
If the breast becomes painful, hot, and swollen, the child should he withdrawn. Hot fomentations are applicd, and the bicast and the arm on the afficted side should be supported.

MASTODYNIA. The painful neuralgia of the breast known as mastodynia sometimes gives rise to a lumpy condition which may be mistaken for commencing cancer. A timcly consultation with a doctor will save a lot of worry. Commonly it is an affection of preg. nancy or of the period of suckling when the breast is overtaxed

MAT : For the Floor. Hall door mats should he of good quality fibre or they quickly wear down in use. Another important point is that they should fit the doorway or the sunk space often prosided for then inside the front door. Fibre centre mints are obtainable with wool borders in various colours.

For use on landings and in the hall outside the doors of various rooms if mats are required they should either match the stair carpet or be of a plain colour that tones with it, or of skin.
Mats for the bathroom may be of non-slip rubber in a wide range of colours, of coarse towelling, or of cork. In terry cloth they are patterned in good designs and all colours. Cork mats wear better if framed narrowly in wood.

For country cottage or bungalow use rush mats, or those in dyed coco fibre are suitable.
Wool mats can very easily be made at home in the same way as rugs. The necessary implements and materials are a gauge, a patent crochet hook, a pair of acisanrs, a piece of canvas and the wools. Charts in colour, giving suitable patterns for these mats, can be bought, or a pattern can be evolved or copied by the worker. Directions for making are given in the article on Rugs.

Making Rush Mats. Rush mats, suitable for bedrooms, kitchens, informal or bungalow living-rooms, loggias and bathrooms, can easily be made at home. The necessary rushes are sold in bundles, and all that is required besides is a packing needle and some atring. Before they are used the rushes should be soaked in water for 8 or 10 hours. They can be dyed to any shade required. Most mats, however, can be made chiefly of natural coloured rushes, coloured ones being only used for forming a pattern in the centre and for making the border.
The rushes should be plaited in strands, each strand consisting of three or more rushes, according to their size and the thickness of the mat. A mat such as is here illustrated is made by stitching the plaits together round
and round until they form an oval. The plaits may cither be sewn flat or edgeways, whichever is preferred.
To work the centre of the mat, take three small plaits, ane green, one natural, and ne brown. Stitch them closely together to form a zigzag pattern and, when a sufficient length has been made, bind the edges with a plait of rush in order to give the oval effect. The rest of the mat, save the border is of plain rushes, with the plait sewn edgewnys To join the rushes, put the hutt end of the new rush to the thin end of the other one. nnd plait it in ahout 4 in . from the end of the last rush. Such mats will wear better if the ends are plaited in and made neat. Any discoloured portions should be cut off. When colour is introduced care should be taken to have an even number of rows A break in the middle of a row shonld be avoided
Useful Hints. To prevent mata from curling'up at the corners, as they are apt to do after a few weeks' wear, turn them occasionally and use then upside down. In the casc of plain rope or hemp mats this can be done without any obvious change of effect, for the two sides are usually alike; but if they are decorative mats with coloured patterns some other method must he adopted. Weighting the corners is usually effective, but if this is done with coloured mats an oddment of material which harmonizes with the predominant shade is necessary. Cut the material into four small squares, turn them in neatly all round, then fold them into triangles and sew them on to the four corners of the mat, first inserting a tailor's lead weight in each corner. Take stitches right through the mat with a long darning needle, and sew firmly so that the weight will not strain the stitches.

Where mats are placed on linolemm the floor immediately heneath them should not be polished, otherwise they will slip when stepped on and may cause accidents. On carpeted lloors, in particular, dust quickly accumulates underneath mats, and for this reason the latter should always be removed when the carpet is swept.
Coloured mats which have faded may be nestored to brightness by washing them with warm, salted water, or with water to which a little vinegar has been added. If made of Indian matting they may also be scrubbed, rinsed well, and left in the open air or in a draughty place to dry. Stains which will not yield to ordinary treatment should be rubhed with benzine or washed with a solution of water and ammonia. Information about tahle mats may be found in the entries on Duchesse Cover, Luncheon Set, Table Mat. Sce also Embrodiery; Raffia; Rug.

MATCHBOARD. One of the most useful materials for the woodworker consisls of narrow, thin boards planed smooth on one side, grooved oll one erlge and tongued on the other. When a number of them are fitted together they form a fairly so!id. firm structure, and the interlocking effect of the tongued joint makes it draughtproof.
There are several varieties of this matrh. board; the ordinary kind is known as tongued, grooved, and beaded, as there is an ornamental bead worked on one side next to the tongue, thus breaking up the surface and offering scope for decorative effect. A plain matching is made without this beading, and when available is uscful when a large, smooth surface of timber is required Another tspe is known as tongued, grooved, and V-jointed, as the edges are bevelled, and when the bonrds are put together they exhibit a V-shaped groove at each joint.

Sizes vary from $3 \frac{1}{4} \mathrm{in}$. to 6 in . wide, $4 \frac{1}{2} \mathrm{in}$. being common. Thickness ranges from ${ }_{k}^{3}$ in. to $\frac{7}{7}$ in., the sizes commonly used being the $\frac{1}{2}$ in and $\overrightarrow{3}$ in. These sizes are nominal and actually measure slightly less, so that when

Matchboard. Showing how to use an odd piece o.
matchboard to drive other lengths up tightly
reckoning by the square-that is, sufficient timber normally to cover an area of 100 sq . ft . -it will be found necessary to add about 10 per cent.
Matchhoard 18 applied by nailing it to the wall or to thin brttens fixed firmly to the walls and packed up where necessary, so that the faces of all these strips are in line. The strips should run at right angles to tha direction of the joints between the boards and should be spaced not more than 2 ft . npart for the $\$$ in matchboard.

When erecting matchboard care should be taken to get the first piece fixed inght and true, as all the others will he affected. The sccond piece is driven home into the groove, as shown in the illustration, by means of $a$ mallet and an odd bit of the matchboard this being inserted into the groove or over the tongue to prevent the edge being spoiled by hammer marks. The tongue and groove is rather tender and should not be strained, nor should the hoands be allowed to lie nbout, as the edges are easily broken. See Bonrd.

MATELOTTE. This is a dish of fresh. water fish stewed in a savoury manner and accompanied by a matelotte sauce. Occasionally birds are cooked in the same way The fish should be all of one kind, and must be stewed gently in wine or stock well flavoured with wine. also one or two cerrots and onions are added to the stew, as well as some spice

After the fish is cooked strain the liquor and add to it $\frac{1}{2}$ pint rich brown sauce and 6 mushrooms, prepared and cut in pieres Let all boil up together, and then simmer very gently about 20 min., removing the scum as it rises. Strain this snuce and add $10 \%$ butter heaten with $\pi$ few drops of anchovy essence and a grate of nutmeg. Mix it well over the fire and sprinkle in a pinch of sugar. Serve the sauce poured over the fish.

## MATERNITY BENEFIT. In Great

 Britain, under the National Health Insurance scheme. this is a benefit prid to insured persons on the birth of a child. The amount is 40 s , pail to the wife of an insured man or to an insured woman on her confinement This henefit is payable after 42 weeks have elapsed since the man or woman became insured, provided that 42 weekly contributions have been paid. An insured married woman whose husk and is also insured is entitled to a double maternity benefit. See InsuranceMATTING. Woven rope, hemp, coconut fibre, etc., are employed to make matting, which differs frmm the ordinary doormat only in that the latter is cut to a certain size, while the former may be bought by the yard Narrow lengths of it are sometimes used to cover the floor of a hall or passage, while it is also frequently laid down during furniture removals to protect a polisherd Hoor from scratches, etc. In certain illnesses where
absolute quiet is essential to the patient's re covery, matting is sometimes laid down on any tiled or uncovered thoors near his room so that the sound of walking may be deadened, and in severe cases it may even have to be used on the pavement outside the house.

MATTOCK. 'The mattock is a too similar to a pickaxe but having two hroad hlades set in different planes Generally the blades take the form of an axe-like edge on one end and a chisel edge on the other. They are made of cast steel, the handle heing inserted in a hole near the centire of the tool
The mattock is used to loosen earth, grub out roots, and the like, the earth being turned up with the chisel end of the tool; any roots, such as would be found in grobbing operations can be cut with the axe end. The chisel end curves alightly inward to facilitate turning up the earth, while the axe end is formed practically at right angles to the helve, as in this position the tool can be used more offectively for cutting through obstructions

MATTRESS. Mattresses are divided into two principal types, top mattresses or overlays and under mattresses or mattress sup. ports The first type are of two kinds stuffed

Mattress. Fir. 1. Overlay mattress with part cu. away to show construction of spring centre encased in luxurious stufting of hair Courtes" of lleal \& Son
overlays of hair, wool and hair, or wool only. and inner spring mattresses. Mattress supports are of four kinds, ordinary woven wire springs, spiral springs in a wooden frame, hox

Fig. 2. Overlay mattress with pocketed springs ensuring resilience and comfort. The layer of hair stuming is cased in an envelope of material before being sewn into the mattress

The older kind of wire spring mattress is difficult to keep clean. Every week it should be brushed with a stiff, dry nailbrush, and the

FiR. 3. Support matress on wood irame for use on an existing bedstead with overlay mattress Courtesu of Staples \& Co.. Led
woodwork wiped with a damp cloth. In bar is repeated, beginning with the right warm weather the cloth should be moistened fo with disinfectant. Once a year the wire mattress should be taken apart by having all its bolts and screws unfastened. It should then be taken out of doors and pure carbolic poured round the holes where the bolts have been. This should be followed by an application of boiling water over the carbolic. The wire springs and the woodwork should then be scrubbed with a stiff nail-brush dipped into carbolic and water. The mattress should be left outside for some bours to become thorough!y dry
A wire mattress that has become rusty can be restored thus: Paint it all over with aluminium paint, using a small, pointed brush that will get inside the mesh See Bedding: Bedstead: Box Mattress; Cot; Divan.
Maxillaria. The culture of maxillaria. a family of hothouse orchids, is the same as that for masdevallia ( $q \cdot v$ ). See Orchid
MASINA. A sequence dance in common time, the maxina is composed of five parts The partners stand side by side facing the line of dance, the man's shoulder just behind the girl's, her left hand in his left, her right hand passing above her shoulder to take his right.
In the tirst part both glide the left foot forward and count 1. Then the right foot forward and count 2, the left again, counting 3, and the right, counting 4. The partners chassé to the left, commencing with the left foot and counting 1 and 2 ; then to the right, starting with the right foot and counting 3 and 4. The next step is to glide the left foot forward and count 1 , then the right and count 2. Both pivot round on the right foot, the girl turning under the hands, cross the left foot over the right and count 3, then point the right foot in front and count 4. The last

The second part is simpler. Placing the left heel to the floor, both partners turning to the left, count 1 , then hop on the right foot and count 2. This is repeated 8 times until a complete circle has been made.
The movements in the third part are as follows: Glide the left foot forward and count 1, then the right, and at the same time dip. bending the knee, and count 2. Bring the left foot forward with the heel to the ground in front of the right foot and count 3. Close the right foot up to the left and count " and" Move the left to the rear with the toe to the floor and count 4. Repeat the movement.
Right and left glides are a feature of the fourth part. Glide the left foot forward, count 1: the right, count 2 ; then the left, count 3 The man closes right to left while the girl pivots round to face him, counting 4. In the fifth part both hold as for the fox trot, (q.v.), and two-step or waltz for 4 bars.

MAXIXE. Like most of the dances intro. duced from South America, the maxixe is danced in such a way that it can be done in long pampas grass. Thus, the feet point straight, the knees are kept a little bent and the legs, wherever possible, are kicked forward, rasing tho feet a little at the back to free them from the grass. The steps. on the whole, are kept small, the movement being taken from the knees and not from the hips, as in other dances, keeping the upper parts of the legs comparatively still. The foot is kept almost flat, with a slight dmp on to each step occupying more than one beat.
The figures may be done in almost any position. The dance usually starts in the waltz position, after which the couple may pass into an open position in which they face the same way. The arms need not be altered, but the man may take the girl's left in his right hand and either stretch it st raight out or turn it at her back, as in his original position. See Waltz.

MAY: The Tree. This is the popular name of hawthorn (Crataegus oxy. cantha). There are varieties with white and red. single and double flowers. Under the name of whitethorn or quick it is largely used for hedge planting. See Haw. thorn: Hedge

MAY BUG. The may bug, also known as the cockchafer. is a rather hulky looking brown bcetle, about 1 in. long and $\frac{1}{2}$. wide, coated with delicate down, the hind body tapering to a point bevond the wing-covers 'Towards the end of May or early in June the bectle may damage the foliage of treea; but it is in the larval atage that it is most harmful. The female deposits her whitish eggs in a batch of nearly 100 , a little
below the surface of
the soil, and the grubs for more than three yeara feed on the roots of grasa and herbaceous planta.

The visita of rooks and starlings to the lawn should be encouraged, as they hunt systematically for the grubs. and their powerful bills enable them to reach their prey. Failing this natural remedy,

Meg Bug of cockchater infested ground should be dressed with a mixture of nitrate of soda and soot, in the proportion of $\frac{1}{2} \mathrm{cwt}$. of nitrate to 7 bushcls of soot for $\frac{1}{2}$ acre of ground. See Insecticide.

MAY FLOWER. This is a hardy and cvergreen creeping shrub (Epiguea repens), which grows well in sandy peat if planted in a shady position, and bears fragrant white Howers in May Planting may be done during spring or autumn; propagation is by division of roots in October.

MAYONNAISE. This name is given to a sauce or salad dressing. The ingredients are : I yolk of egg. I gill salad nil, I teaspoonful dry

Mayonnaise Miyer fitted with
fannel from which olive oll can be mired in drop by drop mustard, tablespounful cream, $\frac{1}{2}$ teaapnonful cas. tor sugar, 2 teaspoonfuls tarragon vine. gar, 2 tea. spoonfuls white vinegar. salt and pepper. Mix together the dry ingredients and the egg yolk Whisk in, drop by drop, the salad oil, then the vinegara Add the cream last, and very grad. ually. Beat all the time with a slow, regular motion, always working in une direction. At the end add a dessert. spoonful of boiling water. It is essential for the success of the mayonnaise that the oil be added drop by drop and each drop mixed in thoroughly.
Mayonnaise sauce is used as a dressing for salads, with lobster, crab, chicken, salmon, etc., which are then known as lobster, crab, chicken, or salmon mayonnaise respectively.

## Mayonnalse Mixer. This is the name given

 to a contrivance which assists in preparing mayonnaise dressing for salads, etc. The ingredients are placed in a bowl, and a small funnel, which is attached, filled with olive oil. The oil then can be mixed in drop by drop. The mixer is worked by means of a handle. See Salad ; Salmon.MAZUS. This hardy herbaceous perennial of creeping growth is suitable for planting in gritty soil in the rock garden. Mazus pumilio and reptans, with purplish mauve flowers, are the species in cultivation. Propagation is by division in spring
MEAD : How to Make. Mead is a drink made with honey, Havoured with hops. To make it, add to each gallon of water 4 lb : honey. Boil together for \& hour, and akim it
well. Measure the liquid and allow 1 oz. hops to each gallon, then boil it upagain for $\frac{1}{2}$ hour, turn it into a wooden vessel, and stand it till the next day. It must now be put into a cask, and to each 4 gallons of mead add $\frac{1}{2}$ bottle of brandy. Iet it ferment, and when it has finished close the cask tightly and leare it to stand. In about cight months it will ber ready to bottle.

MEADOW RUE. This is an attractive hardy herbaccous perennial with ornamental leaves and flowers of various colours in summer. They llourish in ordinary well-drained soil The chief kinds are aquilegifolium. 3 ft., purple : Delavayi, $2!$ ft., mauve ; dipterocarpum, 5 ft., lavender rose: and glaucum, 5 ft., grey leaves and vellow flowers. Adiantifolium $\mathbf{g}$ in., with fern-like leaves, is suitable for the rock garden Propagation is by division of the planta in early autumn or spring or by sowing seeds under glass in autumn or spring

NEADOW SAFFRON. Theso heautiful hard y bulbs bear crocus.like blooms in autumn The leaves, which are very largo, do not appear until apring They should be planted in grass or arnong low growing evergreen plants so that the flowers are not spoilt by soil splashed up in rainy weather. The bulbs ought to be set 3 in. deep in July-August; they thrive best in well-drained loamy soil

Meadow Saffron. Purple crocus-like
flowers of Colchicum autumnale Colchicum autumnale, the common meadow saffron, has purplish blooms : the finest is spociosum with large rose-purple Howers. Pro. pagation is by ofisets which may be taken off the bulbs whenthe leaves have died down. or by seeds which are sown as soon as they are ripe.
MEADOW SWEET. This is the popular name of a wild plant, Spiren ulmarin. It hears cream-white fragrant llowers in early summer. See Spiraen.

MEAL. Meal, in one sense, means grain ground to powder. There are thus various Kinds of menl, e.g. barley meal, maize meal, oatmeal, and wheatmeal, although sometimes the word meal is dropped when referring to them. See Barley; Diet; Flour; Food; Oatmeal; Wheat.
Mealies. This is another name for maize meal or Indian corn. See Maize.

MEALY BUG. One of the most troublesome of the pests that damage fruit and plants cultivated under glass is the mealy bug. Its body is covered with a substance like meal, and is furnished with n number of waxy thread-like filaments, those at the tail end bring the longest. The larvae are hatched from a constant succession of egga, and soon settle down to suck the sap.

An elfective remedy is thorough cleansing of leaves and shoots with an insecticide, using a small brush or a sponge. Isolated bugs are beat dealt with by means of a brush dipped in methylated spirit or paraffin oil. See Insecticide.

MEASLES : How to Treat. Measles is an acute contagious disease which mostly attacks children, but sometimes occurs in later life. One attack is usually preventive of others. It is very infectious and generally spreads in epidemics in spring or nutumn. The cause is

most probably a microbe which has not yet been identified.

Infection is conveyed in the breath and saliva, from the skin if touched, and probably also by clothing and toys. Ibout 10 days after infection the disease begins suddenly, resembling a severe cold with sneezing, running at the nose and eves, and temperature up to $102^{\circ}$ or $103^{\circ}$. Three or four days later red spots appear on the nech, face and body and tiny rose-pink spots may be seen inside the mouth. The rash begins to fade after two or three days; there follows a desquamation of fine scales and convaléscence is rapid.
The chief danger with measles is to the lungs and
 respiratory paseages ; bronchitis often leads
to broncho pneumonia. Catarrhal laryngitis may occur before the eruption; as it may be due to concurrent diphtheris, the doctor should be told if a child suffering from measles becomes croupy. Inflammation of the ear may also occur.

Measics is intensely infections before the eruption appears, and when there is reason to think a child has become infected he should be isolnted at once. A large, airy top room is best. It should have a fireplace and should be kept at a moderate uniform temperature of about $65^{\circ}$, and the air should be moistened by menns of a bronchitis kettle sending steam into the rom. Moist air is necessary to soothe the irritable mucous membrane of the bronchial tuhics. Screens should be placed round the bed. The healthy children should be kept as far as possible from the sickroom, or sent to another house. The diet is that for fever. The child ahould be sponged all over with warm water every day Bronchopneumonia is the most serious complication, and requires constant medical attention.
The patient should not lenve bed until the temperature has been normal for seven days. A week later he may go out of doors if the weather be fine, but in cold wenther not for two or three weeks. The diet must be nutritious and digestible during convaleacence. Cream is a valunble food at this time, and it
is advisable to give cod liver oil for 8 or 10 weeks, with iron if there is annemia; chemical fond would be a suitable form.
The safeguarding of young and delicate children from infection is of great importance. Greater care in recognizing early stnges of the disease in older children and prompt isolation will be helpful. The things to watch for are n rise of temperature in the evening and swelling of the lining of the lower cyelid. II spots have appeared in the mouth it is too late, infection has probably been transmitted.
MEASUREMENT. This means the act and result of mensuring. Correct measurcmenta are necessary in order to make the various articles described in this work, and for many of these diagrams with ineasurements are given. With most of the woodworking articles a cutting list is supplied giving dimensions of the various pieces of wood required.
To measure the height of anything there is a simple method which most persons can put into operation. Take, for example, a flagataff. A certain distance, say. 40 ft., must be marked in a straight line from this, and a stick of a certain convenient length placed in the ground at the spot. The next step is for the measurer to go still farther away from the tree, still in a straight line, until, with his head on the ground, which must bo level, lie can sec the top of the stick and the top of the llagstaff in the same atraight line.

This apot should then he noted and carefully measured. In the present case we will assume that it is $t f:$, making the line from the flag. statif $4(\mathrm{ft}$. in all. These lines should give tivo imaginary triangles, as ahown in the diagram. All that now remains is to work out a sum in simple proportion. As the line $C F$, is to the line $\mathrm{D} C$, so is the line 13 E to tho line A 13 . which is wanted. In the example here taken it can be assumed that the length of the atick above the ground is 4 ft . The actual sum is : As 6 is to 4 , so is 46 to the answer.

$$
\frac{4 \times 46}{6}=\frac{184}{6}=30_{3}^{2}
$$

Thus, the height of the flagstaff is $30_{3}^{\frac{2}{2}} \mathrm{ft}$.
In actual practice calculations will usually be less simple than the one given, but the principles are exactly the same. See Centre to Centre; Drawing, etc.
MEAT: Food Value. Short-fibred meat, such as the breast of chicken and game, is more digestible than long.fibred varietics. In eating the latter-becf, mutton and veal-it is well to cut them in thin pieces across the fibres. Beef is probably best when the animals are about four or five years old. They are then more nourishing, bulk for bulk, than the fleah of younger animals. Veal is less digestible than beef. The fatter the meat, the less water it contains; hence the more economical it is for people with whom it agrees. But it is also less digestible.
The amount of water in meat is very large ; 1 lb . of average heef contains lb . of water and only $\ddagger \mathrm{lb}$. of nutritive matter. The same ap lies to lean mutton, lamb, veal, venison, fowl, hare, and pigeon. Pork is $\frac{3}{3}$ water and goose ${ }^{3}$. But very fat becf or mutton may be only $\frac{1}{2}$ water. Bacon contains very little water, only a hout \& of its weight. The calorific, or heatgiving, value of meat is very high. Too much meat enten in summer is inclined to overhent the blood

Beef and mutton are more digestible when under-cooked, but lamb, veal, and pork are unpalatable and unwholesome unless well cooked. Roasted meat is less digestible than boiled. The roasting or baking of nient leads, however, to the development of appetizing substances "hich are included under the name of osinazone. These stimulate the flow of
gastric juice. The plan of stewing meat in an inner vessel within that in which the water is boiling has everything to recomenend it. Casserole cooking is perhaps the best and most economical metliod of cooking meat, as the meat is cooked in its own juices, which are served up with it. Thus nothing is lost. On account of the high temperature at which meat is cooked in frying it is less digestible than when cooked by other methods. All meat becomes morc tender by hanging for some time, but it is not desirable to let it hang ton long and allow putrefactive changes to develop. Freshly killed meat requires more time to cook than meat that has been well hung.

Hints on the choosing of meat are given under the headings for the various kindsbeef, mutton, veal, pork, etc.-in this work.
It is most essential that meat directly it comes from the butcher should be thoroughly examined and at once put a way in a cool, well. ventilated larder, also that in summertime careful observation should be made that no blow fly has had access to it.

Poisoning by Meat. The symptoms of meat poisoning come on about thrce or four hours after taking food, and are usually due to eating pork pies, sausages, or cold pork which has begun to putrefy, or which has been kept in a hadly ventilated and unclean larder. In rare instances it takes the form of hotulism.

It is gencrally well to give an emetic of a tahlespoonful of mustard in half a pint of warm whter if vomiting has not yet occurred. This should be followed by a full dose of Epsom salts, according to the patient's age For faintness or collapse brandy or other stimulant may be given, and hot-water bottles should he placed ahout the patient. For severe pains put a hot linseed poultice to the abdomen. A doctor should be sent for at once.

Meat Extract. Extracts of different meats may be bought in hottles of varying sizes, and are used ns stimulants or in the preparation of soups and gravies.
Meat Jelly. Jelly is extracted from the boncs, gristle, and sinews of meat. To produce a jelly of any strength the bones are chopped in pieces and must not have been previously conked. The boiling inust be gentle and continuous for from 8 to 12 hours, and the scum must be carefully removed.

Knuckle of veal or mutton, also the feet, make excellent jelly, and one which, having little flavour in itself, can be readily adapted cither for a s weet dish or a savoury jelly. Ox feet produce a very strong jelly, but not so delicate as calf's feet. Cow hicel is obtained usually from the tripe-dresser's, and has already been boiled; but a good jelly for mixing with milk or other ingredients is ohtained from it.

Although meat jellies have little actual food value in themselves, it is possible to mix with them meat which has been cooked, pounded, and passed through a sieve, and either introduce it in the form of amall shapes set in the jelly, or let it mingle with it and give a marbled appearance Pieces of chicken or other delicate meat can be set in meat jelly, and the moulds may be decorated with leaves of aspic jelly and butter put through a forcer.
Meat Pie. There are two kinds of meat pies, those which are baked in pic-dishes, where the meat is covered over the top with pastry, and raised pies, where the meat is cntirely enclosed in paste.
For the pie made in a piedish almost any kind of meat, poultry or game will serve, pork excepted. The pastry covering consists of puff, rough puff, or flaky paste, but it is made with a larger proportion of fat than is considered necessury for most fruit pies. Meat pies are baked from $1 \frac{1}{2}$ to $2 \frac{1}{2}$ hours, according to size, therefore the crust must be rich with
fat or it will become dry during the process of rooking.

The best meat to use for pies is that in which the fat is not superabundant, and all skin and gristle must be left out when cutting it up. In the case of poultry or game whole joints are Inid in the pie-dish, but when butcher's meat is used strips or slices are cut and no hone left.
'To enrich the gravy of poultry or ganie pies, a layer of steak pieces is laid at the hottom of the dish. Flavouringa used are in accordance with the character of the meat They mny consist of shallots, parsley, herhs, mushrooms, oysters, forcemeat balls or hard-boiled eggs Slices or dice of ham or bacon may be arlded with advantage.

The raised pic is made with hot-water crust This crust, being very short, must be kept only warm enough to mould, and is always better for lying covered up with a thick cloth for some hours before it is made up. For raised pies generally pork or veal is required. Instructions for making these will be found under the headings Pork and Veal See alsn Bacon; Botulism; Beef; Iiet; Food : Game; Laınb: Mutton; Pastry; etc

MEAT SAFE. Whether the housewife possesses a refrigerator or not the meat snfe is an important item of furniture in the kitchen This is particularly the case where larder accommodation is limited. No hot food should be placed in the refrigerator, so that a zinclined meat safe with ventilation regulator in which food may be put to cool is a great asset. In a small larder it is alsu often clesirable to kecp meat separate from other dishes and foods.
The newer models have table tops of white porcelain enamel, or in sorne cases of chromium plate. These have all the advantages of $n$ safe and table combined and are constructed on hygienic principles with washable galvanized interiors In some of these safes. sliding, galvanized steel-lined trays for smaller articles of perishable foods are provided. The tinish of the safe is in enamel to match the wood. work of the kitchen, or in oak, and it is mounted on pivot bearing castors, so that when in use as a table it can be easily moved to a convenient position for pastry making or other culinary preparation.

Meat safes form a part of some kitchen cabinets which are provided with a cupboard lined with galvanized stecl for this purpose and properly ventilated. Small enamelled tin meat safes with panels of perforated zinc or iron wire gauze in the door and sides are also useful in the small kitchen as they take up little space and can be lixed to the wall. See Kitchen: Larder.

## MECONOPSIS. This is a biennial and

 perennial herbaceous plant of great heauty. It comes chiefly from China and other far Eastern countrics, and some of them have flowers of most exquisite blue colour. ing. The Welsh poppy (Meconopsis cambrica) with orange or yellow flowers is an excel. lent plant for a shady wall or for shady crevices in the rock garden and often sows itself freely, hut the exotic kinds require rather apecial treatment. They need shade and well drainedthough deep moist soil of peat and loam.Aculeata, hlue ; integrifolia, yellow;

Meconopsis. Flower spike of the Himalayan poppy

Wallichii, hlue: and Baileyi, blue, have flowers of ex quisite beaut These are biennials, raised each year from sceds sown in boxes of fine soil in a framein May. If the secdlings are planted out in autumnthey should be protected from excessive rains in winter by pieces of glass raised a few inches a bove them. Meco nopsis regia, from Nepaul, which hears large prim-rose-coloured
flowers, is the latest novelty in this group
MEDICAGO. Of the large fanily of creeping plants bearing the name of medicago only one is worthy of cultivation in ordinary gardens. This is the Calvary clover (Medicago echinus), an annual raised from seeds sown under glass in April. Its yellow Howers are borne in summer, and are succceded by quaintly twisted legumes. It is generally grown as a pot plant in a sunny window in a mixture of loam. leaf-mould, and some old mortar
MEDICINE: How to Give. The follow ing are important rules to be obscrved care fully in administering all medicines

Read the label every time before pouring out, and again after pouring out, the medicine Never give medicine in the dark. Shake the bot tle, even if not so directed.

Use a graduated measure always; spoons and wineglasses vary. If ininims are ordered. measure them in a minim-glass ; drops of some liquids are twice as large as drops of others. Never guess at a dose.

When pouring out, keep the labelled side upwarl. When dropping a medicine, first wet the lip of the hottle with water Give medicines, especially cod liver oil, out of jerfectly clean smons, glasses, etc.

If ordered to take medicine before or after meals, takic it 20 to 30 min . before or after: unless otherwise directed. To dull the sense of taste when taking nauseous medicine, put a little ice or peppermint in the mouth, or chew a piece of orange-prel. Castor oil is most easily taken in coffee, orange juice, grape juice, or effervescing lemonade. U'npleasant powilers should be given in wafer papers, purchas able at the chemist's. A pill is most easily swallowed if the head be bent forward.

In giving medicine to a resisting child, first try firm persuasion, then bribery. If these fail, hold the nose and put the spoon far back into the mouth The child's arms can be held to the hody with a towel. (See Dosage).
Medicine Case A small medicine case holding some of the most useful of ordinary medi cincs is carried by many travellers. The one illustrated can easily be carried in the pocket. The case is of leather, and inside are
six small bottles containing medicines that are useful to ward off a cold, or in case of
sudden illness. The medicines usually carried in cases of this kind include quinine aspirin, and sal volatile. See First Aid

MEDLAR. This summer - leafing trec, Pyrus (mespilus) germanica, is valued for the sake of its white llowers in spring and for its curious fruits in autunin. though these are liked by few. Medlars nust be left on the tree as late as possible and then stored until they are "bletted" or have become slightly soft The tree thrives best in rather moist but well drained loamy soil and should be planted in autumn. It is propagated by grafting on stocks of pear quince or white thorn and makes an attractive lawn tree. The Dutch and Nottingham are the best varicties.
Uses in Cookery. When gathered, medlars should be atored in a cool place until the early stages of decay are manifest They are some.

Medlar, showine the curious shape of the brown fruit
times employed as dessert fruit, but are more often used for making jams and jellies.
Mediar cheese is inade by cooking some medlars until they are tender in a covered jar placed in a saucepan of water, then rubbing them through a tine sieve and adding $\frac{1}{2} \mathrm{Ib}$ lump sugar and a teasponiful of allapice to every lb . of pulp. When the sugar has dissolved boil the whole steadily until it sets firmly

Medlar Jam. Medlars must be quite ripe and enft before they are used for jam. Wipe them with a cloth and put them in a preserving pian, just covering them with water. Stir then frequently while they simmer beside the tire for $30-35 \mathrm{~min}$., or until they split. Pass the pulp thmugh a rather coarse sieve, but line enough to retain the seeds, and put it back in the pan with the grated rind and juice of a lemon and just under l lb. sugar to every lb. of fruit. The fruit should be weighed for this purpose before it is put into the preserving pian.

Boil the jam fast for $30-45 \mathrm{~min}$., stirring and akimiming constantly. When a little scts when dropped on a cold plate pour the jam into dry warmed jars and tie down at once.

Medlar Jelly. To make this preserve, put the ripe fruit in a stewpan and just cover it with water, adding to every 40 medlars the rind and juice of a lemon. When this has simmered for about 40 min ., and all the fruit
has broken, pour it into a jelly-bag and at rain out the juice without any pressure To every pint of juice add 1 lb sugar, and then boil it in the stewpan for about $1 \frac{1}{2}$ hours, until it sets when tested It will need frequent stirring and skimming Pour the jelly into dry warmed jars and tic them down inmediately See Jaın ; Jelly

MEDOC. No Bordeaux wine is entitled to the name Médoc except that made from grapes grown in the Médoc, a strip of land on the left bank of the Gironde Some of the famous wines of the Médoc are St. Julien, St. Estephe, Pauillac. St Iaurent Cantenac and Margaux See Bordeaux; Wine.

MELANCHOLIA. In the form of insanity known as melancholia there is extreme mental depression. the low state of the feelings being associated with mental pain or distress Delusions tend to develop. There is a grave risk of suicidal attempts in melancholia and in thi depressed states which border on it. Such cases, therefore, require most carcful supervision, and this usually means that tho patient ought to be in an asylum See Insanity; Lunatic.
MELIANTHUS. This is a half-hardy bushy plant, 4 ft. or so high, which has graceful decorative leaves and reddish-brown llowers. The two kinds grown are major and minor, the former being the more valuable. In a horder and at the foot of a sunny wall melianthus is hardy in mild districts, but in other places the roots should be protected in autumn Propagation is by cuttings in August, or by seeds sown in early spring under glass.

MELOCACTUS. The melocactus is a species of cactus known by various popular names, including melon cactus, pope's head, Turk's cap, and melon thistle. It has spiny, ribhed stems, topped by a sort of cylindrical cap, which gives the plant a curious appearance. Being a succulent greenhouse perennial, it requires a sunny position under glass, and a minimum winter temperature of about $45^{\circ}$. The plants need little water between nutumn and spring.

MELON. Unlike other popular fruits, the melon can be raised from seed, but it is not hardy, and with one or two exceptions the varieties require heated houses and a temperature of $65^{\circ}$ or $75^{\circ}$. The season is gencrally from May to October.

How to Grow. As melons love heat and moisture it is customary to grow them in pits, which are half-sunk structures with low walls, sometimes lean-to's, sometimes span-roofs, with brick-encased beds, not as a rule more than 2 ft . below the glass at the front.

When a plant is carrying several fruits, it is desirable to support them with netting.

For melons in hotbed frames less atmospheric moisture is desirable, because there is greater danger of stem canker. Syringing once a day suffices. Ventilation should be practised in fine weather. A piece of tile or slate should be placed under each fruit so as to keep it off the soil. Seeds should be sown singly

Melon cut apen and seeds remaved in order to show the depth of the flesh
in small pots of loasyy soil in spring, and when the secdlings are well rooted they should be planted in mounds of loamy (turfy) soil set about 3 ft . apart on a hotbed made up in a frame or glasshouse When the plants reach the trellis fixed beneath the roof of the Iatter their tops should be pinched off to cause them to form side shoots on which male and female llowers will be horne

An important detail of cultivation is to pollinate several blooms at the saine time by transferring the pollen from the male or staminate bloons to the female or pistillate blooms: if pollination is carried out on different days the early fruits will develop fully but the others will be small. As the ronts push through the mounds of soil fresh loam must be added. 'To prevent the trellis becoming overcrowded with leaves the ends of the shoots must be pinched off at two or threc leaves beyond the fruits.

Some of the hest varietics for the glasshouse are Superintive. Enstnor Castle Emerald, Gein, and King Gcorge. For cultivation in a frame Hero of Lockinge and Little Heath arc suitable varieties.

Table Uses. In addition to its uses as dessert. melon is also frequently served as hors d'oeuvres. For this purpose it should be very cold, and is best placed on ice for some little time before it is served, together with sugar. pepuer, and salt. Melon is also served as a cocktail made by peeling it when just ripe, removing the pips, and cutting the fruit into

Melon Culture. 1. How to sow seed. 2. Seedling ready for repotting. 3. Plant repotted. 4. Position on mounds in trames. 5 and $\theta$. Other methods of planting. 7. Male flower. 8. Female flower. 8. Male prepared for lertilizing. ing. 7. Male flower. 10. Pollination of female bloom
sundae or custarl glasses, partly fill then with the diced melon, and then add a aprinkling of castor sugar and a little kirsch and maraschino mixed. Only a few drops of liqueur must be used, otherwise the delicacy of the dish will be lost. Stand the glasses on ice before serving them on small plates.

Melon Pickle. To make melon pickle, pare off the outer rind of a melon hefore it is quite ripe, remove the seeds and pith, and cut into cubes Put them in an earthen vessel, cover with good vinegar, and let then remain for 10 days, then pour all into a saucepan and simmer gently until they are tender. Drain them, lay them on a hair sicve, and when
cold insert a clove in each. Place the cules once more in an earthen ressel, and pour over them a cold syrup made with sugar and water let it run off them a little, then put them into pickle-jars cover them with vinegar which has lieen boiled and allowed to go cold: cover the jars securely. This pickle is good with roast meats See Greenhouse

MELTON: The Cloth. An old-fashioned woollen cloth excellent for overcuatings, melton is impervious to wind pressure. Usually plain in colour, it can be recognized by its rather sharp touch. In course of finishing the cloth a nap is teased out of it, and this is cut short, leaving upright ends of wool tibie

## Mending: A Domestic Necessity

How to Cope with Wear and Tear in the Home

## Further information about this Imporant feature of rood housekeeping will he found under such headings as Darning: Lace: Linen: Patching, etc.

A well-equipped mending hasket is exsential for cconomy in the household. A good selection of nendles, cottons, silk threads and darning materiala should be stocked, with various widths of elast ic in black and white, tapee and bias bindings. Besides the usual cards of linen and pearl buttons an asset for the mender is a glass bottle with a wide neck into which odd buttons are dropped It can be seen at once whether buttons required are in atock. A large rafety-pin should be kept, and on this are strung loose hooks and cyes Reels of cotton can be strung on a cord or ribhon. A small magnet on a long length of tape is useful to pick up needles which are dropped on the lloor. Pieces of material left over after making garments or other articles should be tied up and kept in a muslin bag for mending pur joses
Nothing that requires mending ought to go to the laundry. If there is not time to mend the holes neatly, then the torn edges can be drawn together with coloured cotton temporarily. Before clean articles arc put awny they should be gone over, and any that require buttons. tapes, or other mending put on one side.
Linen tallecloths or sheets should be damed with linen
 med, or for handages when

floss, and an embioidery ring or hoop is a help in darning large articles. It is also possible to darn household linen and towels on the sewing machine. The foot of the machine should be removed, and the worn place slipped into an embroidery hoop and this placeri underneath the needle. The machine is worked so that lines of stitching are made backwards and forwards over the worn part. The hoop is then turned round and sewing continued in the other direction till the darn is completed.

Whien shicets become worn in the centre, they can be cut down the middle and the raw eiges hemined. The sides should be seamed together so that the little worn parta are in the middle and the worn portion is at the outside When this process has been carried out and the shect again becomes wom, the unworn parts can be made into slipa for under. neath the pillow cases, or into holster cases.

Mending. Fig. 1. How a darn can be made in damask by imitating the design : above, right, preliminary stage in darning a cross cut in damask. Fig. 2. Mending a hole in fine woven materlal by placing a piece of net beneath it and darning over it. Fig. 3. Reatoring atocking web by counterleiting the material ; this is known as rémaillage. Fig. A. Repairing a hola in a
kid glove with buttonhole stitch in silk of the same colour
can be male into table napkins or into centres for round table mats by cutting them to the desired size and neatly trimming the edgea with suitable crochet or lace. larger pieces niay be used as tray cloths or side. hoard runners and trimned in the same way. Towels that cannot be mended again make useful face clothe. dish cloths, or polishing cloths.

Patching and Darning. Daming a damask cloth or napkin requires patience if, instead of the usual lattice work, the design is copied. Fig. I illustratcs how a simple pattern can be copied The lengthwny threads are made in the same way ra those of an ordinary dnrn, but the cross threads are interlaced to forin a pattern The number of threads lifted or mised depends unon the web to be imitated. A croan cut on damask can be darned by commencing, as also shown in Fig. I, on the wrong side of the material and the needle and cotion prased alternately over and under the edges of the cut till they nieet 'These stitcher inust not be removed when this preliminary darning ia finished, but are darned across in the usual way on the lines of the threal of the damask, using a finer thread than that of the material and extending the darn well beyond the cut.

Men's underwear can be strengthened by asving portions of similar worn-out garments and making a double thickness on the new garment where it is most likely to get worn In patching garments it will be found a help if a thick pal of newspaper is placed under the part to be patched, is this aids in keeping the material in posilion.

In mending a worn place on fine underwear a piece of net should be placed on the wrong side under the worn place and the darn carried out over this foundation, as shown in Fig. 2. This inethod is useful when a blause of fine lace or geargette is to be mended. In mending a drawir-thread tea cloth a piece of net will also be found a help. The net should be tacked round the worn place on the wrong side and the broken threads sewn on to the net in position.

It will be possible to draw the threads, with the help of a needle threaded with strong cotton, up to the edges of the cloth, nnd if the work is not very worn it is possible to mend almost invisibly over the foundation of the net. A net patch also makes a good foundation for darning a cotton or silk stocking. 'I'he net should be tacked on the wrong side and cut away round the dan! when the lask is finished. For very fine silk stockings old veiling is excellent as a foundation material for a darn. To restore otooking wel, the material can be counterfcited by rémaillage, as shown in Fig. 3. Note setting of warp threada and the working of the weft with the needle. 'l'he stitch is hrought up through the loop and between two strands and passed under two strands, as shown in Fig. 3.
'l'o mend a tear in a I weed or woollen suit, strands of the wool should be unravelled from the seams on the wrong side. The garment sliould then be stretched over a pad of white
paper and tacked loosely into yosition, the wrong side being uppermost. If the tear is jagged or threc-cornered, it should be drawn into position with a coloured thread. Now darn the torn edges closely together with the strand of wool, and continue taking fresh lengths of wool as they are required until the darn is completed. This is called invisible mending.
'l'o mend a jagged tear, buttonhole round the torn edges with silk as nearly as possible the same colour as the material. On the wrong side draw the silk threads of the buttonholing together firmly, and press with a warin iron over a damp cloth.
Mending Gloves. Kid gloves that have become worn at the tips or at the bottom of the seams can be mended by buttonholing round the worn parts with silk twist of the same colour. Turn the glove inside out and cut away the kid that is worn. Doa row of buttonholing all round the edges, then a second row of buttonholing, slipping the neodle into the first row. Continue this, drawing up the hole until it is filled. Turn the glove right side out. When suede or chamois gloves wear into holes they are more successfully mended by patching. Old gloves should be kept for this purpose. The patch should be neatly sewn in with silk on the wrong side.
A jagged tear in a mackintosh can be repaired by placing the tear flat down on a table, wrong side out, and pressing the edges together under strips of sticking plaster. A rubber mackintosh can be patched if a suitable piece of patching material can be procured by using rubber solution that is, sold for mending bicycle punctures.
Carpet Mending. To mend a carpet, turn it on the wrong side and lay the torn pieces in position. Buttonhole each edge with carpet flax, then draw the two edges together by means of the double row of buttonholing. If there is a considerable worn area around the tear, the carpet should be slit down and a strip, taking in the worn part, cut away. The pattern should then be carefully matched, the carpet reversed, and the join carried out as directed above, by means of buttonholing. If a carpet is worn in the centre, it can have its period of usefulness considerably extended by cutting it down and placing sides to middle. To mend linoleum, first mark out in chalk the worn part. Cut it out with a sharp knife, then lay this pattern on the new piece that is to be used for mending, and cut it out. If the linoleum is patterned, care must be taken that the patch exactly corresponds in pattern to that which it is required to replace. Glue round the edges and underneath the new piece and fit this exactly into the space in the linoleum. Press it down into position and leave it to dry. Further information about mending articles in common household use will be found under the headings Boot Repairing; Chair ; Crockery ; Glass ; Soldering.

MENINGITIS. Intiammation of the meninges or membranes covering the brain and the spinal cord is known as meningitis, and there are several kinds.

Tubercular meningitis is most common in children between 2 and 7 years of age. It accompanies tuberculosis of other parts, and sometimes follows measles, whooping cough, or a fall. The most marked symptoms at first are intense headache, sickness, chills, and the child often utters a short, piercing cry. In all varieties of the disease treatment must be in the hands of the doctor.

## Menopause. See Change of Life.

MISNSTRUATION. The monthly flow of blood mized with other fluids which is known as menstruation or courses begins with girls at puberty, and only ceases with the change of life. Usually the age at which it commences is from 13 to 15. At first there may be irregu-
larity, but as a rule this is of no consequence The discharge continues for 3 to 5 days, and should recur every 28 days. If it is exces. sive or there is much pain a doctor should be consulted immediately.
When menstruation occurs a girl should be careful to guard against chills and should avoid fatigue or any games that involve violent exercise. She will also be advised to keep away from dances and theatres, or any placo where the air is likely to be hot and impure, and she must not touch alcohol By attention to these points the length and the amount of the discharge will probably be lessened on future oocasions. Baths, provided they are not cold, can be taken with impunity.
A great deal of ill-health in after-life reaults from neglect of proper precautions at the time when menstruation commences. Girls are seldom warned beforehand of what they are to expect, with the consequence that many suffer from serious nervous shock. This is particu larly the case when children are away from home in a boarding-school, and are too shy to speak of the occurrence. In these circumstances, and very often even in their homes, they may receive no special care.

It is therefore of the greatest imporlance that mothers should understand how this function affects the health of young girls, and
should see that proper precautions are taken.
Most healthy women are able to perform their domestic duties as usual during the period, but they should be careful to avoid any strain as, for instance, in running upstairs or moving furniture.

MIFNTHOL : Medical Uses. By cooling oil of peppermint a crystalline substance is obtained which is known as menthol or mint camphor. In medicine menthol is often used externally as a local anaesthetic, particularly in neuralgic conditions, because of the sensation of numbness and coolness it imparts when applied to the skin. For this purpose an alcoholic menthol solution may be applied by a brush, or the official plaster of menthol may be used, or the menthol in the solid form may be rubbed lightly on the skin.

The application of menthol may also be of great use in itching skin complaints. It is often used to relieve some forms of nassal obstruction, and in deafness due to catarrh of the Fustachian tubes. For this purpose a small quantity of an ointment consisting of 5 grains or more of menthol in 1 oz . of vaseline may be put into each nostril. This ointment should not be put into the nose of an infant.

MONU. The French phrase menu d'un repar means the particulars or details of a meal or entertainment. A menu, therefore, is the whole of the dishes served at a meal, and the menu card is the card that contains particulars of each dish.

Many of the dishes that find a place on a menu retain their French names, and a knowledge of French cookery terms is necessary in order to make a selection from among them. The main groups into which the foods fall are as follows :

## Demsert $=$ dcssert

Legume $=$ vegetable
Potake, Pure, or Consommé $=$ thick or clear soups Vlande $=$ meat

## Volallle $=$ poultry

Hors d'oeuvres is the name given to dishcs served in small quantities at the beginning of a meal as appetizers. Grape fruit and melons are often useni. Entrées are served after the fish.

French Names for Foods. The French and English names of the various foods are as follow :
Abricuts = apricots
Agneau = lainb Ananas = pineapple Anchois $=$ anchovy

Artichaut $=$ artichoke Asperges = asparagus Betterave $=$ bectroot

| Cabllaud $=$ cod | Maquereau = mackerel |
| :---: | :---: |
| Café = coffee | Merlan $=$ whiting |
| Canard = duck | Mouton $\sim$ mutton |
| Cerises - cherrles | Nolsettes $=$ hazel nuts |
| Choutleur = cauliflower | Noix $=$ nuts |
| Choux de Bruxclles - | Oeufs - eggs |
| Brusscla sprouts | Oie - koose |
| Crevettes $=$ prawns | Oignon - onion |
| Epinard - spinach | Paté - pic |
| Falsan = phcasant | Perdrix - partridge |
| Fole = liver | Petitspois - green peas |
| Fralses - strawberries | Plle - plaice |
| Framboises - raspberrics | Poircaux - lecks |
| Gateau = cakc | Poires $=$ pears |
| Glbicr - game | Pommes = apples |
| Gigot $=$ leg of mutton | l'omines de terre $=$ pota- |
| Glace = ice |  |
| Hareng $=$ herring | Poulct - chicken |
| Haricots blancs $m$ haricot | Prunes - plums |
| beans | Ralfort $=$ horse radish |
| Haricots verts - French beans | Ralsins $=$ grajes <br> Ris de veau $=0$ sweet bread |
| Homard e- lobster | Rognon - kidney |
| Huitre = oyster | Sauclsson-8ausage |
| Jambon = hant | (smoked) |
| Laitue - lettuce | Saumon $=$ salmon |
| Lapin $=$ mbilt | Truite = trout |
| Lard - bacon | Veau - veal |
| Lièvre $=$ linre | Venaison $=$ venison |

These foods are often accompanied by words or phrases indicating how they are cooked.
A la broche a roasted before a fire A la brunolse a garnished with spring vegetables A la crécy a prepared with carrots Au diable - devilled, or with hot seasoning Au gratin = cookel with breadcrumbs Au naturel = cookel very simply, or served uncooked Blanquette - cooked in a thick white rauce Chartreuse - a mould (of frult, jelly, or some savoury mixture)
Chaudfroid = coated wjth chaudfroid ssuce

## Conflt m preserved in sugar

Compôte $=$ stewed (of fruit)
En cocotte = served in a small carthenware dish En karl - served in curry sance
Fourré = coated with sugar, cream, etc.
Fricrasee - stewed with white sauce
Maitre d'hotel $=$ grilled
Roti = roasted
Sauté $=$ fried lightly
Soups are divided into consommé or clear, and purée or potage thick. Kggs are served à la coque, or boiled, or sur le plat, jrached. The roe of fishes is known as oeufs de poisson. Fried potatoes are pommes frites, and mashed potatoes purée de pommes de terre. Café au lait is coffee with milk, or white coffee : café noir is black coffee, or coffee without milk.

For a formal dinner the following courses are usual, hors l'oeuvres, soup, fish, entrée, roast, vegetables, sweet, and savoury." For an informal dinner the hors d'oeurres inay be omitted, as may soup or fish, sweet or savoury.

A Dinner Menu. In coinpiling a dinner menu certain rules should be observed For instance, the colourings of the various courses should contrast with each other and a variety of Havours be secured. The jrincipal ingredient of one dish should not appear in another ; for instance, if the soup is artichoke, artichokes should not be served as a vegetable. Two dishes of beef or mutton should not be served at the same meal; roast beef and fillets of beef, for example. Two fried dishes should not be served in succession, nor should two boiled ones Two sauces of the same colour should not follow each other, and the same garnish should not be used on two dishes.

Variety is also desirable when two dishes are offered in the same course. loor instance, if there are two soups, one should be clear and the other thick. If two fish dishes are offered, one should be plainly dressed, e.g. boiled halibut, and the other should be more elaborate, e.g. lobster cutlets Of two entrées one should be cold and the other hot ; one should be light aird the other somewhat heavier. Of two sweets one should be light and cold ; the other hot and more substantial. Of two savouries one should be hot and one cold.

Menu Cards. Menu cards, or cards which contain the detajls of the ment for a big public dinner, are usually printed, in some cases this being very elaborately done and the card artistically decorated. Menu cards
suitable for the home can be bought. just as postcards can. These are headed and left blank for the cook or someone else to fill in the date and the details of the various courses. Menu cards for dinner parties and other festive occasions are often specially prepared, a design being drawn by an artist. This will frequently contain something appropriate to the particular occasion. Such cards can be obtained from a firm of printers, or are provided by the caterers.

Small white marble or china tablets, with stands to match, are sometimes used as substitutes for ordinary menu cards, and on these the menu is written in pencil. Holders for menu cards can be obtained in oxidized

Menu card sapported in a holder consirting of a amall china animal fagure
metals, plated silver, or china, or in fancy designs suitable for a festive occasion such as a Christmas party. See Course; Dinner.

MERCERIZING. The result of the mercerizing process is to lend to good cotton some of the lustre of silk. Innumerable examples are found in mercerized poplin, linings, and sewing, knitting, and embroidery threads. Linen and even jute may be mercerized, but not wool.

Mercerized cotton absorbs dye much more readily than unmercerized, and should the re-dyeing of mercerized goods be attempted, care must be taken to see that the dye is thoroughly dissolved. Should any particles remain, they will lead to dark spots of colour upon the article. Drying after dyeing must be cautiously done at an even temperature, for if done before the fire with some portions exposed to more heat than others the colour will be irregular. A good plan in dyeing mercerized goods is to soak them first in water to which a little glycerin has been added.

It is only good cottons made from long fibred cotton, combed in course of manufacture, that show any adequate benefit from the treatment. One can thus be pretty sure that mercerized cotton is gond material. Properly done, the process of mercerizing strengthens the article, but when badly done, ruins it. See Cotton.
MERCURY : The Metal. This is one of the metallic chemical elements, and is also known as quicksilver. It is fluid at ordinary temperatures, but solidifies at $-39^{\circ} \mathrm{F}$. and
boils at $675^{\circ} \mathrm{F}$. It is a very heary metal, weighing almost $\frac{1}{2} \mathrm{lb}$. per cubic in. Pure mercury Hows freely as a liquid, has a silvery white colour and a metallic lustre.

Mercury dissolves many metals, forming with them the alloys, known as amalgams. It is used in the manufacture of fulminate, for the percussion caps of cartridgen, and is also employed in electrical appliances. It is the gauging element in thermometers, barometers, and other scientific instruments, being particularly susceptible to variations in temperature.

Another application is the mercury vapour lamp, giving a good light, but devoid of red light rays. See Barometer; Mirror: Pendulum; Thermometer.

MERCURY: The Drug. Employed in many different forms both externally and internally in a wide range of morbid states, mercury is one of the most valuable drugs in the pharmacopoeia, and externally is most commonly used on account of its strong antiseptic qualities. In any form the drug is always a nore or less dangerous one, which should never be used except under a doctor's supervision.
It should never be forgotten that most mercury preparations are highly poisonous, particularly those used for their antiseptic action. The acute form of mercury poisoning is usually caused by swallowing corrosive sublimate. An emetio of a tablespoonful of mustard in a glass of warm water should be given and the doctor be summoned at once.

Before and after the emetic, give the beatenup whites of four or five eggs, and then soothing drinks, such as milk, to each pint of which a wineglassful or two of olive oil is added. Put the patient to bed and keep him warm with hot-water bottles.

MFRINGUE. A meringue is a mixture of whipped whites of eggs and fine white sugar. Flavouring may or may not be added. In making successful meringues two rules must be observed: whip the whites of egg really stiff, and cultivate speed in the shaping of the mixture. The least scrap of moisture or egg yolk will prevent the whites from whipping up stiffly. If the egg whites are allowed to stand overnight they will whip up more quickly.
To make the mixture, whisk the whites of 6 eggs to a firm white snow, then sift in lightly 8 oz. castor sugar. The meringue is now ready to be shaped, and this may be done with a meringue forcer fitted into a stout jean bag or with two dessertspoons. Cover a $\cdot$-in. thick pastry board or a baking tin with white kitchen paper slightly oiled, with pure olive oil, and force or shape the meringue on to the paper. If shaped with the spoons, gather up enough mixture to fill the spoon, smooth it round the edge, scoop the meringue out with the second spoon and drop it on to the paper, turning it over. It will be an egg shape.

When all are shaped sift over some castor sugar and bake them in a cool oven to a very light fawn colour. The oven must be really cool, and the meringues will take 2 to 3 hours to bake. When cooked, remove each meringue carefully from the paper, press in the soft portion inside, or remove it, and return them to the oven, which must be very slack, until they are perfectly diy. They can then be stored in tins. Each egg-shaped piece is the half of a meringue, and must be filled with whipped and flavoured cream before being fitted to its fellow half.
This mixture is used for the decoration of many aweets. It may be made into a covering for fruits or may be forced in patterns on custards, trifles, etc. The meringue covering must always be dried in a cool oven, but the forced decorative pieces are dried on paper by themselves and fastened to the sweet with cream or fondant. Meringues are often filled with ice cream instead of whipped cream. It
is necessary to put the case on ice for a little while before filling it if this is donc.

Meringue Gâteau. This sweet is made by adding a pinch of salt to the whites of 3 or 4 eggs, whisking them to a stiff froth, and then

Meringue GAteau made with a centre of cherries
folding them into 6 dessertspoonfuls of castor sugar. Heat the syrup from a small tin of red cherries, and use it to soak a sponge-cake ring. When saturated, put the ring on a dish. coat it with the meringue mixture, and leave it in a warm oven for about 20 min . so that the meringue becomes crisp and of a pale biscuit tint.

Let it get cold, then fill the centre with the cherries, piling them up high. Decorate the top with some stalks of angelica, and serve the whole with some syrup made thus: Boil 2 oz . lump sugar and a gill of water for about 6 min. then skim it well, and when it is cold stir in $\frac{1}{2}$ gill sherry and colour it with cochineal. Whipped cream sweetened and Havoured may be served separately.

Meringue Jelly. Small meringue jellies, coloured with cochineal, make an attractive party sweet. To prepare them, dissolve a pint packet of strawberry jelly in hot water, and leave it until cold, but not set. Add a pinch of salt to the whites of 2 eggs , beat them to a stiff froth, and then beat them into the

Meringue Jelly. A party ameet for whioh trait jelly and beaten white of egs are used
cold jelly. Continue beating for about 10 min., add the colouring, and stir the whole 80 as to get an even effect Pour the jelly into small wot moulds, and when set turn them on to a glass or china dish.

MISRINO. This is the name of a Spanish breed of sheep bearing exceptionally fine, short, and wavy wool and is the original of a type now reared in many other countries; merino is thus a name for ultra-fine wool, superior to that of cross breeds, and the name of the material has been transferred to the goods that are made from it.
Merino or French merino dress stuff is a fine twill made from merino wool. At once warm and light, made usually $40-44 \mathrm{in}$. wide, and available in cream and light shades as well as in black, it is a serviceable, if old-fashioned, dress stuff. In knitted underwear merino has by long custom a different meaning, and implies a wool and cotton mixture, generally soft to the touch resembling that of pure merino wool. Merino underwear is usually cheaper than all wool, and is bought on that account and also because it shrinks less than all wool in washing.
Merino wool in any of its forms tends to shrink when washed. The tendency is seen in soft, fine baby flannels which should continually be stretched, first in one direction and then inthe other, while drying. Stockings made from merino wool contract and thicken because the material felts easily. Soap assists the felting, and for this reason all soap used in washing should be carefully rinsed out.

MERTENSLA. This borage-like herba- whiting has been placed. ceous perennial is suitable for the border or not for silverware rock garden. It thrives in ordinary welldrained soil and is increased by division in spring or by seeds. The oyster plant (maritima) and alpina are both of low growth and bear blue flowers in early summer. Taller kinds suitable for the border are the Virginian cowslip pulinonari oides) and sibirica: they are about 15 inches in height and bear blue flowers in May

METAL POLISH There are two hief varieties of metal polishes One is made up of rottenstone 2 oz., soft soap 1 oz., and trong solution
 Mertensia. Blace flowers of the speoies Eibirica, a plant suitable or a shady border oxalic acid sufficient to make the whole into a thick cream. The second is composed of fossil earth 2 oz ., oleic acid 2 oz ., oil of mirbane $\frac{1}{2}$ dram, mixed into a smooth paste.

A liquid polish is made as follows: Mix soft soap 2 oz., with solution of ammonia 5 oz . and separately mix kaolin 4 oz ., with petrol 9 o\%. Place the two liquids in a tin and shake them well together. A simple form of metal cleaning liquid is made by dissolving oxalic acid 1 oz. in hot water, 1 pint. This is rubbed on to the tarnished brass work with a cloth and cleaned off with a separate cloth upon which

METAL SPINNING lathe. To exemplify spinning in its simplest form, a piece

floung out Toor

These polishes are screw in the centre, the sheet metal has to be held up to the former by a revolving centre. Since a certain amount of thrust is necessary to retain it in place spinning lathes are fitted with ball-bearing back-centres (Fig. 3) to re. duce the end friction. When the work has half progressed, the back-centre thrust block is replaced by a follower to prevent the work already spun from altering in shape. The job must be annealed between operations if, through tooling, the metal gets too hard to flow properly. The tools used (Fig. 2) are long and stout enough to resist bending. The handles are held firmly under the armpit, the steel end being placed between two pins in the rest. The nose of the tool is held a little below the lathe centre at a point near the centre of the jub: the pressure is applied towards the larger diameter of the disk
of wood is held in the lathe and turned up to any desired profile, with curves and corners suitable to the thickness of the metal which is to be spun. This former. as it is called, appears in the photographs. A special tool rest. Fig 1, is then rigged up, which may be of the ordinary type but with a flat topped tee, having several holes in which the operator can place steel pegs to suit his own convenience. A disk of lead or soft aluminium sheet is screwed by a central screw to the former. By working the shank of the long-handled tool against the steel pegs in the tool rest, using the peg as a fulcrum, and bringing the tool up to the disk with a sweeping action, the revolving metal can be formed into shape. 'Ihe metal is greased before and during the spinning operation, soft soap or vaseline being conmmonly used.
Figs. 4-6 show the method of spinning an ornamental base for a vase or other article. As the object is not pierced with a
Fig. 1

Fis. 8. Method of holding tool for firat stage in spinning a bowl. Fig. 6. Disk span over to shape
with a sweeping movement, continuing the stroke repeatedly. On the roturn stroke a small pressure is maintained on the work.

To prevent the disk buckling, a back stick is employed. This accessory is a short piece of hardwood, like all accountant's deak ruler. It is used in the left hand and held hard up against the rotating sheet metal on the side opposite to that upon which the spinning tool is operating. Rough edges of work are skimmed with a cutting tool, as used in hand metal turning. Internal work needs hook tools. Roller tools are also employed. All tool points must be quite hand and highly polished, like metal bumishers. Each job requires its own former. When the diameters of the job will not allow a solid former to be used, i.e. in spinning an object like a narrow-necked jar or a bottle, where the former would be imprisoned inside, split formers must be used.
Taking a diameter of 4 in . as an average size of work in metal spinning, the speed in revolutions per minute is approximately as follows : soft sheet iron $\frac{1}{32}$ in. thick, 600 ; thicker sheets, 400 ; zinc, 1,200 ; copper, brass and aluminium, 800 to 1,0(0). The work requires so much skill that only the simplest jobs should be attempted at first, using the softer metals like copper and aluminium. For any but the smallest work a power lathe is desirable. See Chuck; Face Plate; Lathe ; Mandrel; Metal Work, etc.

## Metal Turning on Small Lathes

## The Tools and Their Use is Various Operations

This contribution deals briefly yet comprehensively with the main processes in metal turning. described and illustrated in the article Lathe. See also Meta Spinning: Mctal Work, ete.

The process of removing the surface of metal trated in Fig. 2. A second imp!ement, the in n lathe is known as metal turning. The side tool (Fig. 3, b), has a cutting edge on its oloject is attached to a rotating spindle, left-hand side; it may have a counterpart technically known as n mandrel, and a cutting made to the oppositc hand. The pointed or tool is applied to the revolving work so as to produce the required shape and size with a degree of accuracy hardly obtainable in any other way. The tool may be fell up by hand, or in a sliding screw-feed tool fixing, known as a slide rest. For hand turning in metal it is of the greatcst importance that the tools should be long, and have handles of adequate lengtlo and stiffness

To obtain the maximum power over the work, the heel of the tool should be supported by the rest, the adjustable bar near to the revolving work on which it is held during the operation, well under the cutting' clgo, as shown in Fig. 1. The tool should he gripped firmly and especially wherc iron or steel is being operated upon, the handle of the tool should receive a further support by resting in the hollow of the operator's shoulder. It will tend to lift resister this will work and the tool rest, very possibly spoiling the one and breaking the other.

The heavier jobs in metal turning are not usually set out to be accomplished by hand where a modern slide rest lathe is available. Hand turning of this character requires years of practice and great strength of wrist. When work must be done by hand the cutting must be obtained by rolling the tool on its hiel, so that the point enters the metal with the cutting edge at an angle to it.
lighter work on the softer metals, such as brass and aluminium alloys, can be operated

Fir 2. How to hold a metal turning tool when skimming up a projecting portion of the work
on with much less fatigue. The tool can be held as illustrated in Fig. 2. Skimming up a projecting rim with a hand tool, as here shown, is a quick and easy method of producing the desired result. There are many other similar operations, as, for example, the making of an odd-shaped knoh, or producing a curved, conical object like $n$ water-jet, which would prove troublesome to produce singly on $\pi$ slide-rest lathc, but can be made quickly and accurately with a hand tonl, using a shaped template in thin card or motal as a guide to form and si\%e.

Types of Tool. Among the most useful hand tools for a metal-turning lathe is the round nose tool shown in Fig 3, $a$. This cuts at the side to a certain extent, as well as in the front, hence its being used for the job illus.

Metal Turning. Fig. 1. Showing how a band tool cuts the metal
graver tool, shown at $c$ in Fig. 3, is another useful hand tool.

For brass work, the nose and side tools should have flat tops, as shown in Fig. 4. For turning iron and steel a top rake is necessary (Fig. 5), to obtain the best cutting effect. A pointed hand tool is extremely useful in producing a centre pop in a piece of work revolving in a chuck, preparatory to drilling it with the drill held against and fed up by the tailstock. In producing such a centre pop, the difficulty is getting rid of the pip which so readily forms in the centre of thic sinking. A sharp tool is therefore essential. Why this pip forms will be readily understood when it is remembered that the absolute centre is not moving at all, and that the metal around it is only moving with a slow-cutting speed. The thin spike or pip, being frail, is casily broken off.

Where the tailstock of the lathe can he brought up to the work, has a suitable chuck fitted to it, and is sufficiently stiff and accu. rate in alinement, a special device known as a centre-drill may be used. This is, howcver, a matter of appliances; the mechanic should be able to produce the centre by hand.

Use of Chucks. Work to be turned can be held in the chuck. The self-centring chuck is the most commonly used appliance for holding any kind of work which in itself is reasonably round The three jaws in this type of chuck all move together radially, either towards or from the centre, according to which way the operating key is rotated. The jaws are of two patterns, outside and inside, both sets heing supplied with the tool. The outside jaws are used to hold rings and disks for facing, boring, as in Fig. 6, or turning portions which are clear of the jaws. With the inside jaws, a hollow bush can be held by the internal bore, and the outside operated on alinost completely. The inside can only be machined for a part of the way. The pressure of the jaws of the chuck gripping the work inside tends to prevent deep boring.

The inside jaws are generally in place. because their function is also to hold small diameter rods, drills, and spindles on the outside. A self-centring chuck is only approx. imately accurate. For example, if a hollow bush is bored truly cylindrical on the inside, is then removed and replaced in the jaws of the chuck from this bore, and turned up outside, the outside and inside will not be concentricto a degree desirable in anything but rougher work. Independent chucks in which the four jaws are separately operated by screw keys are therefore used. The work can be tested and adjusted during the fixing up in

Metal Turning. Fig. 4. Diagram showing use of flat-topped tool for brass work. Fig. 5. Use of top rake for turning ron
sawn off. Where such an operation is impos sible it is usual to horc the job out accurately, and then to remove it from the lathe. A turned mandrel is made to fit the bore tightly, and the outside operations are accomplished with the work on this trie mandiel.

In feeding the tool, regularity of rotation of the hand wheel on the end of the screw should he observed. The knack of operating the feed handles with an even motion is soon obtained. Every lathe has its peculiarities. Where handles are fitted to the feed screws, the fingers and thumb alternate in propelling the screw. With a wheel, a slightly different manipulation is required, the im of the wheel being grasped by the hand. The tool sliould always be kept noving slowly but evenly; if it proceeds in jerks, the work will show rings.

All screw-cutting lathes can be arranged to obtain a self-acting traverse. The lasd screw which operates the sliding saddle should be connccted up with a train of cliange Wheels to give one of the liner rates of feed, i.e. 100 to 200 turns to the inch. With the self-acting feed, very fine finishes can be obinaned without effort

Screw Cutting. In screw cutting, the saddle of the lathe is traversed along the bed with a rate of feed which bears a predetermined proportion to the revolutions of the mandrel. The lead screw which guides the saddle tool holder is coupled by a train of gear wheels. Thesc gear wheels may be altered in intio as desired.

If the ratio of gears on the change-whecl quadrant is altcred, say, by coupling a 90 tooth change wheel on the mandiel with a 60 -wheel fixed on the end of the lead screw, that is in a proportion of one to three, then the lathe will produce three times 10 pitch, or a screw of 30 thieads to the inch. on the job rotat ing in the lathe. Change wheels for all the usual threads are supplied with screwcutting lathes. Odd sizes are sometimes obtainable.

Short threads can best be produced on a foot lathe by taking definite cuts along

32, 28, 2f. 19 threads per in., standard sizes for pipe work. The ohaser is a hand turning tool with a cutting edge in the form of a screw thread of the particular pitch it is desired to obtain. With the work revolving, not too quickly, the hand chaser is atruck in with a Interal sweep. Milling, drilling, and dividing, also the formation of scrolls, worms, and gear tecth, may be accomplished in the Inthe, by the addition of suitable fitments and accessory devices.
Cutting Speeds. The cutting speeds for various metals differ. The term cutting speed must, however, not be confused with the rate of feed. The latter is dependent on the size and power of the lathe being used. Cutting specds are the same for any lathe. Wrought iron and steel should be turned at from 200 to 300 in . per minute, tool steels at 2011 , cast iron at 190 to 200 , soft gunmetal at 500 ) to ( FO 0 , and brass at 800 in . The speed is found by multiplying the revolutions of the lathe mandrel by the circumference of the work. I piece of work in cast iron, 1 in . in diameter and approximately 3 s in. in circumference, should therefore run at from 60 to 65 revolutions per minute.

With the average foot Inthe it is difficult to get a high enough speed in turning small hrass work, and onc low enough for a large diameter cast-iron object, and therefore a certain degree of compromise in the matter of speeds has to be accepted. Cast iron, brass, and gunmetal are not lubricated in turning operations, but to obtain a good finish on wrought iron and steel requires the use of oil, or any saponaccous solution.
METAL WORK. This term includes a!l the mechanical processes for the fashioning of metal. l'ractically spealing, all metals are worked in onc of two ways: either the metal is cast, or it is rolled into sheets and bass, or drawn into tubes.
Casting is perhapa the first of the metal-working procesocs, as it utilizes the metal practically in the rawstate. Brielly, the process consists in making a pattern or mould of the shape of the
desired casting, and impressing it into damp sand, thus making a ho!e or cavity which is subseguently filled with metal. The casting is afterraids finished by machining in a lathe, or it many be milled.

Ordinary shect or bar metal has generally to tre cut to something spproximating to the desired length or size, and this is done hy sawing with a hack saw or cutting with cold chisels. Metal work that calls for many joints introduces soldering and brazing, hoth of these being nccomplished by melting anot her but aofter metal than that to be united, and working it into the joint between them. In some cases welding is necessary, particularly when dealing with ion and steel. Heavy pieces of metal that cannot conveniently be shaped in other ways are often functioned by forging. Sheet-metal work generally calls for a knowledge of rivets and riveting.

Hammers for metal work do not differ materially from those used by other trades, and may range from a lightiveight riveting hammer to a heavy sledge hammer for fashioning thick pieces of metal while hot, and for delivering heavy blows in general. Files are very necessary in all classes of metal work. The average size is generally between the ranges ( $;$ to 10 in in length, and varying from a smooth to a coarse cut.

Drills of all kinds are necessary for making holcs in metal, and are made in all sizes from something under $\frac{1}{16} \mathrm{in}$ upward in diameter. To rotate these drills, a hand-dri!ling machine is convenient up to about $\frac{3}{8} \mathrm{in}$. diameter. Above this size, however, a treadle apparatus or a powerful bench-drilling machine will be lound necessary.

A vice of some lind is essential in inetal working, and should be sufficiently robust for tho class of woik normally undertaken A small vice can only he suitable for smal work, but for heavier work a good substantial bench vice is necessary. Another useful metal wor!ing tool is the grinder, and com prises a variety of different types.

All manner of turning and shaping processes on metal can he carried out with the lathe. Numerous appliances and tools aie used in conjunction with it. Cold chisels form an important group of metal-working tools, and, while they are inexpensive, they are capable of much useful work in the chip. ping out and cutting of sheet and bar metal Smaller tools include punches, used for riveting and for maling indentations. See Face Plate the threaded por tion, stopping the lathe at the end, withdrawing the cut on the top slide rest, running the lathe backiward, and advancing the cut, proceeding through the same cycle of operations without relensing the lead screw. For longer threads, the lead screw is dechutched at the end of the cut, and the saddle and slide rest traversed back by hand. The proper re-engagement of the clutch or lead screw nut may reguire the challi marking of the work and the change wheels, to prevent a cross-threading cut being taken. Fig. 10 shows a screw thread that is being cut on the end of a pin supported bet ween the lathe centres.

Hand chasing, or screw thread chasing, bears the same relation to screw cutting as hand tool work does to that requiring the slide rest. Its successful use is largely a matter of skill. It is also more usually employed in dealing with brass work and for the finer threads, such as

Metal Turning Fig. 6. Internal boring, showing work teld in a three-jaw chuck. Fig. 7. Face plate work, showing a small piece of work clamped to plate. Fig. 8. Rod mounted and driven betwesn centres. Fig. 9. Roagbing down a mandrel, a swan-necked tool being used in the slide rest. Fig. 10. Screw cutting in a lathe

METER, A meter is an apparatus that records automatically the quantity of a gas or fllid passing through it. Such are used for measuring the amount of gas, electric light, and sometimes water, used in a house Some electric-light and gas meters are worked by the insertion of coins, a penny or a shilling providing a certain amount of light, which antomatically fails when the quantity is exhausted. See Electric Light; Gas; Water.

METHYLATED SPIRIT. Alcohol which has been rendered unfit for use as a beverage by a process of denaturizing is sold as methy. lated spirit and has many uses in the home. It must, however, always be most carefully handled owing to its highly inflammable nature Naphtha and petroleum or paraffin are the agents commonly employed for denaturizing, together with a trace of blue aniline dye. The sale of methylated spirit is regulated by law, and is forbidden hetween $10 \mathrm{p} . \mathrm{m}$. on Saturday and 8 am on Monday.

Methylated spirit is used for heating small stoves which contain an ahsorbent substance, such as asbestos fibre. In filling the stove only as much spirit should be added as can be ahsorbed and no more. It is dangerous to add a surplus of spirit, as when lighted the Hame may be carried on to the table and cause a fire

For glass cleaning there are few things to equal methylated spirit; it is invaluable for polishing wide surfaces of glass, such as wind screens, table tops, or the glass covers some times inserted in polished trays. It is equally efficacious for windows, but is too expensive for the ordinary householder to use in large quantities For small things the quantity needed is not excessive, and is well worth the outlay. A few drops on a soft cloth are generally sufficient. A little methylated spirit put in the water when rinsing white silk blouses gives gloss and firmness. Applied to brown boots the spirit removes stains and produces a fine polish. As it tends to dry up the leather, it should only be used occasionally.

For various medicinal and surgical purposes methylated spirit is of great use. If, for ex ample, it becomes necessary to sterilize bowls or other utensils quickly and there is no time to boil them, a little of the spirit may be poured in and lighted, and when it has burnt itself out the bowl will be ready for use. Lancets or similar small instruments may be stood in methylated apirit for half an hour and are then completely sterilized. For preventing bed sores or any other form of chafing methylated spirit should be rubbed on, and the area powdered. This applies also to tender feet, or to hands which hlister easily when doing unaccustomed work Finally, it makes an excellent lotion for sprnins or bruises, when added to water and npplied as a compress.
METOL: The Developer. Metol is a photographic developer which gives thin, deli cate negatives with full detail but little den sity. It is rapid in action, and is best used with a slow developer, such as hydroquinone. Metol is frequently used with pyro, the com hined developer being known as pyro-metol
The following is a formula for one-solution plain metol developer

## Metol

Sodlum suilphite (crystails)
Sodium carbonnte (cryatals)
Potassium bromide
For ordinary use take 1 oz . of the a bove solution and add 2 oz . of water. For portraits, add 1 oz . of water to each oz. of the stock solution.
In all developers containing metol the metol should be dissolved first, then the sulphite, followed by the other chemicals, using warm, but not hot water. The Watkins factor for metol is 30 .
With some persons metol has an unpleasant action on the skin; the skin cracks and the
fingers swell, resulting in broken mails and sores which may spread to other parts of the hands. In such cases the use of the metol developer should he a bandoned, though the risk of poisoning may be greatly, if not entirely, obviated by the use of rubber gloves The poisoning may he treated by soaking the hands in warm water and rubbing in zinc ointment, using bandages or gloves at night. The following ointment will cure the sores:

| Ichthyol | .. | .. | .. | . | .. | .. | 1 part |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Ianoltne | . | . | .. | .. | . | .. | 4 parts |

If a metol developer has to he used the hands should be washed frequently in clean water while at work, and afterwards washed thoroughly with warm water. See Developing; Pyro
METOL-HYDROQUINONE. An excel lent developer for general use is metol-hydroquinone, usunlly referred to as M.Q., and suitable alike for films, plates, bromide, and gaslight papers. It combines the advantages of both developers, giving the detail rendering of metol and the density and contrast of hydroquinone. If properly made up it is cleanworking and non-staining. The full quantity of sulphite given in the formulac that follow must be used. A good one-solution M.Q. developer is as follows:
Mctol
Sodium suiphite (crystals)
Hydroquinone
Sodium carbonate (crystals)
$\begin{array}{cc}20 \\ 1 & \mathrm{gr} \\ 02\end{array}$
Wium carbonate (crystals)

Dissolve these in the order named, using warm (not hot) water. For use take equal parts of the solution and water. It should only be made up when wanted, and used fresh. A two-solution which will keep is made up thus, using equal parts of $A$ and $B$

Soldtion A.
Metol
Sodium suilphite (cryatails)
Hy droquiuonc
Potassium bromide
Wuter to makc
Solution B.
Sodium carbonate (crystals)
Water to make
(crystals)
The Watking factor for M Q
14. MQ Q .Q. is a very suitable developer for all round use hy the amateur. As long as it is properly made up, used freah after preparation or dilution from stock solution, it is always to be relied upon.
Developers containing hydroquinone cease to act almost entinely when the temperature falls below $60^{\circ} \mathrm{F}$. If the $\mathrm{M} Q$. developer cannot be kept well ahove this temperature in winter it is desirable to increase the metol in the two-solution formula above to 30 gr . and reduce the hydroquinone to 15 gr . It is, of course, useless merely to warin the developer and its dish, as it will quickly talie on the temperature of the dark room. See Developer: Developing; Hydroquinone.

METRE. This common measure of length is the unit of the metric or decimal system. It is equal to $39 \cdot 37079 \mathrm{in}$., or something more than n yard. It is divided into decimetres (10), centimetres (100), nnd millimetres (1,000). The following table gives the equivalents of metres in yards :

| Metre | Yarda | Mctres | Yards | Mctres |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $1=$ | 1.093 |  | 8.748 | 60 | 65.616 |
| 2 | 2.187 | $9=$ | 9.842 | 70 | 78.552 |
| 3 | 3.280 | 10 | 10.936 | $80=$ | 87-488 |
| 4 | 4.374 | $20 \sim$ | 21.872 | 90 | 08424 |
| 5 | 5488 | 30 | 32-808 | 100 | 109-361 |
| 6 | 6-661 |  | 43.744 | 200 | $218 \cdot 722$ |
| $7=$ | 7.655 | 50 | 54.680 | 400 | $437 \cdot 44$ |

The Metric System. The metric or decimal system of weights and measures is a French invention, hut is used to some extent in Great Britain. It aims at uniformity and simplicity, features which are wanting in the system that has grown up in haphazard fashion in England. The alternative name, the decimal system, is
due to the fact that it works in tens, simplifying calculations.
The fundamental unit of the system is the metre, a measure of length, nnd from it the other units are derived. The gram, which is the unit of weight, equals the weight of one cubic centimetre of pure water at its maximum density. The unit of capacity, the litre, is equal to the volume occupied by 1,000 cubic centimetres of pure water of maximum density. From these the other weights and mensures are derived. The Greek words, kilo, becto, and deca mean $1,000,100$, and 10 , a kilogram being 1,000 grams and a decalitre, 10 litres. For small quantities the Latin words milli, centi and deci are used, a millimetre being rod part of a metre and a centigram $\frac{1}{10} \sigma$ part of a gram. The capital letters $\mathrm{K}, \mathrm{H}$, and D are used for the multiples, and small letters $\mathrm{m}, \mathrm{c}$, and d for the weights and measures that are less than a unit. Kg., therefore, represents kilogranı: Km, kilomotre; and Kl, kijolitre; mg. represents milligram; cl., centilitre ; and dm., decimetre. The word myria (M) is used to represent 10,000
In addition, there are special units for square or superficial measure. For instance, 100 square metres equal an are, and 100 ares equal one hectare. In the case of areas the multiples change by 100 , not by 10 at a time, and in the case of volume, or cubic measure, they change by 1,000 . Below are some of the metric weights and measures and their English equivalents

## 1 metre $=39.37079 \mathrm{in}$

kilometre $=0.62138$ miles, or 5 furlongs
sq. kilometre - $247 \cdot 17$ acres
gram $=15 \underline{1}$ grains
kilorram $=2 \cdot 2046 \mathrm{lb}$
1 litre $=1.75$ pints
METRONOME. A metronome is a device enabling a composer to indicate with precision the speed at which he wishes his music to be performed. It is hased on the principle of the pendulum, which differs, however, from that of a clock in being weighted at both ends, and in oscillating from the centre instead of from the top.

The weight upon the upper part of the rod is made to slide up or down so as to rest against certain figures engraved thereon. The figures begin at 40 or a little more at the top of the rod and progress down at intervals by two's to 60, after which they go on by threes to 72, then by fours to 120 , next by sixes to 144 (where some metronomes finish), and finally by eights to 208.
The position of these figures is calculated in proportion to the heaviness of the fixed weight on the lower part of the rod, so that on the movable weight heing placed against

Metronome. Device for indicating peed at which music should be performed any given figure, the pendulum will swing that number of times in a minute. Consequently, all the composer has to do is to indicate the value of the note which repre. sents the pulse or beat of his musio and then to give the necessary figure. In the great majority of casesthe crotchet, either plain or dotted. is the
unit of speed, though the minins and the quaver are occasionally used $P=60$ ) therefore means that the music is to move at the rate of 60 crotchets per minute.

There is more than onc kind of netronome. That known as the Maclzel is wound up like a clock, the mechanism being contained in a wooden casc of pyranidal shape, and when the rod is relensed it oscillates, ticling at each swing. Sometimes there is a bell attach. ment, which can be adjusted so as to strike at regular periods. The Pinfold metronome has no clockwork. It swings silently on two stcel points balanced on a tripod, and is set in motion by the finger. Both of thise are on tho double pendulum principle.

Inotlier hind consists of a circular case containing a tape measure, which can be un wound to any given point and swung from the hand, the case forming the weight. When not in use it can be coiled up by touching a spring, and carried in the pocket. It is handy for an emergency, but is open to the objection that it cannot be in action simultaneously with musical performance.

The use of the metronome is to ascertain the general specd of the music; it should not be employed throughout a piece, except in very stubborn cases of faulty time, which it may help to correct.

MEZZANINE. This term is used in architecture to describe a storey or floor introduced between two principal lloors, thus forming one small room within a larger one, lighted by a large window or windows which give light to the mezzanine floor and the other part of the Hoor hencath it. The arrangement of the mezza. nine floor is largely governed by the architecture and plan of the building as a whole.

MICA. A mineral of complex and variable composition, mica is used in domestic work for windows for anthracite and other heating stoves, and for all purposes where translucence is desired and great heat has to be resisted. It is characterized by easy cleavage in a single direction, and may be divided to very thin shects. When used in front of a stove it is generally about $\frac{1}{2} \frac{1}{2}$ in. thick.

Mica can be purohased from any good class oil and colourman. It is generally stocked in various sizes and shapes, and a size most appropriate to the joh in hand should always he sclected. If due care be exercised it can he cut to shape with a strong pair of scissors. See Stove.

MICE : How to Destroy. Both poison and traps are employed to destroy mice, but there is no more eflicient remedy than to keep a cat in the house. Where no cat is kept mice appear sooner or later. Very often what attracts them, cven where there is a cat, is a plentiful supply of food in the shape of breadcrumbs, scraps of cheese, or other fragments, or seed from bird-cages, left lying on Hoors or tables or shelves of cupboards.

The first precaution to be taken, therefore, is to see that all these tempting morsels for mice are carcfully swept up, and cheese, sugar, grain, bread, etc., covered up, especially at night. Where poison is resorted to only small quantities ahould be employed, not in any case larger than a small haricot bean. Great care must be taken to prevent food from coming in contact with preparations sold for killing mice, as these usually contain phosphorus, strychnine, or arsenic.

An effective method is to bait cheese or bread with barium carbonate. After the poison has been laid all the holes should be stopired up, and a good material to use for this purpose consists of equal quantities of barium carbonate and dripping, made into a paste. The mice usually eat the poison in trying to nibble their way out. Whenever a mouse hole has been treated in this way a piece of paper may be pasted over the hole as a safeguard for pets.

Mouse Trap. The simplest pattern of nouse trap in use consiats of a small piece of flat wood on which is fixed a powerful spring Which operates a square-shaped wire. After the trap is baited the wire is pushed back and held by a catch, one end of which is inserted in a piece of metal on which the bait is laid. The slightest movement of the bait causes the catch to be released, and the sharp recoil of the wire, due to the spring, instantly kills the mouse. This break-back trap has almost entirely superseded the old-fashioned box trap, with wires, which closed on the mouse when it nibbled the bait. Either toasted cheese or a scrap of fat bacon is the customary bait employed, and the trap can be kept clean by being occasionally plunged into boiling water.
MICE : As Pets. Of the amaller animals that are kept as pets white or mottled mice give the least trouble. They should be purchased when quite young. For food the mice are given warm bread and milk, dry breadcrumbs and stale calie, dandelion and lettuce leaves, pieces of apple and carrot, and mixed birl seed. They slionld be licpt in a glass fronted and well-ventilated wooden box, in a perfectly dry and quiet place, away from direct sunlight.

The cage must be kept perfectly clean, and it is an advantage to have two cages in order that one may hic in use while the other is being cleaned and dried.

A convenient cage for mice is easily made from $\ddagger$ in wood and a few lengths of stiff wire. The base is 15 in . by 5 in ., the lixed cage 10 in . long by 10 in . high, and a revolving wheel is formed from two 5 in . disks joined by 4 in . lengths of wire. The fixed cage is divided into tivo parts. Onc, 4 in . wide, is clused with a plain door, the other has a barred door formed by lengths of wire driven into strips of wood ; botll are hinged by naila driven in through the top and bottoin pieces. Three 14 in . holes are bored in one disk and is similar hole in the end of fixed cage, and the revolving portion is hung so that the holes will coincide. The end supports of the cage are 7 in. by 5 in., with 2 in. cut from corners, and are joined with a 1 in . strip.
MICHAELMAS DAISY. This is the popular name of the hardy perennial aster, an important group of allumn Howering plant.s. They thrive in ordinary well cultivated aoil and are increased by division in spring. They may be planted in autumn or spring. In the course of two years the plants form large clumps and must then be lifted, divided and replanted. The finest hlooms
of this plant are olitained by replanting small pieces in spring and setting several together in groups.

In recent years many beautiful new varieties having richly coloured flowers have been raised. Of the large-flowered varieties some of the best are leauty of Ronsdorff, lilac mauve; King George, violet-blue; Perry's Favourite, rose; and Preziosa, violet-bluc: these grow about 2 feet high and bloom in Scptember.

Barr's Pink, carmine rose, $4 \frac{1}{2} \mathrm{ft}$ : Mrs. Rayner, rose-red, $5 \mathrm{ft}$. ; Anita Ballard, lavender-b!ue, $4 \frac{1}{2} \mathrm{ft}$. Beauty of Colwall, lavender-blue, 4 ft . : Ethel Ballard, pale pink, 4 ft . : Maid of Athens, pink, $4 \frac{1}{2} \mathrm{ft}$. ; Mons, rose, 4 ft ; Mrs. George Monro, white, 4 ft ; and Peggy Ballard, mauve, 3 ft . : these bloom in September-October.

Climax, lavender-blue, 5 ft ., and its white variety, alba, are handsome October-flowering varieties. Little Pink Lady and Little Boy Blue anc two charming large-flowered varieties, 2-3 ft. high, which bloom in Scptember. Acris, $2 \frac{1}{2} \mathrm{ft}$., bears a profusion of small lavender-blue flowers in August; Blue Star and Silver Gem yield dainty sprays of small Howers in September-October. Michaelmas

Michaelmas Daisy. Purplish-lilac flowers of a tall free blooming variety
daisies can he raised from seeds sown in boxes of soil in a frame in spring.

MICROBE. The word microbe is applied to inicroscopic living things, animal and vege table, particularly the latter. They are of various shapes, some being globular (micrococci), some like straight rods (bacilli), some wavy, some curved. Most microbes arc harmless to man; many arc very useful, is, for example, those which produce vinegar, the ripening of cheese, the nitritication of soil, etc. On the other hand, microles are the cause of the great army of infectious discases. See Bacteria.

MICROMETER. As a precision measuring instrument the micrometer is generally used in metal work, but it is applicable to the measuring of any material where extreme accuracy is called for. The principle of the micrometer is based on a screw calibrated so that readings of 1000 th of an inch, or even finer, can be taken directly.
The ordinary type of micromcter is illustrated in Fig. 1, and comprises a $U$-shaped body. At one end is a circular projecting portion called a sleeve, which has a screw thread cut in a portion of its length. In the type of instrument to which the following description applies the pitch of the threads is $\mathbf{4 0}$ to the inch. Into the slecse is screwed a spindle rotated by an outer portion called the thimble, which is milled to afford a sure grip. In some patterns this and the thimble are rigid, but in the Browne \& Sharpe instrument, illustrated, a ratchet device is provided in the form of a subsidiary and smaller handle which is situated at the end of the thimble.
Its function is to rotate the thimble to open the jaws of the micrometer, but to close them with a pressure determined only by the amount of friction on the spring pawl of the ratchet. When the detcrmined pressure hetween the measuring faces has been reached, the ratchet will slip and the screw cannot be turned any more. As a consequence of this, it is impossible to strain it. A locking device is provided in the form of a litile milled ring, situated in the upper part of the frame. This, when rotated, grips the spindle rigidly, so that if the instrument is required to incasure
several pieces of tho same sizr, it can be using n micrometer, it is better to think in locked and used as an ordinary fixed type of limit gauge.
The anvil is movable, and by means of the milled nut at the end of the frame opposite to the alceve it can be drawn back, to increase the measuring range of the instrument The pattern illustrated can measure up to 2 in. in diameter with the anvil drawn back. and from zero to $I$ in. when the anvil is pushed forward. To set the instrument, the spindle is set at zero, the anvil drawn back. and $n$ limit gauge in the form of a circular disk inserted between the end of the spindle and the anvil. The latter is then pressed into contact with the disk, and locked in that position.
 thousandths than in any other figures. For example, $t \mathrm{in}$. is more quickly remembered as ${ }^{2} 1000$, and similarly with other fractions Thereforc, to measure the bar known to be $1 \frac{1}{1}$ in in diameter, it is better to think of it as one inch, plus $\frac{13 A}{1800}$, which is exactly $\frac{1}{k}$. Measuring this will neccssitate setting back the anvil, adjusting it to zero, and then unscrewing the thimble sufficiently to mata T0,
 making $1800^{\circ} \sigma$ in all. Therefore rotate the thimble until the line marked 1 is visible, when the zem on the thimble scale is exactly opposite the horizontal line. This is $1800^{\circ}$. and the thimble is then rotated to add the

Fix the spindle in this position, and apply it to the bar. The jaw's should just go on to it amoothly and certainly, but without forcing, and without the least trace of slackness. Suppose it will not quite go on, as the bar is, say, n few thousandths over size.

Fig. © shows the anvil drawn back and the testing disk in position
In use, the instrument is simply applied to the ohject to be gauged, the thimble rotnted until it is almost in adjustment, and the final turn completed with tie aid of the ratchet handle. This drives the spindle intu contact with the object to be mersured. The same principle is applied no matter what the shape of the object may be, so long as the spindle and anvil can bear upon it. Supposing it to be a bar of metal $1 \frac{1}{8}$ in in dianeler, this reading would be taken as thousandths of an inch. as, practically speaking, all micrometers anc calibrated in the same way, or else have metric readings.

Care must he taken that the netal to be gauged has a true and smonth surface; otherwise it will be impossible to obtain an accurate measurement. On the bevel edge of the thimble is a series of lines and marks, beginning at 0 , the next marked division being 5 , and so on by regular steps of 5 up to 20 . The zero mark will also be read as 25 . Therc are thus 25 separnte divisions around the odge of the thimble. On the sleeve is a series of numbers and division marks commencing at 0 and numbered consecutirely to 9 nnd 0 . There are thus 10 spaces, each sub-divided into 4 spaces.

As the spindlo is screwed, the thimble when rotatod travels up and down along the sleeve, and, as it works outward, the marks on the sleeve gradually appear in regular order, 1, 2, 3, etc. The distance which is traversed by one revolution of the thimble is determined by the pitch, or number of threads per inch cut on the spindle and, as this is 40 , it follows that one revolution of the th:mble draws back the spindle ${ }^{\frac{1}{2}} \mathrm{f}$ in. The calibrations on the sleeve arc apaced it in. apart, and, being further divided into 4 , one complete $r$-volution of the thimble will draw it back exactly this amount. that is $\frac{1}{40}$ in. But as the rim of the thimble is divided into 25 , if the thimble is only rotated to move through, say, one space on the thimble scale, the exact amount which the spindle has been drawn back will be $x_{0}{ }^{\frac{1}{0}}$, in. because the spindle has maclo of $n$ revolution, that is of dos in., that is to say, Io ${ }^{\text {d }} \sigma \sigma$ in
All the readings aro taken from the horizontal line marked on the slecvo and from the zero mark on the thimble. Consequently it is perfectly simple to measure ro'sg in., or any other number of thousandths. When

Micrometer. Fig. 1. Complete instrument with adjusting spanner and gauge disk. Fig. 2. Setting micrometer with inch gange disk

Release the clamp and then further unscrew the thimblc. counting the number of spaces on the thimble scale which pass the zero line on the slecve until the spindle has been drawn back sufliciently to fit on to the bar. Supposc that this is 7 spaces. This means yove in. and thus the true reading is $1 \cdot 132$ in. In actual practice the readinga can be taken direct by simply reading of the scale, counting the numbers of thousandths as explained ahove. See Gauge; Limit Gauge.

MICROPHONE. The microphone is in reality the electrical counterpart of the humian ear In the ear the cound waves vibrate the car-drum, and such oscillations are then trans-

Microphone. Pig. 1. Type
of contact microphone usent in telephone apparatus mitted mechanically to the brain.

An electrical microphone has $n$ diaphragm corresponding to the eardrum. The oscilla tion alters the number and pressure of a series of contacts in an elec. tric circuit, thus varying the electrical resistance and the strength of the current. The electricity is normally flowing steadily, but the current is altered by the vibrations of the voice. These

Microphone. Fig. 2. Pair of Reisz carbon microphones, as used in broadcasting studios, showing pulley suspenslon which allows for varying heights Courless of British Broudeasting Cormoration
current variations are then converted back into mechanical vibrations to give speech. The microphone, which forms part of the ordinary telephone, is shown in section in Fig. 1.

The broadcasting microphone is the first link in the transmission chain. The sound waves in the hroadcasting studio are picked up by the microphone, which converta them into electrical currents These currents arc then amplified and caused to modulate the carrier wave sent out by the broadcaat transmitter. Microphones are alao used in conjunction with public address amplifying systems. See Carricr Wave; Modulation; Tolephone.
MICROSCOPE: Its Mechanism. When choosing a microscope the essentials specified below should be borne in mind. As good an instrument as the purchaser can afford should be bought, since a pound or two more on the price will add a great deal to the scope and utility of the microscope. Several firms stock second-hand microscopes, and can usually be relied upon to furnish a satisfactory instrument at a moderate price. What are known as student's instruments are turned out by leading opticians at quite low prices, and the stands cmhody the essential qualities desirable in a microscope for ordinary use.

The chosen instrument should be of good workmanship, rigid, firm, and free from vibration, whether it is being used in an upright, horizontal, or sloping position. All movements should work smoothly, at the same time being free from such defects as slipping. The lower priced stands are generally of the vertical or non-inclinable type. The coarso adjustment should be a rack and pinion movement, and the finc adjuatment should never depend upon the direct action of springs. Instruments may be met with having a screw fine and a sliding tube coarse adjustment. A stand with a rack and pinion adjustment is preferable, even if this is the solc means of focusaing the instrument. With a good coarsc adjustment alone objective glasses up to $t$-in. can be focussed.
The stage should be rigid, and large enough to afford a safe support for any glass vessels the contents of which may have to be examined. The stage should be provided with spring clips, removable at will, to secure the glass microscope slides, usually 3 in . by 1 in . in size.
The best form of diaphragm is the iris pattern, similar to the arrangement for stopping down a camera. This diaphragm is necessary, since the light has sometimes to be cut down or increased, and forms part of the sub-stage condenser, or that part of the instrument found under the stage. The func tion of the latter is to collect into a cone of large aperture the beam of light rays reflected by the mirror. This is achieved by means
of a short-focus system of lenses, and the aperture may he reduced at will, by means of the diaphragm Tho mirror below the condenser is reversible, one side being plane and the other concave. The plane inirror is usually ent. ployed, but the concave The concave Reader for fine
aje should the astment
side
utilized when milled Head utilized when Milled Head using low fine adjustmen powers.
The choice of eycpieces and objectives is governed by the olass of work it is desired to undertake. A pair of cyepicces, magnifying the image formod by the objective 5 and 9 times respectively, and two oljeotives. tin. and t-in., would bo a gooll selection. This is the equipment suggested for the Baker Mic stand illustrated, giving a inagnification of 53 to 406 . The lieck microscope shown, with two eyepieces ( $x 0$ and $x 10$ ) and a $\frac{2}{3}$-in. object glass, magnifies from 62 to 110 .

There remnins the question of lighting, and rs in Great Britain daylight of the necessary quality is usually lacking, it is better to provide an artificial light. A small incandescent mantle is suitable, but electric light ;s best. The bulb should be of ground glass,
 light is required, the bull) may be tinted blue. $A$ very ensy way of doing this is to strenk the glases with a blue grease pencil -of the sort which are sold for writing on glass -turning on the light and distributing the greasy material over tho whole surfacc by means of $a$ piece of cotton-
wool, when the bulb has warmed.

Before plac. ing the slide on the stage, to which it will be secured by the spring clips, the eyepicce ahould be reMicroscope. Sectional diagrain moved, and the from the reflecting mirror mirroradjusted through the condenser to the to givethe best object on the slide, and thence illomination up through lenses to the ege the tube, the iris diaphragm being fully open. The eyepiece should then be returned and the diaphragm closed down until a dim light only comes through. This should all be done with the objective nearly touching the stage. Now rack up the body tube ahout $1 \frac{1}{2} \mathrm{in}$., place the slide in position and, using the low-power objective and coarse adjustment, anck the tuhe down slowly until the hlurred image of the specimen can be seen. Ottain a sharp image by means of tho fine adjustment, and if the light is too dim open the diaphragn a little until the necessary illumination is
as the pinky part of middlings contains the wheat phosphates and the product known as cereline, whioh acts as a digestive agent to the rest of the meal. Middlings contain albumen, 15.6 p.c., carho-bydrates 60.7 p.c., and fat 40 p.c. Giving an albuminoid ratio of 1 to 4 , it is almost ideal for feeding poultry. Sec Chicken ; Poultry.
MIDGE. To prevent the unwelcome attention of midges, nothing is more efficacious than rubbing the neck, wrists, and other exposed parts of the body with olive oil to which is added sono oil of rosemary. lavender, eucalyptus, or pennyroyal. Ono teaspoonful of any one of these should be added to 1 or 2 oz . of olive oil.

The irritation from bites can sometimes he removed by applying chloroform or weali solution of ammonia. The following preacrijption is uscful for the same purpose:

## Menthol

$\qquad$ .. ......... 10 g

MIDWIFE: Her Qualifications.
A woman who attends women in childbirth is a midwife. In an emergency any woman may have to stand by another and give her what lielp she can, but it is unlawful for any woman to act in this way, habitually and for gain, unless she is a qualified doctor or has passed an examination and received a certificate of competency from the Central Midwives l Board. The penalty is a fine of $£ 10$. To ohtain a cortificate by false atatements is punishable by 12 months' imprisonment.

The Central Midwives Board has power to register midwives, to hear complaints ahout them, and to suspend or dehar them from practice. The county (or county horough) council is the local supervising authority with power to investigate all charges of

Mignonette. Fragrant blooms of the giant variety of this old-fashioned plant. See article below
malpractices, neglect, and the like, and with power to report to the central board A county council may dolegate its powers to a
$\Lambda$ person who acts as a midwife-except a neighbour acting in an emergency-is liable for damages for negligence if, through her incompetence, any harm comes to the patient. It is no answer for her to say she did her best, unleas she diaplayed the skill and slowed the knowledge of a competent midwife.
The address of the Central Midwives Board is 1, Queen Anne's Gate Buildings, London, S.W.1. The Central lBoard for Scotland is at 49, George Square, Edinburgh.

## MIGNONETTE.

This favourite annual Rcseda odorata, bears sweet-scented Howers which in modern varieties are of various shades of colourreddish, brown, yellow, and white. This plant is rather capricious and may fail unless suitable con. ditions are providerl. Serds should be sown
in April on well tilled soil to which lime has been added if necessary; the soil must be made firm before sowing. The secdlings must be thinned out to give the plants room to develop. Reseda glauca, with grey-green leaves and white flowers in summer, is a hardy border perennial.

Mignonette will bloom in winter under glass if secds are sown in 5 in . pots in August, the seedlings being thinned out to three in each pot: they must not be transplanted. Firm loamy soil containing mortar rubble or a scattering of lime suits them best. A temperature of 50 degrees is suitable.

MIGRAINE : The Headache. Migraine or megrim may be due to such widely differing causcs as eye strain, worry or fatiguc of the brain, want of exercise, or a too rich diet. Not infrequently it appears to be hereditary.

There may be a sense of depression for some hours preceding the onset of the pain, which commonly begins on one side of the head. The pain is of a throbbing character, and is aggravatcd by noises, jarring and bright lights.
Regular daily exercisc, open bedroom windows, and attention to chewing of food may help in preventing an attack. The diet should be plain. Examination of the eyes by an oculist, attention to decayed teeth and to discased conditions of the nose and ears will be found to be worth while. When an attack threatens, a cup of hot ten or weak coffee may prevent it. Druge are to be avoided until other measures fail. An ersential part of treatment is complete rest in bed in a darkened room, with cold compresses, constantly changed, over the forehead. See Biliousness; Headache.

MILDEW : How to Remove. In appear. ance resembling a blue or a green mould, mildew is found on jam, checse, oranges, and orher fruit, on bread that has been kept too long, and on many other foods, as well as on |cather coverings of furniture, and on linen and cotton. When closely examined the fungus plant is seen to be a collection of fine threads with spore-bearing branches, which may extend in all directions if the mischief is allowed to remain undiscovered. There nre several forms of mildew which may develop as a mould on food or a rust on plate.
Causes of Mildew. Damp is nearly always the predisprosing cause. Clothes or food stored in damp cupboards are always liable to be affected, and such cupboards should be inspected at intervals and their contents carefully examined for any traces of mildew. Where linen or cotton are affected the marks are easily removed if the articles have not been left too long unexamined. A good plan is to wet the mildewed parts, rub them with ordinary laundry soap, and cover them with précipitated chalk, which should be rubbed well in. The clothes are then allowed to remain undisturbed for an hour or more, after which they are thoroughly rinsed out. If any traces of mildew still remain the operation should be repeated once again.

When the mildew has been allowed to spread or become settled, damp salt should be rubbed in and the clothes exposed to warm sunshine if possible: the process may have to be repeated on several days, but is nearly always successful. Strong soapsuds may be used as well as the salt. Nildew on leather can be removed by rubbing with vaseline. In the case of food it is generally sufficient to excise the portion affected.

Besides soap and water, sour milk may be used to remove mildew much in the same manner, the stains being soaked overnight and the article placed in the sun without rinsing. Lemon juice may be employed, and is effective in removing slight stains. l'or old and persistent stains on white fabrics
potassium permanganate is sometimes cm . ployed. It is prepared by dissolving a tcaspoonful of the crystals in a pint of water.

An American remedy is javelle water, which is made by dissolving 1 lb. of washing soda in a quart of water, and adding $\ddagger \mathrm{lb}$. of ordinary bleaching powder. It should not be applied to coloured materials. It is allowed to remain on the fabric for 1 min . only, then oxalic acid solution is applied, and the stain is dipped in water. Sce Damp.

MILDEW : In the Garden. This is one of the most troublesome disenses which affect plants and trecs. It is easily recognized by plants and trecs. It is easily recognized by
leaves and shoots. Its effect is seriously to cripple growth. Fallen leaves from diseased trees and plants ought to be gathered and burnt in autumn, for mildew is carried over the winter by resting spores. Sulphur is the best antidote. Green sulphur scattered on and among rose bushes in winter does good and in early summer spraying with liver of sulphur (potassium sulphide), 1 oz . in 2 gallons of water, is advised. Fruit trees should be sprayed with lime sulphur in spring before the blossoms open. See Lime

Milfoil. Many plants suitable for the border or the rockery are comprised in the milfoil family, also known as Achillea (q.v.).

## Milk: Fresh and Preserved

Food Vaiue and Use of this Important Article of Diet
The reader is referred from this entry to those on Diet: Invalid Cookery, and to the many on the foods in which milk is an ingredient, e.g. Butter: Checsc: Custard: Junket and the various milk puddings. See also Basin: Jug: Lactometer: Saucepan

Milk is called a perfect food, hecause it contains all the substances necessary for the growth and the work of the body. For any young animal its mother's milk normally contains these substances in the correct proportions. In the artificial feeding of infants, and when using milk in a sick or an ordinary dietary, cow's milk is generally used, though recourse is sometimes had to the milk of other animals.

Analysis of Milk. Cow's milk varies widely in quality, but it should have about the follow. ing composition :
(lactose or milk sugar) differs from cane sugar. It is more easily assimilated than cane sugar, and should be used to swecten the feed of cow's milk when the greater cost is of no consequence.

Digestive Qualities. The digestibility of milk varies according to its condition as the following figures prove. Boiled milk takes longest to digest, but this must not be taken to mean that it is not quite as completely digested as raw milk.

Milk clots quickly after reaching the stomach. It is sometimes advisable, therefore, to dilute it with water, lime water, or barley water for an infant, while adults should sip the milk slowly, dilute it if necessary, and eat a biscuit or a piece of toast. For infants a good plan is to add some citrate of soda, in the proportion of 1 to 3 gr . to 1 oz of milk. This can be obtained in 5 to 10 gr tablets.

Milk is so readily contaminated that it should be kept with grent care It should be delivered in closed vessels, glass bottles theing best, as they are easily kept clean. It should be stored in a cool place, separate from other articles of fond it shoulds never be kept in an open vessel or allowed to liccome contamin. ated by dust or llies. The common practice of lenving the milli outside the door in an open vessel in the morning is a dangerous one.
Contamination. The dangers arising from the contamination of milk by microbes can be largely avoided by the process known as pasteurization. To accomplish this, milk is heated to $145^{\circ}$ or $1.50^{\circ}$ and liept at this temperature for 30 min . An apparatus may be purchased for the purpose, but certified pas teurized milk can he olitained from a dairy in a scaled receptacle In using the apparatus the water in which the bottles are placed or in the outer receplacle is brought almost to hoiling, removed from the fire, and covered with a cloth for half an hour, then the milk is cooled rapidly and stored in a cool place. To protect against tuberculosis, milk should be boiled for a few minutes; this should be done where any doubt exists Infants fed on heated milk should be given a teaspoonful of orange or grape juice once or twice a day.

Peptonized or pancreatized milk is often ordered in place of ordinary milk for invalids, infants, and persons of weak digestion. A simple method of peptonizing milk is as follows: To ${\underset{3}{3}}^{2}$ pint of milk add ? pint water and bring to a temperature of $1411^{2} \mathrm{~F}$. Tho required temperature may he obtained by halving the diluted milk, bringing one-half to the boiling noint and mixing it with the ot her. To this milk mixture are added 2 drams of pancreatic solution and 20 gr of sodium
bicarbonate. The mixture in a covered jug is kept in a warm place for 10 to 20 min ., is then brought to boiling point and immediately emoved from the heat.

Artificially Soured Milk. Skinmed milk contains alout $\ddagger$ of the fat of whole milk: separated milk contains little or none. Buttermilk is n thickish, somewhat acid residual milk left behind after churning and removing the butter. It is often a valunble food for invalids and sickly children. Soural milk may be prepared with one of the ferments sold for the purpose, or it may be hought from a reliable dairy. 'lhe Bulgarian bacillus i the organism mainly used for the purpose.

Whey is the fluid squeezed out when milk is clutted with rennet or an acid such as white winc. It contains very little nutritious matter except sugar, but is a refreshing and slightly laxative bevernge. To make whey, add I tensromiful of rennet to 3 pint of milk which is warmed to $104^{\circ}$; with n spoon hreak up the clot that forms and strain through muslin. Junket is milk clotted and partly digested with rennet. It is an cxtremely digestiblc and nourishing food.

Condensed Milk. Sold in three formis, condensed milk is either whole sweetened, whole unsweetened, or skim sweetened. In making the unsweetened variety, 3 pints of whole milk are, as a rule, evaporated down to 1 pint This contains all the nutriment of the 3 pints, and when 2 parts of water are added to 1 part condensed milk the result is the equivnlent of good cow's milk For infants, further dilution and the addition of sugar and cream are necessary. This is an excellent foorl, its one disadvantage boing that it keeps good for only a very short time after the tin has been oplened.

Condensed whole sweetened milk is usually evaporated to the same degree. But to this is added a large quantity of sugar, which in infants may give rise to gastric fermentation. If the various brands of condensed whole milk are diluted according to the directions on the tin, the chilll gets insufficient fat. It may be plump and heavy, fattened by the sugar, but generally is pale and not so robust as he should be. Condensed milk is more digestible as a rule than ordinary cow's milk, and often agrees when the latter does not, but it should only he used for a few wecks at a time, and attempta should he made to replace it as soon as possible by ordinary milk. Ohviously, to supply the deficiency of fat some cream should be added. Cod-liver oil serves the same end.

Condensed skimined milk is wholly unfitted for infunts. It contains only a trace of fat, and is so sweet that if diluted sufficiently to suit the cliild's taste the child will be slowly starved. This should only be used for cooking purposes.

Several reliable brands of milk powder, consisting of milk from which all the water has been removed, are sold; when these are made up with water a quite satisfactory milk food for infants is obtained.
Casein, casumen, plasmon, protene, etc., are highly nutritive and very digestible. They can be added to other foods, such as puddings, soups, etc., and form an excellent article of dict for weakly people and in fevers.

Milk for Invalids. Milk and its various modifications form a most valuable foorl in many diseases, especially in typhoid and other fevers, acute kidney disease, ulcerated stomach, etc. In diabetes the place of milk may be taken by so-called artificial milk, which can be made as follows: Mix 4 tablespoonfuls of good fresh cream with a pint of water, and let it stand for 12 hours in a covered vessel. Then skim of the cream, and beat it up with the white of one egg, a little flavouring of salt, and $\frac{1}{2}$ pint of water.
A few small points are worth mentioning. If milk produces costiveness add some mag-
nesia or brown sugar to it. If it lies heavy on the stomach dilute it, or eat a biscuit with it. If it causes biliousness add half a teaspoonful or less of salt to each pint. A very good way to take milk is in a custard made with gelatin, i.e. milk jelly.

Milk should not be taken at the same times as medicines, or for $\frac{1}{2}$ hour before or after. Never give a child castor oil or other medicincs in milk, which would make him dialike it as a food. Remember that many infectious diseases are conveyed in milk, namely, tuberculosis, diphtheria. scarlet fever, infantile diarrhoca, so fatal in hot weather, and typhoid fever. To avoid these always boil or pasteurize the milk when there is any possibility of its being containinated Sometimes, but rarely, milk also causes ptomaine poisoning like meat

Use in Cookery. Milk forms the basis of many puddings and sweet dishes, and is introduced into soups and sauces, not only to improve the colour but to enrich them and pro vide extra nourishment. Milk also, if made into custard with eggs, becomes a substitute for cream, and can be served with fruit pies and puddings or with stewed fruit.

In hot weather milk should be scalded in order to keep it sweet. If it should become very slightly soured it can be restored by adding a pinch of bicarbonate of sods, and it will often boil without curdling. If really sour and unfit for table use it should not be thrown away, but used in the making of cakes. Cream cheese can be made from sour milk. Wrap it in mualin and allow it to hang until all moisture has dripped from it, scald the curds, dry again, and beat up with salt and pepper to taste.
Testing the Milk. By using a simple con trivance the housewife can easily test milk at home, in order to see whether or not it has been akimmed or adulterated with water. This form of tester somewhat resembles a pocket thermometer, and is marked to scale. When slipperd into the milk, it will sink until the top of the milk reaches one of the coloured divisions. The deeper the tester sinky the greater is the dilution.

Sale of Milk. In Great Britain certa in standards for dried milk liave been fixed by regulations for the protection of the public. No person can sell dried milk for human consumption unless it is properly labelled to show that it contains (1) dried full cream milk, (2) dried partly skimmed milk, or (3) dried machine skimmed milk. Each class must conform to certnin' standerds of milk fat. Some classes of dried milk must show printed warnings as "Should not be used for babies except under medical advice," or "Unfit for habies." The object being to warn parents of the abstraction of fat. l'rovision is made in the reguIations for samples to he taken to sce the public is being protected

No person must put into circulation condensed milk which is not labelled in accordance with the condensed milk regulations. 'lhese have heen deaigned to protect the public and to give them an indication on the labels as to the guality of the contents of the tin. Several grades are mentioned surh as "condensed full creain milk." swertened or umsweetened es the case may be. In the case of skimmed milk it must show on the label "condensed machine skimmed milk" or "condensed skimmed milk." "Sweetened" or "unawectened" to indicate what the tin contains. Standards of milk fat are fixed for each grade and samples are taken periodi. cally to protect the public and to see if the regulations are being carried out.

MILK BISCUIT. A variety of milk biscuit especially useful for the preparation of savouries can be made thus: Warm 1 oz. butter and $\ddagger$ pint milk in a saucepan over the fire, and when they are hot pour them gradually
on to $\frac{1}{2}$ lh. flour previously sieved with teaspoonful baking-powder. Add $\frac{1}{2}$ teaspoonful salt. Stir all to a smooth paste and roll it out as thinly as possible on a floured pastry board. Cut it into rounds each about $1 \frac{1}{2}$ in. in diameter, prick them, put them on a greased baking tin, and bake for about 20 min . When cold pack them in an airtight tin.

MILK FEVER. Fever occurring ahout the third day after childbirth, when the secretion of milk by the breasts is becoming established, used to be called milk fever, but the term and the idea underlying should be dropped. Its existence should always be brought to the notice of the doctor.
MILK JELLY. This dish, which is suitable for invalids, is made as follows: Heat a pint of milk with the thinly cut rind of a quarter of a lemon, but do not allow the milk to hoil. Then add $1 \frac{1}{2}$ oz. White sugar and $\frac{1}{2}$ oz sheet gelatine, and stir the mixture until it is dissolved and is the consistency of cream. Pour it into a wetted mould and leave it until set.

Milk jellics can also be mate by using the ordinary packet jcllies and making them with milk instead of water. A little hot water, not hoiling, should first make the jelly liquid, a pint packet of jelly being made up to $n$ pint with cold milk. Stir it well and pour it into a wetted mould to set.

A double colour effect cart be ohtained by the use of two jellies, lemon and raspberry, the raspberry bcing made with milk, ns alieady described, to fill half the mould, and the lemon, which has been made in the ordinary way, alded before the raspberry jelly is quite set.

MILK PUNCH. To make this, takic a pint of milk, 2 oz . loaf sugar, $\frac{1}{2}$ gill cream, and a tahlespoonful each of brandy and rum. Boil the milk, dissolve the sugar in it, strain it, and when it is cool freeze it partly. Then add the cream, which should be well whipped, and the two spirits. Mix them all together and freeze the mixture further. It should be served in small china cups with a little nutmeg or cinnamon grated over it.
MILK VETCH. This shrub and perennial (astragalus) bears pea-shaped flowers in summer, and thrives in ordinary soil. Most of them are of little value as decorative garden

## Milk Vetch, clump of an effective rockery plant

plants. The goat's thorn (tragacantha) is a low shrub, with spiny branches, which bears lilac-coloured blooms. Monsjessulanus, a trailing plant for the rockery, has reddishpurpl flowers. Propagation is by seeds sown as sonn as they are ripe in late summer.
MILKWEED. The best of the milkweeds (Asclepias) for the garden is tuberosa, commonly called the butterfly weed. This is a perennial, 2 ft . high, which bears showy orange-coloured flowers. It needs soil consisting largely of peat or leaf-mould, nnd must be planted in a somewhat shady place.

MILKWORT. This is a genus ol slıubs and perennials (Polygala) вome of which are suita dle for the greenhouse, others for planting out of dours. They bear pea-shaped Howers of

Milkwort. Yellow flowers of the speciea chameebuxus in a rock garden
various colours. Polygala dalmaisiann, which bears purplish fowers in spring, thrives under glass if potted in o compost of loam, peat and sand. Propagation is by cuttings in summer. The piants should be pruned ns soon as the Ulowers are over. Polygala chamaebuxus is a :ow-growing rock garden plant with pale vellow Howers, needing sandy, penty soil. It is propagated by seeds and division.

MILLET. This name has been applied indiactiminately to the plants of at least four different families, but the generally accepted millet is the hardy annua! Panioum, which thrives in any ordinary soil and position on a sunny border The sceds should be sown in March or April, and the plants thinned out Inter on, as desired The llower sprays will be ready for cutting for the purposes of induor decoration about the month of July

Millet is not used as a food in.Great Britain In countrics where Indian corn and othel grains do not grow well the saeds arc ground into meal for bread. See Bread.
liILLIAMMETER. This is a form of ammeter designed to measure current in thousandths of an ampere. It is a useful instrument for the owner of a bruadeast reoriving set. With the aid of a milliammeter it is a simple matter to determine the anode curtent taken by the valves, and thus to make sure that they are being operated correctly. In making such a teat thic millianmeter is connected between the high tension lend from the H.'I'. battery or climi nator and the appropriate H.T. + terminal on the sct. (The + terminal of the meter is joined to the hightension lead.) For sets employing up to four valves, a meter having a range of $0-25$ milliamperes is suitable. See Anode: Eliminator: High Tension.

MILLINERY. The term millinery coin grises the making and trimming of women's hats and also the fashioning of various trim mings and shapes. See Hat; Head Lining

MILLING. This is a process of removing metal ly a rotating cutter from a piece of work which is bolted down to a tuble capable of sliding sideways and endways and vertioally. In effect, milling is the exact opposite of turning. Tbe tonl used in a lathe is held in slides ngainst the rotating work. In a milling machine the work is held and the cutter, which may be provided with several cutting edges or tecth on its periphery and sides, is rotated.

Small lathes are olten fitted with attach sents which, in effect, convert the tool into a specics of milling machine. Some have only a vary limited range. Where the lathe
has a cumpound rest, the most obvious additional devioc which will provide the third direction of movement is the vertical slide The work can be bolted to this and brought up to a milling cutter fixed in a chuck on the lathe mandrel. Slotting and grooving can be accomplished in this way within the limits of the stroke of the vertical slide. In some cases the vertical slide is arranged to hold a spindle, running in plain or ball bearings, with a pulley at one end and a chuck for holding the cutters at the other. The body of the appliance is bolted to the vertical alide of the milling attachment, and the spindle is driven by what is termed the overhead gear in referring to foot lathes.
This gear consists of an overhead countershaft driven from the foot motor, and $n$ system of pullcys which will drive the milling spindle, but at the same time allow for any change in the position of the milling spindle, both in setting up the work and during the cutting operations. Where the cutter is driven from such n separate and self-contained spindle, the mandrel would he fixcd. The worls is bolted to the face plate or otherwise fixed to the mandrel. The mandrel may be held by tightening the bearings, but this is an expedient which should only be adopted in an emergency. The Inthe should be fitted with a dividing apparatus.

MULLIPEDE. This is a troublesome soil peat which may do much daniage to bulbs and the roots of plants. It is black or brown, with numerous fcet, and curls up when disturbed. It should not be confused with the beneficial centipede, which is tlat, lighter in colour, and has only onc pair of feet to ench sogment of the body. A fumigant of llb. of naphthaline and 1 stone of lime, mixed and used at the rate of 1 lb . per equare yard, should be dug in infested soil. Millipedes are frequently found in lange numbers in leaf mould; this should be sprayed with formalin, 1 tableapoonful to a gallon Centipede: Insccticide

MILTONIA. An casily grown family of orchids suitable for cultivation in a heated

Milling. Complete Indexing, milling and rear cutting attachment fitted to a 3 k ln . centre lathe Courleall of Drummond Bros., Led

Miltonia. Bothouse orchid, the flouers of which
glasshouse. They prefer a shady corner of the house, and may be cultivated in pota or pans in a mixture of peat, moss, and charcoal. They need an average temperature of $70^{\circ}$ in summer, $60^{\circ}$ in autumn and winter, with plenty of water, except when the temperature is at its lowest. They rest during winter, and the bulbs ahould be separated parly in the yenr to increase stuck
Miltonias llower in summer. They are excellent orchids for beginners and amateurs who have the necessary heat at their disposul There are many benutiful varieties of Miltonia vexillaria, the chief species See Orchid.
MIMOSA. So extremely enensitive is the mimosa or sensitive plant (Mimoss pudica) that the leaves will fold up at the slighteat touch. The plant belongs to a small family of greenhouse perennials with diminutive acacialike foliage.

Mimosas should be grown in a mixture of two parta loam, one part leaf-mould, and a good aprinkling of sand. While young the plants require warm-house trentment, bût a cool greenhouse will suit them in the mature stage. Propagntion is by sceds sown in heat in spring.
MIMULUS. This is the scientific name of the musk, or monkey Hower. The cominon yellow musk (Mimulus moschatus) has unfortunately lost its fragrance.

MINA. This half-hardy climhing annual, Mina lobata, bears showy yellow and crimson Howers in summer. It is raised from seeds sown in a heated grecnhouse in early spring and the plants are set out of doors in May agninst a trellis, arch or veranda The secd. lings may be repotted and grown in the greenhouse

MINCE: How to Prepare. The colou of a meat mince must be appetizing and the consistency creamy. It must be thoroughly hot, yet must only just reach boiling point, or the fragments of meat will resemble scraps of leather. It must also be skilfully sensoned

Cut about 1 lb cold meat frec from bones and unentable picces into very sinall cubcs, or man it through the mincing machine. Fry 1 tablespoonful finely chopped onion and 1 oz flour a rich brown in 2 oz hot beef dripping. Stir in gradually fint good stock, and continue stirring it until the sauce toils Cool it a littie and lay in the meat.

Bring to the boil, then cover the pan and let it stand by the side of the fire until the ment is well Havoured with the gravy and
soft through ; this will take at least $\frac{1}{2}$ hour. Serve in a hot dish within a border of toast sippets or mashed potato. A savoury method of using up the renains of a cold joint or portions of game or poultry is to mince the meat and heat it in thickened gravy or sauce. Remove all the flesh from the bones and clear it from skin and gristle. The bones and trimmings should be added to the stockpot. Now chop the meat or pass it through the mincer and mix it in with the gravy or sauce, which should be ready boiling.
Slightly season the meat before adding it to the liquor. Boil it up and let it simmer for 8 min ., never longer. The sance should be brown or white, according to the nature of the meat which is to be used, and a plain dish of minced poultry or game is always garnished with sippets, toast for brown meate and fried bread for white meats

Mince can be adapted for various side dishes or entrées, but the foundation is the same, only the solidity and flavour of the sauce is altered according to the character of the meat See Croquette; Cutlet; Galantine; Shepherd's Pie.

MINCEMEAT. The ingredients for making mincemeat vary considerably, almost cvery cook having her own recipe.
To make a plain mincemeat, pare, core and chop up lincly 2 lb . apples, then add 1 lb . each of currants, stoned and chopped raisins, and brown sugar, $\ddagger \mathrm{lb}$ very finely chopped suet $\ddagger \mathrm{lb}$. candied peel, chopped very small, a level dessertapoonful powdered allspice, a pinch of salt, and the juice and grated rind of 2 lemons. A little brandy or rum may be used to moisten it, and a little raisin or other wine. Mix the ingredicnts very thoroughly, cover with a cloth, and let the mincement stand for some hours before putting it into small jars and tying them down.

A rich mincemeat is made as follows. Chop $\frac{b}{f} \mathrm{lb}$. beef suet very finely, and mix with it $\frac{1}{2} / \mathrm{b}$. curranta, and 6 oz. mixed candied peel, cut up very amall. Add $\frac{1}{2} \mathrm{lb}$. chopped, stoned raisins, 1 lb . apples, pared, cored and chopped, and 2 oz. blanched shredded almonds, and mix all together. Next chop up $\ddagger \mathrm{lb}$ lean cold roast bcef, or of fresh boiled ox-tongue, and add it to the other ingredients, with 6 oz of brown sugar, $\frac{1}{2}$ oz. of allspice, $\frac{1}{2}$ a grated nutmeg, the juice and grated rind of a lemon, and a teasponnful salt

it be too moist, or the undercrust of the mince pies will not rise.
Mince Pie. To make mince pies, grease some rather deep patty pans, and line them with good short or llaky paste, rolled quite thin. Put in plenty of mincemeat, and cover with another round of paste, moistening the edges and pressing them together Make a little bole in the top of each pie, and brush them over with beaten whitc of egg, before baking them in a good oven for $20-30 \mathrm{~min}$.

They are best re-heated by being put on a baking-sheet in a moderate oven for a felw minutes. If the oven is too hot, and there is risk of their burning, it is desirable to leave the oven door ajar. See Christmas; Pastry.

MINCING MACHINE. Frequently known as the mincer, this is a useful kitchen appli ance for desiccating foodstuffs; for instance. cutting up pieces of cold beef or cold mutton so that they can be cooked in various savoury ways. There are several kinds on the market, most of them being made so that they can be fastened quite easily on to the edge of the kitchen table. Before it is put away all the component parta of the mincer should be carefully cleaned and dried

A typical example of the popular type of machine comprises a cast-iron receptacle with a bell-mouthed top and a acreu clamp arrangement at the bottom for attachment to a tahle. The bell-mouthed opening or hopper, with spiral grooves at right angles, forms part of the tunnel in which a screw or worm rotates. Onc end of the tunnel is closed and formed into a bcaring for the spindle of the worm. The other cond is open and has an outlet for the minced food. The outlet aperture is covered by a circular steel plate with holes. The second plate is attached to the outer edge of the worm spindle, and this also has holes in it, but of smaller size. A crank and handle arc provided for rotation of the worm.
The food is cut up and put into the hopper mouth. and as the handle is rotated the pieces are

pressed down on top of the worm, whicts forces them through the tunnel and out through the apertures in the steel plates or knives As one of these knives is fixcd and the other movable, the action is analogous to that of cutting with scissors. The function of the worm and the shaped grooves in the funnel is to propel the fordstulfs towards the cutting knives. These knives cut up the food as it emerges and deliver it in small pieces, when it is ready for whatever cooking operation is necessary.
Parts of the Mincer. Fig I shows the mincer in use, and Fig. 2 the component parts. It will be observed that the crank is attached to the end of the worm shaft by a thumb. screw, and that the boss of the crank has a triangular-shaped hole in it, which fits on a corresponding boss on the end of the worm spindle. The thumb-screw forces the crank into close contact with the tapered triangular end of the shaft. The other end of the worm is provided with a thumb nut, and the end of the worm is formed with a pair of flats, which engage in a slot formed in the centre of the moving knifc. The fixed cutter has a circular hole in the centre in which the worm shaft rotates. The cutter is prevented from moving by a small projecting peg, which engages in a slot in the top of the mincer
Fig. 3 shows the fixed plate in position. the fixed blade fitting into a recess formed in the end of the mincer. It is important to see that the fixed blade fits properly into the recess, and that it is free from little picces of bone or other hard material which would prevent it bedding down flat. The moving blade should bear cvenly against the fixed blade: the pressure between them is regulated by means of a wing nut and can be varied by tightening or slackening the nut. The crank should always be attached firmly to the worm spindle, as if it is allowed to get slack it will specdily wear the hole and the boss will no longer function properly. The crank ought always to be placed and tightened on the spindle before tightening the cutting blades: if this is not-done, the blades may draw the worm too far through the tunnel, with the result that when the thumbscrew is tightened up on the crank handle, it will be found to jam the spindles

Usually this class of mincer is made of malleable cast iron galvanized, and with ordinary care it will give years of satisfactory service. Spare knives are generally supplied with it. When they hecome badly worn it is possible to re-sharpen them by grinding the surfaces, or by cleaning out the holes so that the cdges are perfectly mquare and clean. Grinding may be effected by sprinkling emery powder on a piece of sheet glass, moistening it with oil, and then grinding the knives by press ing them down on the glass and rubbing them on the surface with a slightly rotary movement
Other varietics of mincer are made larger in capacity than the small household type illustrated. In some varieties the knilc blades are attached to the worm shaft, while others have a glass hopper,

MINDERERUS SPIRIT. The solution of ammonium acetate, or mindererus spirit, is a useful and much prescribed diuretic. The dose is from 2 to 6 fluid drams. It has also a mild diaphoretic action, and is thus a valuable ingredient in fever mixtures. See Diuretic.

MINERAL WATER. In a popular sense effervescent watere containing carbonic acid gas only, such as soda water, or carbonic acid
and some tlavouring substance, as lemonade. When spots of mildew appear they should be ginger ale, etc., are classed as minerals or mineral waters: but more strictly mineral waters are those which contain inarganic salts in sofficient amount to be active. These are of two classes: effervescent waters containing carbonic acid and some medicinal salte such as Seltzer, A pollinaris, Rosbach, and sparkling Malrem: mineralized waters which contain no carbonic acid and do not effervesce.

All aerated or carbonnted waters have a soothing effect on the mucous membrane of the stomach, and assist digestion, but if taken in excess they cause indigestion and Hatulence. Mincralized waters are used as table waters or for the medicinal effect, according to the quantity of mineral matter contained.

Kinds of Mineral Water. Table waters should not contain more than onc per cent of mineral matter. Most of them are slightly alkaline, and when used to dilute acid wines they partly neutralize the retarding influence of the wine on digestion. Among these are Apollinaris, Johannis, Kmnthal, Perrier, Seltzer, sparkling Malvern, and Vichy. Some act on the bowels, some on the kidneys

The laxative waters, having a mild effect on the bowels, include Contrexeville, Harrogate, Kissingen, Kronthal (red In bel), Seltzer. The purgative waters, containing sodium and magnesium sulphates, and known as bitter waters, include Apenta. Franz Josef. Hunyadi Janos, Kissingen. Among tho diuretic, kidney-stimulating waters are Apollinaris, Cheltenham, Harrogate, Johannis, Kronthal, Marienbad, Seltzer, Vichy. At various spas there are waters containing iron and arsenic.

Indiscriminate indulgence in active mineral waters is to be deprecated just as much as indiscrimin. ate drugging of any sort. The water used must be appropriate to the unhealthy state which it is proposed to remedy, and this necessitates expert advice. Morenver, the use of any mineral water at home may fail to benefit, whereas its use at the source, whers the treatment may also include baths and other means, and which entails rest of body and mind, may be thoroughly successful. See Ginger Beer: Lemonade, etc.

MINIATURE. These portraits were at first painted in body-colour on vellum or on playing-cards, and afterwards on ivory or paper in transparent colour. An interesting class compriacs those done in plumbago, and also in Indian ink, sometimes imitating the effect of line-engraving.

The posscssor of portrait miniatures should guard them frmm excessive licat, damp and sunlight They are quickly ruined if hung in window embrasures or beside the fireplace. Those which are painted on ivory, after the Cosway manner, are liable to fade if frecly exposed. Should they be valuable it is hest to keep them in closed cabinet-trays.

Ivory miniatures are hest mounted, not on stout card, which tends in oxpand and contract, but on thin notepaper, with dilute gumarabic. After being pressed dry they may be bound to the glass with gold-beater skin, or surrounded by a velvet pad to exclude dust.

Mint Culture. 1. Root of mint. 2. Same planted in box: $a$, fine soil : b, rough soil: c, crocks. 3. Cutting badly cut and planted. 4. Properly prepared cutting. 6. Same wall planted on sand base. B. Wrong way to use dibber. 7. Correct use of dibber

MINORCA : The Fowl. Black minoreas enjoy a reputation as layers of large white egga, and their precocity, hardiness. and adaptability to all soils and place, confined or otherivise, make them one of the most useful of all breeds. In general apprarance they are not unlike the leghorns, having the red face and white ear-lohes, but a much larger comb. They also average in weight 2 lb . or 3 lb . heavier and, though not gener ally ack nowledged as such, are not to be despised as table birds. In addition to the single combed variety of ininorca fowl there is also a rose comb and a white varicty, hoth of which have $n$ large following. See Fowl ; Poultry.

Minton Ware. Porcelain boul dating from about 1800, decorated with Greek key pattern and fanres British Muscum

MINT. This is a hardy perennial plant. with aromatio herbage, which flourishes in ordinary soil. It should be planted in early spring, and. as it spreads freely, the plants should be lifted and replanted once in every 4 or 5 years, otherwise it runs to stalk instead of to leaf. To force mint the roots should be liftedin autumn and placed in boxes of potting soil in a slightly heated glasshouse. Maisturcand warmth will cnsure a crop by Christmas time. Onc of the numerous varieties of mint. Mentha Requicni. is peppermint, and is best grown as a tiny trailing plant in the rock garden. For the purposes of distillation the shoots should be piclied when the flowers are upon them. Shade and moisture are the two chief requirements of inints of all kinds.

Uses for Flavouring. On nccount of its aroniatic propertics mint is much used in cookery for tlavouring sauces, salads, and soup. It is also employed in the preparation of a drink called mint julep Spearnint is considered the best variety for culinary purposes. Mint is full grown in June and lasts well till August, when it begins to llower. It ghould then be plucked, dried, and stored in airtight tins or bottles, for winter use. Dried mint is served with some soups and added to scasonings occasionally. When fresh mint is not obtainable. powdered mint mav be used as a substitute
Mint Julep. To make this, place 3 sprige of fresh gathered young inint in a tumbler and partially fill it with sherry. In a second tumbler put sufficient pounded ice to half fill it. I'our the mint and sherry over this. Transfer the julep from one tumbler to the other several limes, then place it on ice for a fow minutes.

Mint Sauce. To make mint sauce, chop finely the lenves from 6 or 8 sprigs of mint. and put them into a sauce tureen with 8 lumps sugar, pour over them 2 tablespoonfuls boiling water, stir well, and let all stand for a few minutes; then add about $\frac{1}{2}$ pint vinegar.

Mint Vinegar. This is made by filling loosely a pickle bottle with leaves of young mint, and adding sufficient white wine vinegar to cover them. Tie the bottle down securely, and after 3 weeks strain into another buttlo and cork it firmly. This is good for winter use.

MINTON WARE. The productions of the Minton works nt Stoke stand in the front rank of modern Staffordshire cerainics. They embrace a wide range of styles, both useful and ornamental. Some carly Minton resembles 1)erby and Spode, and may sometimes be recognized by its nark, such as
the double L of Sèrres enclosing an M , or later on the arrowhead device which represents ermine in heraldry. There were also descriptive marks, such as Amherst Japan. Later productions included vases and plaques in a white refief called pâte-sur-pâte, which rivals in beauty Wedgwood jasper. These wares usually bear the name Minton sometimes inscribed upon. a globe, or surmounted by a crown.

Among the new developments were Parian statuettes and groups, and reproductions of
medieval majolica, besides Persian style, faience, and Nèvres porcelain. A fine liard paste body was introduced for the manufacture of domestin china A distinctive shape of tea-cup has been given the name of Minton. The Minton works have also played a predominant part in the development of the manufacture of tiles for paving floors and lining walls. See Staflordahire Chinaware.

Mirabilis. The botanical nanic of the plant

## Mirrors for Decorative Purposes

## Choice and Arrangement of Antique and Modern Styies

Other aspects of this subject are dealt with under such headings as Cheval Glass: Dressing Table: Toilet Mirror. See also Dining Room: Hall: Living.Room : and the entrics on Gesso: Gilding: Lead Art Craft; Silvering

A mirror miny be described as a reflecting surface usually made of glass and lined at the back with silver or nnother brilliant metal. Nirrors are often given pride of place in rooms and halls to-day as they are not only decorative, but lend an appearance of space and, by reflection. increase the light in dark corncrs and passages. Another use of mirror glass is for framing and lining niches or the upper parts of glazed cupboards or recessos, so that the ornaments on the sholves may be reflected and their decorative value enhanced. Finger plates for doors and curtain pelmets arc also fashioned of mirror glass, while whole panels are introduced into doors for rooms and cupboards and as rellectors on walls
In the case of such panels they are most effectively used where it is desired to give an air of brightness. as, for instance, in a basement room or darli hall; othorwise the effect might be rather garish and reatless. In page 734 an excellent example of the use of mirror panela in a dark corner is illustrated. The mirror inset of the heavy wooden overmantel is now less frequently seen, the place of the latter being taken by one of the charming morlern mirrors, with inlaid or marquetry decorstion, or by an antique exnmple of beantiful workmanship. Mony clever reproductions of old mirrors ane obtninable. The frame in others is genuine. but the glass has been replared so
skilfully that it is quite difficult to detect the modern touch

In buying an old misror this inatter of the glass is one to which the purchaser should give nttention. Often it is so spotted owing to the corroding of the silver backing, that its decorative value is reduced to a minimum unless it is resilvererl. For practical purroses also, nothing is more uncomfortable than a reflecting surface pitted with spots. With the exception of a really valuable antique piece. which should not be tampored with, the practice of resilvering is quite legitinate. Many mirrors of comparatively recent date have become spotted through carelcss usage or damp.

Mirrors should be hung in such a position that they aro not above the cyc level, and are not crowded by pictures or other mural decoration. In the case of a small fromed mirror, it is best given a slightly forward tilt, as this allows the air to get to the back. The back board of the inirror should not be cracked and left unrepaired, or such a crack will, in the course of time, appear as a mark on the face of the glass.

When choosing a mirror for a room it must obviously be in harmony with the style of the furniture and decorations. An old gilt frame will look merely shably nmongst very new surrnundings which deniand severity of

Mirror. Figs. 1 and 2. Examples of the Queen Anne period: left, in walnut and marnuetry: right, with walnut and gilded frame

outline or at billiant surface to all accessories and ornanients.

Early English Mirrors. 'The carliest domestic mirrors used in England were of polished stecl, which were found in large houses of the lifth and early lith centurics. A cor poration of olass mirror makers, however, wha formel in Venice in $\mathbf{1 5 6 4}$, and proliably a lew examiples of their work filtered through to England, being sent as gifta to members of the roya fanily and other important perso: ages. Glass mirrors, therefore werc very rare in the time of Elizabeth and Janes I, and authoritice are inclined to suspect the genuine ness of any that are said to date from that perio:d
Mirror makers were brought to lingland. and the first putent for minnufacture was obtained by Sir Rohert Mansel in 1615. But the most important manufictory establisherl was that of the duke of Buckingham at Lambeth ahout 167:3: to collentors of old furniture mirrors inale there are usually regarded as the carliest specimons ohtainahle They had hevelled ongos which in themselves show certain charncteristics of genuine hand work. Ihe angle between the bevel and th? llat surface of the mirror is not mechanically

Fig. 3. Early eiphteenth century mahozany marror with gilt moulding inside the frame
sharp: but is somewhat round, and ocea sionally various facets can he distinguished gralually melting from the level plane of the glass to the angle of the bevel.

Although few examples of the actual glass used in mirrors of the late 17 th century are still in existence their frames are of much interest. Gitinling Gilhons carved at numher of then very elaborately, and some frames aro to be found embroidered with panels of needlework. Others are male of silver or of marquetried end lacquered wood. In the Stuart period framza were usually rectangular, with or without a perliment, and this style was still made in the carly part of Queen Annc's reign. A heautiful example of such a mirror in walnut and marquetry, with a semiciccular perliment is shown in Fig. I

Queen Anns Mirrors. A faniliar form of Queen Anne mirior frame has a graceful arched top, somotimes surmounted by a cresting

elahorately ornainonted. The lovely example shown in Fig. 2 is framed in walnut partly gilded. The bird on the podiment is an exquisite picce of carved decoration. Owing to tho dimeutty of making large-sized platea at this period a tall mirror would show two p!ates of glass joined in the middle just bencath the spring of the arch Nearly all Quecn Anne mirrors now show considerable defects, being spotty and damaged at the back

Although the most beautiful frames were designed nt or $n$ bout this time, the mirrors made in the William and Mary and Qucen Anne periods were not all graceful. Some were, in fact, ugly, owing to their over elahorate crestings or pediments which exaggerated fashion made the rest of the frames appear insignificant, while the carving and ornaments were occasionally conrse and of poor design

Mirror. Fig. 6. Modern mirror wall decoration made in pames and studded with roseftea of glass Ilumplires \& Vera Joel

Mirror. Fig. 4. Mirror in carved mahogany irame. English make, dating from about 1740. Fir. 5 . Convex mirrar in an elaborately carved and gllf wood frame, with candle sconces, datlar from about 1790 Fia. 4. by permiasion of the Director, Victolia d Albert
Museum. S. Kenalngton Fiy. 5, courlesu of Bill it
Reigale

A favourite frame for the commoner type of mirror was a prominent half-round section of walnut. Many examples of this style are seen in toilet mirrors, and some of these are inlaid. Such frames arc reproduced to day for socalled Qucen Anno style cheval glasses. Other mirrors were decorated with lacquer work, and gesso was used throughout the 18th century on many gilded frames.

To collectors the most prized mirrors are those contrining the original Vauxhall glass of the carly pirt of the 18 th century. The best are the wide bulbous ones inlaid with floral arsbesques, and having mouldings which may be as much as 7 in . wide. Some valusble ones have marquetry frames, the marquetry being designed in elaborate seroll work.
Georgian Mirrors. An carly Georgian mirror with a mahogany frame is illustrated in Fig. 3, and a somewhat later example in Fig. 4. The former has gilt moulding on the side of the frame, while the latter, which is elaborately decorated, is also gilded and carved. The workmanship of these is very fine, and they are typical of the early Georgian period, but they lack the supreme grace of the best Queen Anne mirrors. The superior beauty of Fig. 2 to that of Fig. 4 in the balance of the design exemplifies this

Wall mirrors deaigned by Chippendale, the brothers Adain, Hepplewhite and Sheraton were often elaborately carved with classical decorations following in the ma in the French atyles of the period. Chippendale designed many mirrors in Gothic and other architectural styles. During the mid-Georgian period framea of a more severe outline were fashionable Robert Adam introduced Wedgwood plaques or medsllions in the centre of surmounting decorations to mirrors which were sometimes composed of threc plates of glass, n larger one in the middle, and smaller ones at the sides.

Circular convex mirrors were introduced towards the conclusion of the 18th century, and the fashionable furnisher of the day produced a great variety of frames. The one illustrated in Fig. 5 has a deeply moulded gilt frame enriched with balls and sumnounted
by a carvod Lird. Candle sconces are titted to the sides. In some examples these had out glass drops suspended from them.

Pier glasses date from the end of the 18th century, for it then bocame possible to get much larger sheets of glass than wore hitherto available. Moreover, plate glass, which had been first made in France a century before, was now to a certain extent used for looking glasses.

These large mirrors were fixed to the walls between windows, with console tables hencath ${ }_{1}$ or over the mantelahelf, a position which was utilized for their display to evon greater elaboration in the Victorian period.

It was in the early part of the 19th century that the mirror began to be employed in the backs of sideboards, at first in a simple circular convex form Mirrors were also fitted into the lids of worktables, and the toilet table was developend with the mirror as part of the piece of furniture. Cheval glasses were more commonly scen at this time, for the sizes of slicets of glass had increased so that it was possible to provide a mirror to give a full reflection of the figure at a reasonable cost.

In modern furnishing coloured mirror glass is utilized for wall decoration. Mirrors are alao scen with chromium plated frames in severely simple outlincs. Pewter frnmes, with inner borders of coloured glass, ornamented with glass rosettea and studs, are copied from Italinn work Mirrors composed of separate panels and studded with glass rosettes form beautiful mural decorations, as shown in Fig. G, with its Gothic design. Another beautiful modern mirror decorated with a marquetry panel is illustrated in page 769

MIRZAPORE CARPET. Large quan. tities of these Indian floor-coverings arc imported into Great Britain. They arc woven in symmetrical patterns supplied by European buyers to the factories, which turn out each quality at a uniform price per square yard.

Those which are loosely woven, of short staple wool, are the least durable. Large numbers have a light cream tone predominating in the field, with strong reds, blucs, and grcens, which do not mellow with age, but acquire a faded look. Nevertheless, they are nnong the least expensive of any oriental Hoor-coverings, and are often useful for hall or landing in small sizes, and for study or smoking room furnished in simple hut so!id style. They are unsuitable for living-rooms as they are not sufficiently hard wearing to stand family use.

MISTLETOE. This is a parasitic ever. green which grows on the onk, puplar, apple

Mistletoe. Sprig of this iraditional Christmas decoration and other trees. Its berried shoots are in great demand for Christmas decorations. The mistletoo is dioecious, i.e. male and fe. male flowers are on separ. ate planta, therefore all mistletne dors not bear ber. rics. It is esta blished by rubhing $n$. few ripe sceds in ctaoks of branches of suitable trees in Mareh. The secds must be protected from birds by netting or other
covering. Slistlatue grows very slowly for several gears.
In Christmas decorntion schemes mistletoe is general!y a characteristic feature, its pale colours contrasting witl, the vivid hucs of the holly See Christmas.

MISTLETOE CACTUS. The popular name of the genus of llowering plants Rhipsalis is suggested by its appearance. These plants are morecurious than beautiful, and are little grown. They thrive in loam, with a liberal proportion of brokion crock at the bettom of the pot, in order to ensure good drainage. Propragation is by cuttings in sandy lonm. It is wise to leave them in tho sun for a few days before inserting them, as this reduces tho tendency to dnmp. ing off. Cassytha is the bestknown species of this cactus.
MISTRESS. A lady who cmploys a servantis not bound to give the servant a character, but if slic does she must give ono leaves of the species cosagtha honestly. A mistress is not entitled to hreak open a servant's box without a search warrant, or to doduct for breakages from the girl's wages unless tho servant has expressly contracted that this may be donc. Shie is entitled to obedience to all reasonable commands; and it is a reasonable command to request the eervant to wear a proper uniform and also to keep reasonable hours. See Master; Servant.

MITE : In the Garden. Onc of the most seriuls garden pests is the mite, which attacks black currant bushes, cansing the buds to become sivollen and usrleas. Swollen huds should be picked uff and burnt and old brunches or parts of them must be pruned out is soon as the fruits are gathered. The best treatment is to spray with lime sulphur every 10 days between mid-March and mid-May.

The pear-leaf inite forms blister-like spots on the surface of leaves. All leaves attacked should be removed and hurnt; trees should be given a lime-sulphur spraying in early spring. The filbert hud is a microscopic mite which is found on tho huds of filhert, hazel, and cob-nut. The damage is similar to that done by the big bud, and similar treatment is required. See Isig Bud; Insecticide : Lime

MITE : On Poultry. Poultry suffer from the attacks of certain mites. Some live on the birds at night, the red hen-mite, for instance; others are permanent parasites, e.g. itch mites, which live at the bnsc of the fenthers, and cause the birds to eat thein; and others live under tho skin and cause scabby growths, such as are sometimes seen on the legs of fowls.

The best method of dcaling with these mites is by cleansing operations. The poultry house should be fumigated with bi-sulphide of carbon or another agent, while some paraffin in the cleansing wash is excellent for the perches For the mites that cause feather-eating the hird should be isolated and oil of cloves ruhbed into the affected part. See Poultry.

## Mitre Joints in Woodwork

## How to Make and Use a Mitre Boz and a Shooting Board

This contribution supplements those on Moulding and Picture Frame. The principal woodwork ioints are dealt with under apeclfic headings, and other valuable hints are given in the general artiele on Joint. See Cabinet Making: Door; Draver, etc.
The tern mitre is applied to various kinds An example is given in lig I, and Irom of joints formed between two pieces of this it will be seen that the parallel lines material, as, for example, in picture frames and representing the mitreing intersect at the mouldings. The ends are butted together in corner, or angles, as at A. B and C. The such a way that the joint between them correct angle to cut tho mitre is determined bisects tho angle between the external edges by joining the interscctions of the two inner of the matcrial. A right-angle mitre is one lines to that of the two outer lines, as at D, C. in which the mouldings are nt right angles, Having ascertained this angle. the bevel the angle of the joint being therefore $45^{\circ}$. The squaro is set to it, and the angle marked particular object of using the mitre is two-fuld: upon the moulding, which is then sawn off, the contours of the moulding should exactly and tho ends planed or shot true.
meet and flow into each other at the joints, and the inner and outer finces of the moulding shou!d not expnse any end grain.

Mitred jointa are often keved at the corners with a plain or dovetniled key, examples of both of which are illustrnted The simple, flat key shown in Fig. 2 is fitted in very small work, by making a saw-cut in the ends of the mitred parts of the frame In stronger work the key is sawn from hardivood, say; about $\$$ in. thick, and is fitterl into slots made in the ends of the mitred joints by sawing nnd chiselling. The grain of the key is set to run parallel with one of its edges. with the result that when
$\qquad$

In this work. the lengths of all mitreings may be menqured to the inside or from the outside, the latter being usually the most convenient method. Fig. 4 shows how the mitre is marked with the bevel square. Tu facilitate marking a standard mitre template can be used. This is a combination of a mitre template and a square. It can be purchased, or a similar instrument made up from a picce of wood. The wooden tempiate is simply a piecc of wood with a lip, or guide surface, upon it, and the ends accurately mitred to the angles dcsired.

Mitre Box. A box for the cutting of material up to 5 in square can be male from ed in place it has the greatest strength. 3 picces of deal, planel up true on the faces The keyed dovetailed mitre joint in Fig. 3 and edges and measuring 6 in. wide and 1 in . is suitable for framing intended to withatand thick. The length of the 3 pieces should be considerable stress, and is simply an ordinary about 2 [t. (Fig. G gives the dimensions.) mitred joint with a double dovetail formed across it Into the double dovetail a piece of X-shaped hardsood is fitted; when this is pressed into its place in the slots which are cut for the purpose. the joint is firmly held. One of the
 difficulties in mitreing a joint is to determine the correct angle for the mitro. Normally, the The next step is to mark out the sides fur willbcupright, block a line at right angles to the length of or atright the box: project this line to the face of angles to the oach of the side pioces, and saw through to flat surface this lino. Then sct a bevel squaro exactly but it will be at $45^{\circ}$, mark this angle on the upper edges of the side pieces. square off on each of the outer sides of the side pieces, nud agatnsaw through Repeat this operation on the opposite hand, and the mitre box is complete and ready for use. Fig. 6shows the plan of the Lox and the correct angles marked out. Fig. 5 shows how the hand saw should bo held in sawing the moulding, and how it works through the saw-cuts.

The moulding to be cut is pressed into the lower corner of the box and he!d with the
left hand while the saw is manipulated with the right.
A mitre block, useful for cutting small noouldings, is illustrated in Figs. 7, 8 and 9 . It may be composed of a basehoard, 18 in . long, 6 in wide and 1 in thick. and a second board of the same length, about 3 in wide and a hout $1 \frac{1}{2}$ in thick, which is glued and dowelled to the bascboned. It is marked of with angles and sawn thmugh as before. This type is used in a similar manner to the mitre box The first pattem fer The pis is gencrally more convenient for amateur usc, as it keeps the saw upright.

If it is intended to use either of these blocko for a great deal of work. an improvement

Mitre Boz. Fig. 5. Home made mitre
boz in use
 and have strong battens screwed to it to prevent it warping or winding; when not in use it should he hung up and given a prer:autionary roat
of varnish or paint. of varnish or paint.
MITTENS. Knit. ted mittens for men may be worked in a gond 5 -ply fingering. which makes then comfortable in wear, yet warm and strong enough to be worn for ordinary sports, and for shooting and motoring when it is desirable to have the fingera free and uncovered.
Fig. 6. Plan of mitre box, showing correct angles. Fig. 7. Solid mitre block. Fig. 8. Section of block showing necessary measurements

Another piece of batten is ghued and dowelled to the top of the fence at ahout the middle of its length, and this piece has its edges cut and planed to the desired angles, forming a mitre template. The complete shooting hoard is shown in Fig. 11. The work to be planed is held against this angle block with the left hand, and a jack plane is laid on its side. resting upon the haseboard, with the sole of the plane against the edge of the with the right ne is pushed up and down towarls it, thereby cutting the end of the noulding and produeing a surface which is flat, but is inolined at the same angle as that of

Guide pieces or blocks can be made to any desired angle and interchanged according to requirements If the board is intended for regu!ar use it should be grooved on the underside of the bascboard
is to line the guide faces with strips of brass, to prevent the sides of the saw wearing away the material and thereby making it inaccurate and unrelialile in use
Mitre Shooting Board. After moulding has licen sawn to the requisite angle to make

Tomake a pair big enough to fit a hand that usually takes size 8 in kid, 3 oz . White Heather 5-ply fingering will be required, with No. 14 stee knitting needles. The one illustrated had the top of the hand and the top of the thumb where the single ribbing occurs worked with ncedles one size smal!er than the rest of the mitten. This helps to close them to the hand, but it is not ahsolutely necessary to nes other necdlea if they are not at hand, as the ribbing serves the same purpose.

How to Knit. To hegin, enst 24 stitches on each of 3 needles, making 72 altogether; join them into a round as for stocking knitting, and work a plain round through the back of the stitches to give a firm edge. For the wristlet, work in ribbing consisting of knit 2 stitches and purl 2 alternately all round; this is known ns double rib, to distinguish it from the single rib at the top of the mitten, which consists of knit 1 stitch and purl 1 all round. Repeat the double rib for 32 rounds, then linit a
plain round, taking together every fifth and sixth stitches to reduce the round to 60 stitches. Knit 6 more plain rounds for the hand on these 60 stitches, then begin the making of the thumb gusset.

Arrange the stitches on the needles as follows : 24 on each of 2 necdles and 12 on the third, which is the gusset needle. The first round begins on the needle containing 12 stitches, and is worked as follows: Knit 12, then lift up the loop right under this last stitch and knit it : finish the round plain. Now knit 3 rounds without any increase on the gusset. For the fifth round, hnit 12 stitches on the gusset needle, lift up the loop below the 12th stitch and knit it. Now lift up the loop below the last stitch on the needle and hnit it, then linit the last stitch Finish this round plain, then do three more complete rounds plain. In the next round increase again alter the 12th stitch, and again below the last stitch before knitting the latter off the necdle. Continue working in this way with three rounds between every increase round, unt il there are 29 st it ches on the gusset needle altogether. This completes the thumb gusset.

The top of the hand is now continued a hove the thumb. To divide the thumb stitches, first knit 11 stitches off the gusset needle, and pass the remaining 18 stitches on a safet $y$-pin to put them aside for the present. Cast $\mathbf{4}$ stitches on the same gusset needle, and these will come at the back of the thumb, and link up the hand
 stitshes intn n complete round. Knit the remainder of the stitches in the round, then knit 18 rounds of plain knitting on all these stitches. Finally do 10 rounds of single ribbing to close in the top of the mitten, and cast off fairly loosely, so that the edse is not too tight. Tocomplete the thumb, take the stitches off safety-pin and divide them equally betureen two needles, then lift up 4 stitches at the back of the thumb, where they were cast on beforc, putting the needle through the edge of these 4 stitches and knitting the loop so picked up. Join these stitches into a round and knit 6 rounds plain. In the next round knit together the second and the third of the 4 stitches that have been picked up at the back of the thumb and do 5 rounds of single ribbing to match the top of the hand, and cast off. The second mitten is the same, as they are reversible. Sce Glove.

MIXED GRILL. A good mixed grill is provided by cooking together in front of a clear fire or beneath a gas or electric grill a sheep's kidney, a slice of bacon, a chop or a piece of steak, and two or three mushrooms, or a tomato. Trim the chop or steak neatly,
cut topen the kidney and remove the skin and part of the shoe, which is finished by thonging core, peel the mushrooms or cut the tomato in half. Brush all over with a little melted butter, and sprinkle them with pepper. Rub the gridiron with a piece of suet and heat it.
Cook the meat for 10 or 15 minutes, adding the mushrooms when it is half done. Serve the grill on a hot dish, with a little lemon juice sprinkled on each mushroom. See Grilling.

MOCASSIN : How to Make. The N. American Indian word mocassin describes a st yle of hcelless slipper. As worn by the
Indians, it is made of deerskin and ornamented with embroidery and bcadwork. Monas. sins are easily made at home. Soft suède, which can be bought in many colours, is a suitable material. The lining can be of lamb's wool, or any soft, lleecy woollen material, while appliqué suède flowers in contrasting colours

Heavy wool-backed velour, the kind of which curtains and furnishing coverings are madc, is a suitable material for mocassins.

Mocassins made in this way look well lined with the same material, so that the velour should be cut out and made to fit the foot on the wrong side as well as on the right side. Stitch all the pieces firmly in position, then slip the lining right side out and into the outside piece. Sew the elges together and bind them with a ribbon ruching or narrow fur. Cut out a single triangle in velour for the top piece and embroider this boldly in thick wool or chenille, then tack it in position. See Leather; Poker Work.

MOCHA : The Coffee. Mocha is a variety of Arabian coffee, excellent in Havour and quality, which is used in the
or coloured beads are effective for decorating. Mocnssins are made in one piece, which is cut large enough to cover the sole of the foot and to draw up round the instep. To make them from suède, procure two good-sized skins of the desired shade. Use the sole of a shoe as a guide in cutting out and cut the skins in an oval about 3 in . larger than the sole all the way round. Punch holes $\frac{d}{d}$ in. apart with a stiletto round the edges and cut some thin strips of the suède, about $\frac{f}{} \mathrm{in}$. thick. Thread these in and out of the holes, leaving plenty of length of the suede as draw strings. Put the foot into the flat part and draw up the suede strings round the instep, fastening securely when the right aperture is secured.

The mocassin should fit snugly and yet be loose enough to allow the foot easily to be slipped in. If the size should be too big, make the mocassin smaller by punching an inner series of holes and drawing the thread through these, cutting away the surplus material. The fullness should be arranged to come at the toe end and at the heel. If jreferred, instead of gathers at the back, the fullness can be folded in two pleats, or a slit can be made and a triangular piece cut out, the ends being neatly drawn together with strong thread.

When the mocassin tits correctly, cut out in the same way a piece of rabbit fur for lining, making it about 1 in . larger than the sucde. P'in it, or tack it over in pleats, to make it the same size in the foot, then cut away the surplus fur underneath the pleats and sew the pieces securcly together, on the wrong side.

Next turn the fur right side out and slip it into the suede mocassin, allowing the fur edges to overlal, the suede and to form an edging. Cut out a triangle of suede to cover the toe front and nick this along the edges to make a fringe. Tack this on to the top of the mocassin to neaten the part that has been gathered, using a contrasting coloured thread. This triangle can be trimmed with beads, or have a design cut out and a strip of brightly coloured suede slipped underneath to show the pattern.

If lambswool or any woollen material is used as a lining, the two edges should be sewn together, and bound with ribbon or narrow fur. Mocassins can also be made from coloured pigskin and decorated with poker work. The we piece has a suitable design traced on it. This is outlined in poker work and afterwards coloured.

The mocassins illustrated are thonged round the toe piece, and this is attached to the main
ame way as other varieties of coffee, but rather less is required, as the Havour is strong. The name of mocha is often given to cakes, biscuits, cte., in which coffee flavouring is used. See Coffee; Coffec Cream Sandwich.

MOCHA : The Glove Leather. Rea Mochn leather, as used for gloves, is a strong heavy skin prepared with a soft, velvety surface and wears better than suède, with which it is sometimes confused. Suèle is glove leather finished flesh-side out, but in moclia the hair side is uppermost, although the grain surface is rubbed away.

Mocha is an especially suitable material for men's and winter gloves, for slippers, tobacco pouches, sports coats, and aviation clothing. Its freshness can be renewed by the use of a wire-bristled brush. Mocha is obtainable in sc:veral colours, and especially in brown shades. See Glove; Leather; Tobacco Pouch, etc.
MOCHA FINGER. To make the iced, finger-shaped cakes known as mocha fingers, break 2 eggs into a basin, add to them 3 oz . castor sugal, and whisk them well for about 10 min . or until they are thick. Fold in $\frac{\mathrm{l}}{\mathrm{l}}$. sieved flour, adding a little milk if required, and put the mixture into somo well-greased tins.
Bake the cakes in a hot oven until they are of a pale biscuit tint, and leave them to cool on a sieve before coating them with coffee icing. A small piece of shelled walnut mav be placed in the centre of cach cake. See Cofice Icing.

MOCK HARE. To make this, fry 3 oz. bacon cut into dice in a stewpan, and when it is lightly browned add $1 \frac{1}{2} \mathrm{l}$. stewing beef, cut into small pieces and coat with sensoned flour. Continue frying for a few minutes, then add 3 pint stock, a bouquet garni, some grated lemon rind. and an onion stuck with cloves. Stew all slowly in a covered pan until the beef is tender, then put in a wineglassful of port. some lemon juice and red currant jelly and gerve it with forcemeat balls. See Bouquet Garni ; Forcemeat.

MOCK ORANGE. This is one of the loveliest of all hardy lowering shrubs Its botanical name is Philadelphus. It is often miscalled syringa. The mock orange flourishes in well tilled soil, flowers in early summer and is increased by cuttings inserted out of doors in autumn. The common mock orange (coronarius) grows 10-12 ft. high, and bears white fragrant Howers; grandiflorus has finer flowers but they have little scent. In recent years many heautiful cross-b:ed
mock oranges of less vigorous gmwth have been raised: they are ideal flowering shrubs. Some of the best are Virginale, Rosace, Bouquet Blane and lame Blanche, all bearing white double flowers. Lemoinci, a slender growing shrub 4 ft . high, bears small white llowers frecly. These newer linds must be prined as soon as the flowers have faded by cutting out old branches and shortening others to where fresh strong shoots are developing.

MOCK TURTLE SOUP. Blanch half a calf's head for 10 min ., put it into a stewpan with a gammon rasher cut into dice and about 2 lb . knuclile of veal, well chopped, a carrots. 2 turnips, 2 leeks, $\frac{1}{2}$ head celery, or a teaspoon ful of celery sced tied in muslin, an onion stuffed with 2 cloves, a bouquet garni, and 2 shallots. Acld 3 quarts cold water and set the soup on the fire to boil ; skim it well and let it simmer gently for about 3 hours.

When the head is tender remove the pan from the fire. Take up the head on to a dish and bone it. removing the tonguo. Strain the etock and put it on to boil, and while it is heat ing up brown 2 oz Hour with $1 . \frac{1}{2}$ oz butler in a small saucepan: stir continually with a wooden spooin, and when it is a dark brown colour mix in by degrees suflicient of the hot stock to make a thin paste. Pour this to the stock, which should now be boiling, and cook for 5 min , stirring all the time. Remove the scum as it rises.

Add 2 glasses sherry, the juice of $\frac{1}{2}$ a lemon. and seasoning to taste. Cut about half the meat fmon the head into dice, lay these in a tureen and pour over them the boiling soup.

Mock turtle soup may also he served clear in which case follow the above recipe, but omit the butter and llour. Also after the stock is made it must be allowed to get cold so that every particle of fat may be removed. It should be clarified as described for clear soup. See Soup.

MODELLING. The modolling of animals is an attractive pastime. Bears, lions, and many other animals can be sawn to shapo from thin pieces of wood, provided with sep arate legs obtained from similar pieces, and assembled logether. They should be very strongly made, and all the joints well glued and pinned together. Bright colours and simple outlines should be the guiding features

Plasticine, plaster, and similar materials also lend themselves to the construction of toys Modelling in cork may also be included and may coinprise nothing nore elaborate than $n$.few quaint figures oil painted. or may

Mock Orange. Fragrant white blooms and glosss leaves of this heautiful hardy flowering shrub
take the form of a model of a house, bridge, or any other building made up from small pieces of cork fixed together with seccotioc and pins
The use of lagge pieces of cork, toycther with other materials. such as cardboard, stiff paper, brown paper, green baize, and linen, enables more ambitious worls to be carricd out Particularly interesting is the modelling to scale of an old village Papor pulp, made by soaking old newspapers and then thoroughly atraining out the water, provides a material, when mixed with gum, that can be modelled into shapes that are difficult to oblain in any wther way further particulars are given in the article on Papier Màché.
An interesting occupation is to reproduce to a small scale either a favourite seaside resnrt or some notable or historic sceno. In carrving out this work, cork should be the main material used, as it is ensily shaped with a sharp knife. large pieces of work may lu modelled in sections and glted together, and if the surface of the material is coated with size, oil paints can lee employed with considerable effect.

Another excellent material for modelling is chalk, which is obtsinable quite easily in many parts of the country. It can be cut to all sorts of shapes with no other tool than a penknife, and it forms an ideal material for relief carving Scalc morlels of stone buildings may be made by using sawn blocks of chalk: a fine tenon saw will serve, and the surfaces can be joined by first coating them with size and applying seccotine when dry
The chalk can be atained and coloured with water colour. Various stages in the development of architecture may be shown by utilizing cork and chalk, and the materials may be combined in maling scale models of famous buildings and old ruins. If chalk in blocks is not readily obtainable, a good subs'itute, easily worked, can be made from plaster of Paris mixed with water and poured into rough moulds Gesso and barbola paste can also be used for this purpose
Modelling Wax. For modelling flowers and fruits pure beeswax is used with a small proportion of lard or olive oil. The wax employed for kindergarten purposes contains becswax, paraffin wax, sesame oil and sulphur. See Gesso: Papier Mâché. Sealing Wax.

MODILLION. This is a word used in architecture to describe a block or bracket used beneath a Curinthian or other cornice, and when so used it is generally enriched or modelled. When employed in a cornice of tho Roman-lonic order, it is plainer in character to suit its surmundings See Capping
MODULATION. In wireless telephony. this is the procedure whereby oscillations of audible f́requency (speech. music, etc.) arc caused to vary the amplitude of tho carrier wave (e.g. that sent out by a broadcast transmitter). See Carrier Wave: Microphone: Telephone.
MOELLON. A mixture used in mason's work, and composed of rubble, stone, and mortar, is known as moellon. It is employed as n tilling to fill up the cavitics between two wall faces built with blocks of stone.

MOHAIR : The Fabric. Properly used, the term mohair signifies yarn or fabric made from the bair of the Angora goat The fabric resembles alpaca, though somewhat coarser. Mohair goods are familiar in several forms, and at one time the braids used on coats and costumes were of this material, instead of artificial silk, as at present. The bootlaces described as mohair are actually cotton Mohair mats and door slips are much used, and must astrakhan, Persian lamb, Teddy bear fabrics, and imitation tiger skin rugs are molhair.
As a dress stuff mohair is generally mado with half cotton, and although cool, clean, bright and durables it is somowhat stiff and
not suitable for draped dresses. Manufactured hy a special process, mohair and mohair and wionl dress goods can be made more lisson. Mats and rugs are often made partly in plain and parily in curled plusle When used as lloor rugs the materia! is sewn upon n heavy jute hacking Mohas plush travelling and motor rugs wear well, talie little damage from wetting, and dust is easily shaken from them. Upholstery mohair fabries are durable and enssess a good dust resisting surface. See Bootlace: Upholstery

MOIRÉ. In order to see a moiré appearance take any light. plain, open-textured fabric like thin silk or canibric, fold it lightiy whid hold the doubled material up to a nond light. An irregularly clouded figure formed by the crossing of the lines will ve seen. These markings, or waterings as they are called, can be permanently fixed upon suitable cloths Goods with ribbed surfaces give the best resulte, and the larger and less uniform these figures are the more they are admired.

The markings are made by laying one wet surface of cloth over another and using very heavy pressure to impress the ribbedness of one surface upon the other. That is not the only method, for moire markings of a less uneven character are obtainable by embossing the cloth between engraved, countersunk rollers under henvy pressure Moiré markings are seen on silk ribbons and dress silks, on velvet, worsted moreens and the cotton material known as moiretto, as well as on book binding cloths.

MOLASSES. The term molasses is seldom used in English cookery books, but in America the word is used synonymously with treacle. Molasses are the drainings of the raw sugar ; while treacle is the syrup which runs from sugar during the process of refinement See Sugar; Tracale.

MOLASSINE. This name is that of a varicty of meals and biscuits designed to meet the requirements of dog owners and poultry keepers. The biscuits are liked by dogs, and for the poultry farmer practically everything is supplied from chick food to meals for laying hens. See Dog; Poultry.

MOLE: The Fur. This is not a hard. weating fur, the leather being very thin, but what it loses in wear is compensated to some extent by the artistic shapes into which its pliancy and softness allow it to be made. Moleskin may he cleaned by means of hot bran

Momordica. Climbing plant with ornamental foliage aud reddish fruit, also known as balsam apple
which is rubbed in with tho tips of the tingers For cutting the sking of the mole an extremely sharp knife should be utilized, the skin split up the belly, the head and feet cu of, when the carcass can be readily removed The skin, freed of dirt and biood, should be stretched on a board, fur side under, and fastened at the corners with tacks It should be allowed to dry, and when a sufficient quantity has been collected the skins should be sent to a furrier to be dressed See Fur

MOLE: On the Skin. Certain tumour formations in the skin are known as moles In one form they exist as slight elecations of the skin of a light brown to a black colour, and are not infrequently the site of hairs.

Several ways of removal of moles are avail able to the surgeon, including carbonic acid snow, electrolysis, X rays, and excision

It cannot be loo strongly emphasized, how eier, that any altempt al home treutnent of moles by caustics or any similar means is most danjerous, nearly always increasing the disfigurement, and possibly converting i into a malignant growth.

## See Birthmark: Electrolysis

MOLE: In the Garden. Generally the mole is of service wagriculture as an exter minator of grubs, slugs, wireworms, and other harmful things, but it can only bo regarded as a pest where the flower or vegetable garden is concerned. Unless quickly caught it will cause great harm, particularly among rows of potatocs or other vegetables growing in well manured, loose drills of soil.

The best way to capture moles is by mean ${ }^{2}$ ul an iron mole trap, sceking the run with a spade, and setting the trap across with a covering of earth. When handling the trap gloves must be irorn, otherwise moles, with their acute sense of sme!l, will avoid the trapped run, and take to another. It is usc less to place the trap in a mole-hill. Anothe: remedy is to make holes here and there with a dibber, drop in picces of carbide, filling the holes with soil packed fairly tight. Doga such as the sharp fox terrier, mav quickly be trained to watch for moles at work.

The animals usually work at 2 a in., 6 a.m., and again at 9 p in . Round about these times their heaving up of earth may be noticed; but the watcher must approach his quarry very gently, as they are extremely sensitive in vibration and smell.

MOLE CRICEET. This fierce-looking insect with lobster-like, head and clawed forefect is sometimes seen in the garden. It lacerntes the roots of plants as it burrows with its mole-like forelegs. It may bo drowned with paraffin emulsion poured down ite holes. In some localitics a thin stick is thrust down and often the insect will grasp this, allowing itself to be drawn to the surface and killed

MOMORDICA. These climbing plants are valued for the sake of their ornamental fruits, which are suitable for cultivation in a hothouse. They are raised from seeds sown under glazs in spring, grown in large flower pots or planted in a border of soil and trained on a trellis or other support. The balsam apple (Momordica balsamina), an annual with orange coloured fruits. is one of the chief species.

MONARCH OF THE EAST. This is a half-hardy tuberous rooted plant (Sauromatum guttatum), which will flower on the mantelshelf of a living-room. The inflorescence is in the form of a greenish-purple spathe, some. what similar to that of the arum lily. The tuber should be purchased in the autumn and will then come into bloon during winter or early spring. When the stem has died down the tuber should be potted or it may be planted out of doors for the summer months. The leaves will then develop. When these have died down the tuber is taken out of the soil and again placed on the mantelshelf.

MONARDA. This is the botanical namo of a acented-lea ved hardy herbaceous perennial. known as sweet bergamot and bee balm See Bergamot.

MONEY ORDER. In Great Britain moncy can be sent through the ordinary post by means of money orders and postal orders. Money orders are more suitable for uneven sums of money, such as $£ 27 \mathrm{~s} .8 \mathrm{~d}$., and for comparatively large ones. They can be purchased from any post office that is also a money order office, for any amount up to $£ 40$. The charges for an order are 4 d . for one under $£ 3$; $6 d$. for one between $£ 3$ and $£ 10$; 8 d . for one bet ween $£ 10$ and $£ 20$; 10d. for one between $£ 20$ and $£ 30$; 1s. for one between $£ 30$ and $£ 40$.

An order is made payable at a particular money order office, and there the person to whom the money is sent must go to obtain it. On giving his name, the amount of the order and other particulars, it will be paid. Money orders can be sent by telcgraph from any money order office, the extra charge being the cost of the telegram and 2 d .

Money orders can also be sent to ncarly all parts of the British Empire and to France, Italy, and other European countries, also to the U.S.A. and Japan. The charges vary, but particulars can be obtained from any post office. To certain countries money orders can be sent by telcgram. See Postal Order.

MONEYWORT. This is the popular name of Sibthorpia europaea, a hardy creeping plant with small, pale pink, anapdragon-like flowers in summer. A shady place in the rock garden is suitable, or it and the colouredleaved varieties may be grown in suspended pots or baskets in the greenhouse. Propagation is by division in spring.
Monkey Flower. This is another name for the plant usually known as musk (q.v.).

MONKEY FUR. Employed almost ex. clusively for trimming purposes, monkey fur has a somewhat shaggy unkempt appearance, and takes the form of narrow strips which may be purchased by the yard. Like all other dark. coloured skins, monkey fur may be clenned by means of silver sand.

MONKEY NUT. In Great Britain the monkey nut, or pes nut, is a hothouso annual. The seeds may be sown in a temperature of about $70^{\circ}$ in springtime, in pota, in a mixture of loam, leaf-mould, and sand. The yellow flowers are borne in May and June, and the sced pod den plant. See article above the sced pod
usually droops
and ripens in the soil. There is only one and ripens in the soil. There is only one
species, Arachis hypogaes. species, Arachis hypogaea.
MONEEY PUZZLE TREE. The name of monkey puzzle is given to a cone-bearing tree, Araucaria imbricata, with wide-spreading branches, which curve upward. The foliage is stiff and sharp at the edges. This tree thrives best in country gardens in deep loamy soil. It is apt to lose its lower branches in towns and suburbs. The only other Araucaria which is cultivated in Great Britain is A. excelsa, which is a half-hardy tree; small specimens make good room plants.

MONESEOOD. Monkshood is the common name which is given to aconite by reason of its hooded flowers. Although poisonous in all its parts, monkshood is an attractive and frec-flowering perennial of distinct value in the garden, especially in shady placer The common blue monkshood is Aco. nitum napellus; the blue and whitc variety, bicolor, is more attractive. Wilsoni and Fischeri are other good blue monkshoods. The plants, which grow 3-5 ft. high, should be left undisturbed, as they are slow in establishing them selves. See Aconite: aiso illus. below.

## MONOGRAM.

 Two or more capital letters combined in one form what is termed a monogram. A good example of this is scen in the diphthong A. Initials formed into a monogram and cut out in thin tin or zinc can be used for marking linen, books, etc. Another method is to engrave or etch the monogram on silver.In designing a monogram, legibility must be considered, and in arranging initials it is often advisable to give prominence to the initial letter of the surname; this may be cffected by enlarging the letter or by utilizing colour. Roman lettering lends itself to gristic arrangements, the best method being to commence with the principal letter, work out as many combinations as possible, and then decide on the best. A symmetrical letter is the easiest to commence with, and where other letters can be arranged in an 0 or C , the work will be comparatively simple. Some combinations of letters are very awkward to arrange, but it is generally only a matter of practice.

Examples of two and three letter symmetrical as well as non-symmetrical arrangements are illustrated. All the examples are suitable for stencil cutting, but care must be taken to arrange the ties between the letters. Monograms are quite as effective in embroidery as initial letters, the method employed in stitching being the same. Interlaced letters as the $O$ entwined, or the C placed back to back, are often mistaken for monograms, but they are ciphers. See Initial; Lettering; Stencilling.

MONSTERA. Only one species of this evergroen climbing hot-house plant, Monstera delicioss, is usually cultivated. It has large green, lace-like leaves and many surface roots; the flowers, which come in summer-time, arc ycllow, and are followed by fruits. The plants require a danip, warm position in the heated house, in the usual mixture, and should be inserted in springtime. They require liberal syringing during the summer months, and may be propagated by cuttings.

MONTBRETLA. This is a splendid late summer flower in shades of orange, orangecrimson and yellow. The flowers are in spikes which rise above the iris-like leaves. The older kinds, e.g. crocosmiaeflora and Pottsii, may be planted out of doors in spring and left undisturbed for several years until they become overcrowded; they ought then to be lifted, divided and replanted in autumn. Recently many handsome new large-flowered varieties have been raised; it is usual to start the corms of these into growth in pots
of soil placed in a frame in March and la plant them out of doors in May. They should be lifted and stored for the winter to obtain the finest results. A fow of the hest of the newer sorts are His Majesty, crimson and old
 gold: Goldfinch ycllow; Lemon Qucen, pale ycllow ; Marjoric, orange yellow and crimson There are numerous others. Montbretias thrive in ordinary well-tilled soil ; on heavy land leaf. mould and sand should be mixed in.

## MONTEITH

The name is given to a vessel made in the eightecnth century, and used for cooling wine glasses. Not unlike a punch. bowl, it is usually of silver, and has a scalloped edge and a inovable or open work rim. See Punch Bowl.
MONIH. This is a period of time. There are 12 months in the year, known as calendar months, to distinguish them from the period of 4 weeks, which is known as a lunar month. The number of days in each calendar month is as follows :

| Jan. 31 | May 31 | Sept. 30 |
| :--- | :--- | :--- |
| Feb. 28 or 20 | Junc 30 | Oct. 31 |
| March 31 | July 31 | Nov. 30 |
| April 30 | Aug. 31 | Dec. 31 |

Legally a month usually means a calendar month. A person whose salary is paid by the month reccives 12 payments a year, receiving the same amount for the 28 days of Fetruary as for the 31 of March. Likewise a person who gives or receives a month's notice must reckon it, not as four weeks, but as a calendar month. A notice given on Feb. 19 takes effect on March 19, and so on. Each of the months las certain special features for the gardener and the housewife, and these are given in this

Montbretia. Hardy plant with brilliantly colourod fowers ranging from red to pale yellow
work under the various headings See April Calendar: February; March, etc.
Monthly Rose. This is another name for the China rose. See China Rose ; Rose.

MOODS: The Game. The game of moods affords a pleasant varinnt at parties, especially those for adults or elder children. One person leaves the room, and the others decide what mood they will be in. They may choose a laughing nood, an insolent mood, a sorrowful mood, or any other. Then the person outside returns and asks questions from the players in turn, the object being to find out from his method of answering what mood has been chosen. When he has guessed correctly another player takes his place. Any question is permissible. The game is also known as ndverbs.
MOON DAISY. The moon daisy (Pyreth. rum (chrysanthemum) religinosum) will grow almost anywhere under any conditions, reaching a height of 4 ft ., and flowering profusely with large daisy-like thowers during late summer. It is excellent for garden decoration or for yielding llowers for cutting. It should be planted in nutumn or spring, and increased by division of roots during the same periods. It is advisable to lift roots and divide them every threc years. See Chrysanthemum; Daisy.

MOONSEED. The leaves of the moonseed, or Menispermum, are not unlike those of the ivy. The plant is a hardy flowering climber with yellow blossoms in summer and grape-like black fruits later on. Menispermum canadense is of rapid growth, and suitable for covering walls, arbours, fences, pergolas, trellises, etc: Moonseed thrives in almost any soil and situation, and is propagated by cuttings or division of the roots. It should be prined early in the year.

MOONWORT. Soldanella, or moonwort, is a family of rock garden plants oi the primula order, with bell-shaped, nodding, fringed flowers in spring; height about 3 in .

Moonwort. Bell-shaped flowers of this Alpine plant The favourite is Soldanclla alpina, with violet - coloured llowers; pusilla has blooms of similar colour The moon. worts like a compost of loam and peat with sand. They are best suited by a damp position, and will not thrive on a hot, dry site. They protected by raised pieces of glass in winter to keep off excessive rains. Propagation is by division in the case of strong tufts in September. The plants may be raised from sced sown in a frame when ripe.
MOP : For House Work. There is a use for mops of all sizes in the ordinary household. Most people are familiar with the long-handled $t$ ype, invaluable for dusting and polishing Hoors and wainscot. Such mops, if well shaken after use, do not need washing often.

A small mop, the head of which is made of unbleached coston, soft and absorbent, may be used for washing up. It anves the hands, and is particularly biseful for cleaning juga or cupls or any kind of lluted work. These mops should be treated lilie dishcloths, and be washed

Moon Daisy. Profusely flowering plant useful both lor Rarden borders and for bouse decoration
in soda-water after use, and hung up to dry Their cost is so moderate that they can he replaced frequently, and there is no need for them 10 grow dirty or straggly. They are usually provided with a loop at the end of the handle by which they can be suspended a hove the sink.
MORAINE GARDENING. The possession of a morainc, which, in gardens, is a mixture 12-18 in. deep of stones with a little sifted soil added, enables the gardener to cultivate certain difficult ligh alpine plants with greater success than is possible in the rock garden proper. The reason is that the perfect drainage afforded by the moraine l-aeps the plants reasonably dry in winter yet conserves the moisture in summer. Such difficult alpine plants as eritrichium, Centiana verna, Dianthus alpinus and others should be planted in a moraine; there also the silvery saxifrages, dwarf campanulas and others llourish.
MOREEN. Shiny on the underside, ribbed and with wavy moire markings on the upper surface, moreen is usually self-coloured. 13oth
moreen and moirette can be used with good effect to make blotting book covers, stout curtains for cuphoards and alcoves, and they wear well as covers for cushions and chairs See Moiré.
MOREL. The edible fungus morel, similar to the mushroom in appearance, is considered by epicures to be superior to it in Havour. See Mushroom.

MORELLO CHERRY. The dark-red morello cherry flourishes in chalky soil, and may be grown as a standard in the open or against a north wall. The morello cherry is not suitable for dessert purposes, as its acids never turn to sugar so completely as they do in other varieties, and its flavour is not pleasing to the palate. See Cherry; Cherry Brandy; Fruit.

MORINA. The chief species of the harily herbaceous perennial morina is longifolia. This has thistle-like, spine-edged leaves and whorls of purple flowers in summer; its height is about 2 ft . It likes a friable soil. Propagation is by division in autumn or spring, or by seeds. See illus above.

MORNING GLORY. This is one of the many names of the genus of plants Ipomea. It includes stove, greenhouse and hardy annual and perennial climbers, all belonging to the order Convolvulus (q.v.).
MORNING ROOM. As its name implies, the morning room serves the purpose of a
breakfast room or a sitting room in the early part of the day.
A morning room should face south-east, more east than south, so as to make the most of the morning sunshine. Its furniture may consist of $n$ round or oval table for breakfast or an informal lunch, a bureau for correapondence and the keeping of the household books, a firm table which can be used for sewing. a cupboard for keeping needlework and odds and ends, or an oak chest, and a couple of comifortable chairs in addition to those needed for tho table. See Sitting Roon

MORNING SICKNESS. One of the earliest signs of pregnancy is sickness, which conmonly occurs when the patient riscs. It commences towards the end of the first nonth, and continues for a month or two, not usually lasting beyond the fourth month. Sometimes it occurs in the evenings, and at times the sickness may continue throughout the day. In that case nedical treat. ment is neces. sary.

In ordinary casca no treatment is called for. It is a good practice, however, to take a tuinbler of hot water or a cup of very weak ten on awakening, and to remain in bed for an hour after

Morina. Thistle-like qoliage and purple flower of the species longifolia. See article below constipation exists, a purgative chould be taken occasionally. A useful lavative consists of 1 oz each of confection of sulphur and confection of senna.
MOROCCO. This is a variety of leather Originally it was made from goat skin by the Moors, and won a great reputation owing to the way in which it was prepared, one point heing that it was dyed before it was tanned To-day, in addition to genuine morocco made from goat skins, there is imitation moroceo

Morning Glory. Specimen of the flowers produced by this climbing plant
made from calf skins and sheep skins. Indeed, owing to the fact that the graining and finish, which are the distinctive mark of morocco, can be imitated by machinery, morocco can be made from all varieties of thin leather. It is used, among other things, for binding books, handbags, and covering furniture. See Leather; Upholstery.

MORSE CODE. This is a system of signals for radio, telegraphio or visual communica. tion, whereby letters of the alphabet, numerals, punctuation marks, etc., are transmitted either as a series of dots or dashes, or as a combination of both. The International Morse code signals are given below.
A dash is of longer duration than a dot, being equal in length to three dots. The time interval between signals which together make up any particular letter is equal to one dot. The interval between any two letters is equal to three dots, and the interval between any $t$ wo words is equal in duration to five dots Full details of the various signals and abbreviations used in radio are given in the Handbook for Wireless Telegraph Operators published by H.M. Stationery Office. This can be obtained from Adastral House, Kingsway, London, W.C., or through any bookseller.
INTERNATIONAL MORBE CODE BIGNAL8

MORTAR. Mortar is a mixture of lime and sand, or similar materials used for making the joints between brickwork and in numerous other building operations Its purpose is three-fold: to distribute the pressure or weight through the brickorork, to cause the bricks to adhere, or bind together, and as \& non-conductor, preventing the transmission of heat and sound, and rendering the wall impervious to water. These functions are governed largely by the proportions of the mortar and the method by which it is applied.

The strength and impermeability of the wall depend very largely upon the mortar. Bad mortar allows wet and rain to find a way through the wall; it rapidly crumbles away, and is invariably the chief cause of the rapid deterioration of the building. On the other hand, a good mortar makes a wall drier, stronger, and more durable.

In many districts of England and Wales the by-laws provide for the quality of the mortar which shall be used, and generally these require that all brick and stone work shall be put together with good mortar, or good cement, and that the mortar must be composed of lime and clean sharp sand, without earthy matter, in the proportion of 1 part of lime to 3 parts of sand. Portland cement mortar may be made with good quality Portland cement, in the proportion of 4 parts of sand to 1 part of cement.

In the preparation of ordinary mortar the first consideration is the quality of the lime. Excellent mortar can be made with lime, such as lias limes, mixed with sand in the proportion of 1 to 2. The Portland cement should conform to the standard specification of the British Portland cement manufacturers. It is best to purchase the lime from a reliable builder's merchant, and to specify a hydraulic lime, such as, for example, blue lias

## Slaking the Lime

Lime has to be slaked, by adding water to quicklime. One way is to excavate a cavity in the ground, line it with rough boards, put the rough, or lump, lime into the hole, cover it with water, and leave it for about a month, at the end of which time the lime will be in a soft, creamy-like state, and should be entirely free from lumps of any kind. The lime should be kept covered while it is slaking, to prevent the dust and dirt getting into it, but the covering should be supported on rough bricks or posts, so that air can have free acoess to the surface of the lime.
If the lime is not properly slaked, it will continue to work and expand, with the result that the mortar joints will be cracked, or, in bad cases, the brickwork itself may be displaced. Another method sometimes used, especially for small, quick jobs, is to mix the lime and sand together in the proportion of 2 parts of sand to 1 of lime, and sprinkle them with water from a watering-can having a rose head, applying as much water as the material can absorb, repeating the process from time to time during the day, continuing until the lime is thoroughly slaked. In any case, the lime should be left as long as possible to temper.

When Portland cement is used for making mortar, the mixture should be knocked up, or prepared, immediately prior to its applica. tion, as cement mortar sets hard very quickly, and must be used immediately it has been prepared; otherwise it will become set. After that stage has been reached, if it is again knocked up, and more water is added to make the mixture workable, it will seriously diminish its strength. Lime hardens by exposure to the air, whereas Portland cement hardens by the presence of water. For this reason, lime mortar should only be used in dry situations, and cement always where dampness has to be resisted.

When applying the mortar, the bricks should be dipped in water or otherwise wetted, as if they are used dry, they will absorb moisture too quickly for the mortar, with the result that it will crack or may possibly crumble.

Lime mortar works with a fat or greasy feeling, whereas cement mortar is very harsh, and far more difficult to use, for which reason a common practice is to make up a mortar composed of 1 part cement, $\frac{1}{2}$ part of lime, and 2 or 3 parts sand. This mixture works much better, and for many purposes is quite satisfactory. Mortar is applied with a trowel or

Hoat, according to the nature of the work. In bricklaying, it is most important that the vertical joints between the various brick courses be thoroughly filled up, or flushed up, as it is termed, with mortar. Walls are covered with mortar, the process being known as rendering (q.v.). Various modifications of the constituents of mortar are used for such specific purposes as plastering the interior of a room, or plastering on lathing.
Mortar Board. Boards that are lastened together with battens to make a table or platform about 3 ft . square are used to support a quantity of mortar, and should be placed adjacent to the spot where the work is being done. Almost any strong, fairly smooth boards will do, the only requirement being a level and solid surface The boards should not be badly split, nor should they have holes through them: otherwise a large quantity of mortar will find its way through and be wasted. See Brick: Cement; Plaster.

MORTGAGE. A mortgage is a sum of money borrowed on the security of buildings and land. The person who lends the money has control of the property, which is conveyed to him by legal documents. He is called the mortgagee ; the person who borrows the money is the mortgagor.

Many houses are built with borrowed money, and building societies, bankers, insurance companies, and private individuals, usually through their solicitors, lend money in this way. In each case a mortgage is created. They will lend usually up to two-thirds of the value of the house or land. The interest charged de pends upon the state of the money market, and is usually paid every six months. The mort gagee can withdraw his money at any time upon giving the necessary notice, which is normally three months.

If the money is not repaid, or if the interest is in arrears, the mortgagee can either sell the property or foreclose. In the former case he must hand over to the owner of the property any balance that remains after the mortgage, interest and expenses have been met. Foreclosing means that the mortgagee becomes the owner of the property. To do this he must obtain an order from a court of law that unless the borrower pays up within a fixed time he shall lose his equity of redemption, i.e. the right to repay the mortgage. If the mortgagee sells the property and does not realize sufficient to pay the principal, interest, and costs, he can sue the borrower for any balance. Sometimes second mortgages are created, but these rank, both as regards capital and interest, after first mortgages.

Stamp Duties. The stamp duties payable when mortgages are created are at the rate of $2 / 6$ for every $£ 100$. Under $£ 100$ they are 3 d . for $£ 10,8 \mathrm{~d}$. for $£ 25$, and $1 / 3$ for $£ 50$. Persons who lend money on mortgage should see that the mortgaged property is fully insured by the borrower. Those who borrow should see that the interest is paid promptly, while it is to the advantage of both to keep the property in good condition, although the mortgagee has no liability in this direction. Borrowers are well advised if they provide for the gradual repayment of the money borrowed. Building societies usually stipulate that this shall be done, and arrange for mortgages to be repaid by instalments extending over a fixed period of years. In sucb cases a payment weekly, monthly or quarterly, as the case may be, includes both the interest and a sum towards the repayment of the debt.

The power to cull in mortgages, and the raising of interest thereon beyond a certain figure, is restricted at the present time under the Rent Restriction Acts, which were introduced during the period of the Great War and have since been extended several times. See Building; Building Society ; House; Rent.

## MORTISE AND TENON JOINTS

## Methods of Making and Their Use in Amateur Carnentry

For fuller information our readers are advised to turn to the wood-working articles, especially Amateur Carpentry; Chisel: Dowelling: Joint: lock; Tenon: and to those on the various pieces for which mortises are necessary, e.g. Cabinet: Cuphoard: Door; Dresser

In woodwork and building construction a mortise is a rectsngular hole formed to receive a peg, or tenon. shaperl on the part to be jointed. Of its varicties the simplest consists of a mortise. or slot, cut in the centre of a beam, to reccive the tenon on the end of an upright. as shown in Fig. 1.

The bare-faced tenon in Fig. 2 has only one ahoulder, the other side being Hush with the face of the post. It is used when one side of a rail has to be flush with the atile, or post, while the other side is set back from the face The tenon inay or may not pass through the post where the mortise is cut In the

parts of the framework separaterd, thus tightening up the canvas.
When the tenon does not pass right through the mortise it is known as a atub tenon The ollique mortise and tenon in Fig. © is used for joints on the ends of braces and struta, and a part from the fact that the shoulders and end of the tenon and two sides of the mortise have to be cut at an angle instead of square, they follow the same principle as the ordinary mortise.
The mortises for a corner post have to be cut with all faces at right angles to each other, consequently the two inortises will have to meet in the centre of the material. They are therefore generally haunched and the rail is mitre tenoned, as in Fig. 7. A douhle mortise (Fig. 8) is often used in jointing a broad rail into a stile or post.

A good method of making a rigid mortise and tenon joint is known as the fox wedge tenon (Fig. 9). The mortise does not go right through the wood, but terminates at a distance from the face, and the walls of the mortise are cut to an angle, so that the bottom of the mortise in the wood is wider than the mouth, or entrance. The tenon is cut to a width that will

clused mortise the tenon is surrounded by wood on all four sides and the end. and the mortise dues not pass right through the wood, but terminates at a distance from the face When the work is completely finished, the joint between the rail and post is not visible, except as a line of demareation between the two parts It is therefore often used in cabinet work, and is also used for the better class of door frame

The joint shown in Fig. 3 is a haunched mortise; the tenon is cut back for the bulk of its length, but a small projecting portion is left at the side to provide a maximum grip on the post. The slot mortise in Fig. 4 is merely a slot cut in the end of one part to receive the tenon formed on the other part. The adjustable slot mortise and tenon in Fig. 5 are only used where it is desired to exert pressure upon some projecting part of the framework, as, for example, the canvas of an oil painting. The wedges are driven in, and the wedges for securing tenon into mortise
just enter the mortise. Two or more "edges are then made of hardwood and inserted in saw cuts made in the end of the tenon When the joint is to be finally assembled the parts are glued, the wedges just inseited into the slots, and the joint driven home with a mallet, or clamped up tightly, with the result that virtually an internal dovetail joint is formed which possesses very great st rength. A similar systenn of wedging is often adopted where the tenon passes right through the mortise. In this case the wedges are driven in from the outside and scrve to make a perfectly rigid joint IVedges of this class are always used when the end of the tenon is aecessible.
General Principles. Usually, mortise and tenon joints are secured by glucing and wedging, by pins or by draw horing. The proportion of the mortise and tenon in the casc of a stub and through mortise should be about one-third the thickness of the minterial. It is imperative that the walls of the mortise be square to ench other and to the joint faces. Similarly, the tenon must be square on all its sides, the two shoulders in line, square with the joint faces.
The general procedure in the making of any mortised joint consists firstly in niarking accurately on the wood. This should be done with a scriber and set-square, and the lines should be squared right around the material, inarking first the length of the mortise. The width is set out with the aid uf a mortise gauge (Fig. 12), which is used to seribe lines on both sides of the part to be nortised. There is thus a rectangular space marked out on opposite sides of the wood, indicating the material to be removed. The tenon should similarly be marked out, with the same setting of the mortise gange.
The mortise is then cut by drilling holes in the material with a centre-bit, keeping just within the lines. This removes the bulk of the timber and the remainder is cut out with a chisel, preferably a pattern known as a mortise chisel, which has a very strong handle and is used with a mallet (Fig. 10). It is driven down into the wood as far as possible, withdrawn, and the chips removed from the hole: further chiselling continues until the bulk of the holc has been cut half-way through. The timber is

Mortise. Showing examples of the legding types of mortise joints. Fig. 1. Plain mortise and tenon joint. Fig. 2. Simple mortise and bare-faced tenon. Fig. 3. Haunched single mortige and tenon. Fig. 4. Slot mortise and tenon. Fig. 5. Adjastable slot mortise and tenon, as used on stretcher of an artist's canvas. Fig. 6. Obllque mortise and tanon. Fig. 7 . Mitred tenons and mortise for use in table legs, etc. Fig. 8. Double haunched mortise and tenon. Fig. 9. Fox
then turned over and similarly cut from the opposite side.

The final fitting may be completed with an ordinary firmer chisel by careful paring. As a
 guide to the eye, an ordinary set-square should he set by the side of the work, this being an aid to keeping the chisel correctly upright while cutting out the mortise. The tenon may he cut out almost entircly with the aid of a liand or tenon saw, as shown in Fig. 11, by carcfully arwing down the
alot in the door stile, to the ordinary type of for its ornamental effects. The materials mortise lock about the same size as a rim lock. Another type is that known as the harrel mortise lock, which may he fitted into a hole boied in the door with a twist bit or auger. Mortise locks are gencrally of the warded tumbler type, and in the case of some of the smaller varietics, such os the smiall harrel mortise lock, only one bolt is provided, which is locked by the key, and whichalso prevents the handle from being turned. Instructions for fitting mortisc locks are given in the article Iock ( $\mathbf{q}^{\circ} \mathrm{v}$. ).

MORTLAKE WARE. The earthenware produced at the Thames side village of Mortlake, for about 70 years after the middle of the 18th century, was almost лs famous in its day as its pictorial tapestry. Any pieces offered as Mortake should be viewed with the utmost reserve, bесяияе there have not been identified enough typical specimens on which to hasc an nssured judgement. There was a factory for common tinenamelled or delft ware, ranging from large punch-bowls, painted with Howers and medallions, to hlue landscape tiles. Annther factory, founded by Joseph Kishere, who marked the ware with his name, turned out a sound, domestic stoneware of the drab or brown typle, which was also produced at Iullam This was sometimes dccorated in low-relief with hunting and convivial scenes, but apparently never reached a high standard of artistic merit. It is not unlikely that pieces of Mort-

Mortige gauge, which marks two lines simultaneously that pieces of Mort Talie origin are concealed in museums

MOSAIC : As a Decoration. This attrac. tive process consists of embedding small picces of stone or other material in cement to form a pattern or design. It is much employed because of its durability, clennliness and comparative noiselessness to the tread, as well ns

mployed comprise marble, pottery, and glass
There are two varieties of mosaic paving, known respectively as the Roman and the Venetian In the former, a foundation of concrete is prepared and the top of it conted with a thickness of ahout $]$ in of neat cement This is lloated off to a level surface, and into it are pressed small pieces of marble, of various colours, principally white, red, black, cream, hrown and green.
Burnt clay or ceramic mosaic, with blocks $\frac{1}{2}$ to 1 in square, beside heing cheaper and more durable, is a vailable in a wider range of tints. Clay cube is best adapted for regular geometrical designs, because it does not udinit of heing trimmed, as marble clocs, to fit the interstices of a pictorial design. When the mosaic consists of a groundwork of stone of one colour with a simple lorder in another liind of stone the border nnay be set in position first and the remainder of the spaces filled in with self-colour stone.

When a pictorial design is wanted the design is first drawn up full size on a large shect of paper, or several sheets if the area to be covered is of any size. The stones are glued to the paper, placing the face side of the atonc against the paper The concrete foundation should previously have been prepared, and when the design is finished on the paper, a lloating coat of neat cement is worked on the concrete. The paper is lifted and turned over on the wet cement and pressed into position. The stones should be pressed into the cement sufliciently to hold them in position, and ns soon as the cement has become thoroughly set, the paper is damped and removed from the stones.
The design will appear in outline form on the foundation, and the spaces between the outline of the design are filled in with other pieces of stone bedded in cement, the whole being levelled as much as possible and finished by polishing. The cement joint should form an integral part of the design ; when the blocks are fitted so closely to obliterate the joint the result is artistically weak.

Venetian Mosaic. Venetian or terrazzo mosaic employs marble chips, that are crushed into irregular shapes and sorted out into grades ranging from ${ }_{i 8}^{3} \mathrm{in}$. to $\frac{3}{3} \mathrm{in}$. mesh. In this style the cement hecomes a filling rather than a joint, and is usually coloured in a cont rasting tint. The marble fragments are spread upon the cement, larger pieces heing strewl upon them here and there, thickly or sparingly, and the interstices filled with smaller chips The whole is then levelled by heavy rollers. Sometimes a border is formed in a darker tint, or in marhle cube design.

When mosaic tesserac are applied to walls and ceilings they arc usually only half as thick as paving cubes $\mathrm{Vall}^{-}$mosaic is most satisfying when carried out in simple and unpretentious designs, with restrained colourings in the borders.

Glass Mosaic. The use of glass mosaic for mural decoration, in emulation of the Byzan. tine examples, is associated with public rather than domestic buildings. The tesserae, vary ing from $\frac{1}{\mathrm{in}}$. to ${ }_{3}^{3} \mathrm{in}$. square by $\frac{3}{16}$ in. thick,

Mosaic. Fig. 1. Roman mosaic. The pattern has been drawn on paper and the process of sticking on the cubes begun. Fig. 2. Desirn transferred to slab and rroundwork being flled In. Fig. 3. Venetian mosaic. showing gronndwark laid before rolling: two of the wooden battens have been removed
are minde of opaque glass pastes, and are available in thousands of tints. Glass-andgold, formed by fusing gold-leaf between two layers of transparent glass, is commonly employed as a filling for the pictorial design.

Fig. 1 shows the pattern drawn on the paper and the process of sticking the stones thereon. Fig. 2 illustrater a mosaic design transferred to the slab and some of the stones standing up in readiness for filling in tho groundwork. Fig. 3 shows the Venetian system with some of the wood battens in position and others removed to receive the coloured stones for the border design
MOSAIC: In Potatoes. This disease, which attacks some varieties of the potato more than others, is frequently responsible for light crops in gardens and allotments. It may be recognized by the mottling of the foliage. Coupled with this there is usually a crinkling oi the leaves, a waviness in the outline of the leaflets, and other indications that the leaves are not normal. In severe attaclis "dwarfing tendency is frequently seen, and with it goes a marked reduction in the yield. The diseasc is distributed by means of the seed tubers; therefore tubers from infected plants should on no account be put aside for seed. Infected plants should be immediately destroyed, as they never recover from an attack. See Potato.
MOSELLE. The vineyards of the lower Moselle yield very fine white wines of the hock character, d:y, delicate, and with an attractive bouquet The best are Piesporter, Brauneberger, Zel. tinger and Berncastler Doktor. Moselle is an excellent beverage drink, going well withmost sorts of food. Sparkling Moselle though apt to be a littleoverswet, is a pleasant wholesome wine. The alcoholic strength of the Moselle wines ranges between 17 per cent and 25 per cent of proof spirit. See Hock; Wine.

Moss Rose. Varlety of rose so called from a mossy growth on the stems

## MOSQUITO. As some kinds of mosquitoes

 carry the infection of yellow fever and malaria it is important in infected districts to take active measures to destroy the larvae. An efficient method is to pour paraffin oil on all ponds and stagnant pools, using one pint to each 200 sq . ft. of water surface. Cisterns and water barrels should be emptied once a week. Old tins, tubs, and other receptacles for water should not be left lying around the dwelling. Oils of pennyroyal or Invender sometimes keep mosquitoes auny if a few drops be sprinkled on the bedclothes, or on exposed parts of the body.Where the insects abound, mosquito curtains should be used round the bed, and windows that are kept open in the evening should be guarded by fine wire or muslin netting.
Mosquito Bites. Mosquito bites are often very troublesome. As a preventive for
warding of the attacks of these insects the following lotion will be found uscful

A little of the lotion should be applied to the skin of the hands, wrists, ankles and the neck when the mosquitoes are about. For relieving the irritation the following preparation can be used

## Menthol

15 gr.
Alcohol ( 80 per cent)
13 oz.
Dissolve the menthol in the alcohol, and then add the ammonia. Dab on to stings and bites as often as required.

MOSS. The popular name moss, which belongs strictly to plants of the Musci family, is applied indiscriminately to many plants Moss is generally a nuisance on gravel walks. The method of eradication usually practised is to sprinkle the walks well with rock-salt during showery weather. A better way, however, is to brush the surface of the gravel with a strong solution of bluestone, or sulphate of copper. The brushing should be done carefully, and the copper solution kept away from turf edgings or bed or border plants.

Fruit trees are often attacked by various grow the which are loosely described as mosses. A precautionary measure is to spray with caustic soda ( 1 lb . in 10 gallons of water) in winter. When moss is found on lawns it is usually a sign of malnutrition. Rake the surface of the lawn over and give it a dressing of rich sifted soil in springtime.

MOSS CAMPION. A very beautiful plant for the rook garden is Silene acaulis, or the moss campion. It is of low moss-like growth and bears rose-pink flowers in spring. It is most likely to bloom well if grown in a moraine. See Moraine Gardening.

MOSS ROSE. The variety of rose known as the moss rose is interesting owing to the mossy growth which surrounds its stems and the bases of its flowers. The principal varieties are as follows: Blanche Moreau, white; Crested Moss, rose; Little Gem, crimson; Mdme. Moreau, rose. Moss roses should be grown in rich soil: pruning in March is done by cutting out weak shoots and shortening the others. See Green Fly ; Rose.

MOTH. These winged insects, though similar to butterfics in general appearance, are as a rule not so brightly coloured. The body is usually larger and more furry, and most varieties fly principally at night.

Moths in the Garden. The caterpillars of three moths do great damage to fruit trees in the spring These are the winter moth, the mottled umber, and the march moth, all being sometimes known as winter moths. Practically every form of standard and bush fruit is attacked by these pests. The caterpillars appear early in spring and feed during the entire period in which fruit trecs are making their foliage, causing sometines great havoc.

Winter Moths. Winter moths may be controlled both by grease-banding the trees in autumn, to catch the wingless females as they ascend the trunks, or by spraying the foliage with a tar-oil wash in winter, to kill the larvae. After the blossoms have fallen in spring, spraying with the poisonous lead arsennte, 4-5 lb. in 100 gallons of water, is recommended. See Buff-tip Moth; Figure of Eight Moth; Grease : Hornct Moth; Insecticide, ctc.

MOTH BALL. The round balls sold as moth balls consist of naphthalene, a product of the distillation of coal tar. Naphthalene is a cheaper substance than camphor for placing among furs and woollen goods to preserve them from inoths. The smell of naphthatene is considered objectionable by many, and on
this account moth bricks are made from a mixture of equal parts of cedar dust, camphor, and naphthalene, made into a brick by mixing with strong soap and water. See Clothes; Clothes Moth; Fur.

MOTHER. The mother of a legitimate ohild is its guardian after the father. The father is entitled to name a guardian for his children after his death, but the mother is entitled to act with that guardian. A court of law will not allow a man who separates from his wife to take away from her young children. If he dues so the court will invariably order them to be returned to their mother, unless she is not a fit and proper person to have the custody of the children.

In the matter of religious education the father is entitled to the deciding word. If, either before or after marriage, a man and woman have agreed that the children, or some of them, shall be brought up in one creed, the father can in law go back on his word and bring them up in another. But if they have begun to be educated in one religion, so that a change would unsettle them, the court will forbid the change

A mother who has property or means is liable to maintain her children. She is also liable, along with the father, under the various statutes which relate to the care of children The mother of an illegitimate child is its only parent in $\ln w$, and the putative father bas no control over it. If the mother of a child marries a man, that man becomes responsible for the maintenance of the child until it can maintain itself, just as if it were his own. See Child: Father; Husband : Illegitimacy, etc.

MOTHER-EVE'S PUDDING. To make this pudding, allow 6 oz. breadcrumbs, 5 oz . castor sugar, 6 oz . currants, 6 apples, 3 eggs, a pinch of salt and of nutmeg. Crumb the bread very finely, and pare and chop the apples. Clean the currants and stone them Mix the dry ingredients together and beat the egys, then beat in the eggs and stir all well together Butter a pudding basin and put in the mixture. Cover it with greased paper and steam the pudding for 3 hours.

MOTBER-OF-PEARL. The oyster shells from which the chief supply of mother-of-pearl is obtained are found off the coasts of N. Australia and New Guinca, some of the slecimens measuring from 6 in. to 9 in in diameter and weighing several pounds each. The inside surface of the shell is mostly white, but some are of a smoky black colour.

By jewellers and silversmiths mother-ofpearl is very largely employed. It is used for buttons, studs, and cuff links; for the handles of fruit knives and forks and pocket knives It is cut into round or oval-shaped beads for necklets and rosaries. Cabinet makers use it for inlaying, and large quantities are employed for this purpose in the manufacture of Oriental furniture, especially small decorative tables.

MOTHER OF THOUSANDS. This is the only species of the saxifrages, $S$. sarmentosa, which is commonly grown under glass. It is useful both for hanging baskets and pots.

The soil should be threc parts loam, one part leaf-mould and sand. Propagntion is by inserting the plantlets in sandy soil in the propagator in spring or summer. A cool greenhouse suits it well, or it is a valuable adjunct to the indoor ruck garden or fernery. The pariety tricolor likes a warm greenhouse The time for re-potting is the spring.

Linaria cymbalaria, also known as pedlar's bnsket, is sometimes given this name. It is a creeping outdoor plant suitable for rockeries and old walls.

MOTHER'S HELP. The duties of mother's help are not very clearly defined, but should be arranged definitcly between employer and employee at the time of
engagement. As a rule, the post involves work ranging from that of a nursery governess to that of an ordinary nurse, a certain degree of education being generally expected.

Primarily, the post means care of the children and charge of their wardrobe. The mother's help is expected to be a good needlewoman, able to make simple frocks for her charges, and to do any necessary mending. She may also be expected to do a certain amount of washing, and to be responsible for the general turn-out of the children. If there is also household work to do, it will usually be only of the lighter kinds. See Insurance.
MOTE ORCEID. The hothouse orchid belonging to the genus Phalaenopsis, and known as the moth orchid, requires a stove temperature, and should be grown in pans or baskets suspended from the ronf of the house. The handsome varieties of Miltonia vexillaria are most popular. See Orchid.
MOTIF : In Needlework. A motif is a piece of lace or embroidery set into a background of ordinary material to form a trimming. There are crochet and knitted lace motifs in ovals, oblongs, circles, and squares, embroidery motifs of all shapes and sizes, and real lace motifs such as those made with Honiton braid and pillow laces, which take the shapes of flowers, butterflies, etc.
There are several methods of mounting motifs to the material. The first is to tack the motif on the right side of the material, then sew down with a small hemming stitch,
in the case of knitting or crochet, taking one hemming stitch through each stitch of cut away at the back of the motif, leaving about $f$ in. to turn back a little hem, or only leaving about $\frac{1}{8} \mathrm{in}$. and buttonholing the raw edge. A second method is to button hole the motif to the material on the right side, and cut away the material at the back of it just below the wrong side of the buttonhole stitches.

Another method which gives a strong edge and a neat finish is carried out thus: Lay the motif on the right side of the material and pin it down so that the edges are quite taut and in the correct position. Now draw a pencil line on the material right round the motif, then remove the latter from the material. With embroidery cotton and a tine crewcl necdle, buttonhole all round the pencilled outline so that the pearl edge of the buttonhole stitch comes right on the pencil line. When the buttonholing is completed, take the inotif and sew it, stitch by stitch, to the buttonholing. If the pencilling and sewing are on the correct line, the motif should be an exact fit, and the material at the back can be cut away. See Appliqué ; Embroidery; Lace, etc.

MOTOR. This name is employed for any machine which changes some form of energy into mechanical power e.g. an elcctric motor, petrol engine or water power motor. See Electric Motor; Internal Combustion Engine; Mangle; Water Motor.

## Motor Cars: Hints for Owner-Drivers <br> How to Choose a Car and Maintain it Economically

The important sublect of the motor car is dealt with in this Encyclopedia in this article, In one on Motoring and in a number of subsidlary entries, e.g. Brake: Clutch; Front Axle: Gear: Internal Combustion Engine: Live Axle: Lubricatlon. See also Garage

The prospective purchaser of a car should carefully consider his requirements before placing an order. There are hundreds of different models from which to choose, which perhaps renders the question somewhat difficult to the novice, but he need have no fear about the capabilities as an efficient touring machine of any car now made, whatever its price. The suitability of a car, therefore, is narrowed down to requirements.

For example, it would be unwise to decide on a baby car if the purchaser's family party consisted of four stout persons, for although the car would carry such a load, and the engine have no difficulty in propelling it, the party would hardly be comfortable. On the other hand it would not be wise to buy a large car because of its good value (there are many such cars now available) if the taxation and general running expenses rendered motoring costs a severe drain on the buyer's income.

The Horse Power of Cars. Motor cars are taxed on what is known as the $£ 1$ per horse power basis, the horse power being calculated on the Royal Automobile Club formula, which takes into account only the diameter of the cylinders of the engine and not the stroke. The R.A.C. rating is also accepted as a guide when the question of insurance costs is being considered.

Modern cars may roughly be divided into four different types. (1) Small cars of 750 c.c. to 850 c.c. ( 7 and 8 horse power for taxation purposes). (2) Light cars between 850 c.c. and 1,300 c.c. ( 9 to 12 horse power, R.A.C. rating). (3) Medium cars up to 2,000 c.c. ( $13 \mathrm{h.p}$. to $20 \mathrm{h.p}$. ). (4) Large cars, over 2,000 c.c. ( 19 horse power and over).

A large car is very little more difficult to handle than a small car, but usually the novice has more confidence if he begins with a small car. The cost of a small car is as low as $£ 100$, and may be as high as $£ 250$ if the bodywork be of a special character. The running costs are exceptionally low; 40 or more miles to
the gallon of petrol and at least 1,000 miles to the gallon of lubricating oil are obtainable. The licence costs $£ 8$ and the insurance about £8 to $£ 10$ per annuin. The fee for a driving licence is 58 ., so if it is possible to garage a small car at home the total overhead charges are about $£ 185 \mathrm{~s}$. Od. per annum.
Should it be necessary to accommodate the car in an outside garage, the charges vary according to locality, but 68 . a week may be regarded as a fair charge for a small car. In the provinces this charge may be lower, while if the car be kept in a public garage with a number of other cars it may be lower still. The latter procedure involves a possibility of the car sus.

Motor Car. Fig. 1. Sectional diagram ol typical modern six cylinder engine with principal parta indicated

Motor Car. Fig 2. Table of average annual costs for typical cars
about the aame figure. The driving licence remains the same ( 6 s .) irrespective of the type of vehicle. Although the majority of cars in this category are of the four cylinder type, a number bave six cylinder engines.

Everything else being equal, a six oylinder engine is much better balanoed and smoother in its operation than the four cylinder engine, alfhough it is an axiom that a good four is better than a poor six. A car with a six cylinder engine costs a little more to run, both in fuel and taxation, the extra expense amounting to about 20 per cent.

Medium Size Cars. Next in popularity to the small car, this class contains mostly six cylinder engines, though there are a number with four cylinder engines, and eight cylinder power units are included in the specification of a few. The "eight" if of equal quality is slightly superior to a "six," since tho turning effort is almost as smooth as that of an electric motor, and gear changing is reduced to a ininimum.
The Large Car. Among the large cars are to be found some of the cherpest now on the market. These are of American design, of the mass production type, and are most efficient, althongh the costs in fuel, taxation and insurance are necessarily high compared with the smaller British designed cars. The horse power is 20 or more.

Coachwork. There are several different methods of constructing coachwork, including 1, all steel: 2, metal panelling. 3, fabric
covered; 4, coach built; and 5, flexible construction

The all-steel body is constructed of sheet steel pressings, and is unly found on cars sold in large quantities, since the tools necessary for their production are very costly and thousands of bodies of one pattern must bc made to make the proposition an economical onc. All-steel bodies are immensely atrong, and a car may roll right over in an accident with little tisk of tho body collapsing.

The metal panelled body has a wood frame (ash) to which the steel or aluminium panels ane affixed. This system of construction is more costly than the one described above, but it allows of economical production in smaller quantities.

The fabric-covered body is similar to the last dealt with, and where small outputs are concernerl is probably the cheapest form of construction, since the panelling beneath the fabric, when such is used, need not bc of the high quality necessary with the metal panelled body.

The coach built system differs only in detail from the methods of the old fashioned coachbuilders. Every body so made may be regarded as built to measure. For that reasun it is very costly, and is only to be found on the highest priced chassis.

Flexible construction is a method embodying special means of isolating each wooden frame member from those immediately ad. jacent. This method ensures an absolutely
silent body, free from the minor squeaks and rattles which in time develop in most other forms of motor body. The inetal panel method is generally adopted for open loodies with folding lioods, but any of the methods described are used for the popular saloon or closed body.

Running Costs. It is possible to arrive at a fairly accurate estimate of the probable running costs of a car, though the actual figure will be largely affected by the annual mileage and the general character of the roads over which the car is mainly used. If the vehicle is driven in all weathers, winter ns well as summer. this must be taken into account also.
The tabulated costs given in Fig. 2 will serve as a basis for the intending motorist, who will thus be able to form an idea beforehand of his likely expenditure on the type of car in view Actual running costs in the first few weeks can be compared with those given here, and the latter adjusted as necessary to the case in question.
The table deals with $8,12,15$, and $20 \mathrm{~h} . \mathrm{p}$ cars, but it must be pointed out that the weight of the car has to be taken into consideration, since a light car rated at $8 \mathrm{~h} . \mathrm{p}$. may weigh from 8 or 9 cwt . to 18 cwt . (the latter figure applying to a saloon hody). Thus, while the running costs for the lightest might be less than those specified, the saloon type ? ) h.p. car might be practically as expensive to run as a $12 \mathrm{~h} . \mathrm{p}$. car of 19 cwt . or so. The table is based on a new car used over a period of three or four years.
The expenditure falls under three main heads, depreciation, standing charges, and running expenses. A new car falls in market value directly it is brought into use, and depreciates by about 30 per cent in its first year, so that this loss in capital value must be reckoned with. In succeeding years the rate of depreciation is less, but the motorist, to be on the safe side, should write ofl his purchase price over a period of at lenst six or seven years, as after this lapse of time the car may fetch leas than 10 per cent of its original cost.

Standing charges, including items like tax, licence, insurance, association subscriptions, and the rent of a garage, are independent of the annual mileage or the use made of the car, and are governed only by time.

Running expenses include petrol, oil, tires, and such costs as repairs, maintenance, and the special erpenses incurred on the road, i.e. occasional garaging, parking, etc.
Some motorists lay up the car during the winter months. If in any case the car would

not be much used during the period, the ouner will be able to make a substantial cut in his annual expenses, since the amount of tax and insurance premium payable are lessened, and the running costs cease for the time being. The question of insurance is gone into fully in the subsequent article on motoring.

Care of the Car. We now proceed to consider the question of kecping the car in good condition. The information given here will enable the motorist to detect running and other faulta and to apply the necessary remedies before they develop into serious defects.

By consulting the fault-finding tables Fig. 8 , p. 812, in conjunction with the numbered para graphs, the motorist may obtain considerable assistance when endeavouring to ascertain the cause of a hreakclown.

At a first glance the magnitude of the tables may lead him to suppose that the possible troubles of mechanically driven vehicles are legion; but, in point of fact, it is quite common for a car to remain in very fair order for a whole season without mechanical adjustment.

The procedure by which defects may be traced is simple, as the following example, taken from the first of the tables, will show. Suppose, for instance, that the engine will not start. On inspecting the carhuretter it is found to flood properly, and a spark is passing across the points of the sparking plug. Then the explanation of the trouble will prohably be found in para. 1 or 2, and by carefully reading these the motorist should in most cases have little difficulty in remedying the defect.

Before passing to the 34 detailed paragraphs it is essential that the term good running order should be properly understood, since the meaning conveyed by it to the ordinary motorist is very different from that placed upon it by the enthusiast. The former is content so long as the car does not actually break down, and loses sight of the fact that some of the faults enumerated may be actually in existence, and may sooner or later cause serious trouble. The enthusiast is never satisfied unless the engine is in perfect tune, developing its full horse power with a reasonable consumption of petrol and oil, the transmission is working efficiently, and the chassis and hodywork generaliy are in good order and condition. To ensure this over a long period calls for regular attention.

The hook of instructions sent out by the maker of the car should be carefully read, as it will amplify the hints given in this article, and will further deal with the special characteristics of the vehicle in question The following numbered paragraphs are intended to be used in conjunction with the fault-finding tables:

1. When the spark is too weak to fire uncler compression it will prohably be found that the points of the sparking plug are too far apart. This may be the case even though a spark is obtainable when the plug is taken out and laid on the engine with the lead still connected to it. The points should be adjusted to give e gap of $6 \mathrm{in} / \mathrm{m}$ or $\cdot 025 \mathrm{in}$. for coil

Motor Car. Fir. 5. Sparking plur, show-
ing how gap hetween inR how gap between points of plug ma be measured
to a chafing of the insulation caused by contact between the leads and some nietal work
4. The magneto sometimes fails because the pivoted rocker arm of the contact breaker stick. The bearing pin works in a fibre bush, and in damp weather swelling of this bush may occasionally cause sticking or a sluggish movement of the rocker arm. (See Fig. 7.) The trouble is only likely to occur with new magnetos, in which the hush may be a very close fit on the pin. It is usually only necessary to clean the pin with metal polish, hut if that is insufficient fine emery cloth may be used with care. The pin should be slightly moistened with thin oil before reassembly
Should the rocker arm be free, the platinum points may be dirty or pitted ; in which case, clean them and, if necessary, very carefully file then dead Hat with a jeweller's file, removing only the smallest possible amount of metal. Now reassemble the contact breaker on the magneto and rotate the armature so as to bring one of the cams into action, and thus keep the points separated; then, by means of the adjustable contact, adjust the size of the gap to $4 \mathrm{~m} / \mathrm{m}$, or 015 in . ( है $^{\frac{1}{2}} \mathrm{in}$.). A feeler gauge should be used, or a special magneto spanner set provided with a file and feeler gauge can be obtained for this purpose (See Fig. 6.)
5. Faulty electrical contacts may arise from dirt or from pitting of the platinum points; or the points may be too far apart when separated by the came, or loose in their scatings. Adjustment of the gap is dealt with in para. 4. Loose platinum points may be riveted by a few blows with a small hammer, which will cause them to become firmly seated; but any serious defect or very deep pitting calls for replacement. A broken carhon hrush is best replaced by a new one. The springs which hold the hrushes against the slip ring, or other part, should he looked to.
6. It is very seldom that the ignition fails on account of a breakdown in the magneto insulation. A repair of this nature is quite outside the scope of the average motorist, and the best plan is to send the complete magneto to specialists in this class of work Complete rewinding is best, although it is more expensive than "baking," which will soot, caused by an over-rich mixture, may more expensive than "baking," which will
cause a short at the sparking plug, this is often effect a temporary improvement, hut is cause a short at the sparking plug; this is best cleaned with petrol and a hard brush, such as a atencil brush.

Sometimes a plug that appears to be quite sound when tested off the engine will short when in use. One reason for this, apart from an excessive gap, is a flaw or crack in the porcelain which closes up when the plug is cold, hut opens when hot, thus allowing the high-tension current to short to earth-that is, the cylinder head and cylinder hlock-instead of jumping the points of the plug.
3. A short circuit may be caused by a faulty connexion at any point of the ignition wiring or a law in the insula. tion. The wiring should be gone over, piece by piece, beginning at the source of the current, i.e. the mag neto, or the accumu lators, according to the ignition system fitted. The occa sional short circuit can often be traced

Motor Car. Fig. 6. Rotating type contact breaker for magnetos. Combetween points may be measured Fig. 7. Details of Fig. 6 failure of the induction coil in a coil ignition system, it is best to replace the unit, this being usually a simple operation:- many motorists carryas spare induction coil.
7. Neglect of lubrication of the bearings is a likely cause of controls sticking or becoming sluggish in action The driver may lose control in an emerg. ency, or in any case may he misled as to the effict of his manipulation on the parts operated. It is well to check the controls separately to sec that they are actually imparting the correct amount of movement indicated by the position of the controlling levers operated hy the driver. Wear at various points often upsets the original setting after a prolonged period of use. Clutch slip may be due to

Motor Car. Fig. 8. Fault-anding ohart which in oonjanction with numbered paragraphs in the tert will asaist in tracing oanse of a defoot or breakdown
maladjustment of the controls, so that the springs cannot properly engage the clutch members.
8. Unless the engine has recently been dismantled it is improbable that the valve timing will be incorrect ; but if an overhaul has just been completed, search should be made for the timing marks usually provided on the timing wheels so that the original setting shall be given, thus ensuring that the cams open and close the valves at the oorrect instants relatively to the crankshaft. Where no marks are provided it is a good plan to mark the wheels at the base of the teeth with a centre punoh before disturbing the gear. Failing this, obtain a chart of the timing. Reference may be made to the typical valve timing diagrams shown in Fig. 9.

A back fire may be caused when starting by hand by the ignition being too far advanced. The engine and starter motor may be pulled up by excessive advance although there may not be an actual backward rotation of the crankshaft. The current from the mag. neto, if it is too far retarded at starting, may not be powerful enough to create a spark at the plug. It may be necessary to adjust the position of the magneto armature slightly relatively to its driving shaft by means of the vernier coupling usually provided so as to obtain a more powerful spark when the ignition is retarded. The ourrent for coil ignition is equally strong whether it is advanced or retarded.
9. There are numerous olasses of air leakage into the induction system which may
upeet the carburation. Wear may occur clearance between the pistons and the cylinder between the valve stems and guides, in which walls. In this case there is loss of power case new guides should be fitted. Air leakage due to leakage from the cylinder during the may also occur through wear at the throttle compression and working strokes and also bearings. The remedy in this case is to excessive oil consumption. This is dealt with rebush or pack the bearings. All joints of in paragraph 11.
the induction system should be overhauled 10. When a petrol stoppage occurs, make and bolted up tight. Another source of leakage certain that the petrol is turned on and then, may be the connexion to the suction-operated if the engine still refuses to start, test the wind-screen wiper, which, if faulty or broken, petrol pipes for clearness. With a gravity. may quite upset the carburation, particularly led system, the petrol will not be able to When starting. flow out of the tank if the vent hole in the A different class of air leakage that will filler cap is ologged up. On the other hand, only be manifest after a considerable mileage failure of the petrol supply may be oaused has been run is that caused by excessive by dirt in the jet of the carburetter. The

Motor Car. Fig. 9. Approzimate timing of inlet and exhaurt valvea. A, induotion ; B, compresion ; C, worting or power stroke; $D$, exhaust strole. Cyoje of operations is then repeated float needle may be sticking, and by remaining on its seating will prevent the petrol from entering the float chamber; the cause will be either dirt a bent float needle, or jamming of the toggle levers
A partial stoppage of the petrol may be caused by loose pieces of fibrous matter at the jet or the fluat chamber of the carburetter, the petrol tank, or the filter. A failure of the petrol supply
with the autovac and fuel pump systems may be caused by air leakage into the suction passages and can only be located by careful examination. Should the autovac become empty it may be found difficult to start it in operation again until the engine is running fairly fast. The autovac tank may be filled with petrol through the plug provided at the top, or the float chamber of the carburetter may be filled after the cover has been removed to enable the engine to be started and operate the autovac.
11. Poor compression hay be due to various causes; for instance, the valves may require grinding in or the pistons a nd cylinders may be hadly worn. Other canses include : a broken piston ring; piston ring slots in line; piston rings loose in their grooves; and a scored cylinder wall, due to the gudgeon pin working out at one end of the piston. Defective pistons or piston rings must be replaced. If the valves are properly ground in, they will not give any trouble for some consideralile time.

## Avoidance of Poor Compression

The joint hetiveen detachablc head and cylinder casing should he examined, as the gasket may be defective, or the holding-down bolts not tightened up uniformly. If the cylinders are worn oval or scored, regrinding and filling of the scores will be necessary Thin, hard steel liners may be forced in after the cylinders have been suitably enlarged. in which case it may be possible to utilize the old pistons. A gasket which is defective in any way should not he used. It is advisable always to keep a spare gasket in hand.
12. Loss of power will occur if the valves are not a perfect fit; but if they are nccasionally ground in, for instance, whenever the engine is decarbonized, trouble from this source will be rare. Where the faces are very bad it may be necessary to have them trued up with a special valve-scating tool before grinding.
The modern valve grinding and decarbonizing equipment now einployed by many repairers trues up the valves and their seats independently, and when skilfully used gives better results than can be obtained by the usual grinding compound.

A weak valve spring should be replaced by a new one since it will not return the valve to its seating quickly enough when the engine is running at high specds. It is futile to attempit to stretch it. The only remedy for broken valve springs is a replacement. When a valve is titted the scating should be re-cut, as the original face angle will probably have been altered during regrinding. The stem of the valve must move frcely, but inust not be loose in the guide, and it shonld be the same length as the old one.

An elusive cause of loss of compression is a stretched valve stem or too little tappet clearance preventing thic valve from scating properly when the engine is hot. The engine should be turned until the can is clear of the tappet, the valve then being seated, and the tappet should be adjusted to give the clearance specified by the makers of the engine. (See Fig. 10.) This varies considerably, but for most side valve engines a tappet clearance of 004 in . is suitable for the inlet valve and -005 in. for the exhaust valve. For overhead valve engines the clearance is slightly grenter. A feeler gauge should be used, and the adjustments should be made when the engine is warm. It is safer to have too much than too little clearance.
13. If the silencer is allowed to become choked with soot the exhaust gases will not be able to escape quickly enough to allow the engine to develop its proper power when running at high speeds. This trouble may never arise if the silencer is of sufficient size and of good design and if carburation is satisfactory.
14. The air supply to the carburetter must be properly proportioned to the amount of petrol supplied if even running and full power with economy of petrol consumption are to be obtained. Carburetters valy so grently in construction that it is impossible to give any rules for the adjustment of air and petrol which would he generally applicable. It may be stated, however, as a general rule, in the case of an over-rich mixture, that it is safer to increase the size of the choke than to decrease the size of the jet, while for a weak mixture it is better to increase the size of the jet.

To obtain maximum power at high speed it is advisable to keep the diamcter of the choke tube as large as possible, thereby avoiding throttling of the gases. The carburetter should always be kept correctly adjusted for slow running, such adjustment being made when the engine is hot. Instructions for tuning can usually he obtuined from the makers.
15. Excessive carbon deposit is most frequently caused by badly worn pistons and cylinders and also by worn piston rings or worn grooves. Through excessive clearance at theso points oil is sucked up during the induction strake and deposited in the combustion chamber and on the piston, and is burnt by the heat generated during the power stroke, thus forming, together with road dust, a hard deposit.
This deposit is liable to become incandescent and ignite the fresh mixture before the end of the compression stroke. When this happens it will be seen that instead of the piston rising on compression, it will be rising against the very high pressure of the prematurely exploded charge. This fault is commonly known as pre-ignition, and can only be cured by a renewal of the worn parts responsible, or by frequently removing the cylinders or cylinder heads and carefully scraping away all signs of carbon deposit Pre-ignition causes knocking, and reduces the power which can he developed
16. Over-heating of the engine may arise from various causes, such as complete or partial

Motor Car. Fig. 10. Tappet or valve clearance is measured by a leeler gauge inserted between end of valve stem and head of screw A, which is screwed into
or out of tappet $C$ to adjust clearance, and is locked or out of tappet $C$ to adjust clearance, and is locke

> Courtesy of Messrs. Armstrono Siddeley Motors
failure of lubrication, shortage of cooling water, choked water pipes or cooling elements, a worn water circulating pump, a slack belt driving the fan or water pump, a choked silencer, imperfect carburation or ignition too far retarded.

The oil level in the sump should never be allowed to get low; it is hest to replenish it frequently and keep, the sump full If the oil is dirt $y$ or contains sludge it must be drained off, the sump Hushed out with flushing oil, and refilled; this should, in fact, be donc about every 1,500 miles or according to maker's instructions.

If any of the oil pipes or passages have become choked they must he cleaned cven though the engine may have to be partly dismantled. If a plunger pump operated in one direction by a cain and returned by a spring is used, the spring, if weak or broken, must lise replaced; it is not suflicient to stretch a weak spring. If the plunger is worn a new one must be fitted. Pumps, whether of the
gear wheel, plunger, or rotating vane type must be replaced or repaired if they do not force oil through properly.

The racliator should always be filled and replenished with rain or other soft water, thus a voiding any deposit of line in the system, which would result from the use of hard water; such deposit, unless very hard, can he removed by running the enginc for a short time with a strong solution of common soda and water in the cooling system. After this mixture is drained off the system must he well washed out before it is refilled with soft water.
17. An imperfect mixture results from the carburetter not being properly adjusted, or not of a suitable size for the engine to which it is fitted Until this is correctell unsatisfactory running at varying engine speeds will be certain to occur. Sec para 14 above.
18. Since water is heavier than petrol aull the two do not mix, the water remains at the bottom of the tank or in the Hoat chamber of the carburetter. With a properly designed tank, water can be present in some quantity without any getting through into the carburetter, since the outlet pipe usually projects slightly above the bottom of the tank. If, howewr, only a little water passes into the float chamber it may get into the jet orifice and cause irregular running. If sufficient water passes through it will entirely stop the flow of petrol, thereby making it impossible to kecp the engine running at all. The tank and the Hoat chamber must be drained com pletely and thoroughly cleansed.

## Points About Ignition

19. If the ignition is too far advanced the explosion will take place against the rising piston. On the other hand, if it is too far retarded the explosion will not take place until the piston has travelled some distance down on the power stroke. Either fault, but particularly the latter, is fatal to power development. With fixed ignition, the timing should be such that the spark takes place just before the piston has reached the top dead centre on the compression stroke. The spark occurs at the instant the points of the magneto or coil ignition contact-breaker separate.

When the timing of the spark is controlled by hand or by an automatic advance-andretard, the setting should he such that the spark occurs at or just after the crank is on the dead centre with the ignition fully retarded This is the adjustment for starting. When the engine is running fast, the ignition may be advanced so that the spark occurs with the crank about thirty degrees ahead of the dead centre. When the engine is pulling hard up a hill the ignition should be retarded so as to avoid knocking and get the hest results
20. Frequent causes of clutch slip are faulty adjustment, insufficient spring pressure or the presence of oil on the friction faces, but the different types of clutch vary greatly. I weak spring or springs where no adjustment is provided should be replaced by new, and this should be olitained from the makers to ensure correct strength. With clutches working in oil, slipping may be duc to worn plates, worn or missing cork inserts, or weak springs : or a thorough cleansing and freah lubricant may be necessary A little oil on a dry plate clutch is soon burnt off, but continued leakage from the engine into the cluteh pit may account for persistent slipping.

Some clutches have an adjustable stop by which the position of the clutch peedal can be determined, so that it is advisable first to make sure that this stop is not preventing the clutch from entering into full engagement. The clutch cannot engage properly if the pedal arm is forced hard up against the under side of the floor board. It should be half an inch clear when the clutch is engaged. Unnecessary wear of the ball thrust bearing wi!! also result frow this defect. A slipping
clutch, if allowed time to cool, will often hold for a short period, thus enabling the motorist to reach a garage or his home if only a short distance has to be travelled.
21. Assuming that the engine is in good condition, difficulty in hill climbing may be due to a change down made too late. With the internal combustion engine the power developod is proportional to its speed of rotation, and the turning effort exerted by the engine, once it has attained a certain speed, is approximately constant. Unless a change down is made sufficiently early-that is, before the engine slows down greatly, the engine will not be able to accelerate again, and a further change down to a lower gear will be necessary. If the engine and car speeds are allowed to fall too low the vehicle may stop before the next gear can be engaged.
22. Stripped timing gears, broken driving keys, or a broken timing chain are causes of breakdown that seldom occur. In such a case no attempt should be made to rotate the crankshaft, as a broken chain or other part might be wedged and cause further damage.

## Flooding of the Carburetter

23. Flooding of the carburetter may be evidenced by overflowing of petrol from the jet into the main air passage or by fuel running out of the top of the flasat chamber. Among the more probable causes may be mentioned dirt or fibrous matter preventing proper seating of the needle valve, wear of the end of the needle valve, binding of the valve in its guide, due, for instance, to its being bent, movement of the collar which engages the ends of the toggle levers, derangement of the toggle levers themselves, or a punctured float. A worn needle valve may be replaced or it may be ground in on to its seat with fine pumice powder and oil, but it should preferably be first trued up conically on a fine emery wheel. If the float is punctured, only a very small hole will generally be found, but this, by allowing the petrol to get inside, will cause the float to sink.
To repair such a defect the hole should be slightly enlarged, the petrol drained out, and the Hoat left for several hours in a warm place to make sure that every vestige of petrol has evaporated and thus avoid risk of explosion. The hole should then be soldered up, using as little solder as possible to avoid making the float heavier and thus upsetting the level of the petrol at the jet. If an increase of weight cannot be avoided, the petrol level may be adjusted in any suitable way, such as by moving the collar on the needle valve.
24. No attempt should be made to run the engine in the event of a sudden loss of compression. The cause may be a broken piston ring, which is likely to score the cylinder wall. Badly worn piston rings must be replaced. Gumming up of the piston rings is due to an accumulation of semi-burnt oil choking up the grooves in which choking up the grooves in which the rings within the insulation, assuming that the ter-
should move freely; should this occur it is minal connexions have been examined and best to remove the rings and carefully clean the grooves. New rings may be necessary and should be fitted if the old rings have lost shape or elasticity.
25. Breakage of the piston, connecting rods, or crankshaft is seldom met with, but no attempt should be made to start the engine if such trouble is suspected, or if there is any

Motor Car. Fig. 11. Ezamples of wheel non-alinement. A, front wheels inclined out wards; $\mathbf{C}$, anles not parallel ;
suspicion that a big.end or crankshaft bearing has run-that is, that the white metal has question can be mended by welding, and specialists in this class of repair will guarantee a satisfactory job, it is usually better and quicker to obtain new parts from the makers Fitting new white metal bearings or remetalling a bearing is a simpler matter than a breakage, and can be done by any competent repairer.
26. Failure of the magneto or coil ignition condenser is exceptional, and can only be dealt with by the makers or by electrical ignition experts. In general a defective condenser will cause excessive sparking at the points of the contact-breaker, resulting in considerable burning or pitting, also a loss of intensity of the high-tension current. Internal short-circuiting of the magneto due to moisture is sometimes experienced during the winter. It can often be cured by removing the magneto from the engine and placing it in a warm, not hot, dry place, such as a mantelpiece, for a few hours.

If this is not successful, it should be taken to pieces and thoroughly cleaned, care being taken that the timing of the high-tension distributor in relation to the armature is correct when reassembling. Over-oiling may result in oil reaching the slip spring, contactbreaker or armature, and so causing internal short-circuiting Excessive moisture, overoiling, or too large a gap between the contact breaker points may damage the insulation of a magneto armature or induction coil, and necessitate rewinding or replacement

## Faulty Wiring

27. When the ignition wiring is removed in connexion with a repair or overhaul, the different leads should be marked carefully to ensure that they are replaced as before. In some cases different coloured insulation is used or the wires are arranged in some special manner which ensures that they cannot be displaced. Should they be wrongly connected up so that the engine fails to start it may be found difficult to rearrange them properly.

Faulty wiring should seldom occur for a number of years if reasonable attention is given to cleanliness and to ensuring that the leads do not chafe against any metalwork. Oil and dirt will frequently be found responsible for many faults, principally owing to their deleterious effect upon rubber or similar insulation. All terminals should be kept clean and dry. It will sometines be found that the wire itself hidden within the insulation has fractured, or that some of the strands are broken, giving imperfect conductivity. Finely stranded wire may be found to be oxidized, probably owing to moisture.
The reason for a short circuit or a defect in a connexion can sometimes not be ascertained even after the most careful search. The most probable cause in such cases is a frac. ture of a wire itself found satisfactory.

To test this defect one end of the suspected wire may be connected to a terminal of the accumulator and the other end connected in circuit with a voltmeter or an electric light bulb of the same voltage as the accumulator. If the bulb fails to light, or burns intermittently or is dim, or if the voltage shown by
the voltmeter is less than that of the accumulator, the whole length of wire should be replaced. It is not satisfactory merely to replace or repair part of a damaged load. The voltmeter is more sensitive than tho bulb, since even a small drop in voltage will be indicated.
28. Non-alinement of the steering whecls should not appear until a considerable mileage has been covered; this defect usually results in the wheels spreading somewhat at the front, as shown at A in Fig. 11. It may be due to worn pins or bushes in the steering heads, or to wear in the joints

Motor Car. Pig. 12. Measurements to check alinement. See text should be between $\frac{1}{8}$ and $\frac{3}{18}$ in., and is measured between the inside edges of the rims with the front of the wheels spread apart to take up any slack there may be in the connexions.
The front and the rear axles should be parallel to one another, and the wheels should track properly. When steering straight ahead want of alinement occasionally occurs through, for example, slackness in the connexions between the springs and the axlos, or may be due to the springs on one side flattening out more than those on the other. Defective springs should be set up by the spring smith and properly hardened and tempered. The wheels may be lined up, should this be necessary, as shown in Fig. 12, the measurements being taken between the points indicated by the arrow heads. The surrounding line represents a cord tightly stretched from crossbars temporarily secured to the frame side members, the cord being level with the centres of the wheels. Corresponding measurements on the opposite sides of the vehicle should be equal.

## Defects in Steering

29. Defects in the steering of a vehicle may arise from a number of causes, and it is first necessary to make sure that the tires are both inflated to the correct pressure. Soft tires or tires which are inflated to different pressures will make the steering stiff and may create a bias or drag towards one side. When the steering stiffens suddenly, or pulls the car to one side a soft or deflated tire is the most probable reason. A burst tire at speed may causedeflection of the vehicle and result in a serious accident. The tires should therefore be kept in good condition and the steering hand-wheel grasped firmly when driving fast.

Assuming that the tires are properly inflated, a persistent drag to one side may be caused by excessive wear in one of the steering head bearings, thus preventing the tire of the road wheel concerned from making contact with the road at the proper point and upsetting any centre-point steering
features which the vehicle may possess. An excessive amount of free play will be due to wear of the worm or other steering mechanism and possibly the joints of the steering transmission In most cases adjustment is possible In worm gearing the worm can often be turned to a new position Should the steering bocome stiff, attention should be given to lubrication, particularly of the steering heads and the worm, screw, or other operating mechanism
30. The bolts holding the body down on to the frame may slack back, or may become slack through the packing perishing or being compressed. This is a frequent but unsus. pected cause of intermittent body noises and is particularly noticeable when driving over a had road surface. New felt packing should be fitted before tightening up the bolts. In older vehicles therc is sometimes a certain amount of settling down of body or frame which may cause doors to jam, and with lightly built bodies this can only be remedied by attention to the packing between the frame and body side members
31. Lack of proper attention to the lubrication of such parts as the spring shackle pins, the brake control joints, and the leaves of the springs, is a frequent cause of intermittent squeaks and rattles while the car is travelling. Other causes may be loose mudguard stays, slack holding down bolts for the running boards, worn windscreen fittings, perished felt, leather, rubber or other seating strips on which the edges of the bonnet rest.

The hinges and the door fittings and the hinges of the hood framework may work while the car is running, and the various lugs and spring brackets, riveted or bolted to the frame side members, are liable to slacken in time. The spring leaves and the shackle pins (other than those fitted with rubber Silentbloc liners) need regular and frequent lubrication, and a little thin penetrating oil applied occasionally to the various joints will check noise. Slack screws and bolts should, of course, be tightened up, and rivets which are slack in their holes should be replaced. They cannot be properly tightened up.

## Failure of the Current

32. Loose battery counexions may result in failure of the electric light or of the starter motor, and attention should always be given to this point first. Failure of the current due to a discharged accumulator may result from slipping of the driving belt, where this method of drive is employed, or it may be due to some defect in the dynamo or to a short circuit or bad connexion in the wiring, the causes of which are dealt with in paragraph 27. Should the lights fail through blowing of the fuse, two causes should be looked for, namely, either an excessive charging rate due to some defect in the dynamo or a short circuit in any of the main wires in the charging circuit or in any of the wires leading to the lamps or other electrical components. Dynamo repairs should only be entrusted to the makers or to some firm specializing in this work.
33. Binding of the brakes or slipping of the clutch may be responsible for poor acceleration. Causes of clutch slip are dealt with in para. 20. The hand brake may have been left on. Want of lubrication, apart from increasing the difficulty of applying the brakes, may cause them to remain in engagement after the hand lever or pedal has been released. One or more of the holding off springs may have broken, leaving the brake shoes in contact with the drum. If the shoes are set too close to the drums the flexing of the springs may cause intermittent contact between shoes and drums.

If the brakes are not used for any part of a run the drums should be cool to the touch. If they are hot or even warm there is some continuous or intermittent binding. One way of

Motor Car. Fig. 18. Tgpioal ohasgis lubrication calendar, giving a general indication as to how often the diferent points should be labricated it satisfactory performance and long life are to be secared. If
the mileage is small the car should reeeive some attention overy week
testing brake adjustment is by feeling whether the drums have heated uniformly at the end of a run when they have had normal use. The operating connexions on an overheated drum should be slacked off, or vice versa.
34. A fierce clutch which grips suddenly and starts the engines with a jerk may cause serious damage to the transmission, and may even twist and ultimately break the axlo driving shafts. A possible but not very likely cause is want of alinement, due to wear of the central spigot bearing between the rear end of the crankshaft and the forward end of the clutch shaft.

The different types of clutch differ so much from one another that it is difficult to give any generally applicable rules, but mention may be made particularly of the following. In the widely used single plate clutch in which friction disks made of asbestos fabric reinforced with brass wire are interposed between the metal driving and driven disks, fierceness can be cured by injecting a little thin oil into the clutch. Very little is sufficient to soften the asbestos surfaces slightly, although any excess is soon burnt off.

Metal to metal single-plate or multiple disk clutches and clutches employing cork inserts engaging metal plates always run in oil, and
fierceness may be due to the oil being too thin or the clutch requiring cleansing or renewal of the wil. The cone clutch, which is seldom seen to-day, may require relining or redrcsaing, or the rivets securing the lining in position may project above the surface.

Breakdowns on the Road. Should the engine fail to run or to start, the trouble is probably some comparatively minor derangement of the ignition or the carburation. In the event of a breakdown on the road the cause should be investigated as follows. First make sure that the petrol is turned on and is available at the carburetter jets. Then find out whether there is a spark at the plugs by removing one of the high tension leads from a plug terminal and holding it so that the terminal on the wire is close to but not touching some metal part of the engine. Then get an assistant to turn the engine by the starting handle and watch for a spark to jump across the intervening gap.

Should the spark be present, the question as to whether the gap between the points of the sparking plug is correct should next be investigated and the procedure outlined in the various headings above may then be followed; it is probable that the trouble will be located long before a more serious breakdown need be contemplated.

## Motor Cycles: Buying and RunNing Them

## Facts and Figures as Aids to Economy and Efficiency

> The information given In thls article is supplemented by that in the entries on the various parts of the machine, e.g. Brake: Carburetter. See also Garage: Gear; Lubrication and the article following on Motoring

The prospective motor cyclist should refer bound to make calls in muddied overalls, to the legal portion of the succeeding article on Motoring, where full particulars are given about the necessary preliminaries such as registration, the procuring of a car licence and a driving licence, and insurance.

All types of motor cycle are essentially more economical than cars, and the lighter machines afford the cheapest possible form of travel, for their cost is less than that of a season ticket on the railway. The chief objection to using a motor cycle for business purposes throughout the year is the exposure of the rider. This is not particularly serious when direct transport from the home to the office or factory is desired; a machine of moderate horse power can be equipped with windscreen and legshields, so that the driver can keep dry and warm in light waterproof overalls. But, if the rider's duties involve numerous stoppages, he will be
bound to make calls in muddied overalls,
which is usually objectionable. No elderly person with a weak heart or chest should face the exposure of a motor cycle, or the exertion of using the foot starter; but to the rest of the community, including women, the motor cycle offers the cheapest means of private transport, available either for pleasure or for utility purposes. Serious stoppages are extremely uncommon with a machine of good class, and petty stoppages are soon set right on the road.

It is not possible to generalise about the cost of owning and running a machine, as the market embraces a great variety of types, ranging from the motor-assisted bicycle, selling at $£ 15$ and weighing no more than 100 lb ., up to the 8 horse power leviathan, capable of 100 miles per hour and catalogued at $£ 150$, whilst sidecars and three-wheeled runabouts are obtainable at any figure from $£ 50$ upwards.

Motor Cycle．Fig．1． 98 c．c．Excelsior two－stroke light－weight．
Fig．2．Ariel＂Square－FTous，＂with four－cylinder monobloo engine and two－geared tly－wheels Courtesy of The Motor C！⿰亻⿻乚㇒

The $£ 15$ machine will go anywhere，and costs about 2 s in out－of－pocket expenses for every 100 miles it covers，whilst its annual overhead charges are limited to tax and insurance， possibly $£ 3$ in all．The expenses rise in pro－ portion to the cost，weight and power of the machine．Some suggestions on choosing a machine follow．

The $£ 15$ Lightweight．These machincs have been recently introduced as the result of their popularity on the European Continent，where they are sold by the thousand to the artisan class，and employed for travelling to work during the week and for pleasure at week－ ends．They are taxed in Great Britain at a reduced rate of 15 s per annum．When the machine has licen lought，it can be run $\mathbf{5 , 0 0 0}$ miles for a total outlay of about $£ 8$ to £10．It is actually easier to ride than a pedal cycle and far more comfortable，as its extra weight（ahout $1(0) \mathrm{lb}$ ．）steadies it，and the large tires and saddle insulate the rider from bumps and vibration．It will climb any main road hill，and though its maximum speed does not exceed 35 miles an hour，it will average over 20 miles per hour all day long．

Larger Bicycles．The touring classes include machines from $2 \frac{1}{2}$ horse power to 8 horse power， varying in price from $£ 25$ to $£ 150$ ．The more powerful a machine is，the more it will cost to run，and the more difficult it will be to handle when its engino is stopperl；for examplo，in wheeling it out of its shed In this touring class the machine of 350 c．c．（about $23 \mathrm{~h} . \mathrm{p}$ ．） is the most practical．Smaller engines must be geared rather low to enable the machine to climb steep hills and to maintain a good speed against a head wind．

But a $2 \frac{3}{3}$ horse power engine has ample power for all ordinary purposes，and can be rin quietly like a good car．It is the best all－round machine for young and middle－aged people，and is quite suitahle for the beginner，heing easy to start，inexpensive to maintain．not cumbrous
to handle in the garage，and a splendid goer． The more powerful types of 500 c．c．（ $3 \frac{1}{2}$ h．p．） and upwards may fairly be compared to the sports cars．They are unnecessarily powerful． and are chiefly bought by the sporting type of rider，who has no objection to weight，and indulges at times in very high speeds．Alter－ natively，the big－engined bicycle may be used for pulling a sidecar．

Pillion Riding．Coroners and magistrates often denounce the practice of carrying a passenger on the carrier of a motor cycle． It is by no means so dangerous as might be supposed．The insurance companies frame their premiums in accordance with accurate statistics．If a motor cyclist wishes to carry a pillion passenger，he must pay an extra 50 per cent on his premiunı．Obviously two people will be endangered in any accirlent with a pillion rider aboard，and we should therefore expect the premiums to be douhle that for a solo machine，instead of being only 50 per cent higher．
Undoubtedly the presence of an extra weight of perhaps 10 st．，high up at the stern of the machine，must affect control to some extent；but the insurance data suggest that the added risk is negligible，and is really limited to the chance of two people being hurt instead of one On the other hand it is obvious that nobody should carry a pillion passenger until he has ridden soveral thousand miles alone， and has becone a tolerably expert driver．It is an offence to take a passenger on anything but a proper seat（see page 821 ）．
Sidecars．Despite the introduction of the $£ 100$ motor car the sidecar retains its popu－ larity．Quite a serviceable sidecar outfit of 2\＄－3 horse power can be bought complete for about $£ 50$ ，half the cost of the smallest new car．Running costs show a similar ratio， as the tax and insurance，fuel bill and tire bill of the small car will be twice as heavy．It is true that $n$ second hand amall car can he hought
for £50，but its maintenance costs will exceed those of a new 8 horse power ear，and com－ pare somewhat unfavourably with those of a cheap sidecar．An 8 horse power sidecar is probably slightly more expensive to run than a bahy car．

Three－wheelers．There are several excellent three－wheelers on the market，which on the average cost about the sume as a small four－ wheeled car both to buy and to run．Having three tracks，they are less comfortable than a baby car on an inferior road；but，as they have plenty of engine power in proportion to their weight，the road performance is extremely vivacious by comparison，and this attraction explains their continued survival．
Specification．As motor cycles are designed by experts who are themselves practical riders，and who can only keep in business by offering the public a machine which is good value for the moncy，it is unnecessary to dis－ cuss specification in detail，with one crception． Some of the cheaper machines have acetylene lamps，or some other inexpensive form of illuminant．There is only one really satis－ factory type of lighting，namely，electrio lighting from a battery，the hattery being charged by a dynamo driven off the engine． Except where every shilling counts，this type of lighting should be specilied，as no ot her system is really efficient and convenient at night．

Purchasing the Machine．The motor oycle should be bought locally．if possible．The agent receives a commission on the sale of a new machine，and is expected to give his customer a certain amount of sorvice，esperi－ ally if the customer is a beginner．But if a customer residing in Westmorland，for example，buys from a London dealer，he cannot hope for any free service．There is only one exception to this rule of buying locally．If a man is buying his second or third machine he may wish to＂trade off＂ the old machine in part payment for the

Motor Cycle．Fig．3． 500 c．e．Royal Enfeld sidgcar outtit．Fig．4．B．S．A． 1,021 c．c．three－wheeler，with 9 b．p．air－cooled V－twin engine Courtesy of The Motor Cycle
new one. If he lives in a remote place, his local dealer may lack facilities for re-selling second hand maohines, and may make him a much poorer allowance than a big London dealer will. In such cases it may pay to sacrifice the service facilities in return for a higher exchange allowance.

Learning to Ride. The three requisites are a good handbook, a friend to act as a tutor, and a suitable machine. Excellent handbooks are published by the motor cycling journals and other firms. A local rider will always give the initial instruction on some quiet road. and confidence comes with amazing rapidity, as the machine is so low and steady that from the outset it feels much safer than a pedal cycle. An initial apprenticeship on a pedal cycle is always desirable, as it familiarises the rider with various road emergencies, and givea him a certain amount of road sense. But such an apprentice:hip is not essential, and many men and women take up motor cycling without ever having learned to ride a pedal cycle.
The beginner need not be afraid of damaging the machine. It is not in the least likely that he will clo it any harm, provided always that he lubricates the engine adequately. If he under-oils it he may wreck the engine in five miles. Therefore he should not attempt to run it until he has had the lubrication system thoroughly explained, and ever afterwands he should verify his oiling nt short intervals until he learns to recognize, from the beat of his engine, whether it is properly oiled or not. The working of a typical simple splash lubrication system is illustrated in Fig. 6. The toolbag will contain a booklet explaining this important matter in detail, and any local rider will demonstrate its action to him.

Before he risks a solitary ride, he should further ask his dealer or a friend to show him how to mend a puncture. In all probability his tires will not puncture for 3,000 iniles, but he cannot turn a heavy machine upside down to get at the tire, as he would with a pedal cycle, so a practical demonstration will be of real value.

Before taking to the road the beginner should master the art of stopping the machine. The engine can be stopped in two ways, either by shutting the throttle or lifting the exhaust valve. Two brakes are available for bringing the machine to a stop-a rear brake, operated by a pedal, and a front brake operated by a pull-up lever under the right grip of the handle bar. Some novices are a little apt to become excited in any sudden emergency, and to lose their heads. They should school themselves to shut of the engine and apply the brakes instinctively.
The ordinary traffic signals must be given. These are explained and illustrated in the article on motoring that follows. Very abrupt braking should never be attempted on wet, greasy surfaces, or on loose gravelly roads. Except on firm surfaces the brakes should be applied progressively and firmly, rather than abruptly. Generally speaking, all changes of speed should be executed smoothly without jerk. High speed should be entirely eschewed except on deserted roads, and the novice should not attempt high speed for at least three months after starting to ride.

Starting the Engine. A lonely novice is all diagnosis of motor troubles is briefly apt to experience some trouble in starting engines of 350 c.c. and over; the smaller engines never give any serious trouble in this respect. Such an experience should not discourage the tiro. Even racing engines of 500 c.c. arc tolerably easy to start when they are tackled in the right way, and the owner will soon learn how to operate the controls so as to obtain a prompt start. If his diffioulties persist, he should ask the dealer or an expert local rider to give him a demonstration, both with the engine cold and with the engine warm.

The first cssential is that the engine should be free: it is quite impossible to start a stiff enginc easily. For this reason the proper amount of the correct oil should be used, since cold oil, used to excess, gums up a piston rather tightly. If the engine is cold the carburetter should be tickled rather liberally, but this should be omitted when the engine is warm. For the rest the spark should be advanced about two-thirds; note the cxact setting whenever a specially easy start is obtained. The throttle should be opened very little. Here, again, it pays to note the exact position when success results.
If there is an air lever, it should be shut

Motor Cycle. Fig. S. Diagram illastrating operation of the valves of a singlo-cylinder four-stroke engine. Fg. 8. Diagram illastrating typical emple aplash labrication aystom
Courtesy of The Motor Cycle
A petrol engine muat work subjec o three conditions, namely: (1) If it is in perfecl order mechanically. (2) If a proper spark is occurring a! the points of the sparting plug. (3) If the carburetter is delivering the correct charge of gas. In other words, the cause of a stoppage is concerned with the ignition, with the gas charge, or with the engine. If the beginner can clear up this initial problem, he can at once dismiss from his mind two-thirds of the polenticl troubles and concentrate on tracking down his actual trouble in a very restricted field.
The trained rider looks th: machine over swiftly when a stop occurs. He makes sure, perhaps, that petrol is reaching the carburetter by pressing the tickler. He eyes the engine to see if he can spot any broken part, and touches his kick-starter to see if the valve tappets are working normally. (The operation of the valves of a single cylinder side-valve, four-stroke motor cycle engine is diagrammatically shown in Fig. ©). If all is well so far, he forms a preliminary expectation that the trouble is ignition, and unscrews his sparking plug. Very probably the point? are fouled with carbon or bridged with soot or oil; he cleans the plug and goes on his way in $\pi$ couple of minutes
Sometimes matters are not so simple as this. Perhaps the plug looks clean and healthy. In this case he may test the spark. This is done by jamming it (with cable still attached) in some nook on the cylinder head. so that only the thick end of the plug touches the machinc. He then raises the valve-lifter and kicks the starter. A splendid spark jumps the plug points, so that his trouble is not connected with the ignition Perhape 90 per cent of motor cycle stops arc due to dirty plugs, and if the novice carries a spare plug and inserts it under such circumstances, he will surmount most of his early stops. shade when the engine is As the spark is perfect the rider has eliminated warm. If there is a mix- a third of the field of possible trouble, and he ture lever, it should be next suspects his carburetter. 'This enubodies set. at "rich" with a cold engine, and at "weak" with a warm engine. The kick starter should be gently felt until it encounters the maximum resistance, from which it should be allowed to return to its topmost position. It may then be eased a fraction of an inch past this position by gently pressing it with the valve lifter raised. The engine should then respond to a strong downward thrust with the foot, the valve lifter being dropped as soon as the kick starter begins to move down.

Trouble on the Road. Nothing is more bewildering to the novice than a complete stoppage of his engine when he has not the fainterst conception of the cause. The handbooks referred to above will give him an encyclopedic analysis of the various possibilities, together with much assistance in effecting a diagnosis and in executing a repair. Such a handbook should be carried in the pocket. At the worst, he need not be seriously disturbed, as there is a splendid camaraderie of the road, and before long some more expert rider is likely to come to his assistance.

However, it may set the beginner's mind working in a scientific direction if the key to one or more very fine holes through which petrol is forced to vaporise it into gas. It is a simple matter for a speck of dirt to seal these spraying holes and in this way to stop the production of gas.
His next atep will be to take out the jet, as it is called, hold it up to the light and peep through it. A carburetter booklet in the toolbag will contain sketches indicating the jet and the manner of dismantling the carburetter. If the jet is stopped up, he blows through it or clears it with a fine wire, and all is well He must, however, be very careful not to alter the size of the jet by using the wira or a needle roughly. Only in the case of a mechanical breakage will further progress be impossible. This is an extremely rare happening, and is best solved by "flagging" a passing lorry and getting the driver to t.ransport the machine to the nearest garage. The principles and working of two. stroke and four-stroke engines are dealt with in the article on Internal Combustion Engine ; systems of Lubrication are explained under that entry, while there is much information of use to the motor cyclist in the article on Motoring.

## MOTORING AND MOTOR LAW

## Instructions for Driving, Licensing and Insuring the Car

As a preceding article has dealt with the choice and care of the car, thls one dealawith the duties and respansibilities of the owner and the driver. especially as affected by the important Road Traffic Act of 1930 . In the legal section the prospective motarist will find information about the necessary preliminaries such as regisiration, the procuring of car licence and driving licence, and insurance. See Number Plate
'The management of a motor car cin the roal gear. In top goar the engins shaft rotates is perhaps a nervous undertaking for the about five times to one of the road wheela, first 100 miles or so, but afterwards, when in the middle gear of a threespeed gear box the handling of the car has beceme more about nine to one, and in the bottom gear, or less automatic, there is a danger that about fourteen to onc. When a lower gear the driser inay become too confident, too is to be engaged, therefure, it is first necessary casual, or too daring. It is not possible to to inerease the engine speed with the gear teach onesclf to drive from books alone, and it is inalvisable to learn to drive on ones own car. The dealer who supplics the new car can usually provide a suitable tutor, and a car. There are also motoring schools where one miny learn the essential mechanics of a car and how to drive it.
The new motorist should get accustomed to the controls before he ventures out alone. He must feel at home in the car and shonld have reached that stage when the various scquences of operation are more or less automatic. This is not so difficult as nuight appcar, although when gear changing the novice may at first be somewhat awkward. To change gear without noise tequires a great deal of practice and is a matter of doing the right thing nt exactly the right time.

Changing Gear. The speced of the sliding gear wheels on the main or final driving shaft is controlled by the speed of the road wheels. The fixed geais on the lay shaft are alwnys driven by tho clutch shaft, their speed correaponding to that of the engine when the clutch is engaged. Therefore, if a silent gear change is to be made, the speeds of the teeth of the two whecls to be engaged must bo as nearly as possible the same at the instant the change is made.

Chancing up from a low gear to a higher is easier than changing down. Wiith most cars all that is necessary is to de-clutch with the accelerator pedal raised so that the engine sped will decreasc. After a secund or two the higl:er gear may be quietly engaged and the clutch may then be reengaged and the engine acceleratel.
Brictly, this procedure is as follows:

1. Accelemte the car up to alrout 8 miles per hour in first gear.
2. Let the accelerator perdal come right up. 3. I'ress the clutch pedal right down.
3. Move the gear levet out of the lirst gear nutel.
4. Wnit for engine speed to decrease a little.
5. Move gear lever into the second gear noteh.
6. Let the clutch pedal in smoothly but quickly.
7. l'ress down the accelerator pedal.
The same procerlure is fullowed when changing up into higher gears.

The main point to re member when changing dlown to a lower gear is that the engine speed is higher in relation to the apect of the car when one of the lower ration is used than when in top

To change down, by the method known as double clutching, the accelerator perlal should be eased slightly, the clutch pedal pressed down and the gear lever moved into nentral. The couine will accelerate when free

Motoring. Fig. 1. Goas soleoting lever lor Wilson gear boz. Vig. 2 (Top). Diagrammatic skotch showing arrangement of gear wheel

This procedure may be yummarised as follows :

1. Ease the accelcrator perdal slightly.
‥ Depress the clutch perlal.
2. Slip the gear lever into neutral.
3. Engage the clutch again to speed up the clutch shaft and countershaft gear wheels.
4. Depress the clutch pedal
5. Slip the gear lever into the lower gear position.
6. Let the clutch pedal up again, quickly but smonthly.

It is possible after some practice to make these changea so rapidly that they may be described as two quick dabs on the cluteh pedal made in time with the two movements of the gear lever. Whether

1. Improved Giears, Lia. 2. 'The Autocar ${ }^{\circ}$
and the clutch should be quickly re-engnged. This raises the speed of the gears on the counter-shnft. The clutch pedal should again be depressed, and the gear lever moved into the desired position when the clutch is once niore engaged, and the engine accelerated. If this operntion is well practised, slowly at first, and gradually speeding un, the driver of the car will be enabled to carry out this apparently complicated operntion in about a second of time at any speed.
tho accelerator pedal is kept hard down or is cased slightly depends upon the characteristics of the car. The former is better if it can be managed.

Gcar changing difficulties are, however. entirely eliminated in the Wilson pre-selective gear box, in which a small lever, carried on the stcering column, as shown in Fig. I, is set by the fingers before making the change. The gear is not changed until the clutch pedal is depressed and ro-engaged.

The gear itself is shown diagrammatically in Fig. 2 with the several epicyclic groups spread out, but actually all four groups are close together. Each group consists of a central sun whecl, an outer toothed ring or annulus, and several planct pinions meshing with both the sun wheel and annulus, the different sets being interconnected as shown. To engage the several lower gears, brakes (not shown in the drawing) are applied to one

Motoring. Fig. 3. Skidding. A. How to steer ont of a skid. B. How stoering the cas in the wrong direction will increase skid
or more of the outer members as required. The direct speed is obtained by engaging the top gear clutch.
The reader is reminderl that the brakes, clutch, and nccelerator pedals should not be preased or released violently. A progressive nction is desirable, cepecially in the case of the accelerator. Further, excessive usc of the brakes is not recommended; in fact a gond driver rarely usos his brakes, but relies generally upon his engine and supplements its ictarding effect by the brakes when descending steep gradients or stopping. An exception to this occurs, however, when the roads are slippery, ns mentioned in the section below.

Skidding. Side slipping or skidding with rare exceptions always affects the back wheels, and is due to excessive retardation by the brakes acting on the wheels themsclves or on the propeller shaft, or hy the engine acting as $n$ brake. The last mentioned is often overlooked, but it is sufficient to start a skid on mads which are only half wet, as when rain has just started or when the surface is drying. It is inadvisable at such times cither to apply the hand brake or to use the engine as a brake, since both act on the rear wheels only. Brakes applied to the front wheels alone cannot cause a skid, and skidding is very improbable with cars hnving four wheel brakes properly adjusted. Fig. 3 shows, A, how th steer out of a skid. and B, how to steer the car in the wrong direction will increase skid.

The New Car. The following hints will be found of valuc to the owner of a new car. When taking delivery ask the agent to explain thoroughly the controls and gencral details of the car, and to go over the important subjects dealt with in the instruction book. The first 500 or 1,000 miles are the most important in the life of n new car, and a limit of 30 miles nn hour on top gear during this period will save a considerable amount of expense in the future, while in addition it will improve the ultimate performance of the notor car when it has leen "run in." I.ower limits should be observed on the lower gears in order to avoid exce.sive cngine sperd.

An enginc should always he given thic opportunity of warming up from cold for a few minutes hefore starting off on the road, to enable the nil to thin down and pass thmugh the bearings and on to the cylindor hores When the oil-pressure gange drops back to the normal running point the engine will be warn enough. After the first 500 miles change the oi! in the engine sump. The old oil has been subjected to heavy work with tight engine hearings, and will have lost its viscosity and contain impurities. Check thic tire pressures at regular intervals. A tire gauge is cessentia! for this purpose.
The new owner should learn how best to start the engine without using the starting motor several tirnes on each occasion. There is a certain position for the thmttle. ignition, and strangler controls which will give thic quickest start, either by hand or when using the starting motor. Learn to underatand the ammeter on the instrument hoard, and the readings shown when some or all of the lights are used, and when the dynamo awitch is in the "off," "charge." or "summer charge" and "winter charge" positions. Remember that coil ignition takes a fair nmount of current from the nccumulator and that. if the ignition is left in the "on" position for some time when the engine is not running, there will be a considerable drain on the accmulator. The accumulator sinould he inspected every fortnight or less nccording to mileage, and the level of the acid mantained about $f$ in. above the tops of the plates by adding distilled water.
Washing the Car. Some sort of routine in washing $n$ car is exsentia! if time is to be saved. (Sec Figs. 4-9.) A good strong sponge should be used for the oxterior, including wings, but not for the wheela, humpers, and so forth. The chamois leather which is used for drying off the exterior of the car can he used for cleaning the interior, and this leather should be kept near the driver's seat for occrasional cleaning of the windscreen or windows on a long journey. A spot of grense will ruin $n$ chanois leather; and it is well to beware of the grease that exules from lubrication nipples and spring leaves under the car The lnw requires a firc extinguisher or supply of sand to be kept in the garage when petrol is storal there Any in tho tank counts ns stored petrol.
Motoring Holidays. The cost of motoring holidays varies enormously. On the one hand they can be very expensive, and, on the other hand, the cost can he actually leas than that incurred when stnying at home. Onc expenae that is often overlooked is that of buying meals away from home, an item which alone can easily excced the entire cost of keeping the car in commission. It is worth rememhering that pienic incals cost little, if any, more than those partaken at home. A tomr in which the party puts up at a different hotel every night is the most expensivo way of holiday-making with a motor car. To tour from a centre is cheaper. In this ease the party stays for some time at an hotel, hoarding-house or rooms and explores the neighbourhood in the car. The other oxticme is to carry tents for camping. Tents and equipment may be hired at very reasonable charges. It is possible to sleep in some cars. (See Figs. 10, 11 \& 12.)
Another form of !noliday is a camping tour

Motorin

with a caravan towed by the car. Caravans along different roads, the policeman faces may be hired at very reasonalile rates, and the vehicle to be stoplied
any car over 9 horse-power will be found sufficiently powerful for this purposc. An actual holiday for two persons with a car and an $8 . f t$. trailer caravan worked out at under $£ 19$ for three wecks, or about $£ 33$ s. per head per weck.
Traffle Signals. The Highorny Code issued by the Ninistry of 'Transport includes a system of standard signals to be used by the polica or other official traffic controllers, and also signals which the driver of $n$ car should employ to give notice of his intentions. The police signals are as follow
(I) A vehicle approaching the policeman is halted hy ex. ending than is halted hy ex. vehicles from his right, he looks towards the tending the right arm and driver and beckons him on with the right arm hand at full length upwards but without turning his boly. with tho palm of the hand (i) When bringing on vehicles from his lefit towards the vehicle. Wherc he looks in that direction, and gives o similar two vehicles are approaching signal to that in (5), but with the left arm.

The recognized signals to be given by the driver are as follow :
(7) A warning that a driver is going to slow down or stop or turn to the left is given by extending the right arm and hand horizontally towards the offside of the car with the palm downwards and moving the hand slowly up and down.
(8) When about to turn to the right, the right arm and hand are extended horizontally straight out from the offside of the vehiclo with the palm towards the iront.

quoted. Most makers give guaranters with their cars and several include free service for some time after delivery. This guarantee and service only apply to parts of the car which the makers have themselves manufactured: it will not apply, for example, to the lighting system and tires.

In the casc of second hand enrs there is no maker's guarantec, but some dealers themselves guarantee the car for some months. In most cases, however, the purchaser must take the car as he finds it, and so, unlces he knows

From the Highuay Code, by permission of Controller of H.M. Stationery Oflice
(9) An invitation to a following vehicle to overtake on the right is given by extending the right arm and hand downwards and moving them backwards and forwards so as to beckon the vebicle forward
(10) The desire to go straight abead is indicated to the traffic controller by moving the band and forearm well forward and back ward in a vertical plane.
(11) When desiring to turn to the left the hand and arm are pointed in that direction across the body in a definite manner so that the signal may be radily seen.
(12) When wishing to turn to the right the arm should be extended horizontally with the palm towards the front, this sigmal being identical with number (8) above.

Legal Considerations: Buying a Car. A motorist who proposes to sell his present car and buy another one will, as a rule, receivo a larger price for his old car if he arranges to get a new car of the samemake and "trades-in" his old car in part exchange. It is always advisable to do business with a dealer who holds an agency for the car to he bought. The terms of the sale of the old car should be put into writing (a letter signed by the purchaser will be sufficient), otherwisc the purchaser can legally refuse to take the car. The agreement does not require any stamp. If any accessories fitted on to the car are not to be sold this should be made clear at the time of sale and committed to writing also.

The prices quoted for new cars are usually ex-works, that is, the purchaser will he required to pay the cost of delivery from the manufacturer's works in addition to the price
something of its history, he will usually be well advised to spend a few pounds on having the car overhauled by oome expert and a report obtsined before purchasing. The motoring associations make examinations of this kind for a small fee.
A prospective purchaser should remember that the mere fact that the seller holds a registration book for the car in which his name appears as that of the registered owner does not necessarily mean that he has any right to sell the car. Cars held on the hire purchase system are registered in the name of the hirer and not in the name of the hire purchase company to which the car really belongs. If the hirer sells the car he does so in breach of his contract with the hire purchase company and they will be entitled to retake the car from any purchaser, who will thus lose the car without compensation, although he can recover the money he paid for it from the seller if he can find him

Reglstration and Licence. Before the purchaser can drive the car he must see that it is repistered and licensed and provide himself with an insurance certificato and driving licence. An insurance certificatc or cover ante must be produced before a road licence can he obtained. If the car is a new one, the dealer will usually arrange for its licensing and regiatration, and hand to the purchaser the registration book. If the dealer does not do this, the purchaser must himself obtain the registration book and licence from his local council. In the case of second-hand oara, the purchaser must get the registration bnok from the seller, insert his own name and auldress in
the book and send it at once to his local council Any licence in force for the car at the time it is bought will continue in force until the date on which it expires
A licence may ba taken out either for the whole or the remainder of any current year, ending December 31st, or for the whole or the remainder of any of the four quarters of the year ending March 31st, June 30th, September 30th or December 31st. If a licence is required, say, in Nay until the end of August, two licences will liave to he taken out, one for the remainder of the quarter ending of that quarter, nnother licence for the quarter ending September 30th. If the car is not to be used in September, a rebnte will be made if the licence is surrendered before the end of August.

Cost of the Licence. The annual duty on a car used for private purposes is $£ 1$ for every unit of horse power, with a minimum of $£ 6$ Where the engine of a car was manufactured before January 1st, 1913, the full licence must be paid in the first instance, but a quarterof the amount paid can then be reclaimed. Goods vehicles are taxed according to unladen weight the minimum (for vehicles under 12 $c w t$.$) being £ 10$ a year. The duty on motor cycles is 168 . for velicles not over 150 c.c. capacity. 30s. for vehiclea over that capacity but not excceding $224 \mathrm{1b}$. in weight, and $£ 3$ for vehicles over that weight. 'The duty on a sidecar is an additional $£ 1$.
The licence may be renewed at any time within the fortnight preceding the date on which it expires. The nuthorities usually allow also $n$ fortnight after the expiry of a licence for its renewal, but motorists should be careful not to use a vehicle during the periorl after the licence has elapsed unless they intend to renew the licence, as the police frequently take the registration numbers of vehicles seen on the mad during that period and institute proceedings if the licence is nnt ultimately renewed. The maximum penalty for using a vehicle not properly licensed is a fine of $£ 20$ or three times the licence duty, whichever is the greater.
If any alteration is made to the car-e.g. by painting it nnother colour, or using a vehiole licensed for private use as a commercial vehicle, or if the owner changes his address, the book and licence must be sent to the local council with particulara of the alterations. It should be noted that the owner must not himself alter the book, but must leave that entirely to the officials.

The Insurance Certificate. The insurance certificate will be obtained from the company with whom the vehicle is insured. Every motorist is now compelled to insure against injuries to third parties, excluding passengers travelling in the car, otherwise than for hire, or servants of the owner.

The first step in taking out an insurance colicy is the filling up of the proposal form. This form contains a number of questions which the motorist must answer relating to (1) the occupation of the motorist: (2) the nature of the risk to be covered and particulars of the vehicle; (3) the previous driving record of the motorist, including details of any accidents in which he has been involved. It is most important that all these questions should be correctly answered, for an inaccurate answer, even if made innocently and even if quite immaterial to the risk, may enable the insurance company to escape liability under the policy. In addition to answering carefully all questions that he is asked, the motorist must also disclose any fact known to him which would be likely to affect the mind of the insurance company in deciding whether or not they should accept the risk.

When the insurance company receive the pmposal form they may not issue a policy at once. There may be some inquiries to be made in consequence of the answers in the proposal form, and until these inquiries have been completed no policy is issued, but a cover note is sent to the motorist. Once this has been issued, the motorist is as fully insured as though he had the policy, but the cover note is only valid for a short timeusually 14 days.

If the policy has not been issued before the expiry of the 14 days the motorist nust apply to the insurance company to have the cover note extended. When the company have made all inquiries as the answers in the proposal form they will either issue a policy or else refuse to accept the risk and return the premium paid, less a proportionate suin for the period during which the motorist has been covered by the cover note.

## Penalties for Non-Insurance

It is nuw a very serious offence to use or to allow anyone else to use a vehicle which is not covered by insurance. The insurance must be against injury to third parties; a motorist is not required to insure against injury to himself or to his non-paying passengers, or against damage to the property of third parties, although every motorist should include these risks in his policy. The penalty for using a vehicle not properly covered is a fine not exceeding $\mathbf{5 5 0}$ or three months' imprisonment, or both. Disqualification from holding a driving licence for at least 12 inonths will follow automatically, unless there are special reasons why the disqualification should not be imposed.

The insurance certificate or cover note must be produced on demand to any police constable while the vehicle is on the road, and also after an accident (see below). If the driver is unable to produce the certificate at the time, he may avoid a prosecution by taking the certificate in person within five days to some police station which is selected by him at the time he is asked to produce it.

The Driving Licence. A driving licence may be obtained at any time from the local council. A form must be filled up stating (1) whether the applicant suffers from epilepsy or sudden attacks of giddiness or fainting; (2) whether he can read at a distance of 25 yards in good daylight (with glasses if worn) a motor car number plate; (3) whether he has lost either hand or foot or is suffering from any defoct in uny limb: (4) whether be is suffering from any other disease or disability that
would make it dangerous for him to drive. If all these questions are answered satisfactorily the licence will be granted automatically.

If questions (1) and (2) are not ansuered satisfactorily the licence will be refused, if (1) and (2) arc answered satisfactorily but the applicant is suffering from some disability under question (3) he will be granted a licence if he passes a driving test (fee 108.). For the purposes of the test he will be granted a provisional licence (fee $\overline{\text { ös. }}$ ) valid for three months. The test involves the usual operations of driving, e.g. stopping and starting on gradients, reversing, turning, etc. No one under 16 can obtain a licence to drive a motor cycle, no one under 17 a motor car, and no one under 21 a heavy motor car (such as a charabanc or lorry) unless, in the case of applicants under 21 , the driver can show that he was driving a heavy car in the last six months of 1929 .

As soon as the licence is issued the driver must write his name in it and must carry the licence with him whenever he is driving a motor-vehicle. He must produce his licence to a police officer when asked, but, if unableto do so, he may escape a prosecution if within five days he produces the licence in person at a police atation selected by him at the time $\mathbf{w}$-hen his licence is demanded.

When a driver has been convicterl of any r.otoring offence, particulars of the conviction
tires of some soft or clastic material until January lst, 1940. All tires must be kept free from any defect likely to cause danger. No vehicle must be excessively noisy, either on account of lack of repair of the vehicle or the faulty packing or adjustment of its load. Both owner and driver will be liable to a fine if this icgulation is not observed. The driver must be at all times in a position from which he can have full control of the vehicle.

Every motor car must carry two white lights to the front and onc red lamp to the rear during the hours of darkness. In " summer time" this means from one hour after sunset until one hour before sunrise, and during the

Motoring. Fig. 11. Tent trailer ready for the road. Fig. 12. Rigid type
Fig. 11, courtess, of Car Trallers, Led. Fig. 12. Eceles Mator Caravans. Lid
rest of the year from half an hour after sunset until half an hour before sunrise. Bicycles without sidecars require only one front-lamp and a rear lamp. Lampa which swivel when the vehicle is in motion (other than dipping headlamps) are not permitted. Draft regulations have been issucd governing the use of dipping headlights and the size of bulbs permitted, and if and when they come into force they can be obtained from
may be orrlered to be endorsed on his driving licence, and these endorsements will be copied on to any new licence. It is a serious offence to apply for a new licence without disclosing the fact that the old one was endorsed. When three years have elapsed from the date of an endorsement, and if no further endorsements have been made meantime, the driver is entitled to a clean licence-i.e. one without any endorsements.
Disqualification from driving may be imposed on a conviction for many motoring offences, and in the case of some offences-o.g. driving while under the influence of drink or drugs-must be imposed unlers special mitigating circumstances are present. While disqualified, the driver is liable to imprisonment if he drives any motor vehicle. The disqualification may be for any period, varying from a few weeks to life. Where the disqualification is for a longer period than six months, the driver may apply to the court after six months to have the disqualification removed, and if this application is refused, he may repeat it at intervals of not less than three months.

Brakes and Lights. Every motor vehicle must have two independent brakes in good working order. Every motor car the unladen weight of which exceeds one ton and which is first registered after January Ist, 1933, must have pneumatic tires, but vehicles registered before that date mav be fitted instead with
the local council. In many towns local regulations permit vehicles to remain in parking places without lights. Information as to local regulations is contained in the Motorist's Pocket-book, which may be obtained from the local registration authority.

As from January 1, 1932, every motor vehicle other than a motor cycle must carry a reflecting mirror. Vehicles first registered after January lst, 1932, must also be fitted with safety glass windscreens, and after January Ist. 1937, all vehicles must be so fitted whenever registered. Every driver will reccive with his driving licence a copy of the Highway Code.

Speeds and Driving Offences. The speed limit. is now abolished for private cars, but local speed limits of 10 or 20 miles on hour still exist in eome towns. Dangerous driving is a serious offence, and a new offence of careless driving, or driving without due care and attention, or without reasonable consideration for other persons using the road, has been created by the Road Traffic Act, 1930. Anyone who drives a motor vehicle while under the influence of drink or drugs is liable to a fine not exceeding $£ 50$ or imprisonment for not more than three months, and to more severe penal. ties for later convictions. Pillion riding otherwise than astride on a properly secured seat is illegal. Drivers must strictly obey all police signals, and stop when requested to do so by a police officer, under penalty of a fine of $£ 5$.

It is an offenco to leave a vehicle standing in a dangerous position, whether in the town or country, and also an offence to obstruct traffic. No motor vehicle must be driven on to any land that is not part of a road, or on to any common land. A vehicle may, however, be parked on any land (not common land or private property) within 15 yards of a road.

Motorists entering strange towns should proceed carefully until they have familiarised themselves with any local by-laws relating to the passing of tramcars and automatic signals, ctc. The useful Motorists' Pockt Book, already referred to, contains a list of these local regulations, and may be obtained from most local councils. In many towns in Scotland it is an offence to pass a tramcar on the near side while passengers are boarding or alighting. Although such regulations are not found in England, the same cffect may be producerl by a prosecution for dangerous or carelces driving.

Accidents. When a vehicle is concerned in any accident causing injury or damage to any person, vchicle or animal (including sheep or dogs but not poultry) the driver must stop and, if required, must give his name and address and produce his insurance certificate. If for any reason he does not do this, he must report the accident and produce his certificate at a police station, or to a police officer, as soon as possible, and in any event within 24 hours of the accident.

A driver concerned in an accident should be carcful not to make any admissions as to his liability, for if he does so his insurance company may repudiate liatility. He shou!d get the namo and address of the person injured, or the driver of the other velucle, and also the names and ardrcsses of any witnesses. He should also find out if he can whether the witnesses think he is to blame for the accident.

The points of importance to be considered are (1) the side of the road on which he was driving at the time of the accident; (2) the speed at which he was travelling ; (3) the exact width of the road and the state of its surface, etc. ; (4) the place on the road at which the collision took place, measured exactly from the kerb or other mark; (5) the position ineasured in the same way of the vehicles after the accident ; (6) the movements of the other party immediately before the accident, including such matters as apped, signals, ctc. No attempt should be made to dcal with any rlaim. The accident should be notified to thic insurance company and the whole matter left in their hands.

A motorist is liable for all damage to property or iniury to persons caused by his negligent driving. It is impossible to say generally what constitutes negligent diving. It may not bo negligent to drive at 60 miles per hour on a clear straight road, whereas it may be grossly negligent to drive at 10 miles per hour in a crowded strect on a wet night. Each case must be decided on its own facts. It may be said that anyone who departs from the ordin. ary rules of good driving will probally be held liable for any accident that may result.

Where both persons concerned have been negligent, neither will be able to recover damages against the other. This will not affect persons who are passengers in a vehicle which has been negligently diven. Thus, if Jones and Smith both drive negligently and collide, neither can recover against the other, but any passenger in either vehicle can recover against either Joncs or Smith or toth. Persons who give lifts to strangers in the country would do well to bear this in mind. Insurance against injurics to passengers (not carried for gain) is not compulsory and diivers who wish to be covered againt this tisk should see that it is included in their policy.

When anyone is killed as the result of an accident the driver of any vehicle concerned
will be required to give evidence at the inquest safes or pantrics at about freezing temperaand the coroner's jury may bring in a verdict of tures With care mould growths can be manslaughter againet the driver. In such a case the driver will later be tried for this scrious crime, but before he can be convicted it must be proved that he has been guilty of gross negligence, something more than the negligence necessary to make him liable in a civil action for damages and amounting to a reckless disregard for human life.

MOTTLED SOAP. The name is given to a variety of soap containing coloured markings similar to the veins in marble. The mottled soap was formerly made from kitchen refuse, and the inarbling was produced naturally from impurities in the fats or alkalis employed in the boiling.
The red mottled soap known as Castile soap owes its colour to the addition of green copperas, and being made with olive oil or similar oil produces a pure soap. See Soap.

MOULD : On Meat. Meat which is kept too long is acted upon by certain bacteria which cause it to become unfit for food. With the increased use of small household cold storage safes, various kinds of moulds will be seen upon meat, especially raw meat awaiting cooking. While harmful bacteria develop very slowly under cold storage conditions, moulds of fungous origin are frequently seen on the surface of the meat. Unlike bacteria, these moulds do not give rise to substances which are poisonous to human beings, and therefore do not render the meat unfit for food. In most cases the moulds are superficial and can be wiped off with a cloth. Black spot mould is the worst kind and penetrates most, but even this can be cut away with a very thin layer of meat, and the joint cooked with safety.
A common mould is the white one, the product of a moist atmosphero in the cold safe. In appearance it is very similar to that often scen upon checse.

The most favourable condition for the growths of moulds is a humid atmosphere in
avoided; they are unsightly even if harmless.

MOULD : The Disease. The term moulid is applied to a fungoid disease nttacking plants in garden and greenhouse. For practical purposes it is synonymous with nildew (q.v.).

MOULD: In Gardening. Mould or loam in gardening is the top spit of earth which has been acted upon by atmospheric influences; it. forms the base of potting composts. Commonly the term is used to express soil suitable for potting purposes, such as that obtained from old turves stacked and limed until they are well matured. See Compnst: Potting; Soil.

MOULD : In Cookery. This is a shape made of tin, aluminium, china, glass, pew'ter, or enamel, into which jellies, blanemanges, cake and pudding mixtures, etc., are poured. These moulds vary greatly in size and design.

Where kitchen equipment is limited and only two moulds are provided, it is a good plan to choose one rather plain oval shape and one border mould. Both sweet and savoury jellies can be moulded in the former and the latter can be used for fish or poultiv or meat mousse or galantine dishes, the centre, when turned out, being filled with a salad covered with mayonnaise sauce. The border mould is also useful for shaping lioine-made sponge cakes.

Ordinary pudding basins can be used as moulds should there be a shortage of the latter. When greasing fancy moulds it is nccessary to go into every part of the design. Pure olive oil is more satisfactory to use than butter for this purpose. See Butter; Cheese; Ice; Jelly.

MOULDING. A moulding is a strip of wood or other material worked to an ornamental pattern on one or more of its faces. In architecture, mouldings may be worked in stonc or brickwork, or other material of which the building is made, to relieve the surface

Moulding. Figa. 1-34. Stock patterns which the home worker can procure from a timber merchant.
The principal types are described in the text
praun from material supplied bu llandicrafls
and act as an adormment. They are generally found in the form of curved section strings at the bases and jambs, and arc used round openings for doors and windows. The householder is mostly concerned with mouldings for the embellishment of the interior of the housc. Patterns are obtainable from timber inerchants. Figs 1-34 illustrate a number of useful mouldings which the amateur can procure from Handicrafts, Ltd., or their agents.

In the first row are beads, astragals and pancl mouldings; Nos. 10, 11, 12 are rehated panel mouldings: 16, 17, 18 are for lid or plinth; 19 is a grooved drawer bottom moulding. In the fourth row are grooved corner moulding, edge moulding (23), glue blocking (24,25), and a door closing moulding (28). Bottoun row shows tray moulding (29, 30), solid cornice (31), door frame moulding (32), and cornice (33). Nos. 13, 14, 20, 26, 27, 31 and 34 are in oak, 16, 17, 18 in hazel walnut, and the rest in suitable hardwood.
Cabinet mouldings are made in a variety of patterns and in many different sizes for the decoration of furniture. Picture anouldings are in a class by themselves, and arc dealt with in the article on picture framing. See Capping; Ceiling: Chest: Corner Dresser; Cupboard I)oll's House; Door: Grandfather Clock; Picture Framing; Wardioke, etc.
MOULTING : Of Birds. Moulting is the process by which every vear birds renew their phomage, shedding their old feathers and growing new ones. As far as the ordinary householder is concerned its interest is confireed to the fowls, ducks, pigeons, parrots, or other kinds he happens to keep.

Although not a disease, moulting is a certain strain on the constitution of the bird, and care should therefore be taken that it is in good condition when the season for it begins. l'recautions should be taken against damp, liut ar a rule very little change of diet is dexirable, although this does good with some binds of birds-pigenns, for instance.
Fowls. In the case of the domestic fowl the process of putting on neiv plumnge starts in July and goes on until September, some birds moulting early and ot hers late. Poultry keepers should endeavour to get their fowls to moult early, so that the birds may recover and get their new plumage before the cold wenther sets in, and much can be done by judicious management. As a rule young hens moult far more casily than old ones, the average time occupied by the former heing from if to 8 weeks. An old hen will sometimes take 3, 4 , and even 5 months. Generally speaking, the average time is about $\mathbf{3}$ months.

The easiest way to accelerate the moult is to curtail the fool supply of the birds, feeding yparingly for a bout two weeks and then giving them plenty of fond of a nitrogenous character. Extra feeding should not begin until the fowla are actually in moult, that is to say, when the new feathers are growing. Feathering will be greatly assisted by giving each fowl a pinch of smphur in its soft food every day. A little suntlower seed or hemp seed with the evening grain food is helpful.
Warm weather is more conducive to a rapid moult than when it is cold and wet, and care should he taken throughout to kecp the birds warm. While the inoulting season is on, the run will be littered with feathers, and these should te cleared away daily.
Pigeons and Canaries. With pigeons moulting usually begins in April, and attention should be paid to the diet and general conditions. In particular the bird should be kept warm and protected from draughts, as a chill may have the effect of stopping the moult and will affect the health of the bird. It is well during moulting to feed a pigenn on hread soaked in water to which a little salt has been added.

Canaries require special care when they are moulting. They should be kept in an even temperature, and for this reason the cage should be hung in a fairly warm room during winter, and well covered up at night. The bath need not be altered in any way, but it is of ten beneficial to add to the water some imon in the form of citrate. See Canary ; Parrot : Pigeon; Poultry.

MOUNTAIN ASH. A summer-leafing tree, with ornamental foliage, flowers and berries, the mountain ash (Pyrus aucuparia) is particularly suited for culture in suburban gardens, as it will flourish in a smoky atmosphere. Its usual leight in and about London is from 15 ft . to 20 ft It may be increased by secd. The white flowers are borne in May and Junc, and are followed in the autumn by deep orange or scarlet berries.
MOUNTAIN AVENS. A family of hardy evergreen trailing rock garden julants, of which the species Dryas octopetala, a native plant of great beauty, is found on the mountains of various parts of the United Kingdom. The flowers have eight petals, arc about 1 in . in diameter, and arc white, with conspicuous yellow stems. Dryas Drummondii has yellow Howers; both bloom in summer.

Propagation is by division in spring, or by seeds sown in the spring when available They flourish in a moist, peaty soil, and should be planted in autumn or spring.

MOUNTAIN BLADDER FERN. The common name of Cystopteris, a genus of bcautiful hardy ferns which flourish in a compost of loani, leaf-inould, sand and mortar rubble in a shady part of the rock garden Fragilis and montana are two favourite sorts of the fern.

MOUNTAIN BUCKLER FERN. This is a species of Nephrodiunn, a genus of easily cultivated and strong.groving ferns which embraces the cominon male fern. It is useful for odd shady corners or exposed portiuns of a fernery where choicer kinds would fail. Ordinary soil with which leaf-mould has been mixed is suitable. See Fern; Garden.

MOUNTAIN CLEMATIS. This is a beautiful climbing plant (Clematis montana) bearing white Howers in May; it is ideal for trellises and pergolas, as well as for covering porches and the fronts of houses. Clematis montana rubens has rose-red flowers. See Clematis.

Mounteln Buckler Fern. An easily caltivated fern which grows to a height between one and two delicate variety would fril. See above

MOUNTAIN SPINACH The mountain spinach, or Atriplex hortensis, is raised from seed like the ordinary spinach. The leaves are cut, cooked, and eaten as spinach. I redleaved variety is sometimes grown in the flower garden for the sake of its colour in summer. See Garden; Spinach.

## MOUNTING: Of Pictures. Photo.

 graphs and pictures are usually improved by careful mounting, the mount consisting of a sheet or frame of paper or cardhoard, of white or that colour which most heightens the effect of the picture. It may vary in size from onc very little larger than the picture to one several times its size. Occasionally, when used simply for stiffening, it is of the same size.Phelographs, prints, etclings, pencil and black-and-white drawings, etc., and also small lightly-tinted water-colours look well when fixed before a solid mount. Mounts of larger and heavier pictures should be in the form of

Molldain Avens. Delicate Bowers of an evergreen trallir plant resembling those of the anemone
frames of cardhoard with be velled edges. Such mounts are not infrequently a part of the frame, in which case they may slope slightly back from frame to picture. By means of a mount an oval, round, or ohlong picture can he inserted in a square frainc. Oil pictures rarely equire mounts.
The size, shape, and colour of the mount depend entirely upon the picture, and can only be decided by individual judgement. The picture need not necessarily be placed in the centre of the mount; it may be nearer the top than the button, though not vice verse. It is well to note, also, that a bold or darkly. coloured picture will be enhanced hy a dark or dull-coloured mount, while a picture in pencil or delicatcly tinted will be killed by a dark onc. The mount sloould never be bright in colour.
Cutting the Mounts. Mount-cultiag is simple work, and iequires but a few tools. Although a penknife may be used, the best results are obtained with a mount-cutter's knife, as ilhustıated in Fig. 1 on page $8 \mathbf{2} 4$. In addition a steel straight cdge with one edge bevelled, a $\because \mathrm{ft}$. rule, a pair of compasses with a pencil point, and a tec square, are necessary. First cut the mount to fit the frame, and then inark the amount of opening required. There are two methods of doing this; either rule the lines very faintly on the mount or place the picture in position on top of the monnt, and then prick the corners carefully with a pin.

To cut out a square or rectangular mount as shown somewhat exaggerated in lrig. $\stackrel{2}{2}$, place the straight cdge a little way from the
line or points, grasp the handle of the knife only be used, rubbing it well into the back of firmly in the right hand, and with the left the print. Other mountants are made of paste pressing on the straight edge make a complete slanting cut along the line as in Fig 3. Repeat this on the three sides, and if necessary ease the corners so that they come away clean. The picture is fastened to the back with a little fish glue smeared on the extreme edge, or it may be secured by pasting narrow strips on the back of the picture and mount.

It is essential to the appearance of a cut-out mount that the mitre cut at the corners should be clean. Thelong cuta should be made in one stroke, and this is not difficult with thin mounts, but in cutting thick cardboard the knife must be very sharp, and it must go through the materials, as two attempts will spoil

Mountidg. Fig. 1. Knife for cutting a mounk. Fig. 2. Mount cut, showing bevellod odge of oponing. Fig. 3.
Diagram showing angle at which knite is beld the effect. The cut ting of round and elliptical openings must be done freehand. It is not possible to have a stock of shapes to suit all openings, but with practice in straight cutting without a straight edge it will not be found difficult to round corners and follow curves. Mounting boards, which are obtained from dealers in artist's matcrials, are supplied in thicknesses known as $4,6,8,10$, and 12 sheat, and in sizes from quarter royal, $11 \frac{1}{\frac{1}{2}} \mathrm{in}$. by $9 \frac{\mathrm{f}}{\mathrm{in}} \mathrm{in}$, to antiquarian, 53 in. by 35 in.

Gilt mounts are often used for water colours, and although the cut edges will be white, they can be gilded by using gold lcaf. Brush the back of the leaf with gold size, both being obtainable from an artist's colourman, and when dry cut into strips a little wider than the bevelled cut. Moisten the size with a camel-hair brush dipped in water, and place the strips on the bevel with the top edge true with the surface. Press gently with a soft rag, and when all the edges are covered turn the mount over and press the projecting edges of the leaf on the back and give a final rub with the rag. See Passe Partout ; Picture Framing.

## MOUNTING: Of Photographs. When

 an adhesive is to be applied to the whole of the back of a print, for mounting it on a card or heavy paper, it should contain a minimum of moisture, and be used very sparingly to a void cockling of print or mount. The best adhesive for this purpose is that sold as photo mountant, of which dextrine is the principal component.A similar paste mountant can quite easily be made at home as follows: Mix $\frac{1}{\frac{1}{l} \mathrm{lb} \text {. of }}$ the best white dcxtrine (the best quality only should be used) with cold water to make a smooth creamy paste, taking small quantities of dextrine with a very little water and adding further dextrine and water as required. When the paste is thoroughly mixed, stir in 20 or 30 drops of oil of cloves or cinnamon and 5 oz of water.

Boil in a clean saucepan until clear. Set it aside in a straight-mouthed jar, such as the white jars used for holding marmalade, to cool, and keep it covered. These mountants are very economical in use, and a small quantity on the tip of the finger or brush need
within a comparatively short time.
If photographs or prints are not to be mounted close up, i.e. the mount is to show, the print should be arranged so that it is exactly central on the mount but with moro margin below it than above. If the margin is equal top and bottom as well as both sides it will give the appearance of being mounted too low. The best rule is to have the margins at top and sides equal, and the bottom margin half as deep again. The place to be occupied by the print on the mount should be measured out and marked at each corner with pencil dots. A little mounting paste is then rubbed into the surface of the mount and the whole of the back of the print is treated with mountant.
The print is placed immediately in position on the mount and pressure applied by rubbing all over with a clean rag or handkerchief. A roller squeegee may be used instead if clean paper is interposed between the photograph and the roller. As soon as it is seen that the print adheres all ovcr, it is put away under pressure.

For photographs or prints that are to be mounted in portfolios or albums, or framed up by passe-partout method, it is sufficient to mount them by the corners or edges with gum or seccotine.

The most effective and permanent method of mounting photographs and prints, and one in which there is no risk of damaging the print, is that described in the article Dry Mounting. In any mountant that is used, particularly in the case of photographs, it is essential that no acid should be present, since this will almost certainly cause stains and spots to appear on the face of the print after a little while. See Dry Mounting; Passe Partout; Paste ; Photography ; Picture Framing.
MOURNING. The conventions governing the wearing of mourning have been greatly relaxed, and the mourners themselves usually decide how long they will wear black, and to what extent it shali be unrelieved. Heary crape is now seldom worn, but no hard and fast rule can be laid down in these matters. Purple in all its shades, black and white mixtures, and greys are considered as half mourning.

For a very near relation, i.e. for a parent, it is usual to wear mourning for a year, and it is quite permissible to wear white collars, furs or scarves to relieve the black Mourning is worn at a funeral by persons attending as a mark of respect, cuen if they are not closely related.

Mourning for men is simpler than for women. It is usually considered sufficient if a man wears a black tic and a black band on his left arin. At a funeral the ordinary black morning coat with dark striped trousers is the correct wear. See Crape: Funeral.
Mouse. See Mice.
MOUSE-EAR CEICKWEED. This ram. pant perennial creeping plant is suitable for rockeries or edgings to borders. It should be planted in autumn or spring. The flowers are white and the leaves silvery green. Cerastium tomentosum and C. Biebersteinii arc the chief kinds. They spread very quickly and are easily propagated by detaching rooted pieces.
MOUSSE : How to Make. Literally mousse means something of a light, mossy texture. In cookery it is either a very delicate steamed pudding, a meat dish made with cream and gelatine, or a kind of ice pudding, packed into a mould or case and immersed in ice or placed in an ice cave without the contents having been frozen in a cylinder or freezer. The mousse is sometimes served in pyramidal form, but more often turned out of a plain mould whole, when made as an ice pudding; but it is the texture which is most important, and this should always be spongy.
To nake the steamed mousse, cream together 4 oz. butter with four tablespoonfuls pounded lump sugar, add the yolks of 8 eggs and vanilla or some delicate flavouring. Whisk over hot water until the custard thickens, then fold in the whites of the eggs, beaten to a stiff froth. Turn the whole into a plain souffle mould, prepared by being greased with olive oil and lightly floured, and steam it in the oven

Mouse-ear Chickweed. White flowers and silvery leaves of a plant suitable for edging. Bee above
for 35 min . To steam it, place the mould into a pan three-parts filled with boiling water. The mould and the pan must be covered. Serve the monsse with a custard sauce.

To make an iced mousse, beat up over hot water $\frac{1}{2}$ pint syrup with 0 yolks and 1 whole egg until the mixture is thick enough to coat a spoon ; it should resemble a sponge. Remove it from the heat and continue beating until it is cold. Add any flavouring desired, sugar, a wineglassful of liqueur, and $\frac{1}{\frac{1}{2}}$ pint whipped cream. Turn it into the mould, and plunge into ice and salt, making sure that no ice can penetrate it. As the mixture is very light, it requires careful handling when being turned out.

Chicken and ham mousse is a favourite buffet dish for parties The ingredients
required are 4 breakfastcups cold chicken and both in silver and Shefham, $\frac{1}{2}$ pint chicken stock, $\frac{s}{1} \mathrm{oz}$. gelatine, 1 gill cream, and seasoning. The meat is finely minced and pounded in a mortar or rubbed through a sieve Dispolve the gelatine in a little stock and add it with the reat of the stock to the meat. Season with pepper, salt and a squecze of lemon juice. Whip the cream stiffly and fold into the mixture Put in a mould to set. Garnish with chopped parsley and serve with aslad. A recipe for a chicken mousse which is suitnble for invalids is given in page 2:36 See Chicken; Ice; Mould.

MOUSSELINE. The usual French form of the English word muslin is appliod especially to mousselines de soie, or silk muslins, which are thin, light, and usually coloured silks. Mousscline de laine, or wool muslin, is also known as delaine.

MOUTBWASE. The following are useful mixtures for cleansing the mouth and preserving the teeth. A teaspoonful of the first is diluted in half tumbler of water :

Thymol .
Benzole acid
OIf of cucalyptus
Oil of pepperinin
Rectifed spirit
Carbolic acld
Bicarbonate of sodis
Glycerin
Rose water to make

15 minims
2 drams
1
8
oz.
oz
8 oz.
A third mouthwash is composed of compound solution of thymol IB.P.C. mixed with 3 or 4 parts of water. Sce Tecth.

MUCOUS MEMERANE. The membrane which lines the mouth, nose, respiratory passages, gullct, stnmach, intestine, eto., is called a mucous membrane, and it always secretes mucus, a viscid and tenacious fluid. Its structure varies greatly in different parts. A cold in the head is inflammation of the mucous inembrane of the nose chambers caused by microbes.

MUFEIN: Bow to Bake. A kind of light yeast dough is made up into flat cakes, called muffins, and baked on a muffin plate or griddle. Sift into a basin $1 \frac{1}{2} \mathrm{lb}$. fine flour, adding 1 teaspoonful salt. Cream 1 oz . dried ycast with $\frac{1}{2}$ oz. castor sugar until it liquefies, then mix in very smoothly l pint warm milk. Make a well in the centre of the flour, pour in the liquid, and work in sufficient flour to make a batter. Cover the basin with a clean thick cloth and stand it to rise in a warm place.

Rubl oz. butter in 2 oz flour till quite fine, then beat in by degrees $\&$ pint warm milk; stir this into the risen batter and beat all together well: $\frac{1}{\frac{1}{2}}$ hour is not too long. Now add sufficient flour to make a soft dough-very little may be required. Set it to rise again antil it is very light and spongy. Make it up into round flat caker, and bake them on a griddle greased lightly with mutton fat, turning each cake over as it begins to colour. A little extra flour may be needed when making the muffins in order to mould them.

Muffins should be toasted gradually or they are inclined to become heavy. Warm the muffin and nearly part it before beginning to toast it. Then toast each outer side, pull them apart, butter the inside of each half, set one on the top of the other, and keep very hot while dealing in like manner with the remainder. Muffins must not be cut with a knife, but should be pulled with the fingers. A proper bright bakestone is made for baking muffins, but a thick griddle makes a good substitute.

MUFEDNEER. This word is used for a pepper castor greatly valued by collectors. They were first made in England about 1700, the early ones being shaped in the form of a cylinder with a domed or curved top, and with a lid that can be taken off. A little later the more graceful, vase-shaped article was introduced into the country. Muffineers are found
ficld plate and in a great variety of shapes. Some are plain, but others are decorated, piercing being a form of ornamentation used on them. Some are part of a set that includes salt cellars and a mustard pot, and a few have glass liners inside. The perforations for the pepper are often artistically done.

Small muffineers arc sometimes filled with salt and placed on the afternoon tea ínblc. They thus serve the purpose' of season-
 Courteay of Chapple \& Mantell
ing muffins or crum
pets. See Pepper Pot; Sifter; Silver.
MUFFLE. In a particular type of furnace the heat from the fire is made to pass around an inner or oven-like member. This is termed a mufflc furnace, and a small one may be used by the home worker. The muffle furnace is employed in the enamelling of jewelry, and also in the heating of tools for hardening. See Enamelling: Furnace.

MUFFLSD GLASS. This term is used for a particular type of glass, the characteristics of which are similar to shect glass. It is blown into cylinders in a similar fashion, but is distinguished by a surface ripple, which is more marked on one side of the sheet than on the other, and varies considerably. It possesses considerable brilliance, and is sometimes used for leaded light work. Muffled glass takes its name from the fact that the cylinders in which it is made are gencrally known as muffs.

MUFFLER : How to Knit. This article, strictly speaking, is a square of silk or other material measuring about 30 or 40 in ., used for tying round the neck. The word is, however, chiefly used for a scarf worn as a protec. tion against the cold and may be woven or knitted of sill or wool.

A knitted muffler is very simple to make, and can be easily adapted to college or club colours, or striped with two other shades or colours. The amounts of wool used are given below, so that the corresponding quantities can be obtained in any colours desired.

For a muffler measuring 41 in . long by 9 in . wide the following quantities of 4 -ply Beehive Scotch fingering will be required: 4 oz . in the main colour, loz. for wide dark stripes, and $\frac{1}{2}$ oz. of a lighter shade for the narrow stripes. Use No. 9 bone knitting needles for a fairly close stitch at a tension of 7 stitches to the inch in width. The pattern is moss stitch, which is compact and very suitable. It consists of knit one stitch and purl one stitch alternately to the end of the row, then as an cven number of stitches is cast on, the second row will begin with purl 1, then knit 1 , and repest alternately to the end of the row. For this width cast on 70 stitches and pro-

Muffu. Plate of the favourite tea cares ready for tosating, splitting and buttering
ceed in the moss stitch, changing the colours as follows: Work 3 in . in the main colour, then $\frac{1}{2} \mathrm{in}$. in the light, 2 in . in dark, $\frac{1}{2} \mathrm{in}$. in light. Now work 30 in . in the main colour, and work off the following end in colours to correspond with the first end of the muffler. Always change the colours on the same side of the knitting, and when changing to the new colour cut off the old, leaving a few inches hanging, and knit it in with the new, doing one stitch with the first colour and the next stitch with the second colour alternately until the old end is knitted in. At the end cast off fairly loosely so that one end is not contracted any more than the cast-on cdge. See Knitting : Scarf.
MUG. The mug is an old form of drinking vessel, still used by children and in publichouses. It is really a small edition of the tankard. Mugs are
mostly made of the cheaper kinds of earthenwarefor children, with the exception of silver christening mugs. They are also made of silver and Sheffield plate. The silver mugs sought by collectors sometimes date back as far as the late 17th cen. tury. See Pewter;

Mug. Silver mag, barrelBhaped, with engraved lines, 1795 Silver; Tankard.
MULBERRY. The mulberry tree is valuable, for its appearance, its flowers and its fruit. The black mulberry, Morus nigra, may be grown anywhere in light, deep loan. It should be planted in autumn. In addition. the white mulberry and the red mulberry are well known. All these have heart-shaped leaves with toothed edges, and inconspicunus, greenish-white unisexual flowers, produced in spikes and wind-fertilized. The tree takes some time to establish itself and is slow growing
The method of propagation is by cuttings or even by pieces of the branches broken off and stuck in deep, noist soil in the autumn, or seeds may be sown in sandy soil in the greenhouse in spring.

The leaves of the inulberry are the best food for silkworms. For this purpose the white mulberry is particularly grown in. China and elsewhere. To feed home-grown silk worms, however, the leaves of the excellent fruit-producing black mulberry will be found equally efficacious.
The fruit, which resembles that of a large raspberry or blackberry in appearance, should not be gathered until it is ready to drop. As a matter of fact, it usually drops unexpectedly before it is gathered, and therefore the mulberry should always be planted as a lawn

Mulberry. Rich frult somewhat resembling that of the raspberry or blackberfy, excellent for dessert?
tree; where this is donc the fruit can then drop uninjured into the grass.

How to Cook. Mulberries may be eaten as clessert, preserved by bottling, made into wine or jam or a flavouring syrup, and also included in fruit compôtes, salads, and ices. They can be cooked in the same way as raspberries, and are particularly good when stewed in syrup and served with custard or cream, or made into pies and tarts.

Mulberry Cream. This is prepared by stalking I pint mulberries, putting them into a pan with $\&$ th. sugar and the juice of a lemon, and cooking them gently until they are tender. When cold, put the fruit into a glasa dish and pile on top of it $\frac{1}{2}$ pint cream and the whites of two eggs whipped separately, then stirred lightly together, sweetened to laste, and flavoured with vanilla. A cheaper dish can be made by covering the fruit with custard und just before serving adding a meringue of whites of eggs and castor sugar. (See Meringue.)

Mulberry Jann. To malie mulberry jam put 2 lb . stalked and rather unripe inulberries into an enamel pan with $\downarrow$ pint water, stew thein gently until they are soft and then add if lb . preserving sugar and the grated rind and strained juice of a lemon. Bring all these to the boil over a low fire, stirring all the time, and continuc boiling until the jam will sat when tested on a culd plate. 'l'ake off any scum that rises, then pour the jam into pots and tie them down. This will make only a small amount of jam.

Mulberry Wine. To make this drink, pour 1 gallon hoiling water over 2 lb . mulberries, let them stand for 24 hours and then

Mulching. 1. Need for mulching: $a_{0}$ cracked dry soll. 2 and 3 . Wrong ways of mulching bushes. 4. Correct method. 5. How to mulch a standard. 6. How to mulch a wall tree. 7. Good method of mulching plants
strain off the liquor, pressing the fruit against the side of the vessel to extract the juice. Measure the latter and put it into a preserving pan, with $f$ oz ground ginger, a clove, and sugar in the proportion of 2 lh. to every gallon of liquor. Boil the whole gently for about an hour, skimming it whenever necessary; let it coul to about $98^{\circ} \mathrm{F}$, and stir in $\frac{1}{f}$ teaspoonful of brewer's yeast. Pour the wine into a cask, cover the bung with acloth, and let it stand for two weeks; then add $\frac{1}{d}$ pint brandy, and cork tightly. The wine will be ready for usc in about six months.

MULBERRY BUSH : The Game. This is one of the inost familiar of the singing games All the players join hands in a ring, and dance round and round singing :
Here we po round the mulleery bush, the mulberry bush, the mulherry bush

## Here we go round the mulberry bush on a cold and

 frosty morning.This serves as an introduction, and is sung to the saine tune as "Here we go gathering nuts in May." The next movement is for thic children to drop hands and sing: "This is the way we wash our hands," repeating it in the same fashion as hefore, with appropriate gestures, and ending with the same refrail. "This is the way we go to school" shows the children crawling round with drooping heads and depressed fuces, while "This is the way we cone home from school" is the signal for them to skip round.

Hair brushing, putting on shoes, going for walks, learning to dance, and a host of other movements miay be introduced, and between cach the opening verse must be sung, during which the players join hands again and dance round in a circle

MULCHING. This term is applied in gardening to the act of apreading a layer of some protecting inaterial upon the ground above the roots of plants to preserve thein from frost or drought. The mulch generally consists of well-rotted stable manure, tan, coconut fibre, decaying leaves or the leaves of fern or of brackon. See Ioganberry.

MULLEIN. This is a hardy biennial or perennial of great decorative value in the gaiden. Most of them are vigorous leafy plants with tall spikes of hloom in summer. The best perennials are Chaixii, yellow, 3 ft. ; nigrum, yellow, ㄹ-3 ft. ; densiflorum, yellow, 3 ft ; and phoeniceum, various colours, 2 ft . Of the biennials (those which bloom the year following seed sowing and then perish) one of the hest is olympicum, yelluw, 4 to 5 ft . Many beautiful cross-bred varieties have heen 1 aised: one of the best is named Cutswold Queen, of salmon. bronze colouring. The mulleins thrive in ordinary soil and may he planted in autumm or spring. The perennials can be increased by division at these seasons: the biennials arc raised from seeds sown in May.

Mullet. This is a general name for two different tish, both of which are good eating. See Fish; Grey Mullet ;

## Red Mullet.

MULLING. Heat. ing, swectening and seasoning wine or other liquor with spiccs is called mulling. Wine can be mulled hy heating it to a certain temperature and then adding to it some sugar and alsoa little nutmeg.

Mulled Ale. The following is a good recipe for mulled ale: Put pint ale, a little ginger, a clove, a small piece of butter and teasioonful sugar into a sancepan and bring to boilingpoint. Beat up 2 eggs with a tablespoonful cold ale, pour the builing ale into them and then into a large jug. Pour the contents rapidly from one large jug to anotlicr for sume minutes; then return the liquor to the sancepan and heat it again to nearly builing point. Serve the ale very hot.

## MIULLION WINDOW. This is a winduw

 in which the upright divisions are huilt in the window frame, and generally form a pait of the structure of the building, the mullion being more or less in the nature of a post or support for the lintel. The type is part ieularly applicable to constructions in stone. See IViadowMUMPS: The Treatment. The chief characteristic of mumpre is the swelling of the salivary glands, the disense, which is highly contagious, being communicated by the breath and saliva of the patient. The incubation period is from 2 to 3 weeks: the quarantina preriod is 25 days.

Languor and feverishness are amungst the earliest symptoms with pain in the glands, expecially near the angle of the jaw, and swelling of the parotid gland near the lobe of the ear. The breath becomes offensive, and there is an increased flow of saliva.

The patient should be kept in bed for a weeis or 10 clays and in his romm for another weeh.

He aloould
have a tluid dict. A warm poultice or a pad ul cotton wool should bo npplied to the swollen face. Tho mouth must he frequently rinsed with warm water containing a littleper. manganato of potash. Whentho patient leaves the sick. room, tho bedding, curpet, "ull everything in the room thoroughly disinfected.
Mullein. Yellow blooms of a
MUNTIN. This is the name given to that portion of a door framing which forms the centre uprights between the iniddle and top and botton rails. It is tenoned into then, and is used in all panelled doors, and in other cases where the widlh of donrs or the framework of panelling is divided into two or more panels. See Door.

MURIATE OF POTASH. Used as a fertilizer, muriate of potash, which is a mineral salt containing ahout 48 per cent of pure potash, is very s slublo and is readily absurhed by plants. The sulphate of potash is nore generally accepted as a plant food. mixing well with other components and giving good results. Muriate should not be used in larger quantities than $\& \mathrm{lb}$ to the square rod

MUSA. The musa, or Lanana, is a hothouse family of vigorous, large-leaved perennial plants. The height is from 4 ft . to 10 ft . Musas are licst started in pots or tubs in enrly spring, in a misture of loam and sand. Tlie plants should he well watered and syringed

Musa. Leaves and fruit of the large hothouse plant, better known as the banana
frequently. Musn ensete is chiefly used for decorstive purposes in sunken pote or tubs in the aub-tropical garden. It may be safely placed out of doors in June and taken in again in Septemher. If the plante are grown under glass to yicld fruit Musa cavendisiliana is recommencled
MUSCADEL. The name of musendel is given to strong French and Italian wines, both whito and red, such as the Lacryma Christ (q.v.) of Nnples. See Winc.

MUSCAT. The name is given to one of the most highly eatecmed grapes in cultivation. One of its most deliciously llavoured varieties, Muscat of Alexandria, was introduced from the East some two centuries ago, and from its amall Lerries are obtained the sultanas of conmerce Other gond muscats are Mrs. Pince, Lady Hastings, and Prince of Wales Under proper cultivation muscats bear long. tapering bunches of sweet, rich, fleshy berries, but they require a ligh temperature. See Dessert; Grape; Vine
MUSCATEL. Muscatels are a variety of sun-dried raisin that is appresiated os $a$ deasert diah. The muscatela are large and jusev, of a purplish colour. and are usunlly served piled on a dessert dish, the raisins being retained on their branches. Shelled alnonds are served with muscatels.
Muscatel Pudding. A baked fruit pudding is made with muscatels by mixing I lb. self. raising llour with $\frac{1}{2} \mathrm{lb}$. finely chopied suet. $\ddagger \mathrm{lb}$. sugar, $\frac{3}{4} \mathrm{lb}$. stoned muscatels, $\ddagger \mathrm{lb}$ candied peel cut into small pieces, and a little grated nutmeg; th these add $n$ beaten egg previnusly mixed with \& pint milk and water used in equal proportions. Beat the whole well, and then pour it into n greased pie-dish. Bake the pudding in a moderately hot oven for $1 \frac{1}{2}$ hours. This is suflicient for about 8 persons See Dessert; Raisin.
MUSCLE. Muscles are of various shapes Some, like the biceps, are rather spindleshaped; others, like the sartorius, form long, narrow ribhons, and others atill, like those in the anterior abdominal well, form broad, thin sheets A muscle is enclosed in a sheath, ruld is found to be male up of bundles of fibre, separated by connective tissue.
Muscle porsesses irtitability; that is. it responds to some kind of irritation. Normally, the excitation is nervous energy, but an electric current, the striking of a muscle, and other causes will also evoke $\Omega$ reaponse.

This takes the form of contraction; a muscle fibre, and therefore the whole muscle, becomes shorter and thicker in response to the excitation.
Muscles perforn a large volume of work They are enabled to do this by the oxidation, or combustion, of sugar aupplied to them by the blool, of which they receive a generous supply. But just as the combustion of fuel may not only supply energy for an engine, but also heat, so the combustion of sugar in a muscle liberates heat, so that blood coning from a muscle is hotter than that which goes into it. This, in fract, is the chief source of the heat of the body, and explains why a person who is cold desires to move about.
Fatiguc supervenes sooner or Inter when $n$ muscle is being continuously exercised, and is due rather to the accumulation of waste products and, notably, sarco-lactic acid, than to the using up of available fuel. Massage, by improving the circulation through a inuscle and washing out this acid, helps to remove the sense of fatigue.
Injuries and Diseases. Overstretching of a muscle is dessribed as a strain. There is pain and stiffness. The murcle should be rested and, if necessary, loot or cold spplications will relieve pain. Early masange and gentle
movements are neccsary. A muscle miny be ruptured by violent stretching when it is contracted, or by a blow when it is in this condition. The severed fibres contract and leave a gap which is more evident if an effort is misle to move the muscle, the wevered ends gathering into knots The linnb should be placed in such a position as to put the muscle at rest and shorten it as much ns possible.

Inflammation of a muscle. or nyositis, miny be due to one of the causes of inflammation (q.v.) in any situation, nnd if this cause be a macrohe an aloscess miny result. The general symploms and tratment of these conditions nre described under their respective hendings. Muscular rheumatism is inflnmmation in the connective tissue mingled through. out a muscle-a fibrositis

A painful spasm of a muscle is usually referred to as cramp. Pain in a muscle without obvious signs of inflamnintion is spoken of as mynalgia; it is generally due to rheumatism. An intensive use of muscles lends to nn incrense in their size, or hypertrophy. Disease, on the ollier hand, causea $n$ dininution in size, or al rophy. There may be a progressive muscular atrophy involving all parts of the body. See Backache; Cramp; Fibrositis; Lumbago ; Rhcumatiam ; Sprain.

## Mushrooms: Growing and Cooking

## Advice About an Appetizing and Nutritious Food

## This article descrihes in detail various ways in which mushrooms can he grawn, afterwards dealing with methods of cooking them. See Frame: Hotbed; Manure: Savoury, etc.

Rich in nitmgenous matter and easily digested, the mushroom is a highly nutritious fungus which grows luxuriantly and very rapidly in warm, showery wenther. The utmost carc, however, is necessary in detecting the nature of the fungus, as the nonedible variety, which is poisonnus, is similar in appearance to the cdible fungus.
The adible mushronm has a dry pleasant smell, its llesh is dry and brittle, and the outer skin peels off easily. Deaths occur annually through the eating of poisonous fungi, under the impression that they are mushrooms.
Testing Mushrooms. To test mushronms, sprinkle a little salt on the spongy part and leave it for a few minutes. If the flesh turns yellow, the fungus is noisonnus; if it turns black it is wholesome. Annther test is to use a silver sponn while cooking the mush. rooms. The silver will be blackened if any injurious property is present. When poisonous mushronms rire eaten, if the effects come on quickly the early symptoms are giddiness, diminess of sight, and weakness. If the poisonous effects are delayed, the symptoms are irritation, pain, vomiting and purging An emetic of tivo tablespoonfuls of cominon salt in a glass of water should be given at once, and afterwards a dose of castor oil. Hints on Growing In England numal. rooms are generally gathered in the fields during the late sum mer nonths, and are most easily found in the early morning. They can, however. be cultivated, andinlaf. let 276 the Ministry of Agriculture give some information on this subject. If kept for any time after heing gathered, mushrooms become unwholesome. and may become poisonnus. Any por tion that is not eaten should be thrown away, ss there is some risk of the develop-

Mushroom. Plate of the nutritious edible fungus which can be grown from spawn in a cellar or shed, and cooked in many attractive ways
opened up it should be hot and ateaming, with a fork and placed on the top, bringing moist, but not wet, and should smell stiongly of ammonia. If in this condition it is ready for making into beds. Where possible the manure should be prepared under cover but in open sheds. If prepared in the open the heap should be protected from heavy rains.

For indoor culture almost any place can be used providing an equable temperature of about $\bar{j})^{\circ}$ can be maintained. Indour beds, except in glaschouses, may be made at any time. The beginner should not, however, attempt to make beds during the months of May, June, and July, as the higher atmospheric temperature during these months neccssitates considerable judgement in the use of water in the preparation of the manure and berls. Outuloor beds are usually made up in late summer
Beds for Mushrooms. The most common types of beds are flat and ridge For indoor culture. where space is limitel, flat beds are chiefly used. The size of the hed will depend upon the weight of manure available, one ton naking 6 sq. yd. of hed !) in. deep Where artilicial beat is available, a depth of 6 in . may be sufficient, but where there is a possibility of low temperature, the bed may be made as deep as 15 in ; 9 to 12 in ., however, is the common range of depth. Before commencing to lay the bed, the site which it is to occupy should be carefully cleaned and dusted over with slaked lime.
The site shou!d then be carefully marked out, and the manure spread evenly to a depth of 10 in , beating it down with a fork as the spreading proceeds. It should now be trodden down compactly. This will reduce the depth to about 6 or 7 in.
The successful construction of a ridge bed requires considerable experience. The usual ridge bed is, in section, the shape of a triangle with the top cut off, 2 ft .6 in . along the base, 2 ft 6 in . high, and 8 in . along the top. The length will depend upon the amount of manure and space available, 1 ton of mamure usually making $2 \frac{1}{2}$ yd of berl. When the base has been accurately marked out, the manure should be carefully and evenly spread the whole length to a depth of 18 in . and firmly trodden down. A further 18 in . should then be added and trodden down in a like manner.
The bed should now be 2 ft . high of tightly packed manure with a lot of loose overhanging material on the sides. This should be removed
the height up to 3 ft . The top and aides should be thonoughly beaten until perfectly compact, smooth and even, any luose material being swept up and set aside for use in the next bed. To prevent evaporation, the beds should be lightly covered with the long litter, previously shaken, and protection from rain should be provided for all outdoor beds.

If the processes described have been properly carried out, the temperature of the beds should now commence to rise, and to follow the progress of the heating a thermometer should be inserted in the bed, the bulb being at least 3 in . deep. Special thermometers reading up to $160^{\circ}$ to $200^{\circ} \mathrm{F}$., protected by a wood or metal case.

When the temperature at 3 in. below the surface has stealily dropped to $85^{\circ} \mathrm{F}$. for flat, and $80^{\circ} \mathrm{F}$. for ridge heds, the beds are ready for spawning. There is much difference of opinion as to the correct temperature for spawning, but as the spawn is only inserted on the surface there is no risk of it being killerl unless the inside heat again rises above $85^{\circ} \mathrm{F}$. If the temperature is allowed to drop to $75^{\circ} \mathrm{F}$. it is possible that the spawn will not develop or will develop very slowly and cause long delay in the production of mushrooms

## Insertind the Spawn

The bricks of spawn, if very dry and if the bed is also rather dry, shonld be dipped in water before use. Each brick should then be broken into 8 pieces, as nearly as possible of equal size. The pieces of spawn sliould be inserted in the bed in diagonal lines as nearly as possible 9 in apart in all directions. After spawning it is advisable to allow the beds to rest a few days before soiling or casing, in order to give the nyycelium in the spawn a chance to start running into the manure.

In casing a ridge bed it is best to begin to apply the soil to a height of 1 ft . and a thick. ness of about 2 in., beating it lightly with the smooth back of a spade to make it bind. This process is repeated another foot in height, leaving only the top and a small portion on each side to be completed in a similar manner.
The casing of a flat bed is a comparatively simple mattcr, but care should be taken to see that the soil is uniform in thickness and firmly beaten down. The bed should now be covered to a depth of 12 in to 18 in ., according to the atmospheric temperature, with the straw litter shaken out in preparing the manure, supplemented if necessary with new straw. Outdoor beds in cold weather will need atraw mats or hurdea in ardition. In frosty weather a little artiticial heat will be needed in vinewies or ot her glasshcuses and in unprotected sheds. In normal circum. stances mushrooms "ill begin to appear in six to eight weeks.

Mushrooms will thrive best in a damn atmosphere, and the beds should, therefore, be watered until damp but not wet. If the casing of soil becomes dry, it should be very lightly watered with a fine rose, koing over the bed several times if necessary. On beds in unheated sheds the water used in cold weather should be
lukewarm. Watering, if properly done should not be required more than once a week.

In normal circumstances the bed will need picking over three times a week, but in cold weather the progress of the crop will indicate how often pioking is required. The bed should ho uncovercd piece by piece, each portion being covered again as sooll as the mushrooms have been picked. They should not be cut, but carefully pulled, bringing away a little soil with the root-like threads of mycelium. The ends are now cut off into a refuse basket and the mushrooms freed from any soil, placed stem upwards in the basket. The holes made by pulling should be filled with new soil

How to Cook. Mushrooms can be cooked in many ways and cumbined with other foods They are also used in sauces and ketchups while button mushrooms are excellent pickled The recipe for mushroom ketchup is given in page 655.
To prepare stewed mushrooms, rub off the outside skin with a flannel dipped in salt and put them into a stewnan with 2 oz butter that has first been melted. Add 1 teaspoonful salt and half the quantity of pepper and stew gently until tender. Serve on a hot dis! Stewed mushrooms can also be served on toast. Stew as above, but add 1 teaspoonful grated lemon rind and a blade of macc. Add a white roux made from a dessertsnoonful of flour stirred into a tablespoonful of melted butter Stir this into the mushrooms, and serve them on a slice of fried bread or buttered toast.

Creamed mushruoms make a good entrćc Trim and rub with a tannel dipped in salt pint button mushrorms. Dissolve 2 oz . butter in a stcwpan, and stir in 1 teaspoonful Hour add the mushroums, 1 tablespoonful chopped parsley, and $\frac{1}{2}$ teaspoonful salt. Stir, cooking slowly, for about 10 min ., then beat up the yolks of 2 egis with 1 tablespoonful cream, and add this gradually to the mushrooms. Stir together for a few minutes, then serve the mushrooms in the sauce.
To grill mushrooms, cut away the stems and rub off the outside skin with a flannel di-pped in salt. Butter the bars of the gridiron and place the mushrooms on the bars, sprinkling them with salt. Serve them, when thoroughly cooked, on buttered toast, or as an accon paniment to grilled steaks, chops, bacon, etc.
Mushroums and scrambled eggs are made by melting 2 oz butter in a pan and simmering in it a \& lb. prepared muahrooms cut into small pieces. When they have cooked tor about $\ddagger$ hour, add salt and pepper to taste, and when tender add 2 heaten eggs, and stir all together until the eggs are cooked. Serve the mixture on hot butterod toast.
Mushroom Croquette. Croquettes or fritters made from mushrooms and boiled rice are prepared thus: Peel and stalk $\frac{1}{2} \mathrm{lb}$. nush. rooms, put them into a saucepan with sufficient milk and water to cover them, and stew them for about $\frac{1}{2}$ hour, or until they are tender. Then strain off the stock, chop the mushrooms coarsely, and mix them with 1 teacupful boiled rice, 2 teaspoonfuls chopped parsley, and the same quantity of chopped onion. Melt $\frac{1}{2}$ oz. butter in another pan, stir in $\frac{1}{2}$ oz Hour, add the mushroom stock, and stir until it hoils.
Put in the mushrooms, etc., and $n$ beaten egg, and atir all over the fire unt il they are well mixed. Season the mixture carcfully, turn it on to a plate to cool, and then shape it into even sized balls. Brush these over with egg, coat them with breadcrumbs, and fry them in smoking hot fat When they are a golden brown colour drain them on kitchen paper, and serve them garnished with fried parsley and cut lemon.
Mushroom Patty. Mushroom patties are made by cutting up into dice and then stew. ing $\frac{1}{2}$ (b). mushrooms, and stirring in about two

[^6]tablespoonfuls white roux or plain white sauce Line some patty tins with puff paste and fill them with the mushroom mixture, placing a cover of pastry on the top. Bake them in a moderate oven for about half hour.

Mushroom Pickle. Button mushrooms only should be used to make this pickle. Stalk, wash and dry them thoroughly, and then rub off the skins with salt. Put them into a pan at the side of the fire and let them cook slowly in the liquid which the salt draws out of them. Continue cooking until this liquid has been evaporated; then season the mushrooms to taste with mace and pepper, cover them with vinegar, and bring the whole to the boil. Boil it slowly for a few minutes, and let it cool slightly before pouring it into bottles or jars. When the pickle is cold tie it down, making the jar airtight.

MUSEROOM CAEE. Mushroom-shaped cakes coated with almond paste and chocolate butter icing, to give them a realistic appearance, can be made from a rich plain cake mixture baked in small cake tins for about 12 min ., or until they are spongy.

When the cakes have cooled, level them to the required shape, and brush the sides and bottons with white of egg. Cut the almond paste into rounds, stand a cake on each, and then mould the paste round it, leaving the tops uncovered. Trim off the rough edges, and place the cakes in a warm oven for 20 min., so that the paste may set. Then leave them to cool, and reserve any trimmings of almond pastc for the stalks. Nake the butter icing and ice the tops of the cakes by forcing the icing through a rose tube fixed to an icing bag. Start from the centre of the cakes and continue in straight lines to the edge where the

Mashroom Cakea, consisting of a plain cake mizture coated with almond parto and ohocolate batter
icing to give them a realistio appearance
almond paste begins. Mould the remainder of the latter into thick stalks, and stick one in the centre of each cake. See Almond Paste ; Chocolate Roll; Icing; Madeira Cake.

MUSICAL CHANRS. Musical chairs is an indoor game, the popularity of which is by no means confined to children. A line of chairs is placed down the centre of the room, there being one chair fewer than the number of players. They are arranged alternately, one chair facing one way and the next the other. Somebody then plays the piano, and the players run round the line of chairs until the music suddenly stops, when each person sits down in the nearest chair. The player who fails to secure a seat is out of the game. A chair is then removed from one end of the line and the game continues with the recommencement of the music. It ends when only two people are left to circle round and round a single chair, the one who first occupies it when the music stops being the winner.

Where there are many players and not sufficient chairs available this game can be played equally well by putting a line of people instead of chairs, standing each with one hand on his hip, alternate left and right. The players have to put their arms through the arms of the improvised chairs when the music stops.

Musical bumps is popular with children. I is played in the same way as musical chairs, but when the music stops all the children sit down on the ground. The last one to do this is out of the game. See Children's Party.

Musk. Oae of the handsome monkey masks
MUSE: The Plant. The favourite musk is Minulus moschatus. Before it lost its scent this was a popular window plant, seen in almost every cottage window. The variety Harrisoni has larger flowers. Rooted pieces should be potted in March, several in a 5 -in. pot in a compost of sand-and leaf-mould. Mimulus moschatus may also be grown out of doors. Other showy musks are lutens, yellow, and the numerous highly-coloured hybrids which have been raised between lutens and guttatus. They are commonly known as monkey musks; the large flowers are very handsome. Seeds are sown in May to produce flowering plants the following year.
MUSE: The Perfume. One of the strongest of perfumes, musk is a dried glandular secretion obtained from the musk deer. Musk is very expensive, but it retains its odour for a long time, and for this reason is added to other perfumes in order to render them more durable. A cheaper substitute is synthetic musk, which is made from a coal tar product, toluene. See Scent.
Musk Mallow. This is a hardy lierbaceous perennial plant, also called Moschata. See Malva.
MUSE ROSE. The popular name of Rosa moschata is musk rose. It is a very vigorous climber with clusters of white flowers. The leaves are groyish-green. It should be planted in autumn and allowed plenty of room for development, for it makes rampant growth. See Rose.

MUSLIN. The successful employment of white muslin is a matter of skill and taste in adding colour touches in the form of a simple ribbon or in other ways. Muslin is again used for dressing table flounces over pale coloured sateens, and cushion covers and curtains to match look dainty in a country bedroom. Sprigged or embroidered muslins are pretty for sum. mer curtains. Madras muslin and silk muslin are obtainable for this purpose in exquisite designs and colourings.

Musk Rose. White flowern and
greyish-greea leaves of this climber

White muslin is easily tinted with the dyes and dolly-sticks used for curtains. In washing spotted muslin it is well to see whether the dots have actually been woven in or merely attached.

Plain muslins equally suitable for dresses, glass or long window curtains, bedspreads, and cushion covers are always procurable, and when they have served for one purpose they can frequently be turned to another. Muslins which have been soft can be stiffened by starching and ironing, and be used for foundations for other light stuffs. Spare muslin comes in for wrapping up food, making flyproof covers for meat and milk. A heavy bead edging round a little mat of spare muslin converts it into an efficient cover for milk-jugs.
Kitchen strainers can be improvised from muslin, and it has many other household uses in making poultico covers, bandages, stretched on frames to prevent the entry of flies through open windows, diffusers for amateur photographers and for drying and polishing. See Dressing Tablo: Organdie.

MUSLINET. Made with coarser threads and in more open texture than fine muslin, muslinet is intermediate between muslin and net. Muslinet makes cheap window curtains.

MUSQUASE. Used mainly in the manufacture of fur coats, musquash, which is obtained from the musk rat, is a somewhat coarse but hard-wearing fur of glossy appearance. Usually dark brown in colour, it is frequently shorn and dyed to imitate sealskin. A more valuable type is known as natural black musquast. See Fur.
MUSSEL. Of all the shell.fish mussels are the least digestible, and should be eaten sparingly. They have a redeeming feature in that they cleanse themselves of any pollutions in about four days if put into water free from contamination. In order to make mussels quite safe for human consumption, a medical man has invented a system by which shellfish are immersed in a large volume of sea water freshly sterilized by means of chlorinc for periods of 24 hours In the case of mussels two such periods only are neccssary. The mussels so treated are packed in bags and have special labels attached to them which the public are advised to look for.

To prepare mussels for eating, they should be allowed to soak for some time in cold water and the shells scrubbed with a stiff brush. The water should be frequently changed in order to get rid of sand. When the inussels have soaked sufficiently, put them in an iron saucepan, without water, over gentle heat. As soon as the shells open they are ready to be served in the shells with brown bread and butter after all foreign bodies have been removed, special carc being taken to remove the green grass-like "beard" that is to be found in every mussel. Vinegar or lemon juice should be taken with mussels to counteract any irritants or poisonous substances.

Stewing the Mussels. To stew mussels, boil them, then take them from their shells Fnd carefully remove the beards. Strain all the liquor from the mussels into a pan. To every quart of mussels allow 4 oz butter. Roll this in flour and melt the butter with the liquor Add the mussels with a spoonful of chopped
parsley, a sprinkling of pepper and salt, and a spoonful of lemon juice. Shake the contents of the pan and simmer for about 10 min Serve with sippets of toast.
Scalloped Mussels. To make acalloped mussels, propare them as directed above. Take the mussels out of the shells and remove the beard. Strain the liquor and add to it 4 o7. butter rolled in flour. When the butter is melted, add the mussels and simmer for 5 min . Butter a scallop shell and sprinkle it with browned crumbs. Put in a layer of mussels, then a layer of crumbs with a piece of butter on top. Continue this until the shell is filled. Pour the liquor over and brown the disli under the browning shelf of the oven.

Poisoning by Mussels. The popular idea that cooking destroya all poisons does not a pply to mussels, which are often virulently pnisonous whether raw or cooked. There is nothing to indicate this fact before they are eaten. The poison is present chiefly in the liver of the mussel.
The symptoms are of two typer. In some cases the patient suffers from irritation in the stomach, colic, vomiting, purging, cramp in the limbs, and nettlerash. In others he becornes numb and cold, the pupils of his eyes dilate, paralysis may develop, and he may become comatose. So virulent is the poison that death sometimes occurs within two hours.
As quickly as possible give an emetic composed of a tablespoonful of mustard in a large tumbler of warm water. As soon as the patient has vomited, give him a dose of 1 to 2 o?. of castor oil. If he becomes very weak before the arrival of the physician, weak brandy in tablespoonful doses every half-hour may be administered. The patient should be kept warm, and poultices or hot-water bags may be applied to the a bdomen.
MUSSEL SCALE. Mussel scales are injurious to apples and lese frequently to pears and currants, black and red. The insects also attack hawthorn, broom, and other plants Trees that grow against walls suffer more than others, as the pests flourish most in warm, sheltered situations. The injury to the tree is caused by the loss of sap which is sucked up and devoured by the pests.

In the case of a bad attack, the trees or bushes should be sprayed when dormant, November to February, with an oil emulsion made as follows :
l'arafln oll
oft soan
1 gal
Water
10 gal.
The soap is first dissolved in about a gallon of boiling water. The soap solution is then removed from the fire, and the paraffin is at once added, the whole being emulsified by squirting the liquid back into itself with a hand syringe. The strong emulsion may be kept until required for use, when the remaining 9 gallons of water should be added and the whole thoroughly stirred or emulsified again with the hand syringe.

If the pest has not been dealt with in winter -the best time-it may be greatly reduced by spraying when the eggs are hatching, about the end of May or early June. At this period a weak paraffin emulsion has proved satisfactory, and probably any other contact insecticide, such as nicotine and soap, would do as well. A suitable paraffin emulsion may be made as recommended in paragraph above, but using the ingredients in the following proportions :

See Apple ; Insecticide; Pear; Spraying.
MUSTARD : The Plant. The hardy annual mustard plant is usually grown for table purposes in conjunction with cress. Secds may be sown on the surface of fine soil at the
end of March, watered in, and followed by successive sowings every week until September.

Mustard and cress may be grown indoors all the year cound by sowing seed on the surface of shallow pans or boxes of soil, watcring in with tepid water, and keeping wet and warm. It may also be grown on flannel placed in a dish and kept moist in a sunny window. The truc mustard is Sinapis.

Use for Sandwiches. The young leaves of mustard, which have a pleasant and rather pungent llavour, can be mixed with cress into a green salad or may be used alone with bread and butter and salt. Mustard and cress makes excellent light sandwiches. The leaves should be washed thoroughly in cold, slightly salted water, to renove any seed cascs or grit, and then swung in a salad shaker until dry. As a garnish for cold meats, etc., must ard and cress is invaluable; also, if a little is thrown into a saucepan of soup a few moments before serving, the flavour of the soup will be very much improved. See Cress.

MUSTARD : The Condiment.
Two variet ies of mustard plant, the black and the white, are cultivated in England, the mustard of commerce being the powdered sced of both. The black variety contains a volatile oil from which mustard derives its pungent odour, and this is accentuated by the use of turmeric for the bright yellow colour of the powder.

As a condiment mustard is taken with beef, pork, bacon, checse, and other foods, though not usually with mutton ; it also enters largely into the composition of most piquant sauces and dressings. To prepare it for table use, a amall quantity of the powder is mixed in a cup with a few drops of water to the consistency of a thick paste, all lumps being broken up. More water is added, stirring all the time, until the mustard is just thick enough to lie on the edge of a plate without running down. The addition of a little salt is held to improve the flavour of mustard. It is best to make only a small supply at a time, and to replenish the mustard pot with freshly made condiment.

A very pleasant table mustard and one which will keep can be made by dissolving $1 \frac{1}{2} \mathrm{oz}$. salt in 1 pint boiling water, then pour it upon 1 oz . grated horse-radish, and let it atand 24 hours. Strain it and mix in, by degrees, sufficient dry mustard to make a smooth rather stiff paste. Equal quantities of horse-radish, chilli and tarragon vinegar can be substituted for the water.

French Mustard. French mustard is made from the black mustard seeds. which are much more pungent than the white or yellow seeds. Steep them in vinegar, garlic, thyme, mint, and tarragon until a full-Havoured vinegar is obtained, then grind the mustard seeds and pound them, adding vinegar by degrees to work them into a paste. Season it with salt.
Mustard Pots. A mustard pot is one of the nembers of a cruct or condiment set. It takes a large number of forms, and is in various sizes, but is usually fitted with a hinged lid and supplied with a spoon to match. Sets are made in glass and in coloured pottery, com-

Mustard Pot. Three gilver mustard pots of the Georgian period. 1. Erample with beautiful pierced body abowing blue inner receptacle, 1770. 2. Pot with domeshaped lid and finted base, 1802. 8. Octagonal apecimen mounted on a pedeatal, 1775
prising a mustard pot, one or two pepper pots and salt cellars. Mustard pots should match in style the other condiment containers on the table. The better pieces are in silver with glass liners.
Old silver mustard pois are much valucd by collectors. They date, as far as England is concerned, from about 1750 , and were often, as they are to day, made with salt cellar and pepper pot to match. The majority are glass lined, the glass being usually bluc, but occasionally rose in colour. The marks may be on the front, near the handle, or on the bottom, and, like all lidded articles, the cover should bear the sane initials as the body. Some cxamples are beautifully decorated, those pierced and engraved with festoons and rosettes being especially noteworthy.

The three inustard pots illustrated on this page are beautiful examples chosen out of a large selection in order to give an idea of the varied shapes in which these articles were made. Mustard pots, remarkable for the beauty of their chased work, were made in Sheffield plate, and there is a representative collection of these in the Victoria and Albert Museum, South Kensington. See Silver.

MUSTARD : Its Medical Uses. In medicine mustard is used as a handy and reliable emetic, and also as an external application. As an emetic, the dose for an adult is a tablespoonful in half glass of water. Externally, mustard acts as a counter-irritant, and may be applied as a plaster or a poultice. The most convenient form for use is the mustard leaf.
Mustard Plasters. To make a plaster, mix the mustard with cold water to form a thin paste, and spread upon brown paper. A little vinegar incrasases the strength. The mustard may be covered with a layer of muslin. poultice is made by sprinkling a linseed meal or other poultice with mustard and covering it with muslin. The plaster or poultice may generally be kept on for $15-30 \mathrm{~min}$., but for not more than 10 min . with young children or sensitive and delicate adulta. A safe plan in the case of children is to mix the mustard with $\underset{\sim}{2}$ or 3 times its weight of common or corn Hour. The part may then be covered with a layer of cotton wool. When the plaster or poultice is removed, the skin should be wiped clean from all traces of the mustard, using for the purpose a very soft cloth.
Mustard Bath. For a bath the mustard should be made into a thin paste with culd water. and then stirred into the bath. For a foot bath add 1 to 2 tablesjoonfuls of mustard to each gallon of water; the water should be as hot as can be comfortably boine. For a sitz bath, a tablespoonful of mustard should be used fur cach gallon of water. For the full bath of about 30 gallons of water, $\ddagger \mathrm{lb}$. to $\frac{1}{2} \mathrm{lb}$. of mustard may be used. The temperature should be about blood temperature. This is an admirable cure for chills, commencing colds, sleeplessness, etc.
MUTISIA. The kind generally cultivated is Mutisia decurrens. a climbing perennial which is not hardy except in a few exceptionally mild places. The Howers, which open in summer, are of orange-sellow colouring. Propagation is by cuttings under glass in spring. The plants mayle grown in as greenhousc from whicli frost is excluded.

## MUTTON: VALUE AND COOKING METHODS

## The Housewife's Guide to a Popular Article of Food

In addition to similar articles on Beef: Lamh: Pork, readers arc referred to Boning Breast: Corving: Diet: Food: Meat, etc., and other entrics dealing with the subject of food. See also Caper Sauce: Cold Meat: Cutlet; Haricot Mutan. Mince. Onion Sauce

Bcing highly nutritious and yet easy of digestion, mutton is preferable to beef for delicate persons or young children. The best meat is obtsined from a sheen from 3 to 6 years old; under that age the flesh does not acquire the Havour of choice mutton. The leg is the most economical joint, as there is ess hone and waste in proportion to the flesh : but it is liable to become tainted sooner than other portions of the carcass, especially if the kernel is not at once removed
Leg of Mutton. A leg of mutton about - lb. in weight and a shoulder about 5 lb . are good average joints for family consumption. Mutton should be cooked rather longer than beef in proportion to its weight, as it should not he underdone, with exception of chops and cutlets, which may be slightly undercooked if preferred. Mutton requires due attention when roasting, for if not thoroughly hasted and the temperature regulated it will be dry and hard.

The leg can be boiled or roasted, but somelimes it is boned, stuffed with sage and onions. and trussed in an oblong shape, slightly Hattened both sides, and baked or braised. It is then called mock duck. If intended for invalid diet, vegetalles must be omitted when boiling a leg of mutton; but when served as a family joint it is usun) to cook carrots and tumips with it, and to hand then separately as a vegetable, either whole or mashed
For a braised leg of mutton a very small joint is the best. Remove the kernels and trim the leg neatly; it should then be partly roasted and afterwards braised on a hed of vegetahles, adding 1 or 2 slices of fat bacon and a bouquet garni. Care must be taken to tum the meat in the braise. The gravy, after being strained, must have the fat skimmed off before reducing it and pouring it over the meat.

Shoulder and Other Parts. Shoulders of mutton should never be boiled; they are too fat to allow of the meat looking appetizing, and the llavour is insipid. They should either be roasted or braised-roasted for preferenceand served with a sauce which has some distinct llavour, such as onion. 'They may be boned and stuffed by the method described earlier in this article for the leg

The haunch (hind quarter) should hang as long as possible without heing allowed to become tainted; then the shank should he removed and the flap trimmerl, and it should he roasted and served with rich gravy. Red currant jelly should always be served as an accompaniment to this joint.
'I'he saddle (double loin) Irefore lieing roasted must be trimmed and the flaps folded under A smoll skewer must be run through the kidney in each loin to prevent it becoming detached. The tail is left on, but is split in half and curled over each side the reverse way A 10 lb . saddle will take from 2 to $2 \frac{1}{2}$ hours to roast. It must be remembered that the loin is not such $n$ thick joint as the leg, and does not take so long in proportion to cook. Serve with good gravy and red currant jelly.

Loin of mutton can he roasted whole, but must never be boiled. When roasted, superfhous fat must he cut away, and it is easier to carve if the chine bone is sawn off.

The brcast is usually hoilerl, but can be boned, coated with stuffing, rolled up, and roasted, as described under the heading l3reast. The neck is an economical joint for family consumption. When sold in the piece it is known as the target and comprises the best end, middle neck end scrag end, and is
very cheap if the whole is bought. The best end can be roasted or made into cutlets, the middle neck can be used for Irish stew, or a ragout with or without the scrag, while the tter can be made into broth
Mutton Broth. Cut up I Ib. scrag into small pieces, and put these, together with the hones and a quart of cold water, into a saucepan over the fire. Add a little salt, bring the broth to the boil, and after skimming it add $1 \frac{1}{2}$ dessertspoonfuls rice, a leek, and a piece each of carrot, turnip, and celery cut up small. Simmer the whole for ahout 2 hours, then skim t again; take out the bones, add $1 \frac{1}{2}$ teaspoonfuls chopped parsley and seasoning to taste, and serve. Mutton broth is often made with hones only, no ment

Mutton Chop. Grilling is the best way of cooking mutton chops, but they may also he fried or steamed. For grilling they should be at least I in. in thickness and should be cut from a well-hung piece of mutton. Rid them of skin and any superfluous fat, and after trimming the edges llatten them with a cutlet bat and brush them over with melted butter. Place them on a hot gridiron before the fire or under a gas griller and cook them for nbout 10 min . 'This is the approximate time reyuired, but it will naturally vary with the thickness of the ment. Serve the chops garnished with watercress, and with a pat of maitre d'hôtel butter on top of each

To fry mutton chops, prepare them in the same way as for grilling. omitting, however, to brish them over with butter. Melt a lump ol butter in a frying-pan, and when it is smoking hot put in the chops. Brown them on hoth sides, and when

Mutton. Left. side view of the carcass of a sheep, showing position of joints into which it is cut by the butcher. Ripht, back view, showing the position of the joint known as the saddle
cooked, as they should be in $8-10 \mathrm{~min}$, drain and serve them in the same way as grilled chops.

Mutton chops may be steamed by trimming and flattening them as already described, and placing them on a grensed plate over a pan half filled with boiling water. Dust them lightly with salt, cover them with greased paper, and then with a basin. Take care that the water in the pan continues to boil, and add more if necessary during the course of cooking. After ahout 15 min . turn the chops, and continue cooking them for another 15 min .

Kebobbed Mutton. Mutton kebobbed makes a choice dish, and one that can be cooked in the Dutch oven. Remove the meat whole from a loin of mutton and cut it into steaks, trim ming off some of the fat. Mix with some breadcrumbs a little sweet herbs, a sprinkling of grated nutmeg, salt and pepper. Dip each steak into beaten egg, then into the prepared crumbs: place the steaks together as if they had not been cut asunder, and tie them back into shape with string. Cook them either in the Dutch oven or in a baking-tin in a fire oven, hasting them with good dripping and $\pi$ small lump of butter. When serving pour off the fat, sprinkle a little lour over the tin, mix it with the sediment from the meat, and stir into it by degrees $\frac{1}{2}$ pint of good gravy. Adil a little mushroom ketchup, boil up well. and pour this liquor round the meat.

Uses of Cold Mutton. Suggestions for doing up cold mutton are given under various headings. Excellent minced, curried, stewed in a casserole or made into a shepherd's pie, it may also he used to prepare the following dish :

Free the meat from skin and gristle, then weigh out ${ }_{3}^{3} \mathrm{lb}$. and mince it finely. Melt a lump of butter about the size of an egg in a saucepan, add a breakfastcupfil of tomatoes-previously skinned and rubbed through a fine sieve-the minced meat, three well-beaten eggs, pepper and salt. Stir the whole over the fire, taking care that it does not burn, and when it is thomughly hot, dish it on slices of toast, with chopped parsley on top.
To utilize the knuckle end of a conked leg of mutton, trim it neatly and then put it into a pan containing a pint of hot hrown gravy made from meat extract. Add a tablcspoonful of Worcester sauce or ketchup, a little allapice, and a large grated onion. Cover the pan, and let its contents stew slowly at the side of the tire for alout an hour, or until the meat is thoroughly heated. In the meantime, cook 2 oz. macaroni, cut into short lengths; wash and peel 2 large carmts and turnips, cut them with a vegetable cutter into balls about the size of marbles, and cook them in hoiling salted water until they are tender. Dish tho stewed knuckle on a hot dish, place a paper frill round the bone, and strain the sauce round. Around the meat arrange alternate heaps of vegctable and macaroni, sprinkling a little chopped parsley over the latter as a garnish.

Another good way of using up cold roast or curried mutton is to make it into croquettes. To prepare these wash $\ddagger \mathrm{lb}$. rice and boil till tender in plenty of fast-boiling salted water.

Drain off the water thoroughly, and put the rice on a plate in the oven to dry.

Fry a teaspoonful chopped onion in 1 oz dripping in a saucepan, and when it is well browned add $\frac{1}{2} \mathrm{oz}$. flour and $\frac{1}{2}$ dessertapoonful curry powder, frying theae for a coulple of minutes. Pour in $\ddagger$ pint stock, stir the mix ture until it hoils, and then add $\frac{1}{\mathrm{lb}}$ finely chopped cold mutton, 1 teaspoonful lemon juice, the cooked rice, some salt and pepper to taste, and lastly the beaten egg. Mix all these ingredients thoroughly together, spread the mixture evenly on a plate, mark it into even-sized divisions, and leave it until it has become cold.
Shape the divisions into neat balls, brush the latter over with beaten egg, and cover them with breadcrumbs. Put plenty of frying fat in a pan over the fire, and when a bluish smoke rises from it put in the croquettes, frying them a golden brown. Drain them, and serve them on a lace paper garnished with pieces of fried parsley
Either the shoulder or the neck may be done up as a stew or ragout in a casserole. Cut up 2 lb . into neat pieces, removing any superfluous fat and bone, and fry them. lightly in 1 oz. butter melted in a cassero slightly browned on both sides, take out the meat and put in its cut into dice, and oz. flour. When these ingredients have browned thoroughly, pour in $1 \frac{1}{2}$ pints warm stock or water, stirring all the time, and bring the whole to the boil.

Then put in the meat, a bay leaf. 2 oz. pearl barley which has been soaked overnight, and seasoning. Place the lid on the craserole and gently simmer its contents in a moderate oven until the barley is soft. Then skim off the fat, take out the bay-leaf, and servc

Mutton : the jolnts. 1. Shoulder. 2. Loin, showing position of kidney under the fat. 3. Ler. All are good joints for roasting. 4. Target, showing the positions and shape of the scrag end, middre neck and best neck

MUZZLE. In Great Britain the Ministry two kinds, the leather and the wire cage shape to make orders regarding the muzzling of dogs, in outbreaks of rabies. It is not as comfort. the seizurc. detention and disposal (including able as a leather one, and if the latter fita

Muzzie. lig. 1 (lett). Wire muzzle for a Pexinese or other small dog. Fig. 2 (above). One made of leather and wire, suitable for a terrier destruction) of uninuzzled dogs, and the animal's jaws too closely together. See Dog.
recovery from the owners of the expenses incurred in respect of their detention. The same authority may make orders as to collars for clogs, and so also may a local suthority ; but the latter cannot make such orders in respect of packs of hounds. A muzzling order may be revoked nnd may be made to apply either to the whole country or to a particular area.

The effect of a muzzling order is that any person who kecps a dog is liable to $n$ fine and to pay the cort of the summons if the dog is found in any public place unmuzzled, whether it is the person's fault or not. It will not avail him to prove that the dog was muzzled when he let it out and that some one must have stolen the muzzle; nor that the dog esoaped unmuzzled through the negligence of $a$ third person.

Apart from mizzling orders, the Town Planning Act, which applies to most towns in England, makes it an offence to allow a ferocious dog to be at large unmuzzled, i.e. to be in a public street or place. The word allow implies knowledge on the part of the dog owner. It is a moot point whether this means knowledge that the dog is ferocious, or knowledge that the dog is at large.
Types of Muzzle. Dog muzzles are of of Agriculture and Fisheries possesses the power The latter is usually ordered by the authoritics properly it should be equally effective. In the wire muzzle for a toy dog, shown in Fig. 1, a small pad has been arranged so as to avoid pressure of the wire joint on the animal's head. Fig 2 shows a combination of leather and wire for a larger dog. Whichever type of muzzle is used, care should be talien to get one of the proper size that does not pinch the

MYOPIA. The technical name for short sight is myopia. Parallel rays of light falling on the cornea are focussed in front of the retina, or, in other words, the eye is too long.

The condition may be progressive, and it is lesirable that children who are shortsighted should not have their books or similar work too close to the eyer, not nearer than 10 to 13 in, also that the type should be large and the light good. See Eye : Spectacler
MYOSOTIDIUM. The perennial plant myosotidium also known as the Chathain Island for. get - me -not, is a difficult plant to grow, but when it succeeds it becomes a very handsome object, bearing flowers like very large forget-ine-nots. It requiresa moist, sheltered position, and must be roown in lon my soil. It does best in maritime counties in the south. west district. Propagation is by seeds, which should be sown in the summer.
Myosotis. This is the botanical name for the popular hardy plant forget-me-not (q.v.).
MYRICA. Of thesc hardy shrubs, one, Myrica gale, grows wild in boggy ground in parts of the British Isles. Myrica ecrifera is known as the wax myrtle; it has fragrant eaves and the fruits exude a wax-like substance. Another kind is Myrica californica.

Using the Wax. The was from the minute fruits, which arc knows as candle berries, can be obtained in the following way : A pot of boiling water is prepared, into which the herries are placed; the wax melis and floats on the surface of the water, from which it is collected and farhioned into little candles, which give off a delightful fragrance when hurnt. Such candles would make excellent Christmas decorations.

MYROBALAN PLUM. Used as an alternative to privet and quick the myrobalan plum (Prunus cerasifera) is often seen in heriges. Its variety atropurpurea has purplish leaves When full grown the
myrobalan plum is from 8 ft . to 10 ft . in height, and in favourable situations has reddish fruit in the autumn. Plants may be successfully raised from fruit stones. See Hedge.

MYRRH: The Herb. Myrrh, or sweet cicely, Myrrhis odorata, is a hardy perennial herb with sweet-smelling leaves and white

Myrrb. Mucb-divided leaves of the sweet-scented berb Myrrbis odorata
Howers. It thrives in the opien border in any soil, and reaches a height of about 2 ft . Propagation is by seed, or division of the roots.

Medicinal Uses. The gum resin known as myrrh is the product of the balsamodendron, a small tree grown in Arabia and elsewhere in the East Combined with horax, as in the following prescription, myrrh is a favourite gargle in inflamed conditions of the tongue, cheeks, or gums, and in a relaxed thront.

Tincture of mytrh
Borax
Eau-de-Cologne to inake
4 fluid drams

| 24 gr |
| :--- |
| 1 llui |

2 oz. Jram
A teaspoonful of the above mixture should be used in a small glass of water as a mouthwash or gargle. The tincture of myrrh is given in doses of $\frac{1}{2}$ to 1 dram. See Mouthwash.

MYRTLE. The fragrant inyrtle (Myrtus communis) is a greenhouse and half-hardy evergreen shrub, which can only be grown out of doors in mild distriots, or against walls with winter protection in cold localitics. The Howers are white and fragrant ; thev produce black fruits. Myrtles do best in fertile loany soil, well lightened with leaf-mould and sand. They require a good deal of water in summer, and will benefit by frequent syringing. Any necessary pruning should be done in spring. Propagation is by cuttings in sandy soil under a hand-light in summer.

Myrtle. Fragrant white flowers of the evergreen shrub which needs a sheltered outdoor situation

## Nails and How to Use Them

## The Various Kinds and their Proper Uses

This article suggests reference to almost all the woodworking articles in this work. Of these
only a few can be mentioned, e.g. Amateur Carpentry: Cabinet Making: Capping: Door only a few can be mentioned, e.g. Amateur Carpentry: Cabinet Making: Capping; Door Drawer. See also Brad; Clasp Nail ; Clout Nail

Of the many varieties of nail in use a number are illustrated in Fig. 1. Iron and steel nails are liable to rust if exposed to the air or nllowed to becoine damp. They should be liept in their original packets or arranged in a box divided into sections.

French or wire nails are made in sizes from 1 in . to 6 in . long, and in various thicknesses. Useful sizes in the 1 in. length are known as 16 gauge, in the $1 \frac{1}{2}$ in. 13 gauge, in the 2 in. 11 gauge, and in the 6 in. 4 gallge. The oval wire nail or brad does not hold so well as the French nail, but it has bess tendency to split the wood, and for internal work the head, being long and narrow, easily sinks into the grain of the wood and is almost invisible. The shanks of the oval and wire nails are generally roughened near the head, so that they hold better in the wood and there is a sinaller chance of their coming loose.

Cut nails are made by punching from sheets of thin metal. They are rectangular in section, and generally tapered or wedge-shaped. The amateur will find it wise to use this class of nail only when the work is fairly substantial and not less than 1 in . in thickness, otherwise the wood is likely to split. The ordinary cut clasp nail is provided with a T -shaped head, so that when driven into the wood it draws the two parts firmly together.

The floor nail has an L-shaped head, and is used almost exciusively for nailing down floorboards to the joists, the purpose of the projecting piece on the head being to draw the floorboards tightly against the joists. The wall nail is a stout round nail, resembling a thiek French nail, and is intended generally for driving into brickwork. Rose-header nails are made witlı a round and modelled head and long, flat pin: they are used in exterior work where the head will be exposed; the large area under the head serves to hold one part to another.

Joiner's brads are a variety of floor brads, ranging in length from $\frac{7}{2}$ in. to 2 in. ; being small in size they are useful for nailing on the baoks of furniture and similar purposes. Hob nails are generally used on the soles of boots, but as they are of variously shaped heads they are often employed as a decorative device on doors. The lath nail is a form of wire nail with a broad, flat head, intended chiefly for nailing laths to the stud partition intended to be plastered: a variety is made in the form of a cut lath nail.

Cast wall nails are often utilized for garden purposes in the training of plants; they should he driven into the mortar joints in the brickwork, since, not being very strong, they are liable to break if driven into hard material. Clout nails have a very broad head circular in scction, and are made in the form of a wire or wrought nail. They are employed for fastening roofing felt and similar material.

Brass-headed nails are made in many fancy patterns, the heads being of polished brass. They are intended for the support of pictures or for fastening an overmantel or similar pieces of furniture to the wall, the brass heads alone being visible. Brass-headerl nails of small size are used for many decorative purposes. The panel pin is a fine wire nail with a conical. shaped head of small dinmeter. It is invaluable for fastening two pieces of thin material together and should always he used with thin wood of any description. Although the nails are small in diameter, they are very efficient and hold well.
Use of the Hammer. The whole secret of driving a nail lies in the use of the hammer. It should be held rather loosely and near the end of the shaft. The nail must be struok fair and square on the head, and the liammer should fall in a straight line with the path of the nail otherwise the nail will not be driven in straight. There are other methods, however, beside the ordinary one of driving the nail straight in. For example. if a nail be driven $n t$

Nail. Fig. 1. Typical varieties of nails; their uses are described in the text
an angle through a piece of wood it will drive the wood in the direction in which the nai! is pointing. Consequently, if two bnards are to be nailed on to joists or battens, the joint between the boards can be brought close up by first nailing one of the boards and then nailing the sccond with the nails inclining toward the hoard already fixed This is illustrated in Fig. 2. Another way of driving nails is known as dove tailing, in which each nail is driven at an angle into the wood so that it can be drawn out readily A common method of driving a nail to prevent its being withdrawn is known

Nail. Fig. 2. Nails set diagonally draw a joint up ighty. Fig. 3. Clenching a nail right to left
are shown the three sfages in the process
right through the material so that about $\frac{1}{2}$ in projects on the opposite side. This portion is then stmack with the bammer near the point so that the pointed end of the nail is hent over. Further blows drive the remainder of the projecting portion down into the work. The object of first knocking over the point is that the point may then be driven into the wood, thereby holding the clench firmly.
The work to be nailed should rest upon a solid base, as it is very difficult to drive a nail into a springy piece of wond. If no support is availahle, it will be neceasary to hold a hammer, or some heavy tool; bshind the place where the nail is to be driven through the thinner piece of material into the thick.
Splitting of the wood is a frequent cause of trouble. It is always advisable to make small holes with a bradawl through wood that is liable to split, and then drive the nails through the holes. In very hard wood it is sometimes difficult to drive a nail unless a hole is bored first, but in this case the hole should be somewhat less than the diameter of the nail, so that the latter may get a firm hold. Another point is to a void having two nails in the same grain of wood. The nails should be rig. zagged, or staggered. Re in Fig. 4, so that each nail is separated by as much untouched wood as possible.

Secret Nailing. When several hoards are to be laid and nailed so that the joints do not show a great deal, a method of diagonal nail. ing may be used. The nailscan then be driven diagonally into the edge of one plank so that when the next plank is placed against it and driven home the nail will be invisible. Generally this method is adopted with rcbated boards on that the scconil plank may interlock the
 first Another method of secret nailing consists of making an incision into the wool with a tool like a very line gouge. This raises a shaving, which is bent hack and the nail driven in the cavity and punched well down, as in Fig. 5. The shaving is glued and then pressed back into position, and after the glue has set the face should he sandpapered till smouth and all traces of the nail is lost. In good work the nails are always punched helow the surface of the wood, and cspecially should this be done when the work is to be finished by painting, as the nail holes may then be filled with putty or one of the numerous stoppings on the market Nail punches or nail sets are made for this special purpose, but almost any plain punch will answer. Cross nailing, Fig. 6, or skew nailing, as it is sometimes called, is generally used to fix the uprights on to the bottom pinte. It consists in driving the naile diagonally through the lower part of the upright into the bottom plate.

NAILS: Their Care. Growth at the root of the nail constantly pushes it forward, hence the need for cutting or filing. In the case of finger-nails the points may be rounded ; toe-nails must be left square.
Nail-biting is a habit with many children, sometimes persisting on to later life, and mothers cannot be too decided in checking it while the child is young. Something bitter, such as aloes or quinine. should be put on the finger-tips. If this fails, mustard may be used, but only while the mother or nurse keeps watch, as he might put his fingers to his eyes. A child who is inclined to bite his nails will generally do so on first waking

Fig. 4. Corfect spacing of each nail in different grain of wood. Fig. 5. Secret nailing, left to right: Chip turned up: nail partly driven home; punching nail home; opposite arrow, chip pressed home on nail head.
Fig. B. Skew nailing an upright to a hoizontal member
from sleep, so it is well to put the hands in gloves when putting him to rest.

If nails are filed daily with an emery board, instead of cutting them once a week, they will be kept nicely shaped and always the desired length. The skin will not encroach unduly on the nail if an orange stick is dipped in peroxide of hydrogen and passed all round the cuticle, pressing it down. A well-manicured look is thus easily maintained, especially if occasionally the nails are first soaked in soapy water and then a cuticle cream is applied to solten the skin before using the orange atick. A nail varnish can be made of paraffin wax I drachm, chloro. form 2 fluid ounces. A good cuticle cream is composed of powdered white castile soap 1 drachm, white vaseline $\frac{1}{2}$ ounce. Discoloured nails can be bleached by mcans of peroxide of hydrogen or lemon juice.

Abscess in the Nail. An abscess may form under the nail or at the root as the result of some injury, or a small infected wound such as may be caused by a splinter of wood. The pressure of the confined pus (matter) causes severe pain. When an abscess threntens, the end of the finger should be wrapped in lint soaked in hot solution of boric acid (one teaspoonful to the pint of water). The lint should be removed frequently or covered with oiled silk or a large rubber finger-stall. The hand should be kept well raised by means of a sling. If the abacess forms, relief can be obtained only by haring it opened and letting the matter escape. Inflammation of the nail matrix, or onychia, may arise from several causes, including infection by the microbes which produce suppuration.

Toe Nails. With ingrowing toc nails the edge of the nail, by pressing against the soft skin near it, may set up great irritation. They are caused chietly by weuring boots and shoes which are too narrow. Harm is also done by rounding the toe nails when cutting.

Keep the edge of the nail from getting em. bedded in the flesh by forcing a small piece of cotton wool under it. The pressure can be eased by soaking for 10 min . in very hot water, and gently scraping the centre with a sharp knife. It will be easy to raise the corner of the nail and put in the cotton wool, which should be well pressed in under the nail. This wool must be renewed morning and night. Keep the toe nail out square and in a perfect state of cleanliness, and wear sufficiently easy boots and shoes, and the trouble will disappear.

The Nail Brush. The choice of a nail brush ranges frum a very plain, cheap article to the superior varieties, which may be regarded as a better investnient.

A convenient addition is often made by firing a thin brush of one row of short, stiff bristles flat to the back, this being helpful in cleaning the under surface of nails. A concave back may have two or threc rows of knots so arranged that each row brushes a different part simultaneously. In all qualities the knots may be either punched into holes by a machine process or hand-made, the knots being drawn into position by wire.
Ton hard a nail brush is deleterious to the nails. On the other hand, a brush of which the bristles have become soft can be slightly stiffened by being rinsed in cold water after each time of using. The brush should never be allowed when wet to rest on the back, as if this is done frequently the bristles are apt to rot at the root. See Brush; Foot; Hand.
NAINSOOK : The Material. Although a very thin cotton material, a good quality of nainsook wears fairly well for children's finer undergarments. It has not quite the strength of a cambric made with more threads in the square inch and should be washed and ironed with extra care.

## Names: Some Legal Considerations

## With Suggestions on the Choice of Christian Names

This contribution concludes with a list of some of the more popular Christian names in use in Great Britain with the meaning of each. See Christening ; Naturalization

The names given to a child, together with its surname, are told to the registrar when the birth is registered, and are recorded by him. When a child is baptized, its Christian names are pronounced by the clergyman or other person officiating at the baptism, and are cntered in the parish or other register. The names are thus on record for all time, and cannot legally be changed except by deed poll, although in practice many persons add an additional name to those given at baptism. This should be done cautiously, however, as it may be difficult for a man who has made himself known as Thomas Wilson Jones to prove that he is the Thomas Jones entitled to a legacy of $£ 5,000$ under an uncle's will.

Changing a Name. In Great Britain an alien is not allowed to change his name without the leave of the home secretary. A British subject can, however, change his name and can in effect call himself anything he pleases. This, however, is subject to the requirements of the Business Names Regis. tration Act, which makes it compulsory for anyone who carries on a business not in his own name to register the name of the busincss and his own name as proprietor, and to put his real name on all his busincss notepaper, cte.

Subject to this, anyone who wishes to change his name may do so without any formalities at all. If, however, he wishes for any reason to put the fact on record so that it sball be easy to trace the fact that he has changed his name, the easiest. way to do it is to have a deed drawn up in which he declares that he, John Scott, intends for the future to take the name of Moncrieff. This deed he can enrol at the royal courts of justice. He will be well advised also to advertise in a fow leading newspapers. There is a 10s. stamp on the deed and a small fee for enrolment. Some persons, however, obtain a royal licence, the fee for which is about $£ 40$.

Wills and settlements relating to family properties sometimes contain what is called a name and arms clause. The estate is given to somebody, very often a man who has married the female heir to the property, upon the condition that he shall assume for himself and his children the name and arms of the original family. In such a case it is proper to apply for the royal licence and also to the College of Heralds for a grant of the arms.

Glving a False Name. Anyone, other than an alien and except under the Business Names Act, may call himself any name he likes, unless he assumes a name which he has never previously been known by for purposes of deceit. In such cases he may easily find himself prosecuted for obtaining money or goods by falsely pretending he is Jones when he is really Smith.

It is also an offence to give a false name on applying for a licence or publication of banns for purposes of marriage. But supposing a man for some reason of his own, as, for instance, that he does not like his father's name, chooses to call himself by another name, any legal transaction that he enters into in his adopted name is perfectly good.

No one may change his Christian name, i.e. the name in which he is baptized. But anyone can use any first name he pleases and give up using his Christian name. If within 12 months of the registration of a birth the parents wish to add a name, as, for instance, on baptism, or a mistake has been made about the name, the new name can be added by the registrar of births But if, however, the new name is one which has been added on baptism,
a certificate from the clergyman or minister must be produced. Every limited company must show in all trade circulars and letters the present Christian name and surname of each of its directors and also any former Christian names and surnames, nationality if not British, and the nationality of origin if he lias changed his nationality.
Christlan Names. An enormous number of Christian names, both for boys and girls, are in existence, and parents are sometianes bewildered when thcy have to choose a name for a child. This is especially so in modern times, because so many children are given two or thrce Christian names. In former days one was deemed sufficient. The choice is usually fairly easy in the case of an eldest son or daughter, for there is almost always a family association with ccrtain names.

Long association has in practice given certain families a claim on certain names. The eldest son of the Knightleys must be Rainald, and the eldest son of the Wakes, Hereward. The Percies have a long associa. tion with Algernon, the Bridgemans with Orlando, the Curzons with Nathaniel, and the Yorkes with Philip. Parents bearing the surname of Ralcigh can hardly refrain from naming a son Waltor, and the Sidneys have a like affection for Philip. Some persons like to go back to a fairly remote ancestor for a name. An early Winston Churchill accounts for the names of the English politician and the Amcrican novelist.

## Reasons for the Choice

Associated with this practice is that of giving children a surname as a Christian name. This is frequently the maiden name of the mother; less frequently that of some dis. tinguished family to which the child is allied. This accounts partly for the use of Percy, Douglas, and Neville as Christian names, and for the linking of Gascoyne Cecil, Spencer Churchill, and Godolphin Osborne.

Millions of persons, however, are without known associations with the distant past, while younger sons and daughters must be named, for boys cannot, in practice, like the ex-princely family of Reuss, be all named Heinrich and then numbered.

A favourite plan is to give a child a name or names borne by a godparent, and this, a practice of great antiquity, accounts for many Christian names Another plan is to name a child after the saint on whose day it was born. Thus a child born on Oct. 18 will be named Luke if a boy and Lucy if a girl. A boy born on Nov. 30 will be named Andrew. Associated with this is the practice of naming a boy Noel if born at Christmas, and a giri May or June if born in one of these months.

Fashion, however, plays a large part in the naming of children. Sometimes it shows itself in vagaries which cannot aliways be explained. A name, Joan or Alan, suddenly becomes popular. At other times the fashion can be traced, and in this royalty plays a large part. This accounts for the popularity of George and Charlotte for a century after the marriage of George III; for the later vogue which Albert enjoyed, and the still later one of David used in the royal family for the Prince of Wales.

Great men, too, leave their mark on Christian names. The vogue which Arnold and Stanley enjoyed in the 19th century was due to the fame of the schoolmaster of Rugby and the explorer of Africa. Gordon is another case in point, while later Peter became popular owing to the play Peter Pan. The Great War
led to a demand for names borne by the soldiers and sailurs who distinguished themselves during that period.

The most popular Cbristian names, however, are still the simple ones originally borne by the saints, John and Mary, Margaret and Thomas, for example. This is due, perhaps, less to their religious associations than to the fact that they are found in a!most every family circle, and are, therefore, sure to be chosen very frequently. Allied to this are the patriotic associations which are responsible for the frequency of Rovert and Andrew in Scotland and Pritrick in Ireland.
One class of girls' names consists of those which are formed from masculine ones, thus following a Roman model. These include the many feminines of John-Joanna, Jane, Joan, and others-while Philippa, Josephine, and Wilhelmina are other examples. In this way girls can perpetuate the name of a father or a distinguished member of the family. Another class of names for girls is taken from flowers and plants, Rose, Lily, and Ivy, for instance, the one chosen being perhaps the mother's favourite flower. Another draws upon the various Christian and other virtues, whether in English, as Hope and Faith, or in Latin, as Vera.
In choosing a name it is well to consider whether the child can in this way be linked to the family to which he or she belongs by blood. On the other hand, this should not be carried too far and relationships with great families assumed without examination. If the names of the near rclations, parents, and grandparents are alrendy taken by elder brothers and sisters, a search may be made for more distant ancesturs.

A consideration of inportance is euphony. Preference should be given to a name that sounds well when linked with other Christian names and with the surname. Henry Higgins or Robert Robertson do not sound particularly well ; still lese so does Montagu Tigg. Combinations such as Victoria Alexandra and Irene Phyllis also lack cuphony. On the contrary, Mary Morrison and John Lindley have simple dignity. Algernon and Reginald go well with some surnames but ill with others, and the same can be said of many other names. In some cases the obstacle to euphony is in the surname, and the choice of a Christian name should avoid accentuating this. Parents and godparents should also avoid giving children names the initinls of which may form an unpleasant word. For instance, a girl whose surname is Dawson or Davis should not be named Margaret Alice, nor a boy with the surname of Gillespie be christened Douglas Orme.

Below we give a list of many of the names in general use in the British Isles for both girls and boys, with the meaning of cach.

## Name Plates for Private Houses

Graceful Styles and Novel Ideas for Town and Country Homes
Several ways of making name plates are suggested in this article and practical directions are given. See also the articles on Chip Carving: Lead Art Craft: Lettering: Repoussé Work; Stencilling: Wocdcarving

While the chief use of a name plate is to indicate the house as a guide to visitors and tradesmen, the decorative side of this accessory need not be overlooked. In choosing a style the type of house will be borne in mind. What would look pretentious on a cottage porch may be quite in keeping with the entrance of a large house on the outskirts of a town, and what would be somewhat aggressive on a terrace door, will be pleasantly arresting on that of a seaside bungalow.
In town streets of any length it is always advisable to have a number as well as a name on the gate or door. There is nothing so irritating for those visiting a house for the first tinie as the search for a name only, without the assistance of a number, in a row of villas which all look alike. It is also a convenience where the front door is only a little way from the gate, and the latter does not mask the former, if name and number are repeated on the door. Taxi-drivers and tradesmen frequently only look at doors in such cases. At night the name on the door can be lighted by a lantern fitting, or, where there is a porch by a lighting fixture in the roof of this. If there is a glass fanlight the number can be written on the middle pane, or better still for visibility, on a glass lamp projecting from it.
For houses where the front door is concealed behind a high gate and brick walls the name plate can be placed symmetrically to balance the letter box or number, or can be affixed to the gate where this is of wrought iron, the plate taking the form of a circular iron disk with the name in neat lettering.
As a general rule, in choosing a name plate for a town house the simpler it is the better

Name Plate. Fig. 1. Name plate for a town house which, by means of plain but dignifed lettering, does not detract from the beautiful design of the doorway chosen.

The first illustration shows an example of a suitably designed and perfectly placed neme plate for a decorative door. For the 18th century style of entrance the name plate looks best either just above the door, or on the upper part of the door itself when the panelling permits. Displays of name and number on the walls at the side of the door, or painted on the columns, when such an entrance possesses these, take away from the beauty of the doorway. Any exaggerated type of lettering would be disfiguring.

In the country, signposts and wrought iton brackets are sonetimes utilized to carry more ornamental name plates. Such a stylc can be delightitul for a picturesque stone-tiled house or a thatched cottage, as shown in Fig. 2. The name plate illustrated is cut out of wrought iron plate. It will never wear out, warp or crack, and such plates can be obtained in a variety of designs. Painted signhoards are suitable and gay for a seaside bungalow, if carried out in a modern design descriptive of the title, and liave the advantago of being little likely to be passed by unnoticed when suspended from a wrought iron bracket. As the colours used to paint such a sign will be exposed to the weather, paints with a hard glossy surface should be

Suitable for a sedate littlo house, either in town or in country village, is the nane plate shown in Fig. 3, with its white painted wooden letters on a base which matches the door in colour. Perfectly simple in form, it is the position of the plate which attracts the eye in this case and is far more effective placed on the wall than on the door itself. On a chestnut pale gateway, or any rustic most suitable.
Constructive Details. For a house the size of a name plate varies not only in accordance with the amount of the lettering thereon, but also with the style chosen. The smallest size is about 10 by 3 in. Brass plates used for business or professional purposes vary from 8 by 5 in . to 18 by 12 in . on the average, and are engraved with one line or two line lettering in sizes from $\frac{1}{2}$ in. to $3 \frac{1}{2}$ in. Name plates are also employed indoors for various purposes, to distinguish particular 100nns, or for drawer fronts and boxes.
Name plates can be made up from various materials, the choice being governed to some extent by considerations of durability and appearance. For exterior work oak, copper, brass, and lead are good both on the score of durability and of general suitability. Urnamentation may be effected by various processes. In the casc of a wooden name plate, the letters may be incised as in Fig. 4, or may be raised by carving. Another method is to cut the letters to shape from comparatively thin material, and apply them to the plate. Such a plate is seen in Fig. 3. Here the wooden letters are painted,

Name Plate. Fir. 2. Name plate on a sign-holder Name Plate. Fir. 2. Name plate on a sign-bolder design is cut out of wrought iron plate Courtesu of Capt. G. C. Clarle
but wooden letters may be left in the natura colour and glued and tacked to a dark atained luase, or the letters might be dark and the base light. Poker work and chip carving are applicable to wooden plates; stencilling and painting in colours are also employed

A name plate may be made in wrought iron Pierced metal, and applied metal lettors are other processes. For brass and copper, engraving is generally adopted. Leaded letters applied on glass is another suitable
method of making a name plate, which is described in the article on Lead Art Craft.

Wooden and lead letters can be obtained in various aizes. All that has to be done with these is to get a haseboard, say a piece of oak, and clean it up amooth in the vice, and mould or otherwise decorate the edges. The lettering should be set up by temporarily fixing a batten towards the lower part of the plate and placing the separate letters upon it, arranging them until the space between them is accurate and pleasing to the eye, noting each of the characters, marking their position on the basehoard, glueing and pinning if necessary. When dry, the edges of the letters can be modelled or left plain, and the background coloured, oiled or polished. If the name plate is not exposed to the weather, the letters could be cut from good plywool. In making a repoussé name plate the deaign should be drawn and a tracing made. The latter is transferred in reverse to the back of the metal plate, which is then mounted on to a cement block and the work of eminossing proceeded with The article on Repoussé work should bc referred to

A simple way to make a name plate for a pratected doorway is to build the letters up from thin strips of from thin strips of Fig. G. Fixing the letters by means of glue wood, such as can be obtained for atrip work. to secure good nankeen waistenats. In order The lettering is marketal ask and and pieces of the wood strip cut off to the laundered by immersing it in cold salted right length. These have then to be glued and water for 24 hours before washing and pinned to the haseboard. The construction is hanging it up to dry without wringing it.

Name Plate Fir. 3. Suitable for a small house standing baok from the stret, the colour contrast of the unobtrusive name plate catches the eye. Fig. 4. Incised lettering on a wooden base forma a simple but effective name plate for the chestnut pale Rateway of the coltage type of residence Humplireu \& Vera Joel

NANRGBN LIIY. This is the popular name of the beautiful hardy lily (Lilium testaceum) that owes its name to its nankeenyellow flowers. See Lily.
NAP: The Game. Nap or Napoleon is a card game for any number of players, but it is best played by five or six. An ordinary pack of 52 cards is used, and the cards rank as in whist.

In the simple game of nap each player is dealt five cards, and the eldest hand has the right of first call, the call passing as usual to the left. Each player calls according to the number of tricks he can make up to five tricks, or nap. Any player who cannot beat the previous player's call says " pass." Whoever makes the highest call has the privilege of leading, and all the other players play against him. The first card led by the player making the highest call makes the trump suit. Players must follow suit if possible, but if not may trump as desired. They are not bound to try to win a trick. The winner of each trick leads for the next.
The caller is only paid for the number of tricks he declared, though be may make one or two more. Similarly, if he fails to make the number of tricks nominated, he only pays on the amount of his call. The game is usually played for money, and payment given for each trick. Thus at halfpenny nap a player will receive $1 \frac{1}{2} d$. from every other player for a successful call of three, and pay out $1 \frac{1}{2} \mathrm{~d}$. to every player if he fails to make his call. Usually, on the Napoleon call, he receives double stakes for winning, i.e. 5 d . at halfpenny nap, but only pays out normal stakes, $2 \frac{1}{2}$ d., if he loses. Often even money is paid out on this call, i.e 6 d . and 3 d . respectively.

Variatlons of the Game. The above is the ordinary game of nap. In the first variation there is a call known as Wellington. By this call the player undertakes not only to take all five tricks, but at double the usual stakes Wellington can only be called if nap has already been called by a previous player.

An adaptation from solo whist is the call misery, by which a player undertakes to lose all five tricks. There are, of course, no trumps, and the call ranks between the ordinary calls of three and four tricks, and is paid for as for a call of three.

Sir Garnet is an extra hand of five cards dealt face downwards on the table. Each player in turn has the privilege of taking the hand up and combining it with his own, throwing away the five cards he does not want, but any player who does this must declare nap.

NAP CLOTE. An old favourite for winter coats, woollen nap cloth is warm without being unduly heavy. The nap is produced by a process of rubbing, and the motions of the rubbing surfaces control the pattern. Besides the pimples, large or small, of Petersham nap there are also wary naps, known sometimes as Elysians or Witney naps.

The weakness of nap cloth is that the surface rubs amooth at the points of most friction, and in the cheapest qualities this defect soon appears. Nap cloths aro made at widely differing prices, and the best are much the most satisfactory in the end.
NAPRTREA. The liquid product obtained by distilling wood or paraffin is known as wood naphtha or mineral naphtha. Wood naphtha has solvent properties similar to methylated spirit; it is used by French polishers as a solvent for shellac.
Mineral naphtha is not so volatile as petrol, but it possesses similar cleansing properties, and can be

Naplin. Wethod of mating the bishop style. Pis. 6. Naplin vith one-third of width tarned op. Fig. 7. Upper single layor iolded between lower layers. Fig. 8. Threo-iold length with onds tonching. Finished shape resalting from other point being tacked in

in. $\mathrm{Ba}^{2}$
made slightly to overla!, and then soft soldered, as in Fig. $3^{\text {a }}$ Allowande for the jointing must be made when fixing the proportions of the strip

Having soldered the joint, all six iaces should be cleaned up with fine emery paper and ncatly grained. Then the finest grain emery paper should be atrucli across the surface in one direction only until the whole exhibits a uniform surface. The next step is to decice upon n suitable design, such as that shown in Fig. 1,
fold lengthwise in two so as to inake a crease, and turn it back again. This crease is represented by the dotted line. From the middle, fold over the right side as seen in Fig. 2; then turn the napkin over and do the same thing on the other side This produces Fig. 3. Turn the napkin over again, foid up the bottom ends, Fig. 4, and then complete the shape by taking the bottom corrers and inserting them well into each other.

The bishop, style is achieved by laying the napkin Hat on the table and bringing the bottom edge up in one fold, making the size of the whole one-third less. A reference to Fig. 6 will make the process clearer. Fold the single layer of the upper part in between the two layers of the lower half, making three thicknesses, as in Fig 7, and then, by creasing over, find the centre of Fig. 7, and fold in the edges at each side to meet this line, Fig. 8.

The top right-hand corner must now be brought down, and the bottom left-hand corner up, as in Fig. 9. Turn this over and lay it on the table according to Fig. 10, and fold the top over to meet the buttom, Fig. 11. Turn this over to get Fig. 12. The dotted lines show the fold on which the right-hand part must be brouglit over, the angle E being tucked under tho folds. This gives Fig. 13. Turn the whole over again to produce Fig. 14. Tuck in the right-hand corner of this exactly as in the last process and the finished shape, Fig. 15, will result. This must be opened out by pushing the fingers into the opiening underneath. See Drawn Thread Work; Embroidery ; Hematitch; Linen ; Table Laying.

Napkin Rings. The most important point about a naphin ring is that it should be individual, so that napkine shall not get mixed u] when laying the table. Various devices are adopted for distinguishing rings, the simplest being to have an initial or monogram engraved, carved, or painted on them. Sometimes they are numbered, or, in the case of childien, wooden rings are painted with some simple design and with the child's name in block letters. More elaborate enamelled ringa may have a different design on each one of a set of rings, or they may have the same design but a different colour for the background
Siniple but pretty rings are inade of strips of white linen, cut with one pointerl end and just long enough to go round the napkin when rolled up. Each ring is fastened by means of a loop and button, and has $a$ different Hower, fruit or bird design em broidered on it. A tiny single hem is turned up all round and the edges are buttonholed.
Wooden rings can be obtained for enamelling or painting. Having sandpapered the ring, the selected design may be stencilled and painted in oil colours, afterwards

Fig. 2. Showing how to bend the metal strip on a large hexaganal nut held
in the vice. Fig. 3- Soldering the ends together. Fig. 4. Application of prepared enamels with a small brush. Fig. 5. The inished ring
varnishing the ring. Bronze colours may be and carry it out with some of the specially
used or the ring may be decorated with Chinese prepared enanel as descrihed in lacquet used or the ring may be decorated with Clint by piercing or by repousse work Instructions for carrying out these processes will bo found under their own headings.

Making the Rings. A pleasing type of ring takes the form of a hexagon and can be made froin brass, pewter, copper or silver. A sct of such rings could be worked out using a different predominant colour for the baclsground in eaclı case.
Suitable proportions are given in Fig. 1, and it will be seen that in the first stages the metal is simply a strip. It should be perfectly tlat and accurately marked out where the bends are to be made.
The next stage is the bending of the strip, as shown in Fig. 2, to the correct angle This must be bent very carefully, otherwise the ring will be unequal and look very bad. A large size hexagon nut such as is used by engincers for large-size bolts is very useful as a guide in bending
 vori on metal in page 681, or with the regulation stove enamel. The paint is applied with a very small brush in the manner illustrated in Fig. 4, and naturally calls for the greatest care if a satisfactory result is to be achieved. When this part of the work has been finished, the ring must be dipped in laçuer varnish in order to pacserve it from the atmosphere The result is seen in Fig 5. See Embroidery: Enamelling: Lacquer Work: Piercing; Re-

NAPKIN: For the Baby. Turkish towelling is the best material to use for infants' napkins, owing to its a bsorhent quality. The squares may be bought separately or the material may be purchased by the yard and cut up and hemmed at home. See Baby.
NAPLES CAKE.

This is a mixture which is buked in six rounds, each rather less than $\frac{1}{2} \mathrm{in}$. thick When the layers are coolied and cold they are piled one on the top of the other, with a lilling of preserve between them. The preserve must be rich and should be passed through a hair sieve, or ininced nuts and whipped cream may he used us a filling

The top of the cake is decorated with an even coating of almond icing and finished with sugar icing and a horder of crystallized fruits or flowers, as shown in the illustration in the next page. For the mixture $\mid \mathrm{lb}$. fine flour will be required, also $\frac{1}{2} \mathrm{lb}$. butler, $\frac{1}{2} \mathrm{lb}$. castor sugar, the grated rind of a lemon, one teaspoonful orange-flower water, 7 oz ground sweet almonds, and 1 oz . pounded bitter almonds. Rub the butter into the flour, add the other dry ingredients with a pinch of salt, mix well, and then make into a paste with the yolks of 4 egge.

The mixture is made up into rounds and baked in a slow oven till crisp and firm and

Naples Cake, consisting of lagers of cake with fllings of preserve, the top layer being iced
about the colour of shortbread. Small flan hoops may be used to keep the rounds in shape. See Almond Paste; Icing.
NARCISSUS. This is the innst popular of all the spring-flowering bulbs; there are many types or classes and numerous varieties of each type. The classification is based on the length of the cup or crown, the central part of the flower, in comparison with the nuter psurt called the perianth
The first class or group is the trumpet, in which the trumpet is as long ns or longer than the perianth Varietios in this eroup are usually called daffudils Soine of the best are King Alfred, Emperor, Empress, Horsfieldii, Glory of Leiden and Mime. cle Graaff.
The second group of incomparabilis or chaliceoupped narcissi consiste of flowers in which the cup is not less than one-third the length of the perianth Populas varieties are Sir Wethin, Beauty, Gloria Mundi, Stella Superba and Frank Miles.
In the Barri or sta, narcissi the cup is less than onn-third as long as the perianth. Favourite varictios are Barri ounspicuus, Albatross, Agnes Barr and Seagull.
The Leedsii narcissi are beautifll flowera with pale perianth and cup. Mre. Langtry, Waterwitch, Duchess of Westminster and Minnie Hume are well known varieties. Then there are the poet's narrissi, jonquils, double daffudils, and various species or wild types, among which are many charming miniatures.
In recent years innumerable new and beautiful varieties have been raised; some of them cost as much as 30 guineas a bulb. The greateat advance has been in the intense and brilliant colouring of the cup or crown, which iq in striking contrast with the pale or yellow perianth. One or t.wo new trumpet daffodils are of pale salmon colouring, and no doubt as the vears pass this will be intensified.
Narcissi thrive in ordinary soil, but flourish best in that of loamy character, which does not dry out in summer. The bulbs whould be planted in September-October, about 3 in. deep. They are invaluable in spring flower beds, in the herbaceous border and shrubbery, and look particularly well in grass. If grown in grassland the grass must not be cut until the leaves have died down. Bonemenl, to the amount of 2 oz for every square yard, is the best fertilizer to mix with the soil. The bulbs may remain undisturbed for years, until they become orowded; they ought then to be lifted in July, separated, and replanted at once or in early allumn

Narcisaus. Blooms of the lavourite

In Pots and Bowls. Daffodila and narcisa make admirable pnt plants for the greenhouse in early spring. The bulbs should be potted in September-October, in loamy soil, placed out of doors and covered with old sifted ashes In six or eight weeks they will be well rooted and should be taken out, shaded for a fow days and then placed under glass. After the flowers are over the bulhs may be planted out.

Narcissi and daffodils do well in bowls of fibre in the home: they should be kept in a cool, dark jlace for six weeks before being brought to the light. The bunch-fowered narcissi may be grown in bowls of fibre or in bowls of pebbles and water
A few of the most beautiful of the minia ture kinds, suitable for well-drained snil in the rock garden, are angel's tcars daffodil (Narciseus triandrus). hoop petticoat daffindil (Narcissus bulbocodium), and Narcissue cycla mineus. These are also admirable bulbs to grow in pots in the unheated greenhouse

Pests of the Bulb. The chief pest is the bulb mite. The simple romedy is to dust the affected part with flowers of sulphur. To bulbs in the ground the application of a tepid solution of sulphide of potassium, 1 lb . to a quart, is recommended.
The narcissus fly sometimes affects the bulbs. The presence of the fly can be detected by pinching the neck of the bulb. If the neck feels soft, the bulb should be cut open at the top and the eggs taken out and burnt. There is, of course, a risk that the bulb will be killed also, but this is a risk that is necessary to run for the sake of the others. It has been found by experiment that immersinn of bulbs in hot water for one hour at a temperature of $110^{\circ} \mathrm{F}$. is fatal to the larvae of narcisaus flies. This investigation has been carried further, and developed also in the direction of eelworm control As the latter is the more serious pest and most difficult to kill, the treatment found efficient for its eradication may be adopted as a combined measure for both eelworm and narcissus fly Jarvae. This consista in soaking the bulbs at a temperature of $110^{\circ} \mathrm{F}$. for three hours. Sec Bulb: Daffodil ; Flower Garden : Jonquil, etc

Nasturtium Cultare. 1. Seeds correctly sown. 2. Seedlings ready for planting out. 3. Support for climber. 4. Planting on wall: a, boards.; to carl roots round pot. 9. Roota ourled and top dressing (c) added

NARTHECIUM. A hardy herbaceous, iris-like plant, Narthecium ossifragum, the hog asphodel, is suitable for moist snil by the side of ponds. Planting is done in spring or autumn in bnggy peat, or ordinary soil mixed with annd and leaf-mould. Planta are best propagated by division in apring or autumn. Narthecium grows 10 in. high and bears yellow flowers during July.

NASAL CATARRH.
Inflammation of the lining membrane of the nose is usually acconipanied by a mucous discharge, and hence is known as catarrh. This may occur in an acute or chronic form, and be due to such irritants as dust. snuff, tobacco smoke, or other irritating vapours, or to microbic infection, the most frequent example of the latter being the common cold.
In acute cases smoking should be discontinued, the room should be kept at an even temperature, though well ventilated, while quinine and other remedies prove useful when given inwardly. A chronic nasal discharge calls for douching or spraying, and probably surgical treatment of sources of irritation within the nose. See Cold; Nose.

## Nasal Douche. See Douche

NASTURTIUM. The most important of the true nasturtiums is the watercress, but the name is commonly used to describe the annual tropaeolums, of which there arc both climbing and low growing varieties. The former are useful for covering trellises, fences and other supports in summer; the dwarf varieties are invaluable for poor soil and dry sunny places. Seeds are sown out of doors in April, where the plants are to bloom. There are numerous varieties with blooms in yellow, orange, crimson and other showy colours. See Tropaeolum; also illus. p. 841.

Uses of the Plant. Both the flowers and leaves of the nasturtium plant are used for salad making, and as a filling for sandwichos, while the seeds are pickled as a substitute for capers. The flowers, because of their bright colour, also form an excellent garnish.
Nasturtium Pickle. The seeds required for making nasturtium pickle should be gatherod ripe in dry weather, as any dampness may spoil the pickle Spread the soeds in one layer over a large dish, leave them for 1 or 2 days. and turn them about each day. Then put them into a jar and aprinkle with salt.

To prepare the pickling vinegar, simmer for 40 min . some white wine vinegar with garlic and spice, allowing 1 olove of garlic, 1 chopped shallot, and $\frac{1}{2}$.oz. mixed allspice, cloves, and mace, to each quart of vinegar. The spices are tied in muslin and afterwarde removed.
When the vinegar has simmered the allotted time, give it a quick boil up and pour it over the nasturtiums. Let all go quite cold before bottling the pickles, and remove the spices. Keep the pickle 4 months before using.

Nasturtium Vinegar. To make nasturtium vinegar, fill a widemouthed bottle with some full-blown nasturtium flowers, ndd ${ }^{1}$ a clove of garlic and a finely-chopped shallot, and pour over them as much vinegar as the bottle will hold. Let the whole stand for two monthe before

Nasturtium. Brilliantly coloured flowers of the rubbing it through a fine sieve ; then add a little cayenne pepper and salt, and keep the vinegar corked until required. See Vinegar.
NATIONALITY. In Great Britain nationality depends in the first place upon birth. A person born within the British Dominions is of British nationality, but, subject to the rule that if he be born of a father who is an alien, he cain, when he is 21 , or as soon thercafter as possible, renounce his British nationality and take that of his father.

In some countries a child takes the national. ity of the father wherever the birth takes place. so that it is quite possible for a bo to be English by English law and German by German lan. It is also possible, according to recent Jinglish decisions, for a person to have no nationality at all. If, according to the law of the state of which he was a natural citizen, he was entitled to renounce that nationality and he has renounced it, and has not acquired another nationality, then he is not a national of any country for the time being.

A woman on her marriage at once takes the nationality of her husband, and if he changes his nationality she automatically changes hers. See Naturalization.
NATIONAL MARK. This consists of a map of England and Wales in silhouette, with the words "produce of Fingland and Wales" inscribed in a circle placed centrally in the map within which circle is a design representing the Union Jack. Its object is to sccure for home.grown meat, poultry. fruits, vegetables, eggs, canned goods, etc., the same commercial advantages as are at present enjoyed by impoited supplies. Among foodstuffs to which the scheme is applied are eggs, toinatoes, apples, pears, broccoli, wheat flour, canned peas, fruits, cider, etc.
The packer is bound to state on the label of the package the variety of the article, his own name or identification mark, the grade, the date of the packing, and either the weight or the nuinber of the contents. The advantage of this lahel is that it gives the purchaser all the inforination required, and it is not even necessary for him to see the contents of an unopened packare. In 1931 a shop for the sale of national inark goods was opened in London.

NATURAL COLOUR. Any fabric which has not been treated with a dye is said to be of natural colour, but the tern is applied particularly to woollen underclothes of a grey or hiscuit colour, and to shantung silks. One advantage of buying natural-coloured clothes is that they cannot fade through exposure to the sun or lose their colour in the wash, as most dyed materials may do.
The term natural colour is also applied to flesh-tinted face powders.
NATURALIZATION : The Law. Naturalization takes place where a person is made a British suhject by a certificate of the home secretary. A natural-born British subject is one born within his Majesty's dominions and allegiance; one horn out of 13ritish dominions, but whose father was at the time of the child's birth a British suhject, either by birth or naturalization; or one horn on hoard a British ship in foreign or territorial waters.

The child of a British subject is to he deemed to have been horn within his Majesty's allegiance if horn in a place where by treaty or otherwise his Majesty exercises dominion over British subjects, e.g. if horn in Turkey before the aholition of the capitulations by the Treaty of Lausanne, or in one of the independent native states wherc the British are not subject to the local native courts. A child born on a foreign ship in l3ritish territorial waters is not born British by reason of that fact.

An alien who wishes to become naturalized must make application to the Home Oltice in writing, and must show that he lias cither resided in British dominions for not less than 5 years, or heen in the service of the crown for not less than 5 years during the 8 years preceding the application. The residence required of not less than 5 years must not he less than 1 year immediately proceding the application, and 4 years in any British dominion, the whole 5 years to bc within the 8 years preceding the application. The applicent must show that he is of good character, and has an adequate knowledge of the English language. Further, he inust satisfy the Home Olfice that he intends to reside permanently in a British dominion, or else to enter or continue in the service of the crown.
Change of Nationality. When a British woman marries an alien she takes his nationality, and on his death or divorce may wish to resume her British status. The home secretary may grant to such a woman a certilicate of naturalization without any requirements as to residence; he inay also dispense with the residential qualification in other sıecial cases to the extent of not requiring that the 4 years' residence or 5 ycars' service shall have been within the 8 years preceding the application for naturalization.

An appplicant who hases his certificate on service under the crown should procure a certificate from the department under which he served (c.g. foreign oflice, colonial office, etc.). The home secretary may also treat a period spent in the service of the crown abroad as equivalent to a period of residence in Great lbritain. If a person applying for naturalization has minor children not British born, he may apply to have them included in the certificate. If they are so included they become British, but on attaining majority may inake a declaration of alienage.

When douhts have been raised the home secretary may grant a certificate to anyone upon whose British nationality questions have arisen. This certificate must state that it is given to resolve doubts, and is not an admission by the holler of a certificate that he ever was an alien.

When the home secretary is satisfied that a certificate of naturalization has been obtained by false representations or fraud, or suppres-
sion of material facts, or that the person in question has shown himself by act or speech to be disaffected or disloyal to the crown, the certificate is to be revoked.

In addition the certificate is to be rev ked if the home secretary is satisfied that the holder has during any war unlawfully traded or communicated with the enemy, or with a subject of an enemy state, or has knowingly engaged or assisted in any business which might help the enemy. A certificate must also he revoked if it is slown that the holder: was not of good character at the date of its grant. or that since the grant of the certiticate he has resided out of the British dominions, unless he was in the service of the crown abroad, or was the duly occredited representative of some 3ritish subject or firm. The home secretary shall also revoke the certilicate where the holder within 5 years of the date thereof has heen sentenced by any court in a British dominion to imprisonment for not less than 12 mont hs, or penal servitude or a tine of not less than $£ 100$

The consequences of revocation are that the person hecomes an alien again, and the home secretary may order that his wife and children shall also cease to be British suhjects. In default of a special order the wife and children remain British. But such an order is not to be made against a woman who was by birth a British subject, unless she personally has been guilty of such conduct as would have been, sufficient to justify revocation if she had held a certificate. See Name.
NAUSEA: How to Treat. The sensation of sickness or an inclination to vomit is, denoted by the term nausea; them may be retching at the same time. The most frequent causes are sea-sickness; food not easily digested or even poisonous; pregnancy (morning sick ness); olfensive smells or tastes; poisoning; indulging too freely in fermented liquors; tick. ling in the throat, as in chronic pharyngitis; the onset of febrile disorders; stones in the kidney; diseases of the stomach, ete. A severe knock on the head will often give rise to a feeling of sickness, and with some people any. acute pain, or even excitement, may produce this effect.

The patient should lie down on his left side in a quict room in a subdued light, with the head on a low pillow, taking care that he is comfortably warm, but not overheated. He should not be permitted to talk much or make any attempt to amuse hinself by reading. Slowly sipping a glass of soda-water or other effervescing drink may help to relieve the condition. Should the feeling of nausea continue, a mustard plaster may be applied to the pit of the stomach.
If the feeling of nausea still continues, or constantly recurs, it is inost important that the cause should be ascertained. If it is likely to be caused hy irritants, food, or poisons in the stomach, give an emetic consisting of a tahlespoonful of mustard in a glass of warm water. Afterwards give sips of cold or of sodawater, though some get more benefit from sips of hot water.
If the nausea is caused by tickling in the throat, or violent coughing, a draught of cold water, if it can be swallowed, will be found helpful at the moment. A gargle should be used to tone up the throat, such as the following :
Tincture of myrril
$2 d$ drams
Glycerin of buras
1 oz.
8 oz.
For the feeling of nausea induced by seasickness it is well for the traveller to lie down, if possible, on deck, but weather will not always permit of this. He should be warmly covered with a rug. Chloretone is often successful in preventing this complaint. As soon as he feels equal to it the patient should have a light meal, such as a hasin of soup or gruel, or perhaps
some cold chicken. He should avoid any rich or greasy food. See Biliousness; Gastritis: Morning Sickness, etc.

NEAPOLITAN ICE. To make this sweet. meat beat the white of an egg and add to it a tablespoonful of water strongly flavoured with liqueur. Rub llb. icing sugar through a fine hair sieve, and into the white of egg, etc., stir enough of it to make a dry yet pliable mixture which can be easily moulded in the fingers. Dust a pastry board with some more icing sugar and knead the mixture on it until it is smooth. Divide it into 3 portions, colouring one with cochineal and Havouring it with raspberry essence; another with finely grated chocolate and using vanilla essence to flavour, and leaving the third portion its natural colour and using any flavouring desired.

Roll out each piece to about $\frac{1}{8} \mathrm{in}$. in thick ness, arrange the colours one on top of the other, brushing between each slab with a little cold water. Press them firmly together, trim the edges evenly, and brush over the top with a little melted coating chocolate. Let this surface dry before turning over the sweetmeat and coating the other side in the same way. Sprinkle over all a little finely desiccated coconut, and with a sharp knife cut the sweetmeat into slices or cubes. They will require about 24 hours for drying. See Chocolate.

Neapolitan Violet. This is a favourite double mauve variety of the sweet violet. See Viola : Violet.

NECE: In Equan Beings. It is most important that nothing tight should be worn round the neck; giddiness is often due to this cause. Special care on this point should be taken by people who are inclined to suffer from apoplexy or any kind of fits, or those with short necks. During sleep always leave the neck as free as possible, and take especial care that in a child's night clothing the neckband is loose.

Stiff neck is a form of rheumatism of the muscles, generally caused by a chill. A person who is liable to suffer in this way should be careful never to sit in a draught. Discretion must be exercised in the use of furs, etc., round the neck, as they may make the part too warm and expose to chill later.

Glands in the Neck. In swollen glands the condition may arise from a bad oold, adenoids or diseased tonsils, bad teeth, or in young children from the cutting of teeth. A more serious cause is tubercalar disease. No treatment other than the removal of the cause may be noeded. The glands should be protected from irritation. When the enlargement is caused by the tubercle germ the general health should first be attended to. Do not paint the enlarged glands with iodine unless instructed to do so by the doctor, who should always supervise the treatment.

Wry neck may be an affliction from birth or have come on later. It is caused by the muscles of the neck contracting, and so drawing the head to one side. When the condition is congenital treatment by manipulation may be successful if it is commenced early enough, so no time should be lost in procuring medical advice. Full throat results from enlargement of the thyroid gland in front of the windpipe.

Care of the Neck. The back of the neck should be protected from hot sunshine, as this part of the body is particularly sensitive and blisters are painful. Sunburn and freckles on the neck may be reduced by a bleaching lotion composed of equal parts of lemon juice, rosewater, and peroxide of hydrogen. This lotion is also helpful for removing discoloration after wearing a dark fur round the neck. Suitable emollient or astringent cosmetics used for the face should also be applied to the neck to keep the skin smooth and firm.

A good line of neck is best preserved by proper carriage of the head. An ugly defect
noticeable sometimes in middle age is an accumulation of fat at the back of the neck. The following exercise will help to correct this condition and restore suppleness :
Stand erect, with hands on hips. Bend head and rotate it very slowly up towards the right, then, with head back, down to the left and round. Repeat several times and then reverse the direction, keeping up on the left and down on the right. See Face: Goitre : Stiff Neck: Throat.
NECE : In Cookery. In beef that portion of the ox which lics between the head and the chuck ribs is called the neck.
In mutton the neck portion extends from the head to the loin, and is divided into the scrag, middle neck, where the shoulder has been detached, and best end of the neck. In veal, as in mutton, all meat bet ween the head and the loin is called the neck. The scrag piece is used for boiling or stewing, and the best end can be either boiled, stewed, braised, roasted or divided into cutlets.

In pork, that part of the neck which joins the hcad is called the spare-rib, and can be roasted, or it is sometimes added to the head when making brawn. When cured as bacon the neck part next the head becomes the collar and is a good piece for boiling.

It must be remembered that meat is cut up differently in various parts of Great Britain, and that the joints are not always named alike. See Beef; Joint; Mutton; Pork, etc.
NECKLACE. Of the expensive necklaces pearl ones are the most generally worn. Filigree necklaces and varieties of designs in enamel work, or composed of medallions or jewelled plaques, are worn when fashion permits.

In choosing a necklace, whether of a valuable or inexpensive kind, regard should be paid to the shape of the neck. Women with short, thick necks should not wear large ornaments round the throat, but select a necklace which by falling well below the base of the neck has a slimming effect. A woman or girl with a thin or long neck is usually suited best by a necklace which fits the throat closely. While pearls suit nearly everyone, coloured necklaces should be chosen with due regard to the eyes of the wearer. For instance, gold and amber shades are particularly becoming to brown eyos, while jade enhances hazel eyes, and blue stones will give a deeper colour to grey or blue eyes. See Jewelry : Pearl, eto.

Nectarine. 8mooth-nkinnod type of peach which is a delicions dessert fruit
forwards through an emery cushion. In warm weather this makes them easier to use if it is done occasionally while working.
The threading of a needle is facilitated by holding the eye before a sheet of paper or any white object.

Other kinds of needles used in the home include knitting needles, varieties of which are deacribed in the article on Knitting, special packing needles, larding needles. and gramophone needles.

When a splinter of a ncedle is broken off in the palm, the finger, or elsewhere, a doctot should be consulted at once with a view to its removal. If there is any delay the splinter may move away from its point of entry X-rays are invaluable in localizing such frag. ments. It is usually necessary to open down on the needle, but this is often possible under a local anacsthetic.

Needle Case. Various kinds of needlc cases are easily made, and provide a good means of saving needles which might otherwise be lost or allowed to rust. The simplest is made by sewing together in the form of a book a few small pieces of flannel cut to a uniform size. Flannel is preferable to other cloths for this purpose because, being composed of wool, it is a better preventive of rust. A small leather case to which the leaflets can be stitched, or some stiff cardboond covered with satin, makes the whole stronger and more compact. Ser Gramophone: Knitting; Mending; Needlework; Woolwork

NEEDLEWORK. The art known as needlework can be summed up as a knowledge of how to make the best use of needle and thread. Under this wide term come many variations, such as tapestry, crewel. and appliqué work, other embroidery of all kinds, lacc and beadwork in which a needle is used. clarning, and plain sewing, as well as knitting. netting, and crochet.

Plain needlework is the first essential to learn Besides its practical value, it teaches neatness, cleanliness in handling delicate materials, and accuracy, and gives scope for artistic expression. Those who have all their needlework done for them need a knowledge of it in order to be able to distinguish good work from bad, and those who must do their own will find a good groundwork of plain needlework helpful for everyday use, and with such a knowledge, proficiency in fancy work is more easily achieved.

Objections are raised against handwork on the ground that it is not worth while, as machines can copy most of the stitches, and that it is unhealthy work. Machine work may be a good substitute, but for fine materials it can never equal handwork, and a certain amount of the latter is always necessary.
Conditions of Work. For the sake of one's health it is important never to sit in a stooping position; see that the chair and table suit NECTARINE. This is a smooth-skinned each other in height, and hold the work so that type of peach, and is cultivated in cxactly the same way. Some of the best varieties are Downton, Lord Napier, Early Rivers, Elruge. and Spencer. See Bottling; Fruit; Peach.
NEMDLE. Needles for sewing purposes are sold chenply in small packets, and can be bought either in one particular size or in vary. ing sizes. Needles used on damp materials should be wiped thoroughly before being put away, or they will rust and become unfit for further use. A little asbestos powder in needle packets will present rust. Rusty needles should be passed backwards and
it is only necessary to bend the head a little. When doing a piece of work that requires pinning down, such as the stroking of gathers on a large piece of work, never pin to the knee, but use a weighted cushion placed on the table, so that when pinned the work is at a convenient height for manipulation. Always sit so that the light comes over the shoulder; never work in a dim light, and avoid uaing black or very dark materials when working in an artificial light. Choose a steel thimble rather than a silver or bone one. The latter soon splits and silver ones wear thin quickly.

Needles, Scissors and Thread. Use rather short needles for ordinary plain sewing and longer ones for dressmaking, while darning needles should be longer still, with a long eve. The nsedle should be a little thicker than the working thread, so as to make a smonth passage for the latter through the material. Bent needles should not be used.
Two kinds of scissors are indispensable, a large pair with a blunt and sharp end (the latter always being kept down) for cutting out large pieces of material, and a small pair with two very sharp proints for cutting fine materials and embroidery. See that the handles are large and smoothly rounded, as if they are too tight they mark the liand and hurt the thumb.
When using tacking threars keep a reel of tacking ootton, which is much cheaper than sewing cotton, and answers the purpose just as well. The most efficient work is done through the work being tacked into the correct position first: sticking pins in is the lazy method, except in very few instances. Do not put a long thread in the needle for ordinary sewing ; a hout 18 in is quite enough. looi tacking, a very long thread can be used, as several stitches can be put in at once before drawing up the whole length of thread. Ir the casc of cotton from the roel, thread the needle with the end just cut off the recl, as the opposite end is likely to be more trouble to thread through splitting. Cotton for sewing, whether from skein or reel, should always be cut, as breaking weakens it at that point See Buttonhole: Embroidery: Hem : Seam; Tapestry

NEEDLEWORK PICTURE. Piotures worked with the needle are rarely of carlier date than the middle of the 17 th contury; they hear a resemblance to tapestry on a small scale. The design is worked in silk on a brownish linen canvas in tent stitch or petit point. The costumes of the figums are easily recognizable and often date the picture
More valuable are the examples of stump work, which is a form of raised and embossed needlework in feather stitch. A typical example of the Stunrt period consists of figures of the king and queen, trees, birds, marine monsters. caterpillars, and other sub-

Needlework Picture. Beantifal example, aboat 100 years old, of this torm of embroidery. The picture is worked in black silk on a white corded silk background, the clouds being put in with Indian Ink
jects all quaintly woven together in a picture measuring, perhaps, 2 ft by 13 ft . The caterpillar, being an emblem of the Stuarts, gives the date to the picture, which is encrusted with seed pearls, sequins, and apangles.
The stumps were followed by elahorate beadwork depicting animals, fish, trees, etc., with a landscape background. Many tentstitch pictures of Queen Anne's reign are extant, and they show a considerable advance in workmanship. Somewhere about the close

## Negatives and Their Care

## Some Useful Information for the Amateur Photographer

A negative is a photographio plate which after development shows the image reversed, blaoks being represented by clear spaces nnd high lights by dense portions, varied according to the high and low tones in the origina object. When sensitive paper is placed in contact with it and exposed to light, a positive is produced showing all the tones and details of the original. Negatives may be on glass, roll films, Hat films, when they ale thicker and stiffer than roll films, or else on paper.

It is open to the amateur to vary the quatity of his negatives in the course of development according to the purpose for which the negative is required. Ruughly speaking, negatives may be divided into three classes, vigomus or contrasting, normal, thin or soft This is most satisfactorily achieved, not by varying the developer, but by increasing or reducing the time of development. The amateur will always find it best to cunfine himself to the use of a particular developer which he knows well, and he will find that the makers of practically all the standard plates and films give development tables with several standard developers showing the time of devclopment required for each of the three classes of negatives deacribed.

The vigorous or contrasting negative is roughly one which gives a brilliant print on silver paper (P.O P) and a very brilliant one
of the 18th century Georgian black and white pictures were produced; in these a drawing was made on white satin or sarsenet, and worked upon in black silk or in colours to imitate engravings of landscapes and buildings, as well as figures. Sometimes parts af these pictures were done in Indian ink. Sampler and fire-screen work in wool came later. The techinical name for needlework pictures is acupictura. See Embroidery; Fire Screen; Sampler; Tapestry; Woolwork.

> This article, which contains a sectlon on the storing of negatives, sugrests reference to other articles dealing with photography. Among such arc Developing: Enlarging: Film Flxing; Panchromatic; Photography; Plate; Washing
with sharp blacks and whites, on ordinary gaslight paper. It gives prints whioh are particularly suitable for reproduction by the half-tone process in newspapers or magazines The normal negative gives good prints on either silver or gaslight paper, and, although it is not so suitable for half-tone reproduction, prints made from it are somewhat more artistic, contrasts being not so strong. The thin negative is always required when it is to be used for onlarging, unless great controst is required; it also gives the most pleasing results in portrait work

Defects and Stains. Defects of various kinds, chemical and physical, are liable to occur in negatives even with the careful worker. Treatment of the negatives after development, fixing, and drying are complete ia always a risky matter, involving the possibility of making things worse and sometimes of ruining the negative altogether. In all photographic processes prevention is better than cure, and the amateur should take every possiblecare to ensure cleanliness at all stages: this clennliness is not a mere matter of soap and water, but is a chemical question, as described under Developing. Fixing, and Washing.

Chemical dust in the dark room, caused by solutions spilled on the floor and allowed to dry, often gives rise to spots on a negative. Dust in a dark slide or in the air of the dark room when the slides are heing loaded will cause pinholes on the plates.

By taking care in these and similar directions negative defects may he very largely prevented It is not a wise plan to wipe a plate to free it from dust before placing it in the slide. The photograplier can rely upon the plate being absolutely free from dust when he unpacke it from the maker's. since extrandinary care is taken to prevent the deposit of dust at all stages of the manufacture. In fact, brushing the plate attracts dust to it by slightly electrifying the film. When the plate is removed from the slide after exposure it may be tapped sharply on the glans side with the knuckles to remove any dust particles that may have settled on it during exposure in the camera. This will prevent. to a large extent, the pinholes caused by dust on the plate during de. velopment.

Physical defects in a negative most often met with are frilling, blistering. smal! holes, pinholes due to dust, as explained above, and drying marks. The treatment of pinholes consists in filling up or spotting up the holes in the negative with Indian ink.

Small round holes larger than pinholes are due to air bubbles which have clung to the plate or film and have prevented the developer acting
nt that particular spot They are best Probably more damage is done to negatives avoided, particularly if tank development is in the way of scratches, finger-marks, etc., by employed, by getting rid of the air in the water. This can be achieved hy boiling the water steadily for ten minutes before use and allowing it to cool undisturbed. In dish development wipe over the plates gently in the ileveloping dish with a pad of cotton wool
Frilling, in which the edge of the film is separated from the glass, and blistering, in which the film rises in small blisters. are both due to solutions of different temperatures, and are particularly liable to occur if a some what warm de veloper is followed liy a cold fixing solution Thicir occurrence in hot weather may be pasily avoided by the usc of a cont bined fixing and lhardening bath.
Drying marks aredue to unequal drying of the negative after washing, and are very troublesome If a number of negative are put in a according the plotor negative loctween them, particularly in in damp wir space it is probable that they will be found after some hours to have dried round the colges, but still to be wet and swollen with muisture in the middle. The centre will dry if the negative is taken out of the rack, but will show a permanent mark or line round the part that was dried last Re-soaking the negative for an hour or more in water that is not too cold, i.e. alout 60 degrees, and drying with the negative stood on elge in a place where air has free access, will sometimes remove or reduce the mark. Gencrally it cannot be so cured. It is hest prevented by secing that air has free access to the negative when drying and a voiding the use of racks in which negatives are not well spaced out.
Chemical defocts, i.e. stains, are largely due to lack of cleanliness in the various processes as already explained. Stains may also arise from specific chemical causes. Contact of a negative with sensitive paper in the presence of moisture will cause silver stains, which, if large, may be reduced by careful rubbing with a pad of cotton wool and a little globe polish or finely powdered pumice, followed by a strong hypo bath. A small stain may be almost entirely got rid of by prolonged immersion in the ordinary toning and fixing solution used for silver prints.
Pym stain can be removed if the nega tive is not allowed to dry after the ordinary washing, by a clcaring bath made up as follows:

Thesc haths are also useful as general cleaning baths, where marks or stains cannot be removed by other methods.
Ordinarily there is no objection to pyro stain, as it improves the printing quality of the negative, unless it is very deep.
How to Store Negatives. The amateur photographer is quickly faced with the pro hlem of storing his ncgatives. When the numher to be kept rises above forty or fifty, some methodical arrangement becomes necessary
ated liandling than by any other means.
Many devices are on the market, but it is casy to contrive an arrangement which is both less expensive and bulky than many of the commercial negative cabinets. For negatives that are not more than a quarter plate or 9 by 12 cm . in size an ordinary 6 by 4 card. index box, as seen in the illustration below, supplies the best solution of the problem. The negatives are kept each in a negative envelope, with short details and a number out. sidc. Proper negative envelopes, or ordinary envelopes of the best quality only, should he used, as the chemicals used in making cheap paper are liable to affect the negatives.
The negatives should be classified under a few general headings interests, such as landscapes, portraits, family groups, sport, etc., devoting a box or a portion of a box to each classified heading. Under each heading the negatives are arranged in alphabetical order, with guide cards, as seen in the photograph, on the ordinary card-index system. The negatives thus supply their own index, and no other is required. In this system film and glass negatives can he kept together without harm.

Another method, where shelf room is avail. able and a large number of negatives of larger sizes have to be stored, is to arrange them in envelopes in a mumhered order, standing on edge on the shelves with partitions for every fifty negatives. Short details are noted on the flap of the envelope and a separate index is kept. A small number of negatives may be kept in their original boxes, separated by means of sheets of pure paper, with a list on the top of each hox. Film negatives are much more easily stored than glass negatives Special alhums are sold for them of the correct size, consisting of transparent envelopes into which the films are slipped, space for a list of the contents of the album being provided.

NEGLIGENCE : In Law. Negligence has been defined as the doing of something which a reasonably prudent man would not do, or the omission to do something which n reasonably prudent man would do, having regard to the circumstances. In practice, the juige or jury has always to find whether the act complained of amounts to negligence; but no action will. lie for damages unless the plaintiff can first establish that there was some duty cast upon the defendant to be careful.
Such a duty may arise by contract or otherwise. For example, if $A$ engages to drive $B$ from London to Brighton in his motor car for payment, A is clearly under a contractual duty to be careful both as to the condition of his car and as to the manner of his driving ; and should any injury hefall $B$ because $A$ drove rashly or carelessly, or hecausc the car had not been properly overhauled for the journey, $B$ can sue $A$ for negligence. The duty to be carcful may be a puhlic one, c.g. it is cverybody's duty to walk, rile, or drive in a public highway carefully. To rush along without any heed to the safety of others is negligence.

A duty may arise by implication. If a man nvites people to come on his premises on
business common to both, e.g a gasfitter ordered to come and mond a pipe, it is his duty to have the premises in such a state as to he reasonably safe. Invitation in this scrase may lee implied; for instance, a shopkeeper is said to invite people to enter his premises with a view to becoming purchasers. To a guest a man merely owes the duty not to have traps on the premises, by which is meant concealed dangers.

Negligence in Driving. The nost frequent cause of action is for negligent driving by the driver of a public or private vehicle. When anyone undertalies to do anything which requires special skill or knowledge, and which may cause injury or damage when performed unskilfully or ignorantly, it is no defence to say, "I did my best," unless, indeed, the act was done in an emergency, as where a layman, no doctor being present, tries to help someone who appears to be in a dangerous condition; and where an unskilled person tries to mend a bruken pipe because no plumber can he found, and only succeeds in making matters worse No action can bc brought for negligence unless the plaintiff has suffered injury or pecuniary loss.

The damage nust not be too remote. Thus, if $A$ is run down by $B$ 's negligent driving, and has to suffer the amputation of an arm or the loss of an eye, and A's rich uncle, who had left A all his property, alters his will and cuts $A$ out on the ground that he will not leave his property to a fellow with only one arm and one eye, or A was to have married an heiress, who jilts him because of his altered appearance. A cannot claim against $B$ the loss of his uncle's fortune or the profitable marriage. The loss is too remote.

The damages in such a case will be loss of wages, salary, or profits of business or profession while laid up; medical expenses; expenses of convalescence, and any extra nourishment required; depreciation in the labour market, if any; compensation for pain, suffering, and disfigurement.
Other Kinds of Negligence. Therc arc other forms of negligence that concern the householder. For instance, when coal is delivered it is often shot into the cellar through a coal shoot or hole in the pavement covered with an iron grating. Care should be taken not to leave the shoot unguarded, and the occupier of the premises should make sure that the grating is replaced after the coal has been shot into the cellar

Damages may be recovered where a fire that has been caused through negligence spreads to adjacent property. Thus, if a haystack takes fire and some cottages near are burned down, the owner of the haystack is liable. A tenant is responsible for the condition of the chimneys of his house ; if one which lias not been swept gets on fire and the sparks set light to a neighbour's fowl. house or other building, danages may be claimed against the tenant. Areas or cellars adjoining a street must be kept properly fenced to prevent accident, and the occupier is responsible if any person falls down and sustains injury through insuflicient fencing. See Accidents; Driving ; Flat; House; Landlord; Motoring; Repairs.

NEGUS. Wine, usually port, mixed with hot water, spiced and sugared, is known as negus. Port wine negus is made from the following recipe : Put l pint of port wine into a jug, into which pour the juice of a lemon, lb . sugar, and a little grated nutineg. Add 1 quart boiling water and serve when cool. Sherry negus is inade in similar fashion, and a wineglassful of noyau or maraschino nay be added. Sec Wine

NEIGHBOUR. Disputes between neigh. hours arise about such things as fences, overhanging trees, party walls, rights of way and water, rights of light, and rights of support.

The remedy for interference with any of these rights is by injunction and damages
The right of support for and of one neighbour by the adjacent land of another is a natural right of property, so long as the land which clajms support is in its natural state unencumbered by buildings. In other words, B must not excavate his land so near to the edge of A's as to cause the latter to fall in. If A has a build. ing on his land, and his neighbour B digs on his own land in such a way as to cause A's building to crack or fall, A may or may not have a lcgal remedy He has such a remedy if his building has stood with the support of his neighbour's land for 20 years, hut not otherwise, unlcss, indecd, B may have granted him by deed or sold to him for calue the right of support for his building.
When two houses or more are built so that they support each other if they are built at the same time, the law implies a mutual easement or right of support If the owner of a middle house in a row wishes to pull down and retuild, he must prop up the houses on hoth sides during the process.

If a neighbour's tree overhangs a man's fence, he can cut it off level with the fence, but must not pluck the apples from the overhang. ing boughs. If the tree is a poisonous one, and his cattle eat of it and die, the neighbour must pay their value

A man may not take or collect upon his land anything of dangerous character which, if it breaks loose, will damage his neighhour or his neighbour's property. ujon penalty of being liable to pay all the damage done if the dangerous thing escapes This not only applies to dangerous animals, but also to auch things as artificial collections of water Where a man made a reservoir and it burst, he was held liable for the damage caused to his neightoour's property by the flood, though he was able to prove that he had not been guilty of any negligence, having employed skilfal engineers, nnd supplied them with the best of material for the construction of the reservoir See Fence; Hedge: Nuisance.
NEILLIA. These are spiraea-like hardy, leaf-losing shrubs of which Neillia opulifolia is the most useful. It bears white flowers in May. A variety named lutea, which has yellow leaves, is ornamental. These shrubs thrive in ordinary soil and are propngated by cuttings in sandy soil in a frame in summer.

NELUMBIUM. This is a greenhouse aquatic perennial plant belonging to the waterlily family. The rhizomes sliould be planted in a pool or tub of tepid water at the bottom of which a layer of loam has been placed The chief kind is Nelumbium speciosum, with white, sweet-scented flowers tipped with rose

NEMESIA. This benutiful half-hardy an nual, 8-12in high, bears brilliantly-coloured flowers in blue, crimson, orange, yellow, rose and other colours. It is invaluable for summer flower-beds and for groups in the herbaccous border. Blue Gem is a particularly attractive variety. Seeds are sown under glass in March and the seedlings are planted out of doors in May.

NEMOPHILA. This pretty. low.growing, blue-flowered hardy annual is easily raised in ordinary soil in a sunny border. Seeds arc sown out of doors in March-April where the

Nepaul Poppy a show biennial for heltered spot in the garden
plants are to blonm in sum mer. A sowing may be made in September to provide spring flowers

NEPAUL POPPY. This is the popular name of Meconopsis nepalensis, a Invely biennial plant which bears yellow, poppy-like flowers in summer It is raised from sceds sown in fine soil in a frame in May and the seed lings, when large enough, are planted in well. drained, loamy soil in partial shade. It is a good plan to place a covering of glass over them to keep off excessive wet in winter.

NEPENTHES. Pitche, plant is the popular name of nepenthes, which is a very curious and interesting family of hothouse shrubby perennials. The different sorts have pitchers of various colours. See Pitcher Plant

## NEPETA. The favourite

 plant in this group is the mauve catmint (Nepeta mussinii) which has grey leaves and bears a profusion of lavendermauve flowers in June and July. It Hourishes in ordinary well-drained soil and is easily propagated by cuttings in summer. The mauve catmint is a delightful flowering plant, often used as an edging : it also locilis well in a wall or by the side of garden steps The variegated ground ivy (Nepeta glechoma variegata), with green and white leaves, is a usefu! carpeting plant for damp placesNEPHRODIUM. Many species of nephrodium are tropical ferns which need to be grown in a moist, warm glasshouse. The commonest hardy kind is the male fern (Nephrodium filix-mas), of which there are many beautiful named varieties; these are admirable ferns for $n$ shady border. Jeaf. mould should be added frcely to the soil Planting is best done in autumn

Nemesla. Brilliantly-coloured blooms of a hali-nardy annual which flowers all through the summer

Nerine. This is an alternative name for the bulbous flowering plant known as the Guernsey lily (q.v.).

Nerium. The greenhouse evergreen flowering shrub nerium is better known under its popular name of oleander ( $q . \nabla$. ).

NERTERA.
The small perennial nertera is also called fruiting or coral-berried duckweed. Its tiny flowers are followed by round berries of reddish - orange. Although the plante are of perennial character they require protection during hard weather, a suitable place to plant them being a moist and sheltered position in a shady rockery. Spring is the most suitable lime for plant. ing, and propagation is by means of division. Nepeta The mauve catmint, a Nertera makes a pretty pot plant for the greenhouse
NERVOUSNESS. 'The apprehensive ex. citable atate of mind and hody connoted by nervousness is a sure sign that the general health is not at its best. It may be brought about by exhausting mental work, or by some occupation which does not allow of sufficient exercise for health. Another common cause is exhausting the hody by leading a dissipated life. Nervousness may be the result of n sudden shock or accident: in some cases it is inherited

In every way a quiet, healthy life should be led. A daily cold or tepid bath must he taken in the morning followed by a rub down with n fairly rough towel Diet should be plain but nourishing. Tea or coffee inay be taken weak and in moderation, but alcohol in all forms should be avoided. Strictly regular hours should be observed Plenty of fresh air is another essential

In Children. A child witli any tendency to nervousness demands constant and careful watching Treatment is on the lines described above for diet and exercise, with a warm bath at night to promote sleep. Such $\pi$ child should not be left alone or forced to go to sleep in the dark It is most important that his nurse, or whoever has charge of him, should be kind and patient, but firm. He must be taught as far as possible not to give way to his temper, which will naturally often be irritable. At the same time, constant scolding and worrying over trifles likely to annoy the child must be avoided, and the pcrson with him should be of a cheerful disposition.

Under these conditions the child may be the better for a tonic, and one likely to suit him is:
Iron and quinine citrate
Spirit of chloroform
Water to make
45 gr.
40 m.
4 oz.

The dose for an eight-year-old child is a teasponnful three times a day after meals. Nervous children sometimes develop St. Vitus's dance. See Hysteria; Neurasthenia St. Vitus's Dance.

NET. Net is an open fabric of twine, silk, or other material, and is employed for a great numher of domestic and other purposes. Nets are used for several games, e.g. lawn

Iennis and table tennis, and are much em ployed in the garden for keeping birds away from fruit See Radminton: Buttertly: Netting: Tennis Net.
NET: The Dress Material. Nets are made chiclly in two materials, cotton and silk, cotton being most employed. They are made with both coarser and finer threads. and in meshes of different shapes and sizes. Hexagonal mesh is the most common. Mechlin is hexagonal, Lille is dinmond shaped, and some are square or filet, much used in dyed shades for curtains. Network forms an integral part of the design of hand-made laces. See Filet Lace ; Lace
NET BALL. This is played with a large ball and two nets for the goals. The ball is the same as is used in Association Football The field of play should measure 100 ft . long and 50 ft . wide, but the game can be played on a smaller piece. The uswal number of players is seven a side, but this, ton, can be varied
In the centre of each end line the goals are tixed Each goal is a single upright post. to which an iron ring, 1.5 in. in diamcter, is fitted. This should be 10 it above the ground and should project $i f$ in froin the post. Attached to a ring is a net. open at the bottom, and the ball must pass ihrough this in order to score a goal. Around each goal a semicircle, having a radius of 16 ft ., is drawn; this is known as the shooting circle. In the centre of the field is a circle 4 ft . in diamcter. If a smaller field of play is used, these measurements should be reduced in proportion. The playing field is divided into three courts of equal sizo by lines drawn from side to side
The seven players, in a full game, are: goal scorer. attack. attacking centre, centre, defending centre, defence, and goalkeeper. The game begins with one of the two umpires bouncing the ball in the centre circle, while the players stand. each party on its own side of the circle. the centres in front and the

Net Ball, an outdoor game for girls. The illustration shows a shot being made for goal
others behind them After one of the centres has caught the ball, the game proceeds, the aim of each player being to throw the ball to a colleague or prevent an opponent from securing it. They try to get it to tho player who stands within the shooting circle; when he or she gets it. his or her aim is to thow it into the net

As in foot ball, there are penaltics for getting offside and other offences, and the rules for throwing the ball in after it has gone out of play are very much the same as at association football. Two players of one side must not hold the ball at the same time. nor must $a$ player carry it. Obstruction is also an offence. The penalties arc a free pass or a ree throw at goal.
NETTING: How to Make Netting for la won tennis, fishing, garden purposes and haininocks is usually bnught, but it can be made at home. The neceranary implements consist of a piece of hone, steel, or wood, made with notched ends, called the needle (Fig. 1), and a smooth flat or round rod called the mesh or gauge. The circumference of the mesh used controls the size of the loops, and meshes can he bought in numbered sizes. A lead-weighted heavy cushion is required, or in the case of conrse twine netting, a stirrup to slip over the left foot and provide a fixed point to pull upon may be used. To this cushion or stirrup a cord is attached to form the foundation loop : the first loop or loops of the net are cast upon this foundation. Netting consists of loops of thread called atitches, secured by knots.
The thread inay be fine silk for netted purses, knitting cotton, crochet cotton, cabled twines, or tarred string. Knots of different kinds are inade for different purposes; lonps of different shapes and sizes can be worked into a pattern, and different colours of thread can be introduced. The work is done a row at a time, and sufficient thread for one row should be wound upon the needle at the start.
Netting stitches are oblong or square and the patterns are produced in plain netting by the different ways of passing the thread over the mesh and the manner of connecting the loops, as well as by the various sized meshes Plain netting is given the simplest form of pattern by the last method. Two or threc lows are worked over a narrow mesh and then the same number over a coarser one, continuing the use of lirst one mesh and then the other at regular intervals.

Plain netting is the one to learn first. The mesh is taken in the left hand, thumb on top and fingers beneath. The mesh is held close to the foundation loop and the thread is passed over the mesh and two forefingers. The thread is brought under the mesh and placed under the thumb; then it is put round the hand and held by the little finger. The needle thus brought in front of the mesh is passed under the first loop between mesh and finger, and into the foundation loop and the thread is drawn tight close to the niesh.

The fisherman's knot is made by holding mesh and needle in the manner descibed, and passing the thread round the mesh but not over the fingers. then passing the needle upwards through the loop that is. to he made, drawing the loop up to the mesh and holding the thread tight under the thumb. The thread is allowed to fall to the left, and the needle is put upward behind the loop and the thread is drawn tight.

The work may be begun, with only a single loop directly attached to the foundation; or as many as 100 lomps of fine silk may le cast on the foundation, as in maling jong netted silk purses. Steel or ivory netting nendles are used for finer work of this kind. An example,
showing the stages of constructing the simplest form of wide meshed netting, is illustrated in Figs 2 to 8 . A foundation stick is used for this; in the casc of finc netting, $\Omega$ foundation loop of coarse thread takes the plare of the stick. The first stage is to wind the string on to the necdle. One end of the string is looped and tied over the centre prong, as shown in Fig. 2, and the string is then turned around the needle lengtiways between the jaws of the slouted end, passed over the point of the prong at the top and on alternate sides of the prong, until sufficient string has been wound This operation is shown in Fig. 3.

The next step is to provide the foundation stick. Make a bridle of string and attach it to a nail or other convenient point of support on the wall, work bench, or any other suitable place, and attach the free end of the string to it by means of an ordinary reef knot. Then, holding the mesh stick in the left hand, pass the needle behind it, underneath and ncross the front of the mesh stick and on to the back of the foundation stick to the josition shown in Fig. 4.

Next bring the needle with the string down over the front of the foundalion stick and pass the point of the ncedle between the strings (Fig. 5). This forms a knot and the string is then drawn up tight, thereby bringing the mesh stick nearly into contact with the foundation stick, as in Fig. 6. The requisite number of throws are then cast in this manner on the foundation stick until the end of the stick is reached or the requisite number of casts have been made. The foundation stick is then removed, the mesh stick turned over and the finishing point made the starting. point of the next row.
Then, holding the mesh stick in the left hand, the needle is passed over the mesh stick, hehind it, and then through the first mesh of the row. as shown in Fig. 7. The thumb is then placed on the string around the mesh stick and the necdle passed beneath the first mesh of the completed row, making sure that the string is tight round the mesh stick: this is accomplished by the pressurc of the thumb and forefinger of the left hand, as shown in Fig. 8. The needle is then drawn right through and drawn up tightly, thus

Netting a strawherry bed, showing method of andporting the mesh on atakes driven into the groand Courlety of Amateur Gardening
completing the mesh. This operation is com- out quitc suddenly and often vanish just as decayed tooth is probably the most frequent
pleted until the end of the row is reached, the mesh stick turned over, and the operation repeated until a sufficient size of net is completed
For garden purposes old fish netting is uscful in several ways Gencrally it is used
quickly. They itch, sting, and burn as when one is stung by a nettle. In infants they are very common, appenring as red pimples.
In older children and adults the following

to cover young growing fruit trees to protect thein from the ravages of birds and frost. Pockets of such netting are also uscful if suspended in hammock-like fashion beneath tish, mushrooms, wall and standard fruit-trees in order to catch the ripe fruit when it falls. It is likewise employed to ksep off the attaclis of wasps and other flying pests. See Hammock; Knot: Wire Netting.

NETTLE. The stinging nettle is one of the inost difficult weeds to eradicatc; the only way is continually to hoe olf the tops of the plants as they push through the soil. If this is done for 2 or 3 years the plants will dwindle and perish. The variegated leaved variety of the dead nettle (laminm) is worth growing in an odd corner in poor soil.

Uses of the Plant. The young shoots of the stinging nettle can be cooked and served in the same way as greens, hut they make a more palatable dish if they are blanched first, and then cooked like spinach. Nettles are also used to make broth or vegetable soups, or added as a llavouring, but they have a bitter taste.

The traditional remedy for a nettle sting is to rub the part affected with a bruised dock lea', and this is usual!y efficacious; but a better cure is to use cold water. A handkerchief should be soaked and tied over the part stung, when immediate relief will usually follow. If the sting is very severe, the bandage may be changed as soon as the cold feeling dies away. A solution of bicarbonate of soda and water is also useful in this connexion, while leaves of rosemary, mint and sage also afford relief. See Sting.
Nettle Toast. This is a good substitute for spinach on toast. To prepare, wash and boil about 2 lb . of young nettle leaves and tops, chop them finely, and put them in a pan with 1 oz . butter, a little lemon juice, salt and pepper. Stir these over the fire until the butter has melted; then pile the mixture on 3 or 4 rounds of buttered toast.

NETTLERASH. This skin ailment, the medical name of which is urticaria, is characterized by whitish firm elevations or wheals surrounded by a red basc. They come
 cheese, eggs, crabs, lobsters, pork, pickles. pastry, strawberries; wearing rough flannel garments next the slin; violent emotion; the irritation caused by worms in the intestine; goutiness; taling certain drugs, such ns quinine, copaiba, turpentine; the use of irritating cosmetics and hair dyes; the bites and stings of wasps, bees, caterpillars, jelly fish, bugs, and lice, and oontact with nettles and otherstinging plants
In treatment the causc should first be ascertained. If it is acid indigestion, a dose of 10 to 15 gr . of bicarbonate of soda in a wineglass of plain water may bring relief. If the affection is severe in children and accompanying digestive disorders, give an emetic (q.v.), and when this has acted give one to thrce teaspoonfuls of castor oil. Regulate the diet, experimenting to find out the food which secms to diangree. If Ilannel irritates the skin, wear cotton, linen, or silk
To relieve the itching (q.v.) many simple remedies are available, among which the following are the best: Dissolve a teaspoonful of bicarbonate of soda in a tumbler of warm watcr and sponge the itching part with it; sponge with solution of carbolic acid (1 in 40); apply calamine lotion with $n$ soft sponge or piece of lint.
Young children should he prevented from scratching by sowing the sleeves of their nightdress to the body of the garment, or by loosely tying the hands to the waist.

NEURALGIA. The acute, paroxysmal pain that is usually known as neuralgia is most often felt in the head or face, though it may attack any part of the body. In neuralgia attacking the nerves of the face and head, a
origin of the mischief. Other common causce are eyestrain, irritation in the nose or ears, and exposure to cold. In the cases of persons predisposed to neuralgia, sitting in a draught may suffice to set up a severe attack.

If the tneth are decayed, the dentist's services must be sought. If the patient is suffering from eyestrain, an oculist must he consulted. When gout, rhemnatism, Bright's disease, or any other general affection is present, it inust be treated appropriately at the same time that local measures are taken to relieve the pain

Change of air is often one of the bost remedies, especially in the case of nervous women. The patient must have plenty of sleep, and spend a good part of the diny in the open air. The diet should be gencrous and contain abund. ance of fats, such as fat hacon, butter, and cream. When the patient is gouty, however, a strict vegetarian diet often effects a speedy cure. Neurotic patients sometimes derive much benefit from ammoniated tincture of valerian. Cod liver oil is a valuable medicinc in many cases, and may be combined with malt and hypophosphites.

Netting. Fig. 2. First stage in loading needle. Fig. 3. How gtring is wound on needle. Fig. 4. Preparatory stage in netting. Fig. 5. Forming first knot Fig. 6. Tging frst knot. Fig. 7. How a new row is begun. Fig. 8. How knot is made at beginning of each row

There are many uselul measures for the relief of pain during an acute attack. Let the patient have perfect quiet. Warmth to the affected part will frequently give relief, such as a llannel or sponge dipped in water as hot as can be borne. Dry heat is sometimea preferable. Rolays of heated ilannel or cotton wool may be applied, or a hot-water bottle is cffective

For neuralgin in the face or head $n$ bran poultice will often prove a good remedy. Let the patient go to bed and be warmly covered. Make a poultice of bran and put the face down on it After using heat great care must be taken not to get fresh cold in the face. Have ready a shawl to throw over the head in passing from one room to another through a cold passage or staircase.

The number of drugs that may give relief in onc case or another is considerable. If one fails, another should be tried, but always under medical direction Sce Faceache :

## Tic Doulourenx

NEURASTHENIA. This term, as generally understood by the layman, refers to all those forms of nervons disorder which are functional in character, such as hysteria. The medical profession, however, limit the term to a particular form of these disorders charactcrized by increased susceptibility to fat-igue.

Neurasthenia in adolescence is often associated with the difficulties arising from
physical development. Failure on the part signals received from of parents or teachers to nppreciate these difficulties and impart clean, wholesome, and truthful information on the essential facts of life often contributes to the condition. Later in life neurasthenia may result from any form of mental strain, such as overwork, anxiety, fright or shock; physical accidents, particularly in circumstances in which the individual has no timo to pull himself together to meet the shock, as, for example, a railway accident, or chronic ill-health.

The most marked symptom of neurasthenia is the readiness with which the person complains of fatigue with either physical or mental effort. Other noticeable symptoms are pain or fecling of pressure in the head, pain in the back, disorders of sensation, insomnia, and indigestion. Flushing of the skin and sweating may be present, and there is often oonsiderable loss of weight

In adolescence treatment should be directed towards establishing a more normal and healthy frame of mind. Difficulties should be investigater and explained, carc being taken that nothing is said that is calculated to reduce self-respect or inerease any apprehonsion or ferling of guiltiness

In older persons only palliative mcasures, as a rule, can be adopted When the condition results from strain or overwork, a holiday, rest in the country, or a sea voyage may bo recommended. In cases due to clironic illhealth efforts shouid be directed towards cemedying the bodily condition which is at fault, particular attention being paid to the state of the bowela and to the condition of the teeth and of the gums. Druss to produce sleep should be avoided if posaible Alcohol, if taken at all, should be indulged in very sparingly.

NEURITIS: Its Treatment. Inflammation of a nerve is known as neuritis, and it may be limited to one nerve, as in sciatica and inflammation of the facial nerve ; when it affects a number of nerves it is termed multiple neuritis. Exposure to coid is one of the commonest causes of local neuritis.
Multiple or peripheral ncuritis is the result of poison in the blood, the most common cause being the taking of alcohol continually over a long period. The symptoms are tingling in the limbs, twitching of the muscles followed by loss of muscular power, and acute pains.
Rest and warmth arc essential conditions in treatment. Cover the part with a thiok layer of cotton wool, and bandage it loosely. If the arm is affected, put it in a sling; if the leg suffers, the patient must lie down a good deal. Drugs such as those used in neuralgin may be given to relieve pain. In chronic neuritis massage and minersi baths are recommended with occasional blisters and full doses of iodide of potassium.

NEUTRALISING: In Wireless. This is a method whereby the effects produced by the inter-electrode capacity of a high frequency amplifying valve in a wireless rcceivor are balanced out by the application of an external capacity or neutralising condenser connected to suitable puints in the grid and anode circuits of the valve.

The capacity betwcen the anode and grid of a three electrode va!ve employed as a high frequency amplifier is sufficient to cause energy to flow from the anode oircuit back to the grid oircuit, and thus to produce insta. bility. This effect may be counteracted or neutralised by a suitable circuit arrangement, utilising a very small variable condenser which when correctly adjusted permits a reverse flow of energy equal but spposite in phase to the energy flowing through the internal capacity of the valve.
A common method of neutralising is to adjust the neutralising condenser on the
a powerful local station. The station is first of all tuned in with the neutral. ising condenser set to about one-half of its maximum valuc. Next, the positive lead to the filament of the high frequency amplifying valve is disconnected from the valve holder, or alternatively a piece of paper may be wrapped round the positive pin of the valve, so that the pin is isolated from the positive socket clectrode capacity of the valve.

Neutraíising Condenser, a device used in wireless reception during the summer. the handrail.
of the valve holder, thus paircase, and be in thus permitting no L.T. keeping with the architecture of the home high to pass through tho filament. The itself. See Staircass act as an ancy valve will, therefore, no longer act as an amplifier, but signals from a powerful station will still be audible in the loudspeaker or telephones, owing to the inter-

The adjustment of the neutralising condenser may now be carried out, the objcot being to find a position in which the signals from the station to which the receiver is tuned cease to be audible. It will be found that as the neutralising condenser is adjusted, signals will gradually decrease in volume until the
"silent point" sreached. Further ad. justment ol the condenser will cause signals again to becoine audible. The silent point is the correct neutralising adjustment, and the condenser should be locked in this position. The positive filament of the bigh fre. quency ampli. fying valve may now be connected up, so that the low frequency current passes through it in the normal manner and the set will be stable.

NEVIUSA. The deciduous flowering shrub called neviusa alabamensis belongs to the order of Rosaceae, and bears the popular name of Alabama snow wreath. The plant bears whitish flowers along its shoots during summer. Ordinary well-drained soil suits it. It is propagated by cuttings of half-ripe wood inserted in sandy soil under a hand-light or cold frame

NEWEL POST. The post in which the steps of a winding stair are fitted is called a newel post. The term is also applied to the posts situated at the top and bottom of an ordinary staircise, which act as supports for

In a small house the neivel post may be made from deal about 3 in. square, and tenoned into the timber framing of the staircase, if on the upper floor. On the ground flour suoh a post would be similarly mortised into the Hoor joists and into the string of the staircase. It is often capjed with a rectangular block.

NEWFOUNDLAND DOG. With the St Bernard, the Newfoundland shares the distinction of being essentially a life-saving dog. His powerful frame, deep chest, capacious ribs, broad loins and heavily-boned legs, together with his thick coat, mark him out as an ideal water dog. He can swim in almost any sea, and many stories are told of Newfoundlands that have rescued human beings.
They may be all black, or white and black, or white and bronze, the latter being popularly called Landscers, after the painter who immortalized them. The eyes should be dark brown in colour, light ones being objectionable, as they are in most breeds. The head is, less massive than in that of the St. Bernard, but at the same time if should be big and broad, as befits the body. The coat is flat and dense, rathet coarse in texture, and of an oily nature, so as to resist the water: The gait usually has a slight roll. A weak loin or cow. hocks are most undesirable. The height of a dog is about 28 in ., weight from 140 to 150 lb ., bitches being 2 in . less, and weighing from 110 to 120 lb . See Dog; Kennel.

NEWMARKET. This card game, sometimes called stops, can be played by any number of persons between three and eight. Two packs are necessary, also a number of counters, which should be distributed among the players.
To begin the game, four cards arc taken from one paok and are laid out upon the table. On these each player puts his stake, whatever he pleases, although sometimes a limit is agreed upon; he can put it all on one card, or divide it between two, threc, or four. The cards of thc other pack, having been shuffled and cut, are dealt out one one to the players, and an extra card in every round is placed on the table. These extra cards are known as the stops.

The deal over, the player on the loft of the dealer leads. He can lead any card in his hand, provided it is the lowest of the suit in question, and he continues to place cards upon it as long as he can keep up a sequence. When the sequence fails, the next piayer continues, and so the game goes on until the sequence is broken, because the necessary card is among the stops. The one who played the last card before the stop then leads, and so the game continues until the cards are all out. The interest of the game lies in the fact that when a player plays a card that is a duplicate of one of the four cards of the other pack, he is entitled to all the stakes that have been placed thereon. In this game the ace is counted as the lowest card.

NEW YEAR. In Scotland New Year's Day is still regarded from the popular standpoint as a more important festival than Christinas, although the latter has acquired greatly
increased importance of late years, and is almost universally celebrated exactly as in the south. The closing week of the year has thus a double significance across the Tweed, and also in a lesser degree in the north of England, where the Now Year ceremonies are popular. In Scotland New Year's Day is a bank holiday.
Parties arranged for New Year's Eve usually begin at 9 o'clock, and should be so arranged that the guests are all together by a few minutes before 12. In many houses it is customary to brew punch or some other liquor, and hand it round, so that, when the clock strikes, the health of the New Year may be drunk with due honours. The darkest member of the party should slip out of the house at the crucial moment and demand entrance so that the first footing shall be lucky. Alter the New Year has been thus ushered in the guests, host and hostess join hands and sing Auld Lang Syne. See Christmas; Hogmanay.
NEW ZEALAND BROOM. The broomlike half-hardy evergreen shrub, bearing the name of New Zealand broom or Notospartium Carmicheliac, requires the protection of a wall, except in the wariner parts of the country. It bears pink, pea-shaped Howers during late summer. Propagate by seeds.
NEW ZEALAND FLAX. This name is given to an omamental plant, Phormiun tenax, a striking perennial distinguished by its long, erect, dark green leaves, a hout 4 ft . in height. The yellow or reddish-yellow Howers are produced in August.

This graceful plant looks well in a sheltered position near water, but it is rather tender, especially while young, and should have the montstock protected with ashes or litter in winter. It likes a friable. sandy toam. Pro-

New Zealand Flax. Bardy perendial for the waterside
garden, with long, erect leaves and reddish flowers
pagation is by seed in heat in spring, or by division at that season. There are several varieties, with variegated leaves.

NEW ZEALAND HOLLY. This name is given to a group of evergreen shrubs which thrive in loamy soil and peat in a sunny position. The chief kind is Osmanthus aquifolium. a Japanese shrub, 5 ft . high, with holly-like leaves; it hears white flowers in winter.

NEW ZEALAND SPINACH. A hardy annual plant, the New Zealand spinach is cuil. tivated in many gardens as a substitute for summer spinach. The seeds may be sown in March in sandy soil in the heated greenhouse, and the young plants placed out-of-doors in May. Seeds may also be sown in the open ground in May if heat is not available. The tips of the shoots should be picked off frequently, whether required for cooking or not. The plants should be put out in rows ahout 3 ft apart, and the leaves cut and treated in the same way as spinach (q.v.)

Nicandra. Trumpet-shaped flowers of the annual
border plant sometimes known as apple of Peru
NICANDRA. This tender border plant is sometimes called the apple of Peru. It is an annual plant, growing about 18 in . high, and bearing showy white and violet-hlue Howers during summer. It shonld he raised from seeds sown in heat during February or March, the seedlings being transplanted to hoxes, hardened off, and planted out in June. See Border

NICHE. This shallow recess in a wall can always be used to good effect in the decorative scheme of a room, hall, landing or staircase. Niches are usually either domed or rectangular, but occasionally the top is in the form of a pointed arch. A delightful fitment for a living-room, when building, is a larger domed niche with shelves for china, flanked by two smaller rectangular niches with bookshelves, the lower part of each recess being fitted as a cupboard.
Simple decoration sets off a niche either by framing with narrow mirror glass, or woodwork, or plaster ornament and moulding, using a contrasting colour for the interior of the niche to that employed for the walls, or by painting a design within the niche itself as shown in the illustration. In this case recesses either side of the chimney breast have heen utilized to hold decorative china, the design of the rising sun being painted in gold. A niche over a fireplace forms a pleasing alterna tive to the conventional overmantel, and can be either lined with mirror glass, gold or silver leaf, or merely contain some beautiful object See Drawing Room; Recess; Shelf.

NICKEL. Nickel is a white metal which takes a brilliant polish and resists atmospheric corrosion very well. Numerous household articles made of iron or steel are often nickel plated, for instance, scissors, thimhles, pins, pliers, and other small tools, small keys, etc. The process is used also for handle hars and other parts of bicycles, and similar metal fittings. Nickel-plated articles that get rubbed in usc keep themselves bright, but such as are not exposed to occusional friction get dull in time, though slowly; they may then, however, be polished in a few scconds by merely wiping
or washing off dirt and rubbing with a cloth or leather.

The nickel coating generally adheres firmly enough to stand service conditions, but it may sometimes get chipped or worn off in places, exposing an ugly black patch due to the corrosion of the underlying steel. Nothing but replating will then restore the appearance of the article. See Electro-plating; Enamelling.
NICOTINE. Tobacco contains, amongst other substances, a liquid alkaloid called nicotine. The drug has been used in medicine as an anti-spasmodic in tetanus and strychnine poisoning hut is rarely employed. It has a marked effect in raising blood pressure, resembling adrenaline in this respect. Pipe mixtures are said to contain most, cigarettes less, and Havana cigars the least nicotine. Many, but not all, of the evil effects of smoking to excess are due to the amounts of nicotine constantly being absorhed

This alkaloid or juice plays an important part in the colouring of pipes; but it is injurious to the tongue and throat of the sinoker, and should not be allowed to accumulate in the stem, where it forms a soft, dark deposit. It may be removed with a small wire brush.
Where boiling water is availahle, a simple and effective method is to hold the bowl of the pipe tightly againat the hot water tap, so that a strong jet of boiling water is forced through the stem and thoroughly cleanses it of the nicotine. The process is much accelerated if the mouthpiece is removed and the end of a wire covered with soap is inserted into the stem, and the soap well worked in. This absorbs or loosens the nicotine, which is then easily washed a way when the pipe is held under the tap. Any ordinary wire is suitable; a wire paper clip may be straightened out and used effectively as a pipe cleaner.

Another method is to heat the wire in the fire until it is red-hot, and then plunge it into

Niche in a chimney recess. It is ornamented with a design of a rising sun and contains old china llumphrell \& Vera Joel
the stem of the pipe The nicotine is burnt up in this way by repeated applications of the wire; but the use of soap and boiling water is clenner and more effective The mouthpicer can be treated in the same manner

Garden Uses. Nicotine is also useful to the gardener. Nicotine soap wash, as it is called, is a very useful contact insecticide which is recommended for the destruction of apple aphis by the Ministry of Agriculture (Lentlet 330 ) It is made up as follows
Nicotine ( $95-89$ per cent)
Soap (anft)
$30 \%$
$\frac{1}{2} 16$
Winter (soft)
10 gal
If the water is hard, $\mathfrak{i}$ ib. of вол phould be used. Dissolve the soap in hot water, dilute to the required strength, add the nocotine, and stir well. If soft soap is unobtainahle, hard soap should be used instead. It will also kill apple sucker, capsid buga, young caterpillars, and other garden pests. See Apple: Insecticide; Pipe; Smoking; Tobacco.

NIELLO. This Italian word is used for a process of decorating metal with incised designs filled with a black alloy. To some extent it resembles both inlaying and enamelling. The alloy is one of sulphur with silver, copper, or lead. Nicllo is used also for the piece of work decornted in this fashion, and for an impression on paper taken from the engraved and incised surface before the niello alloy has been laid thercin. See Enamelling; Inlaying.

NIEREMBERGIA. The species rivularis is a protty creeping plant suitable for the rock garden. It bears white pink-tinged flowers

Nierembergia rivularis, a beautiful creeping derennial for the rock garden
and thrives in a compost of loam, leaf-mould and sand. Propagation is by division in spring. Nierembergia fruteseens grows $18-20$ in high and bcars beautiful blue flowers in summer; it is increased by cuttings which should be taken in July or Inguat.

NIGELLA. This is the botanical name of a favourite hardy annual, love-in-a-mist, which bears blue Howers in summer. Seeds are sown out of doors in apring where the plants are to bloom

NIGHT BLINDNESS. The condition of partial inability to see at night or at other times when the light is dini is known as nyctalopia, or night blindness. Sometimes it may be cansed by the eye having been exposed to too strong a light. In most cases the abnormality is hereditary.
It may be a symptom of changes in the eye due to syphilis, when treatment for this disease will be urgently necessary. Apart from congenital cases treatment must commence with complete rest of the eyes, and it is usually neccssary to improve the health by a generous dietary and tonics. See Blind; Eye.

NIGHT LATCH. This is a kind of latch which can only be opened by a key on the outside, but can be opened on the inside by turning a knob with the hand. It is a very convenient form, as it enables the door to be securely fastened against anyone who is not in possession of $n$ key. It can be obtained in either the warded or in the lever pattern, and also in the pin tumbler form

The keys are generally small, and so are convenient for carrying in the pocket, and owing to this advantage night latches arc often fitted to hall doors The latch is fixed to the door so that the case is on the inside, while the keghole is cut through from the outside. The carc and attention which should be given to this type of latch is the same as should be given to other locks and latches, and includes periodical oiling See Latch; Lock

NIGHT LIGHT. A form of short candle that gives a feeble light over long periods, as during the night, is termed anight light. It is often used in the nursery, and is also employed in photographic dark-lamps as an illuminant

The two varieties in use consist of the short, thick cylinder and the pyramid shape. The former consists of a paper case into which melted paraffin wax or candle material has been poured, having in the centre a Hax wick supported upon a tin disk. The night light of this form is placed in a sancer of water in use. It lasts about 8 hours. The pyramid or cone form of night light has n base of plaster of Paris, which supports the wick of rushpith. This variety is generally burnt in glass dishes without water

NIGHTMARE. The feeling of oppression and terror, accompanied by horrible dreama, to which the name of nightmarc is given, is not uncommonly the result of some digestive disturbance. Either the evening meal has been too heavy, or something lias upset the stomach. People who suffer from nightmare should take their last heavy meal not later than three hours before bedtime. and avoid all mental work, such as study or engrossing reading, for the last two hours before retiring.
The mattress should be hard and smooth. The pillow should be just thick enough to leave the neck comfortable. The bedclothes should be light. The feet must be kept warm, if necessary, by wearing socks or by the use of a hot-water bottle. The patient must not lie on his back. To prevent this, if necessary tie a cork or large spool over the lower part
of the back where the spine is prominent. Constipation must be prevented When an attack of nightmare is followed by inability to sleep, a glass of warm water with a tablespoonful of whisky, or a teaspoonful of sal volatile, will often prove an effectual remedy.

Nervous and delicate children often suffer from night terrors, and will wake crying out in fear. In nervous children the injury of iepeated attacks may be considerable. The trouble is often due to a badly ventilated ronm or the use of heavy bedclothes. A noor common cause is indigestion, resulting from faulty feeding. Over-pressure at schooi, great excitement before bedtime, $\Omega$ fright, or a creepy story told to the child may sometimes give risc to one of these painful attacks.

The child should be examined by a doctor for adenoids or other affections. The hedroons should be airy, and the bedclothes light but sufliciently warm. If the child is constipated, an aperient, such as castor oil, $\frac{1}{2}$ to 1 teaspoonful, should be given. The mother should see that the child has only a light supper, no pastry, meat, or anything difficult to digest. Milk and biscuits or bread-andbutter will generally be found the best fare for a child late at night. In some cases a small cup of bcef tea given the last thing at bedtime will stop the trouble.

When the child cries out, it is generally best to go to him quickly, as the presence of a grown-up person will tend to soot he his fears. When he is quiet, give a small drink of water and change his position, and it will be found that he readily sleeps again. Never under any circumstances speak impatiently to a child who wakes in fear, as it will only increase his distress. It is a great mistake to send a child to bed in a dark room when he dreads the dark. In these cases where night terrors are troublesome a night light should be placed in such a position that it will not 1 hrow shadows on the ceiling or walls, and if possible the child should not be left alone

NIGHT-SCENTED STOCK. This is the popular name of Matthiola bicornis, a hardy annual, 10 in . or so high. It bears small lilac coloured blooms which give off a delicious fragrance in the evening. Seeds arc sown out of doors in spring where the plants are to bloom.

NIGHTSHADE. The deadly nightahade is Atropa belladonna, the berries of which are poisonous. See Atropine; Belladonna: Deadly Nightshade.

## Night Wear Cases and Sachets

## Decorative Suggestions for these Bedroom Accessories

For further helpful information the housewife is rcferred to the articles on Appliqui Work;
Drawn Thread Work: Embroidery; Leather Work: Painting on Textile Fabrics; Ribbon W'ork; Richelieu Work
Cases to hold nightdreases and pyjamas organdie would be charming; on an art silk can be made of n variety of materials, such as linen, silk or suede. The term sachet is usually employed for such cases when made without a flap and when padded with a layer of wadding, which may or may not be perfumed with lavender or a sachet powder. Satin and silk taffeta, trimmed with tinsel lace, or frilled or gauged georgette, are often selected to inakc up into sachets; if padded these cannot be laundered, but have to he dry cleaned, so that such unwashable materials are liked when it is wished to make this bedroom accessory a particularly decorative one.

Whether the case or sachet is simple or elaborate, it should always be chosen with due consideration for the colours already in the room, and in particular to accord with the belspread. For instance, on a lace and linen spread a black satin night wear sachet would look out of place, whereas one in pale blue talfeta, broderie Anglaise, or frilled pink of talfeta, broderie Anglaise, or frilled pink of linen ineasuring about 8 in. and, after
embroidering it, faggot it to, or use ornamental hlanket atitch to attach it to, the centre of the flap
The night wear case illustrated in Fig. 1 is cut out to the measurements given It is made of a decp ahade of lavender linen and embroidered and scalloped in a pale shade of green. Welicate pink and bluc coulit be used for the floral detail of the initial, or all embroidery could be carried out in white. the edges of the third Before being made up forms the flap are traced the length which lots are embroidered in satin stitch. The design for the required initial is also transferred and embroidered in raised satin stitch and stem stitch. 'The superfluous raw edge is then cut away from the scalloping. Press the embroidery on the wrong side and fold the linen into three. 'rack the sides of the plain two-thirds to form the pocket together and seam neatly so that they do not show beyond the scalloped edges of the flap.
Edges may be hemstitched instead of scal. loped; the flaps of such cases may be embroidered in Renaissance or Richelieu work, in broderie Anglaise or in cross stitch If the last is employed, the edges should have a fancy cross stitch border. Crash may be used to make the case and woolwork for decoration in bright colours. the elges being finished with ornamental blanket stitch.

Flaps niay be rounded at the corners or made envelope shape if liked and bound with a contrasting colour Stranded cotton is best used for embroidery on linen cases. The simplest stitches are employed for floral designs, such as satin and stem stitch, buttonhole, rose and lazy-daisy stitches for stalks, leaves and flowers and French knots for the centres of the latter. These stitches are illustrated in pagc 419. Plain blanket stitch is the same as buttonhole stitch, with a coarser threal and larger stitches and spacing.

Velvet sheep skin or suède finished splits for pyjamia cases can be cut out to the same measurements, the edges thonged, and a design or monogram stencilled on the flan which is usually lastened down by means of one or two press studs (see Leather Work).
Noah's Ark Case A delightful case for the pyiamas of nur sery folk is illustra. ted in Fig. 2. It is made of linen, red for the roof, fawn or cedar brown for the walls and bright blue for the hull. The cmbroidery, which is of the simplest description, is done with one skein each of red. blue, cedar, darker brown and black stranded cotton. The preliminary stitching of the edges of the various pieces must be done firmly

Night Wear Cases. Fig. 1. Case made from linen, with scalloped edges and initial embroidered on flap
and neatly or the case will not wash and wear well.

First cut out the linen according to the dingrams in Fig. 2 Turnings are allowed for. Tack down a neat hem all round the red roof piece, sloping sides first and then the two straight edges Hem the tops and bottoms of the two cedar pieces, using one thread of matching strander cotton and tack down a single $\frac{1}{4}$ in turning along the sides.
back, but leaving the front loose open Slipstitch together the ends of the boat projecting from the walls A transfer (No 166) for the embroidery, which is used to decorate this Noah's Ark Case, may be obtained post free from Good Needlework Magazine, Transfer Dept., 291, Oxford Street, London, W 1 The cost is threepence, which may be remitted in postage stamps.

More Elaborate Sachets. Benutiful nightdress sachets are made from shot silk The simplest is an oblong bound with a heavy silk or tinsel cord For this cut four pieces of taffeta shot mauve and blue or llame and gold or whatever colouring is most suitable for the room-measuring 17 in . by 13 in Cut two shapes of cotton wool half an inch smaller than the taffeta all round. Lay one piece of taffeta for lining on a top picce and seam all round the edges, leaving about if in. open Tack a warlding shape on the lining at the

Along the bottom of the front
wall, having first drawn or traced the design, embroider the figures, door and windows. Fold the blue piece for the hull in half lengthwise and join the sides with French seams. Then tack down a single $\}$ in. turning all round the remaining edge

Next tack the walls into position in the hull, the hem just under the turning, making sure they are in the centre of the hull and using three blue threads and $\}$ in. long blanket stitches with $f$ in. spaces between. Blanket stitch all round the top of the boat, thus attaching the front walla to the front of the loat and the back wall to the back ol the boat. Tack the walln together at each side and hlanket stitch them together with matching cotton, using $\Omega$ amaller stitch and spacing.

Fold the roof in half and stitch the top edges ( X and Y ) firmly to the top of the front wall (points A and B). Tack the lower back edge of the roof to the back wall. Now blanket stitch in sed, as before, all round the roof, fastening down the

Cedar front wall

Fig. 2. Noab's Ark in colourad linen makes a practical pyjùma case for a child. The roof lifts upfor tha night wear to be placed inside Courtes, of Good Nèdlework Maoazinc

Fig. 3. Nightdress sacnet in black satin, trimmed witr a border of kold lace, and a basket of flowers in bright colours Courtes" of Good Needlework Mayazine
extreme edge and turn them all inside out Finish off the last 6 in. invisibly and prepare the second paided half of the sachet in the same way. Stitch the two pads together and leave one side open to slip the nightdress in Trim with the cord and a motif of padded flowers or one in gold or silver embroidery. Such motifs can be olitained ready made o hand embroidered as desired. Gold is uscd for a shot silk with yellow in it. silver for blue or mauve.

A pretty trimming is made by using $a$ 2 -in. wide tinsel gauze ribhon and a gold or silver lace to finish the front of the sachet. Take running stitches along the edge of the riblion and draw up to fit the sides of the sachet. Tack it into position round the edges and atitch a narrow tinsel lace on one side of it facing to the centre of the sachet, and another on the outside of the ribbon and on the erlge of the sachet. The inner lace trimming should lie flat on the edge of the gauze and on the sachet and the outer lace trimming should be slightly gatherel.

The black satin case illustrated in Fig. 3 is comnosed of two ovals of black satin, two of pink talfeta and two of wadding and trimmed with a basket of silk flowers in vivid colourings and with $\Omega$ gold insertion and lace each $\frac{3}{4}$ in. wide. First cut a pattern of an oval measuring 16 in . by 19 in . deep.

Lay this pattern on double black satin and cut out two ovals; then cut out two more of the same size from rose pink taffeta and two more $a$ trifle smaller from wadding.
On one of the black satin ovals the basket ol flowers is arranged A suitable design may be accomplished by means of appliqué work (q.v.) by painting on the satin, by embroidering the Howers or by making them in ribbon work (q.v) The basket is made from five rows of the gold insertion sewn over a piece of gold coloured satin shaped like a basket. Stitch it down on the sachet and arrange the flowers over it.

Lay a taffeta and a satin oval face to face and seam them together three-quarters of the way round. Lay a wadding oval on the taffeta one and catch it down with slip-stitches all round the edge. Turn the seamed ovals right side out, and the woulding will be in its correct position between them. Finish off the last part of the seam invisibly. Seam the remaining three ovals in the same way Slip-stitch the two padded halves together, leaving them open for about eight inches at the left-hand side. The nightdress is alipped in here.

All round the edge of the top oval, with the basket on it, stitch a strip of gold insertion $\$ \mathrm{in}$. wide, gathering it on the inner edge to fit the curve of the oval. Then. round the extreme edge of the sachet stitch a strip of gold lace about $\frac{3}{3} \mathrm{in}$. wide gathered slightly along the straight edge These laces must, of course, be stitched only to the top oval where the sachet is left open at the side.

A circular sachet can be made in the same way as the oval one previously described, merely cutting out and making circular pads instead of oval ones A pretty finish is shown in Fig. 4 This sachet is lined with pink silk and covered first in black satin, and then has a top covering of gathered black georgctte The trimming consists of a large shaded pink silk rose and green silk lesres (q.v.).

Nine Bark. This hardy deciduous shrub is known botanically as Neillin (q.v.).
NIPPLE : Its Care. That portion of a woman's breast by which milk is conveyed to the child should be prominent in the healthy, well-developed woman, and especially so during prognancy and after childbirth. Great care should be taken that the clothing is never sufficiently tight across this part of the body to crush the nipples.

If through pressure or any other canse the nipples are not sufficiently developed for it to be easy to suckle the child, the following treatment should be carricd out. During the last few weeks of pregnancy the expectant mother should gently pull out . the nipples each day, using cotton wool and n little vaseline. For the last two months before the child is born bathe the nipples night and morning with ean-de-Cologne (1 part eau-deCologne to 3 parts of water). After bathing, dry with a soft clotl or piece of flannel.

After childtirth the nipples must be carefully attended to. They should be bathed with boric solution (a teaspoonful of boracic
ncid to the pint of water) before and after suckling, and then carcfully dried with cotton wool. Should crack. ing or chapping take place, amear with a paste made of equal parts of bismuth carbonatc and castor oil between feedings, and have a nipple shield for the child to draw the milk through.

Sometimes when the nipples are very sore it is necessary to keep the child from suckling for a few days, and then the milk must be drawn from the breast by means teat attached, or a shield with tuhe and teat attached, or breast pump. Sometines while a woman is nipple. This should be opened by the doctor. and dressed with antiseptic lotions, etc.
Eczema of the nipple may he very troublesome. It results from neglect of cleanliness a fter suckling. The nipples swell, and become more or less raw. There is usually some pain and itching and the skin around the nipple may become involved. If the outbreak of eczerna is severe, the child should be weaned. Bathe the parts with an alkaline lotion such as bicarbonate of soda (l dram to $\frac{1}{2}$ pint of water), carefully dry with a piece of clean, soft linen, then apply zinc ointment, lanoline cream, or the paste above mentioned, and cover with lint or linen See Bahy

## Nit. See Lice

NITRATE : For the Garden.
In gardening the term nitrate usually means nitrate of soda, though sometimes it is applied also to nitrate of potash. Nitrate of sod a is a particularly good stimulant for vegetables in spring and early summer, as it helps on the growth. It must bc used with care. as it promotes luxuriant leafage. One oz. per sq. yard is sufficient. One oz. dissolved in 1 gallon of water makes a good plant stimulant. Nitrate of potash is very stimulating, as it contains 15 per cent of nitrogen and 40 per cent of potash, but is too expensive for general use. See Garden; Lime: Manure.

NITRATE OF SIIVER. Also known as lunar caustic, nitrate of silver is much used in medicine, in the form of crystals or moulded into pencils or sticks. It is largely used as a caustic for the removal of warts, proud flesh, etc. A solution forms a useful astringent spray for an inflamed pharynx or larynx, and a weaker solution may be used as a gargle. If it is desired to stop the local action of the nitrate use a little common salt. Internally it is frequently prescribed as a remedy for gastric or duodenal ulcers, diarrhoea, and chronic catarth of the stomach.

In poisoning by nitrate of silver there is vomiting, purging, severe inflammation of stomach and intestine, and also violent pain. The treatment while awaiting the doctor consists in administering a strong solution of common salt, keeping the patient warm, and giving milk, olive oil, and soothing liquids.
NITRE : Its Household Uses. Potassium or sodium nitrate, known as nitre, is chiefly used in the household as a meat preservative, retaining the red colour of the meat better than common salt. For making a pickle for hams, a mixture of common salt 3 lb ., nitre 2 lb , and boric acid 1 lb . is usually employed

Nitre is also a constituent of fertilizers. As nn example, a mixture of equal parts of nitre and phosphatc of potash is employed. One teaspoonful of this powder dissolved in a gallon of water is used for watering plants in pots; for outdoor plants the proportion is one iablespoonful to every gallon.

In medicine nitrate of potassium, also known as saltpetre, is frequently used in fever mixtures on account of its mild diuretic and diaphoretic effects. Poisoning may result from large doses, usually taken in mistake for sodium sulphate or for Epsom salts. The symptoms are vomiting, purging, with blood in the stools, suppression of urine and sometimes convulsions. While awaiting the doctor, if vomiting has not occurred it may be induced by giving an emetic, e.g. common salt, or by tickiling the back of the throat Thereafter milk and olive oil may be given, and hot poultices or fomentations applied to the abdomen to relieve pain.

Nitre Paper. The breathing in of the smoke from burning nitre papers often gives relief to pcople who suffer from asthma. Nitrc paper niay be prepared at home in the following way: Take $f$ oz of saltpetre and put in a pint of water, which should be nearly boiling. Let the saltpetre thonoughly dissolve, and then dip into the solution pieces of white blotting-paper a few inches square Let them thoroughly soak, and then lift out and allow to dry, but not near a fire. To use them, fold like a tent, then place on a dish or in the fender. and light at the folds so that they burn slowly. Two or three nay be burnt one after the other in the patient's room See Asthma.
NITRIC ACID. Aqua fortis or nitric acid is a strong mineral acid which gives off irritant fumes when exposed to the air. It is a powerfill caustic. Poisoning by nitric acid is indicated by yellow discoloration of the lips Alkalis such as chalk, bicarbonate of soda, etc., should be administered as antidotes.
Nitric acid has many applications in industry for such purposes as the inanufacture of explosives and aniline dyes.

Nitric acid is poisonous and the fumes given off are injurious to health. It shotuld never be left loose, but leept in a well-sloppered bottle, stored in a safe place, and prominently labelled.
The use of nitric acid in the home is restricted chiefly to such operations as the etching of metals, although in the form of a salt, such as nitrate of silver, there are important applications in photography. Barium nitrate and strontium nitrate are used for the namufacture of many kinds of fireworks. When used as a very weak solution in water nitric acid forms a useful cleansing agent for badly discoloured brass, copper, and similar alloys; but the metal must be thoroughly scoured in boiling soda water immediately afterwards, as the action, unless stoppcd, will corrode the metal. See Caustic ; Poisoning.

NITRITE OF AMYL. This very volatile liquid is usually inhaled, but it may also be swallowed. Nitrite of amyl is much used in angina pectoris and other convulsive attacks. The dose for inlialation is 3 to 5 minims. This is supplied in thin glass capsules, one of which the patient places in a corner of his handkerchief, crushes bctween finger and thumb, and then inlialea the vapour. This should be done slowly, for the action of the drug is extremely sudden, and at first may cause alarm.

## NITRO - CELLULOSE FINISHES

 These are enamels and lacquers prepared by dissolving nitro-cellulose in special solvents and incurporating pigments to give the desired colour or tint. The drying, which is rapid, takes place by evaporation of the solvent. Cellulose finishes, as these products are usually deacribed, are prepared specificallyfor apraying or for brush application. The former class is extensively used for industrial work (c.g. in enamelling coachwork, furniture, etc.). The home worker can obtain a portable spraying outfit with" pistol," foot punip, and air reservoir, for about 50 s.

Brushing finishes are ohtainable in a wide range of attractive colours, and, though slower than the spray class, are comparatively rapid in drying. The technique of their application presents no difficulty, It is described in detail in the article on Enamel
The brushes used should be rubber set ones having soft bristles, and care should be taken not to mix together the products of different makers, since the hasc or solvent used might be different in nature and composition. For a like reason both undercoating and finishing cont should be those of the same maker

The solvents employed are inflammable, and the material should not be used near a fire or any open flame. When the uork is done indoors the room should be well ventilaterl

NITROGEN : For the Garden. Plants need nitrogen when they are without vigour and their foliage has a washed-out, pale-green appearance. Application of a quick-working nitrogenous manure, such as nitrate of soda, in amall quantities will rapidly encourage new growth, and reatore health to a sickly plant.
Soot contains a percentage of nitrogen, and apart from its value in this respect is useful in making a plant's immediate vicinity dis tasteful to slugs and other pests ; it must not be used carelessly, however, as it is injurious to the leaves of tender plants.
Sulphate of ammonia is preferable to nitrate of soda, 1 oz. to the sq. yd. making a good ground dressing, or 1 oz . to the gallon in solution. Generally it is unnecessary to apply nitrogenous manure to leguminous crops, as these naturally draw the element from the atmospherc and in conjunction with bacteria convert it into fond form See Fertilizer: Guano: Manure.

## The Noah's Ark and its Contents

## How to Make a Popular Nursery Toy

This work contains numerous articles dealing with children's amusements and nursery matters generally. Among them are Doll; Knitted Toys: Rocking Horse; Toys. Sec also Nursery

Arks containing animals can be hought n a number of sizes, from small ones including only a dozen or so animals to quitc large ones with two or three hundred. The animals are almost always in wood. In the larger arks they are made in pairs, each pair representing an animal or bird, with other wooden figures representing Noah and the members of his family.
A typical ark (Fig. 1) is made with $\ddagger$ in. and ${ }_{1}^{3} \mathrm{in}$. wood. The base is $12 \frac{1}{2} \mathrm{in}$. by $3 \frac{1}{2} \mathrm{in}$. by tin., shaped at cach end and chamifered along the lower corners. The ends are 5 in. by 27 in by $\ddagger \mathrm{in}$., with the top corners sloped off to $3 \frac{1}{2}$ in., and the sides are cut from $\frac{3}{16}$ in wood to $8 \frac{1}{2} \mathrm{in}$. by $3 \frac{1}{2} \mathrm{in}$. Ghue and brad the sides to the ends, and then attach in the same way to the base, leaving an equal amount at the sides and ends. The slope of the ends should he carried along the top edges of the sides with a smoothing plane. The roof is made from two pieces of $\frac{3}{16} \mathrm{in}$. wood, hoth $9 \frac{1}{2}$ in long, one $2 \frac{5}{8}$ in., and the other $2 \frac{1}{2}$ in. The wider piece is glued and bradded on one side, over-lapping the npex of the ends by $\frac{3}{16} \mathrm{in}$., and the other piece is attached with two or three strips of linen or canvas, which measure about 1 in . by $\hat{E}_{8}$ in

The outside of the ark is coated with white or cream paint and the imitation timber work and windows indicated by grey and black paint. The effect may be brightened up by using red and blue if desired. A narrow slit should be made in the hinged lid and a piece of wire cut from the end of a hairpin driven in the side to project through the opening. The roof should be coated with glue, and covered while
sticky with finely granulated cork and flat particles of straw. A catch is attrched to the top to fit in a loop made in the wire.

Any number of ligures and animals may be placed inside They should be cut out with a

fretsaw from planed fretwood; yellow pine is best, but either whitewond or satin walnut may be used. The simplest way of making the figures is to shape them out of round wood, as in Fig. 2. Pine or deal is the easiest to cut, but whitewood is stronger. First cut off a number of lengths about is in from $\frac{3}{3} \mathrm{in}$. round, and mark off $\frac{7}{8}$ in or so and $\frac{1}{2}$ in. ahove, as indicated at A. Place a knife on these marks and cut into the wood, molling it backward and forward to form the cuts shown at $B$. Cut down as at $C$, and then make other cuts as at $D$, these being $\frac{1}{8}$ in apart. and finish with a file

The next stage, shown at $E$, is done with a narrow-bladed penknife and finished quite round. This leaves the back to be cut flat, as at $F$. To complete the ligure, the arms, $\frac{3}{3} \mathrm{in}$. by $\frac{1}{8}$ in. by $\frac{1}{1}$ in., should be tapered slightly and glued on, leaving the painting to finish. Much time can be saved in making these figures by turning them on a lathe to the stage shown at E, the back, arnis, and
painting only being left The hody is usually painted in one colour, the top. forming the hat, in another, and the head palc pink, with the features indicated by spots of black paint.

The Animals. Thesc are drawn on the wood and cut to shape, some from $\frac{3}{1}$ in., others from $f$ in and is in iwood Three typical exainples are illuatrated. The horse, cow, pig, shcep, and similar shaped animals, are made by taking the block shape as left hy the fretsiw (shown in Fig. 3, A), and forming the legs by making a tenon saw cut across, as indicated at $B$. The ears are formed hy cutting a V-shaped nick, as at $C$, and the horns of the cow by fitting in a shaped piece of $\frac{1}{16}$ in. wood in a saw-cut made in the head. as at $D$.

Most of the blanks, after they liave been divided by the saw to form the legs, are given a slight shape by cutting off the sharp erlges. Some of the animals will bear a little more modelling to give a good shape to the head, particularly with the dog, sheep, and hirds. In the latter the benk should be brought to a point by cutting the wood outwards as in sharpening a pencil. It is usual to give a little shape to the sides of the birds, slightly tapering them towards the tail. but keeping the latter portion full width so that it will stand properly. Both the cat and the cow are made wider at the back: this can be done hefore the lege are cut, but it is not difficult to cut a slice off each side when cutting the corners off. As it is usual to make the animals in pairs, time is saved in cutting out if two pieces of wood are frastenel together. To prevent the saw from catching, both of the pieces should be pasted on a sheet of paper.
Although ordinary paint may be used for finishing the animals, it is usual to employ a spirit varnish coloured with aniline dyes. Ordinary shellac varnish is expensive for large work, but a coating of size applied to the work beforehand will prevent the varnish soaking into the wood. A good varnish paint may be made by disalving reain in methylated spirit and adding a little dye, but this method is not suitable for bright colours.

Another method of forming small animals is to cut the plain shape out of thin fretwood and form the legs with scparate pieces of

Noah's Ark. Fig. 3. A, fretwood block: B, legs formed by tenon saw-cut; C, ears formed by $\nabla$-shaped nick: D. use of a shaped piece of wood for borns

wood. The legs may be made movable by cutting to a larger shape and riveting them By using this method, which is only suitable for animals more than 1 in high, the trunk of the elephant, the horns of the cow ears of other animals, or wings of birls may be made to move, as shown in Fig. 4.

A good method is to cut the animals out in $\frac{3}{18}$ in. fretwood and mount them on suitable bases. Unlesa it is desired to model the shapes, they may be rapidly sawn from prepared wood, sycamore, satin or black walnut being suitable. The shapes are drawn out on thin white paper, keeping as closely as possible to the proportions shown in Fig 5 Ordinary drawing-paper is too thick for this purpuse. In order to obtain a good line for the saw to run against, the pencil lines on the drawing should he outlined in Indian ink.
The usual method is to fill the whole of the shape in with black; the white paper shows up clearly against the black, and helps in cutting a true shape. The paper is pasted to the woorl, which must have a true and smooth surface. In order to ensure that every portion of the paper adheres to the wood, it is advisable to use a roller or a solt piece of rag, and carefully preas down the surface, working with another piece of paper over it from the centre to the outside. (The article on Fretwork should be referred to for useful hints on this point.)

When the paper is dry, drill holes in all the enclosed spaces. In dealing with the slephant, for instance, five holes will he required, one between the trunk and the tusk, three underneath between the lega, and the fiftl at the back for the tail. If possible, the continuation of the lines of the limhs, indicated by hlack lines on the illustrations, should be made by saw.cuts; this is only possible when the figures are mounted All the lines should be sawn square, and particular care exercised in turning the corners. The shape of the head may be quite spoilt if the saw-cut is allowed to stray, and as the animals are so small, even a slight difference in a saw-cut may be disastrons. When all the shapes have been cut out, both surfaces should be rubbed over with glass paper; the paper is cleaned off with a coarse grade and finished with a fine.

Methods of Attachment. There are various methods of attaching the animals to a hase : one is to glue them on as in Fig. 5. The basea are $\frac{3}{16}$ in. thick, $\frac{7}{4}$ in wide, and long enough to take the whole length of the bottom strip with about $\frac{1}{8} \mathrm{in}$. to spare at both ends. In order that the gluc joint should hold
securcly, the surface of the slape fitting on the Lase must be quite level; this may he ensured by rubhing each strip on a llat piece of fine glass-paper. holding it quite upright.

Another method is to fit and glue the cutout shapes in a grooverl base, as in Fig. 6 . A long strip of $\frac{3}{3} \mathrm{in}$. by $\frac{3}{16} \mathrm{in}$. wood can bc prepared hy using plywood and gauging lines in the centre to the required width. The cutting edge of the gauge nust he sharpened, and the cut must be decp enough to carry it below the thicliness of the first layer of the plywood; the waste can be removed with an f in chisel.
The strongest method of securing the shapes is to tenon and glue them into slots cut info the base, as slown in Figs. 7 and 8 . If this method is decided on, there is no need, as a general rule, to make more than two slots, and in many shapes one will be sufficient. The wolf requires three slots, the hear two and the chicken one; these will scrve the purpose of examples.
Larger fretwork sets of moving animals can be made by utilizing the samc shapes drawn out to a larger scale and cut out in thicker wood. The four legged animals are the most difficult to nake. For the hull, one piece for the head is cut out as indicated at A, Fig. 9, two pieces for the hody, two picces each !or the front legs ahove and helow the knee, as indicated at $B$ and $C$, similar pieces for the hack legs $D$ and $E$, and one for the tail $F$. Small round hearled nails and thin washers will be required for fixing, as shown in the section at $G$. If the joints are riveted up tightly by tapping the end of the nails with a hammer, it is possible to stand up the animal in any position. The separate rars and liorns that are to he fixed to the hearl are shown at H and K
The ostrich shown at Fig. 10 may be jointed up in the same way as the bull, but it will not be necessary to joint the legs.

NOGGIN. A messure of capacity for the sale of liquids known as a noggin is normally a gill, or quartern. By liquid mrasure, the noggin has a capacity of 8 -665 cubic in., or 1420 of a litre. In old wine measure 4 gilla or noggins made a pint. The measure is a variable one, and to some extent is used as a convenient term to describe a portion, or helping, rather than a unit of measurement. For instance, if the liquid purchased were measured by the old Winchester gallon, one of which is only 8831 of the imperial gallon, the noggin would he 14 p.c. or there about less than the imperial. The word is also applied to a small wooden vessel.

NOGGING: In Brickwork. Although mostly found in brickwork, nogging may also consist of pieces of wood built into a masonry wall upon which to fix other woodwork, such

Nogging Example of nogging in brickwork in on old half-timber bouse
as a window Irame ; or it nuay be used as a tie, or stiffener for the wall. In half-timber work, in which the houses were built with a franework of lieavy timber, the spaces between the parts of the framing were often filled in with hricks in the manner illustrated, and this is known as nogging. Most of this old work is held in high esterm, owing to the arrangement of the bricks (often in a herringhone or other ornamental pattern), and the natural weathering which has produced fine colouring effects. Ses Brick.

NOISETTE : In Cookery. Noisette is the name given to small round pieces of meat cut from the fillet or loin, all fat removed. and fried quickly in dripping without coating. The noisettes are then served with a garnish of vegetables. Sometimes they are covered with brown meat glaze. See Beef

NOISETTE : The Rose. This is the name of an old-fashioned type of rose, raised by a Monsieur Noisette, by cross-breeding betwcen the musk and China roses. Few varieties are grown nowadays, hut W. A. Richardson, orange yellow, and limée Vibert, white, are still popular. See Rose.

NOLANA. Sonetimes called the Chilian belltlower, this is an annual. It may be raised from seeds sown in heat during spring,

Noab's Ark. Figs. 5-8. Animals cat out in fretwood and monnted on suitable bases, showing use

and transplanted in May, or it may be sown in patches, in $\Lambda$ pril, where it is to tlower. Atriplicifolia, with hlue Howers, is the chief species

## NONPAREIL.

 The handsome cago bird called nonpareil is a native of warmer parts of N America, and is nbout the size of the British linnet. It is kept chiefly on account of its hright plumage ; the song, though soft and pleasing, being little more than a repctition of short notes, like the song of the

Nolans. Blue flowers of the yellow hammer
The head and neck above are rich purple blue, the other upper parts are diversified with yellow, green. and red, and the lower parts are red. The hen bird is more soherly coloured ; the upper parts green-olive and the lower parts yellow. Its natural food is seeds and insects. In the aviary it should le given sceds : millet, rice, canary, and poppy: alan llies and other small insects.
NOODLE, or Nouille. A paste made from flour, eggs, and salt, which is known as noodle or nouille paste, may he used with equal success as a foundation for savoury dishes, a pudding, or as a garnish. It is also known as ribhon macaroni.
To make it, sift $\frac{1}{2}$ lh flour on a pastry board. then melt $\frac{1}{2}$ teaspoonful salt in sufficient water to dissolve it. Nake a well in the centre of the Hour, add the salt and the yolks of 5 eggs and incorporate these ingredients, working in the flour from round the hollow first. The paste must he kneaded thoroughly and vigorously When well worked, sprinkle it with a few diops of water, make it into a ball, roll it in a clean cloth and let it lie for an hour or two. or till wanted. If the eggs are small an extra yolk may he required, hut the paste, although pliable, should be very stiff

After standing an hour or so roll the paste very thinly and cut it into strips six to seven inches wide. Roll the strips up tightly and cut them across with a sharp knife into narrow strips about an eighth of an inch wide Shake these out and straighten them, dredging them with a little flour. Put them into fast boiling salted water, stir them for a few minutes to keep them separated, and then boil then for 10 minutes. Lift out and drain them through a sieve or colander and put them in layers in a huttered haking dish, with grated cheesc between the layers Put a good layer of grated cheese and fine breadcrumbs on top, pour over a little oiled butter and bakic in a quick oven until well browned.
Noodle Dishes. A savoury dish is made by cutting the quantity of noodle paste given above into strips and parboiling them in hoiling water to which salt las been added. and draining them on a sieve. Then put thein into a stewpan with 3 gills strong well-Havoured chicken or veal stock, 1 oz. butter, a little grated nutmeg, mace, pepper and salt. Place the lid on the stewpan, with a piece of greaseproof paper underneath it, set the pan on the stove over slow heat, and simmer gently until the noodles have absorhed all of the stock.
Then take it up, add a teacupful cream, $1 \frac{1}{2}$ oz butter and mix these in with the contents of the pan by lifting them up with a fork and turning thein over. Pile them up on a
hot dish. scatter over a thick layer of grated chicese and the yolk of a hard-boiled egg whioh has heen passed through a wire sieve Put the dish in the oven to colour the cheese, and sen it to table garnished with croûtes of fried bread

To make a sweet pudding, prepare ith noodle paste, then lay aside $\frac{1}{s}$ of it. Treat the remainder as in the recipe for a savoury but substitute 3 gills milk for the stock and add also 2 oz . hutter, 4 oz . sugar, a pinch of salt and flavouring of vanilla or any other essence preferred About $\frac{3}{3}$ hour will he sufficient to allow for the pastry strips to absorh the milk When ready mix in 4 well-heaten eggs Take the remainder of the pastry strips and coil them closely round a well-buttered plain mould. Turn into the centre the prepared noodles. put the mould on a thick haking sheet and hake till it is a fawn colour. Ser Ravioli.

NORFOLK CAKE. To make a Norfolk cake. which is a kind of rich bread, take $1 \$ 1 \mathrm{lb}$. flour and sift it into a hasin with $\frac{1}{2}$ teaspoonful salt. Cream 3 oz. (light weight) yeast with 1 teaspoonful castor sugar Melt 6 o7. butter in 3 gills water, and when cool mix it smoothly with the yeast Turn the liquid into the centre of the llour, make it into a dough, and knead it thoroughly. Set it to rise. covered with a cloth, and when very light make into round cakes and bake about 20 min in a hot oven Brush over the tops of the cakes. when baked with nilk or eggs See Yeast.

NORFOLK DUMPLING. Nortolk dump lings may be served either with hoiled meats or as a sweet with butter and sugar preserve, or a sweet sauce. They should be made with about 1 lh of very light white bread dough and each piece of llough should weigh roughly about $1 \frac{1}{2} \mathrm{oz}$. before it is hoiled.

Make up the dumplings into smooth round halls and drop them, if to he served with meat into the pan in whioh the meat is hoil ing, ahout 20 min hefore it is cooked If they are intended as a sweet, drop them into a pan of fast-boiling, clear water and cook them from 15 to 20 min . When placed on the dish. each should he torn apart with two forks, and a lump of hutter and sugar inserted. the halves being closed together again. Sometimes jam sauce accompanies the dish, hut on no account must these dumplings he cut asunder with a linife

As it is not always possihle to be provided with yeast dough or to make it, use instead a dough made with Hour, salt, baking powder, and suflicient milk or water to mix it to a stiff paste. Knead quite smooth and shape and boil as directed ahove. One teaspoonful baking powder should raise $\frac{1}{2} \mathrm{lb}$ flour See Dough ; Dumpling.

NORFOLK ISLAND PINE. This is the common name of a half-hardy tree, Araucaria excelaa, which in Great Britain must he grown under glass. It is familiar as a pot plant, and is largely used for room and window decoration. Propagation is by cuttings in spring under glass. It should bc potted in a compost of sandy loam with a little peat added.

NORFOLK LATCH. This is a form of thumb latch. It comprises three parts. One consists of a metal plate on which is fixed a handle, a hole heing formed in the plate at a convenient distance ahove the top of the handle, through which passes the latch The end of the latch is flattened so that the thumb can be placed upon it while the fingers grip the handle The other parts consist of the catchi and the keep, the catch being operated by the latch, while the keep engages the catch so that the door cannot be opened unless the catch is raised.

When fitted, the Norfolk latch should be sos placed that the handle and latch are fixed on one side of the door. while a hole is formed through the door so that the latch canoperate
the catch, which is placed on the opposite side of the door. The keep is placed on the door post to correspond with the catch The door may be opened on hoth sides, on one by depressing the latch and on the other by raising the other end See Door: Isatch
NORFOLK PUDDING. lor this pudding take $1 \frac{1}{2}$ th good cooking apples: any sort which are quick cookers will he suitable Make a hatter with 3 eggs. $\frac{1}{2}$ |b flour, salt. and I pint new milk. Greasc a pic-dish thickly with hutter. lay in it the apples, which should havc been peeled and cored Fill the hole where the core has been with sugar well flavoured with pounded clove or grated lemon rind Pourover the apples the hatter. and bake in a moderate oven ahout half hour Try the apples to see if they are quite cooked hefore removing the pudding from the oven
NOSE. The nuse consists of hone and cartilage. Two nasal bone compose the bridge, from which are continued the cartilages or movable portion of the nasal organ. The interior is divided into two portions by a partition termed the septum. From the nostrils the cavities run backwards for about 2 in and open into the naso-pharynx.
The nasal organ is very liahle to catarthal inflammation, as in what is popularly termed a cold in the head. Adenoids tend to keep up a chronic catarrh, and hoils often cause troublo.
Nose Bleeding. Bleeding of the nose, of epistaxis, may be due to such general causes as severe anacmia, scurvy, or plethora, a full-blooded condition of the liead Lncal causes are blows, ulcers, and picking of the nose. In cases where the bleeding is exccssive any of the following measures may be used to stop it: raise the arms above the head and have someone apply cracked ice in a towel to the nose and back of the neck; or lay a cloth soaked in very cold water over the nose; inject very cold water into the nostrils: gently squeeze the nose hetween the linger and llumb, the patient lying down quietly. Sit on a chair with the head thrown back as far as possible and put the feet in hot water. Relief can generally be obtained by snufling up a weali solution of alum such as 10 gr to 1 oz of water
Injuries to the Nose. Children sometimes push into the nose peas, fruit stones, buttons, or even slate pencils, which lead to swelling, discharge, and blecding. Before this foreign body has hecome fixed it can be treated by pressing the finger on the other side of the nose while the patient blows down forcibly. Another methorl is t.o administer snuff or

Noriolk Latch. Door in part section, showing bow latch and catch are fitted a feather to induce snee. zing The nostril may he syringed gently with warm water. The mother should never attempt to remove the obstruction by pressing any instru. ment into the nose, as this inay lead to serious damage to the organ.

Most frcquently chronic red. ness of the ก ose is caused by
indigestion Some people are particularly prone to this disfigurement, and suffer after exposure to wind or sun. The indigestion must be prevented by proper dieting. The following may be applied nightly to the nose with advantage

For this trouble, too, everything should be done to improve the general circulation. A daily tepid bath, followed by a brisk rub down with a rough towel, and regular brisk outdoor exercise are two invalua ble measures. A tonic suol as Easton's syrup should be taken for a few weeks. For covering over the disfiguring redness, a liquid to dry on and leave a powder is sometimes to be preferred to the ordinary face powders. The following is a simple preparation of this sort

Cisence of nose ..
Before applying, shake the bottle well, and then pour a little into a saucer and, with a fine brush, paint the liquid lightly over the nose. Then gently remove with a soft linen handkerchief any excess of the powder, and allow the remainder to dry in. See Adenoids; Blackhead; Breathing; Cold; Douche; Eustachian Tube; Nasal Catarrl.
NOSE BIT. This is a brace bit in the form of a semicircular sectioned tool with a lip at the cutting end. It is used for boring holes in wood, particularly when the hole is to be bored in the same direction as the grain of the wood, as the lip at the end of the bit enables the core of the hole to be drawn out. See 13it.

NOSING: In Woodwork. This is a term commonly applied to any projecting rounded edge. A typical example is that usually found on the tread of a step in a flight of staira

plane to form a plain nosing
There is also the nosing of flat lead roofs, a roll placed on the edge of the lead flat when the sides of the roof are slated.

Other ex. amples of nos. ing are found on the edges of window boards, or the projecting portions of a table. It is one of the most practical finishes, as it does not hold dust, is easily worked, and has no sharp corners to wearrapidlyor give trouble.
In working nosings the rough and ready way, which often gives excellent results, is to plane over the two corner edges at an angle of $45^{\circ}$ and then plane off the 4 corner edges which will result from the first planing. This produces 9 flat surfaces on the edge, and it only remains to plane off these edges one into the other. Another plan is to use a hollow plane, or spokeshave, and produce the required shape by virtue of that of the cutter. Generally, however, both of these implements are used after the edge has been roughly rounded. In either case, the finish should be effected with fine sandpapering.

NOTEPAPER : Its Varieties. The sizes of notepaper in most general use are Czarina ( 6 by $4 \frac{1}{2}$ in.), Octavo ( 7 by $4 \frac{1}{2}$ ), Viscount ( $6 \frac{1}{2}$ by 5), Imperial ( $7 \frac{1}{2}$ by $5 \frac{3}{3}$ ). Some people prefer single sheets to folded notepaper, and these are usually in sizes known as Post Octavo, Diamond, and 6th Avenue.

There are various finishes in all the qualities. The best known of these are linen finish, which is a trifle rough; white wove; and cream laid, which is smooth. Parchment is more expensive. Bond is another white, smooth finish. Vellum is not much used in notepaper as, although quite amooth, it has rather a dull appearance. Hand-made deckleedged paper is the most expensive. Notepapers are obtainable in various shades, including mauve, yellow, orange, green and blue, in linen and smooth makes. Envelopes are sold to match, generally at the rate of 100 envelopes to 120 sheets of note paper (5 quires).

The water mark in notepaper is not peeuliar to any particular make or size. It appears in every quality except the very cheapest.

The best kind of mourning paper is called Italian, and can be bought in all the finishes except cream-laid, where the colour is unsuitable. The black border is in three sizes narrow, medium, and broad. These vary somewhat according to the make.

If it is desired to have an address at the head of the paper, an addrcss die can be purchased. Einbossing presses for home use, complete with die and counterpart and brass paper gauge, are obtainable.

NOTICE: In Law. When the occupier of a house or flat intends to leave at the expiration of his tenancy the landlord has a right to be informed in good time, so that he can arrange to find another tenant. What notice is required in a particular instance depends almost entirely on the nature of the tenancy and the terms of the agrecment. An important point to bear in mind is that the notice must be given by a certain date, and failure to observe this condition will invalidate it.

When a house is taken on a three or five or seven years' lease the tenancy determines automatically when the last year has expired, and no notice is legally necessary; but if the tenant stays on without entering into any fresh agreement he becomes a yearly tenant. Six months' notice has to be given on a yearly tenancy, and it must expirc on that day of the year on which the tenancy commenced. For example, if a yearly tenancy commences on June 24, notice will in that case be given on the following December quarter day, this being six months prior to the date on which the tenancy expires.

Small houses and tenements are taken by the quarter, month, or week, as the case may be, and the notice required on either side is three months, one month, or a week. Thus in the case of a weekly tenant he must give seven days' notice, expiring on the day the rent is due, usually a Saturday. Unfurnished apartmenta are commonly engaged for a year or for six nontha, and a quarter's notice is stipu. lated for. Furnished apart. ments are usually engaged by the week, and subject to a week's notice being given on either side.

Should a tenant fail to give notice at the proper time the landlord may and generally will hold him to the terms of his agreement, will hold him to the terms of his agreement, Nottingham in the 17 th and 18 th centuries.
with the result that he becomes liable for It is a fine stoneware with a lustrous brown
another quarter's rent, and so has to remain considerably longer than he had intended. He should be careful not to make any agreement, either verbal or written, in respect of any new house he intends to move into until he has given proper notice to his present landlord.
Another form of notice is that given to or by a servant. Domestic servants being almost invariably engaged and paid by the month, a month's notice on either side is the general rule. If it is desired to terminate the engagement at short notice, a month's wages must be given instead. A servant is always entitled to her proper notice unless she has been guilty of serious misconduct. See Distraint; House; Landlord; Master; Rent.

Written Notices. Even where there is a written agreement, a verbal notice is perfectly in order; but it is best to put it in writing, with date and signature. It may be delivered into the landlord's own hands or sent by registered post or delivered at the door. In the latter case the correct procedure, although it is not always done, is to keep a copy of the notice and get it signed with the date by the person who receives the original document on the landlord's behalf. These regulations were modified to a large extent by the operation of the Rent Restriction Acts.

NOTIFICATION. The occurrence in any dwelling of certain diseases must be notified to the medical officer of health as soon as the diagnosis has heen made. The discases to be notified are as follows: smallyox, scarlet fever, cholera, diphtheria, membranous croup, erysipelas, typhus fever, enteric fever (including typhoid and paratyphoid), relapaing fever, continued fover, puerperal fever, acute primary pneumonia, acute influenzal pneumonia, tuberculosis, ophthalmia neonatorum, cerebro-spinal fever, acute poliomyelitis, acute polio-encephalitis, encephalitis lethargica, plague, dysentery, and, if contracted in England or Wales, malaria. From time to time other diseases, such as measles and chicken-pox, may be made notifiable.
The word dwelling includes every ship, vessel, boat, tent, van, shed, or similar structure used for human habitation. Legally the obligation to notify falls on the doctor, and also on the householder or person in charge of the patient, but in practice it suffices if the doctor notifies. The object is that the disease may be prevented from spreading.
When lead, phosphorous, arsenical or mercurial poisoning, or anthrax, is contracted in any factory or workshop, the fact must be at once notified to the chief inspector of factories by any medical practitioner called in to visit, or attending on the case, who believes the patient to be suffering from any such condition, unless the case has been previously notified. To the Home Office must also now be notified cases of epitheliomatous ulceration due to tar, paraffin, and similar substances, and of chrome ulceration due to chromic acid and some of its salts.

In towns and districts where the Notification of Births Act, 1907, is adopted, the birth of a child must he notified within 36 hours after the birth to the medical officer of health. This applies to stillborn children. In addition to this it is necessary to comply with the requirements as to the registration of births. See Birth; Death; Infectious Diseases.
glaze, and is representer to day chiefly by jugs and pots. A good example is shown in the illustration Nottingham ware is not unlike that known as Fullam ware, which was started by John Dwight about 1670. The Not. tingham potters, who flourished in the 18th century, owed something to the influence of Dwight, and something also to the German stoneware that was imported into England in the 17th century. See Stoneware.
NOUGAT. The
blanching of 3 oz . almonds and a few pistachio nuts is first a to be talien in making French nougat. After and boil till the temperature reaches $244^{\circ}$ the skins have been removed, dry the nuts Rinse out a bowl with cold water and pour thoroughly and put them on a plate near the augar into it, stir it round with a wooden the fire to warm. In the meantime, stir spoon till creamy, and then add 2 tableapoon2 oz. each honey and icing sugnr, together fuls honey, which should be liquefied by being with the whisked white of an egg and a few heated over boiling water. Add also some halved glacé cherries, in a pan over the fire, delicate Havouring, such as orange fower water and continue stirring until they are cooked. or vanilla.
Drop a little of the nougat into cold water, when it should break evenly and be erisp.

Move the pan to the side of the fire, stir in the nuts, and then turn the whole on to a slab sprinkled with icing sugar. Mould it first into the shape of a ball, and then press it into a small shallow confectionery box lined with wafer paper. Place another sheet of this on top, and then leave the nougat to get cold, when it may be cut into square or
oblong-shaped pieces.

Another kind of nougat

Nougat, a delicious sweetmeat made with icing sugar, almond, honey, and white of egg
can be made by blanching and cutting up and then drying $\frac{1}{2} \mathrm{lb}$. almonds. Put $\frac{3}{\frac{1}{l} \mathrm{~b}}$ castor sugar and a dessertspoonful of lemon juice into a lined saucepan, stir them over gentle heat with a wooden spoon until they acquire a pale brown colour, and then add the almonds. Turn the whole on to an oiled or huttered slab, press it out with a hot, wet knife, and then mark it into squares or strips, breaking these apart when the nougat is cold.

For chocolate nougat, cook together 1 oz ench butter and grated chocolate, $\frac{1}{2}$ gill water, 1 teaspoonful glucose, and 1 lb . sugar, and When they are dissolved boil the syrup to $240 . \mathrm{F}$. Then draw the pan to the side of the fire, add 2 oz . shredded nuts and some vanilla flavouring, and stir the whole till it thickens. Let it cool in a tin lined with waxed paper.
Another variation of chocolate nougat is made by cutting the ordinary nougat into squares and dipping them in coating chocolate. See Chocolate

NOUGATINE. To make these cakes, prepare about 6 oz . short crust pastry, and with it line some greased cake tins Beat 2 oz butter and the same quantity of castor sugar to a crean, then beat in an egg, and add also 1 oz . cake or breadcrumbs. 1 oz . ground almonds, and about $\$$ teaspoonful ratafia essence. Half fill each pastry case with the mixture, sprinkle the top with a few

The noyeau must now be worked like fondant, and at the same time $\mathbf{3 o z}$. almonds, blanched, dried, and cut into halves or quarters, according to size, must be introduced and mixed in. When ready to mould the swect should be soft and creamy, and then should be pressed into a shallow, oblong box if there is no noyeau frame available.

The box should be lined with wafer paper, but it is sufticient to line it with wax paper and have merely a layer of "afer paper at the botton and on the top. The mixture should be about 3 in. thick and quite level. Just before placing the wafer paper on the top, hrush it over lightly with cold water. Weight it to keep it in place and put away the noyeau in a cool place to grow firm When set cut it into bars.

Noyeau can be inade with preserve instead of honey. The janı must be pressed through a hair sieve and the colour reatored with cochineal if red jam, or a little saffron colouring if yellow ; jam invariably loses colour whon sieved Either apricot or raspberry jam is most suitable. Add some suitable essence, such as vanilla, orange, or almond, as well as a few drops of llavouring corresponding to the fruit of which the jam is composed.

## Notes for the Month

Novemabr 1.-All Saints' Day. Stock Exchanges closed
November 1.-Elections for city and torough councils outside London
attorney-general. The latter is, however, as a rule, only the nominal plaintiff, merely lending lis name to the real plaintiff. Instances of public nuisances are ohstructions on a highwny and to navigation of rivers

Private Nuisances. Private nuisance, which gives rise to an action for damages and an injunction. consists in some interference by the defendant with the plaintiff's right of property, that is, with his enjoyment of his own property, but not amounting to trespass. Thus, to interfere with a right of way is a nuisance; so it is to block up or diminish another's ancient lights; so also to use adjoining land or buildings in such a way as to unduly interfere with the reasonable comfort and enjoyment of his own property by a neighbour, as by setting up a noisy or evil. smelling or smoky business next door
It must not be supposed that everything of which neighbours may complain amounts to a nuisance. For example, a man may object to a butcher's shop being set up next door to him; but so long as the butcher conducts his business properly he need take no notice of such complaints. On the other had, if he allows offensive smells to penetrate into adjoining property, a nuisance will be created for which he is liable. The principle is that every man has a right to enjoy the comfort of his house or to conduct his business without let or hindrance, provided that he on his side does nothing that can reasonably be held to be prejudicial to his neighhours. See Animals; Drains; Negligence; Pig; Tenant

NUMBER PLATE. This term it used to describe a plate which bears a numher, such as may be seen attached to an entrance door or gate. It is often made in china or earthenware, with a glazed white surface bearing the number in black. Others are engraved or etched in copper or carved in hardwood.
Motor Car Plates. All cars must have number plates attached at the front and back in prominent positions. The plates must be rectangular, the letters and figures being in line or the letters above the figures. Each letter and figure must be $3 \frac{1}{2} \mathrm{in}$. high and every part of it must be in wide The space between adjoining letters and figures must be $\frac{1}{2}$ in. A margin of $\frac{1}{2}$ in. must be beft between the nearest part of any letter or figure and the top and bottom of the black surface upon which they are inscribed When the letters are placed above the figures, a space of $\frac{子}{3}$ in must be left between the two lines, but when the identification marks are in line a gap of $1 \frac{1}{2}$ in. lontween the last letter and the first figure is required.

The plate itself should be black, and the letters and figures painted on it with white or aluminirm paint, though sometimes they are stamped on the plate, the raised marks being painted or stove ennmelled The driver must do nll he can to prevent the plates from being obscured by dirt, luggage or straps, and to ensure that the rear plate is oo illuminated that it can be read easily at night. If he faile to show he has taken all reasonable steps to beep them clean and clear of obstruction he will be liable to $n$ fine not exceeding $£ 20$ for a first offence and $£ 50$ for subsequent offences.

On metor cycles the front plate may be placed parallel with the front wheel. The rear number plate of a motor car may he illuminated at night, but a motor cyclo may have ita front number plate illuminated instead. When a vehicle is being towed, the towed car must have its back number plate obscured and must show instead at the back the index mark and registration number of the car which is towing it. See Motoring; Name Plate.

NUMBNESS. Generally numbness is caused by bad circulation, and often takes place in one portion of the body only, especially the fingers, which will become white and
almost without feeling. Treat by rubbing gently till warmth is reatored. Keep the patient in a warm room and give him hot drinks People who suller in this way should not use cold water to wash with, and should take great care to keep both feet and hands thoroughly warm cluring the winter.

Numbness may be caused by pressure on a nerve supplying the part. This sort passes off as soon as the pressure is removed. Numbness is not uncommon in hysteria. neuritis and other nervous diseases.

NUN'S VEILING. As a light, warm wool material giving good wear and less inclined to shrink than flannel this fabric is popular for babies' frocks and children's dresses. It is an excellent material for winter nightdresses. Cream nun's veiling yellowed by age can be improved by bleaching, and re-dyes well.
NUPHAR. This is a hardy aquatic plant of the water-lily family. Nuphar lutea is the commonest; it bears yellow nymphaea-like flowers in summer. One better suited to small ponds is Nuphar minimum. Planting should be done in April-May: the roots are put in a basket of soil anil sunk to bottom of pool.

NURSE : For Children. I nurse's work in any household consists of the care of the children, their clothes, and the rooms they use. If she is engaged as fully trained she must understand the diet suitahle for varying ages and conditions, and the amount of sleep, air, and exercise necessary to health. In most bouscholds the nurse will undertake the wash. ing of the baby clothes and the woollies of the older children If she is also able to make, inend, and knit, all the better. Instead of being off duty one half-day or evening
a weck, many children's attendants prefer to have a whole day free once a month. It makes a bigger break in the monotony of nursery routine, and as they are out of doors every day, they do not require the fresh air like other maids. Time of during the Sunday should be given to the nurse as a matter of course.

An under-nurse, or nursemaid working under an experienced nurse, receives from her training in the handling of children nad nursery routine. She must be healthy willing, obedient and teachable; not ton sinall or young, or she will be unable to do the heavier work, such as carrying coals and trays, scrubbing floors and general cleaning of the nurseries. Her duties usually include the washing and dressing of the older children It is wise to leave the training of her to the nurse in charge, and her off-duty time should never he the same as that of the upper nurse.

The Uniform. The indoor uniform of a chikdren's nurse may be somewhat similai to that of hospital and district nurses, and consists of a washinble linen frock, a bibhed apron of white linen, and a small cap to match. In some cases a white overall is wonn and the cap is replaced by a square of linen, folded triangle-wise, and fastened round the head. The colour of her outdoor uniform ia generally of dark grey or other subdued shade. such as navy blue or dark brown.

There are institutions for the training of nurses, and from these they can be obtained One such is the Norland Institute 10, Pem. bridge Square, London. W.2. Nurses must be insured under the National Health Insurance scheme

## The Nursery and Its Essential Features

Pleasing and Healthful Arrangements for the Children's Quarters

## This article deals with the decoration and furniture of the nursery. Entries bearing on the same subiect are Baby Chair ; Baby Walker; Cot; Play Pen. See also the articles on Babr; Child; Toys; and those on Central Heating; Electricity : Frieze

'The ideal arrangement in a roomy house is to have separate ilay and night nurseries, with bathroom exclusively devoted to their occupants. Unfortunately this is not possible in a big percentage of homes, nnd the tendency in modern building is rather to decrease than increase the number of rooms, while the rents of town fats and maisonettes necessarily limit space for many families. 'I'he essential thing nbout nursery quarters, whether combined or in scparate parts, is that the children may lee able to develop in them to the best advantage both mentally and physically.

Where only one room is available it should be particularly light and airy, and if possible have a S.W or S. F. asperst. It should he large enough to allow of proper air upace at night, and, to accommodate one nurse and child, should not be less than 12 ft . square or, if oblong, ahout 14 ft . hy 10 ft Windows should he large enough to admit plenty of light and air, and sloould in all cases be effectually barred across the openings. In town houses where a nurse is in charge nurseries aro best situated at the top of the house. The children thus get better light and air and are awny from the coming and going of the bousehold on the lower Hoors. There should be a sufety gate at the top of the stnirs.

If two rooms are available it is better to keep the larger for the night nursery. 'Ihe size of the room for play and meals is not so important, hut naturally the more space there is here, too, the jollier it is. For a small playroom the lighter and scantier the furniture the hetter. Many pieces get in the way of free movements nnd cause unnecessary knocks and fa!ls Warmth and nir without draughts, so essential for children, are more
difficult to regulate in the very small room in cold weather and there should be an upper ventilator to the window.
Perhaps one of the greatest advantages of two rooms is that as children are sensitive to their surroundings the disappearance of all suggestion of daytime activities and exciting toys or games and the apprearance of all that gives the idea of quiet restfulness is conducive to sleep. Certainly the two rooms give delightful scope for decoration The brighter colours and gay cretonnes, pictorially drainatie events painted on screen, frieze or furniture. or worked on rugs and cushions, are usually kept (with discretion) for the day nursery, while the quiet tones presominate in the night nursery and the furnitute is of simple bedroom type
Suitable Decoration. It is pleasant to think that the days are gone when anything was good enough for the nursery, nnd that architects and furniture designers have concentrated in producing charming quarters for amall chiddren; that shops and stores and firms dealing in floorings, wallpapers, fabrics, furniture, chinn, bed and oneal time accessories, stock and manufacture all kinds of pleasing articles especially for the use of nursery folk On the other hand, in some of the super-lecorated nurscries, specialization is overdone The colours employed are too glaring, the white fumiture is varnished to a dazzling deg*ee, stencilled or painted with strange creatures, while the antics of a medley of grotesques straggle over the walls and screens, appearing on chinaware and table cloths at meal times---to say nothing of bils and feeders - on the down quilt and toot of the cot nt night, all over the linoleum and the cretonne curtains. Mother Goosc.

Nursery. Fir. 1. Day nursery with plenty of window, lizht, air, and floor space. Tbe walls are bung with gaily patierned paper and the rest ot the equipnient is simple but charming
in some cases, is cven painted flying across the ceiling with favourite characters attendant, to aidd to the restless effect

All this Invish ormamental stimulation is probably as bad for quick-witted or highly strung children as the neglect of their neculiar requirements was in the past. Modern life tends to make children more active minded. Mechanical toys and gramophones, the ordinary events of an everyday walk, for those who live in large towns, the general noise and bustle around then, are quite sufficiently exciting without the distracting turmoil of a nursery where things appear seldom to stand still and nearly every spot tells an adventurons story.

Small chiddren certainly like bright colours, but it is not necessary to surround them with these. Instead of highly decorated walls, flat paint in a pale shade is desirable; but the colour chosen should he soft and beautiful. Rushing from the iden of exuberant ornament one does not want to fall into the other extreme of a nursery like a hospital ward, so severely painted in white and so strictly hygienic in its furnishing that no child could regard it as a homely playroom or place for cosy rest. Ifter all the room is for the child not an exhibit for visitors. or a place where clcanliness, however important, is the only consideration. It serves his purpose if he can live his life happily in it, and his life is mainly occupied in cating, sleeping and play. 'lhe last is of immense importance to himi and means not only amusement, but development and education. He wants to bring furniture and accessories into his own scheme of things, and up to this point specially designed surroundings are helpful, beyond it they probably retard his mental growth. as they provide too many cut and dried idens and do not allow scope for his inventive mind or individuality.

Choice of actual colour for the walls must be governed, as in ot her rooms, by the aspect. When there arc two nurscries, either a pleasant pale green, dove grey or blue are gool for the slecping room, as these shades are conducive to rest. Should the room be dully situated palc pink is more soothing than yellow, which, however, is an admirable choice in a clear shade for the playroom. Dark or violent colours are obviously a mistake for walls, but a lighter colour or deeper tone may be employed for skirting, door and window frames.

When possible enamel should he used Although the first cost is greater, it lasts far longer than listemper and can be washed clean from grease and finger marks, which distemper cannot be. Where expense has to be considered, the part of the wall above the painted dado can be distempered to match, or in a lighter tone which is carricd over the ceiling. A varnished or washable wall paper with an unobtrusive pattern is a better alternative to paint than is distemper. A paper with a deep cream ground looks well with either a coloured paint to tone with the pattern, or with natural onk woodwork White should not predominate on the walls, either painted or papered, as the glaring effect of this may have a deleterious effect on
children's eycs. The smaller and darker the nursery the more important it is to keep the mural decoration plain and of a pale colour that is also suitable for the ceiling (such as pink, primrose, or deep creain). so that the impression of space may be given and the light increased by reflection.

For a day nurscry a plywood dado has heen employed with success. Blackboard panels are placed at intervals. These are covered with a specially prepared black paper on which the children can draw with chalks to their heart's content. The drawing can be casily rubbed off and the hlack rencwed occasionally by an application of special waterproof ink. The rest of the dado is painted in a light colour to miatch the walls ahove it. The children use the plywood as a picture gallery, and with drawing pins affix any posters, prints or cards which they fancy. Sometimes unbleached calico is used as a surface for the dado, and decorated with cutouts of gummed coloured paper. The children copy simple designs, directed and helped only when necessary. These pancls and blackhoards afford endless amusement and waken the child's creative and artistic powers. Another idea is a notice hoard covered with serge or baize on which cuttings from a children's paper or cards which he receives are pinned
Where there is only a single nursery these excellent idens need not be abandoned if one end of the room is kept as the playroom and the plywood dado or board is limited to that part. When pictorial wall panels arcemployed these also need not be repeated on those portions of the wall visible from the cots, which can be further separated by the use of draught screens. Nursery pictures, whether applied or detachable in frames, should be hung at a level where they can bc easily seen by the children. Where the latter are old enough they should be encouraged to choose such things for themselves. Pictures, if any, should be few and restful in the night nursery.
A nursery hathmom provided with a sink. gas ring, a baby's bath, as well as the usual one, and a lavatory basin, and large enough to contain $a$ gas fire and plenty of

Nursery. Fig. 2. Small nursery, a feature of which is the folding wooden play pen get on a thick ruab mat. This is a boon to busy mothers, for a toddling child can thus be left in satety

Courles! of lleal \& Co
airing accommodation solves the pmblem. of where to wash up the meal crockery, etc., and where to do the essential laundry. In the bigger household friction is often avoided by making the nursery quarters self-contained with store cupboard on the landing and built-in cupboards for linen and utensils.
Heating a Nursery. Central heating is a desirable method of warming the nursery Gas fires combined with rings are very suitable and economical, especially for the night nursery, where a conl fire which requires making up is disturbing. On the gas ring foods are heated and also water as needed.

A closed anthracite stove or fire is suitalle and ensures a warm room in winter. The open coal tire, though it means more work, is often liked for the day nursery. If the cxisting grate is unsatisfactory, a slow combustion stove may be chosen and if it has hobs on either side, these will heat irons, water or food. The day nursery should be kept at a temperature of $60^{\circ}$ to $65^{\circ} \mathrm{F}$., while that of the night nursery should be at least $55^{\circ} \mathrm{F}$.

In districts where gas and electric light are not available a modern type of oil stove, provided it is of good solid make with a firm base, is suitable for warming the night nursery. A strong fireguard of wire mesh must be placed round an open fire, electric, coal, oil or gas stove. The top of the fireguard should be securely fixed to the mantelpiece or wall with neat iron hooks. A useful type of inner firo guard is illustrated in page 458, but a nursery fender should be used as wel!, with an outside rail for airing clothes.

Electric lights should be shaded. If oil lamps are used these should be placed on brackets or shelves at such a height that there is no possibility of their being knocked over. A hanging green nursing lamp is useful for the night nursery. Dark blinds or practical curtains of light resisting fabric are essential for the windows. These curtains should be of a wrishablematerial such as Bolton sheeting. Cretonne should be lined unless blinds are also provided for the night nursery

Floor Coverings. Cork carpet is much used for floors, but is not so suitable as

Nursery. Fig. 4. An attic is here shown adapted to a sleeping and play room. There is a comfortable window seat with toy cupboards underneath, and a delightfui iaea is the notice board
linoleum. The rough surface of the former allows dirt to penetrate, so that it is less easy to clean thoroughly with soap and water. Carpets are not recoinmended, as they hold both dust and dirt. Linolcuin on a Linovent underlay is the best choice, with one or two washable rugs. Inlaid rubber floorings are suitable, as they are waterproof, warm and noiseless Where there is a good floor of wood blocks, these are left bare with the exception of the rugs. Sometimes the floor is coloured or stained and finished with waterproof varnish; but thesc bare floor treatments have the disadvantage of not heing so coinfortable for the toddler, who spends much of his time on the floor. Also, nursery Hoors should not be polisherl, as this leads to
many tumbles and accidents. Practical floor cushions which harmonize with the room and are covered in terry cloth or some such pleasant material should be provided. A cretonne floor minttress is also a very usefu! accessory.

Furnishing the Room. Furniture for the nursery should have rounded corners, be light, strong and washable. In the night nursery natural oak is often used. Here the furniture should be that of an ordinary simple bedroom, the cots standing out in the room with air circulating round them, but free from draughts. A cot should be on enstors and should not be placed between a vindow and the fireplace, or between a window or door without the protection of an efficient draught screen. A really comfortable bed should be provided for the nurse. There should be neither cot nor bed valances. Pretty washable hedspread and cot coverlets should tone witb the curtains. A trolley service wagon is useful when the nursery is in a flat, or when day and night nurseries are on the same floor.
The day nursery may have oak or painted wood furniture. A firm table is essential for ineals, an ironing table, a confortable armchair and one or two ondinary sized chairs; and $\Omega$ baby's chair. Otherwise the furniture for sinall children should be to scale. It should include low shelves for toys, or a practical cupboard, low tables on which to place toys or games while being used, low chairs, and if possible an indoor play pen and a wide cushioned window seat or a settee.

Painted furniture can be renovated with a coat of fresh enamel at small cost. Elm or oak lasts well, but mahogany is not so suitable for the nursery. The old wheelback windsor chairs are hardy and ornamental and hare no sharp corners. They can frequently be picked up inexpensively at second-hand shops A plain kitchen table is not to be despised, and an oak chest of drawers and linen chest may be acquired. Some modern nurseries have cupboards built into the external wall, with ventilators, and these make an airy and cool receptacle for milk and food. The nursery crockery and table linen should be chosen to tone with the scheme of decoration, and bright colours with cheery but not ugly designs are desirable.

- Planning of Nurseries. Our first illustration is of n nursery in a modern house planned with wide bay windows, of which the children
have the benefi on the first floor There is a wash able wallpaper in softly multi coloured pattern but the curtain: are of heavy cotton fabric with a unobtrusive floral sprig and the aimple wicker chairs and table are of plain type, o that the pat temed effect is not overdone. Jaspe inoleum in a soft hade of blue, to tone with tho ground of the wall. paper and curtains, would provide the fooring The two pieces of oak fur iture enhance the light colours o
he rest of the room, while the toy chest on wheels, the little gate-leg table and low chairs could be painted in dove grey, the colour used for the woodwork of the room There is nothing exciting or ugly in the whole scheme. The night nursery (not shown) is furnished in the same style, hut with plain walls
A day and night nursery combined is shown in Fig. 2. This is planned on simple but pleasant lines. No childish decorations appear on walls, floor or furniture. The few pictures arc restfully coloured, the linoleum and curtains could be in soft leaf-green, and the walls of rose pink with a paler shime of pink for the ceiling. The furniture is of natural, unstained oak, light in colour and unpolished except by hand rubbing. Comfort for the toddler, when husily engaged within the folding play-pen, s insured by the thick rush mat.!

A large room in a town house has been converted into the day nursery seen in Fig. 3. The windows are high up, so a play house has been constructel by a handyman with a stairease and roof sufficiently strong to hear the weight of the children with perfect safety. The roof is on the window level. It is in turn a roof garden, $\Omega$ fortress, and a place for playing games where toys will not be disturbed. The ower part of the window, hidden by the safety surround of plywood, is well harred. The door into the play house is practical and there is an electric light fitting inside.

Fig. 6. Comfortable work chair for mother or nurse. Under the seat are two large hinged drawer and a sliding lea rest
Courtesy of Gill d. Relgate, Ll

Nursery. Fig. 5. Ingenious piece of furniture which iolds into a compact capboard when not in use and when open provides a desk and many shelves Courtesy of Gill it Reigate, Ltd

There are also shelves and an individual locke for each child. In this room there are no decora. tions beyond the pleasant colour scheme of corncoloured paint for the dado, with deep cream distempered walls and ceiling and paint work in bright bluc in order to match the curtains.

A modern day and night nursery is shown in Fig. 4. This is a country attic room, and the delightful window trentment, with its dainty voile curtains, dark blinds and cushioned seat, is the principal feature The linolenn is in two shades of brown, and is laid over a sound-deadening felt paper. More decoration is allowed on the walls in this room, but the cots (not seen in the picture) are placed and screened, so that no erciting things are visible to their occupants at night. Favolurite nursery rhyme figures have bect stencilled on the frieze, and a few on the picce of wall by the novel book-house, and on the wastepaper basket. There is snfety ventilator for the lower part of the sash window. The walls and ceiling are painted decp cream, and the woodwork ivory
The nursery cupboard, made of oak, illus trated in Fig. 5, is most useful. When not required for play it folds awny into a compact cupboard. When open it is a delightiful piece of furniture on whose shelves toy-rooms or shops can bo built. There is also space for picture books and a lift-up flap deak at which painting or scrihbling can be done in comfort.
The chair shown in Fig. 6 is a particularly useful and conifortable one designed for mother or nurse. It is well upholstered and possesses two large hinged box drawers for all sorts of requisites and a sliding leg rest. There are also receptacles for books and oddments under either arm.

## Nursing in the Sick Room <br> Simple Suggestions for Looking After Invalids

In addition to the articles on the various illnesses, e.g. Chickenpox; Measles, the readcr is
advised to consult the entries Bednaking; Bedroon; Disinfection; Hot Pack; Hot-water Bottle ; Infectious Disease. See also Invalid Cookery

Home nursing comes into the experience of alnost everyone, and there are certain general rules which should be ohserved. The sick room must be clenned and dusted every lay ; ashes raked out of the fire and cleared awny ; no soiled linen or dressings left littered ahout. All these matters may be attended to when the patient is the least fatigued or distressed, and with as little fuss and clatter as possible Unless the doctor in nttendance orders otherwise, the patient must be washed all over once daily.

The process is as follows: Take the patient's temperature Put the fresh clothes to warm if the weather is cold. Fill the hot bottle. Shut the window. Fill a basin with water as hot as the hand can bear. Have soap and towel handy. Remove shcets and superfluous cover ings from the licd, remembering always to Leep one of the blankets over the patient. Now roll the patient into an old blanket or thick bath-towel, and wash quickly and thoroughly, not forgetting to wine quite dry. Wish and dry each part separately, and cover immerliately with the bath-llanket. IVash the back especially well, and note any pressure marks which might develop into hed sores. All sores should be reported at once to the doctor Water beds and ring pillows can always be borrowed or hought if required.

Remove the bath-blanket, still keeping the patient covered with the upper blanket, put ous warm, fresh clothes, and brush and comb the hair. If the doctor permits, the invalid can be lifted out on to a clair or conch when the bed is re-made, hut this is not at all necessary, for the under-sliect and blanket can be rolled under the body and renewed. It is important that all under-sheets and blankets be free from creases and crumbs. All this is best done in the morning; but restlessness and slecplessness in the evening are often relieved by sponging the face and hands.

In all cuses of pneumonia, high-fever, or gastritis, the mouth should receive special attention. It should be cleaned out before and
after food with glycerin and horax, or glycerin and lemon.
The diet of all invalids should be light and easily digested, and the doctor's orders must be obeyed implicitly. The foorl should be given at regular intervals in appetizing form, and never kept in the sick room. Medicine and trentment must be given at the hours ordered but the patient should not be wakened.
The regular action of the bowels should be encouraged daily, and the urine measured and saved for the doctor if required. The hedpans and urinals must he kept apotlessly clean and well scoured with hot sola water or disinfectant every day; they should be covered with $\Omega$ cloth when carried to or from the room. It is a great conifort to an invalid if such utensils are warmed with hot water before use and warmth also aids the evacua tion of the bowels and the passing of urine. If the patient is in a recumbent position a small pillow or pard placed under the back relieves pressure when the hedpan is in use. Excent in chest or kilney cases the windows should be opened wide after the action of the bowels. Any dificulty in the daily functions must be noted and reported.
All matters likely to alarm or agitate must be kept from the invalid, and visitors to the room should avoid any appearance of anxiety or fussiness. Every effort should he made to ail suloquate reat and sleep. A gloved hand may be used for putting conls on the fire or lumps may be wrapped in newspaper. Small coal and damp dust in a blue sugar bag. if placed at the hack of $n$ fire, will keep it in or hours at night.
Infectious Diseases. Infectious illnesses reguire special preventive measures in a private house. i shect soaked in a strong solution of carholic or lysol should be hung over the bedroom door and kept damp. Carpets and curtains must he removed at once from the hedroom and suitably dis. infected, and the floor must he washed over at least once a day with disinfectant. All soiled clothes and bed linen must he removed
in a covered pail, and immersed in strong disinfectant if they cannot be at once boiled in a copper. With typhoid all the motions and urine should be disinfected for 4 hours before being emptied down the drain.

An enveloping overall and cap should be worn by anyone entering the room, and removed on leaving. Hands and nails must be well scrubbed and disinfected, and if possible different shoes worn outside tho sick room. Anyone nursing an infectious case, especially measles, diphtheria, and scarlet fever, should gargle her throat 2 or 3 times a day with a very weak solution of disinfectant. All cups, spoons, and utensils of every description must be kept apart.
Looking after the Nurse. Special care should be given to the health of the friend, relative, or trained nurse upon whom falls the responsibility and care of the patient. Her meals must be regular and sustaining, and always served in a room other than the patient's room. A trained nurse takes her meals with the family, never with the domestio staff. If she is on night duty she must be given a good digestible meal on rising and before she returns to her work. Provision must also be made for a meal or meals during the night.

Most trained nurges are prepared to do 12 hours' continuous duty, but the untrained woman should not undertake more than 8 or 10 hours'. On being relieved from duty, all persons would be well advised to take brisk outdoor exercise. If the case is specially fatiguing, a long bus or motor ride is refreshing, or a seat in a quiet part of the garden with a congenial book. The recreation should extend over a minimum of two hours. Night nurses will find outdoor exercise especially beneficial, as it stimulates the circulation and produces a certain amount of fatigue, so that sleep, even by daylight, comes more easily.

The minimum of sleep allowed is seven hours, and if possible eight hours' consecutively. Those doing night work should be shown especial consideration, and be given the quietest room in the house, at the greatest possible distance from the siok room. All members of the household should be warned of her hours of slumber. Where a trained nurse is employed, her advice must be followed as to her own mcals, etc.

A trained nurse can usually be procured from the private staff of one of the great hospitals, from a co-operative society, or on the personal recommendation of the doctor in charge of the case. In the two former cases the nurse will be under the rules laid down by the hospital or institution from which she comes, and the fees will not be paid to her direct, but to the hospital. Should she be a private individual working single-handed she will have her own regulations and will be paid direct. The weekly fee does not include the nurse's laundry, whioh is also payable by the employer.
As a general rule a nurse supplied by a society or institution is not allowed to remain more than three months with one case. It is, however, usually possible to have this time extended under certain circumstances, but six months is the extreme limit allowed. Nurses working privately are froe to make their own arrangements. Male nurses are procurable for chronic cases with male patients who require much lifting or moving, or for mental cases. As to off-duty time, they must be treated exactly as the female nurse.
NURSING HONE. The charges made by a nursing home vary with the locality and with the room; but the charge invariably includes the patient's entire board and ludging together with expert attendance by trained nurses. As a rule the doctor's fees are extra, though where a patient is in the
doctor's own nursing home the medical fces baking-powder, 1 teaspoonful bicarbonate of are occasionally included. In surgical cases soda, and 1 cupful chopped walnuts. Add the surgeon's fee is paid separately, but his a pinch of salt, and mix the whole to a fairly visits to the patient while in the home are stiff paste with 1 pint milk, either fresh or included in the charge for the operation.

People who cannot afford nursing home fees can frequently arrange to be taken into a private ward of one of the great hospitals, where charges are considerably lower. In London and many other large cities there are also institutions endowed by charitable bequests where persons of small means are received at almoat nominal pricos.
NUT: In Enginearing. A nut is a fastening device, generally with a hole in it, the sides of which are screw threaded. It is employed in conjunction with a screwed bolt or stud, or fized on to a cylindrical piece having screw threads corresponding to those in the nut. See Bolt: Castle Nut; Lock Nut ; Stud.

NUT: The Shrub. The name nut is generally applied to the genus Corylus, which inoludes the oob, hazel, and filbert. All are summer leafing shrubs, and may be grown in any open sunny position, either as a plantation or as hedge plants, for which latter purpose they are splendidly adapted. A stock can be raised from nuts sown in the open garden in autumn. Suckers may be taken from old plants in October, and replanted. See Chestnut: Cob Nut; Walnut, etc.
NUT: As Pood. highly nutritious food is provided by nuts, but they are indigestible unless very thoroughly masticated. When eaten largely it is best to grind them, or to buy one of the preparations sold by vegetarian depots. Nuts contain a large quantity of both protein and fat. Coconuts and Brazil nuts are very indigestible. Chestnuts are the most easily digested, and next in order come walnuts and pea-nuts. Walnuts are said to be laxative when eaten between meals.

The following table shows the average composition of nuts in common use :

| Nuts | Water | CarboHydrate | Pro- teln | Fat |
| :---: | :---: | :---: | :---: | :---: |
| Almond | 6 | 10 | 24 | 54 |
| Brasll | 5 | 7 | 17 | 07 |
| Cheatnut (freah) | 38 | 45 | 6 | 8 |
| Pea-nut . . . | 9 | 10 | 28 | 42 |
| Coconut | 47 | 8 | 5 | 36 |
| Walnut (dried) | 4) | If | 151 | 63 |
| Filbert | 38 | 13 | 16 | : 6.5 |

The chestnut is especially useful as food ; it is rendered far more wholesome by being thoroughly boiled for 10 min ., and afterwards roasted. Nuts can be dangerous to people with weak stomachs and to young children.

Nuts are employed in cake-making and confectionery, and form an important in. gredient of such foods as nut butter, nut galantine, nut sandwiches, etc. Chestnuts are used in a variety of ways, which include the making of a special forcemeat for foods, while almonds, walnuts, coconut, and pistachio nuts, somotimes shredded and coloured, decorate cakes, trifles, fruit ices, chocolates, and creams.
Nut Bread. Nut bread can be made by mixing together 2 breakfastcupfuls wholemeal flour, half that quantity self-raising flour, I breakfastcupful brown sugar, is teaspoonfuls

Futoreckers. 8trong plated eilver nutaraokers, the pair on the left being provided with special teeth lor cracting Brasil nats sour. Turn the mixture into a greased tin and bake for about 1 hour in a fairly hot oven, testing with a skewer to see if it is done.

Nut Butter. To make nut butter, shell and skin some nuts of any kind, grind them to a powder, and then pound them in a mortar with the butter. When a smooth paste is formod, the butter may be put into jars and used as required. See Almond; Brazil Nut; Chestnut; Coconut; Vegetarian Cookery ; etc.

NUTCRACEBRSS. The implement that is used for eracking a nut consists of two levers, or hand grips, joined at one end by a small link piece on which each of the levers is separately jointed. The nut is placed as near to tho joint between the two levers as possible, and when pressure is brought to bear on the ends the shell of the nut is cracked. Nutcrackers are made of steel, brass, and other metals, usually electro or silver plated.
The designs vary, some being grotesque in appearance, others ornately carved, and the rest plain. In some varieties, of which the pair of nutcrackers on the right of the illustration is an example, the levers are so jointed to the link piece that when they are turned over or reversed they come close together, and are used for cracking small nuts, but when turned in the opposite direction the space between the levers is larger, and will take any size nut.
NUMMEG. The fruit of a tropical plant known as Myristica moschata is the nutmeg of which there are many varieties with different names, but none are suitable for practical cultivation in Great Britain.

In a grated form nutmeg is used as a flavouring for various kinds of food, and to milk puddings particularly lends a distinctive taste. The essential oil is used as a perfume, and also made into a flavouring essence which is useful in cookery and confectionery. It is made by adding 102 of the essential oil of nutmeg to 1 pt . of rectified spirits.

In medicine nutmeg acts as a carminative and may be given in indigestion accompanied by flatulence. It is sometimes used in mixtures as a flavouring agent; for example, it does well in a mixture containing ferrous sulphata. It has also a somewhat narcotio effect. Its preparations are: the powdered seed, dose, 5 to 15 gr ; the oil, to 3 minims ; and the spirit, 5 to 20 minims. Large doses produce poisonous effects.

Nutmeg Grater. This is a small device of pierced tin by means of which nutmegs are grated to powder. See Grater; Junket.

NUTRIA. The durable fur obtained from the rodent known as the coypu, a species of beaver, is of a warm golden brown shada. Nutria is specially dressed to resemble the more costly beaver. Sometimes it is given a silvored effect. It is chietly used for fur coats and for winter trimmings for women's cloth coats. See Fur.
NUTS IN MAY. This popular game can be played by any number of children up to 20 ur a few more. It is most suitable fur indoors, but can also be played outdoors.

The players are divided into two equal parties and, standing in line and holding hands, these face each other, leaving as much space as possible in the centre. One line then advances and retreata, singing this verse as they march o and fro:

## Here we come gathering nuts In May <br> Nuts in May, nuts in May <br> Here we come gathering nuta in Bay <br> On a cold and frosty morning.

The other side does the same, singing the second verse as they march :

Who will you have for nuts in May.
Nuts in May, nuts in May
Who will you have for nuts in May
Un a cold and frosty morning?
The first side quickly choose one of their opponents, whose name is inserted in the verse which they sing as again they march to and fro.

We will have (Ethel) for nuts in May
Nuts in May, nuts in May,
We will have (Ethel) for nuts in May,
On a cold and frosty morning.
The side to which the chosen player belongs takes up the song, asking :

Who will you send to fetch her away,
Fetch her away, fetch her away?
Who will you send to fetch her away.
On a cold and frosty morning ?
The side which has named the player names one of its own members to fetch her away thus :

> We will send (Mabel) to fetch her away.
> Fefch her away, fetch her away,
> We will scnd (Mabel) to fetch her away.
> Ou a cold and frosty morning.

The two chosen players advance for a tug of war. A mark is made on the ground by laying down a handkerchief or in some other way, and the two, having clasped hands, tug. The one who is pulled over the mark joins the side to which the winner belongs. The verses are then gone through again with the side that sang the second verse last time now taking the first and it can continue until one side is reduced to few or no players. See Children's Party.

NUTMALIA. This is a hardy leaf-losing shrub, Nuttalia cerasiformis, which grows 4-5 feet high. It bears white flowers in early spring: the flowers are not particularly attractive. A crop of red fruits will result if bushes bearing male and female flowers are planted. It thrives in ordinary soil, and may be increased by division in autumn.

NUT WEPVIL. There are two weevils destructive to nuts, one attacking the kernels and the other the foliage. Remedies are free dressing of soil round the bushes with a soil fumigant during winter or early spring, and apraying with a good wash in May. Where bushes are badly infested with leafweevil the branches should be shaken over sheets of paper smeared with some sticky oubstance to catch the weevils as they fall. See Insecticide.

Nymphaea. This is the botanical name of the family of aquatic plants called water lilies (q.v.).

OAR: The Tree. The chief native British tree, Quercus robur, or the oak, is useful alike for timber and ornamental purposes. There are evergreen oaks and others, the bark of which yields cork. Ordinary trees for lawn and specimen purposes can be raised from acorns planted in autumn at a depth of about 6 in . When the trees are about 1 ft . in height they should be planted out about 1 ft . apart every way, and again transplanted, when the sturdiest specimens still survive.

The planting of oak trees in gardens is not recommended; it is a task for the forester in the plantation. An ocoasional tree to celebrate a coming of age or other festive event will be
quite sufficient for the welfare of an ordinary garden. Acorns gathered in autumn will germinate if sown during the following spring.

OAS: The Timber. There is no other wood equal to English oak in durability, hardness, toughness, weight and flexibility. It has great strength in proportion to its weight and is subject to very little warping and shrinking. If only one or two of these qualities are wanted to predominate, other woods can be found that are superior to oak in one or two respects, but are inferior to it in others.

A good proportion of oak is cleft instead of sawn, that is, it must be sawn across the grain but is split lengthwise. The cleavage follows the grain, and for many purposes the wood is stronger than it would be if sawn. The cleft pieces are not so straight as sawn ones, but they may be planed or turned and retain the advantages of
cleft wood. Wheel spokes and ladder rounds are made in this way. Pales for fences and hurdles are used roughly cleft, and rails for field gates are often cleft. Sawn wood, however, is cheaper than cleft.
No wood, except perhape mahogany, has been so much used for English funiture. Oak is also used in building. Rooms are occasionally panelled in oak, while in large houses and public buildings it is sometimes used for floors, staircases, doors and other interior woodwork. Oak contains
present this face. The silver grain seen in radial cuts is much more marked in oak than in any other wood. Cleaving should alwaye be done in the radial direction.

Wainscot oak means the same as quartered oak. Pollard oak has twisted and knottec grain, due to the tree having had its top and branches lopped.

Bog oak is found in Ireland in a fossillized state underground, still hard and sound but black in colour : it is occasionally used for veneer and for small fancy articles.
How to Polish Old Oak. There aro several polishes for old oak. One of the best is made wood around the metal.

Difference in Grain. In reducing logs to boards a large proportion of oak is quartered, that is, all the saw cuts or lines of cleavage are in a radial direction from the centre of the trunk, the same as the medullary rays. A $\log$ is treated in the first place as in Fig. 1, which gives eight radial surfaces. A thickness is sawn from each of these and then further radial cuts may be made on the remainder, or it may be cut in any way which happens to be most economical. To cut a log entirely in radial directions wastes material, because a number of comparatively useless wedges are left after pieoes of parallel thickness have been cut. Quartered oak, therefore, is more expen. sive than plain oak, for the amount of waste is a great deal smaller when a log is sawn in parallel slabs, as in Fig. 2.
The difference in appearance is shown in Fig. 3. At A in Figs. 's and 3 there are quar. tered surfaces, showing what is called the silver grain. At B and C the appearance changes, being farther a way from the radial direction and cutting at a tangent to the annual rings. The surface at A (Fig. 3) is preferred, partly for appearance, but mainly because the piece is supposed to be more tlexible and will shrink and warp less than that at C, besides which it is more waterproof. For the latter reason the staves for liquor casks are always cut to

Oak. Pig. 1. End view of quartered

of cutting logs to get dry, when it will be ready for the necessary repairs. The work corrodes iron and causes a dark stain in the must next be oiled with linseed oil and given
a coat of yellowish polish. When this is dry it should be rubbed with fine glass-paper, and any new wood shaded by mixing a little vandyke brown with yellow polish or gas black, if necessary. It should be laid on with a camel-hair brush. To remove the linseed oil, the whole of the work should be rubbed over with a little turpentine and should then be
wax-polished. with a little turpentine and should then be
wax-polished.
Use of Stains. Oak is brown of various shades, and in finished work its colour is often darkened or otherwise changed. It is easily darkened and improved in a number of ways. Oil may be rubbed into it for this purpose, or a solution of bichromate of potash and water applied, or it can be fumed with ammonia. Stains used are vandyke brown, burnt umber, yellow ochre and others, generally with am. monia. Brunswick black and turpentine make a brown stain. All these can be diluted to
make the shade required. Aniline dyes are a brown stain. All these can be diluted to used also, sometimes for other colours than

B. it should be mbin wine

Oak. Fig. 3. Oak cut longitudinally, but at diferent angles in relation to
Oak. Fig. 3. Oak cut longitudinally, but at diferent angles in relation to by dissolving $\&$ oz each of shredded beeswax and brown sugar in a pint of warm beer. This should be applied while it is warm and then allowed to dry on the wood, afterwards being polished with a soft cloth.

To restore dirty old oak furniture, it is well to clean it thoroughly first. This can be done by adding 1 lb . of American potash to 3 pints of boiling water and applying it with a swab made by tying a piece of coarse rag round a stout stick or lath. The hands must not be put into the mixture or the skin will be injured. After going over the work a few times it will be soft enough to be scrubbed off. This must be done with a fibre brush, not a hair brush. When all the dirt has been removed the work must be allowed the work must be all

#### Abstract

 rings and medallary rays of trank
the natural ones of wood. Care should he or varnish, but it inust not be lustrous, or the taken, when reproducing the oak colour for Jacobean style furniture or panelling, not to err on the dark side. The wood should show a rich brown finish

## Finishes for Oak.

Antique oak, as it is callerl, can be made by darkening the wootl, which must be straight.grained oak, with hurnt umber, or vandyke brown, or a mixture of both, or with burnt umber and drop black. Antique oak stain can be made from 1 lb . of raw umber, 2 lb . of vandyke brown, and $\frac{1}{2} \mathrm{lb}$ of drop black, all ground in oil. Mix them all with a pint of the beat brown japan, and thin the liquid for use with turpentine. Several coats of ammonia water will also give the antique appearance, which can be simulated in another way with a stain of iron filings in vinegar or with a concentrated solution of permanganate of potash.

Cathedral oak is another good finish; it slows best on white oak nicely preparcd. To make it the surface should first be glasspapered smooth, after which n stain made from 2 oz . of jermanganate of potash in two quarts of water should be applied. Let this dry, and then rub it over lightly with fine glasspaper. Give it another coat of the stain, and when this is dry glasspaper it again lightly and apply a coat of black filler. Wipe this off at once and let the work stand for the night ; in the morning glasspaper it lightly, and give it a coat of white shellac. When this is dry, glasspaper it lightly again and wax finish the oak. As the finish must be quite Hat, the wax should not be rubbed.

## Flemish Finish for Quartered Oak

Flemish oak finish can only be used on the best quarter-sawed oak. The wood should be glasspapered and then a coat of Flemish water stain applied. This is made by dissolving $\frac{1}{2} \mathrm{lb}$. of bichromate of potash in a gallon of water. Having been strained, this should be applied witl a briatle brush. When it is dry, glasspaper the oak again. Mix up some japan and droj black with turpentine, making it very thin, and give the work a coat of this stain. Wipe it off clean in a few minutes, and then apply a coat of orange shellac. After the work has stood for a few hours it should be smoothed up with glasspaper and another coat of shellac given. When it is hard it may be rubbed with pumice-stone powder. Flemish oak should never be finished with a lustre, nor should the wond pores be filled.

Mission oak can be produced in several ways, the idea being to show a dead black effect in the grain of the wood with a kind of grevish cast to it. The stain should be made from i lb. of drop black, in oil, and $\frac{1}{2} \mathrm{oz}$. of rose pink, in oil, thinned with a gill of good japan drier and $1 \frac{1}{2}$ pints of turpentine, the whole being strained through double cheese cloth. Japan colours can be used in place of oil colours, but in this case the drier must be omitted and a litile rubbing varnish added to bind the stain. It should be finished with wax.

For forest green oak mix together 1 lb . of chrome green and $\frac{1}{2} \mathrm{lb}$. of chrome yellow, both of medium shade. Apart from these, mix 3 pints of turpentine, a pint of raw linseed oil and a little gond white japan. Thin the colour mixture with the latter, and apply one coat of it to the wood. When it is dry apply to it a coat of white shellac coloured with a little turmeric and a few crystals of green aniline. This, too, should be finished with wax.

For silver-grey oak, make the surface perfectly smonth with sandpaper and then stain it with a preparation of silver nitrate, 1 part in 50 parts of water, both by weight. Apply two coats of this, then a coat of commercial hydrochloric acid, and when it is dry apply a coat of ammonia water of ordinary strength. If the work can be left to dry in the dark the effect will be better. The finish may be in oil
or varnish, but it inust not he lustrous, or the
cffect will be spoiled. Sce Fumed Oak: Furniture ; Graining; Hall; Panelling; Stain.
OATMEAL. For growing children oatmeal is a valuatile food, as it is rich in phospliates and promotes the formation of bone and the nerve constituents of the body; but it must always be given with discrotion, and be discarded for a time if it causes any apparent digestive trouble. For delicate persons or those pursuing sedentary occupations oatmeal is considered rather difficult of digestion, and if served to invalids it should be considerably thinner than for those in health, and on no account should butter be dissolved in it. Some people should never cat oatmeal at all in bulk, and if cakes or scones are made for them, a proportion of ordinary houschold llour should be mixed in with the meal.
Oatimeal con be cooked in many ways, the most common preparation licing porridge, but a variety of other (lishes can be made, and it is also employed for biscuits, cakes, scones, and puddings

Oatneal reguircs to be stored with care, and should never be used if it is stale or is im. pregnated with a strong taste of some article of food with which it may have come in contact. It should always be placed at once in a well-covered store-jar or a wooden receptacle, and it should bo examined frequently to see that it is in good condition
Oat Cake. To each Ib. oatmeal allow I pint hoiling water, with $\frac{1}{2}$ oz. salt butter or lard inclted in it to make the cakes crisp. The water should be noured over the meal, and the whole made up very quickly into a fairly stiff dough
Roll it out about as thin as a half-crown piece, form it into a round, and cut it across and across again. Balie the cakes on a girdle and. when they are a light brown underneath set them before the fire to dry and colour slightly on the top: also to induce the edge to curl over a little. When quite dry and crisp the cakes may be stored really for use.

A recipe containing a proportion of flour, more suitable for people who cannot take ontmeal in bulk, is as follows: $\frac{1}{2} \mathrm{lb}$. medium oatmeal, $\frac{1}{2}$ teaspoonful salt, $\frac{1}{4}$ teaspoonful cream of tartar, 4 oz . flour, 3 oz . butter or lard, \& teaspioonful bicarbonate soda, 3-4 tablespoonfuls milk. Mix all dry ingredients thoroughly, rub in the fat, and form into a stiff paste with milk. Bake as in previous recipe.

Oatmeal Biscuit. A good biscuit is made by mixing together $\frac{1}{2} \mathrm{lb}$. medium oatmeal, 4 oz flour, $\frac{1}{2}$ teaspoonful salt, and $\frac{4}{}$ teaspoonful bicarhonate soda. Dissolve 2 oz . butter in 3 tablespoonfuls of warm milk, pour this into the dry ingredients, and make the whole up into a dough. Set it aside to become firm, and then roll it out and cut it into biscuit sha pes: then prick each and bake them in a good oven about 6 min . To make these biscuits sweet add 1 to $1 \frac{1}{2}$ oz. castor sugar to the llour.

Oatmeal Cake. Small calies are made with oatmeal flour and golden syrup, from the following recipe : Sicve together lb . fine oatineal, $\frac{1}{4} \mathrm{lb}$. Hour, and $\frac{1}{2}$ level teasponnful bicarbonate soda, adding to then 2 oz . candied peel cut into small pieces. Into a saucepan over the fire put 4 oz . margarine, the same quantity of granulated sugar, and $\frac{\mathrm{l}}{\mathrm{z}} \mathrm{lb}$. golden syrup, heating them until the sugar has dissolved, but taking care that they do not boil When they have cooled, pour them into a well made in the centre of the oatmeal, etc., and mix the whole to a rather stilf consistency. Turn the mixture into some small greased cake-tins, and bake the cakes in a moderately hot oven for about 20 min.

Oatmeal Scone. Mix together 3 oz. medium oatmeal, 2 oz. flour, a pinch of salt, 1 teaspoonful cream of tartar, and $\frac{1}{2}$ teaspoonful hicar bonate of soda; rub in 1 oz . fat, and then add 3 oz . mashed potatoes. Mix these ingredients
well, adding enough milk to form a dongh; then turn the mixture on to a Houred boaid, roll it out about $\frac{1}{2}$ in thick, and cut it into rounds Bake the scones on n greased tin in a hot oven or on a girdle. They can then be buttered, and caten hot or cold Sec Gruel;

## orridge ; Scone

OBESITY: Its Treatment. The abnormal development of fat throughout the body produces ohesity, and an excess of fat is a menace to health. Nornally fat is chiefly found under the skin, under the membrane lining the abdomen and covering the bowels, and between the muscle fibres. Any large increase of this fat is nssociated with weakness of the muscular tissue. Hence arises sluggish action of the bowels and inability to take much cxercise on account of the state of the muscles generally, and because shortness of breath and palpitation are easily induced through enfeeblement of the heart muscle. Stout neople stand acute diseases badly. There is a tendency for any individual to put on fat after the age of 40 , more capecially women. But the condition is largely due to over-eating and over-drinking, combined with too little exercise.

A person who is in danger of becoming stout should increase his outdoor exercise, and restrict his intake of fat-forming fonds, i.e. fats and carbohydrates, especially the latter, e.g. sugar, bread, milk, milk puddings, malt liquors, and sweet wines. He should be sparing in liquids at meals. Green vegetables may be taken frecly.

When an unwholesome degree of corpulence already exists, vigorous exercise may be impossible, and to begin with gentle walking on the level may be all that can be attempted. As the powers increase, the rate should be faster and the hills should be taken. In some cases it may be desirable that a course of massage should precede or supplement cxercise out of doors. In thesc cases, a strict diet must be prescrihed and sustematically followed.

After the patient's weight has been reduced one or two stones or so, a special diet which he can keep to indefinitcly should be devised. This should be moderate in amount, with no potatoes or sweet foods, no sugar in the tea or coffce, and a minimum of bread-about 4 oz . In place of sugar in the tea or coffee saccharin tablets, which can he obtained from any chemist, may be employed. Fatty meats, such ns goose and pork, also salmon, cels, and herrings should be strictly forhidden.
The diet, however, should include plenty of such vegetables as cabbage, spinach, etc., as on account of their bulk they give a sense of satisfied appetite, Peas, broad beans, lentils, carmots, parsnips, and beetroot should be avoided. Alo, beer, stout, sweet wines and spirits should be given up entirely.

Artificial nostrums should be avoided and drugs are only to be taken on medical advice. Some of those popularly recommended are useless, others are harinful. A Turkish bath may be useful, but must only be taken after the patient has been examined by a doctor as to his fitness for it. See Diet ; Exercise.

OCCASIONAL TABLE. By this name is understood tables that are only used occasionally and for casual purposes, being thus the opposite of dining tables, kitchen tables, and others that have a definite use. They are generally small and light, so that they can easily be moved about, and are chosen to suit the other furniture of the room. Nests of three or four tables are useful and obtainable in lac quered, painted and polished voods. When not all required the largest of these tables gives accommodation for bnoks and Howers, etc., the smaller sizes being neatly stowed a was under. neath it Low tabler are convenient for uso heside a settee or divan; Moorish designs look well with oriental surroundings and small gate-leg tables are popular for oak furnished
rooms. Reproductions of the table illustrated are suitable with mahogany furniture and are particularly graceful in shape. See Gate. leg Table : Table.

ODONTOGLOSSUM. One of the most benutiful orchirls, this is suitable for cultiva tion in a glasshouse having a minimum winter temperature of 45-50 degrees. During summer cool moist conditions, ensured by free ventila. tion, shade from sunshine and syringeing between the plants, are necessary. The pots should be filled to the extent of one-third their depth with drainage: a suitable compost consists of orchid fibre, peat and sphagnum inoss in equal parts Repotting is done in February or towards the end of summer; the peeudo-bulbs must be set on the surface of the compost.

Odontoglossum crispum and its varieties, which are heavily blotched with various colours on a white ground, are particularly beautiful, the long arching sprays of bloom being most decorative. Other easily grown kinds are harryanum, Rossii, luteo-purpureum, grande and citrosmum. Innumerable crossbred or hybrid odontoglossums are raised an-
OCTOBER

## What to do in the Garden

## Flower.

Plant hyacinth, tull $p_{2}$ daflodll and other springflowering bulbe in beds and borders
llant wallfower, for-get-me-not, polyanthus and other spring-flowering plants
Lay down turf to make a new lawn

Prepare the ground for rose trees by digging deeply and manuring

Lift and atore tuberous begonia and dahlia as soon as the plants are spolit by froat

Plant border carnation, sweet william, Canterbury bell and bulbe of Spanish and English irises
Sow sweat peas in pota Sow sweet peas in pots garden frame Take cuttings of leatloaing surndy soll out of doors

Insert cuttings of evargreens In sandy soll in a frame or on a sheltered border

Lift nummer bedding plants and place in pote or boxes of soll under glass to supply cuttings In spring

Move Chinese primula, cineraria. and herbaceous calcoolaria irom the frame to a greenhouse Lift and repot arum Illies and place under glass

Pot spring-flowering bulbe, set them out of doors and cover with old ashos for 6 weoks
Re-arrange and repiant the hardy flower border

## Fruit

Gather applea and pears on dry daya only Lift. root-prune and replant frult

Take off runnera rom atrawberriea and manure between the
Cut out old frulting nea from raspberriea Take cuttinga of goose berries and curranta and set in sandy soll out of doora
prune black-ourrant bushes by cutting out old branches or parta of them
Prune loganberries and blackberries by outting out the canes which have borine frult

Notes for the Month

Ocrobge 1.- Pheagant shooting begins
OCTORER 21.-Trafaigar Day
Ootorer 31.-Hallow-0 on

To ripen late grapee ventllate the glasshouse ireely, keep the hotwater plpes uarm and the atmosphere dry

## Vedetablea

Lift and store beetroot, carrot and late potatoes

Dig and manure all vacant land, leaving the surface rough

Lift and force rhubarb roots for an early supply of produce
plant lettuce and endive in a cold frame Plant apring cabbages as and place in a box in a warm room to ripen in a warm room toripen Lime land which if in fected
disease

Look over potatoes in are and remove decay ng tubers
Burn the haulm of potatoes to deatroy dis ease apores
Complete the earthing pof celery
Sow seedn of Brussels prouts in a frame
Pot caullfowers and keep them in a frame for

nually, and these are now chiefly grown : the flowers are of brilliant and fascin. ating colours. Orchid growers' catalogues should be consulted. See Orchid.

OFFAL. The term includes the heart liver, kidneys, head, tail, and most edible pieces of an animal killed for food which are not sold in joints. In fish, ofial denotes low grade and very inferior fish. See Heart: Kidney: Liver.

OHM. The chief unit of electrical resistance is the ohm. It is that resistance which will limit the current produced by a pressure of one volt to one ampere. Other units are the megohm (a million ohms), and the microhm (one millionth of an ohm). See Electricity

OII: For Domestic Use. The grade of mineral oil mainly used as fue in the house is that known as kerosene or paraffin oil. The heavier grades of petroleum known as fuel oil are used to fire domestic boilers and to a limited extent for cooling purposes. A steam or air jet is required to atomise them before burning and a gravity or pressure fced is necessary.

Kerosene can be applied practically to all the domestic heatinf ${ }^{\prime}$ and cooking purposes to which
coal gas is put, and it has the advantage that the applinnces employed in burning it are self-contained and do not involve the installa. tion of permanent piping. For heating, various forms of oil stove can be purchased. Needing no Hue, they can be moved about from place to place as required ; and as all the heat they produce passes into the room, they are very efficient and can warm the air of an apartment to a comfortable temperature in a very short time. On the other hand, they do not ventilate the room, and the products of combustion are not carriod away. Further, the effcct of such stoves soon dies away after they have been extinguished
For cooking, oil-burning appliances are made in many sizes, from single-burner stoves that serve to boil a kettle up to those with an oven and several burners which will boil, steam, fry, and bake and perform every cooking operation required. Representative types are illustrated in the artiole Cooker.

The burners fitted in oil heating and cooking appliances are of two kinds. In one the oil is sucked up from the reservoir to the flame by means of wicks, either straight or circular, which resemble those employed in lamps except that they are larger. In the other form the oil, bv a slight pressure produced in the reservoir by a hand pump, is forced up to a point above the flame, and after being vaporized by the heat passes to the burner, where it is mixed with air and burnt as a gas. In this form there are no wicks, and consequently the trouble of trimming is avoided. Oil stoves of any kind must be kept scrupuloukly clean.

With the pressure type of burner, the nozzle through which the vaporized oil issues before being burnt has first of all to be heated up (usually by burning a small quantity of methylated spirit in a small trough surround. ing the burner), before the issuing oil will ignite. Also the pressure inside the oil container has to be pumped up before lighting up, and from time to time during use, in order to force the oil out through the nozzle in a fine spray. Fig. 1 shows a pressure type heater in which an asbestos mantle is raised to a high degree of incandescence, a copper reflector projecting the heat out into the room. It holds 14 pints of oil, which is enough for ten burning hours.

Of the wick burner pattern the heater illustrated in Fig. 2 is typical. It consumes about half a pint of paraffin per hour. If the wick of this stove is kept free from carbon deposit (which can be rubbed off with a piece of newspaper every time before the stove is lit), and the burner kept clean, there is very little danger of smell, and the stove needs no special atten. tion when starting up or burning.

Smalloil engines are useful as a means of providing power for such purposes as driving electric generators or pumping water from wells. In the article on Internal Combustion Engine is illustrated type which is started up on petrol and then runs on paraffin oil.

Oll. Fig. 2. Dsefal wick type beating stove. It consumes aboat ball a pint of parafin oil per bour

Anolo-American Oil Co., Lid

Oil Fuel for Boilers. 'The use of fuel oil for central heating and hot-water supply presents a number of oulvantages, apart from the question of cost, in which latter respect fuel oil at about 75 s per ton compares with coke at 35 s per ton A fully automatic system can be arranged, controlled by thermostats. Therc is a saving in labour, of course, since no stoking is needed nud there are no clinkers or ashes to

volving at high speed, and is thrown off the edge in a finely divided spray The air necessary for combustion is sup plied by a fan, driven by a small electric motor Fig. 6 shows the burner fitted to a central heating boiler. The oil feed is by gravity, from $\Omega$ storage tank (capacity 3(H) gallons) a few feet above the burner level. When arranged for automatio control the ignition is by means of an incandescent electric element at the nozzle, which is switched on and off by thermo static control.

A burner of the pressure jet cluss is illus trated in Fig. 4. Oil is fed under pressure through an stomizing nozzle and issucs as a fine snray, being mixed with air supplied by a blower. A smal electric motor drives the oil pump and blower, and a transformer furnishics the high voltage ignition ourrent. The apparatus once startex, is sutomatio in action, and needs no attendance. A thermostat in the flue sluts off the ignition current as ooon as the burner is alight and functioning regularly Another thermostat. connected with the boiler, shuts of the apparatus when a pre arranged water temperature is reached, and a room thermostat in one of the apartments switches off the burner when the desired room temperature is attained. A temperature drop of from two to ten degrees (as pre arranged) causes the switches to be operated in the reverse manner, so that the burner is. started up again and the atomized oil spray simultancously ignited.

Householders who desire fuller information about oil fired boiler plants should write to the fuel oil department of Shell-Mex, Ltd. P.O. Box 148, Kingsway, W.C.2. This firm does not supply oil burning equipment, but maintains a stall to advise intcrested persons on the selection of appropriate equipment See Conker : Fuel: Heating : Lamp: Lighting
remove Fuel oil can be hought economically in lots of two tons (approximately 500 gallons), and costs from 3 dd to $4 d$ per gallon. A atorage tank holding 3 tons is desir. able, and this if rectangular in shape would be about 6 ft . by 5 ft . by 4 ft . The tank need not be indoors, but can be located in some corner of the garden and screened by a hedgo, ets. Delivery from the oil wagon is carried out in a few minutes, the oil being pumped direct into the consumer's tank
Two representative systems are here illus. trated. Fig 5 shows a hand-operated oil burner working on the rotary principle. a system which is applicable to quite small installations. In this type of burner the oil is delivered into a cone shaped cup re-

OII: In Cookery. Olive oil is the best of all oils for the purposes of cookery. When pure it is practically tasteless and of a pale yellow colour with $n$ slight tinge of green Only the best quality should be employed Olive oil is the foundation of mayonnaise sauce and most salad oreams. It also enters into the composition of dressings for plain salads. It renders fritter batters exceedingly light, and is often used for the purpose of fry ing. In Jewish cookery oil is always used.

When moulds or slabe have to be greased in sweet-making oil is employed. Creams and delicate

Fir. 6. Ray Midget burner fitted to central heating boller dinner sweets areset in oiled moulds. Almond oil may be used in place of olive oil for this purpose. Oil of any quality or description is not adapted for making pastry or good cakes, but fish may be preserved in oil. If oil has been kept in store some time and has deteriorated it can be improved by turning it into a larger hottle and pouring upon it cold water, then shaking it vigorously and letting it stand two hours. When decanting the oil the rancid matter is detained by the water
OIL: In Medicine. There are two distinct classes of oils. The tirst consists of the fixed oils, such as linseed, flaxseed, olive, nimond coconut, castor, cod liver, and other oils Except for cod liver oil all these are of vegetable origin. The second class consists of the essential or volatile nils, including the oils of peppermint, cloves, caraway, oinnamon, lill, lemon, juniper, rosemary etc.
Some of the fixed oils are nourishing foods, and most of them form soothing applications to inflamed surfaces. Others are valuable medicines, e.g. cod liver oil in consumption and other diseases. The essential oils, which are distilled from plants, stimulatc the appetite and promote digestion, or act as an anti septic. See Castor Oil : Cod Liver Oil : Linseed Oil, etc.
Oilcloth. See Linoleum
OILING. Suitably prepared oils are employed for lubricating machinery of all kinds, and oil serves also as the vehicle for many semi-liquid lubricants. The oiling of domestic appliances is dealt with in the article on Lubrication, which is followed by one devoted to the oiling of motor vehicles See Grease ; Lubrication: Motor Car.

OILSKIN. Cotton cloth coated with boiled linseed oil and dried takes the yellow appearance of a cured animal skin and becomes waterproof and airtight. Seamen's overalls made frmm this material arc called oilskins. They are stiff and heavy, and cold to the touch

Lighter oilskins made in oiled silk are translucent and made into women's wetweather coats. The fabric is lighter in weight and dyed in pretty colours, hit it tends to tear easily. Efficient ventilation is a difticulty, as body moisture condenses upon the underside of the cold, wet garment Oiled silk is used for hathroom curtains.

OILSTONE. Various kinds of hard stone, composed mainly of silica and quartz, when smoothed and polished and suitably mounterl are invaluable for sharpening knives and tools of all kinds. Oilstones are usually luhricated with machine oil; in a few cases water is used for the purpose.

For the amateur, who will mostly use the oilstone for sharpening chisels, plane irons, gouges, and the like, the Wrshita stone is as good as any. A convenient size is a bout 9 in . long, 2 in wide, and 1 in thick. The stone should be fine in grain, frec from cracks or hand places, and should cut freely and not exhibit any tendency to choke readily. These features are only detected when the stone has been in use for a time; and when a good stone has been found, it should be retained and used until it is entirely worn out. A liner-grain stone, known as the Arkansas. is also a natural stone. It is more expensive than the Washita, but more useful for sharpening delicate tools requiring a very keen edge

Rougher oilstones, such as the India, are made of various compositions, employing emery and carborundum; they are very quick cutting. A carborundum stone will cut almost as quickly as a fine file, and if much work is to be done, it will pay to have one of this class of stone for rough sharpening, and a finer-grained stone for the setting and finishing-off touches For sharpening gouges, a

Fig. 4. Showing use of oilstone slip for sharpening edge of hollow-ground gouge
sistent with easy sharpening, as the longer the cutting edge, the keener will be the tool After the stone has been in use for a time it becomes hollow in the centre and generally rough towards the ends, and will then require rubbing down. This can be donc by grinding, holding the oilstone against the side of the revolving grindstone and luhricating it with water and a little sharp sand.
What are known as ragstones are a rough sort of whetstone, and the coarsest $k$ ind is the sandstone, with which gardeners sharpen scythes. This is an example of dry sharpening. See Grindstone; Hone: Knife; Kazor.

OINTMENT. A preparation that has the consistency of butter and is intended to keep some inedicinal agent in close contact with a skin or other surface is called an ointment. The hasis may be lard, lanoline, vaseline, cocoa-butter, goose fnt, or a mixture of one or more of these with sweet almond oil, olive oil, g'ycerin, sjeermaceti, wax, suet, etc. Water is added for the elled slips are ob tainable, shaped to suit the curva
ture of the gouge. Diagonal shaped stones, square, and tapered slips, as they are called, are also a vailable for appropriately shaped tools.

Using the Stone. The whole secret of tool sharpening consists in rubbing the tool on The stone so that the cutting ellge is formed at the right angle. Figs. $1-3$ illustrate the correct methods of holding a chisel, plane iron, and gouge on an oilstone In the case of the chisel, this is first ground on a grindstone to the proper angle, and then the extreme end, or cutting edge of the tool, is sharpened on the oilstone by rubbing the chisel on the stone, using the greatest length of the stonc
and pushing the chisel backward and forward with a regular, steady motion.

Press upon the chisel with the fingers of the left hand, while the right hand guides the direction of the tool. If the chisel is allowed to mok a bout the cutting edge will he rounded instead of Hat, with the result that the tonl will not hold its erlge for any length of time The great object should be so to sharpen the edge that the end of the chisel is straight and square with the sides, but the face in clined at a slightly steeper angle than the other hevelled portion produced by the grinding process.

The plane iron is sharpened in a similar manner, except that, as it is much broader it inay be necessary to sweep the imn diagonally across the stone, so that all the parts receive their full share of it. The gouge is sharpened by rolling it to and fro, and at the same time traversing it up and down on the face of the stone, thus sharjening the whole of the cutting edge. In general, when sharpening cutting tonls, keep the handle as low down as is con-
 I.

 is solinght when necessury. Sleeplessness hypnotic drugs must be used with great caution.

An old man or woman requires only a sniall quantity of food compared with a young and active adult. As age advances the quantity of food taken must be diminished, or otherwise indigestion, rheumatism, skin troubles and other penalties will have to be paid. In middleaged and elderly people all the organs work less actively than in the vigorous period of life.
The food should be light and given in small quantities. As a rule four light meals a day should be given. The principal meal should be taken in the middle of the day. Although the diet should be varied, not more than two, or at the utmost three, dishes should he partaken of at anyone menl. Most old people should eat vegetnbles sparingly, as thcy are apt to cause fatulent indigestion Fruit is most suitable in a cooked state. If eaten raw, it should be perfectly ripe. If inclined to put on fat, an elderly person should be sparing in the use of sugar, starchy foods, and fats. Oatmeal is too difficult of digestion, but on the other hand the prepared or patent wheaten foods are especially suitable.

An old person should depend largely on milk for his nourishment This he should take in sips, spending about 20 min . in drinking a half pint. If stimulants are taken at all, the quantity should be small-not more than $n$ single glass of the stronger wines, or two glasses of a light dinner wine, or a little whisky or hrandy well diluted. The heat time to take any of these is at dinner. Sometimes, a tablespoonful of whisky in hot milk at bedtime will prevent sleeplessness. See Diet; Sleep.

OLD AGE PENSIONS. In Great Britain most persons are entitled, on reaching the age of 70 , or in certain cases 65 , to receive an
uld age pension. The amount of this is normally 10s. a week, but those with a certain amount of unearned income are only entitled to smaller sums Normally the pension begins at 70, but persons who have insured under the national health insurance scheme and their wives are entitled to pensions on reaching 65, without any inquiry as to their other means.
To be entitled to a pension at the full rate a person's income inust not exceed $£ 2058$., or £52 10s. in the case of husband and wife living together, but in arriving at this figure no account is taken of the first $£ 39$ of unearned income, or in the case of a married couple the first $£ 78$ Thus, a person with a total income of just under $£ 655$ s. a year or a couple with just under $£ 130$ 10s can receive old age pensions at the full rate.

I'ensions below 10s a week are given tu thuse whose incomes, after the first $£ 39$ has been deducted, are as follows:
Between $£ 20358$. and E 31 103

## $\begin{array}{ll}£ 31 & 108 . \\ \text { £38 } & 158 .\end{array}$ <br>  <br> ${ }_{\text {£ }}{ }^{247}$ 5s.

88. Od. per week

| 447 | 58 |
| :--- | :--- | :--- |
| 49 |  |

In the case of a married couple living logether, these sums are doubled.
To receive a pension a person must have been a British subject for 10 years, and must have resided within the United Kingdom for at least 12 years since reaching the age of 50 . A British subject is defined as a person born in the United Kingdom, or the child of a British father, or a person who has taken out a naturalization certificate. Persons who receive outdoor relief can also receive pensions, but indoor paupers are not eligible, nor are persons who have been treated in a poor law infirmary for any period exceeding three months in one year.

Blind persons are entitled to receive pensions when they are 50 years old, the conditions being similar to those for others at 70. To secure a pension on this account the person must be so blind that he or she cannot perform work for which sight is essential.
Estimation of Income. In eatimating the income account is taken of the income the person is likely to receive during the succeeding year and of the yearly value of any advantage or benefit enjoyed by him, such as the right of living rent free. No account, however, need be taken of the yearly value of any advantage accruing from the use or enjoyment of furniture or personal effects or of the first $£ 25$ of capital in possession of the claimant. The next $£ 375$ of capital is regarded as earning interest at the rate of 5 per cent., and all capital in excess of this at 10 per cent. In the case of a married couple living together these figures are doubled.

When a husband and wife are living together in the same house the means of either is taken as one-half of the total means of the couple. Thus, a man who has an income of $£ 50$ a year is entitled to the full pension if he has a wife living with him who is without separate income, or if the incomes of the two do not exceed $£ 5210$ s. a year. Old age pensions cannut be alienated.
Method of Application. The conditions outlined above permitting, the first step is to apply for the necessary forms at any post office. These must be filled up by the claimant and the statements made attested by reliable witnesses. They should then be returned to the postmaster of the post office where the pensioner wishes to receive his pension, or to lis lical pension officer.

The pensions are paid every Friday at the various post offices, generally to the pensioner in person, although a relative or friend can receive them in case the pensioner is unable to get about. The pension book must be presented and stamped each time. In each locality a pensions officer controls the dis-
tribution of pensions, and to him all com plaints in connexion therewith should be made. He is also responsible for investigating cases

Ireland was included in the scheme of old age pensions, but this liability was transferred in 192: to the Parliaments of the Irish Free State and Northern Ireland, who now pay them. Australia and New Zealand have also old age pension schemes. See Insurance : Pension.
OLD MAID. This card game is suitable for two or more players. One card is taken from the full pack, usually a queen; a variation is to take out one card haphazard, the

Oleander. A favourite greenhouse and conservatory shrub which bears rose-coloured blooms in summer
card not being shown. Supposing, however that a queen is removed, the cards are shuffled and dealt round one at a time to all the players until the pack is exhausted. Each player then looks at his cards and throws out of his hand into the centre of the table all pairs, e.g. two kings, two sevens, etc.

When all pairs have been thrown out by each player, the one on the left of the dealer offors his cards, face downward, to his lefthand neighbour, who can draw any card he chooses. If the player draws a card which pairs with one in his hand he throws the pair so made into the centre of the table; if not, he places it amongst the cards he already holds, and offers his cards in turn to the next player to draw from, and so on.

In the course of time all the cards, except one queen, are paired. It is the object of each player to try to pass this queen on to the next player. The holder of the unpaired queen is old maid. With the variation of discarding any unknown card no one has any idea of which card in the pack will make him or her old maid, and this form of the game is often preferred.

OLD MAN. This is one of the many names of the slirubby perennial artemisia. It has fragrant foliage, and is known also as lad's love, wormwood, southernwood, and by many other names. It is an old-fashioned country cottage garden plant See Southernwood.
OLD MAN CACTUS. A member of the Pilocereus group of cactaceous plants, and one of the most popular in small collections is $P$. senilis. This name, in conjunction with its remarkable covering of long white hairs, has made it familiar as the old man cactuo See Cactus.

OLD MAN'S BEARD. This is one of the popular names for Clematis vitalba, which is

Pamiliar in British hedgerows and also known as traveller's joy. Its roots are in demand as a stock upon which to graft the ohoicer kinds of clematis. It blooms in July and beara large clusters of greenish-white Howers. The seeds are provided with long hairs which become covered with a soft pale grey Hluff, from which the jlant takes this name. Old man's beard is useful for covering bare banks or for training over trellises and tree stumps See Clematis.

OLEANDER (Nerium oleander). This is a beautiful flowering shrub suitablc for cul tivation in pots under glass. A temperature of 45-50 degrees is high enough in winter: its rose-coloured blooms are borne during the summer months. It should be potted in pots or tubs of loamy soil enriched with decayed manure. During the summer months the oleander requires an abundance of water, and must be fully exposed to the sunshine in order that the stems may be well ripened The oleander often fails to bloom well because of the neglect to remove the shoots, while they are small, that develop at the base of the Hower buds. If allowed to remain they grow and the flower buds perish. This shrub flowers most freely when well rooted in the pot or tub: weak liquid manure should be given occasionally in summer.

OLEARIA. This is the name of a group of evergreen shrubs of which the favourite kind is Olearia Haastii. This reaches a height of 3 or 4 ft . and bears white daisy-like flowers in August. It makes a useful ornamental garden hedge as it is of compact growth Olearia stellulata, 2-3 ft., bears white flowers in early summer; it blooms very freely in a sheltered place in mild districts, but it is less hardy than Haastii. Olearia macrodonta, a more vigorous shrub, is suitable only for the milder counties of England. These, shrubs need no pruning other than that required to keep them shapely, which should be done after flowering. Propagation is by cuttings in a frame in summer.

OLIVE : The Shrub. A group of evergreen trees and shrubs is called the olive. It includes the common olive (Olea europaea), which is a distinctive feature of the landscape in southern Europe, and may be grown in this country only in mild places or against a wall in other gardens. The olive oil of commerce is obtained from the fruits. Propagation is by means of cuttings or seeds.

Uses of the Fruit. The green fruit of the olive yields olive oil, and is, also pickled and sold in bottles and tins for cooking purposes. The oil, which is contained in the flesh, and not in the stone of the olive, is the very finest which can be used for all purposes of cookery. It is excellent for, dressing salads, frying, making light batters, and for preparing entrées.

Stuffed olives make an appetizing dish for hors d'oeuvres. Spanish olives should be used, as the Italian variety is small and more oily to taste. Various mixtures can be prepared for the filling, which must be of a savoury character, or a savoury butter can be used. To prepare the olive for stuffing or cooking by other methods, it must be stoned or turned. To do this, start from the top and pare it round and round, using a small, sharp-pointed knife and shaping it like a spiral. Keep the knife close to the stone all the time to avoid losing the Hesh. After the stone is removed and the filling inserted, form the olive into its correct shape again. A special fruit stoner, which is scissor-shaped, holding the olive in a metal circle and cjecting the stone by means of a prong, can be obtained cheaply. The stuffing is in serted in the cavity.

A good way of preparing these savoury olives is to fill them with anchovy butter and
serve them on small, thin rounds of bread and butter, each about the size of a two shilling piece. Shell 2 or 3 hard-boiled eggs and separate the whites from the yolks, chopping up the former and rubbing the latter through a sieve. Spread some of the yolk on the rounds of bread and butter, press an

Oliv: Savouries made witu nara-oolled egrs, olives and small rounds of bread and butter
olive on each in an upright position, and garnish with the ehopled white

Olịves à l'Indienne provide another way of preparing stuffed olives Cut a hardboiled egg into halses, remove the yolk, and slice the white into rings. Pound thic yolli with 1 oz butter, a teaspoonful of mustard and 2 oz chutney, and use this mixture for filling the stoned olives. Cut some brown bread into small rounds, spread any remaining stufling over them, place a ring of white of egg on each, and put an olive in the centre. Arrange them on a glass or silver dish See Anchovy Butter: Hors d'Ucuvres

Olive Oil. By pressing the ripe Iruit of the olive tree olive oil is obtained It is a valuable food, and is also a mild aperient. For people who suffer from mild constipation, a tablespoonful taken every night will often prove most lenoticial. As an enema it is very useful for constipation with tho presence of hardened faeces in the bowel. Large quanti ties are sometimes given to people suffering from gall stones. For burns and scalds olive oil is one of the best remedics for immediate use when the slin is not brolien.

OLIVINE. The word olivine is used to deseribe a large number of stones of the semiprecious variety, among which are the chrysulite and peridot. Usually they vary in colour from straw yellow to dark yellowish green, but the best specimens are of a rich green hue

OLLA PODRIDA. The Spanish national dish linown as olla podrida consists of a stew made with fresh and salt meats, poultry, and vegetables, all cut small and highly tlavoured with garlic and pepper. The whole is stewed for a considerable time in a closed pot or iar.

OMELETTE. An omelette is a preparation of egga fried in a amall pan with butter, and served either as a sweet or savoury. Success depends largely on the dexterity with which the pan is handled as well as on the quality of the ingredients and the way in which tho egga are beaten. The yolks and whitea should be well mixed but not frothed except in the case of the soufté varieties. The best pans for the purpose are those with slightly sloping sides, and the pan must not be either too thin or tou large If it is too thin the omelette will burn before it is conked through, and if it is too large tho mixture will spread like a pancake The omelette pan should be kept for omelettes only, and should not often be washed out. Rub it with soft paper to clean it. The egga should bo new laid and the butter perfectly fiesh.

If a savoury omelette is made, with the addition of meat or fish, this must be ready cooked and seasoned and all bones removed When the omelette is nearly tinished tho savoury mixture is laid on it, and the sides folded over with a Hexible or palette hnife. Checse or tine herbs are mixed in with the cerrs. For kidney omelettes the kidney is first chopped up finely and cooked 10-15 minutes in butter before putting in the centre of the
plain omelctte It shalluts are used they must always be chopped and fried tirst of all. Three or four eggs nay becooked in a 7 -in pan, and 2 eggs should be allowed for each person

The most appruved method for making omelettes is to heat 2 oz butter in the pan till smoking hot, then pour in 4 eggs well beaten and scasoned if for savoury omeletto Sti, thom and as they begin to set and brown underneath, fold over the side of the omelette near the handle of the pan into the middle then fold over the other side, making an oval cushion shape Add meat, lish, kilney mushrooms, etc. tefore folding for savoury omelcttes 'lurn it on to a hot dish.
Sweet Omelettes. Thesc are made and Iried as savoury omelettes, but $\frac{1}{2} \mathrm{oz}$ sugar is adderl to the ergs instead of scasoning and jam is laid on the umclette before folding When dished sugar should be sprinkled over Use a stiff lind of jam . Lemon omelettes are made by adding lcmon curd instead of jam For rum oneleties the spirit should be poured over just before serving, and lighted
A gond-sized omelette can be made by breaking 2 eggs into a basin, beating them slightly, and then adding teaspooonful of chopped parsley, and some salt and pepper to taste. Melt $\frac{1}{2}$ oz butter in an omelette pan pour in the egg mixture, stir it for a few secunds, and as it sets, lift it up and allow the liquid portion to How to the bottom of the pan Lift this again. and then double the omelette over and slip it on to the paper doily arranged on a hot dish The omelette should be quite soft and Haliy in the middle. It can be varied by adding a tablespuonful of grated cheese, chopped cooked ham or meat, or couked and seasoned tomato, or cooked tish, liaked and seasuned, or coolied mushrooms immediately before it is doubled over.
Friars' Omelette. This is made with a purée of apples sweetencd and ila voured, then butter and eggs mixed in, $1 \frac{1}{2} \mathrm{lb}$. apples requiring 2 oz . butter and 2 eggs Butter a baling.dish and coat it with a thick laver of breadcrumbs. Pour in the purce, cover it with another thick layer of crumbs, strew over it small pieces of butter, and bake it for 15 min in a moderate oven Serve the umelette with crean and sugar. It will be found sufficient for 4 persons.

Omeiette Souflle. To make omeictte souffic work togother the yolks of 4 eggs and 3 oz . castor sugar until they torm a thicli yellow cream then add $\frac{1}{2}$ oz. Hour $\frac{1}{2}$ teaspoonful vanilla and 0 stiflly beaten whites of eggs. Puur the mixture into a well-buttered augratin dish and bake it in a moderate oven for 10-15 min or until it is pale brown in colour and spongy to the touch Dust it with castor sugar and serve it immediately A !ittle jar may be put in the centre of the souffle befors it is bakeal See SoulHé

OMPHALODES. These are annual or perennial plants with forget-me-not-like Howers. Nust of them are auitable only for the rock garden The chief kinds are cappadocica 12 in : nitida 12 in verna 6 in. and lusiliac 6 in All have blue flowers They need slight shade and well-drained, gritty, sandy loam During winter they should be protected by pieces of glass raised a few inches above them to keep of excessive rain Propagation is by seeds sown in spring Omphalodes linitolia is a hardy annual. 8-10 in. which bears white flowers. Seeds are sown in the rock garilen in spring tor summer flowers All bloom carly in summer

ONCIDIUM. This is the name of a slow y group of orchids some of which must be grown in a hot house, while others flourish under the same conditions as oduntoglossum (y.v.). Tho prevailing eolour of tho llowers of many kinds is yellow with reddish brown marlings. Tho plants must be watered sparingly after the year's growth is linished Kramerianum and papilio are favourite sorts for the hot house : concolor, varicosum and marshallianum are among those suitable for the cool house

ONE STEP. The one stcp is similat to the quickstep in construction, but is danced to 2-4 instead of common time. Sonic of the steps in this dance may be used in the one step, but owing to the quicker time the simplest ones are best. The dancing should be very smooth. The three step turn is used, that is, turning on every third step, both to the right and reverse As in tho quiclistep, the man begins with the right foot and the girl with the left. Sec Dancing; Fox Trot : Quickstep.

## Onions: In Garden and Kitchen

The Growing and Cooking of this Useful Vegetable

For additional information on this and kindred subjects see the article Kitchen Garden also Chive: Flavouring: Garlic: Goosz; Leek. Pickles; Shallot; Vegetarian Cookery

The culture of this vegetable is not difficult if the soil is suitable, but for good results a deep rich loam is necessary.

In preparing the soil, the best manure is undoubtedly well-rotted stable manuro, ap. plied to the ground in the autumn before cultivation commences. Soot, soon after sow. ing, and nitrate of soda when the plants malie their appearance, are also recommendel as stimulants. A dressing of salt applied a fort. night before sowing, and dug in if the rain has not already washed it in, is alan a useful aid If the soil is light, cow manure is necessary.

The main cropl of onion seed should be sown in March, choosing a day when the ground is as dry as possible. It should be put in in drilla or rows about 9 in. or 1 ft. apart, and lightly covered with soil. After sowing, however, the surface of tho soil must be dusted with soot, and pressed down firmly by a light rollor.

A second sowing of onions should be made in August, when the method of procedure is similar. As soon as the young onions are large enough they should be thinned out. The thinnings are useful as spring onions. the plants should be left at 6 in. apart.

For pickling onions, seed may be sorrn in May, in ponr suil 'Thinning need not be drastic, and the bulbs will be ready for pulling by the
autumn. The crop of ordinary onions will be ready for handling about the middle of September, when they should be taken up, cleaned, and put in a dry shed or sunny prosition in the onen air, if the weather is favourable, until thoy are ready for storing.
Thero are many different sort of onions Ailsa Craig is one of the best as regards shape, size, flavour, and kecping properties Otheis for various uses are Lemon Rocca, Giant Rocca, and 'Tripoli, usually sown in August. White Sjanish, Nuneham Park, James Long Keeping, l'remier and Cranston's Excelsior. are suitable for spring sowing.

Gathering the Onions. The time which is best for gathering onions is about the middlo of Septenber, when the tops hegin to wither and the plants can be pulled up easily. They must be laid out to dry in a cool, airy place, and then mado up into reeves. This is done by fastening the tails together with a strand oi matting, and forming them into a rope with the onions appearing in even rows all along. This rope should be about I yard long, and is called the reeve. It can be hung in a corner of the larder for convenience. Onions keep better when reeved.

Diseases of Onions. One of the chiel diseases of onions is known as the white rot. In sone

Onion. Weil-grown bulbs of a variety of this aseful and antartions vegetable
parts of England it is called mildew and in Bedfordshire it is mouldy nose. In Leaflct 345 the Ministry of Agriculture deals with the best method of combating the disease. Widely distributed throughout the country, it is specially common where onions have been cultivated for a long time. During the early months of summer it causes much destruction, both to spring and autumn sown plants.

Onion Pests. The worst trouble with which growers have to deal is the onion maggot, which may ruin the young plants if not checked or destroyed. In some gardens the crop is more liable to serious attack than in others. When the seedlings are thinned out carc must be taken to trcad the soil firmly alongside the remaining plants. Sawdust soaked in paraffin and scattered alongside the rows helps to keep away the onion Hy, and frequent dustings of soot are helpful. Seedlings which are attacked by the maggot should be uprooted and burnt, together with a little of the surrounding soil. An occasional sprinkling on the soil of nitrate of soda or sulphate of ammonia, 1 oz . to the yard run of row, stimulates the growth of the seedlings and thus does good. Mildew often attacks the onion crop: Badly affected plants should be pulled up and burnt and the others sprayed with a solution of liver of sulphur, 1 oz in 2 gallons of water.
The Cooking of Onions. By the cook the onion may be regarded equally as a vegetable and a condiment, and is, in fact, almost indispensable as an adjunct to souns, stews, and made dishes of all kinds. When eaten raw it is nourish. ing and stimulating, but difficult to digest. Much of the pungent property of the onion is dispersed by boiling, and if blanched before the actual cooking commences it is much less likely to disagrec, and forms, to most taster, a pleasanter and milder vegetable.
When roasted, the onion should 10 previously blanched or parboiled, and it will be more wholesome and lose some of its richness. Fricd onions, also, might with advantage be subjected to this treatment.
The amall round onion is the correct kind to use for making pickled onions or for mixing with other vegetables for this

How to Grow Onions. 1. Seed sowing in box ; $a$, crooks: $b$, leaves ; $c$, compost : $d$, fne sandy soil : $c$, slass, 2. soot, wood ashes and soil. 7 and 8 . Onion fy and its reault. 9. Thinning : $G$, fine bulb resulting. 10. Soil dearing to mature buibe. il. Top aing : $G$, ancing for exhibition. 12. Rope of onions for storing
purpose. Spanish onions are in scason in the autumn and winter, when they are imported in a dry state. The Spanish onion is much larger than the British variety, and is better for serving as a vegetable and also for roasting. Being milder in quality, it has not the pungency that is required for flavouring soups and stews. Other varieties of the onion used in cookery are leeks, shallots, chives, and garlic.

Onions leave a most pungent and unpleasant odour on any cookery utensils used in their preparation. Table knives and forks, also, if onions form part of the menu, require special cleansing: this applies particularly to onions served in a raw state, as in salads, etc. The forks should be cleansed in hot suds, with a small piece of whiting in the water, and may be rubbed lightly with cut lemon: if so, they must be rinsed before being wiped. The knife blades, after washing, should be thrust into earth or coffee grounds and then rinsed, wiped. and cleaned as usual.
The board on which onions are cut should be rubbed with vinegar or lemon before being acrubbed. Silver sand should be sprinkled on the board before the brush is applied.
Never use a pastry board in preparing any kind of vegetable ; a distinct board must be kept for this purpose. It is better, also, to keep one knife only for onions, and to mark it in some manner that can be easily recognized. To remove the odour and stain of onion from the hands, rinse them well in cold water, and rub with cut lemon or pumice-stone before washing them with soap.
Bralsed Onions. To braise onions, remove the skins from medium-sized Spanish onions. Heat a piece of butter or good beef dripping and fry the onions (whole) lightly on all sidcs. Then pour in brown stock or gravy to come half-way up the onions, season with pepper and salt, and let them cook gently in the oven or on top of the stove until tender when tested with a fork or skewer. Then thicken the stock with a little flour or cornflour and pour over the onions to serve.

Roasted or Baked Onions. Remove the untidy outer skin from the onions, but do not peel them. Put them, with their skins on, into boiling salted water and let them boil quickly for an hour. Then take them up. dry them, and wrap each in a piece of buttered paper, and bake in a moderate oven about
two hours or until tender. They may be served in their skins and melted butter handed with them ; or pecled, with niled butter or brown sauce poured over.
Onion Sauce. This sauce is served usually with roast mutton or boiled rabbit. When apple sauce does not accompany goose or ducks onion sauce may take its place. It forms sometimes a garnish for cutlets or, if made rather thicker, a coating.
To make it, boil till tender I lb. onions. Peel and blanch them, then drain and chop very fine. Put 1 pint milk into a bright saucepan, add onions with 1 tablewpoonful flour mixed in with them. Bring all to the boil, stirring to keep the sauce smooth ; add I oz. butter and seasoning of salt and pepper Simmer it for 5 min . and serve very hot.
Onion sauce for an entrée is prepared thus. l'cel and boil in salted water 1 lb . onions After 55 min . pour off the first water and boil till tencler in fresh water; drain and chop very fine. Return them to the pan with 2 oz . butter, $\frac{\{ }{3}$ oz. flour, $\frac{1}{2}$ pint milk, 1 gill cream, and seasoning. Simmer for 10 min ., then pass through a hair sieve or a tammy cloth.

Onion Vinegar. All that is required to make onion vinegar is to steep 1 oz . of chopped onion and shallot in 1 pint of white wine vinegar for a fortnight. This condiment gives a piquant flavour to salad dressings and mayonnaise.
Medical Uses. Boiled Spanish onions, taken frecly, are said to benefit people suffering from boils. A poultice made of onions is an old. fashioned remedy often used to hasten the brcaking of a boil. To use in this way, roast the onions, and mash them before sprcasling on a piece of muslin or linen and applying to the spot. Both onions and garlic are slightly aperient and diuretic.

Onion Sellers. In the autumn, generally in October, the onion sellers from Brittany arrive in Great Britain and inay be seen at all coast towns and villages, and even far inland, going from door to door, offering their wares for sale. These consist of strings of French onions slung from long poles which the Breton fishermen carry on their shoulders.

These onions are somewhat milder in flavour than those which are grown in British suil, and consequently they are of practical use to many housewives for the preparation of dishes in which onions form an ingredient, eapecially when only a mild fiavouring is desired. The Breton onions are plaited together in strands, a convenient arrangement for hanging up in the pantry or from the rafters of country kitchens. They are specially good for flavouring soup.

ONONIS. This is a low-growing hardy shrub or herbaceous perennial which bears pea-shaped Howers in summer. The pink Howered rest harrow (Ononis spinosa) is a British plant. Some of the beat kinds for gardens are fruticosa and rotundifolia, with rose pink blooms, and aragonensis, yellow, which reaches a height of 18 in . or so. They need well-drained soil and a position fully exposed to the sun ; they are usually grown in the rock garden. Propagation is by cutting: in a frame in summer or by sowing seeds. It is important that the shoots should be shortened after flowering.

ONOPORDON. This giant thistle-like plant is suitable for the wild garden, edge of the woodland, or the back of a large herbaceous border. They reach a height of 6 ft . or even 8 ft . in good soil. and have pale purplish Hower heads. One of the best is Onopordon acanthium, known as the Scotch thistle. They are raised from seeds sown out of doors in spring.

ONOSMA. This is the name of an important race of rock-garden plants. The species demand hot and dry positions, with
ight, well. drained loam and a little lime. The plants are of varying heights, ranging rom merc inches to a foot or so Onc species, Onosma taurica, is the old garden favouritc golden drop. But there aro esser known and cqually attractive kinds, including albo-roseum, white, changing to pink; and caurica, yellow All bloom from
 June onward,
and can be raised from seed or propagated by cuttings. Protect in winter by raised picces of glass. See Golden Drop; Rock Garden

ONYX. A variety of tinted agate, onyx is formed of alternative lavers of white and coloured chalcedony. It is used in jewelry for bead necklaces, and fancy ornaments Blac nyx is used with liamonds in rings pendants, and other ornaments. Sec Jewelry

OOLONG TEA. Oolong is a black China tea somewhat resembling in llavour a green tca, and of a rather light character. Oolong teas are sometimes exported from Japan. See China Tea; Tea.

OPAL. The most costly of these gems are known as precious opals, and have rainbowlike tints of pink and red ; fire opals are of a rich orange-red colour, while cat's eyc opals which are rare and usually of a green colour, have in their centre a wavy line similar to that in a cat's eye. Other kinds include the black and the common opal. The latter is the least valuable. Opals are cut in cabochon form and never into facets. They combine especially well with diamonds or silver See Jcwelry.

OPERA GLASSES. It is desirable that the selection of opicra glasses should be made by the person who is going to use them. Those with bending bars in the middle, so that they can be adjusted to the width between the eyes arc a convenience; also it is desirable to have large dianteter lenses in both the object glasses and eye pieces. The
 and ivory; fancy glasses are
made with small lenses to kcep down the weight. The aluminium pattern enables glasses with large lenses to be practically the same weight as others with small lenses.

Opiera glasses are miade so that very little dust can penetrate, and with ordinary use they should last many years without being touched inside. When they liave to be cleaned on the inside all that is necessary is to unscrew the cell which holds the lens and wipe it lightly with clean chamois leather, which will not scratch or injure it. The lenses should be taken out one at a time, cleaned and replaced; this ensures their going back in their original position. The outside surfaces should be cleaned with chamois leather The lenses ought not to be touched cxcept when they require cleaning, as small particles of grit are liable to get on the surface of the glasses and will greatly impair their value.
The usual magnification of oper glasses is about $2 \underline{d}$ dianieters. A simple way to judge the magnification is to look at a brick wall through the glass with one eye only, but keep, ing both eyes open The image seen through the glass will cover the space of $2 \sharp$ bricks which are seen with the other eye.

Ophioglossum. This is the botanical name for the adder's tongue fern (q.v.).

OPHRYS. The wild orchids of Great Britain are called by this name. The favourites are the bee orchid (apifera), purplish and green ; spider orchid (aranifera), brown and green; and tly orchid (muscifera), green and reddish. They are all low-growing plants which flower in carly summer. They should be planted in the rocls garden in slight shade, in loamy, chalky soil.

Ophthalmia. See Conjunctivitis
OPIUM. The dried juice obtained by cutting into the unripe capsules of the white poppy (Papaver somniferum) is a useful remedy in medicine. Crude opium contains a number of alkaloids, of which morphine. which may he present to the cxtent of 12 p.c., is the most important. Opiuin acts as an anodyne and narcotic almost entirely in virtue of the morphine it contains. It is used
in various forms 10 relieve pain, and in the treatment of insomnia, but should never be given except under medical supervision. It is delinitely dangerous to young clildren

The best antidote in poisoning by opium is permanganate of potassium, enough dissolved in half a glass of water to make a decp red solution. After this hot, strong coffee should be given freely, and the patient must at all costs be kept awake.

In 1925 an international convention was signed at Geneva. This provided for the establishment of a board of control to suppress the illicit traffic in drugs derived from opium and other came into This 1928, when, accord. ing to agreement, it had been ratified by ten countries.

OPIUM POPPY. This is a very showy and easily grown inardy annua! (Papaver somni(erum), of which there are many brilliantly coloured varieties, e.g The Mikado, Cardinal, White Swan, and Carnation - llowered. The plants grow 18 24 in . high, and have greyish leaves. Seeds are sown out of doors in March-April where the plants are to bloom in summer. The opium of commerce is obtained from Papaver somniferum.

OPOSSUM : The Skin. There are two varieties of opossum, onc of a delicate bluishgrey colour and the other a hard, wiry fur of a brownish shade, known as American opossum. Both kinds are used for trimming purposes, especially on winter coats of velour cloth. Sce Fur.

## Optical Lanterns in the Home

## The Nature and Use of Projection Apparatus

## The reader is referred from this article to those on Lantern Slide and Lens, where relaled

The optical lantern is generally understood any form of illuminant that may be con to be a modern form of magic lantern, taking venient. The actual lantern remains the the standard 3 f in . square slides and having same, but the chimney and internal arrangean improved optical system with an efficient ments will dejend upon the kind of light used. and powerful source of illumination. The Bi -unial (double) and tri-unial (triphe) lantern most frequently consists of a well- lanterns are used for dissolving views. A ventilated box of wood or metal in which lantern-slide picture is projected in the is an illuminant with a reflector behind it. usual way by one of the lanterns upon the Opposite the light is a condenser, which is an screen; the second picture is then shown arrangement of one or more largo lenses. Its purpose is to collect the light rays and throw them through a lantern slide placed on the other side of the condenser. The picture is thus cast into the front lens, usually called an objective, which focusses the picture and throws it in a highly inagnified form upon a screen.

For home work the common form of japanned tin o: Russian iron lantern, burning oil, has been very popular, but acetylene, spirit, electric and other illuminants have displaced the oil lamp. Many of the modern electric lanterns are specially suitable for tho ho me, hecausc of the possibility of connecting them to the ordinary housc supply. High power metal filament lamps are used. Most lant. erns are made to take

Various parts of the optical system. A, illuminant : B, condenser: C, slide stage ; D. objective
over the first onc upon the screen, whell the first one is made to fade out, usually by lowering the light. In this way day scenes are made to dissolve into night scenes and summer scenes into winter scenes.

The Optical System. Standard lanterns have condensers measuring 4 in . to $4 \frac{\mathrm{t}}{\mathrm{in}}$. in diameter. The circular condenser must be at least 4 in . in diameter to illuminate the standard $3 f$ in. square stide. The condenser consists usually of two lenses, called a planoconvex compound, mounted in a cell with the Hat surfaces outward. A condenser should never be suddenly heated or allowed to cool too rapidly, because of the danger of cracking. The lenses should fit loosely in the coll, and the latter should bc provided with suitoble holes for

are wanted, it is not enough to hang up an ordinary white linen or calico sheet and project the picture upon it. A lantern shect or screen should be quite white and absolutely opaque. Opaqueness is necessary to keep the light and the picture upon the surface, and so reflect rather than absorb it. When an ordinary sheet is used much of the light cast upon it goes through and is lost, the picture suffering from lack of brilliancy and clearness of outline.
ventilation. The heat generated during a show causes the glass to expand slightly, and if this expansion is not allowed for the glasses will crack.

The objective is often a lens of the Petzval type, like a photographic portrait lens; it is generally about 2 in . in diameter and from $5 \frac{1}{2} \mathrm{in}$. to 6 in . in focus. Upon the focus of the lens depends the size of the picture upon the screen: or, in other words, the distance of the lantern from the screen.

The $5 \frac{1}{2}$ or 6 in . focus lens commonly supplied with lanterns for use at home gives, approximately , a 5 ft . picture 10 ft . from the screen, a 6 ft . picture at 12 ft ., a 7 ft . picture at 14 ft ., and so on, the picture being half as high as the distance measures. For large halls, objectives of longer focus are used. Thus with
an objective of 12 in . focus the lantemist an objective of 12 in . focus the lanternist would get, using the same lantern and condenser, a $2 \frac{1}{2} \mathrm{ft}$. picture at 10 ft ., and 3 ft . picture at 12 ft . Put in another way, if the lantern is 12 ft . from the screen, then a 4 in . objective would give a 9 ft . picture, a 5 in . one of 7 ft ., a 7 in . one of 5 ft ., and an 8 in . a picture of $4 \frac{1}{2} \mathrm{ft}$.

The size of picture obtainable depends upon the quality of the light employed. With an oil lantern it is rarely possible to enlarge the $3 t \mathrm{in}$. slide to more than 5 ft . and get at the same time a brilliant picture. It is better to have, say, a 4 ft . bright picture than a dull one of 6 ft . in diameter. With incandescent gas or acetylene good 6 ft . pictures are possible if the illuminants work well, while with the electric gas-filled lamps 8 ft . can casily be obtained.

The Screen. The screen upon which the pictures are shown deserves more attention than is usually given to it. If the best results

Optical Lantern: action of condenser lens. R. sonrce of light: A and B, normal path of light ray, if no condenser is ased: $L$, objective lens on which tie lijht raya are made to converge by the condenser uens, C: 8, slida

Optical Lantern. Above, electric projection lantern for lecture hall or clasaroom ; adapted for lensei of 8 to 18 in . focus. Below. epidiascope, for projocting an image of opaque objects, or tor tranaparent slidea ; it is converted to either nat by moving a lever. Part of casing removed to thow interior Courtesy of Ensiun, l.id.: and af Chas. Baker

The best screen on which to show lantern pictures, small and large, is a whitewashed or distempered plaster wall, which absorbs no light ; for the same reason white cardboard is also excellent. Opaque screens of a size large enough for home work are to be had front the makers of lanterns and accessories.

The aluminium lantern illustrated is one of a class developed in recent years. It has a superior lens system, and the illuminant is a 500 -watt electric lamp which can be con. nected to the housc lighting circuit. The back
of the globe is silvered to act as a reflector. The bellows extension permits the usc of lenses having a focus of 8 in . to 18 in ., giving a distance from the screen of 20 ft . to 75 ft ., according to the lens employed. This model is particularly suitable for lecture halla, or classrooms, but a smaller one, designed on similar principles, is available for home entertainment.
Projection of Opaque Objects. At lectures, demonstrations, etc., it is often necessary to show an enlarged image of an opaque ohject, such as a picture, diagram, or jage of letterpress from a book. An optical lantern for projecting on to a screen the image of an opaque object is known as an episcope. Such an apparatus is generally, however, designed to show transparent slides also, when it is termed an epidiascope. The opaque object is placed on a platform beneath the apparatus and is illuminated by one or more powerful electric lamps. The light rays reflected up ward from the object are passed through a lens system and projecteil on to a screen We illustrate a type of epidiascope in which one objective is used for the dual purpose, the movement of a lever converting it from episcopic projection to lantern slide use, and vice versa.

OPTICLAN. A person who makes or aells spectacles or other optical instruments is called an optician. A doctor who specializes in dis. arders of the eyc is an oculist, and his work deals very largely with errors of refraction, for which glasses have to be prescribed. Many opticians also test vision and prescribe glasses where these are necessary.

Pcople who bave little knowlelge of optical work, and who are in no sense opticians, frequently undertake to supply glasses, which may be either unnecersary or actually harmful. The bona-fide optician is skilled in making up and fitting glasses; he is depended on to supply lenses of the precise kind and strength required. He also may have skill in sighttesting, and amongst opticians there are many who have qualified for a diploma in the subject. See Eye: Sight Testing

OPUNTIA. The cactaceous plant called opuntia includes the Indian fig, prickly pear, Barbary fig, and other natives of Central America. Nost of them need ordinary treatment in the grcenhouse in rich loam, with a liberal admixture of lime or old mortar: they must be watercd sparingly in winter. The hardy species need similar soil in a sunny, sheltered situation in the garden. Propagation is by seeds or cuttings. Among the hardy kinds arc monacantha and raffinesque See ndian Fig: Prickly Pear.
Oranges and Orange Dishes

## A Popular and Health-giving Fruit in Appetizing Forms

## Marmalade is one of the entries in our work to which reference should be made; others are Candied Peel; Crysullized Fruit. See also Diet; Fruit; Icing; Jelly : Tangerine

The orange is an evergreen flowering shrub telonging to the Citrus family, which embraces the lemon, tangerine, grape-fruit, and citron, as well as the Seville or marmalade orange. Uranges may be grown from pips planted in pots in loany soil. The temperature of a cool greenhouse is all that is necessary, and the pots or tubs inay be stood out of doors on verandas or in porches during the summer months. The small Utaheite orange is the best fruiting variety for amateurs. Seedling plants are slow in reaching the fruiting stage.

Chief Varieties. Of the two main varieties of this fruit, sweet oranges are used for eating and dessert purposes, while the bitter sorts are employed chiefly in making marınalade. There are a large numter of varieties of the sweet orange, each having its characteristics. The
tastc, and dark coloured with a rough skin.
Azores has a specially choice flavour and is juicy and seedless. Majorca also produces seedless oranges, while Malta is celebrated for its blood oranges, the pulp being of a dark crimson colour and very sweet and juicy. The Lisbon variety has a thick rind like that of Jaffa, while the China orange is thin, and the juice very abundant. The rind of the Mandarin is thick, heavy, and loosely attached to the pulp, the fruit being of excellent flavour. Tangerines are amongst the smallest of oranges, being flat in shape and possessing an aromatic flavour.

Sweet oranges are imported from Alicante and other parts of Spain, but the most important variety from this country is the Seville orange, which is extremely bitter in Sweet oranges of good size and excellent
quality, both seedless and other kinds, are grown in Australia and South Africa, and are on sale in most towns in Great Britain. One of the largest varietics is the American navel orange, so called from a characteristic formation on the top of the fruit, which is oval in shape. This variety of orange is also grown in South Africa.

Amongst the many uses of the orange, the fruit may be preserved in sugar as a sweetmeat. The peel of the bitter orange is candied and is much employed in confectionery. In an early stage the small green fruit, no larger than berries, is used in the manufacture of the liqueur known as curaçao The bergamot perfume is distilled from the rind of Italian oranges, and a liqueur named rosoglio is a lso made in some parts of Italy from oranges. An essential oil is obtained from the rind of both sweet and bitter oranges, and is sold by most perfume dealers.

Medicinal Value. Both sweet and bitter oranges are used in medicine, but chiefly the latter, which are of great value in the sick room. Only the juice, however, should be given to invalids or young children, as the pulp is very difficult to digest. Squeeze the orange juice into a glass and give in that way. A teaspoonful of orange juice should be given once or twice a day to hand-fed balies to prevent scurvy, for which it is also a reniedy

For a patient who is thirsty, a welcome drink can he made by pouring over the thinly cut peel of an orange a pint of nearly boiling water. Add 4 tablespoonfuls loaf sugar. and let it stand fo: aul hour ; then put to it the juice of 3 oranges, and strain. Serve quite cold
An excellent tonic for promoting appetite and aiding diges. tion can be made by taking 2 oz dried orange neel, the fresh rind of 2 lemons, and pouring over them 1 pint boiling weter. Let it stanil for an hour, then strain. Take $\underline{d}$ wineglassfil twice a day,
half an hour hefore luncheon and before dinner.
From the flowers of the orange a water is distilled which lias a beantiful perfume. Besides this, other preparations of orange used in medicine are the tincture and the syrup, the dose of each being $\frac{1}{2}$ to 1 dram; these both act as flavouring agents, and the tincture also as a tonic and appetizer.
Uses in Cookery. Oranges are a very useful cookery ingredient and can be employed in a variety of dishes, such as pies, tartlets, creams, jellies, cheese cakes, cakes, and salads. The flavour is delicious in icings and sweet fillings, and the juice is in some cases added to rich, made gravics.
Orange Basket. The sweet known by this name is made by cutting 2 or 3 ripe oranges into halves, scooping out the pulp and mashing it up in cold water, making about $\frac{1}{2}$ pint liquor in all. Add sugar to taste, and after letting the

Orange Baskets, a novel method of serving jelly made from the troit
liquor stand for a couple of hours, strain it through muslin.

Add $\ddagger$ oz. isinglass and just warm the whole over the fire until the former melts. Colour it pale pink with a little cochineal, and then pour it into the halved orange skins, leaving theae in a cool place to set. When the jelly is tirm, handles to complete the basket-like effect can be made from thin strips of angelica, bent over

Orange Biscuit. Boil 6 Scville oranges in 2 or 3 waters till the bitterness has almost dis. appeared Cut them in quarters and remove all the inside. Beat the peel very fine in a mortar then weigh the pulp thus ohtained. Add an equal weight of castor sugar and work both to a firm paste. Spread it smoothly on a dish or tin, set it in a cool oven to dry, and when dried sufficiently to shape cut it into fingers. 1)ry these again, turn them upside down, and return them to the oven so that all moisture may be absorbed. Store them in tins. These biscuits should he alout of in. thick, and are useful as wafers to serve with ice cream

A spongy biscuit can be prepared by beating 2 eggs with 4 oz . castor sugar until thick and quite light. Mix in the grated rind of an orange with 1 teaspmonful orange flower water. Sift 4 oz . Hour with a pinch of salt and fold it into the sponge. Bake it in little paper cases, and when almost cooked dredge it with sugar. Finish baking afterwarls. These hiscuits nre sometimes iced, and in that case the icing should be mixed with some of the orange-juice.

Orange Cake. A sandwich cake flavoured with orange can be made by beating $\frac{1}{2}$ tea. cupful butter or margarine and 2 teacupfuls sugar to a cream, adding separately 2 eggs, and then beating the mixture well. Pour in $\frac{1}{2}$ teacupful milk, then add 1 lb . sieved flour, grated rind of the orange, and 1 teaspoonful baking-powder, and continue beating. Line a tin with greased paper, put in the mixture and bake it until it is firm and lightly browned. When cold, split it into two and spread the sides with a gill or more of whipped and sweetened cream, llavoured with orange essence.

Another cake filling is made by mixing the strained juice of 2 or 3 oranges with $\ddagger \mathrm{lb}$. castor sugar, gradually adding to them the grated rinds, 2 tablespoonfuls corntlour and a gill of water. Mix all to a smooth paste, then stir in 1 oz melted butter and stand the basin over a saucepan of hot water Stir its contents over the fire until they be come creamy and taste cooked; then leave them to cool. When cold, stir in the whites of 2 eggs and spread the filling over the cut sides of the cake, afterwards putting the latter toget her again. If it has risen too much in the centre, level it with a knife before icing.

Orange Cream. To make this sweet, cut 2 oranges into halves and remove the pulp carefully, so as not to split the rinds. Extract the pips, rub the pulp through a fine sieve and mix with it 3 dessertspoonfuls castor sugar. Whip a gill of cream until it thickens, add half of it to the orange pulp and sugar and fold in also the stiffly whisked white of an egg. Dissolve $\frac{\ddagger}{} \mathrm{oz}$. leaf gelatine in $\frac{1}{2}$ gill water, strain it into the other ingredients and mix all thoroughly. Half-fill each orange-case with

Orange Cream, halved orange gkins glled with a cream miriore and decorated with angelica
the mixture, and when the latter is set, decorate the top with the remainder of the cream and a few pieces of angelica on top.

Orange Fool. Peel and then mash 3 or 4 large oranges to a pulp, rub the latter through a sieve to rid it. of pips, and then mix it with 1 pint custard. Iet the mixture stand in a cool place so that it may thicken, then put it into custard glasses and pile a little whipped cream on top of each. If preferred, $\frac{1}{2}$ pint cream may be substituted for the custard.
Orange Fritters. These are made by peeling some oranges, breaking them into quarters, removing the white skin, and then sprinkling them with castor sugar. Leave them thus for about 15 min ., then drain and cont them with frying batter. Have ready a pan of smoking hot fat, put in the slices of orange, and fry them till they are a golden brown. Drain them from the fat, dredge them with some more castor sugar, and serve at once Allow half an orange for each person.

Orange Pudding. A small orange pudding can be made ly mixing together $1 \frac{1}{2} \mathrm{oz}$. castor sugar and the grated rind of an orange and putting them into a basin with 2 oz . finely chopped suet, the same quantity of bread crumbe, 1 oz. rice flour, $\frac{1}{2}$ teaspoonful bakingpowder, and a good pinch of salt. Into the centre of these ingredients strain the juice of half an orange and a well-beaten egg, mixing all well and adding a little milk if necessary. Turn the mixture into a greased basin or mould, cover it with a piece of greased paper, and steam it for two hours or more. This pudding should be served with orange sauce.

A baked orange pudding can be made by peeling 6 oranges, breaking them into small sections and after removing the seeds, putting them into a pudding dish. Sprinkle over them t lb. castor sugar, and leave them to soak thercin while preparing the following mixture : Stir together a tablespoonful of cornflour and a little cold milk, and when they are smoothly mixcd add them, together with a well-beaten egg, to a pint of milk that has not quite reached boiling point. Stir the whole until it thickens, then pour it over the fruit and on top spread the stiffly beaten whites of two eggs. Bake the pudding until it is firm and lightly browned.
Orange Sauce. This sauce is made by warming the strained juice of half an orange, together with the rind and 2 oz sugar, in a small pan near the fire. When the sugar has melted, add a teaspoonful of cornflour mixed smoothly with a small teacupful of water Stir the sauce until it boils; then siminer it for a few minutes to cook the cornflour before serving.

Orange Syrup. When orange flavouring is required this syrup may be used with excellent results. To make it, squeeze the juice from 12 oranges, strain it, and then boil it up in a saucepan with 8 lb . lump sugar. When it thickens, skim and bottle it.

Orange Tart. To make this, rub the grated rind of 2 oranges with 2 heaped tablespoonfuls sugar and then cream these with 2 oz . butter. Add to them the yolks of $2 \mathrm{eggs}, 2 \mathrm{oz}$. finely crushed biscuit, and the strained juice of the fruit. Then beat the whites of eggs to a stiff froth, stir them in, and pour the mixture into a tart tin lined with puff pastry (see Pastry). Bake the tart in a fairly hot oven until the pastry is lightly browned and the mixture set. Just hefore serving, sprinkle the surface of the tart with castor sugar.

ORANGEADE. To make orangeade, pare the rinds of 3 ordinary and 1 Seville orange and put them into a jug; pour on them 1 pint boiling water and let them strep, covered up, for $G$ hours. Make a syrup with $\frac{1}{2} \mathrm{lb}$. sugar and $1 \frac{1}{2}$ pints water, and add it ta the steeped rinds, together with the juice of the oranges from which the rinds have been taken, and the juice of 3 additional oranges. Stir the whole well and when cool atrain it through mualin. The juice of a lemon may replace that of one orange.

ORANGE BALL TREE. This is the popular name of a handsome hardy flowering, shrub (Ruddlcia glohora) It. thriver in

Orange-ball Tree. Evergreen ahrub with globalar gellow flowers which will brighten a dall garden
ordinary soil, reaches a height of 8-10 ft., and bears round heads of yellow flowers in summer. Any required pruning to keep the bush shapely should be done after Howeling. Propagation is by cuttings in a frame in August. Buddlleia variabilis and its finer varieties veitchiana and magnifica bear racemes of mauve Howers, which attract the buttertlies and bees, in July and August They must be hard pruned in spring.

ORANGE BITTTERS. An excellent recipe for orange bitters is the following : Take 1 oz . Sevillc orange peel, $\frac{1}{2}$ oz. gentian root, $\ddagger 07$. cardamonıs. Husk the cardamoms and crush them with the gentian root. Place the whole in a wide-mouthed bottle and cover it with brandy or whisky. Allow the mixture to remain for 12 days, then strain it and bottle it off for use, adding 1 oz . lavender drops.

ORANGE BRANDY. March is the best time to make orange brandy. Place in a stone jar the rinds of 6 oranges cut thin and add $\frac{1}{2}$ pint orange juice st rained, and $\frac{1}{2}$ gallon gocd brandy. After 3 days add about 1 lb . loaf sugar, stir till the sugar is dissolved, and lat the liquid stand for a day. Then strain it, pour it into bottles and cork it tightly. It improves with age. See Brandy.
ORANGE LILY. This is the cominon name of Iilium croceum, a hardy lily, which bears billiant orange-coloured blooms in summer on stems $2-3 \mathrm{ft}$. high. It thrives in ordinary soil ; the bulbs should be planted 3 in . deep in the itutumn.
ORANGE LIQUEUR. This drink is made by peeling 2 Seville oranges and 2 small lemons, putting the peel into a jar with $1 \frac{1}{2}$ pt. whisky and 7 oz . lump sugar, corking it down tightly and leaving it for 5 or 6 days. Keep it well shaken daily, then strain it through mus!in, or a very fine strainer, and bottle it for use. See Liqueur.

ORANGE WINE. In making this wine 8 large Seville oranges should be allowed to cach gallon of cold water. Put 4 of these into
the water with the peel on; pare the other four, cut them into halves and then add them to those in the water, saving the peel for other purposes. Leave the whole for 10 days, stirring it two or three times daily; then atrain it through a hair aieve and add 4 lb. lump augar to cvery gallon of liquor. When the sugar has dissolved the wine may be put into a cask. Bung it loosely for threc or four days, then tighten the bung and after six months bottle for use.

ORANGES AND LEMONS. This is onc of the old singing games, and is still much in voguc for amall children Two people join hands, making an arch beneath which the others have to pass. As height is important it is better for adults to take this part. The children then form into a chain, cach child with his hands on the shoulders of the one in front of him, and pass under the arch formed by the two adults. Meanwhile all sing the following rhyme:
Oranger and lemuna, say the Lella of St. C'ement's;
You owe me five firthings. say the bella of St. Martin's.
When will yoin pay me 9 say the brills of Old Balley. When 1 grow rich, say the bella oi shorediteh. When will that br'? apy the bellg of Stepney. $I$ du not know, says the great lell of Bow. Here comes a candle to light you to bed.
And here comea a chopper to chop off your head.
When the last couplet is reached the two adulta drop their hands over one of the chain, imprisoning him. He is then asked whether he prefers oranges or lemons, and having made his choice in a whisper, he is put behind the person representing that fruit, a matter which lias been settled by the two before the com-

## Orchids: Varieties alnd Their Cultivation

## Beautiful Flowers that the Amateur Gardener can Grow

This article is a companion to those on Daffodll ; Iris; Lily : Rose: and others throughout our work. See also Greenhouse and the entries on the various orchids, e.g. Cattleya; Mitonia
Orchids are rightly regarded as the most called the intermediate house, with a mininum fascinating of all Howering plants grown under winter temperature of 60 degrecs, and cool glass: there are many genera or groups, house orchids will thrive in a greenhouse in innumerable species, and an untold number of which the temperature does not fall below varieties and hybrids. Orchid growers raise 45-50 degrecs in winter. Orchids suitable for new hybrids or crossbreeds annually, and these the greenhouse are odontoglossum, Ada now form the bulk of the orchids grown by those who specialise in these Howers

For the purposes of cultivation orchids atc grouped in three classes according to the temperature of the glasshouse suited to their s:eeds. Nome must be grown in a hothouss having a minimum winter temperature of (:5-70 degrecs. Others are suited to what is
mencement of the game. When all the players have been captured in this fashion and are ranged behind one or other of the adults, the game ends in a tug-of-war between the two parties, the first couple still holding hands. See Children's Party.

ORCBARD. The best apot for an orchard or fruit garden is one that is sheltered from north and east winds, as far as posaible, and has a southern or south-western aspect. loamy soil is best, but other kinds can be made suitable by cultivation. A gentle slope is better than a dead level ground, on account of drainage.

Young standard trees may be planted in pasture land in which to form an orchard, and in that case they should be put in about 30 ft . apart cvery way. Such land may be used for sheep, but in the home garden orchard the usual plan is to economise space by planting bush fruits, strawberries, etc., between the large fruits. When an orchard is iirst planted the young trees should be staked until they are thoroughly established, and the soil round the trees must be kept clear of grass.

The grass should always be kept closely grazed, preferably by turning sheep into it, and must never be allowed to get so long and rank that it has to be cut with a scythe or mower. See Apple: Cherry: Fruit: Pruning: Strawberry, etc.

ORCEARD HOUSE. A heated greenhouse used almost entircly for the culture of fruit is known as an orchard house. It may be either lean-to or span in structure. See Apricot: Grape; Greenhouse; Nectarine: Peach: Pineapple, etc. aurantiaca, odontioda, lycaste, cypripedium, and masdevallia.
Those. which should be grown in the intermediate house are cymbidium, cattlcya, laclia, epidendrum, oncidium, miltonia, воphronit is, coelogyne and dendrobium. Orchids which need the conditions of a hothouse are vanda, aerides, phalaenopsis and calanthes. Some of the chief

Epiphytal Orchide. 1. Wood basket for drooping apecies. 2. Another type of hanging basket. 3. Plant grown apon sphagnam covered bark. 4. How to
pot erect-growing kinds : $a$, crocks and charooal: $b$, peat and aphagnum ; $c$, sphagnum moss kinds suitable for cul. tivation by amateurs are dealt with in the following notes. For particulars of specics and the countless beautiful hybrids now available the catalogues of orchid growers should be consulted.

Some Examples. A charming orchid suit. able for the cool house is the orange scarlet Ada aurantiaca. Repotting is necessary when new growths are about 3 in . long, a suitable compost being fibre, oak leaves, and sphagnum moss.

Cattleya is an orchid of exquisite shape and delicate colours, containing species excellent for the warm and intermediate
houses. Pot culture is necessary, in a compost of tibre, peat, and spliagnum moss, plants being repotted every 2 years with removal of all decayed or dead roots and hulbs. Each plant should he dealt with as soon as new growth has reached about 3 in., using fresh small pots in scrupulously clean condition.

The free flowering Coelogyne cristata has blossoms of white and a yellow lip. Being very shallow rooting, it is hest grown in an orchid pan in the intermedinte house. When repanning becomes necessary, an operation not often required, a compost of peat and aphagnuni moss should be employed. Large plants are to be encouraged if free flowering is required
Cymbidium is a magnilicent orchid for aniateurs, suitable for the intermediate or even the cool house. Plants should be repotted very firmly in a mixture of lonm, leaf-mould, peat, and sand, damping it well, and placing upon plenty of well-cleansed crocks.
Cypripedium is an extensive genus containing many species and hybrids. It is a bulhless kind, producing leafy growths, and bearing, as a general rule, large, liandsome hlooms, populatly known as lady's slippors, on stiff, crect spikes. These orchids bloom successfully in turfy prat and a little loam, sweetened with charcoal.
Some of the beautiful genus Dendrobium are suitahle for amateur cultivation, either in cool or warm house, the following being recommended: Falconeri, Jamesianum, which are coul house kinds; nohile and thyrsiflorum, for warm house cultivation. Suitahle compost is turfy peat and sphagnum moss.
Disa grandillora, commonly called the llower of the gods, bear's blossomis of bright scarlet with light markings during October. It requires special cultivation. From spring until autumn the compost must be kept in a state of even sponginess, but without excess of moisture; during winter the plants are best in a light position at the coolest end of the house. From April to September the plants may he placed in shady frames out of doors. A suitable compost consists of equal parts of peat and living sphagnum moss, with a little sand. Pots or plans must be perfectly clean and well drained.
Epidendrum vitellinum majus is the name of an orchid bearing orange-scarlet flowers on

Orchid : three hardy kinds. Left to right: bee orchis, a small orchid for the rock garden; Madeira orchis, a plant needing a dampsituations ard Calgpso borealis, bearing nurple, white-lipped flowers
enect spikes, with summer and autumn flower. ing forms. It may he grown in pote, pans, or haskets, ${ }_{j}$ full of clean crocks, topped with a compost of $\because$ parts lihrous peat, some sphagnum moss, and silver sand $f$ of the whole. All dead and decayed roots, leaves, or hulbs should he renoved before repotting, and the plants kept on the dry side during winter to prevent spotting of leaves.

The genus Laelia contains some bcautiful species. Kinds recommended are ancejs, autummalis and praestans. Laelias have been crossed with Cattleyas, and the hyhrids known as Laelio-cattleyas are vigorous and freeflowering. A fine exaniple of the many hybrids is known as St. George. Flowers are all very widely varied in this section, spikes producing 2,3 , and sometimes 4 and 5 on a spike. No class of orchid is more suitable for a house where a minimum temperature of $50^{\circ}$ can be maintained. A winter-Howering orchid that docs well in a cool house is Lycaste Skimeri

Orchid: some greenhouge varieties. Top, left to right: Laelio-cattlega St George, Coeloggne cristata, and Oncidium papilio. Bottom, Odontcriossum crispum, and Cypripedium Germaine opoix

There are many varicties, the blossoms being usually pale pink, with mottled crimson lip. They are casily cultivated in pots of loam, peat, and sphagnum moss in equal parts, with a surface layer of the latter. Repottin: every second year is heneficial

Masdevallia ignea produces large bright scarlet blossoms during the summer months. This orchid is suitable for the intermediate house.

Miltonia exhibits great variety of colour. from purest white to a lovely shade of rose Vexillaria will grow in a warm, mixed greenhouse if placed in a light position at its warmest end. It is best cultivated in a pot containing 3 parts of clean crocks. then a compost of fibrous peat, chopped sphagnum moss, and charcoal, with a surlace of sphagnum.
The various hybrids of odontioda combine the hright red colourings of Cochlioda with the varied shades of odontoglossum. They should be grown in a cool greenhouse. A compost of osmunda libre and fresh splangnum moss in equal portions is employed, together with a little decayed oak leaves; the whole is made damp and placed in a perfectly clean pot containing $-\frac{p a r t s}{}$ of clean crocks.

Odontoglossum is an extremely beautiful genus of orchids which contains many gems for the cool house, hearing sprays or branching spikes of blussoms, each varying from 5 to about 40 in number. The colour is infinitely varied, langing through transparent white. chocolate, violet-purple, clarct, vellow, lilac, and chestnut, with spottings and markings in perfect harmony. Two of the most popular species are crispum and grande, but there are many othery

Abundant air is essential, with nicely diffused sunlight whenever available. Whein in full growth, and wbile tlowering, water must be copious and free ; but after flowering only sufficient moisture should be allowed to prevent the soil becoming dry. Broadly, the plants require a long reating period, covering a couple of months. Suitable compost contains 2 parts fihrous peat and $\frac{f}{2}$ a portion each of splagnum moss and charcoal, top-dressed with a laver of fresh moss. It is important to notg that regular damping-down must be maintained during summer to keep the atmosphere uniformly moist.

The choice greenhousc varicty Oncidium papilio is illustrated here. Crispum, concolor,

Hexuosum Marshallianum. tigrinum and varicosum Rogersii may be selected. The compost is composed of oak leaves and polypodium fibre. Flowes spikes must be removed directly they begin to fade.

Peste and diseases will not give great trouble amongst orchids if house and plants are kept thuroughly clean. New plants should always be thoroughly inspected for parasites before placing them with general stock; and where insects appear thorough clcansing with insecticide is the rule. The plants may be steeped in warm solution, provided this is done very carefully Common pests are slugs. green-fly, thrips, mealy bug, wood-lice, cockroaches, and red-spider.

Wild Orchids. There are sonie beautiful flowers among the hardy orchids, some of which grow wild in Britain. They are most likely to Hourish if planted in the rock garden in slight shade in a compost of loam, peat, and sand.

The bee orchis (ophrys apifers), spider orchis (ophrys aranifera) and fly orchis (ophrys muscifera) need chalky, loamy soil. Other beautiful hardy orchids are the Madeira orchid (orchis foliosa), purplish. 18-24 in. : the Marsh orchid (orchis latifolia), purplish, 12-15 in. : the spotted orchid (orchis maculata) 8-10 in., with spotted leaves and rose purple Howers: lady's slipper (cypripedium spectabile), 18 in., white and rose ; butterty orchid (habenaria bifolia), 12 in., white; epipactis latifolia, 12-18 in., creenish purple ; and bletia hyacinthina, 12 in., purple.

ORCHIS. This is the name of a genus of hardy orchids. Some of them grow wild in Great Britain. A description of thc different species will be found in the article on orchid above.

ORGANDIE. The thin, semi-transparent material known as organdie is used for summer dresses, women's collars and cufis, for glass curtains, and for night wear cases and handkerchief sachets. It can be obtained in colours, and its chief virtue lies in the stifiness which prevents it from creasing so easily as most of the other cotton summer fabrics. To achieve the best effect, coloured organdie, when used for non-transparent articles, needs a foundation of the same shade, while collars of this material need to be tacked in position, otherwise their stiffness will not allow them to lie neatly over the dress. See Starch.

ORIEL: The Window. This term is used to describe a particular form of window, the characteristics of which are that it is overhanging, or projecting, divided into different bays, and located upon an upper floor. It is also used to describe a recess within a room. See Window.
Oriental Poppy. This vigorous hardy perennial (Papaver orientale) bears large showy flowers in May and June. See Poppy.

ORIGANUM. This is the botanical name of a group of low-growing herbs. The most familiar is the marjoram (Origanum vulgare), which is raised from seeds sown out of doors in spring. Origanum dictamnus, called pink hops and dittany, is a pretty little pot plant with bunches of pink hop-like fowers: it can be increased by cuttings of the young shoots. See Marjomin.

Ormolu. Oblong table with rounded ends, three drawers and futed legs. mounted with chased ormoln. Prench : period of Louis XVI

ORLOFF: The Fowl. This breed of Russian fowl possesses what is known as a raspberry comb with small feathers growing between the little rounded nodules. This distinguishes it above all other breeds in Great Irritain. The Orloff is bred in five colours, mahogany, spangled, black, white, and blue. It is a muffed breed and also bearded, but it is a good laying breed and a non-sitter. Eggs average 7 or 8 to the lb. Adult cocks weigh 8 lb . to 10 lb . and hens 6 lb . to 8 lb . They do well cither kept semiintensively or on free range.

The mahogany variety are the most handsome ; next to them come the spangles. The mahogany chicks are like Rhode Island red chicks. The spangles vary, being either buff or buff with a brown stripe down the back, and sometimes almost white. Chicks of the other varietics follow their colour. See Chicken; Fowl ; Poultry.

ORMOLU. From the time of Louis XIV to the First Empire, French cabinet makers employed for the enrichment of their productions bronze mountings, which were cast, chased, and gilded. Similar metalwork was used for the mounting of porcclain and stone By permission of the Director. Victoria \& Albert Museum, $s$ Kensinuton
vases, and for the fabrication of cluck cases, wall brackets, mirror frames, and the like.
The castings at their best were exquisitely chiselled, and finished with a mixture of gold and mercury, sometimes tinted, such as the greenish ormolu of Gout hière and other masters. Similar mountings were used by some English makers, but very sparingly; Adam is said to have employed French and Italian artists for the purpose. The plain brasswork, gilded or ungilded, to be seen on the door fittings of 18th-century English furniture is not ormolu, which is essentially chased and gilded bronze.
The metal mounts used on modern reproductions of old furniture, although often styled ormolu, are usually finished by more or less superlicial methods of electro-gilding, by cheap spirit lacquer, or by the water-gilding employed by French makers for current styles of ormolu clocks and the like. Copies made by the galvanic battery can be detected by the granulated surface on the back. The modern alloys contain much zinc, with a thin gold or lacquer wash, and readily lose their brilliance, especially when exposed to gas fumes. The imitation mounts may be made to appear old by chemical means. Good reproductions exist, but are costly to make.

Collectors seldom meet with old mountings in a detached form, because anything of the kind worth having can generally be turned to better advantage on faked furniture. Sometimes the metal handles of broken vases, lion masks, inkstands, and other ornamental
pieces may be acquired as examples of French chiselling. They should be examined with caution, and accepted only if they possess some artistic merit of their own. Old ormolu should never be clcaned with metal pastes nor touched up with gold varnish, but should be treated carefully with dry leathers See Directoire Style ; Louis Style; Marquetry.

ORNAMENTAL GRASS. Many beautiful annual grasses are suitable for association with cut flowers in summer or fo: winter decoration, and for growing in pots. Seeds are sown out of doors in March-A pril where the plants are to bloom. The right time to gather these grasses is just before the blooms are fully open. After cutting they should be exposed to the sun until thoroughly dry.

The following are particularly recommended : hare's tail, love grass, Job's tears, animated oat, quaking grass, squirrel-tail, feather, cloud, golden spiked, and three-horned grass. See Flower Garden ; Garden; Grass.
ORNITHOGALUM. This group of hardy and greenhouse bulbs contains several valuable garden flowers. The commonest is the Star of Bethlehem (umbellatum), which bears star-like greenish-white flowers in spring and will thrive in shady places out of doors. Other hardy kinds are pyramidale and arabicum, both with white flowers, and nutans, greenish-grey : they grow from 12-18 inches high. The bulbs should be planted in Septeinber and Octuber. Arabicum and lacteum are often grown in pots in the cool greenhouse.

ORPINGTON DUCK. Although smaller than the Aylesbury, the buff Orpington duck is hardly inferior to it as a table bird, and it is a prolific layer. Its general characteristics are a good carriage and an aspect of alertness. The drakes attain a weight of from 7 lb . to 9 lb ., and the ducks from 6 lb . to 8 lb . There is an offishoot from this breed known as the blue Orpington, which lays large eggs and is a good table bird. Blue Orpingtons are of active habit and mate without the aid of pond or stream. See Duck.

ORPINGTON FOWL. This breed has a reputation as a layer of fair-sized tinted eggs and as a table bird. There are rarieties in several colours, the buff being the most largely kept. They are very hardy and do well under any conditions, and as sitters and mothers they are uncquali. ed. When fully matured themalc birds should weigh between 9 lb . and $10 \mathrm{lb} .$, and the hens between 7 lb . and 8 lb . No other fowl presents such a perfect com. bination of excellent lay. ing and table qualities. See Fowl; Poultry.

Orpington, a breed of Sowl nn-
equalled for its all-round qualities
ORRIS ROOT. The root of the iris, the blue tlag of suburban gardens, is largely used in various toilet preparations under the name of orris root. Roots of the following irises lend themselves to treatment: Iris Germanica, I. Florentina, and I. pallida.

Because its scent resembles that of the violet, orris root is employed in the making of violet powder, and a perfume known as essence of violets is distilled from it. See Flag: Iris; Scent.

ORTHOCHROMATIC PLATE. In phuto. graphy partially correct rendering of colours is obtained by the use of special plates
or filnıs with or without light filters. Such plates or films are said to be orthochromatic or isochromatic. They are made more sensitive to greens and yellows than ordinary plates by being specially sensitized with eosin or erythrosin dyes, and arc intended to be used with yellow light filters. In some cases a yellow dye is included in the emulsion on the plate, no separate light filter then being required.

All these plates give better senderings of greens and yellows in landscape and other objects containing colour. The undue influence of blue and ultra-vioier rays seen in ordinary plates is reduced by the yellow filter or dye without serious increase in exposure. They are still, however, not sufficiently sensitive to reds and even yellows; for truly orthochromatic results panchromatic plates and tilms must be used. In practice the useful. ness of orthochromatic plates lies in the fact that improved renderings of colours are obtained with little increase in exposure, and that the red light can still be used in the dark room if care is taken to sce that the plate is exposed to it as little as possible during development. In sonse plate. in which the filter is included as a yellow dye in the cmulsion the speed of the plate is slightly increased.

Orthochromatic roll films, as well as selfscreened plates, can be used without a filter, but even with these slightly better results can be obtained if a filter is used. Both with these and with the plates designed tor use with filters only a pale screen, such as the Kodak Kl or the Ilford A (alpha), which increases exposure by two, should be used. Deeper filters not only increasc the exposure, but tend to overcorrect and give unnatural results In artificial light and at sunset, when there is a good deal of yellow in the light, all these plates can be used without a filter. Sce Light Filter; Panchromatic.

ORTOLAN. The sinall birds known as ortolans are about the size of larks and are in season in September. They are rare in England, being mostly imported from Belgium, but are considered a delicacy. Ortolans are usually dressed with savoury forcemeats and laid in cases or on crouttes of fried bread.

Cooking the Bird. To cook them make a rich liver farce, using 1 fowl's liver or a corresponding portion of calf's liver to each bird. Fry the liver with 2 or 3 rashers of fat bacon cut in dice, adding 1 tablespoonful dried sweet herbs which have been passed through a line sieve, a little grated nutmeg, and seasoning of pepper and stuce. Pound the liver and press it through a sieve, then mix with it 2 tablespoonfuls panada or fine breadcrumbs and the yolks of two eggoenough for 4 fowls' livers.

Talie $t$ rouncls of bread about $\frac{1}{2}$ in. thick and rather larger than the ortolan, make an incision all round the edge, leaving a narrow border, then fry these crountes to a light brown. Take them up and scoop out a hollow in the centre, which must be lined with a portion of the farce; place in each an ortolan and spread over a small lump of butter. Bake in the oven about 15 min . When ready, glaze them and dish, pouring over and round some rich brown sauce to which has been added a glass of madeira.

These birds are sometimes fried in a small amount of salad oil with a little chopped shallot, a rew chopped mushrooms, chopped truffle, chopped parsley, and a little grated nutmeg. Cook for 10 min ., then add a lump of glaze, 2 or 3 tablespoonfuls brown. sauce, and the juice of half a lemon. Divide the birds in cases or on croutes, pour over them the contents of the saucepan and place them in the oven for 10 imin . to brown. Then dish and serve them with rich brown gravy.

OSCILLATIONS. These are Ligh-tro quency alternating currents which flow round a circuit containing inductance and capacity, when the circuit is supplied with energy from some extemal source, such as a broadcast transmitter or other gencrator of high-frequency currents.
A wireless set may itself produce oscillations through the misuse of reaction. These oscil. lations if permitted to flow back into the acrial circuit may heterodyne the carrier wave of a broadcasting station and thus cause interference to nearby receivers. A condition govern-

Ing the issuo of a receiving licence is that reaction must not be used in this way. A wireless receiver having reaction on the acrial circuit should not be employed in an oscillating condition during broadcasting hours. When a set is oscillating the received broadcasting will be distorted, and if the tuning control is varied squeals will be heard in the loud speakei or telephones. This is an indication that the reaction contiol knob should be immediately readjusted so as to decrease the amount of reaction applied. See $\Lambda$ iternating Current: Heterodyno: High Frequency.

## OSIERS FOR BASKET MAKING

## Apparatus and Weaving Methods Fully Explained

This article may be described as a continuation of the one under the heading of Basket Making. Entries on other related handicrafts will be found throughout the work, examples being Canc: Raffia; Rush W'ork; Wicker Work. See also Linen Basket

In Great Britain there are about 40 varieties paring a path for the insertion ol rods ; a mau of the osicr used by the basket-maker. They (Fig. 6) for a hammer; a commander (Fig. 7 ) are grown in the low-lying land of the river for straightening stout rods Shears for cutting valleys. When cut the osiers are known as rods (Fig 8) are required, and 3 or 4 way cloaves and are sold as cither green, hrown, buff, or (Fig. 9) lor splitting. A shave (Fig. 10) is white. The freshly-out green are partially dried employed for trimming the split rods to form in stook in the field and are afterwards stacked skein, the latter being similar in appearance to in a shed or in the open and thatched until chair cene, and used for finishing handles, etc. quite dry, losing 50 jer cent. in weight 'The worker also needs a lead weight to keep Fully matured brown rods are used for the work on the lapboard, a yard measure,

D
 in position

Osier. Fig. 1. I'ypical rod lor baske! work. Fig. 2. Boarc for holding work and block which secures upright stakes
coarse basketry in making all kinds of hampers and fruit baskets. Buff rods are prepared by removing the bark from either green or brown rods after they have been boiled in water from 2 to 5 hours; they are then dried in the sun to intensify the colour.
White rods are prepared by removing the bark from green rods, either directly after cutting or after they have been kept during the summer stacked with the bottoms in running water. Pecling is effected by splitting the bark by pulling the rods betwcen a pair of upright iron rods, termed a break, and then removing the bark by hand.

A rod has 4 parts, as shown in Fig. 1: the butt A , the top B , the belly C , and the back D All rods are sorted into lengths; the ehort lengths of brown are called luke, the mediunn lengths long small, threepenny, and middleboro, and the long are great or rods. Buff and white rods in the small lengths are termed tack and small. Brown rods must be soaked from 2 to 7 dnys according to size before they can be used, buff and white rods from half to 4 hours, and allowed to mellow for several hours. The uprights or "sticks" used for bottoms are cut from osiers of 2 or 3 years' growth for large baskets. The radials in a round bottom or cover are also termed sticks.

Tools Required. The tools and apparatus used in working osiers comprise a lapboard and a screwblock (Fig. 2), the former for holding the work in progress and the latter for securing the upright stakes in square work. A shop knife (Fig. 3) is used for cutting the rods; a picking knife (Fig. 4) for trimming the short ends and bending; bodkins (Fig. 5) for pre.
a piece of sponge, and a grease-horn for use with the bodkin.

Methods of Weaving. Single weaving (Fig. 11) between stakes is done in square work by sly ping. (Fig. 12) or trimming the butts of upright sticks, and securing them in the screwblock. The rod is slightly bent as it is carried round each stick, and when the end uprights are negotiated, the rod is gradially

Tools used in working osiers. Figs. 3 and 4. Knives Yor cutting and trimming. Fig. 5. Bodkic. Fig. 6. Mzui. Fig. 7. Commauder. Fig. 8. Shears for cutting. Fig. 9. Cleave for splittine, Fig. 10. Shave for trimming split rods to form skein

Scallomed Work. This method (Fig. 17) is used in making a frame for a bottom or cover and also for staking some forms of basket. It consists of making a long cut at the butt end of a rod (Fig. 18) so that the rod may be turned round the frame and held in place by the next stake. It is useful in making light round and oval baskets and all kinds of covers where lightness and strength are required. The frame to which the scallom rod is attached is called a hoop. Any kind of shape can be made. Scallomed stakes are commonly used in the light and cheap hampers made with slewed weaving. This is because they can be inade in much less time.

Preparing Skein. Skein formed by the trimming of split osiers is used in covering handles and for filling up the sides of small baskets used for holding letters and for pienic, lunch, and linen baskets. The method of preparation is to take a long, straight, dry white rod and cut a few inches off the top Suitable cuts are made at the top, either 2 or 3 according
brought upright, passed round the stick and worked down on top of the others. Slewing, as it is usually called (Fig. 13) is a quick method of weaving, several rods being worked at the same time. It is employed for rough work, but is not so neat or strong as single or randed weaving. If, however, the rods are the same size, the weaving can be kept level. Byc-stakes are used mainly in round work, and consist of supplementary stakes inserted between the original stakes and held in place by the first rows of weaving, called the upsett.
Fitching (Fig. 14) is a method of working two rods alternately under and over each other, so as to hold a stake or bye-stake at each turn. It is useful for open work when it is not necessary to fill up the sides of a basket with weaving. It may be commenced with either the tops or butts, and in practice the rods are worked one after the other in the orles: shown. Cross fitching is done with clouble stakes in cases where the stakes are crossed, a common method of dealing with open-sided baskets. The foot of a basket is formed by driving short

Fig20.Rib Randing

Fig. 2l.Simple Border

Fig22. Triple Twist

stakes in the sides when the work is upside. down : the rods are laid down and worked in the same way as a border. Oval bottoms (Fig. 15) are formed by a slath (Fig. 16), and the sticks or radials separated by working a pair of rods together.
A pair of rods worked alternately over and under each other, the reverse of a litch, is called a pair. This method is used in forming round bottoms and also in adding a second round of weaving on top of a fitch.
licking is the operation of cutting off the projecting ends of rods which are left after the weaving is completed. The edge of the knife must be very sharp, and care must be taken at first to avoid cutting the woven rods. Sufficient material should be left to prevent the end working out past the stake. Pricking up the stakes to bring them to an upright position ready for weaving the upright sides is cffected by the point of the shop knife. This operation prevents the bark or skin from breaking, but this is effective only if the rod bas been properly soaked and allowed to become mellow.

Fig. 26

Oder. Fig. 19. Alternative to plaiting. Fig. 20. Efeotive close weaving. Fig. 21. Mothod of woshing a border. Fig. 82. 8trengthening atakes for a border. Fige. 28 -27. Progressive stages in the maling of an upright plati. Details are given in the text
means of the bodkin. In the sides of square bottoms the outside sticks in the bottom must be pierced lyy the bodkin and the pointed stake driven in alter being dipped in water.

In driving a stake home, it should he grasped firmly in the left hand a few inches above where it cuters the weaving, and the right hand should he slid down the rod on to the left. A fair amount of force should be used, especially when the stake is nearly far enough in. An odd number of stakes is necessiny in slewed quired in randed work. After the stalies have heen pricked up, the tope should be gat hered together and held with. in a honp. In siding up or weaving, the stakes muat lie kept upright and parallel with each other when working straight sides, and when doing work where the sides are splayed outward or worked inward the spacing should be quite even. It is important that the rods used in siding up should be worked to the statics by pressure of the left thumb. As it is essential to the appeasance of the resulting work that the stakes should be even, the latter should be held in the right hand while the left hand shapes the weaving. Horein lies the whole art of basketwork.

Tracking. This is a methorl of finishing covers. and is an alternative to a plait. The method is as follows (Fig. 19) : Place the lirst rod hehind the second and leave it in front of the third. The second should be placed behind the third and left in front of the fourth. Pace an extra rod in front of the first, place the two in front of the third, behind the fourth, and leave in front of the lifth. Noxt place the third alongside these two, add a second rod in front of the second. and place them beoth in front of the fourth, hehind the fifth and in front of the sixth, with the fourth alongside. Continue with the lirst two of the threc (the remaining one, the lirst commenced with having done its work), place in front of the lifth, hehind the sixth and in front of the seventh. To continue, place the fifth alongside, dropping the outside of the thice at each atroke, and when the round is complete work each onc of the rods thmugh to its proper place.
l'jpett is the commencement of the weaving in all except the coarsest work and comprises two, three, or more rods worked alternately on the upright stakes to secure them firmly in position. Wale is the name given to the stroke used in upsetting and other parts of weaving, and formed by working two or more rods alternatcly, one by one, in front of two or more stakes, and then behind one. Wenving is effected in osiers hy coarse randing for heavy work with stakes $2!$ in. apart, slight randing with stakes 2 in . apart, light randing with stakes $I_{2}$ in. apart, and fine or close randing with stakes about 1 in . to $1 / \mathrm{in}$. apart, the work heing driven in close with the iron. Rib. randing (Fig, 20) is an effective method of siding up, and consists of working each rod altermately in front of two and hehind one for two strokes before being worked out in simple randing.

Borders. Simple borders are worked as at Fig. 21, but the stakes may be strengthened beforehand by working the triple twist shown at Fig. 2:). This form of stroke may take the

place of fitching where extra fyll. ness is desired. forming a linish. ing border is the plait. of which there are two forms, upright and llat. The upright plait is made by hendingdowneach upright stake, or spolic, in turn, and placing each one behind the next one on the right Fig. 23. When the last atatic is reached it will have to he thrcaded under the first one that has been turned down. A as at Fig. 24. Each stake is now taken in

Osier. Firg. 28-32. Stares in weaving a fat plait, used for arms and backs of chairs, etc.
turn and placed under the next on the right and made to stand vertically alongside the mecond stake, the last one being threaded through, as at Fig. 25. Each stake is now threaded to the front, lrehind the stake next but one to it, as at Fig. 26, and then each stake in turn is crossed over, the two stakice lying together and passed to the inside, as at Fig. 27. Any surplas ends left on the inside of the basket should be cut off.

The Flat Plait. This plait, used for tinish. ing trays, arms and backs of chairs and other pieces of basketwork is more difficult to make than the upright form, but if it is followed out with actual material, the following instructions, with the accompanying illustrations, will simplify the work. On the surface the finished plait appears continuous.

Commence by turning down three stakes as shown at A, B, and C at lrig. 28. The stake at $A$ is curvel round to the right, passed over 13 and $C$ and placed in front of 1 ), which is now turned down over it and the end left in front as shown at Fig. 2!). The stake at 13 is now picked up and carried in front of the nest two and the first upright of those standing is turned over on it as at E . The same method is followed with C , but, before the upright at $F^{\prime}$ is brought down over it, the stake A, which was left on the inside, is brought across C, and then F, as shown at Fig. 30, is brought down heaide it and the two are treated as one stake. At this stage of the
work there are three mods outsidc, one
heing a douhle stake, and two rods inside. The first of the three is taken round the first upright stake to the inside, crossed with the first of the two to the outside and then the upright stake is drawn down. This method is continued, remembering to draw down the upright stake at every conss of the osier. When the double mods are reached they should be treated as one, both inaide and outside. When the triple rods are reached, the two Innger or outside ones are used, the shortest one being dropped and cut off at the finish. When the last upright atake has been turned down, there will he three triple rods outside and two douhle rods inside the basket. The method a- fiar as this is illustrated at Fig. 31 .
The lirst two long rods on the ontside should he passed under the lirst statie $A$, which was turned down. leaving the short one as usual to be cut off at the finish. The next tivo long mols are passed over the first atake $A$, and under $B$, the sccond that was turned down. The remaining two long rods are passed over the first two, $A$ and $B$, and carried under the third, $C$ : this gives five double rods on the inside of the basket. Each two in turn should now be threaded to the outside under each single stake, as shown at Fig. 32, until all the live pairs are threaded to the outside. There are now five double rods on the outaide, and the longer of the two is threaded from the underside, through the first single stake. Follow to the inside of the basket, and out again to make it double, like the rest of the plait. A bodkin will be weeded to lift the stakes in order to make room for the last five single rods.

OSMANTHUS. This is the name of a hardy evergreen shrub. The nost useful onriety is the Japanese Osmanthus aquifolium, which has holly-like lenves, small white fragrant flowers in winter, and grows 4-5 ft. high. l'ent and loam should the added to the soil before planting. Iropugation is by cuttings in a frame in August

OSPREY. Osprey, aigrette, and egret ale terms used to denote the decorative tufted head plumes of the egret, or smaller white heron. Osprey is the trade name for the egret, but the real osprey is a bird of another species known also ns the lishing hawk. See Aigrette.

OSTRICH FERN. This is the popular name of Onoclea sensibilis, a handsome North American hardy fern, 18-24 in. high. It Hourishes in deep, moist soil in a shady place. Like the Royal fern it bears sjores on special fronds, not, ns in most ferns, on the backs of the ordinary fronds. Onoclen (struthiopteris) germanica is another striking species. See Royal Fern.
OSWEGO TEA. This is another name for bergamot, betanioally Monarda didyma, which heals various other popular names, including hice balm and horsenint. It is a hardy perennial, with sage-scented leaves and bright scarlet Howers in summer. See Berganot.

OTTO CYCLE. This is the cycle of operations by whioh many types of internal combustion engines function. The cycle is made up of four strokes: induction, the fresh gases are drawn into the cylinder; compression, the gases are compressed: explosion, the gases are fired (power stroke); and exhanst, the exploded gasas are expelled. See Intermal Combustion Enginc.

OTTOMAN. A stuffed sent without a back, the ottoman is not often seen except in the form of a floor poufie or box ottoman, its place having been taken by the divan. The Victorian types of ottoman are sometimes divided in the centre with a long padded roll about 12 in. in diameter; others have a centre rail, with a padded top. See Box Ottoman; Divan; Poufle; Victorinn Style.

OTTO OF ROSES. Known also as attar or ottar of roses, this perfume is obtained from an oil distilled from rose petals, damask and musk roses being the kinds generally used. Because of the large quantities of petals needed in its manufacture, otto of roses is comparatively costly. What remains after distillation is made into rose water. See Rose Water; Scent.

OUNCE. This measure of weight is in constant use when buying meat, groceries, etc. ; 16 oz . go to the pound avoirdupois and 12 oz to the pound troy. The ounce avoirdupois contains $437 \frac{1}{2}$ grains and the troy 480.
In the ordinary way the ounce is divided into 16 drams, but apothecaries divide it into 8. They usc it for measuring medicines, when one tablespoonful is equal to $\frac{1}{2}$ fluid ounce, as the apothecaries call it. A dessert. spoonful equals $\frac{1}{4}$ fluid ounce, and a teaspoonful $\frac{1}{8}$ fluid ounce. The usual abbreviation for ounce is oz., which is used throughout this work. See Avoirdupois; Troy.

OUTHOUSE. An outhouse is a small shed or building, remote from the dwelling. Most houscholders at some time or other feel the need for a small outhouse, for storing garden tools, minor crops such as apples, potatoes, and the like. Some small buildings are obtainable commercially in the form of sections ready built up, so that the householder can erect them by simply bolting the sections together.

Examples of this class are available in timber, others clotherl with asbestos cement sheets, and in a number of combinations of both methods, varieties being covered with galvanized iron and roofed with the same material, with tarred felt, bituminous sheeting, or otlier proprietary material.

By-laws. An important point before ordering or arranging for the building of an outhouse is to ascertain the requirements of the building by-laws, as there are sometimes certain restrictions to be observed and certain formalities to be gone tbrough, these varying considerably with the particular district.

It is well to bear in mind that to be a tenant's fixture it is generally understood that the building is of a portable nature, resting upon the ground or upon some brick or cement footings, and not a permanent building. See Fixtures; Shed; Workshop.

OVEN. Whereas must of the operations performed in cookery, such as boiling, frying, and stewing can usually be carried out upon an open fire grate, a small oil or spirit atove, or gas ring, those for which an oven is used cannot be mannged at all without the oven.

Nothing can be more aggravating than an ineffective or inefficient oven, and more failures occur in cooking through the use of an underheated or overheated oven than from any other cause. The article on Baking may be consulted by the housewife. Particulars about ovens in connexion with gas, electric and oil cookers are given in the article on Cookers, while further information about ovens is in the entry on Range. See Anthracite; Baking; Cooker; Dutch Oven; Grate; Hot Water Supply; Range; Stove.

OVERALL. This is a garment which is worn by large numbers of men and women as a means of protecting their clothes while at work. Workers in shops, factories and offices, doctors, artists, sculptors, nurses, and the woman at home, all find it equally valuable, while it is also a useful garment for children to wear while at play.

OVERCAST'ING. This is the name applied to a stitch that is largely used in dressmaking for finishing the raw edges of seams, to prevent the threads from ravelling or fraying. As a rule, the stiteh is worked along each edge of the seam separately, though in some cases it is worked over the two edges
at once; but here it shou!d be noted that for the latter method the scam must be well pressed beforehand, as no thorough pressing can be done after the stitch is taken over both edges. The stitch should be worked with cotton or sylko, according to the nature of the fabric.

To work it, secure the end of the cotton in the matcrial at the left-hand end of the seam with one or two back-stitches, and push the needle through the material towards you, a few threads telow the edge; draw through. and again push through from back to front a little further along towards the right. Repent until the seam is done, and lightly press to take out any puckered effect. Do not draw the cotton tightly when making the stitches, or a puckered effect is bound to ensur, and to get a neat effect make the stitches all of the samo size and to slant at the same angle.

When oversewing a curved seam, in order to prevent any dragging, lirst snip the seam edges at intervals with the sci sors, and round off thic corners caused by the snipping. See Scam.

## OVERDRAFT. This is a banker's term

 for a loan made to a customer on a current account. When by chance or design $a$ customer has drawn out from the bank more than he has put therein, an overdraft results. Overdrafts can be obtained by customers from their banks, provided the security offered is regarded as adequate. See Banking.OVERFLOW PIPE. Any pipe that is connected to the water system for the purnose of discharging an abnormal rise in the height of the normal water leved is an overflow pipe. Generally, in the home, such a pipe is con nected to the hot or cold water tanks to avoid the flooding of the premises. In the case of the ordinary cold water tank or cistern, such an overtlow pije should be as large in diameter as the supply pipe. It should have a regular gentle fall from the point where it leaves the cistern to the point of dischurge, which should be over a gutter or in some place where the water can get away without running or splashing on to the buiiding.

It is advisable that the overflow pipe be visible, so that should the water be wasting, its loss will speedily be made apparent, and the cause can be remerlied. Generally, an overHow will be due to the failure of the ball valve In a hot-water tank, the overfow pipc is generally arranged in such a manner that it acts as an expansion pipe. It relieves the tank of all pressure due to the generation of steam or the expansion of the water, and acts as an overflow should the cistern flood.

Such an overllow pipe is usually set in a vertical position and terminates in an elbow or bend at water level. This is because the water as it heats will risc, and a certain amount of such expansion is not detrimental to the system ; it is only when the expansion is above the level of the water supply that it should be possible for it to drain away. The

Overfow Pipe, showing how the pine should slope gradually from the cistern to the outfall
up with leaves. It should be regularly examined nand any obstructions remored
Overtlow pipes generally take the form of a short pipe passing through the wall and mercly projecting into the air. This arrangement is usually satisfactory, as it is seldom, if ever. that the water ovcrllows through it. They arc provided as a safety device The materials for such pipes may be lead. wrought iron, galvanized iron, brass or copper Of these, galvanized iron or galvanized steel is the most durable. See Plumbing: Tap: Water Supply

OVERMANTEL. This, as the name suggests, is a fixture over the mantelpicce. Such fixtures are made chiefly of wood, which may be oak, walnut, maliogany. or enamelled or painted deal. They are made in a great variety of styles, with inset mirrors which may be square round or oval. Unless the overmantel forms an integral part of the chimney piece, it is often the better plan to remove it and to use a panel of embroidery, a flower or landscape painting, a mirror or merely a good ornament on the mante!shelf, according to the typc of fireplace and style of the room. See Chimney Piece; Dining Room Drawing Room; Fireplace; Mirror.

OVOLO PLANE. This is a specially shaped plane, which is used for working an ovolo noulding on wood. The usual form is made in beech, and the sole shaped to a reverse of the shape of the moulding which

Ovolo Plane. A common type of the tool in use
the plane will produce. The plane iron is similar to other plane irons, but is shaped on the cutting edge to correspond with that of the ovolo moulding. In use the plane is traversed along the woorl in the same way as a jack plane, but should be guided on the wood either by a fence or temporary strip tacked to it, or by careful manipulation of the plane. esprecially when commencing operations. If this is not done the shape of the moulding will vary in respect to the edge of the work.
In sharpening such a plane iron, it will be necessary to use an oilstone slip, of a shape and size to suit the curvature of the plane iron, employing this as though it were a file, to work up a keen cutting edge. The care is similar to that of other wooden planes. See Plane

OXALIC ACDD : Poisoning By, Because of its resemblance to Epsom salts, oxalic acid, which is popularly known as salts of sorrel, or lemon, and acid of sugar, may be taken accidentally. When strong oxalic is swallowed violent inliammation of the stomach and intestines immediately follows. Follow. ing on an intensely sour taste, a burning pain is felt in the throat and stomach; vomiting occurs, and often the vomit contains blood. Collapse suon ensues from the severe pain, and this may pass into stupor, and death may spoedily take place.

Treatinent must be very prompt to give any chance of life While awaiting the doctor, if vomiting has not occurred, give an emetic of a tablespoonful of inustard in $\frac{1}{2}$ pint of tepid water, but only if dihite acid has been taken. As an antidote, give chalk, or 2 tablespoonfuls of inagnesia mixed with water. Bicarbonate of soda or potash, or aminonia, should not be given, as these form soluble
compounds with the poison. Put the patient on a couch, cover him warmly and surround his body with 5 or 8 hot-water bottles.

OXALIS. Of these low-growing plants, some of them aro hardy, while others are suitable only for cultivation in the greenhouse. Of the former a charming kind is the unod sorrel (Oxalis acetosella), which grows wild in Britain and is suitable for shady places in the rock garden ; it bears white flowers in spring, and is sometimes sold as shamrock. The two best hardy kinds for the rock garden arc adenophylla, pink, and enneaphylla. white : they like partial shade and a compost of peat and sandy loam. A familiar plant in many gardens is the bronze-leaved yellowHowered Oxalis corniculata rubra, which spreads rapidly and soon becomes a wecd. The rose coloured floribunda is a beautiful piant to grow in pots under giass.

OX CHEEK : How to Cook. Ox cheek makes a substantial and appetizing dish if baked, or it cani be made into $a$ very good soup or stew. The cheek should come ready cleaned from the butcher, but requires soak:ing and well washing before any attempt is made to cook it.

After it is thoroughly clean, place it in a arge saucepan and cover it with warm water, add a teaspoonful of salt, and boil it up. As the scum rises take it off, and, when clear, let it simmer for an hour. Lift it out of the pan. let it cool a little and then bone it carefully. This must be accomplished with a sharp crook's knife to avoid ragyed appearance.

While the cheek is boiling a good stuffing must be made. Spread it in the boned ox cheek, roll it up and tie ur skewer it securely in an oblong shapc. Bake in a moderate oven for $1 \frac{1}{2}$ hours, basting frequently, and serve with a good, thick brown gravy.

To make soup, prepare ox cheek as for baking, and place it in a pan with enough cold water to cover it well, and $\frac{1}{2}$ oz. salt. When it boils, skim it and add 2 onions, 2 carrots, 1 turnip, and $\frac{1}{2}$ head of celery. All vegetables must be prepared and cut up Add a bouquet garni. Let the cheek simmer $2 \frac{1}{2}$ hours, then lift it out and remove the meat from the bones. Strain the stock, clear it of fat, and thicken it with brown roux. Cut the meat into squares, boil it up in the soup, and pour into the tureen. The bones will make $\Omega$ good addition to the stock-pot. See Becf.

OX-EYE DAISY. This is the common name of Chrysanthemum leucanthemum a familiar wild Hower of Britain May Queen is a splendid variety for the garden. The Shasta daisy or hardy marguerite (Chrysanthemunı maximum) is a vigorous hardy border plant, 2-3 ft. high, bearing large, white, longstemmed flowers in summer. Particularly fine varieties are Mayfield Giant and Rentpayer. Buphthalmum salicifolium, another ox-eye, bears large hright yellow flowers in late summer; it grows 2 ft high. Propagation is by division in nutumn.

OXFORD FRAME. A characteristic of the Uxford picture frame ls the arrangement of the corners, which crons or overlap, and are not mitred in the usual way. The frame may be made in any wood, but one of the hardwonds, such as oak, is perhaps the most appropriate. The frame may be plain or have chamfered edges. . See Picture.

OXFORD SHIRTING. The most usual pattern of Oxford shirting is a neat check in blue and white or red and whito. It is rather warmer and thicker than ordinary calico, and hence specially suitable for winter wear There are imitation Oxford shirtings with a printed instead of a woven coloured pattern. In the real article the pattern is the same back and front.

OX GALL. Purified ox bile is sometimes used in medicine. chiefly as a laxative. It
stimulates the action of the liver and emulsifies
fats. It also acts as an antiseptic. The dose is $\overline{5}$ to $\mathbf{7 5} \mathrm{gr}$ of fresh ox bile, which may be taken as a bolus, wrapped up in wafer paper, or in capsules

## Oxidation. See Rust: Verdigris.

OXDDIZING: Of Metals. Oxidizing is a term given to the coloration of metal objects by changing the surface to a brown-bronze or black tint by a chemical or electro-chemical process. As every metal is attacked by chemicals in varying degrecs and with various results, it is best to treat each separately. In general there are three methods, chemical, electro-deposition, and heat treatments, which latter may or may not introduce chemical changes in the surface.

The amateur can electro-plate on hase metals some of the finer metals, such na copper, silver, nickel, brass or gold, with a view to applying an oxidizing process. Among these preparatory processes brassing may be mentioned, silver, nickel and copper plating being reforred to under the heading of electroplating (q.v.). It is usual to adopt a brass coating on the baser metals, iron, zinc, whitemetal alloys, etc. The finishing coat for oxidizing may bo applied as in the case of a solid brass. The electro.deposit should be thick enough to withstand the penetration of the chemicals used in colouring.

31 ost of the chemicals employed are highly poisnnous, and the yrealest care should be taken in handlin! them and in disposing of the spent solutions so that no ilanger to animale or liuman beings is incurred.
The brass plating bath may be made of 1 oz . each of zinc and copper sulphate, 2 oz . of carbonate of potash, and 3 oz . of cyanide of potassium. The first two are dissolved in hot water, the potassium carbonate separately. and added a little at a time. The cyanide is made up into a 25 per cent solution and mixel with the others, stirring the bath all the while, the final result being a muddy yellow liquid of about $2!$ pints in bulk.

The solution is boiled for about half an hour, filtered, and watered out to 23 pints. The intensity of the current largely controls the depositing. If the coating is too white, denoting the zino, a reduction of the current will deposit more copper. Brass may be used

Ox-eye Dass. Larke white blooms of an easily growa plant
for the anode, but separate strips of copper and zinc are perhaps better. It is best to deposit mainly copper towards the end of the process. For coppering only, the solution is the same except for the zinc sulphate, and $n$ copper anode would obviously be employed. The processes involving electro-deposition require clectrical power of low voltage and comparatively large amperage. The article on Electro-plating should be consulted for further details

Treatment of Silver. Silver oxidizing is a proccss with quite a misleading name, as silver oxide is not formed, and is not a part of the colouring film. Sulphur is the chiof agent. For oxidizing silver or silver plated artioles from light golden to brownish black, a hot solution of barium sulphide, I oz. to the gallon of water, is often employed. The work, if not just emerging from a plating process, must be cleaned in a hot potash solution, rinsed, and given an acid dip, swilling afterwards in a large body of water, and then passed through a cyanide dip, rinsed in hot water, and driel. For producing a matt surface, the acid dip is composed of sulphuric acid, 1 part; nitric acid, 2 parts : sodium chloride (common salt) and zinc sulphate, each.ahout one-tenth of an ounce to the pint.

When in the oxidizing solution the silver work is shaken about until the desired blueblack density is obtained. It is a fterwards rinsed in boiling water. Oxidized silver work can be locally lightened as desired. Brushing with bristle brushes and pumice powder will give a grey colour, and the original silver may be exposed where necessary for artistic effect by rubbing in the pumice pow ler vith the fingers. Varnishing may be accomplished with a colourless varnish of the nitro-cellulose type, or one of the proprietary brands of lacquer may be used.

Another oxidizing formula is $\frac{3}{} \mathbf{o z}$. of potassium sulphide and 1 oz . of ammonium carbonate to the quart. The solutions are mixed separately and worked hot. This conting is quite robust, and ivill stand the scratch brushing process employed in ordinary plating. The work only requires immersing for a short period. To produce a matt, or dead surface, the article should be dipped in a sulphate of copper bath, after electro-plating with silver in the ordinary way. A insted white results, and the whole or portions of the work may be treated to obtain the desired effect

The paste method involves a mixture of plumbago (black lead) and turpentine with n little red ochre or muge. It is spread over the work and allowed to dry. The parts in relief in the artiole are then rubbed with a chamois leather or soft rag dipped in methyInted spirit. This is only applicable to engraved, moulded, or chased articles, and, with such, gives the old silver effect. The work can be cleaned off in n caustic potash or cyanide bath. Sulphuring silver gives a blued stecl colour. The work is subjected to the action of sulphur fumes in a tin box with a tray to hold red hot charcoal or cinders. lowdered su/phur is spread over the cinders and the lid closed with the work suspended in the fumcs. The work must be quitc clean both chemically and mechanically

Oxidizing Copper. For copper a solution of amenonium sulphide, $\frac{1}{}$ to 1 oz to the quart of water, is used. The depth of tone, light brown to black, depends on the time of immersion, and the temperature of the bath, and the colour is more completely controlled if the bath is not hot. The work can be lightly scratch-brushed and rinsed. The uniformity of colour, independently of the cleanliness of the work, depends on the purity of the copper; therefore, it is better with objects that have been coppered by electrodeposition. In any case, a copper artiole might be passed through a copper plating
bath as a proliminary, to improve the surface for oxidizing.
Potassium sulphide, $\ddagger$ oz to the quart of water, with a few drops of ammonia, provides a brown tone imitating Japanese bronze work. The solution is used warm. Copper nitrate, 8 oz . to the pint of water, gives a deep black tonc. It is used warm and the work should be immersed several times, allowing it to dry between the dippings. Brass oxidizing is more difficult to control and to predetermine in the matter of colour, because of the varying characteristics of the alloy. Such work is often plated with copper first.

Iron and Steel. In iron and steel oxidizing, brown colours may be obtained by covering the work with a paste of antimony chloride and olive oil in equal parts and heating it slightly for 12 hours. The paste is rubbed off with a suft cloth and finished with a wased brush. The work requires a preliminary cleaning in a picklo of nitric acid. A black colour may be obtained on iron or steel by an inımersion in a hot solution of sodium thiosulphate, $\frac{1}{2}$ oz. to the pint, and greys in $a$ hot pickle made by diluting a mixture of 2 oz of arsenious oxide in strong hydrochloric acid in onc gallon of water. The heat treatment of iron and steel by the BuwerBarff process provides a protective coating of black oxide of iron, $\mathrm{Fc}_{3} \mathrm{O}_{4}$ and involves heating the work to redness in superheated steain.
Perfect cleanliness is absolutely necessary in the colouring of metals by any of the processes described, and it must be remem. bered that acids do not remove grease, and contact with oily or naturally greasy fingers should be a voided. If ostensibly clean objects are handled promiscuously before oxidizing they aro likely to show marks where the oxidizing reactions have been prevented by the finger marks. The use of rubber fingerstalls or gloves is to be recommended in all operations where they can be employed. P'ermanent results are also often dependent on the final lacquering, many suitable coloured and colourless varnishes lring obtainable. ree Bronzing; Electıo plating; Putina.
Oz-lip. This is the popular name of Primula elatigr see Primula.
OX-TAIL SOUP: Cut into juints 2 ox tails, dividing the pieces in as uniform a size as possiblc, and soak them for an hour in cold water, adding $\frac{1}{2} \mathrm{oz}$ salt to 3 pints of water Remove the pieces and wipe them Iry; then fry them in 2 oz. butter or good clarified dripping until of a rich brown colour. Put them into a stewpan with 2 quarts stock, 1 good-sized onion stuffed with 2 cloves, 1 carrot, 3 sticks of celery, or celery seed if the fresh vegetable is not available, and a bouquet garni. Let all boil up. skim and simmer for 3 hours or until the neat is tencler.

Remore the pieces of tail and thicken the liquor after carefully clearing it of fat. The thickening should be made by frying 2 oz . Hour in 1 oz. butter and then thinning it down to a liquid with a little stock. Add by degrees to the soup and boil for a few minutes. Meanwhile boil in clear stock or water a medium-sized carrot, turnip, and onion, prepared and cut in julienne shape. Strain when cooked. Put the pieces of tail into a $t$ ureen and strain the soup, boiling, over them, then add the shredded vegetables. Give the soup a stir and serve hot. Keep the tails hot while thickening the soup. See Carserole.

OX TONGUE. In town an ox tongue can always be procured ready pickled from the butcher, and all that remains to be done is to soak it, thoroughly wash it, and boil it, putting it into cold water and letting it come very slowly to the boil. After it has been skimmed it should simmer $3 \frac{1}{2}$ to 4 hours, according to size, and be allowed to go cold in the water in which it has boiled. Take it up,
remove the white skin and trim the ront. The tongue may then be skewered into shape on a dish, with a rolling-pin unclerneath to support it. When cold, remove rolling-pin and pour liquid glaze over to coat the tongue. Or it may be pressed into a round mould or cake-tin and covered with a plate, and a weight on top. and left till colrl.
A fresh tongue, one that has not been nickled, is sometimes prepared and cooked, but before boiling it blanch it in order to remove the whitc skin. The root must be well trimmed. and it is better to soak the tongue before blanching it Serve hot with a piquant

Ox'Tongue, shaped and pressed, a delicious cold dish tor breaklast of supper
sauce. When boiling a fresh tonguc use stock instead of water, and add soup vegetables to Havour it. See Glaze.
OXYGEN. About one-fifth of the atino. sphere consists of oxygen, which is a colourless, tasteless gas. By the act of breathing, oxygen in the air is drawn into the lungs, and becomes absorbed by the blood, which gives out, in exchange, carbonic acid gas.

Oxygen is also necessary to com bustion. The air in a closed room becomes used up by breath. ing and by using coal gas or candles for lighting, its place being taken by carbonic acid. This carbonic acid if it accumulates beyond a certain quantity makes the air unfit for people to breathe. That is why it is 80 ) necessary to have a room well ventilated. An open fireplace is of greal assistance in this; fresh air should, be admitted by the windows.

Oxygen is sometimes inhaled by perple who suffer from illnesses which cause difficulty in breathing, e.g. pneumonia, and for this purpose it is stored in cylinders, obtained through a chemist. See Ozone ; Ventilation.

OXYMELS. An old-fashioned yet valuable remedy for cold and sore throat is made of vinegar and honey, and is known as oxymel. Mix together 2 oz . of vinegar and 2 o7. of water and add to 1 lb . of honey. Stir well together, and put in a jar, which should be kept covered. Give as a dose a teaspoonful three or four times a day.

13y mixing squill vinegar with the honey, oxyinel of squill is formed. It is obtained made up from a chemist's. This is used as an expectorant, the dose for an adult being $\frac{1}{2}$ to 1 dram. It is a favourite remedy in the bronchial troubles of children. A child of six would be given a fourth of a teaspoonful of it in water every threc or four hours.

OXYTROPIS. This perennial plant, 12 in or so high, is popularly known as milk vetch. It bears small, pea-shaped Howers in summer. They need a warm, sunny place and light soil. Ochrolcuca, yellow; Lambertii, carminc-rose, are two of the best.

OYSTER. Although oysters do not suit everyone, they are to most jeople very digestible when eaten raw. Conking makes them hard and tough, and they are not recommended in this state to peiple whose digestion is weak. The composition of the oyster is as follows: Water, 88 per cent; protein, $i$ per cent : and carbohydrate, 3 or 4 per cent. It will be remensbered that they are out of season during the four months of the
year whose names do not contain an " $\mid$ " in
It is not advisable to and Angust.
It is not advisable to drink spirits with oysters, as this may retard digestion. If from any cause troublesome symptoms should arise after eating oysters, a glass of milk frequently gives relief. Unopened oysters improve if kept some days and fed with oatmeal whieh fattens them and makes them more luscious The sunall native oyster is considered best for taking raw, but the large sorts can be used for soups and stews

To prepare oysters to be eaten raw, first scrub the shells. Hold the oyster in a thickly folded cloth in the palm of the left hand, with the hollowed shell downwards to hold the liquor. Work all oyster-knife, or a sharp tinopener, between the two shells with a sec-saw action till enough of the knife is inserted to force them apart. Renure all bits of shell. Serve the oysters in the deep halves of their shells, standing on ice if pussible. Lemon cayenne, and thin brow'n bread-and-butter should always be served. Grated horseradish Tabasco saucc, and celery (when in season) are also liked by some people. Raw oysters may be served as cocktails ( $q . v$ )

Cooking Oysters. In cookery thie oyster is used for small savoury dishes stufting, and sauce. It is sometimes bearded, blanched and added with the strained liquor to a steak-pie or pudding. It is also fried in a light fritter batter, after coating with egg and brcad crumbs.

Oyster Aigrette. This dish can be made by putting $\frac{1}{2}$ pint water and 1 oz . butter in a pan over the fire, and when they boil adding to thein 4 oz. sieved Vienna Hour. Take the pan from the fire, beat its contents until they are smooth, and then cook them over gentle heat until the panada leaves the sides of the pan. Let the mixture cool a little, then beat in separately 2 eggs and an extra yolk, and add 3 oz . grated Parmesan cheese and season. ing to taste. Turn the whole on to a plate where it may cool; then beard a dozen oysters and season them with cayenne and lemon juice.

Have ready a deep pan of smoking hot fat, and into it dip a dessertspoon. Then half fill the latter with some of the cheese mixture, make a hollow in the centre, and in it lay an oyster, covering it up with a little more of the inisture. Drop the aigrette from the spoon into the pan ; prejare 11 more in the same way, and fry them slowly for about 5 min . After clraining, serve them with thin rolled brown bread and butter, cayenne and lemon.

Oyster Forcemeat. Oyster forcemeat is used for stufting boiled or roast turkey. To make it, beard 18 oysters and cut them into quarters, then mix them with $\frac{1}{\frac{1}{2}}$ pint breaderumbs, $\frac{1}{2}$ teaspoonful dried mixed herbs, 1 oz. finely chopped suet, and seasoning to taste. Bind the mixture with a beaten egg, adding more beaten egg or a little milk if necessary.
Oyster Fricassés. A nice Iricassée of oysters can be made by boiling up a dozen oysters in their liquor, straining them, and then reserving the liquor. Melt I oz. butter in a small pan, stir in the same quantity of flour, and then add the oyster liquor by degrees, stirring the whole until it boils. Continue cooking for a few minutes, then move the pan to the side of the fire and add the yolks of 2 eggs, the oysters, a squeeze of lemon juice, and seasoning to taste. Dry toast should be served with this dish, which is suitable for invalids.

Oyster Patty. The cases are prepared first for oyster patties. Take $\frac{1}{1} \mathrm{lb}$. hest puff paste for these and roll it out abont $\frac{1}{6}$ in. thick or rather more. It is impossible to give the exact depth as so much depends on the pastry maker and the size required. Cut out 10 or 12 rounds of paste with a small round cutter. Mark out a smaller round in the centre, using another
cutter not quite so large, hut do not cut right through.

Cook till the pastry is quite done and a fine brown Now lift the cases on to a wire tray, remove the small centre round, scoop out any uncooked paste and lay aside ready for the filling.

Blanch 2 dozen oysters for a fow minutes, drain and beard them, and cut each in two. Now mix them with a rich white sauce, add a wineglassful of white winc and some of the oyster liquor. Fill the cases, cover with the lids, and re-heat or serve cold. An average size fur the case is $2 \frac{1}{2}$ to 3 in . arross.

Oyster Sauce. Blanch 18 oyaters in their own liquor, adding a glass of white wine : beard them, and clarify and anve the liquor. l'ut into s saucepan 2 oz butter and, when melted, cook in it for 4 min ., without hmonn. ing, the sume amount of flour. Add ly degrecs I pint warm milk or white atock and simmer till all is cooked and quite smooth Add scasoning, a little grated inutmeg, the oyster liquor, 1 teaspoonful lemon juice, also the oysters. Heat up before serving See Patty : Soufflé.

OYSTER GRAIN. This term is used by furniture collectors and others. It refers to veneered pieces of walnut which, owing to the appearance and direction of the grain, resemble tho insides of ovster shells. It is frequently found on Queen Anne furniture See Qucen Anne Style.

OYSTER SHELL. When hented until they crumble, or when ground, oyster shells make a useful addition to potting composts These shells can also he put to good use in a fowl-run if they are first crushed to a fine powder. In this form they supply hens with the necessary amount of lime to ensure the laying of hardshelled eggs.

OYSTER SHELL SCALE. Various fruit trees are attacked by this scale insect. The Ministry of Agriculture suggests the following methods of dealing with the pest.
The oyster shell scale is much reduced in numbers hy the attacks of its natural enemies. One valuable enemy is a jet-black ladyhird with two red spots on its wing cases. When husing young stock all trees hearing scales or showing the characteristio little white scars should be rejected, unless the seller can guarantec that the stock has been fumigated with hydrocyanio acid gas or otherwise cleared of scales. The scale insects can he killed by thoroughly washing the treas in winter with lime-sulphur.

OZONE. When clectic currents are passed through oxygen, as in worling an electrical machine, a peculiar odour hecomea noticcable. This is due to the formation of ozone, which is n form of oxygen. It exists in the air hut in populous neighbourhoods hecomes used up by combining with earhon particles in the air. It is ahundant in the air at the seaside and up mountains. It is a powerful oxidizing agent, and in virtue of this property is employed as a disinfectant. An excess of ozone may produce headache, cough, etc. See Oxyゥe"

PACK. In the medical sense a pack is a covering in which the palient's hody is swathed. A hot pack is used to promote perspiration in disorders of the kidneys and other complaints ; and a cold pack for reducing the temperature in high fevers. See Cold Pack; Hot Pack.
PACKING. In packing clothes, the first thing to decide is the number and kind of boxes required, which will vary according to the conteinplated length of ahsence from home, the number of persons travelling, and the nature of the wardrohe that it will he necessary
to take. The expanding type of suitcase often is suflicient for the short holiday; or another convenient form of luggage is a verv light suitcase, with a stronger onc for heavier articles
To pack, place the suitcases on stands or on a bed, when care should be taken to spread something over the coverlet first. Into one of the cascs should be put, well wrapped up, boots and shoes Books, woollengarments, stockings, coldar hox, and any hard or heavy articles are wedged in as flat as possible, so that at the top there is room to lay lieavy ouler sports clothes and rolled-up felt, wollen or clath hats or caps.
In the other suitcase a woman would put light underwear, night wear and dressing. gown, laid flat het ween lavers of tissue-japer ; then a light coat, frocks or suits, with n good roll of tissuc-paper wherever they are folded

## Paching Men's Clothes

A man might pack the second suitcase in this way: 'To ohtain full advantage of the Hat surface, hegin with evening clathes folded according to the length of the case, with a layer of soft papier at each fold. Then, sandwiched between pyjamas and light underwear, come the shirts. Evening shirts slonuld be reversed the was of the launilry, folding them so that the fronts are inside and thus protected. the ends heing carcfully tucked, into the neckhand. Place all thesc llat with handierchiefs and tie-case nicely levelled against them, and then on the top fold the suits and flannels.

Men's clothes should be tightly packed, so if the suitcase is not quite full, it is hetter to put in an extra garment than to riak the shifting about of all the contents. A heavy dressing gown, if required. may he put into the first suitcase, a thin one into the second. All toilet things, including bottles, can go into the small case. and as this would he carried. there is little risk of breakage.

For the luxurious travellet, the American wardmbe trunk saves much trouble. These travelling wardrobes, however, are too expensive for general use, so where a large quantity of clothes has to he packed, cuening and other dainty frocks can be carefully folded, with plenty of soit paper, in cardhoard hoxes, which keeps off the pressure of heavier clothes, and placed at the hottom of a trunk. When packing hats into a tray or hat hox the insides of the hats may be filled with such articles лs handkerchiefs, gloves, and ties.
A large hold-all and a hig folding hasket are both excellent things to keep ojen till the last moment for forgotten family necessaries A hahy's things can be packed in its hath with fitted lid strapiel securely on to it, and where a perambulator is taken, a number of necessary things can be stowed away in it under the waterproof cover Careful overhauling of the
family wa rdrohe several days liefore the actua day of departure grently facilitates packing

Packing for domestic purposes usually requires a strong container, and some wood wool, shavings, crumpled newspaper, or bran Large articles, such as a piece of furniture or a perambulator, are wrapped up in sacking. making up ropes of straw, and winding it round all the exposed parts, or entirely covering it with the sacking sewn together at the joints hy means of a packing-needle (sce Necdle) and pack thread. which is fine, thin string, but strong cnough to ensure firm stitching. Whecled vehicles should he made up so that the packing does not prevent the wheels rotating, and thev can then he moved ahout as required very easily instead of having to he lifted and carried.

Packing Fruit and Flowers. Fruit is difticult to pack if it is to arrive nt its destination in sound condition, but it can he placed in hay or straw, if both of these are perfectly d.y, firsh, and clean. The householder will generally prefer to use n light wooden box as a container, with paper and bran as pack ing material. This gives entirely satisfactory results, if a layer of hran is placed on the hottom, and then a laver of crumpled paper: as illustrated. Each article should be separatcly wrapped in tissue paper, bran poured round it, then covered with another layer of paper, another laver of bran, and so on until the case is full. Flowers to he sent hy parcel poat are heat packed in a stout cardhoaril-hox They should be made up into bunches and wrapped in tissue-paper with slightly moist ened moss or grass round the stems; this is secured by more tissuc-paper and inserted into the box, and the cavities filled with tissuepapier. See China; Crate; Parcel; Removal.

PAD. This word is used to denote several different articles. There is the writing pad or hlock; the boot pad, made of velvet. for polishing boots; the pad of lint. or gawe and cotton wool, usod in surgical dressings, and the ink pad used with a rubber stamp. Sea 1)ressing; First Aid: Ruhber Stamp.

PADLOCK. This is a form of.detachable lock, intended to hang on the part to he fastened. The usual type comprises a casc containing the lock mechanism having on onc part of it a slackle or curved metal har, so that it can lic hinged or turned, and the opposite end fastened to the lock case by the look holt and mechanism. Patterns are made of japannerl or galvanized iron. Common onea have a one $w$ heel ward, or a sham lever mechanism. Ket ter types have two or three ward wheels and levers, the mechanism being similar in principle to other forms of locks. The cyiinder or pin tumbler system is adapterl to the mechanism of the pradlock, and such locks possess all the well-known advantages of that system. Some very small padlocks ano made with asimplespring lock Another type with a small metal key is convenient for locking small articles, e.g. cash boxes. See Bolt: Door: Lack
Pad Saw. See Keyhole.

PAGODA TREE. This is a small family of hardy and green house flowering shruhe, known as Sophora. The only onc worthy of note, except in large collections, is S japonica, a summerleafing shrub with bluish-green leaves and white flowers. It should he planterl in
autumn, pruned in February, and is propa gated by seeds or by division. There are a fers varieties which need only ordinary greenhousn treatment. See Shrub.

Pail. See Bucket.
PARLLASSE. This word is sometimes used for an under mattres. Originally a paillasse was a small bed of utraw or chaff. As comfort became more general this was used to put benenth mattresses or beds of a better kind

PAIN : Its Relief. Pain is of many differen: kinds It may be constant; or only occurring at intervals. Sometimes it is dull and aching as in chronic rheumatism or sharp and cutting, ns in pleurisy ; throbbing as in the case of an abscess, or burning or smarting. as when the skin is inflaned Pain is not always felt at the exact spot where the harm is For instance. neuralgia may be felt in the head and the cause be a bad tooth
One great use of pain is that it draws attention to disease which might otherwise be overloulied In times of great excitement or when the mind is fully occupied, it is possible to forget even severe pain. Pain is, however very exhausting, and if only for that reason calls for relief.
In treatment the first cunsideration is, it possible, to get at the root of the troublo If an insuund tooth is cousing neuralgin
have it removed An abscess in the same way should be lanced It is generally pussible to relieve pain, for the time at least, by giving drugs, which quicten the nerves and dull the senses, either simple analgesics like phenacetin or aspirin or narcotics Care must bctaken in using ana цcsic remedies, and narcotics should only be taken under medical observation.

For home treatment, nothing is more likely 10 succed in soothing pain than heat. especially when it is combined with moisture For internal pains, a hot-water bo tle mny be useful, or fomentations (q.v.) of hot water. For pain in the chest, arising from cold, a mustard and linsced poultice is a suothing remedy. A mustard poultice may also relieve lumbago

Electrical current: are often auccessful, and in some cases ionization. Friction will sometimes give relicf in muscular pain, as in chronic rheumatism, and the use of a little cainphor, well rubbed in by the hand, will often ease joints that are stiff. A strong cup of coffee will often remove a bad headrache It must be remembered that quiet is often desired by persons in pain, and this. tugether with rest and warmth, will go far to relieve many forms of suffering. Sec Enubracation Fomentation : linsed ; Mustard : Neuralgia Poultice : ctc

## Paints \& Painting in Home Decoration

## The Best Methods and Materials for Paint Work and its Cleaning

The following is one of the many articles that deal with the question of decorating the home, others that fall into this category including Enamel: Graining; Panelling Paperhanging. etc
Certain precautions have to be cxercised in monly called turps, is also used for thinning paint work of almost every kind. If the paint the base and making the paint more easily is to dry nicely, the surface to which it is applied must be clean and frec from grease or dirt ; the paint itself must be of good quality and suited to the class of work; while the material to be painted must be prepared by conting it with mixtures known under such names as fillers, stopping and underconting The brush also should be of suitable shape size and quality.

Paint is applied to impore the appearnnce and to assist in the preservation of the object painted. It bas alsu a sanitary and hygienic value. If the surface to be painted is greasy and dirty, and the paint is applied to it in this state, it is obvions that the dirt will remain, although covered by the paint. The proper method is to remove the dirt and grease bo fore applying the paint, and this can be done by scrubbing with bot water and soda.
The Ingredients of Paint. In connexion with the home, painting is generally done with oil colour paint, but in a more comprehensive sense it includes the use of water paints and other decorative material applied in the form of paint, Therc are also available the various nitro-cellulose finislies (sec Enamel). Oil paints often have white lad an a base, or body. This material has great covering power and weathers well, but as it is very poisonous, a zinc white base, composed of oxide of zinc, which does not possess the poisonous qualities of white lead, is largely employed. The base is diluted with a thinner, generally composed of lin. seed oil, and both this and the hase should be of first quality. Oil of turpentine, com-

Paint. Fig. 1. Implements which are essential lop the amatent painter. Reading in rows from lelt to right: paint kett!e, tin of paint, blow lamp,
patty knife, sponge, dusting brish, backing knife, stripping knile
obtainable, and although the genuine turpen tine is to be picferred, the substitutes answer very well for most paint work Pigmente are finely ground colouring materials used to culour paint for ornamiental purposes and to give opacity. They are made from various animal and mineral substances, and are ob tainable either as finely ground powde: of ground in oil : in the latter case they are paste like in substance, and are used in that form for tinting oil paint. Knotting and fillers ready for use can be purchased from nost oil shops

Ready mixod paints, if made by a reputable firm, are very convenient to the amateur but for matching up existing work, or prepar ing a special tint, it is preferable to use white lead, or zinc white, diluted with linseed oil or turpentine, and stained or coloured by mixing with it sulficient of the desired colull to impart the requisite tint. Nany of the ready mixed puints are available either in the form of the common paint, which drics with a lustreless surface, or with the addition of a !ittle varnish, which resulta in the paint drying with a semi-glossy surtace. Generally the common paint answers very well for the second coat and the varnish paint for the finishing cuat IVater paints are really a form of distemper, in paste or powder lorm, and only reguire to be mixed with water For interiurs they are particulariy effective.

The technique for applying ce!!ulose finishes is explained in the article on Einamel (q.v.).
To carry out painting work properly the amateur should posyess several cleantins with handles, known as painters' kett!ow, a Iarge sized sponge, a goud piece of pumice-stone, a blow lamp for burning off the old paint, a scraper, or stripping knile, hacking and stopping knives for clcaning ont the bad places and working the stopping into them These are illustrated in Fig 1

When the colours are to be hlended, a clean earthenware jar is required for mixing a palette and palette knife, and some fine muslin for straining are necessary A dusting brush leather, clean duster, and regular painter's apron are very handy, and the amateur will find it a good plan to wear a pair of old gloves.
Paint Brushes. A selection of btushes for general use consists of an oval ground brush ahout 2 in . wide, a varnish brush about 1 in . wide, two or thrce arsh tools of various sizes, and a fitch about 1 in. Wide for painting the edges of narrow vork. The best brushes are made of hogs' bristles; some are adulterated by the addition of vegetable fibre

The size of a brush is denoted by a number, $1-0$, up to $8-0$, and $10-0$, the latter being for house painters. In some cases the bristles are bound to the stock or handle with cord or twine, in ot hers with copper wire or tin band or ferrule. The bristles are arranged to form flat, oval, or round brushes, and for general purposes the oval is preferred. Sninller sizes, termed sash tools, are useful when painting the smaller surfaces in door and window frames.

There are also brushes for dusting the surfaces preparatory to putting on the colour They are usunlly round in shape, with much longer bristle than ordinary bruslies, curving olltward. Brushes for varnish are of a finer bristle, and flat or oval; the former are bound with tin, and will be found most useful for general purposes.

A brush known as a stippler is used for going over painted surfaces whilst still wet to remove brush marks. It is a large, llat brush, rather wider than a hoot brusla, and the bristles are set so elosely together that when the brush is lightly and evenly dabbed all over the surface, a minute nid even granulation results.

Brushes for use with cellulose tinishes should be set in rubber, as the solvent. employed
would dissolve the binding material of the ordinary type of brush.

On no account should a new brush he put into immediate use without some previous preparation. The bristles will have become dry since the brush was made, and are liable to come out on to he painted surface apoiling the work and ruining the brush All new brushes should be soaked in clean, cold water for at least $2 t$ hours. This will enuse the bristles and the stock to swell so that they will not 80 readily part company Brushes hound with a tin hand should not be soaked for quite so long, or the band may burat.

New brushes should not be placed in an upright position when soaking, but should be laid in a flat, shallow vessel, and this also applics to brushes that have heen lying aside unused for some time Brushes should never be put away without cleaning them of paint. this can be accom plished by "ashing thoroughly in a little turpentine, and rubbing dry with a clean cloth. A loop of string should be tied on the end, and the brush hung up, the bristles being covered with paper to inside quality, and the work then painted in cxclude dust Treated in this manner brushes will last much longer.

Exterior Work. As an example of outdoor work, suppose it is desired to paint the rainwater gutters and down pipes with, for example, niddle purple brown. The first step is to rub down the old paintwork, if in fair condition, give it a coat of anti-rust priming, and after this is dry apply two coats of ready mixed varnish paint (Fig. 3). A wooden fence, if in fair condition, should first be brushed down with a stiff hristle brush, like a scrubbing brush, dusted with a dusting brush, given a good coat of undercoating of any reputable make intended for outside work, or known ay uutside quality, and then given a coat of the common ready mixed paint; when this is dry and hard a coat of ready mixed varnish paint is applied. If the svork is not in good condition, the old paint should be burned off with n blow Inmp, the surface levelled up with stopping, and the painting operations proceeded with as. if for new work
On the exteriar woodwork of the house the windows may require the old paint to be burnt off with a blow lamp. Fig 4 shows this operation in progress. When the paint is alightly warmed and burnt with the flame from the blow lampi this has the effect of softening it, and it is then cleaned off with a stripping-knife, as shown. The work should receive one or two conts of good quality outside undercoating or stopping, and be finished with two coats of ready mixed paint.

A door is treated in the same way, except that it should receive particular attention in the way of stopping all the cracks and holes. This may be effected with any of the special stoppings sold for the purpose, or ordinary putty may be used if the work be given a primary coat of undercoating, the putty being applied nfter this has dried.

If a particularly good finish is required, the work should be well sandpapered when the undercoating is thoroughly dry. Exterior
stone or cement work should be prepared by brushing it over with a hard brush, filling in the holes or cracks with Keene's cement, and preparing the surface with red lead priming This is followed with a coat of stopping or undercoating of outside quality, and finielied with the paint, or may be pointed with liquid cement, if cement colour is preferred

Indoor Work. Interior work is prepared in the same way as the exterior, except that inore attention should be given to the surface to make it as smooth as possible This is followed with a primer or underconting of with a wire brush before applying a new coat ol naint
dust it down, and give it a coat of undercoating or flat paint, and then linish it with a glossy or flat paint, whichever is desired.

The llat, or wall paints, as they are celled. are intended specially for painting "alls; but if the surface is new plaster the result is scldom entircly satisfactory. The procedure is to apply a priming coat and follow this with a fat colour, using the primer supplied by the miakers of the wall paint. Water naints are generally applied to plaster work after it has been given a coat of size or priming, which ever is recommended by the makers of the narticular paint to be used

Woorlen ..ours are often painted in the same way as any other work, so far as the pre liminary cleaning and preparing are con cerned, but the finishing may be carried out with one of the special floor paints
Ironwork. The decoration or repainting of a stove is often carried out with a goorl quality Brunswick black when a glossy effert is required, but if a dull or so-callerl antique black is wanted, it is best to use Berlin black. If either of these colours is too thick to work nicely, it may he thinned with oil of turpentine For painting radiators, interior water-pipes, cisterns, and the like, an aluminium paint is very effective. The first thing is to thoroughly clean the imonork, removing all traces of rust either by scraping or by using a wirc brush, ne in Fig. 5. Water should never bo applied to metal work; if neceasnry use instead one of the recognized paint removers, or wipe over the metal work with a rag saturated in turpentine
When undertaking any painting operations, it is best to work in dry weather, and this applies specially to outlloor work The paint should never be applied on a dainp surface, as the dampness will almost certainly make the paint crack and peel off. To avoid dust settling on the wet paint surface, when dealing with interior work, water should be sprinkled on the floor, or wet cloths may be placed about the room to keep the dust down, and the doors and windows should he kept closed

Cleaning Paintwork. One of the simplest methods of cleaning painted wood work is as follows: The surface is first washed over with warm water whioh has been whisked into $\pi$ soapy lather with a good soap, clean, soft flannel being used for this purpose. The sufface is

Paint. Fig. 3. Applying anti-rust priming to a rain-water pipe. Fig. 4. Process of burning and scraping of the old paint by means of a blow lampand stripping-knife. Fig. 5. Cleaning radiator pipes
eone over a sccond time with a cloth dipped in clear warm water and left to dry A clean flannel is soaked in linseed oil, and when it has nosorhed all the oil it is put aside until it is just moistened with the oil. The wood work is then wiped over with the oily cloth, rubbing it one way all the time This process makes the paint look like new, and the lin sced oil applied in the operation sets as a preservative to the wood
Where the paint is very dirty the following mothod may be tried : To 2 quarts of hot water allow 2 inblespoonfuls of turpentine and 1 of skimmed milk or mil: and water. Stir these ingredients together and ndd just enough soft soap to make the mixture soapy, but not a thick lather. The paint should be gone over with a clean flannel dipped into the preparation and wrung out so that the woodwork docs not become sloppy. When all the paint has been wiped over, it is gone over again with a clean dry flannel, and will then be found to have taken on a nice lustre.
l'aint that is badly soiled should be cleaned with a mixture of whitening and soaj, flakes To nlake this, a packet of soap flakes is dissolved in sufficient hot water to make a thick, creamy lather. Crush to a powder a lump of whitening, and add enough of this powder to the soapfather to make it creamy
'Two howls of hot water and the whitening and soap mixture in a basin should be at the workor's hand. A clean piece of rag is moistened from the one bowl of water, dipped in the whitening and soap, and then rublied well into the dirty paintwork. It is advisable only to attempt to clean a small surface at once. When the stain has been gone over with the preparation, the rag is dipped in the howl of clean water and the paint wiped over with this. Another dry rag is used for wiping it dry. The whole surface of the paint is cleaned in this way.
White paint can be cleaned with onion water. Hoil 3 or 4 onions, or more if a large surface is to be cleaned, until all the gondness has gone out of them; then strain off the liquid. This can be used without soap for cleaning white paint. A clean rag should be dipped in the onion water and this rublied over the paint. Polishing should be donc with a dry duster, but a very slight rubbing up will result in a high gloss on the paint

Milk can be used for white paint, or milk and water, the same method being followed as with the onion water. Fuller's earth can be used instend of soap for cleaning white or coloured paint; it is useful for cleaning $n$ painted wainscot that hos become very grimis. The fuller's carth is made into a paste with water, and a rag dipped into this is applied to the paintwork. A clean rag is used to wije away the preparation and another rag to polish the paint after it has been cleaned Soda should norer bo used. An excellent result is obtained after any of the above methods of cleaning have becn followed if a little furniture cream is rublied into the woodwork and a final polish given with a duster.

Paint Stains. Paint marks on clothes should be treated while they are still wet, otherwise they may be difficult to remove. Wipe off as much of the paint as possible, then rub the nffected part with spirits of lurpentine or spirits of wine, applying it with a soft rag or flannel. The same method should be adopted for dry paint marks, though the result may be less successful. If preferred, benzine may be used instead, but owing to ts inflammable nature the operation should he carried out in the open air well away from any llaine or fire.

Health Precautions. The sinell of paint is unpleasant to most people, frequently causing licadache and a feeling of nausea. When a house must be freshly painted, have it done if possible, in warm, dry weather, so that the
windows can the kept open and the paint dry quickly. If green paint is being used, special care should be taken that it is free from arsenic. A freslily paintel room should never be slept in until the paint has been dry for quite two days, and in winter a firc will be necessary in the room as well as open windows.

Painter's colic is chronio lead poisoning due to a want of care in cleaning the hands before taking food on the part of those who handle paint. In the case of an attack an emetic should he given at once.

Little children are always inclined to carry cverything to their mouths, and therefore gaily painted toys should not le given them.
PAINT BOX. This may he purchased empty, designed to hold either water colour paints in pans or tubes, or tubes of oil colour, or may be obtained stocked with the requisite colours and brushes. 'The choice of a box depends in a large extent upon the nature of the work which is to be carricd out by its aid. Thus, if most of the work is to be done out of duors, a more portable hox will be necessary than when working in a studio or painting room. The simplest, and probably the inost useful, is the small japanned tin variety with sections for colours, pencils, etc. Wator colour hoxes can be obtained in miniature sizes for sketching at any good artist's colour shop.

For oil colours a convenient size measurcs 10 in . by 6 in . by 1 in ., and contains l! tubes, with two glass bottles, one containing linseed oil (purified), and the other spirits of turpentine, fitches, pencils, ctc., and a palette. If the colours are chosen carefully, with duc regard to the type of work to becarried out. a box of this size will be found to answer
most purposes satisfactorily. Cheap colours naturally lack the purity, transparency of tonc, and smoothness of texture which accompany the better qualities, and they are also inclined to lack permanency.
The particular oil colours and brushes sclected will depend upon the lines to be followed, but the following gives n suitable selection for gencral work: llake whito, vandyke brown, light red, ivory black permanent blue burnt sienna, yellow ochre, raw sienna, and Prussian hlue, in 4 in tuhes: with Naples yellors, chrome No 1. vermilion, and crimson lake, in 2 in tubes

A 4 in. tuhe of McGuilph should be obtained in addition. This is the medium most generally used to mix or thin the colours and consists of a mixture of mastic varnish, linsed oil cte. If it is intended to specialize in landscape work, Indian red, hurnt umber, raw umber and terra vert should be included. in which casc it will bo necessary to substitute 2 in tuhes for some of the 4 in . ones.

A useful selection of brushes consists of 2 sable and 2 squirrel hair brushes, 3 flat hog-hair brushes. French if possible, Nos 1 3, and 5 ; and a larger one, No. 11 A palette knife dippers and cleaning ray aro

PAINTED CUP. This is a half-hitridy perennial, botanically known as Castilleja. with lloral lenves, or bracts. Threo species aro in cultivation, pallida coccinen, and animata, all requiring a very sunny and sheltered position, with protection during the winter Planting is best done in April, from scedlings which are raised in heat and then hardened off in a cold franic

## Painting on Textile Fabrics

## Simple Ways of Decorating Accessories for Home and Dress

Directions for other methods of applying ornamental designs to fabrics-are given in the articles Embroldery; Pattern Printing: Pen Painting; Poker Work; Stencilling. For further related Information see Bag: Fan; Gesso Work; lampshade: Needlework Picfure: Pencil Painting

In common with other decorative arts for the home worker, painting on silk, satin, georgette, velvet, gruze, cloth or linen depends ainost entiroly for success on suitable choico of design and colouring for the article selected to be ornamented in this manner. Painting on linen or canvis can be particularly beantiful when employed for panels to be used as mural decoratio:s or to be framed and glazed as fire screnns. Special mediums are recpuired for painting on woven fabrics and can be obtained at shops which stock colours and matorials for artistic crafts.

Perhaps one of the most important things is to find the correct consistency of the colour for the meterial on which one is working. For instance, $a$ delicate, transparent effect is essential for linen and taffeta, while velvet or cloth must be treated with opaque methoils. Satin in light colours requires the delicnte method, and in dark colours the opaque. Either elfect may be successful on gauze.
lvory coloured inffeta or sation can be painted in a style which has somewhat the appearance of ctching It is done with noist water colours, line sable brushes, pre'erably Nos. 1, 2, or 3 , and delicate effects are obtained by using tints of sepin or black. 'The piece of silk or satin, with white blotting paper bencath, is fised to a drawing-board with drawing-pins, and the selected design is drawn in pencil or transferred by moans of tracing paper. The outline is lightly defined with a brush and the shadows indicated. The brush must not he too full. Details are added and shading accomplished by cross-hatching lines, sky and water being lightly washed in. Seascapes are successfully copied in this method and old prints.

A combination of ncedlework stitclies to raise portions of the design and of painting produces heautiful and uncommon janele for
sminll screens or for use, under glass tops, on dressing tables. Flower pieces can he painted in the same way, but require flat washea of delicato colour after the manner of old prints. loor other atyles of painting on silk suitable for Inmpshades or candle shiclds the reader may consult the article on Inmpasiade. These methods can be adapted for clegigis for dessert doilics and for handkenchief sachets. l3lack or bluc carbon paper should not he used for transferring designs on to delicate mintcrinis, but the design should he triced on to tracing paper, turned so that the heavily pencilled lines face the minterial and these are then gonc over with a hone or ivory tracer. Special tranafers may also be ohtained from a good art demaitinent in a store

Ordinary oil colours or stencil colours can lie employed for painting on textiles, but must be used with the correct nedium to prevent the paint from running or cracking. I'en painting is also used, and is described under a separato heading. It is well to avoid loaded materials. The preparation used to atiffen certail silks miny appear on the paintel surface like specks of gummy substance. Such a material should, if possible, be washed hefore pninting, in order to remove the dressing.

An Effective Method. A good method of decorating gauze, silk, satin or cloth is by using a special outfit of colours made for painting on thesc fabrics. A feature of this style of painting is a ruised edge which forms a setting for the design and makes it effective for such accessories as satin night woar sachets, pochettes, cushions or gauze doilies. Bronze colours are used to outline the work, but these must be employed very cautiously or n garish appearance will result. Special coloured gold and silver flakes are also obtainable.

To paint a set of dessert doilies a 7 -in. square of silk gauze will be required for each piece.

Painting on Textile Fabrics. Fig. 1. Making the raised oulline on a gauze dessert doily. The tin nozzle is screwed on to the tube of special enamel. A hin, even line flows through the hole in the nozzle and resembles a fine Courtcsu of Winsor \& Necton

Place this over the design selected (if a transfer is used, lay a piece of tracing paper between it and the gamze or the transfer ink may spoil the material) on a drawing-hoard covered with clean white blotting paper. Pin the with clean white blotting paper. Pin the for the leaves. Green and gold dlakes
gauze, as shown in Fig. I, on to the board with were used for the enamel outline of the drawing-pins. Do not atretch ton tightly. On leaves and the flower outlines were covered a saucer or china pinlette put out a little of the colours required; thin with turpentine and a little medium. A No. 3 sable brush can be used for filling in the dosign. The colour must be laid evenly on the gauze and the palcr shades used first. When these are dry the darker shades are painted in.
'Jhe blotting paper should not he removed until the patinting is linislied. The colours percolate through the gnuze to some extent, and unless left on the blotting paper or tracing paper till diy, the tints will le very pale.

The raised edge is made almost as if using $\Omega$ funnel for loreing ieing on a decornted cake. A tiny paper cone can be used, filled twothirds full with apecial enamel, the top turned over and pressed down till the bag is taut, and then a minute hole cut at the point. The bag is held hetween tirst linger and thumb and the point must not touch the work or the hole will be stopped up and the line hecome uneven. The enamel flows in a thin line to form a line cord. A tuhe of silver or gold llake or a bronze powder as used in gesso work is liept at hand to sprinkle over the line. This is allowed to dry mid then the surplus fake is removed with 8 soft brush. For rather bolder outline a tin nozzle can he fixed to the tube of enamel end used ns shown in Fig. 1. Nozzles are olitainuble in two sizes.
When painting on dark materials, as, for instance, dark satin for a nightdress sachet, yellow carbon pejer can be used for transferring the design. Fix the work as already described. To paint, first fill in the design with white to kill the dark material and proseal, using steacil oil colours. Outline with the cnamel, putting the small nozzle on the tube, and lust on gold flake for llowers and silver for leaves.
The pochette illustrated in lig. 2 was made of beige suède cloth, but such adesign could

Fig. 2. Suede cloth pochette decorated with a conventional degign in special colours for painting on fabrics and outlined with gold Courlesy of Winsor \& Neulon
with flakes to match. The design is repeated on the other end of the scarf. 'Tlie special paints, medium, tin nozzles, priper cones, ellamel end llakes used for this work are known as Jargeena materials for painting on febrics. Other somewhat similar paints are known us Silkart.

Washable silks and georgettes which have been printed with these colours can be cleansed in a lather of good soap Hakes and warm water. The hest method is to shake the article up and down in the lather in a glass preserving jar with it screw top (p. (i99)).
Having rinsed it, press the article gently with $\Omega$ clean cloth to absorb the moisture, then iron carcfully, placing a clean cloth betwcen the material and the i:on. Iron on the
be equally well wrong sidc, and use a blanket or a soft painted on n moire folded towel to avoid finttening the raised edge. pochette. The design Painting on Linen. Outline very The design may be traced, ironed off from it finely, using gold transfer, or drawn freehand. bronze dusted over the chamel.
An idea for a scarf end is illustrated in Fig. 3, which is equally adaptable to a work bag. If using georgette or material in a pale colour for a scarf procced na described for the doily. Tlie art of painting on all such fabrics is to use ns little colour as possilile, leaving the
manterial itself to form the high lights. The design was worked out in pastel sliades of pink, mave, blue and yellow with green e painted is placed over white blotting paper and pinned down to a drawing-board. For a
design similar to the one illustrated a Japanese print could be copied on to the linen in pencil, but the sinateur, unless skilled in drawing, should practise with some simple design, such as a galleon in full sail or a floral pattern which can be traced in the ordinary way. Scraps of linen will do to experiment on before attempting an ambitious panel. Unblcached linen gives a beautiful effect, a white pencil being used for high lights and the colour of the linen being left in places for half tones.

T'o paint. dip a paint bruslı in water and moisten a small portion of the design. The colour is applicd in strokes with the stick or pencil and afierwards distributed evenly with the brush. Be careful not to spread the water over the edge of a piece of the design where a firm outline is desired for the particular colour. Fill in the tints as desired, leginning with the palc ones. Detail can he superimposed by outlining with a pencil dipped in water. Before using carmine, yellow or sap grcen. fill in the portions of the design with the white pencil and work the colours over white.

For darkening red, and for ontlining when shading, as for instance, on the red lapanese

bridge in the illustration, use violet over scarlet. For darkening grecn, as for the detail of the foliage, use dark blue over green ; to darken orange, use carmine for the shaded portions. 'To lighten any colour use the white pencil, either over or under the colour.
After completing thic art work, fllow the materina to dry thoroughly. To fix, dissolve one tableapoonful of plain gelatine in a pint of hot water. When cool lay tho painted linen in it Take out without wringing, lay it tlat on a towel, and leave it for 24 hours to set. Then press out by ironing on the right side. When soiled, the pancl, or other article made of linen painted in this method, can be washed in the following way. Put three tableapoonfuls of table salt in is quart of water and let the fabric soak for five minutes. Then wash lightly in soap finker. Rinsc in clean cool water without wringing Lay smoothly on a towel, roll up for a few ninutes, and then iron on the right side.

Water colour pencil painting can also be used on georgette and other silks. It has a softer appearance on these fribrics than the other colouring mediums already described, but some excellent effecta are possible.

PALETTE. A palette is usually oblong or oval in shape, and occasionally it is made to fold. Artists who work a great deal in the studio often use a large palctic known ns an elbow palette, which is shaped to fit the arm, and may be 16 in . to 18 in . long. $A$ palette may be made of various materials, such as Honduras or Spaniah mahogany, baywood, sycamore, satinwood, 3-ply wood, porcelain, etc. It should be sufficiently light to causc no inconvenience when held in the hand for any length of time, and yet it should be thick enough to ensure it against warping.

To obtain and preserve a good surface on a wooden palette, take a piece of superfine sand paper, rub gently but firmly all over, along the
grain of the wood, and when satisfactorily smoothed pour n small quantity of fat oil on the palette, or usc olive oil if fat oil is not procurable. Then spread all over with a rag, allow it to soak in for $n$ few minutes, and remove the surplus. This process must be repented until the desired gloss is obtained, which will probably take about a week The final result, however, makes the trouble well worth while
No oil colour should be allowed to stay on the palette after finishing for the day All colour must be carefully removed with the palette knife and placed either upon a porceInin palette, into small cups and saucers, or even upon a sheet of glass, and placed under watter. The palette should then he rubbed over until clean with a rag moistened with spirits of turpentine, and finished ofl with an vily rag
A nother variety is the scenepainter's palette, which is really a hoard 3 ft. $U$ in. by 2 ft. (i) in by ? ill thick, around three sides of which are small compartments, wherein are placed the various colours to be used on the screen or cloth, mixed with the fixing medium. size, etc., and blended in the centre space. This palette is stood firmly upon a stand or "pmn a pair of small trestles.
Palette Knife. This is used mainly for scraping the paint from the surface of a wooden palette, and is made of highly tempered steel, tapered to a round end, and fitted in
a wooden handle. It should be kept perfectly clean and bright, and when not in use coated with vaseline or oil. In the bold and massive style of oil painting, the palette knife is often used to spread the colour on the canvas; and, when used with care, paint may be removed from a canvas as from a palette. A paletto knife is a most uscful kitchen implement for turning omelettes, etc.
Pallet. Strictly speaking, a pallet is a mat. tress made of straw. The word, however is sometimes used for a mattress of any kind.

PALLOR. In most people pallor is an indication of ill. health. It is $n$ common symptom among persnns who live without sufficient light or fresh aị, or who are overworked, or have not enough nourishing foud. It is also oftell to be noticed in growing ohildren, who bv their rapid develo!!) ment have exhanated their strength. This must be trented by more fresh air and sunlight, better food and iron tonics, etc A child who is not sent to bed in good timc will invariably have a pale face
A suclden pallor may occur fromemo-

How to Grow Palms. 1. Sowing the Rooseberry-like seeds: $a$, drainage : $l$, eaves: $c$, find sandy peat. 2. Boz planred under frame: $a$, manare $b$, beat pipes. 3. Seed soaking for 24 bours belore sowing: a, heat pipes. 4. Seeding potted : a, crocks: $b$, cinders; $c$, compost. 5. How to water palms. 6. Rool bound plant needing repotting. 7. Repotting in larger pot: $a$, new compost in water for palm manure. 8. Effect ol scale insect on palms

Another fan palm is latania borbonica: both single stem it becomes bushy owing to the are suitable for rooms, though their large development of suckers or shoots which grow leaves take up a good deal of space. Geonoma from the basc.
gracilis, kentia belmoreana and kentia fosteriana are palms which are in great demand for toom and window decoration owing to their graceful habit of growth.

The date palm, phoenix dactylifera, is of less value in greenhouses and conservatories; than phoenix canariensis, which develops into a large specimen. Tho palm called rhapis tlabelliformis differs from the others in habit of growth: instead of being restricted to a

## Palmistry for the Amateur

## An Entertaining Feature for a Garden Party

## This article is one of those that deal with the social and recreative side of life, others in the same class being Evening Party; Garden Party; Thearicals. See also Bazarr

l'he amateur palmist is often a successful entertainer at garden or indonr parties or charity fêtes. Out of doors she should he provided with a small tent, which may le decor ated with stencilled black cats, crescent moons, signs of the zorlinc, etc, and indoors with either ת curtained alcove, or screened corner in which to reccive her clients singly. Sometimes she wears $\Omega$ Spanish gipsy's costume, or eastern garb with a vashmak, and an aromatic brazier may add a touch of mystery.

Sitting opposite her sulject at a small table, she can most conveniently study hands lying loosely on a cushion. A magnifying glass may be used, and a good light is essential The hands should be laid palm downward at first in order to observe the nails and relative length of fingers to thumb. For a strong will the thumb should reach the middle joint of the first linger. Short shaped nails are a sign of critical faculty and fondness for detail; round nails indicate hasty temper; broad nails, aancasm and love of argunent; filhert shaped nails, retinement, but leck of aggressive power unless allied to a stiong thumb. In turning over the hands hold the palins firmly to ascertain whether hard or soft ; the hard palm is one of the signs of strength, the soft of luxury; $a$ long palm denotes obstinecy and selfishness ; a wide palm courage; a narrow, bigotry. It should be remembered that good or bad qualities are often emphasized or neutralized by comparing one point with another.

Types of Hands. When the hands are lying palm upward they should he classifiel as one of seven types. The elementary has short, stiff fingers and palm large in proportion, indicating small brain power or self-control. The spatulate has wide, llattenedout finger tips, and broad rather thick palm equal in length to middle finger, indicating self-reliance, courage, patriotism, love of property; but if the heart line be poor, arrogance and lack of sympathy. The syuare has squared finger tips and firm, flat palm, indicating love of order, business acumen, and conventionality, but with undeveloped mounts of Venus and Luna, hypocrisy.

The conical has tapering fingers and smooth, slender palm, indicating love of beauty, refinement, good taste, but with snall thumb and poor headline, laziness

Palmistrg. Diagram of left hand illustratng principal lines and signifcant parts. Fingers : A, Jupiter ; Bercury ; three phalanges shown numbered. On the band, $1,2,3$, and 4 are mounts of Jupiter, Saturn, Apollo, and Mercury respectively ; 5, mount of Linna; A, mount of Venus; 7 and 8 , mounts of Mars. Péncipal lines : E'E, life; FF, head: G G, heart ; H H, tate ; XX, Apnllo
and discontent. The philosophical has tapering or square finger tips, and knotted joints; a long hand, indicating deep reasoning power and appreciation of beauty, with the dominating interest of truth. The psychical type has rounded finger tips, narrow palm and slender thumb, indicating idealism, imagination, and occultism. The mixed has one finger spatulate, another tapering, and so on, indicating a person with facility for many things; but in a weak hand, indicating instability.

The Mounts. The next points to be studied are the mounts or fleshy risings on the palms Jupiter's mount is at the root of the first finger and shows gencrosity and ambition; if rising excessively arrogance is denoted, or if deficient, selfish coldness. Saturn's mount is at the base of the second finger, and indicates prudence and wisdom ; if highly developed it denotes occultism, if excessively so a tendency to melancholia, and if deficient insignificance. A pollo's mount, at the base of the third finger, indicates love of beauty, artistic talent, and desire for recognition; if excessive it denotes vanity and love of notoriety at any cost ; if deficient, materialism dominates the rest of the character.

Mercury's mount is at the base of the little finger and indicates love of change and excitement, activity and cheerfulness, good practical capacity or inventive power; if excessive it denotes an inordinate desire for gain; if deficient, a lack of brain power. There are two mounts of Mars, one helow Mercury's on the piereussion of the hand and the other helow Jupiter's. If full, hoth mounts denote courage ; the former also passive endurance and coolness in emergency, the latter leadership; if excessive they indicate tyranny and violence; if deficient. lack of sclf command and timidity. Luna's mount is op posite the root of the thumb and indicates imagination and romance; if excessive, it denotes love of mystery, caplice or morbidity; if it is deficient, lack of imagination.
'The mount of Venus is the lower part of the thumb and indicates love of beauty, harinony and pleasure ; if excessive it denotes inconstancy and luxurious tastes; i deficient, coldness and lack of sympathy. A hand in which all the mounts are equally developed shows a well-
spatulate hand a goos Mercury's mount indicates scientific ability, or with hoth mounts of Mars full, a soldier or sportsman. In a mixed hand a good Apollo's mount with Luna's well developed denotes the characteristics of a practical artist.
Meanings of the Lines. The principal lines of the hand are the lines of life, of the heart, head, fatc, fortune and health. lied lines are an indication of cheerfulness and vitality; pale lines of weak character, purple lines of melancholy. Chained or broken lines are a sign of obstacles or weakness, wavy lines of periodical bad luck. Double lines are good; sometimes the second line appears by the side of a break, counteracting the misfortune or ill. health which would otherwise be denoted Many lines on a palm, besides the six mentioned, indicate a nervous temperament, capable of keen joy or sorrow, while few extra lines may be talien to mean that the subject is not easily impressed or worried by sutround. ings. Lines on the left hand are said to denote the character and fate at birth, on the right what the subject or circumstances make them.
A good life line should be clear cut and surround the hase of the thumb, starting from midway between the fork of the thumb and ront of first finger. A break indicates illness or an accident, if shown in the right as well as the left hand. Fine lines crossing the life linc from the mount of Venus indicate the influence of other persons.
The line of head should go right across the palin near the middle and he clearly defined. Should it join the begimning of the life line it shows lack of self-conficlence, but if there be much space hetween the two lines rashness is denoted. Many small lines crossing the head line indicate headaches, and if it lie close to the heart line it is a sign that the heart rules the head. A fork at the end with a good mount of Mercury means argumentative power; with tho mounts of Apollo and Luna well developed, literary ability.
Tho heart line starts leneath Mercury's mount and crosses to Jupiter's. Without branches it indicales a loveless life, forked under the first finger, ideal affection. When it ends lietween the first and second fingers it denotes a temperament lonely from in. adaptahility.

The line of late runs up the centre of the hand more or less to Saturn's mount. If this ine be clear and long it inny balance a poor lifc line, especially with a good mount of Mercury. Age on the fate line is reckoned from the wrist upwards (the opposite epplics to the life line), the head line cutting it ct about :30, the heart line at 45 and the iest of the fate slown above. Should the upper portion be firm and clear, in contrast to the lower, success or happiness will come rather late in life.

Sometimes this line is inissing, in which case the existence is uneventful. If it goes direct from the wrist to Satum's mount it means good fortune without much struggle for its attainment. When broken below the head line it is an indication of mental and moral struggle, hut if the line of fortune le good and the fate line start cgain, success will eventually be achievel. If the fate line is broken, but a second line starts by the break and cargies on to Saturn's mount, it means that a new career is enterel upon; when lined or chained at the beginning it indicates an unhappy childhood.
The line of fortune, or Apollo, may start from near the life line, from the fate line or from the heart line, and goes to the soot of the third finger, denoting success in art, fame, tiches or lionour. Should this line be absent, even with $\Omega$ good fate line, the subject will have to work hard with small success. With a well-developed mount of Venus, music or painting is indicated; with a good mount of

Luna and lorked head line, literature; with spatulate third finger and full mount o. Apollo, dramatic work. Should the line be weak before mecting the heart line and then lear ahove, it shows that difficulties arising in the way of artistic success will be, or have been, overcome.

The insrriage line is on the percussion of the liand, at the side of Mercury's mount and above the heart line, running horizontally with the latter. An early marriage is indiated by the line being near the root of the linger; midway between that and the heart line the marriage would be ahout 30 , lower down at 35 or later. A line from the mount of Venus will probably be found to cut the life line at the age.

Should the marriage line be forked on Mercury's mount it is a sign of separation, and many small lines on the percussion denote short love affairs. A second deep line, if the first he cut through, denotes a second marriage. Small vertical lines to the root of the little finger from the marriage line are said to indicate children. The ring of Venus encloses the mounts of Saturn and Apollo, and when clear and unbroken is is sign of ardour, ability. and a sensitive nature

Three good lines across the wrist at the basc of the palm are said to denote prosperity and to strengthen the life and fate lines. Crosses on lines are indications o! trouble, the nature of which is decided by the line on which they appear. Stars are talien to he circumstances outside control. On Jupiter's mount a star means ambition, gratified by others; on Saturn's, undeserved misfortune ; on A pollo's, selebrity; on Mercury's, dishonesty; on the mount of Venus, a happy marriage. A star on the life line signifies a catastrophe, on the hend line an accident. Squares indicate protection from some evil; a syuare round a star nullifies a bad meaning and intensifics a good one. A triangle, formed on a linc by two other small lines, is an indication of added power
PALM OIL. The yellow solid fat yielded by a $W$ African palm is used in the manu. lacture of soap, and when purified, as one of the ingredients in margarine. On account of its rich yellow colour palnı oil is employed for colouring pomades, only a small proportion, 1 dram to 1 oz , of other fats being required. See Oil

PALPITATION. In health the action of tho heart is not noticed. Under certain circumatances, however, a violent, irregular beating or fluttering may take place, causing distinct and often most unpleasant feelings in tho chest. Any strong emotion, such as fear, joy, sorrow, or anger, may bring this about. A very coinmon cause is indigestion, and a heavy or unwholesome meal taken late at hight will frequently bring on an attack. Too much tea, coffee, or alcohol, or excessive smoking, are other frcquent causes. Palpitation is a symptom of annemia and sone diseascs of the heart.

The canse should be ascertained, and if naemia, indigestion, or any similar condition is present, it should be rectified When associated with a nervous condition, a healthy, regular life is the best remedy
During an attack give the patient air, and let him keep still, lying down, but with the head and shoulders well raised on pillows, as palpitation is wont to give a feeling of suffocaion. A teaspoonful of sal volatile given in threc quarters of a wineglassful of water will help to relieve the patient ; or a little brandy or whisky will answer the same purpose. A large mustard plaster applied over the heart will be beneticial. See Heart.
PAMPAS GRASS. With its tall silvery plumes in autumn the hardy perennial pampas grass attains a height of from \& ft . to 8 ft ;
the sma!! flowers are white, blue, or ye!low according to species It is uscful as a centre kroup or specimen on lawns, and is jropagated by seeds It prefers sheiter to sun, and the plumes may be gathered for the purpose of indoor decoration a eoon as they are developed. The technical nam is Gyncrium.

PAN. A pan is a broad, shallow vessel used for cooking and other purposes in the home Pans are of several kinds, rach made

PANAMA HAT. This is a very light lolding hat made from the young leaf of a palm whieh grows in America. The leaf is finely plaited into hats, which can be rolled up into very small compass, and are prized for their lightncss, flexibility and wearing quality

Thong h Panama hats scldom or never wear out they become tanned with the sun or soiled, and necd periodical cleaning. This can be done at liome by rubbing the hat all over with a clean rag soaked in lemon juice, which has a whitening effect, or by using a straw hat cleaning preparation obtainablc at a chemist's See Hat

PANCAKE: How to Make. The success of this dish depends on the quality of the ingredients employed, fresh eggs and purc milk being cessential, and on the thorough beating. The fat also in which the cakes are fried should be white and tasteless, and should not have been used previously for any ot her purpose.

For family use an economical batter will answer the purpose, and to make this, lake 1 pint milk, 3 eggs, $\frac{1}{2} \mathrm{lb}$. fine tlour, and a saltspoonful salt. Sift the flour and salt together
to suit the purnoses to which it is put, e.g. frying pan, porridge pan, preserving pan, etc. See Baking; Bed-Pan; Bread Pan; Frying Pan: Saucepan, ctc.

PANADA. The meaning of panada is bread soalsed or boiled with milk or water. The term is applied to any thick boiled paste made with flour, butter, and water, or flour and milk, as the basis of a savoury or sweet dislı. For example, water, butter, and Hour boiled together to form the foundation of choux jastry is called a panada

To make a bread panadn, place the crumb of a new roll or a small portion o the crumb of a loal in a stewpan with about a tcacupful of water and alittle salt. Boil until it becomes a pulp and add more water, as that which was first put in boils away or is absorbed When quite soft iemove it from the fire and beat in quickly the yolks of

Pancakes, a dish widely recognized as the Strove Tuesday sweet 2 or 3 eggs, previ. ously whipped togother. to taste Sugar may be added in a basin make a well in the centre of the to taste, also Havouring of nutmeg, cinnamon flour and beat in the eggs one by one, using
or lemon, and a glass of wine, if approved only aufficient of the Hour lo form a thin of, for those who are adults. Milk panada is paste. 13y degrees beat in sof the milk and made much in the same way, but the bread the iemainder of the Hour, and continue should be boiled with ns little water as beating until the whole looks light and possible, and when cooked new milk should frothy. The consistency of the batter while be added to it, and it should be flavoured and sweetencd to taste. The milk should not be allowed quite to boil, but must be very hot. Sec Creanı Bun; Pastry.

Pampas Grass. Tall plame-like seed beads and folizge of a hardy nereanial useful for an open space io a large garden

When mixed, add by degrces the milk left over, pour the whole into a jug and put it by for an hour or two: giving it an occasional stir. Before frying, have ready, melted in a small saucepan, some land or clarified fat l'our in enough fat to cover the bottom of the pan, let it become smoking hot, then add a thin layer of batter, move pan about until batter spreads evenly, and fry it until the underside is a rich brown. Toss the cake, or turn it with a thin aluminium slice, and fry the other side. To toss the pancake, shake the pan gently until the nancake slips down over the edgc of the pan, give pan a sharp, up. ward flick with the wrist, when eake will
turn completely over into the pan. When the eggs are whipped separately. For a dish brown drain it on a hot dish covered with of French pancakes. take 5 eggs ; separate kitchen paper, dust it with castor surgar, the yolks and heat them up with 3 oz casto sprinkle it with lemon juice, roll up, and keep hot until the other pancakes are fried.
Castor sugar should be handed round with them, also lemon cut into convenient pieces. To rary the flavour, jan or orange may be substituted for the lemon. A richer batter may be made by increasing the number of eggs to 5 , and decreasing the milk by 2 table. spoonfuls for each egg thot is added.
Irish pancakes are made with 4 yolks and 2 whites of egg to each $\frac{1}{2}$ pint milk. To make them, melt in the nilk $1 \frac{1}{2}$ oz. butter and $1 \frac{1}{2}$ or. castor sugar Whip the eggs well and stir then into the milk, then beat to them by degrees a small teacupful of flour. Fry these pancakes without turning them, and use n very thin layer of batter. They should be piled, when dished one on top of the other and served with sugar and whipped cream.
French Pancakes. The French pancake differs in method, as the yolks and whites of the yolks and heat them up with 3 oz. castor sugar and the same quantity of very fine sifted flour; add the juice of $\frac{1}{2}$ a lemon and a pint of inilk. Now fold in lightly the whipped whites of the eggs. Half fill buttered snucers with the mixture Bake in a quick oven $15-20 \mathrm{~min}$ Turn out on to sugared paper, put a spoonful of jam in middle, and fold.

Yeast pancalics are made from the sane mixture as doughnuts and cooked in the same way, hut arc rolled into small, round, fat cakes about $\frac{1}{2}$ in thick. Jam is put on one piece and annther pieco put on top and the two pressed well together before frying.
Savoury Pancakes. For savoury pancakes an ordinary batter may he used, and about 4 oz. of finoly chopped cooked ganie or chiclien, well seasuned, should he adtled just before figing. The batter should be flavoured with parsley herlis, a shallot or chive chopped fine, 4 oz. meat to 1 pint of batter.

## Panchromatic Photography

## Modern Methods of Obtaining Correct Colour Vaiues

The usc of panchromatic or "all colours" plates and nims for coricet renderip of colours in photographs is shown in this article to he simple and well. suited for the amateur. see Developirg; Photography: Portraiture
Panchromatic photography is a method by help in dealing with the renderings of reds which correct renderings in monochrome are and browns, and are not perfect in their obtained of all colours. The ordinary photographic plate is far more sensitive to rays of blue light than the eye, and also to ultrnviolet rays, which the eye does not perceive at all. In addition it is very slightly sensitive to rell, which it renders as black (hence the red dark room lamp), and is not sufficient!y sensitive to ycllows and greens The effect given by an ordinary plate is very similar to that gained by looking through dark blue glasses, such as are used by clinabers for overcoming the glare arising from sunlight on expanses of snow.
It is not mercly that all objects are seen through the blue glass as one colour or monochrone. The relative brightness of the different colours has changed ; bright yellows, reds and greens become dark, while blues and violets, which are usually seen as dark colours, become light. Furthor, the clouds in the blue sky have disappeared. Orthochromatic plates and films overcome the difficulty to a certain extent, but they give very litt!e

Panchromatic Photography. Pig. 1. Greek vase in browns, reds and yellows. as photographed on a flm with ordinary uncorrected emulsion. Fig. 2. Same vase photographed on a Kodak Eastman panchromatic film bringing out correctly the colours ss seen by the eyd
ranslation of yellows.
Films with increased colour sensitiveness have recently appeared which give colour correction superior to any orthochromatic medium, especially with filtors. Such is the Kodale 'Verichronie,' a double-coated highspeed film with an anti-halation backing and wide latitude of exposure.
No plate has yet been made which, without a light filter, is not more sensitive to hluc than to other colours. It therefore follows that to get a correct rendering of colours in monochrome a panchromatic plate or film with n light filter must he used
The principal purpose of the light filter is to cut out a portion of the blue rays. The extent to which a correct rendering is then oltained with n panchronatic plate depends upon the depth of the filter, the time of exposure increasing with its depth Even without the use of a filter at all panchromatic plates will give a better rendering of colours than ordinary plates. On the other hanil, panchromatic plates used with a filter will give a correct colour rendering with shorter exposure than an orthochromatic plate us.d with the same filter That is to say, the panchromatic plate is more sensitive and more rapid than the orthochromatic, becanso it is more sensitive to yellow light rays
The best form of light filter is that which consists of dyed gelatine, either uscd alune or mounted with Canada balsam on glass Filters in which the glass itself is stained are not so satisfactory, as it is difficult to get pure yellow in stained glass. The gelatine filters can be bought either as pieces of gelatine or ready mounted het ween plates of thin glass. Ordinary glass or thin
plate which has been optically worked may he used The latter is much more expensive, but with a high-class, long-focus, anastigmatic lens is almost essential, since ordinary glass is liable to impair the definition.
The filter may be placed in front of the lens in a holder with a spring adlapter to clip over the lens mount. Alternatively, if it is cut to size, it may be placel letween the components of the lens, i.e. behind the front lens and in front of the iris diaphragn.
Below are given the filters to be used with the Kodlak Eastman panchromatic filmis and Ilford panchromatic plates. "ith tines of exposure (daylight only), sulyjects for which they should be used, and the comparative exposures :

| l-ilter | His. posure Fiactor (A) | Uses | IRclative Facini (13) |

(A) Expused iactor on panchrom:atic plates or tilms Jelative cxposure factor os urthorliromatic plates or flinis
For Kodak ' Verichronic 'flm the exposure factore are as follows

Exposure factors of K (Kodak) and Ilford filters are average figures, and only to be considered correct when used with Kodak panchro tilms and Ilford panchro plates respectively. Weather conditions and different forms of artificial light will affect the factors to a very considerable extent. Thus, in a room lighted by gas-filled electric lamps, which give a yellow light containing little blue, good colour correction may be obtained on a panchromatic film without the use of any filter. Conversely, arc light may increase the filter factors.
For general work K 2 or the IIford $a$ is the deepest filter which should be used, otherwise over-correction would result, with harsh, unnatural contrasts, giving in bad cases what is known as the "soot and whitewash" elfect II ith both the Kodak and 1 iford panchromatic plates and films time and temperature development figures, for development in the dark, are supplied with each box of negatives

Care should also be taken to see that with panchromatic plates exposure is reasonably correct. Serious over-exposure will give thi same harsh contrasts as the use of too deep a

Filter. The amateur photographer will be complexionz have amall patches of hardly wise it he makes it an invariable mulc to use visible red, which the ordinary plate repro the exposure meter when working with duces as black blotches. It also accentuates fanchromatic plates. wrinkles and freckles, while red or golden lair
It is a mistake to suppose, as many amatcur comes out much too dark. A panchromatic photographers do. Ihat panchromatic plates plate with a K lf or a filter overcomes these
difficulties without retouching the negative In landscape work the ordinary plate ren ders the sky as a harsh solid white, since it is unduly sensitive to the blue ol the sky, so that the white clouds are altogether lost, that portion of the negative receiving relatively greater exposure than the foreground portion With panchromatic plates it is possible to get clouds and landscape on the same negative, as the filter lieeps back a portion of the blue rays. Moreover, a landscape usually contains many different tones of greens and yellows which the ordinary plates reproduce in one mono chrome tone
Striking examples of the improvenents achieved by panchromatic films and plates are shown in the illustrations. The panchromatic rendering is enormously superior in every case to that of the ordinary plate it is only the tact that photographis talien on ordinary plates have been seen for so many years, and generally but mistakenly accepted as being accurate. that makes it necessary to enlarge upon the superiority of panchromatic plates

There is a tendency to avoid the use of pan chromatic films or plates, since they render impossible the use of the ordinary dark room lamp because of their great sensitiveness to red. This difficulty is largely inaginary All plates can be fogged it exposed long enough to the safest dark room lamp.
With Ifford panchromatic plates no light at all is to be used in developing or loading; this instruction must be carefully observed With Kodak films the Wratten safelight may be used This consists of a large lantern with a safelight which gives a dim green light suffi cient to show after a little time, the position of dishes, etc., in the dark room. Even with this safelight the developng dish must be kept covered with a picce of card. The salelight is actinically correct for Kodak panchromat ic films. and is designed for a maximum total exposure of 30 sec of the negative 3 ft . from the light, the lamp inside being of 16 candle-power.
Panchromatic plates and tilms maty be developed with any ordinary developer de. scribed in this Encyclopedia and the amateur is advised to use that to which he is accustomed.
A simple method of developing panchromatic plates and films which overcomes almost entirely the difficulty of developing in the dark is to use a desensitizung solut.on, wh ch fermits the use of an orange tight as explained under the heading Dosensitizer.
A modern development of the panchiomatic tilm is its application to the hone c:nema. Tho
or tilmes should or need only be used for specia purposes, and that they need a skill only to be acquired in the advanced stages of photography. They will always give with the palest lilters more accurate and pleasing results, and as shown by the talile of relative exposures, they are available for all kinds of snapshot work if a moderately fast lens is used. Ex. posures can only be relative, but to take a specific case, with a lens working at $\mathrm{f} / 8$ (see F/Number) correct exposurc on an open landscape midday sunlight (May to September) will be so second with a liodak pan chromatic film.

Three varieties of panchromatic plate arc made by Ilford, Ltd, the Ilford special rapid and soft gradation panchromatics and the Iford rapid process The first is a very fast panchromatic plate of general utility; the second is claimed to be the fastest colour sensitive plate existing. The third variety, the process panchrumatic, is designed for technical purposes where the maximum contrast is required.

In portrait work, even of the snapshot variety, with portraits taken out of doors, very great improvements will be obtained by the use of panchromatic films Almost all

Above, photograph taken on a plate with ordinary uncorrected emulsion on a sunny Dut misty November day. Detail in the distance is badly rendered and the sky is an unnatural hard white. Below, the same scene taken on a Kodak Eastman panchromatic flm with a Kodak G flter. Panchromatic flms and plates ars particularly valuable in landscape photography

Kodak "Cine Supersensitive panchromatic safety film" (for 16 mm . cameras) permits indoor filming and outdoor night scenes. Without filters it is claimed to be about twice the speed of the ordinary Cine-Kodal panchromatio film. With CK1 or CK2 filters no apparent increase of exposure is required, the stop indicated by the exposire guide being correct. With CK3 the next larger stop is required.
PANCRATIUM. This is the name of a genus of vigorous bulbs of which the chief favourite is Pancratium fragrans. It bears umbels or bunches of white sweet-scented Howers and must be grown in a hothouse in a compost of loam, peat, and sand. During the period when the bulbs are at rest little water is needed, but in the growing season the soil must be kept thoroughly moist. Pancratium illyricum is hardy in sheltered places in mild districts.
PANEL: In Woodwork. The term panel is used for an area recessed below the general surface. Usually the panel is a piece of wood soparate from the framework enolosing it, and in the majority of cases it is thinner.
Roughly speaking, the object of the panel is threefold. It is the result of an effort to obtain lightness in construction without detracting from the strength of the work; it reduces the risk of warping and splitting, and it effects an economy in material. Fig. 1 shows a panel of $\frac{1}{2}-\mathrm{in}$. material surrounded by a framework of l-in. stuff. The requisite strength is maintained by the grain of the top and bottom rails running at right angles to that of the panel, and at the same time preventing it from twisting. Fig. 2 shows how the panel is held in the framework within a groove without being fixed, so that it is free to shrink independently of the frame, thus lessening the risk of splitting. If the panel in Fig. 1 had been glued in, or otherwise rigidly fixed to the frame, the pull caused by its shrinkage, as shown by the arrows, would be opposed by the fixed resistance of the top and bottom rails, and this would result in splitting.
Where a panel is not grooved into the frame, but kept in position by two mouldings, as in Fig. 3, the nails holding the mouldings must be driven into the frame as shown, and must not pass through the panel. When it is desired to groove a panel of more than $p_{0}$ in. thick into a framework of 1 -in. stuff, the panel should be bevelled off at the edges, as in Fig. 2. The panel should fit hand tight in the groove, and the best method of testing it is to groove a spare piece of wood, called a mullet (Fig. 4), with the same size of groove as that to be worked on the frame, and test this round the edge of the panel.
False and Ralsed Panels. A false form of panel is shown in Fig. 5, a moulding being mitred round a solid piece of wood to give a panelled effect. Fig. 6 shows a particularly effective type known as a raised panel. The stuff is first thicknessed. and the width of the bevelled portion and its inner and outer depths gauged round. It is then rebated down to the shallowest gauge line, working across the grain first, and then bevelled down to the lower guige line, care being taken to prevent the corners from chipping out: the small hollow moulding is worked last. First thickness the stuff carefully, or the bevelling will result in the edges being uneven in thickness.

All the stuff used for the panel should be as clean as possible, and when the work is to be polished should, wherever possible, be of one piece. Very wide panels are jointed up in their width, using either dowels or a tongued and grooved joint when the wood is sufficiently thick to take them.

Another type of panel is that used when conditions require that the panel shall finish flush with the framework, as in certain large
table tops. The face side is rebated, form ing a tongue which fits into the groove in the frame, as in Fig. 7 A good plan is to run a bead along the rebated edge of the panel with the grain. as shown. The reason this is done is that in the event of the panel shrinking the open joint will not be so noticeable The best method of securing a panel not grooved into the framework is to pin a bead in the rebate at the back, as in Fig. 8. This not only leaves it quite free to shrink independently, but the panel can be re moved easily by raising the beads. Fig. 9 is a decorative panel for use in oak work; as in the case of the other panels. the mouldings are attached to the frame. work and not to the panel. Fig. 10 shows the main construction, consisting of a plain square edged frame mortised together and having picces planted on to the edge wherever the break. forward parts occur. A rebated moulding is mitred round as shown, and the panel is then cut to a cor-
responding shape and fastened in with insured persons can choose their own doctor, beads. See Cupboard: 1)ado: Door; Hall; but if a particular doctor has already as many Marquetry. etc.

PANRI DOCTOR. A panel doctor is one who attends persons who are insured under the national beath insurance scheme the loctor signs the insured person's card The majority of general practitioners take and the latter is then entitled to free medical panel patients. With certain limitations attention from him. See Insurance

## Panelling: Antique and Modern Work

A Beantiful Form of Household Decoration
Practical advice is given here about the actual performance of the work. Attention may be drawn to such articles as Celling: Chimney Piece: Decorstion: Dining Room: Hall: House Library : also Georgian Style ; Jacobean Style ; Linenfold: Oak; Paperhanging

Panelling may be described as covering the surface of a wall, door, ceiling, or other part of a building with panels, which are raised or sunk compartments, generally framed at the edges. The materials used are wood, stone, and plaster.

Panelled walls in the interiors of houses in England date from medieval times and in crude form appeared before tapestry began to be used. Panelling was not unknown to the Normans, but it was during the period of Gothic architecture known as Early English that it began to develop in this country. In work of the 12 th and 13 th centuries the square panels were ornamented and the larger ones were often deeply recessed, so as to form niches with trefoil heads and sometimes withcanopies.

History of Panelling. In the Decorated or second period of English Gothic architecture, the enrichments of the panel became more elaborate, and the latter were often filled with shields, foliage, or figures. The use of panels became very common in the third period, known as Perpendicular, when the walls of
the buildings of importance were frequently entirely covered with long, short, or square panels, the square ones being frequently filled with almost every kind of ornament Most of the existing examples, however, are not earlier than the 17 th century, though Tudor panelling, often with characteristic linenfold ornamentation, is still seen. All through the 18th century panelling was employed in comparatively small housea, and its use was not seriously interfered with or lessened until the introduction of cheap wallpaper

In Elizabethan and Jacobean work the small wood panel appeared sometimes with an inlay of coloured wood, and with gradually increasing elaboration of the moulding of its frame. The plaster panels of the ceilings of the time became correspondingly rich in decoration.
The beautiful room illustrated in Fig. 1 shows to perfection the fine workmanship in English panelling of the early 17th century. The overmantel consists of the royal arms carved in very high relief and having on either

Panelling. Fig. 1. Panelling. princlpally of oak, and Arenlace from one ol the upper rooms of the Old Palace at Bromley-by-Bow, which was built in 1806 $u_{u}$ permission of the Director, Vietoria \& Albert Muxrum. South Kensington
side a niche between two partially fluted then painted or stippled any desired tint, ivory, columns; the whole resta on a long shelf, decorated with flat strapwork omament, and supported by two terminal figures The panel. ling is divided at intervals by pilasters with flat atrapwork. The cornice is enriched with a dentil noulding and brackets, and the frieze beneath has similar strapwork ornament
After the middle of the 17th century the size of these wood panels was greatly increased, and towards 1700 they developed the long oblong of the Palladian style with bolder mouldings. In the 18th century the taste of Robert Adam reduced the size of the panel to more reasonable proportions, especially in his treatment of doors. About the same time the moulding was simplified, and it lecame the falion to paint panels in white or cream colour.

There is no form of wall treatment which has so satisfactory a relationship to the structure of the building as panelling. It ahould be designed 10 fit in with chimney breast, door, and windows, forming altogether a co-ordinated scherie. The careful design of manelling can correct an unsatisfactorily proportionel room, molifying its apparent length, height, or width. Panelling is in itself a decoration, and although it is a backgiound to furniture, it essentially restricts freedon of applied ornamentation to the walls in the form of pictures and other hanging details.
Modern Panelling. For modern roonis. which are very often too high for their length, it is usually satisfactory to stop the pranelling at about 7 or 8 in. from the ceiling. This leaves a frieze above, between the upjer noulding of the panelling and the cornice. It presents an opportunity for introducing a valuable decorative feature which may be treated in numberless ways. Should the panelling be dark brown, however, it is wise to allow the frieze and ceiling to be cream or a very pale buff or apricot shade to preserve a large area for reflecting light into the room, for one of the draw backs of dark panelling is its absorption of light. It is not a good reflecting surface. On the other hand, a room may be treated with deal or pine in panel formation from skirting to cornice, the whole wall being
then painted or stippled any desired tint, ivory,
pale or deep green, or grey leeing common, and the moulding picked out with a lighter or deeper colour. or with gold or silver leaf.

Painted panelling also looks well with modern furniture when the colour is stippled and shaded to deeper tones towarls the

mouldings Grained effects may be used to imitate cedar, mountain ash, or wainut Beautiful and dignified panelling for hall and stair case or dining roons is carried out in the grained effects enriched with judiciously applied gold ornaments and mouldingr-

British Columbia pine is used for modern panelling either with a waxed satin finish which lends a fawn shade to the figuring of the wood, or stained and finished in brown. Another British Empire timber employed is Canadian birch, with a silver-grey finish which looks well when inlaid with a cross-banding of hlack to divide the panels. The rapid progress made in the menufacture of plywood brings panelling effects within reach of many more peopie. The most beautiful woods, by means of improved veneering mothods, are obtain able at a fraction of the cost of the old style panelling. Any kind of classical panelling can be fitted in an existing house at a reasonable price

A point to be taken into consideration with regard to this form of mural decoration by those who are building or reconstructing houses to be nowly furnished is the fact that far fewer accessories and pieces will be required in a panelled room than in one that is painted or papered Many ornaments or pictures simply kill the design of a well panelled room When building, panelling lends itself naturally to the inclusion in the dining or living-room of built-in furniture such as cupboards, bookcases, niches with shelves and sideboards. A great saving in buying such or equivalent pieces of furniture is therefore effected, and a uniform result obtained which makes a harmonious setting for beautifu furnishing fabrics in styles selecterl to correspond with the panelling of the room

An additional noint in favour of natural timber panelling is that such decoration does not involve the recurring expense of periodical renewal, whereas the sum spent on repainting and papering the walls-for instance-of a

Fir. 2. Example of English old oak panelling. showing the characteristic small size of the panels. Fig. 3. Fine example of early English work in heavily carved panelling But permission of the Dircetor, Vietoria ad Albert Museum. South Kenaington
hall and staincase in one's own house would be considerable over a period of years.
The development of modern wallpaper decoration has placed at the disposal of the builder an almost infinite variety of imitation panelled walls. Many patent materials are employed in the design of papers which closely reproduce the effect of wond. The danger of this imitation panelling is its facility of application, for under inexpert or careless handling it can easily be made to look as though its features do not fit the room, and the essence of the decorative value of panelling lies in its close relationship to existing structural features. The greatest care is necessary to select imitation panelling of such proportions of moulding, rail and panel as suit the size, shape and style of the room to be treated

Repairs to Panelling. The framing of panelled work is not so linble to faults sa the panels themselves, which, owing to exccssive shrinkage or decay. sometimes require attention. Those poitions which, owing to decay, are in need of repair, should becutout as far as possible at an oblique angle, and new material, matching in grain and colour, arrefully fitted and glued into position. The removal of a defective panel is not difficult if the framing is moulded on the edges, the method being to cut away the moulding surrounding the panel in the form of a rebate. After the panel has been repaired or renewed, the original moulding is reproduced in the form of beading and glued and bradded into position.

For plain work, apart from taking the whole of the job down so as 10 work from the rear, the only method of dealing with a defective panel is to cut away aufficient woor from stiles and rails to allow of its removal. In this case the rebates should be very carefully trued up, using a atraightedge, so that new pieces, matching in grain and colour, can be glued in when the panel has been fitted in.

Panelling a Room. Panelling can be done by the home worker in two chief ways. He can use grooved framing, or may employ a perfectly plain framework and secure the panels with suitable beading, the latter being much the simpler method. Although oak is generally used for the whole of the work, n good effect is obtained by using deal for the framework. This can be stained to $n$ suitable colour, and the fitted panels cut from oak plywood. The use of plywood is preferable to thin boards, as the beauty of the grain is retained and it is not liable to shrink. Ready machined oak or other hardwood can be obtained which is grooved for panelling. Some has a $\frac{3}{16}$ in. groove for use with plywood

In the older types of panelling the panela were amall, and two characteristic examples are illustrated in Figs. 1 and $2 . \quad$ Fig. 3 is a close-up of a finely carved example of early English onk panels, which shows the possibilities in this direction.

The preliminary work is much the anme in all the various methods adopted, and consists in working on the wall a series of vertical and horizontal strips of wood known as rough grounds. The grounds should be approximately 2 in. wide and about $\}$ in thick. The purpose is to produce a fair surface on which to work the panelling and fix it to the wall. The room should be planned out and working drawings prepared, showing where each panel is to go, the grounds then being fixed accordingly. In general it will be necessary to have grounds at every corner, on every angle, one almost at the top of the wall, and one close to the bottom,
where the skirting bard is locsted This latter, if only a plain board, should be removed, and can be replaced later

Only a part of the wall will be panelled in some cases, ns. for example a aado, or a ? in pracel taken only to the frieze, or picture rail. The ground having been prepared. the panela are then applied

A simple way of simulating real pane!ling. or procuring a panelled effoct, is by the use of plywoud, or alternatively one of tho modern buildiny or panel boards. If this latter is used as a groundwork the whole wall surface may be covered. and the panelled effect obtained by employing beads or moulded strips of wood properly jointed at all intersections. 'Tlicse strips will be simply nailed to the grounds with amall oval brads, or panel pins, punched lelow the surface of the strips, and the holes atopped with putty. coloured to suit the finishing colour if 3 -ply boards are used as the ground. work they may be attached similarly to rough grounds, and Fig. 4 shows this operation in progress on a ceiling.

Framed Panelling. The forogoing method, although it produces a panelled effect. cannot

be considered us true panclling. The framework, which is represented by the strips, should, in fact. be a framing constructed as such with proper joints, and the edges grooved or rebated to receive the panels, which are fitted in then in the same way as the glass is fixed in a picture frame. The panela may be plain, as in Fig. 1, and the pilaster enriched by carving, or the upper panels only may be carved, as in Fig. 2, or each panel mny be separately carved as in Fig. 3. The examples given will serve as a guide for anateur work. When the wall panelling is framed up, it is fixed to the ground as already described, and the joints are fastened. Care must be taken to ensure that they always meet where they will be
ceiling and sometimes in the walls. Clainis made for this method of warming are that the heat is distri: huted almost solely by radiation at comparatively low temperatures, being projected from the warmed surface of the ceiling: that there is an ahsence of the stuffy condition is an ahsence of the stufy cond ition
sometimes associated with convec. tion warming systems ; and that a tion warming systems : and that a
reasonable amount of air movement for ventilating the apartment is possible without any great heat losses. See Central Heating.
PANICUM. Of this ornamental grass there are both hardy and greenhouse kinds. Panicum variegatum has green and white leaves, and is a popular greenhouse plant. leing useful ns an edging for the
covered by another panel moulding or pilaster. Ceilings may be panelled on the same principle as the wal!s, or by framing the work in sections. Often a ceiling is panelled in fibrous plaster moulds, or enrichments, which are worked on to it while the ceiling is being made. Gond resulta are obtained by the use of strips of rough-hewn oak about 3 or 4 in wide and about $t$ in thick which may be placed on the plaster ceiling, to represent the exposed edges of the joista: when carefully done, it gives an air of spaciousness to the room, as shown in Fig. 5.

Imitation Oak Panelling. Where it is desired to give a panelled effect in a simple and inexpensive fashion, an oak grained paper may be employed. The whole surface is first covered with the special paper, applied in the anme way as ordinary wallpaper, and the panels then formed by pasting on strips of moulded and grained paper. The skirting board should be stained to a dark brown colour, and simply finished with a plain chamfered edge. The frieze or picture moulding is treated in a similar way. If the worker carea to go to the irouble of forming the panels of thin atripa of deal, planted on and ctained to match the grained paper, the rcault, as will be evident from Fig. 6 , is hardly distinguishable from real panelling.

Various methods of employing embossed and other panels with wallpaper are lescrihed in the articles on Paperhanging and Wallpaper.
PANEL PIN. The fine straight nail known as a panel pin is used or cabinct work and other woodworking processes. It has a llat head with a tapered portion that blends into the shank of the nail. For many domestic purpores a panel pin 1 in . long and 16 gauge can very well take the place of a larger nail. See Nail.

PANEL WARMING. This is the name given to a method of central heating in which the heating units (hot-water pipe coils or elec. trically heated elements) are embedded in the

Courtesu of Amaleur Cardeníno
staging. It is easily increased by division. Panicum miliaceum is the millet. Some of the best hardy kinds are plicatum and virgatum.
PANSY. This is a popular hardy, summerflowering perennial of which there are many fine strains and named varieties Viola

Pansy blooms of mized colours tricolor, or heartsease, is the chiof species or wild type from which the pansy has bcen develop ed during many years. Bedding pansies are commonly raised from seeds sown in boxes of tine soil in a frame in May or June, the seedlings being planted on a reserve border when large enough and finally set out in autumn where they are to bloom the following suminer. Named varieties are propagated by cuttings made from flowerless shoots in July-August, and inserted in sandy

Pansy. 1. Seer raising in pit sheltor: $a$, oinders; $b$, glass. 2. Alternative method. 8. Seed preparstion: $a$, fine soll; $b$, seeda; $c$, soil; $d$, leaves: $e$, drainage. 4. Good type of soodling. 6. Bed outting. 6. siurdy outting with heel (a). 7. Potting a outting: $a$, eand
soil in a frame. Planting out of doors done in autumn or spring.

Named varieties of show and fancy pansics grown for exhibition are given special cultivation, and the number of blooms on each plant is limited. Pansies flourish best in deep loamy soil in slight shade, but they will grow in ordinary well-tilled soil and flower throughout many weeks if care is taken to remove the faded blooms.

PANMERER LILY. This is the popular name of Lilium pardalinum, one of the showiest lilies for the garden. It grows 5 ft . high and bears very handsome flowers, orange tlushed with red nnd marked with dark spots.

PANTILE. This is the name given to a form of clay tile used for root covering. It is usually hollow or semicircular in cross section. Some are not curved in this way, as, for example, the Roman pantile. The pantile is one of the cheapest forms of tiling. It is a thick tile, dark red in colour, and about 155 tiles will be found neoessary to cover a roof surface of 100 sq . ft.. or a space measuring 10 by 10 ft . Some pantiles

Pantile. Two types ot this rool covering : tett, interlooking form : right, Roman pantile
are made of asbestos cement and other materials, and these are light in weight, while retaining the appearance and quality of the old-fashioned clay tile. See House: Roof: Tile.

PANTOGRAPE : For Copying Drawings. This is a simple piece of apparatus made of 4 narrow strips of wood drilled with holes at definite positions and pivoted together. It is used for copying drawings, maps, etc., to an enlarged or reduced scale. It is provided with a screw at one end for fixing to the drawing board, a pointer for following the lines of the original drawing, and a pencil for tracing the new drawing. It is simple in action, does its work accurately, and saves a great amount of time and labour.

In the diagram above the pantograph is set for enlarging to twice the original size. The point $A$ is fixed to the board: at B is a pointer which is moved along the lines of the original drawing, and the pencil point at C traces the lines on the drawing paper. The joint at
$D$ is fixed, but those at $E$ and $F$ are adjustable, and are altered to suit the proportions of the required enlargement. For reducing, the tracing point is placed at C , and the pencil transferred to B. By making

Pantograph. Instrument set for onlarging drawing of vase to twioe its original sise. Soe tert

B the fixed point, with the pointer and pencil at the opposite points $A$ and $C$, a drawing can be reproduced the same size as the original.
To fit up the instrument, the fixed pivot at A is secured to the left-hand side of a drawing board, and the original drawing is pinned so that the tracing point is about the centre of the drawing when the arms of the pantograph are parallel. The sheet of drawing paper is pinned down centrally under the pencil point and set square with the drawing Providing that the point of the pencil is sharp, and the correct distance from the paper, there is no need to watch it, attention being devoted to moving the tracing point on the drawing to be copied. If the original drawing is very small, great care must be taken to move the pointer accurately, as any mistake will be doubled on the resulting enlargement. The instrument may be purchased quite cheaply from a dealer in artist's materials.
PANTRY. In a small house a pantry is an aid to service if it is well fitted with a sink and cupboards, and adjacent to the dining room. Washing up of silver, glass and table china may be done there, and the articles put away on their proper shelves. Dessert, wines or spirits, cakes for afternoon tea, and supplios of tea and coffee may be kept in a cupboard in the pantry and also the requisites for their service. An electric kettle and chafing dish or a gas ring are most useful. Sometimes a small cooker is included in pantry equipment for convenience when the cook is out and the mistress of the house wishes to prepare a hot meal. The pantry is also a place where flowers can be arranged and the silver and ornamental pieces of brass cleaned without disturbing arrangements in the kitchen. Where the latter is of the compact labour-saving type, a pantry is sometimes built in preference to a scullery.

The sink should be placed near a window with a draining board on either side. An enclosed dresser where the best china and glass can be kept on the upper shelves and silver in baize-lined drawers below is a convenient fitment. Shelves for vases and trays, a small cupboard for jam, pickles, sauces and condiments in use, and for supplies from which the dishes and containers can be replenished, are also necessary, together with a small table or a table shelf which can be folded down when not in use.

The most satisfactory plan is to locate the pantry between the dining room and kitchen, as shown in our illustration of a modern labour-saving arrangement in a small house. There are communicating doors and also a service hatch. Used plates and dishes may be placed on the folding shelf, which when closed conceals the hatch. The china is transferred directly from the shelf to the sink, which has

Pantry, Labour-saving paniry situated between kitchen and dining room. Used plates and dishes can be placed on the folding shelf which, whan closed, conceals the service hatch a constant hot water supply. By such an plate, packing dresses, polishing mirrors, clean. arrangement the process of washing up is simplitied

A pantry sink should be glazed white, straight-sided and deep. The outlet should be closed with a plug so that the sink itself can be used for washing up. A papier mâché bowl should be kept to liand for fragile china and good glass.

Where there is choice in the matter electrio light should be preferred to any other illuminant. As the pantry is intended for storage of food and the larder may be situnted here the greatest care must be taken to keep it well ventilated. This can be assisted by fitting an air brick or ventilation shaft in the bottom of the wall, just above floor level. To prevent the entry of llies, the window opening can be covercd with perforated zinc or wire gauze, or a clean muslin curtain can be fixed in a small frane to be inserted in the opening. See Dining Room; Kitclıen; Larder; Service Hatch; Sink

PAPAVER. This is the botanical name of the poppy, a race of showy plants including annual, biennial, and perennial species. The first class contains the opium poppy and the popular Shirley strain, whilst the biennials and perennials include those important garden favourites the Oriental and Iceland poppies respectively. See Poppy.

PAP BOAT. This name is given to a little bowl, good examples of which are sought by collectors They were first made in England early in the 17th century. Usually of sil ver they are about 4 in. long. Some are pinched in the middlc in order to afford a holding grip.

PAPER: Its Uses Lace plapers for tlecorative purposes are sold in packets in the form of doilies and dish papers. Both white and tinted papers of light quality are made into frills for decorating cutlets, hams, or pie-dishes; others are specially madc for sweet cases, dish collars, and tray cloths. Crinliled papers, either quite plain or with designs in colour, are employed for making paperserviettes. Coloured papers are obtainable for lining cupboard shelves and chests of drawers.
Semi-transparcnt creasc-prool paper is used for lining cake tins and for other similar culinary purposes.

Kitchen wrapping papers of cheap quality, white or brown, are sold mostly in double crown size, 20 in. by 30 in ., or demy, $17 \frac{1}{2}$ in by $22 \frac{1}{2}$ in Toilet rolls of thin manilla or other paper are generally retailed in 12-oz rolls. Blotting paper is usually supplied for home uso in pads, but may be purchascd in demy sheets of various colours. Tissue paper, sold in sheets a trifle under double crown size, is used for wrapping
ing lamp glasses, wrapping up tlowers, etc.
For firelighting purposes pieces of twisted paper can be used instead of tirewood. These
are made about the same sizc as the ordinary sticks, and sometimcs bent or even doubled up to suit the requirements of the grate. When properly twisted they burn slowly, giving out a strong heat, and are effictive in kindling coal. In addition these pieces of twisted paper are economical.

Paper, especially coloured ciêpe paper, can be used for decorative purposes in a variety of ways. Artilicial Howers and Christnas decorations can be made from it. See Artilicial Flowers; Candleshade: Christmas Notepaper ; Papier Mâché

PAPER BAG COOKERY. The main principle of this system of cooling is to enclose the food in a greascprool, airtight paper bag, and place it on the wire grid of an oven or on a trivet. It is an econornical method of cooking, as less heat is required in tlie oven than when cooking is done by the more usual means. The greaseproof paper has the effect also of retaining all the natural juices in the food, thus rendering it more nourishing and digestible

Special bags are sold for cooking purposes A bag that is at all damaged should never be used. Before the food is put into the bags they must be well greased inside with butter, lard, or olive oil. Any projecting edges of the food, meat or fish bones that might tear the bag, must be removed. Small fish, fillets of fish, cutlets, chops and steaks can be cooked in the oven in paper bags. Brush over the fish or ment with oiled dripping or butter, scason it with pepper and salt, and slip it into the well-greased paper bags. Place these on the grid of thic oven, which should be hot, turn down the heat alter 5 min., and in 15 to 20 min they will be cooked

PAPER ENAMEL. The name is given to brands of prepared enamel intended for application to prier. A typical use is in the enamelling of a moulded paper ceiling, the enamel imparting a pleasing finish and at the same time making it durable and damp resisting. See Enamelling.

## Paperhanging for Walls and Ceilings

## Practical Instructions on the Re-decoration of Rooms

## This aricle helongs to the important proup that deal with the decoration of the house, among these heing Colour; Dado: Decoration; Distcmper; Enamel; Paint; Panelling; Wallpaper. See also the articles on the various rooms, e.g. Bathroom; Bedroom; Dining Room; Klichen

Paperhanging is the process of covering the but bright colours and deep shades have surface of wall or ceiling with paper manu- definite character and use. Bright yellow factured for the purpose, applied with the aid and orange can be employed for hall and of $a$ suitable adhesive. The tools necessary staircase; amber, maize and golden tints for are a large pair of scissors with blades about sitting room, lounge or dining room. Browns 7 in. long; a large paste brush; a brush and greens are also in lavour for dining rooms with long bristles closely set into the back, Mottled effects resembling vellum and old which is also its bandle, used for smoothing parchment are very decorative.

Choosing Paper. When selecting paper the purpose or use of the room should be given first consideration, and the aspect is of scarcely less importance. Warm tints, such as yellow, brown, and shades of red are helpful in north and east rooms. Blue and grey should be reserved for rooms with southerly aspects. Special types of paper are made for particular purposes. White grounds with "satinette" prints aro made for ceilings, also embossed papers. Some of these with definitely geometrical patterns are also useful for dado decoration. Bathroom papers should be either varnished or of the " sanitary" type. The latter is printed with an oil medium, so that the colour is unaffected by moisture. The most satisfactory treatment for bath. room walls is, however, to hang an unvarnished paper and apply the varnish after it is hung. By so doing the joins of the paper are sealed Two coats of size must be given hefore varnishing.

Quantity of Paper Needed. To estimate the quantity required to cover the walls of a room add the total length of the room to the
width, multiply by twice the height, and divide this total by the area of one piece of paper in square feet, which may be taken as approximately 60 sq . ft. The result is the number of picoes required. When measuring the room, include the window openings, fire place, and doors, as in practice it is found that by including them in the whole area it allows for outting and waste in the paper. The following table gives the number of pieces required for a room, provided the height to cornice and total feet run in inches round the walls are known.

|  | Height in feet from Cornico to Skirting |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 71 | 8 | 81 | 0 | 01 | 10 | 101 | 11 | 111 |
| 29 | 4 | 4 | 4 | 4 | 4 | 5 | 5 | 5 | 5 |
| 32 | 4 | 4 | 5 | b | 5 | 5 | 5 | 6 | 6 |
| 80 | 5 | 5 | 5 | 5 | 6 | 6 | 6 | 7 | 7 |
| 40 | 5 | 5 | 6 | 6 | 6 | 7 | 7 | 7 | 8 |
| 44 | 6 | 6 | ${ }_{6}$ | 7 | 7 | 7 | 8 | 8 | 8 |
| 48 | c | 0 | 7 | 7 | 7 | 8 | 8 | - | ${ }^{8}$ |
| 52 | 7 | 8 | 7 | 8 | 8 | 8 | ${ }^{9}$ | ${ }^{9}$ | 10 |
| 56 | 7 | 8 | 8 | 8 | 9 | 9 | 10 | 10 | 10 |
| 60 | 8 | 8 | 8 | 9 | 9 | 10 | 10 | 11 | 11 |
| 04 | 8 | 8 | 9 | 9 | 10 | 10 | 11 | 11 | 12 |
| 08 | 8 | 0 | 9 | 10 | 10 | 11 | 12 | 12 | 13 |
| 72 | 9 | 10 | 10 | 11 | 11 | 1: | 12 | 13 | 13 |
| 76 | ${ }^{10}$ | 10 | 10 | 11 | 12 | 12 | 13 | 13 | 14 |
| 90 | 10 | 11 | 11 | 12 | 19 | 1.3 | 14 | 14 | 15 |
| 84 | 111 | 11 | 12 | 12 | 19 | 14 | 14 | 16 | 16 |
| 88 | 11 | 12 | 12 | 18 | 13 | 14 | 15 | 16 | 10 |
| 92 | 11 | 12 | 13 | 18 | 14 | 15 | 111 | 16 | 17 |
| 96 | 12 | 18 | 18 | 14 | 15 | 15 | 18 | 17 | 18 |
| 100 | 12 | 13 | 14 | 14 | 15 | 16 | 17 | 18 | 18 |

This scale is for papers of English measure. ments ( 21 in . by 111 yd. approximately). For papers 7t yards long 28 in . wide add to the above table in the proportion of 1 in 7.

In dealing with ceilings, multiply length by breadth in feet and divide by 54 . The result will give approximately the number of pieces required.

Stripping Old Paper. Old paper should be stripped before new is hung, not only for hygienic reasons, but also because paste perishes in the course of time and the applica. tion of new paper is likely to raise blisters which cannot be smoothed out. If, for some reason, old paper cannot be removed, all edges and angles of walls should be carefully examined and loose places pasted down. When dry, s cost of size should be given over the whole surface. It is advisable to obtain the best powder size and mix according to the printed instruotions. Size should be diluted so that when cold it will set in a weak jelly. It is better to apply two coats of weak size than one strong coat.
Old paper is removed by saturation with water until it has penetrated to the plaster. The stripping knife is then used to releasc the paper, and must be handled so that the points do not damage the plaster. The vigorous use of the knife is unnecessary. It is better to apply more water. A large distemper brush is best for wetting the paper. Commence at the top of the wall, working right and left as far as the arm can reach, and proceed downward. A sponge wrung out in clean water must be used frequently to abeorb the water which will collect at the skirting. After stripping, the wall should be sponged with clean water, and when dry a coat of sive should be given.

Papering New Walls. New walls are sometimes distempered and left for a while before papering, on account of the risk of detriment to the colours if papered before the walls are properly matured. If, however, the risk of discoloration is accepted it is wise to hang inexpensive papers at first, choosing those in which shades of maize and yellow predominate, and avoiding blue and green as much as possible. Light grounds with well covered patterns are very serviceablo.
If possible a " lining" paper should be bung as a preparatory whenever good quality
paners are to be used. Lining gives a uniform surface which onables good joins in the finished work to be made more easily. Lining paper is of distinct value on outside walls, especially if their surface is of hard and non-absorbent naturc. On such walls in cold and damp weather moisture readily condenses inside and is frequently the cause of paper loosening nt the edges.

Before hanging, wallpaper needs to be trimmed. It is sometimes possible to have this done by machine when purchased, but it is not difficult to accomplish by hand. Take a low seat and, with the legs extended, unroll a piece of paper, holding the end in the left hand and letting the roll rest on the feet Operate the scissors with the right hand whilst the left rolls up the paper on the lap. The paper must be trimmed to the edge of the pattern, or to the line which on many papers is printed to ensure accuracy (Fig. I).
Making Paste. Good paste powder, to be mixed with either hot or cold water, can be procured in convenient size packages, but the best paste, however, is home-made. To $3 \frac{1}{2} \mathrm{lb}$. of beat household flour add oaly aufficient cold water to make a stiff batter. Mix in a clean pail and add 1 gallon of boiling water in which two small tablespoonfuls of ground alum have been boiled. The batter should be well beaten up as the water is added, and the paste should be free from lumps or it will need straining through butter muslin. When the paste is cool cover the top with a little cold water to prevent a crust forming. and then leave it to get cold. This paste should be of a stiff consistonoy, requiring thinning with cold water before use.

Paste should not be used thinner than can be easily spread A stout paper can be pasted with thicker paste than one of less substance. Heavily embossed papers may require paste to which a little glue has been added. The glue should be made in the usual way and poured on to the paste whilst hot, mixing thoroughly. Alum must be omitted from paste if the latter is to be used for papers with any "gold" or metal in their printing. Washing soda must be added to the water in. stead, but not more than $\ddagger \mathrm{oz}$. for 1 lb . of flour.

Cutting Paper to Length. Before prasting, the rolls must be cut into the required length. If the paper is plain or does not require special matching at the edges, this length will be the vertical dimension of the space to be papered plus six inches, this for trimming at top and bottom (i.e. 3 in . at each end).

If the paper is patterned further consideration is necessary. The design must be examined and choice made of a suitable place for finishing at the top so that the details of the pattern shall be as complete as possible. It is wise to select the most important details and choose a line ncross the width so that these shall not be mutilated. At the bottom of the wall the line is not so important, but with care it is often possible to arrange that the lengths are finished so that both top and bottom are pleasantly completed. Three inches beyond the line selected for finishing at top and bottom must he allowed for trimming.

Always examine the edges of rolls before trimming, to see whether there are marks indicating where the pattern joins. These joining points are given in cases where any difficulty might arise, also arrows showing the correct way up.

Pattern Repeats. In large patterns it may be that the important features do not repeat horizontally on each length but on alternate lengths. This characteristic constitutes a drop" repest, and in such cases the second length requires consideration at top and bottom in the same manner as the first. It is advis able before cutting to unroll three trimmerl rolls on the floor, joining up the pattern and
laying rods at top and botton, the distance between the rods being the vertical dimensions to be papered. Thus the choice of line for finishing on both lengths is casily made.

To take the curl out of the roll of paper unroll about 24 in . and let it drop over the edge of the table and back to it. Hold the opened roll in the left hand on the edge, with the right hand lightly pressing on the face of the paper. Then witn the left draw the paper upward between the right hand and table edge. Repeat the operation two or three times and the most obstinate curl will be flattened.
Pasting the Paper. When the line for cutting and dimension are decided, the paper can be unrolled on the table face upwand, with the uncurled end dropping over one end of the table, the dimension marked off and the required length cut. Repeat this until the roll is finished. Then turn the 'ongths face downward, any surplus beyond the ends of the table being equally distributed right and left. P'ush all the lengths about 6 in . away from the front edge of the table, then bring the top length toward the front, so that its front edge is quite level with the front edge of the table, and at the same time, with the right hand, pull the length so that its left end is rosting on the table ready for pasting. Work the paste from the centre towards the edges, completing the left and farther edge before the front edge. The paper should be lifted between finger and thumb (as shown in Fig. 2), while the edges are pasted, so that the paste does not get on the face of the paper.
When rather more than half the length is pasted it must be folded over, pasted surface to pasted surface, being held as shown in Fig. 3, edges meeting exactly and lightly pressed with the hand. This folded picce can be folded again and the folds drawn to the left end of the table so that the unpasted right end can be dealt with in the same manner.
The right end should be folded over with the extreme end overlapping about an inch and then turned back, so that it can be gripped when releasing the folds for hanging. The extreme end of the left fold should be turned up in the same way, but no pasted surface must be left exposed between these two ends. When complete, the pasted length can be lifted off the table and placed on one side whilst another length is pasted, unless the paper is thin or absorbent, when it may be necessary to hang immediately after pasting. Avoid the use of sloppy paste. Enough paste must be applied so that when the paper is folded over the surfaces will just slide casily under slight hand-pressure to bring the edges together. Heavy papers may require to be "freshened up" with a second applica. tion of paste. It is no use to attempt to hang paper before it has become supple ; this does not mean saturated, however. A little experience will quickly enlighten the worker on these points, and the procerses themselves which, to the reader, may appear claborate will be found simple in practice.
Where to Begin the Work. Paperhanging should be begun at an angle of the room nearest to the light. If there are two important windows, start work centrally between them. working away to right and left. In this way succeeding lengths on each side are laid towards the Jight. The work should be finished in an angle where any join would be inconspicuous
Presuming that the first length of paper is to be hung at the angle of a wall, commence by marking off the width of the paper from the angle at a point at about half the height to be papered. Using the plumb bob and line as a guide, mark several points above and below the centre so that a vertical line can be
male by using a straight edge. This line is toward the centre, upward and dowinward to be the guide in hanging the first length. When the paper is smoothed out hold the If a long flank is to he hung, succeeding surplus top cdge with the left hand and press lengths should br tested with the plumb linc and corrections made, if necessary. It is advisable to plumb a line at every angle. as walls are rarely as accurate as the paperhanger's joins need to be.

When ready for hanging take a length of the folded paper on the left forearm, the top nearer to the body (Fig. 4), mount the steps (which should be placed so that they are opened out in the direction away from the space to be papered), and when sufficiently high casily to reach the top, take the near loosc end between finger and thumb of each hand and let the length fall gently, opening the pasted surfaces in falling Apply the top of the length lightly against the top of the !ine. allowing the $3-\mathrm{in}$. surplus for trimming to liang over. With the left hand holding the left top. use the right hand to adjust the edge of the paper against the line. Run the liand lightly up and down the edge, then use the smooth.
 or picture rail, and then with the back of the scissors, or a soft pencil, run a line along where the paper has to he cut off. Pull the paper away sufficiently to enable the scissors to be accurately handled, and when cut replace the end and fit down, making a good finish (Fig. 5).

The lower portion of the paper has to be dealt with in similar manner. Fig. 6 shows how the lower end is taken between finger and thumb and opened out The bottom edge is finished the same way as the top. Use the padderl roller lightly to get rid of blisters In the case of embossed papers use the sinoothing brush only for this.

The eecond 'ength must be hung to fit closely up to the first (Fig. 7). The position of the steps must be reversed for this length, as the adjustment is to be made in the opposite direction in relation to the plumbed line. When several lengths have been hung the edges should be rolled down, but not immediately after hanging.

How to Paper Ceilings Ceilings are papered in the same way, but the paper has to be folded in a number of short folds after pasting. These are
made under one another in succossion until the length is in a neat pile of folds which must he turned upside down, and can be held on a roll of paper in the left hiand, whilst the right opens out the folds, adjusts and brushes the paper on the ceiling.

Papers in high relief require to be well pasted, and need time for the paste to render them applicable. The raised pattern shonld be carefully guarded, and rollers should not be used except on flat surfaces which adhere to the wall or ceiling. Manufacturers of these relicf matcrials issue special instructions for hanging, and these should be carefully observed.

Borders are frequently used with un patterned papers, and present no difficulty in hanging, cxcept that they must to be placed with accuracy so that paste is not transferred to the paper which the border docs not cover Borders which have a "cut-out" edgc are generally supplied perforated in the roll, and should be pasted before tearing apart Any waste lengths of paper are useful for laying borders on, face downward, for pasting. Use fairly stiff paste for this purposc

Panels. Panelling with borders is a very effective method of decoration and adds im portance to the appearance of a room Spccial borders ternied "stilcs" are made for the purpose and can he obtained in several widths, the narrower being used for bedroom and the wider for reception rooms. Setting out requires to be carefully done, and the proportion of the panels in the relation of height to width is important. A rectangular panel does not look well if the width is more than three quarters its height. A square panel is satisfactory, as is also a double square. Very fine examples of panelling are frequently to be found in Georgian and Adam houses.

General Hints. Old distemper should be removed by scraping and washing before papering. Walls that have been painted should be cut down with coarse glass

Paperhanging. Fig. 1. Trimming edge with scissors. Fir. 2. Pastlng. Edre lifted to prevent paste retting on face of paper. Fir. 3. Folding pasted paper, edges meeting. paper, treated with clearcole and then lined, otherwise the paper will not adhere but open at the joins If a straight edge is not available, lines can be "snapped" on a wall by the use of a chalked line, this being a fine cord covered with coloured chalk. Fasten the line with pins at the ends or otherwise hold it tautly in position, lift the centre and let it snap, when a chalk impression will be left on the wall. Printed instructions for hanging papers are frequently enclosed in rolls by the makers Such instructions should be carefully followed.

PAPER KNIFE. Used for cutting paper and opening envelopes, ctc., the paper knife is obtainable in a large number of shapes and sizes in gold, silver, ivory, mother of pearl, bone, wood and other materials. Small paper knives can be madc from old piano keys, which are often discarded as useless a: a piano repairer's. If the ivory or composition is scraped with broken pieces of glass to clean and level the surface. the edges filed to shape and smoothed with glass paper, they may be polished with French chalk mixed to a paste with sweet oil, applied with a nail brush and finished with a soft rag.

The fretworker can exercise his craft to advantage in cutting out shapes both in wood and metal, utilizing initials and monograms as ornamentation for the handle. Boxwood, sycainore, and ehony are all useful for this purpose. The design is drawn out on a shect of paper and filled in with ink, afterwards being pasted on the wood. In working ou: suitable designs, especially in lettering, ties must be provided to keep the design together.

The metalworker can utilizo copper, brass, and silver, working out flat forms with pierced, engraved, etched, or repoussé ornamentation The metal may be left quite smooth and bright, polished up with pumice powder applied with a hard brush, and then lacquered

PAPER NEGATIVE. Negatives on sensitized paper instead of film or glass have their uses, and special sensitized pajer of various speeds can be obtained from the photographic dealers. Exposure and development are on normal lines, but the developer must be a clean, non-staining one, such as metol-hydroquinone, azol, kotol, etc.

The chief use for paper negatives is in the production of enlarged negatives, for producing large prints by the platinotype or carbon processca, as well as for obtaining a considerable number of copies of an ordinary bromide enlargement. A positive or transparency is required for each of these purposes, and can be made by contact from the original negative on a slow-speed plate, the method being the samc as in the production of a nositive transparency for a lantern slide (q.v.). When this transparency has been obtained, it is placed in the enlarging lantern, and the necessary enlargement made on ordinary thin bromide paper or the special negative paper, the latter showing less grain. With the enlarged paper negative so obtained as many large prints as arc required can be made by contact, or the carbon or platinotype processes.

Paper negatives offer special facilities for easy, broad retouching. If for instance in a landscape it is desirable to strengthen the high lights (the parts that print white), it is only necessary to work with a pencil on the back of the paper negative. Similarly, if a light background is required to a portrait, appropriate and judicious working on the back of the paper negative will produce the effect in the positive print, without betraying the fact that retouching had been done. Alternatively strengthening of the shadows can be done by ordinary methods of retouching on the positive transparency before the print is taken of the enlarged negative. See Carbon Printing; Developing; Enlarging; Negative; Platinotype ; Printing.

## Papier Mâché: Plain and Decorated

How to Make Useful Household Pieces

Additional information on the subject of decorating papier mliché articles can be found under the headings Italian Renaissance Work; Laequer Work: Pattern Printing; Stencilling. Sec also Artificial Flowers: Paste Tray: Vietorian Style

Papier mâche is manufactured from highly water until it is thoroughly soaked through,
compressed paper pulp moulded to shape during the pocess of making and then painted and varnished or enamelled. The commercial articles are machine made, but papier mâchí can be made at home Vases, bulb bowls, trays, fire screens, powder bowls, wasto paper tubs, and washing.up basins can be constructed from materials which cost very !ittle bcyond the time and skill expended on them

Although used for the simplest objects, this material affords a light and excellent basic composition for painting and lacquer work and has becn decorated for centuries by artist craftsmen of many nations. Our first illustration shows a beautitul example of must ove

a. Persian papier mâché box with an exquisitely painted design. In the 17 th contury this material was enployed for lovely Persian bookcovers, and much early English lacquer work was done on papier mâché trays.

Moulding the Shape. For a first attempt a bowl or tray should le made, as the method is simple. Procurc a bowl of china or metal to serve as a mould. 'Take any old newspapers or magazines and tear them into irregular shaped pieces, the size depending on whether a small or large object is being made. On no account must the proper he cut; tearing gives it a bevelled cdge, which ensures a bettor fit when pasted on to the mould Leave the paper in and meanwhilc prepare soine ordinary flour paste, to which a litile alum is added, as this minkes the paste more adhesive It should not be very thick, but should be of a semiliquid consistency.

Coat the inside of the bowl with solt soap, to prevent the paper sticking to it. Then take the paper from the water, dipping one piece at a time in the paste and drawing it through the fingers to make sure the paste is evenly distributed. Spread the paper over the lottom of the bowl Repent the process until the whole of the iuterior is evenly covered; each piece must overlap slightly so that they ndhere to each other. Allow the paper to extend from $1 \frac{1}{2} \mathrm{in}$. to 2 in beyond the rim of the bowl, and continue laying on the pieces of paper until the layers are $\frac{1}{2}-\frac{1}{8}$ in deep.

Large objects require to be thicker, whilst small bowls need not be more than $\frac{1}{10}$ in thick. Now place the bow! before a bright firc or in $a$ moderato oven until thoroughly dry l)raw a pencil linc round the rim of the inould on to what will be the outside of the new bowl. Remove the mould, and with a sharp keyhole saw or strong scissors cut of the edge along the pencil line. Rub down this edge as well as the whole of the interior and exterior of the papier mâché bowl, first with a medium, then with a fine glass paper. Number 00 is best for the final rubbing down. To finish, size, paint, and varnish the object. A bowl or anything that is being used for a mould can be equally well coated with the paper from the outside as shown in Fig. 2. This method is necessitated when the mould in use is vase-shaped

For a washing-up bowl, such as that illustrated in Fig. 3. two or threc coats of ordinary white enanel arc most suitable for the intcrior, while blue, grey, or brown can be used for the outside. A niarbled or mottled effect is ol. tained as described in page 681. Vcry attrac. tive and decorative bull bowls can be made by

Papier Miclé Fig. 2. The paper is torn into irregular pieces, soaked in water, then covered ovenly with paste ard spread, each piece overlapping the other, on the surface of the bowl or other mould

Papier Mâché. Pig. 8. Bowl which lessens the risk of breakage when
painting the inside in some bright colour that contrasta with the outside, such as orange and black, primurose or grey and apple green. A still more artistic effect is obtained by lacquer decoration in colours as well as gold, bronze, and silver A fruit howl lacquered hlack with a design of gold or merely lined with gold is uncommon, and goes well with achemes where a brilliant colour would be out of keeping. Stencils can be employed with good results, and so can gesso decoration. A good hard varnish must he used in the case of bulb bowls to withatand the damp from the fibre.

A tray or any article which tapers towards the bottom can be made in the way described. One like that illustrated in Fig. 3 can be modelled on an old tin tray and enamelled in a bright colour.

Should there be no object handy that can be used for a mould, a lump of modelling clay may be shaped into the form desired. A simple method is to roll out the clay on a board in the same way as pastry to a thickness of 1 in., and cut it out into circular pieces vary. ing from the amallest to the largest diameter. Place one on to the board and huild up the mould with the rounds in required order of size, filling in the steps between each layer with clay If the mould is not going to be used immedi. ately, keep it covered with damp cloths to prevent cracks appearing. Well cover the clay model with soft soap and alao the hoard round it for about 4 in., or the edge of the paper will stick to the hoard. The procedure is then the same as before.
Any skilled worker who wishes to produce narrownecked vases, jugs, etc.. in papier máché, can first make 2 models in clay, each one a longitudinal sertion of the object. The edges of the papier mâché, after the preliminary moulding has been completed as already de. scribed, are cut absolutely true and then glued together; when the glue is quite set 2 or 3 coatings of paper are applied to the outside of the vase or jug. These last coats of paper must not be dried artificially, but merely left in a diy room, or the ohject will warp and get
washing op; and a tray ensmelled in bright colonrs Courlesy of Staines Kitclien Equipment

Fig. 4. Beautiful early 18th century example of a papier mathed table top.
Fig. 4. Beautiful early 19th century example of a papier mathé table top.
decorated with shell, bronze and colour
 decrath with brane and
out of shape, as it has no mould inside.
To make a waste paper tub or basket from papier mâché is an casier task. An old size tin, or any other round tin of suitable dimensions, will make a hood model. Failing a tin, a piece of stout cardboard can be rolled to fit a circular bottom, then glued and allowed to harden. Plastioine is used to round off the join on the outside so that anycracks are eliminsted in the finished article and it is given a slightly moulded base. The procedure is the same sa for the bowl in Fig 2. Sperial attention must be paid to the rubbing down, as if the surface is large any rough ness will be very noticeable. The old papier mâché workera used pumicc-stone for the final rubbing down, and then polished the work Inboriously with a chamois leather. This was worth while, as it produced an excellent surface for decoration.
Flower, sporting or other prints form excellent panels for decorating such irticles after the final enamelling is completed. In order to cnsure better wear the whole aticle is varnished after the print or if prcferred. a hand-coloured panel has been pasted on and out lined with black. The top is given a finish of gold or silver bronze paint outlined with black. Mottled paper may be used to line the hasket or it may be finished in enumel. Chinese lacquer designs are particularly suitable for a handsome waste-paper tub. Cheap enamel diahes and sugar basins make serviceable moulds for small trays and lowls

Decorated Panels. A papier mâché panel for a table top or fire screen is madc on any fat tin or metal plate If really good decoration is intended by a skilled amateur, the old method of making the panel may be followed. An odd length of cheap mat-surfaced wallpaper is quite a satisfactory substitute for the apecial paper that was used. Ahout 12 sheets should be cut out of the desired size for the panel.
The metal plate is oiled before the first damped sheet is laid and covered with paste and alum. The old workers used a mixture of
glue, flour and resin Another sheet was laid over perfectly flat and then plate and sheets were placed in a cool oven to dry. The surface was then rubbed down with pumice-stone to ensure amonthness before the next sheet was spplied. All the sheets were thus applied and dried in the oven hefore the panel was completerl and atrong enough for a table top or tray. To form a moulderl edge the paper would be taken over the edge of the metal shaped hy hand and cut off with keyhole saw
In some of the beautiful floral designs of the first half of the 19th century pearl was used, as in the table top shown in Fig. 4. In others large flowers and leaves were painted in bronze colours and gold. After 1845 oil colours and bronze colours were utilized in the same designs. Pearl was atill employed, but was leas scen sa the more gorgeously coloured designa became popular.
The pearl effect was gained by use of thin layers of nautilus shcils and these were stuck on to the surface of the papier mâche with gluc. In modern papier mâché decoration the thinnest ahells ohtainable for artificial flower making can be specially cut and coloured with spirit stains sold for the purpose. Fish scales can also be used. Very rich effects can be ohtained by use of such shells or scales for portions of flowers with oil and bronze colours, for other portions and for leaves, when carrying out a lloral design for a pancl
Care of Papier Mâché. Old pieces of decorated prpier mâché require careful cleaning. Sometimes a beautiful piece has been mo neglected that the original colour and lustre seem quite lost. A soft finnnel, damped with a very little pure curd soap on it is the best cleansing agent. When the dirt has been removed the papier mâché must be gently dried with a flannelette duster, a little furni ture cream put on with the tip of a finger and the surface immediately polished with an old niece of softest silk Valuable decorsted papier mâché articles should not lie exposed to damp, and should liquid be spilt on tray or table top it should be dried off at once
PAPILLON. This toy dog is popularly known as the butterfly dog owing to the sup posed resemblance of the ears to the winge of a butterfly. They were introduced into England during 1923. The papillon has a very profuse coat of a silky texture, and the large ears can be well feathered. It is a loosely coupled little dog with a wedge-shaped head. The bolly colour is white and the markings either lemon, brindle, brown or black. If thesc are evenly distributed it gives a better appearance to the dog. The smaller they are the more highly esteemed, providing the dog has quality in otlier respents. The Papillon Club has done a great deal for this breed. See Dog.

PAPYRUS. The ornainental grass of Egypt that is known as papyrus requires aquatic treatment in a heated glasshouse. It attains a height of about 6 ft ., and has dark green leaves. Cultivation is in pots of loam, leaf-mould and sand, plunged in tubs or tanks of water. Propagation is by division of the root stock. The name papyrus is applied to the writing material made from the stem, and to a manuscript written on this substance.

PARADISE: In Budding. This is the name of a variety of crab which is used as a stock on which to bud apple trees, particularly those grown in the form of pyramids, low bushes, or trained trees. It is known as the dwarfing stock because it induces a dwarf, aturdy and early-maturing growth in the applea budded on it. The true broad-leaved paradise stock is recommended for budding the trees. See Apple; Grafting.

PARADISIA. This hardy perennial grows 2 to 3 ft . high, and has grass-like leaves and white llowers in early summer. Paraclisia
lilinstrum (Anthericum lilinstrum) flourishes in ordinary garden soil. It is known as St. Bruno's lily.

PARAFFIN. The name of paraffin is a pplied to a whole series of organic substances, which includes marsh gas, naphtha, henzine, petrol, petroleum lamp oil, heavier lubricating oils, vaseline petrolatum, cosmoline, adepsine, and the hard paraffin of which candles are made.

Paraffin oil, which is also known as kerosene, is chicfly used for illuminating and heating purposes. The thinness of the oil gives it the peculiar property of spreading or creeping, so that it is important when filling lamps to avoid excess of oil. After filling a lamp all traces of oil on the outside of the container should be wiped off, as otherwise the unpleasant smell of paraffin will be given off when the lamp is lighted.

Heavy paraflin oil forms the base of lubricants for sewing machines and lawn-mowers, and a good deal of petrol is made from paraffin Floor-sweeping compound is made by mixing 1 pint of paraffin oil with 10 lb . of dry sawdust. This is used for hardwood floors, a little being eprinkled on the floor before it is swept. See Burner ; Lamp; Oil, etc.

Parafin Wax. The white solid that is obtained as a residuc in the purification of petroleum resembles white beeswax, for which it is a cheap substitute. The chief commerical use is in the manufacture of candles. As a lloor polish, paraffin wax is made into a paste with either oil of turpentine or a mixture of equal parts of paraffin oil and benzine. Paraflim wax has another important application for electrical insulating.
Some Medical Uses. In therapeutics liquid, soft and hard paraffin and paraffin oil or
petroleum are utilized. It should be noted that liquid paraffin is quite a different thing from paraffin oil. Liquid paraffin is used internally as a laxntive and also in the form of petroleum emulsion to aid assimilation of food. It is often used to spray the pliarynx and the nose. Soft paraflin or vaseline is an excellent basis for ointments. Hard paraffin is sometimes injected under the skin of the nose to correct deformities. Paraffin oil is applied to the head to kill lice.

PARALLEL BARS. One of the most commonly used of all gymnnastic apparatus, parallel bars are subjected to considerable strain, and must be strongly made. The framework may be of deal or pitch pine, but the bars are always of straight-grained ash, and in the best apparatus they have a core of steel. A satisfactory pair of bars (Fig. 1) can be made in the following manner with ordinary deal and two lengths of selected ash. The width between the centres of the bars for liome use ahould be 2 ft., but they can be wider apart if required. The total height is 4 ft ., with fixed bare which are 8 ft . long.

The bottom framework is made from 5 in by 3 in. wood, planed smoot $h$ and true to these sizes; but 6 in . by 4 in . deal can be used, and when passed through the planing machine will not be much larger than $5 \frac{1}{2}$ in. by $3 \frac{1}{2}$ in Two grooves marked out on the long pieces are the exact width of the wood, and 12 in from each end. Gauge lines are marked halfway down, and the waste removed with a chisel (Fig. 2). The
cross pieces are 4 ft . long;
the grooves are the same width and depth as the others, and $0 \frac{1}{2}$ in. from each end. The ends of all four pieces should be rounded.

The four uprights are tenoned into the base, and are cut to 4 ft . from 5 in . by 3 in . wood. The ends are marked down 3 in . for the tenon; then 1 in . from the edges and $\frac{1}{2}$ in. from the sides, as shown at A , Fig. 3. The tenons are then sawn down as shown at B. Corre. sponding mortises are cut in the bottom framing as indicated at Fig. 4; an enlarged view of one corner is shown at C. Each of the uprights is now tapered, lines heing marked as shown at D, Fig. 5, and anwn down; the top is hollowed, $E$; the sides planed, $F$, and finally the top cornery are chamfered, $G$.

The uprights are glued and wedged in position as shown in the section at Fig. 6 leaving the 8 ft . ash poles to fit in position First smooth the wood carefully with glass paper, and then provide eight $4 \frac{1}{2}$ in. ateel ribbed brackets and attach them to the underside of poles and sides of uprights with round-headed screws. The uprights are also strengthened with large steel brackets, 10 in . by 14 in . Owing to the sides being tapered they must be let into the wood as shown at Fig. 7. The bottom can be boarded in by nailing on 2 in. by 1 in . strips on the inside of the long hotton lengths, and then fitting 1 ft .7 in . lengths of I in. Hoor hoarding bet ween. The framework may be painted or varnished, but the bars themselves are left clean from the glasspaper

PARALYSIS: Its Causes. Paralysis is the loss of power to contract the voluntary muscles. There are two sharply divided groups namely, paralyses which are hysterical and those which are of organic origin. Hysterical paralysis may follow a physical or a mental shock. The physical cause most frequently responsible has been a railw'ay accident. Mental causes include disappointments in love, grief, fright, anxiety, overwork, prolonged strain, etc. In a large number of cases, however, these influences are merely the precipitating factors, the condition being due fundamentally to some psychic influence.

Hysterical paralysis differs from organic paralysis in that in theory every case is curable and in practice the great majority are cured. this being effected by purely psychical methods
Organic paralysis is duc to injury or disease of the nerves or brain. A common cause is apoplexy or stroke, due to rupture of a blood vesal in the brain, with resulting damage to the nerve cells in the neighbourhood. A familiar form is locomotor ataxia, a condition characterized in the early stage by inability to control the muscles, thus leading to an irregular jerky gait. Neuritis, or degeneration of the nerves, may result from prolonged alcoholism or chronic poisoning by lead or arsenic. Infantile paralysis is a condition, seen most often in young children, in which paralysis of one or more limbs supervenes The treatment for organic paralysis varics very much with the cause. When due to detinite disease, the treatment must be directed towards combating that elisease. In acute cases the patient should be kept in bed, and care must be taken in preventing the formation of bed sores (q.v.).
Paralysis of the Insane. This disease is due to inflammatory and degenerative changes in the brain, by reason of which both mental disorder and paralysis of muscles occur. It occurs mostly in middle life among men who have overtaxed their brains or put a prolonged strain on the nervous system. Injury to the head, abuse of alcohol, and worry favour the onset of the disease.

In a majority of cases it is advisable to remove the patient to a mental hospital, and very often this should be done early in the disease, both in the interests of the family and of the patient himself. See Infantile Paralysis ; Insanity ; Locomotor Ataxia.

PARAMIDOPEENOL. The photographic developers of the paramidophenol class are very clean and stainless in working and keep well in a single stock solution, needing only the addition of water before use. They are effective for all kinds of photographic work. The best known exainples are a\%ob, kodol, rodinal, and rytol. Taking azol as an example, the following are the quantities to be used:

|  | A 8.01 | Potassium Uromide $10 \%$ | $\left\lvert\, \begin{gathered} \text { Water } \\ \text { to } \\ \text { make } \end{gathered}\right.$ |
| :---: | :---: | :---: | :---: |
| Plates and films (normal develop. ment) | 20 drops | - | 10 \% |
| Gaillaht papers (rolt or normal prades) | 40 | 2 to 5 drope | 1 |
| Do (vigromue qrade) Rromlde papers | 40 15 | 10 |  |

The Watkins factor for development with azol is 30 for average contrast. The detailed tables for development by time and tempera ture for all the plates and films on the market are publisherl hy the makers of the azol developer See Developing.

PARAPET. A low wall or parapet is often used to protect gutters and roofs of houses, and it should be periodically examined to see that it is perfectly sound, and not liable to crash to the ground. A consideration with the roof and guttering, when $n$ parapet forms part of the building, is that the mortar is liable to weather very rapidly, and the result is that a heavy fall of snow or other cause may result in the parapet being entirely demolished. A preventive of this is to rake the mortar joints, and then to re-point them with cement mortar. The parapet illustrated above is shown with simple capping. In many types of building a parapet of stone or cement is employed as a decorative feature. These weather rapidly owing to their exposed position and the smoke from adjacent chimneys, and can be treated effectively with proprietary brands of waterproofing materials.

A simple treatment available to the ninateur is the use of a cement wash composed of equal portions of Portland cement and sand, brushing it on with an old stiff hrush. Where the parapet is painted, it requires to be given a fresh cont at least once in every three yeara with a thoroughly durable and first-grade paint of outdoor quality. See Wall.

PARCEL : How to Pack. If a parcel must be made of several items of divergent si\%es and shapes, the only safe plan is to procure a cardboard or wonden box large enough to take them all. Any creviecs should be tightly packed with n stuffing of crumpled newspaper to prevent the contents from inoving. Breakable goods such as bottles of medicine should be wrapped in corrugated cardboard before being put into paper, the outside of the parcel being marked "G!nsa, with care."

A parcel which is of considerable weight or which is being sent a long distance, should be wrapped in paper, firmly tied with plenty of string and addressed. Then the whole process should be repeated. The second wrapping gives extra solidity and strength, and the second addressing provides for the accident of one being torn off in transit. Photographs should be sent in the special wrappers, backed with cardboard, which are sold for the purpose ; failing these, the parcel or envelope containing them should be stiffened with a sheet or two of cardboard.

Book Parcels. A book should be placed in such a way that the edges of the cover cannot suffer. One method is to enclose it, as shown in Fig. 1, between tivo boards, cut $\frac{1}{3}$. larger on every side than the book covers, and to tie this up carefully before wrapping in

Parapet of brickwork built on a house for the porpose of protecting rool and gutters
strong paper. Another method is to use corrugated card board

This is cut roughly crose-shaped, as shown in l-ig. 2, the hroad centre-picce folding over the spinc and front edges of the book, the narrower length protecting the upper and lower erlges. The corrugated side of the card. board is placed innerinost, and the cut edges must overlap those of the book. If packed in this way, however, it will not travel by book post, which demands open ends. If no cardhoard is available, a book can lie first wrapped in several thicknesses of newspaper.
String of suitable thickness should never be sparel, and it should be fastened tightly. Each parcel should he addressed very clearly, in full, and twice over. This may be done on the outer wrapping itself, if the paper is of a colour and surface to take ink well:

Parcel. How to nack a baok. 1. One method is to place it between boards before wrapping in paper 2 Corrupated cardboard cut to the shape required. Curbbard folded over. 4. Wranping in stout paper 5. One end tolded and strong string tled tightly. B. Finighed parcel calculated to dely rough postal treatment
otherwise labela, one stick on and one tie-on, should always be addressed on an accompanying tie-on lahel and not on the parcel itself, as the heavy stamping of the postmark if made on the parcel, may crush the contents Parcels intended for registration are not accepted for delivery by the post office unless every intersection and knotting of the string is sealed with sealing-wan Also, the outer paper wrapping or cardbnard box must be intact.

All these precautions apply with double barce to the sending of Christmas parcels, for at that season the mails are so crowded that they may receive rougher handling than usual. Gift parcels not intended to go through the post may be wrapped in gaily-designerd papers and tied with tinsel rihbons See Christmas; Packing : Postage

PARCEL POST. In Great Britain gouds, provided the parcel does not exceed 11 lb . in weight, can le sent to their destination through the post oflice. The parcel can be handed in at any post office, where it is weighed and stamped. In rural districts it can be handed to a postnian The chargea (1931) are

> Between 2 iin, a nud a ib). Md
> ketween 616 and 8 ll ., 1 smd
> Hefwen 8 ll . and I: ii ., is. 31

The parcel muat not exceed 3 fk , $\mathfrak{G}$ in in length, nor 6 ft in length and width combined ft should be marked parcel post and bear on it the name and adilress of the sender $A$ pircel can be registered at a cost of $2 d$ which payment carries with it the right to compensation for loss or damage up to $a$ naxinum of $\mathfrak{i} 5$. For 3 d compensation can

be obtained up to a maximum of $£ 20$, and every additional ld means an additional $£ 20$ for compensation up to a maximum of is 10 d . for $£ 400$ Compensation up to a limit of $£ 2$ will be given on unregistered parcels if the sender obtains a certificate when sending To secure compenation the parcel must be securcly packed, while it will not be paid for damage to egga and other very fragile articles

Parcela can also be sent to British possessions and to most foreign countries The maximum weight of the parcel that can be sent varies, but in no case does it excecel 22 lh . Parcela up to this weight can be sent to France. These parcela are subject to the ordinary custom duties The charges and regulations as to size vary, but the information can be obtained from any post office. Parcels sent to most countries can be insured. but not registered. The insurance is limited to $\mathbf{~} 400$, for which a payment of 5 s . 10 ot is necessary.
Parcels by Air. Parcels can be sent by air to foreign destinations under the same general conditions as if sent through the post in the ordinary way. They can be handed in at any post office that accepts parcels for abroad. A special blue air mail label must be nffixed to the address label of the parcel and to the relative despatch note, and the words air mail should be written conspicuously on the cover of the parcel. In addition to the more rapid transit, an air parcel is usually given a speedy clearance at the customs. The Post Office issues regularly nn air mail leaflet which gives full details about this кervice.
PARCHMENT, Made from the skins of sheep, goats, and other animals, parchment is used for book binding and illuminating, coarser kinds being used for drumheads, banjoes, and tambourines. It is prepared by freeing the akin from hair and flesh while it is attached to a stout wooden frame, aubsequent treatment being similar to that adopted for leather.
For the repair of musical instruments it is not necessary to use new material ; old deeds, which are often obtainable, are quite suitnble. For use in the panels of lamp shades, parchment may be made nearly transparent by soaking a thin skin in a strong lye of wood ashes, wringing it out ngain and again until it is fairly transparent. It may then be varnished with mastic varnish. Staining is effected with aniline dyes or waterproof inks, but the skins must be stretched tight while drying. Illuminated parchment which has become dirty and greasy may be cleaned with benzine, and if the colours require touching up, ordinary water colours mixed with Chinese white can be used, but specially prepared colours are supplied for the purpose. Stiff parchment will soften in water, but a fairly permanent Hexibility is obtained by soaking the skin in glycerin. For new drumheads or tambourines preliminary sonking in water will be quite sufficient.
The parchment mainly used in the home is known as vegetable parchment, and is made by dipping ordinary, unsized paper for a few seconds in diluted sulphuric acid in the proportions of one part of acid with half its volume of water. It is thoroughly washed in water and acquires a parchment-like texture and becomes about five times stronger than ordinary paper. It is impervious to water but is rendered soft and limp when dipped in it. The atout qualities are used for bookbinding, and although not so durable as animal parchment, it may be worked up in the amme way. For making lampshades and covering small screens or writing desk sets it is very useful, as it may be varnished to render it more durable; it can be stained to any colour and may be painted.
Such parchment is employed for covering jars containing preserves or anything that can
be contained in n jar from which air must be excluded. Several thicknesses are obtainable. but before use it should be cut to the approximate shape and dipped in water to soften it. Owing to its pruperty of stretching when wet. care must be taken to prevent it soaking too long; if this is allowed and the jar is covered with it and tied up tightly, it is very likely to split when it dries.

Vegetable parchment is an excellent material for making moth-proof baga; it can be obtained in large sheets; it is not expensive, und when the bags are properly made the contents are airtight as well ns moth-proof. The baga should he made with a double fold at the edges secured with thin tish glue nubbed on evenly See Candleshade ; Lampshade.

PAREGORIC. Compound tincture of camphor, commonly known as paregoric, is inuch used in cough mixtures, and also for the relief of colicky pains. It contains, besides camphor, aniseed, benzoic acid, and opium In view of the presence of opium, which gives paregoric its soothing effect, the remedy should not be used except under medical direction.

Parent. See Father; Guardian ; Mother.
PARFAIT. Except for the fact that it is usually richer in cream and served in tall glasses, a parfait is an iced swect, similar to a 3undae, made with fruit syrup, grated nuts, ice cream and whipped cream.
PARGING. The process in building known ns parging renders the inner surfaces of a brick-built flue smooth and fire resisting. Parging is similar in its essentials to cement rendering, and various mixtures are used by different operatives. A commonly used composition is one part of Portland cement to two parts of good, clean, sharp anded, the proportions being gauged by bulk.
In some cases a mixturc of fireclay and cement is used, but generally much ol the parging of a flue is done with ordinary lime mortar. Parging is done sa the work procerds, that is, as the bricklayers construct the Hue; the inner surface is rendered with the cement and trowelled of smooth.

PARIAN WARE. The moat valued period of the statunry porcelain known as Parian ware lasted for about 30 yeara nfter 1845. Invented in the Copeland works, as the outcome of n search for the lost secret of Derby biscuit ware, it was adopted at the Minton, Wedgwood, Worcester, and other factories. Some early figures are recognizable by having a sinall proportion of glass mixed with the body-paste, but the finest were inadic of china clay and felspar alone, in a mixture which enabled them to be fired at a lower temperature than ordinary boneprorcelain.

The best examples, pure white and unglazed, are superior in transparency to the opaque Derby biscuit, and have the general effect of the Carraramarble, which they sought to emulate. Sometimes a lead glaze was added, and this was especially well done at Longton. Unfortunately the designs are not particularly

Parian Ware. Statuette in pure white unglazed dorcelain
good. Unglazed Parian should be kept clean with purc water, in the same way as biscuit, becnuse of its porous surface. See China.

PARING CHISEL. The blade of a paring chisel is considerably longer than that of the ordinary firmer chisel, and there are two forms, the ordinary parallel type of blade, and that with a bevelled edge. The latter is preferable for paring, that is, cutting wood across the grain, as the blade is thin at the edges.
Since the tool is intended chiefly for cutting across the grain, it must be kept in very good condition. properly ground and well sharpened. It is handled in substantially the aame way as the ordinary firmer chisel Under some conditions the extra length of blade is an advantage, as, for exainple, when working at the bottom of $n$ deep slot for a mortiac, or under any other conditions where a deep hole has to be dealt with. P'aring chisela are gencrally obtainable in widthe from $\ddagger$ in to 2 in., and the sizes most useful for the amateur are $f, \frac{1}{2}, \frac{1}{2}, \frac{3}{3}$, and 1 in See Chisel.

PARIS. The hardy perennial known as Herb Paris grows about 10 in . high, bears yellowish green flowers, and is suitable for $\AA$ moist and shady position. It is planted in autumn or apring, and propagated by division of roots during the same periods.

PARIS GREEN. This is an arsenical insecticide made of nccto-arsennte of copper, and is highly poisonous, particularly if inhaled in its ordinary powder form. A preparation known as Blundell's paste is the safeat form in which it can be used. The paste is not soluble, but may be mixed as n Huid at the rate of 1 oz . to 10 gallons of water, with an addition of 4 oz lime. It is used as n fine apray, the mixture being constantly stirred during use. It is efficacious as a wash insecticide for fruit trees, but when applied to the pench, nectarine, or apricot, the quantity of paste must be reduced by $\ddagger$ oz. Trees should not be sprayed when in Hower. It is beat applied just before the buds open, and directly the petala begin to fall. See Insecticide.

PARKIN. This is a Yorkshire speciality. To make it, allow $\frac{1}{2} \mathrm{lb}$. butter or margarine to $1 \frac{1}{2} \mathrm{lb}$. treacle, $\frac{1}{2} \mathrm{lb}$. brown sugar, 2 lb . oatmenl. 1 lb . llour, 1 oz. ground ginger. Dissolve the butter in the treacle over gentle heat or by standing at the side of the fire. Stir in the sugar and the ginger and mix the Hour and the oatmeal together. Stir in the flour and oatmeal and mix with a wooden spoon. Add 1 or 2 beaten egge and a little milk if neccessary to mix to a soft but fairly stiff consistency. Put in a greased pudding tin. It should be 1 in. in thickness. Bake in moderate oven 40-50 min. Let it cool in the tin, then cut in squares and store in airtight tin.
PARLOUR. This oldfashioned name for a sitting room or drawing room is still preserved by some peoplc who own period houses, or who furnish a cottage sitting room in old-world atyle. The parlour should suggest the cosiness of a Queen Anne style (q.V.) of sitting room and stuffiness or formnlity should be wholly absent from its furnishing. See Furniture.

PARLOURMATD. A good parlourmaid can command high wages, and is next in importance to the cook as far as female servants are concerned. Where there is no butler she is responsible for the glass and silver, and for the care and decanting of wines. She also waits at table, answers the front door, ushers in and announces guests, and takes in afternoon tea. All the dining room table work is hers. She is, moreover, expected to act as valet to any gentlemen in the house, laying out their dress clothes and keeping their wardrobe brushed and tidy. See Insurance ; Servant.

PARMA VIOLJT. flowering and fragrant variety bearing blossoms of pale bluish lavender. It is largely grown for market purposes. It is excellent for culture in frames. See Violet.

PARMESAN CBFESE. This is made from skimmed milk. It is not used until it is several months old, and the best varieties are kept for two or three years before being sent to market.

In most localities, Parmesan cheese is bought already grated, as it is used to garnish savoury dishes, soups, and salads, It is however, rather expensive. See Cheese.

## Parquet and Wood Block Flooring

## Effective Methods of Decoration and Construction in Floor Coverings

An article that should be consulted in connexion with this subject is the one on Floor. See also Carpet; Polishing; Rug; the entries on the various rooms of the house, e.g. Dining Room; Drawing Room: and those on the various woods, e.g. Oak

The name is used to denote a floor of wood arranged in diaper formation. It is constructed by cutting thin boards into geometrically shaped pieces, and laying them down to form a pattern, much in the same way that tiles are laid. The thickness of the wood may be as much as an inch, but is usually thinner, $t \mathrm{in}$. being common.
Parquet is mostly laid over existing flowr boards, and may be regarded not as true construction, but as decoration. On the other hand, wood blocks are frequently employed in the way parquet is used, but laid on a solid foundation, such as concrete, forming part of the structural floor; but this is not true parquet. Almost any geometrical pattern can be rendered in parquet, consistent with the limitations of the material, which does not admit of very small detail. Both types of flooring are illustrated and described below. lnstructions are also given for preparing and laying wood blocks which the amateur can make from commercial timber.

Austrian oak is generally used for parquet, owing to its close, even grain and freedom from knots. It has a rich, uniform colour, but is comparatively soft, easily showing marks. English oak is employed, but is uneven in quality, figure, and colour. Russian, Japanese and American oak are also used, and a very fine Hoor can be constructed of teak from Kangoon or Java. The beat kind of parquet is what is called plated, consisting of about $\frac{3}{16} \mathrm{in}$. oak or teak pressed upon a backing of ${ }^{1} \mathrm{in}$. deal. This method prevents buckling and is suitable for the best class of inlaid work. Parquet is usually laid down in made-up panele, varying from 12 in . to 1 yd . square.

Before the laying of a parquet floor can be commenced a design has first to be drawn. To do this, the room is measured, the size of the angles being noted as well as the length. breadth and the various breaks, such as the breasting of the fireplace, and a scale drawing of the plan is made on paper. Two typical designs with borders are shown in Figs. 1 and 2. When a decorative border is required, it is made sufficiently wide to extend beyond any of the smaller breaks or projections of the walls, so that the plain centre portion will thus finish against a straight line, as in Fig. 3. All larger projections or recesses must be followed round. From this drawing, the number of blocks required can. be estimated and the length of the border decided upon.

The next consideration is the groundwork upon which the parquetry is to be laid. In new buildings it is usual first to lay a counterfloor on to the joiste, this consisting of deal battens $f$ in. thick placed diagonally and butted square into each other at the ends so that the joints will run diversely to those of the upper flooring. When levelled and cleaned off, this forms a good surface for the laying. In older houses a common practice is
to disguise well-worn deal floors with a layer of thin parquetry

It is essential that the boards are first levelled, and any weak or creaking boards either replaced or the cause of the trouble rectified. The levelling is done by planing, first transversely across the grain with a jack plane, and finishing off with trying plane, the edges by the walls being brought to the general level with a rebate plane. It is very seldom that all the blocks are laid individually in position direct on the floor. The usual procedure is to build up the individual patterns on a bench and then to apply these patterns to the floor.

Fig. 4 shows a complete pattern ready for fixing. With very thin parquetry and in the cheaper kinds there is sometimes no binding joint between the blocks. In this case the patterns are built up on tho bench and a piece of canvas glued to the back. When set they are placed in position on the groundwork and nailed through the face, the nails being punched in. long thin nails are used, similar in shape to pins used for laying oil cloth, having no heads and tapering to a point. In better-class work, and in the thicker varieties, the sides of the blocks are grooved to receive metal tongues, or are dowelled. Wherever possible the patterns are first built up, this being comparatively easy when the blocks are dowelled. The decorative borders are treated in a similar way, being put together in lengths of about 18 in. to 3 ft ., according to the pattern.

Figs. 5 and 6 show methods of securing the blocks to the Hoor when it is required that no nail holes shall show on the surface. In Fig. 5 the block is fitted over the tongue of the preceding block and a nail driven askew

Parquot. Fis. 1. Deeige in two diflerent coloured woods with simple border. Fis. 2. 8howing use of both reotangular and square slabs. Fis. \& Plan 0 room showing parquet deaign to be used, and arrangement of border

length. In all cases where the parquetry is not finished against a wall, as for instance by the hearth and the door in Fig. 7, a batten should be mitred round as a protection to the edge. When parquetry is laid on an already existing floor, the door, if it opens inwards into the room, must be taken down, and a strip equal to the total thickness of the parquetry sawn off the bottom.

When the laying has heen completed, the whole surface is levelled with a smoothing plane and finished off with a steel scraper and glasspaper. If the blocks have been laid in sections comprising a complete pattern, only the juncture of the several patterns will require planing, the individual eections having been trued up on the bench prior to being laid.

The usual polish for these fliors is was thinned out with turpentine, the mixture being rubbed well in and left to stand for $\pi$ day before heing polished with dry dusters or with a brush. In some cases a hody of french polish is put on to keep the dirt from hegriming the surface. Another method is oil polishing, which bas the advantage of not heing so liable to tread off or mark ; it takes. however, a great deal of labour to keep it in a fair condition of freshncss.

Wood Block Floors. The laying of the thicker wood block floors entaila a more claborate process; no nails are used to fix it, the blocks being held down thmugh the medium of a coating of mastic benenth. Fig. 8 shows sections through a few typers of block, the under sides and edges being grooved in the form of a dovetail into which the mastic is forced, forming an exceedingly strong fixture When the blocks are to be laid on a counter floor, a mixture of glue and whitening is used to fix the blocks, but in other work a mixture of pitch and coal tar is often used.

Fig. 9 shows a section through the flooring. A hed of concrete about 6 in . to 1 ft . in
thickness is first put down and allowed to harden thomughly. It is essential that this should completely dry, as otherwise the moisture will causc the woodwork to swell. This bedding is levelled by floating a coat of cement over the top, and is again left to set,
the time varying according to the weather In aome cases a series of plugs are floated in the concrete level with the surface of the cement at a distance of about 6 ft . apart, as in Fig. 9, and to these the blocks are serewed
The lower sketch in Fig. 8 shows a method of interlocking the blocks with tongues litting into grooves cut in the side of the blocks. Another system is that in Fig. 10, in which the same result is ohtained by dovels. When laying the blocks the latter are stacked in a handy pile, and a small portion of the lloor boarded round to keep the mastic in bounds and to prevent it from spreading over too large an area at a time.

The mastic is then poured within the space at hoiling heat and the blocks quickly rubhed in position, having been first dipped in the mastic up to about half their thickncss. The size of the arca hoarded off will vary according to the number of men engaged on the task. two men being able to tackle an area of alout 2 yards. Fig. 10 shows a herringhone floor, the blocks being numbered to show the order in which they are laid. When the work has been completed it should be left to set for a few days, and is then levelled off
Making Wood Blocks. The amateur can readily construct a wood block floor covering from atrip material. This may be oak or any other ornamental wood, or it may he ordinary builder's deal of the kind sold as door stopping and known as 4 in . by $\frac{1}{i n}$., but which actually measures 33 in wide and $\frac{7}{16}$ in. thick. It is cut to lengths of 11 j in ., as the length of the strip must be exactly equal to three times its width. If some other width material is used the length should he adjusted accordingly. It is important that the atuff should be uniform in width and thickness. The timber merchant will thick ness the strips, and plane them on three surfaces If the whole supply is bought at onc time the wood can be put through the machine without altering the gaugea, so that uniformity is assured Suitable oakstrips, $\frac{1}{t}$ in by 4 in., may be procured from Handicrafta, Ltd., Kentish Town, London, N.W.5.

If the worker has a lathe with a saw table

Parguet. Simple wood block fooring wlich the home worker can prepare. Fig. 11 Cutting strip to length with a sawing Rnidc. Fig. 12. Planing the ends of the blocks. Fir. 13. Testing for length with a simple gaure. Fig. 14. Laying and flting the blocks. Fig. 15. Corner of floor when completed
the work of cross cut. ting the strips to size will he greatly reducer Failing this, a simple sawing gruge should first be made, such as that illustrated in Fig. 11. This eomprises a basebonrd constructed from 9 in . hy 1 in deal. At the left-hand end a cross hatten is secured by screws. Two tapering upright pieces are screwed to the sides of the board, and a vertical saw.cut made through them exactly $11 \frac{8}{6}$ in. from the in side edge of batten. The extra $\frac{1}{6} \mathrm{in}$. is provided to allow of the end grain of the mate. rial heing planed up.
A few pieces only should he cut out at the start, and the ends planed by the use of an ordinary shooting board, as in Fig. 12. A smoothing plane or jack plane may be used To ensure all the pieces of timber being of uniform length, they should he inserted into n gauge, as in Fig. 13, comprising a wooden baseboard to which cross pieces of hatten are fitted to either end, the space between the inner faces being exactly $11 f$ in.

Having prepared a few lengths in this way, they should be tested by laying three of them side by side and placing a fourth at right angles across them. The ends of the cross piece should exactly coincide with the outer sides of the three pieces. Should there be any variation, adjustnient should he made accordingly until the length is exactly three times the breadth This having heen determinell, the necessary number of hlocks may be prepared. If it is desired to stain them, this can he done before commencing to lay the blocks, as the colour effect is hetter than if the hlocksarestained after they are in position.

## Forming the Pattern

The next step is to determine the pattern Generally the blocks can be laid direct on the floor boards, provided the latter are reasonably level and sound. They may be attached by glueing the underside of the blocks and further secured by secret nailing. A long strip of stopping equal in thickness to the blocks nnd about 2 in. broad is fitted all around the walls, butting against the skirting board. If the latter is unequal, or displaced, the stopping should he acurately scribed to fit, so that when secured in its place the narmo strip of wood will fit tightly ngainst the skirting and present a perfectly straight lining on the other aide; the object is to provide a good working surface against which to build the blocks

Fundamentally, all wood block floors are laid on geometrical lines, and consequently they must start on some straight line, and anything in the nature of curved work is practically impossible. Having prepared the atrips for a sufficient area for the mom, and glued and bradded them to the floor, the hlocks may be laid in position as in Fig 14. They are laid one after the other, so that the second row overlaps the first by the width of one block. A fair nuinber of hlocks should he laid, commencing with one corner, before they are glued, juat to get an idea of their arrangement and the way in which they are to be placed, niter which they may be drawn aside and glued and hradded to the floor. In this case 1 in oval hrads will be strong enough for the purpose: they are driven diagonally through the edge of the block, the beads of the nails being punched into the wood.

Parquet. Fig. 16. Wood block flooring, showing good effect resulting from dark-coloured stringing and centre panel in berringbone blocks

The work proceeds in the same manner until the opposite corner is leached, but as it is possible that the distance to be covered will not be an exact multiple of the lengths of the blocks, it is beat to lay one complete row and nscertain whether they will fit exactly, or whether some of then must be cut specially. There are reveral ways of dealing with the problem. In some the blocks are laid from corner to corner, and the closers or sperinlly cut pieces fitted about the middle of the room. In others the fit is arranged in the inost inconspicuous corner, or at some other part of the room-as, for example, where the chimney breast or other projections intercept the natural rin of the blocks. The blocks should he driven up closely into contact with a minlet. The reault of laying them thus is shown in Fig. 15.

Good results are ohtained by the use of strips of darker coloured wond, inserted in the form of $\Omega$ framework or border. Fig. 16 represents a small panel such ns might be needed in a recess, or at the entrance to a room. Alternatively, a series of such patterns can be laid over the whole area of the floor. The method of laving these follows the same lines already indicated, and comprises an outer atring, or framework, and then a row of hlocks, followed by a second string. The panel is filled in with other blocks laid in a herringbone pattern. To complete this. the ends of the blocks are cut to an angle, and other small angular pieces cut and fitted to fill up the odd spaces. If the proportions are carefully arranged. these apecial cut hlocks will bc low in number, but they add to rather than detract from the appearance of the joh when finished. If it is desired to fit the hlocks without any angular cutting, another pattern than the herringhone must be used.
It will be found best to make a large scale drawing showing the arrangement of the blocks, or to lay them out on the floor hefore commencing the actual work, as often a alight modifi. cation in the size and projertion will enable blocks to le used without outling them specially. to fit.

Where the floor is very uneven the blocks may be bedded in mastic cement, or superimposed on thin felt paper, such ns is used under linoleum. It should be a hard variety $t h a t$ will not yield unduly, as if it does the blocks might
he displaced A little care in laying them and especially in the nailing, will result in a satisfactory job. Such a floor covering is extremely attractive in appearance. has the merits of heing durahle, and is by no means expensive when made $u p$, in the manner suggested.
PARRISH'S FOOD. The compound syrup of iron phosphate, B.P.C., that is known also as chemical food or Parrish's syrup, is one of the most useful tonics for children who are weak and annemic and have loat appetite The dose for an adult is to 2 drams, and that for a child can he calculated according to the rule given in the article on dosage Parrish's food is often given in combination with cod liver oil. See Dosage.

PARROT. The method of kecping the bird upon a perch, with a long, light chain attached to the leg, is better than the small cage, for it enables the bird to nove freely, to descend to the floor and to stretch its wings Such a perch may, in fine woather, be trans. ferred to the garden, and if on such occasions the chain con he attached to the hranch of a tree so much the better. Indoors the length of the chain muat not permit the hird to reach any of the furniture, or the latter will he spoiled by the powerful henk
The Cage. In any case, a cage must he provided for sleeping, and the perches should be of two thicknesses, one about $\frac{1}{2} \mathrm{in}$. and the other $\frac{3}{} \mathrm{in}$. in diameter The hest cage is the large square metal one, with a tray floor which can be withdrawn for cleaning The tray should be covered thickly with dried garden mould, which is better than annd. and there should be a block or thick stick of soft. unsplinterable wood to engage the bird's bill. Water for drinking ought not to be kept in the cage : it should he given morning and evening. nncl then withdrairn. The bath should be provided daily outside the cage; if the bird objects to a wet hath, a pan of dusty earth may take its place, and will he used for dusting the plumage.

Food. Food must be varied, and no meat or meat products should be given. Hemp and canary seed may be offered, and to these may he added sunllower, maize and onta The bird will show a marked preference for one or more of these, and an objection to, or at least a distaste for, some others. The favoured food should he ndopted for its staple rations. Nuts should he added as their seasons come round: filherts, Brazil, walnut, chestnut, or a slice of coconut, with an necasional apple, pear, orange, banana, a few dates or a raw carrot. A dry biscuit or an unbuttered crust of hread inay be given at times: also a knob of sugar. Coarse sand must be prave vided, from which the plar-

Parrot. Left, bird of dove-grey plumage, with pink tail, one of the best talkerg. Right, red and blue macaw
w. S. Berridae, F.z.S
grains lor lurnishing its gizzard, without which birds cannot assimilate their food.

It is important to notice the effect of the various foods on the parrot's health. Certain loods may be found to produce diarrhoea, others constipation. Either conditions will be mitigated hy at once giving a few dropa of castor oil floated on the drinking water, and the bill of fare should be amended accordingly. The suspected food may not be a harmful one, but its proportions may need reducing. An unsuitable position for the cage may cause catarrh, bronchitis or inflammation of the lungs A large percentage ol parrots dic soon after their artival, as the reault of the unsuitable conditions of the voyage; and, therefore, if possible, a bind should only be purchased when it is known to have been in Great Britain for several months

Indigestion is probably caused by a lack of grit in the gizzard. Yawning and distaste for rood indicate biliousness. and may be put right by a pinch of carbonate of soda in the drinking water for two or three days. A fit of giddiness may be the result of indigestion and the castor oil treatment may dispose of it : if not, it may be due to the presence of intertinal worms, for whose ejection a little seraped areca nut should be given. In the casc of catarrh, five or six drops of tincture of aconite in water will abate the symptoms. Feather plocking is due usually to the presence of parasites under the plumage, which should be dusted with pyrethrum powder.
The most popular bird, undoubtedly, is the African grey or ash-coloured parrot, which holds the premier position for its linguistic attainments and its general good qualities
Since May, 1930, the importation of parrots into Great Britain has been prohibited, on account of parrot disease. See Psittacosis.

PARROT TULIP. This varicty of tulip has curiously cut or laciniated petals to its llowers, which are vivid nnd of many hues, like the plumage of the parrot See Tulip

PARSLEY: How to Grow. This herb is in great demand for garnishing purposes. It is raised from seeds sown out of doors in April nad again towarda the end of .luly:

Parsleg. Bunct of the curly-leaved variety of this usefal calinary berb
the secdlings should be thinned out till they ame 6 or 8 in. apart.

As the leaves become tough and coarse, cut them off to induce fresh growth, especially when the plants show signs of beginning to flower It may be necessary to protect parsley from frost with mata or a frame. The botanical name of parsley is Carum petroselinum.

Uses in Cookery. To prepare parsley to be finely chopped for garnishing, first blanch it by washing it well and picking it free from the stalks. Put it into a pan with a little cold salted water and bring to the boil Strain off the liquid and dry the paraley in $n$
towel Now chop it with a sharp knife or chopper When finc enough place on a clean towel and hold the paraley under the tap squeezing the towel, until the water tuns away green. Wring dry in a dry cloth, and use. When parsley is being used for seasoning. care should be taken that too much is not used. ns its flavour is extremely penetrating

Parsnip. Fine apecimens of a root vegetable ot considerable food palae
Fried parsley is used for garnishing certain hot dishes After the parsley has been picked. washed and dried well, it should bo put in a wire basket and fried in hot fat for a hout 1 min . It should then be quite crisp If atored in an airtight tin, fried paraley can be kept for some days. To dry parsley for winter use, it should be picked during May June or July, on a dry day. After well washing, strip the leaf off the stalk and diy it in a moderate oven until crisp. Kub it with the hands into a powder, and sieva Store it in airtight bottles, which should be labelled.

Paraley can be preserved wholc by washing and then plunging it into salted boiling water for 2 min . Let it then drain on the hot plate of the atove or in the oven, and when quite dry store it in an airtight bottle in a dry place Before using, soak it for a few minutes in warm water.

Parsley Sauce. To make good parsley sauce, use a tablespoonful each of chopped parsley, butter, and flour, and $\frac{1}{2}$ pint of liquid. which may be either fish stock. milk, or equal quantitics of each.

Dissolve the butter in a sinall saucepan and stir in the flour Cook for 2 min., then add the liquid and stir until it boils Season to taste, and add the parsley. Do not let the parsley boil in the sauce or its colour will be spoiled. See Cod: Fish.

PARSLEY FERN. This is the popular name of Allosorus crispus, a hardy fern, 6 in. or so high. It is suitable for planting in shady crevices in the rock garden or dry wall in a com. post of lonm, peat and sand

PARSNIP. This invaluable hardy root-vegetable is in season from late autumn until early spring. It is raised from sceds sown in March-April in deeply dug land fres from fresh manure ;

Parsnip Growing. 1 and 2 Parsnip fy and laroa. 3 and 5. Wastelul sowing and the resalt. 4 and 6. Economical sowing and its produce. F. Misshapen roots through shallow digzing and obstructions. 8. Resulf of deen digging and no mnnure. Q-11. Exbibition parsnip: 9. Crowhar hole flled with Gine soil (a). 10. Seeds sown. 11. Resulting root. 12. Storing in box ol sand.

How to Cook. The root of the parsnip furnishes a valuable food which contains a large percentage of sugar As a vegetable it can be cooked in a variety of ways, either boiled, fried. stewed or used with other ingredients. It is cooked after the same manner as the carrot, and when boiled or stewed is usually served with lumps of butter.

To prepare then for boiling, wash and scrape them clean or peel them thinly, remove the tops and throw them into cold water Then slice them according to size, and put them into a saucepan of alightly salted boiling water. Cook them sloviy for about I hour tcsting them with a fork to see if they are tender. Serve with white sauce.

Fried parsnips, which are usually served with roast inutton, are prepared by firat boiling them and then cutting them into strips Dip, each strip in batter or in egg and breadcrumbs and then fry in hot fat

Creamed parsnips are made by first boiling the parsnipa, cutting them into alices, and theis spreading the latter with butter. Lay them in a vegetablo diah and cover with white sauce See Carrot: Kitchen Garden
-
 months the soil be tween the rows, which should be 15 in . apart, must be hoed frequently. In lato autumn, winter and enrly spring the roota are dug as required. In frosty weather it is wisc to cover some of the roots with straw or other protective material to prevent tho ground being frozen, and thus allow the ronts to be lifterl. The Student is a popular variety of parsnip possessing laige, long roots. 'Tender and True riable suil which the roots can penetrate
asily is required. The most economical practice is to sow groups of three or four seeds at 9 in . intervals along the drill: only one scedling must be left in each group. The drills should be about an inch deep. Alterna tively soeds may he sown thinly along the drill and the secellings thinned to 9 in . apart

During the summer -
 1  considered to le of better flavour.

[^7]Partan. In Scotland the crab is called n partan, and crab sauce is known as partan sauce. See Crab.
PARTERRE. Used in connexion with gardens, a parterre is a formal arrangement of Hower beds with walks of turf or gravel between See Garden : Italian Garden

PARTITION : How to Erect. An internal wall that divides a room into two compart. ments is known as a partition. When built of ordinary bricks laid with a simple bond auch a partition is fireproof and practically soundproof. Another method is to build it of coke breeze blocks, bedding these in cement mortar.
With the foregoing materials a firm foundation has to be provided. In most cases, where the partition is in the natum of an addition to

Portition. Dingram of nortion of wall, showing
Partition. Diagram of portion of wall, showing
wall boards nailed on cross pieces and studding
an existing building, the only practical plan is to take a piece of stout timber, preferably onk, equal in breadth to that of the building bricks or blocks. In the case of bricks, this mny be reckoned as $4 \frac{1}{2}$ in : for coke breeze blocks or slabs allow $2 \frac{1}{2}$ to 3 in. The timber should be continuous from one side of the outer wall to the other. Alternatively it should extend for the whole length of the new partition, and should be placed in position regardless of any doorvay thnt it may be intended to provide in the partition wall.

The opening will, in any case, have to be made up of a framework consisting of uprights of timber at lenst as wide as the thickness of the intended partition, and 2 in. or more in thickncss. These should he mortised and tenoned into the floor plate, provided with a head or cross piece, as for example at the top of the door, and built into a plate, or piece of timber forming the top of the partition. In some cases the uprights may be joined to existing roodwork, such as ceiling joists. The essential point is to provide continuous uprights from the floor to the ceiling level, or some other strong support at the top The continuous floor plate tends to keep the partition in line, and after the partition is up it is quite aimple to cut away the unwanted piece at the bottom of the doorway opening. The wall is then erected on the top of the floor plate, built up to the framing around the door or any other openings, and continued to the top. The surfaces must be rendered with cement or worked up to a good face with a rough coat of plaster known as a pricking up coat, and finished with a fine or setting coat. The door is then linged in the opening and finished in the usurl way.

Use of Wall Board. A much sinipler partition can be made up with timber framing, covered with asbestos cement sheet, plywood,
or any of the patent wall or building boards The timber is fixed to the floor, uprights erected around the doorway openings, and the other studs spaced so that an upright is available for supporting the edges of each of the sheets. For example, if the wall boarda are 4 ft . wide, the studs may be spaced about 2 ft . centres, three of them being available for the support of one shect. This saves cutting the sheets to waste, and also obviates the need of fitting extra studs.

The studs should be not less than 3 in . wide and 2 in . thick, and should bu supported by uniform braces nailed between them, or jointed with a halving joint or some similar simple joint. Both sides of the work are finished up smooth and level, and consequently all the studs should be of the asme thickness to provide a level surface whercon to nail the wall board One side is fixed first, and then the other side, and the joints covered with strips of wood moulding to form panols, or finished in any desired manner. The result is a very light partition, which is both casily constructed and fairly soundproof.
With some of the patent boards, of which several are obtainnble, the makers advise that the edges should not be nailed, or that one edge only in each direction should be nailed. A gap of about $\frac{1}{}$ in should be left between the edges of adjacent sheets, to allow for expansion and consequent movement.

If a soundproof partition is desired, n special form of building board can be obtained which has sound-absorbing qualities Other varieties are waterproofed, fitting them for external use, and thesc are dcalt with in the article on Wall Board (q.v.)

Lath and Plaster. An excellent partition is made by making up a stud or framework as previously described and covering it with plasterers' laths nailed on with lath nails about 1 in . long and leaving a gap between each lath of in . When completed the surfaces are plastered with a pricking-up coat and the whole brought to a fine and true surface with a hard plaster.

The advantage of this type of partition is that the surface is perfectly amooth and can be worked into any existing wall arrangements. The doorway should be finished with an architrave, and such items as the skirting. board, picture rail and so forth, can easily be matched up to the existing work and continued across the partition at the same levels. A partition made in this way sliould not normally be distempered or papered until at least six months after it has been built, as it may spoil the distemper and discolour the paper. There are compositions nvailable which arc claimed to overcome this difficulty, and can be used on practically wet plaster. One of these may be used if it is impera. tive to complete the quickly.

A point to be noted with all partitions is they should be litted into the existing walls as strongly as possible. In the case of the stud partition, that is, one made of wooden uprights, the uprights should be securely spiked to the wall, taking care to set it up perfectly plumb and true with the aid of a plumb bob and line, or with a plumb rule.

In the case of a partition made of
brick to be bonded intu a wall ul similar material, the plaster should be cut away closely and neatly. If the existing walls are 9 in. thick, a few of the stretchers may be cut out about every 2 ft . apart and the new work bonded into the existing work by setting the brick halfway into the existing wall from which the stretcher has been removed and half in the partition wall. When coke brecze blocks are used, short stout pieces of iron may be embedded between the bricks of the existing wall and set on the top of the breeze blocks.

The amateur should obtain expert advice before interfering in any way with the walls or principal timbers of the house. Apart from considerations of safety, such an operation may be contrary to provisions of a lease or tenancy agreement, or may need approval by a local authority.

PARTRIDGE : How to Cook. For some dishes old birds may be used, but for roasting or broiling they must be young. The flesh of the young birds is easily digested, and is most suitable for invalids, and is highly nutritious.
To distinguish the age of the birds it is nccessary, when purchasing, to examine the bills and the pinions, also to notice the colour of the legs. If they are young, the bill will be of a dark tint, and the legs will be yellow, while the flesh of the pinions will be tender when pressed, and the long wing feathers will he pointed. If old, the bills will be whitish, tho legs blue, and the long wing feathers rounded. If stale, the vent has a greenish appearance. At the present day game is eaten much fresher than formerly, but partridge chould alwaya hang for at least a week.

General rules for cooking partridges and for making pies, puddings, or entrées from these birds are the same as for other game, and will be found under that heading in page 508 of this work.

Cooking with Cabbage. One of the most tasty methods of cooking partridge is to stew with cabbage Savoy cabbage is best, as it seems to impart a peculiarly agreeable Havour to the birds. Prepare and truss a brace of partridges and fry them in a stewpan with 4 rashers of bacon and 1 oz . butter, then add 1 gill stock. Have ready a savoy cabbage well washed and drained. Cut it into slices. pat it in the stewpan with the partridges, and stew for 1 hour, turning the birds occasionally To serve, dish the rashers and lay the partridge on then, and arrange the cabbage and liquor round the dish.
Another way of cooking these birds witli cabbage is to roast them for 10 min . and then cut them into neat pieces. Butter a plain charlotte mould, about a 3 pint size will do, and cover the bottom with a layer of savoy cabbage which has becn cooked, pressed,

Partition. Attic bedrooin panclled in "Sundeala" wall board

Passe Partout. The raised framing of a picture. 0: Fig. 3. A niece of gold passe-partont binding in trips are cut off to the exact length of the glasy. and laid on ic, being flemly pressed down with a bone creaser. Fig. A. Glue is applied llabtly to the two covered strips and they are then placed in position on the glass exactly level with the edge

Courlesy of Dennison Manufacturing Co., L.Id
seasoned and softened with butter. Place on the propared cabhage a layer of pieces of partridge, and fill up the cavities with cabhage to ensure an even surface Lay over the part ridge 6 thin slices of pickled pork, add the remainder of the bird, and over that the rest of the cabbage ; press all well down into the mould and tie over the topl a stout piece of buttened paper. Put the chartreuse into a moderate oven for from 15 to 20 min ., taking care that it does not brown. When conked, turn it over on to a hot dish, lift up the mould, and serve with a rich brown gravy round. This dish can also be made with old birds.
Braising. To braise partridgea prepare 2 or 3 birds as for roasting, with hacon tied over the breasts, put them in a casserole with 1 oz . butter. Moisten with 1 pint good stock and a wineglassful port or madeira, then season, add a bouquet garni and close the casserole tightly down hy laying a buttered paper over the top underneath the lid. Cook gently in a moderate oven till the hirds are tender. Serve then on a hlock of fried bread, and keep hot. Strain the liquor from the hraise, thicken it with llour, skim it free from fat and pour it over and lound the birds. Garnish with fried button mushrooms or any suitable dressed vegetable. If the sauce secms acanty prepare a little extra rich brown sance and serve it in a sauceboat. See Devilling; Game; Pheasant.
PARTRIDGE BERRY. This is the popular name of a low-growing hardy evergreen shirub, Gaultheria procumbens. It bears white Howers in sping and red berrics in autumn, and nceds loamy or peaty soil and partial sliade. Gaultheria shallon, ist. high, is a valuable evergreen shrub, with hlush coloured Howers in spring and dark fruits later on, which is useful for planting in shady places; peat and loam should be added to the soil.
PASQUE FLOWER. This is the common name of the Anemone pulsatilla, a hardy plant which bears beautiful mauve coloured tlowers in April and May. It grows ahout 10 in . high and llourishes in loamy soil with which lime or mortar rubble has heen mixed. It likes partial shade. See Anemone.
PASSAGE. In the domestic sense this word is employed for the space in the house
that leads from one room to another, or from a front or back door to the rooms. It is practically covered hy the articles on hall, landing, and staircase. See Hall; Landing; Staircase.
PASS BOOK. This name is given to the book which shows the receipts and payments of a banking account. The book is supplied by the hank to the customers, and the items are entered by the hank ofticials. It is desirable that a pass book should be sent to the hank for the latter purjose at least once a quarter and that the customer should inspect it now and again. See Banking: Cheque

PASSE PARTOUT. The method of framing by means of passe-partout linding. for photographs, prints small drawings and water-colours, is frequently more effective than by a raised frame. All that is required for framing a picture by this method is a piece of glass, mount, and cardhoard back identical in size, 2 small metal hangers. made much on the principle of brass paper fasteners, a small pot of gum, and a roll of passe-partout binding. The binding should harmonize with the mount, being best, as a rule. darker in colour, while hoth should harmonize with the picture Bindings can be obtained in a large range of colours, widths, and surfaces.
In the cardhoard back, about 1 to $1 \frac{1}{2} \mathrm{in}$. from the top and equidistant from the sides, punch two small holes, and into these fix the metal hangers. It is important that these should he at exactly equal distances both from top and sides, or the picture will not hang straight. Next fix the picture to the mount and the mount to the hack by means of dahs of gum at the corners. Make sure the glass is quite clean, then place it liat on the table on a piece of paper ruled with atraight lines to indicate the required depth of the framing. This will act as a guide in getting the passe partout straight.

Cut 2 pieces of binding 1 in . longer than the sides of the glass, moisten about half the width, and apply immediately to the glass so that the edges just reach the ruled lines and $\frac{1}{2}$ in. juts out at either end. Press them down until firmly fixed. Turn the glass over and put on it the picture, mount, and back. Moisten the projecting binding, fold it over the back, and press it down until set. Cut off the ends, both top and bottom, to about $\frac{1}{\frac{1}{8}} \mathrm{in}$. from the glass.

Cut 2 pieces of hinding 1 in. longer than the top and hottom of the glass and mitre them at each end. so that the shorter side is exactly the length of the space between the side bindings. Moisten the shorter side of each strip, apply them to the glass, and press them down. Be sure that the part fixed to the glass is exactly the same in width as at the sides. Turn the picture over and fix the rest of the binding as before. folding in the ends neatly.

Fig. 5. Two more lengths of cardboard strips aie cut to ft exactly between those glued on the glass, the onds being mitred. and the same process of glueing is followed. Fig. 6. Two pieces of binding of the chosen style are cut 1 in . longer than the picture, gnd laid over the inner binding abont of an inch from inner edge. Picture, backing board mount and glass are placed togather and the binding brought over to the back. The corners are finished as shown. Fig. 7. Two pieces of binding the exact length of the remaining sides are cut and applied. Fig. 8. The finished picture

Courtesu of Dennison Manufaclurinn Co.. I.td

Making a Raised Frame. The passe-partout method of framing can also he applied to make a raised frame. The articles required for this include, as well as those mentioned, some strips of pastehoard, $\frac{d}{}$ to $\frac{1}{2} \mathrm{in}$. Wide, and 2 rolls of binding, one for the frame itself. the other for a frame lining. Fix the metal hangers in the back, Fig. 1 and fasten picture, mount, and back together as descrihed above. Cut off 2 strips of the pastehoard exactly the length of the glass, Fig. 2, and also cut off 2 pieces of gold binding $\frac{1}{2} \mathrm{in}$. longer, Fig 3. Moisten the hinding and cover the pasteboard with it carefully and evenly: then gum lightly the underside of the strips, Fig. 4, and fix them to the glass, level with the edges.

Two strips of cardboard must now be cut for top and bottom, to fix exactly between the side pieces. Fig. 5. These are also covered with hinding, so that the binding projects $\frac{1}{2} \mathrm{in}$. or $\frac{1}{2}$ in. at each end. according to the depth of the pasteboard. These ends of binding should be cut off at an angle of $45^{\circ}$ before the pasteboard is gummed and fixed in place on the glass. Noisten the triangular ends and fix down to neaten the corners. The passepartout framing is then carried out as deacribed in the earlier method, the inner hinding being all but covered by the outer framing, Figs. 6 and 7. Many variations of both these methods will suggest themselves, but should not be tried until the simple passe-partout framing can he carried out easily and with perfect neatness. See Mounting.

PASSION FLOWER. The passion Hower belongs to a family of climbing plants which are mostly natives of Central and Southern America. Most of them need the teinperature of the hothouse, but there are two hardy sorts which are the nost important. These are Passitlora caerulea, the brautiful blue passion Hower, and its white variety, Constance Elliott. They will thrive in any gond ordinary soil with the protection of a south or west wall. When the plants have filled the apace allotted to them they should be pruned in spring; othertrise little pruning is needed.

The hothouse linds have flowers of various rich colours. They must be potted up in the ordinary mixture of loan, leaf-mould, and silver sand, or in heds of 2 ft . Wide by at least 1 ft . in depth. They can be trained up rafters or walls, and need pruning just as do the outdoor varieties. It temperature of between ( j$)^{\circ}$ and $70^{\circ}$ should be maintained.

PASSOVER CAKE. The Jewish cakea which are eaten at the feast of the Passover are made from 1 lb . hest llour, $\ddagger$ teasponnful salt. and enough cream to mix the whole to a stiff paste. Sieve the flour and salt into a basin, "arm them hefore the fire and then stir in the crean. Rull the pastry out thinly on a lloured board, then stamp it into large rounds and cook these on a girdle over the fire. When one side begins to blister, turn the cake and cook on the other side. They should be crisp and of a pale brown colour when cooked.

PASTE : Various Kinds. 1 paste made of tour and water is capable of joining inany light articles. To make the ordinary household paste, mix 1 lb . wheaten flour with 1 oz alum and add 4 pints of cold water, stirring all the time. Run the mixture through a sicve to ensure that no lumpe remain, then transfer to a saucepan and boil for five minutes, stirring all the time. The paste will be thick, and to ensure it keeping for a few weeks add as a preservative thirty drops of oil of cloves and the same quantity of carbolic acid.

For Mounting. As an adhesive for mount ing photographs it is necessary to avoid the use of acid ingredients, such as alum, as this would act on the photograph and cause it to fade. Professional photographers use freshly made starch paste, made by first mixing powdered starch with a little water to form a
paste and then adding boiling water, stirring all the time. Dextrin can he employed for an adhesive that keeps, one pound of dextrin being boiled with 2507 . of water until it has dissolved, then, after adding 30 drops of oil of cloves as a preservative, pour into small ars lor use.
For Paperhanging. Paste for paperhanging is made from 31 lb. llour mixed with cold water to a stiff batter. A gallon of boiling water is then added, in which two tahlespoonfuls of ground alum have been boiled. The top of the paste should le covered when cold with a little cold water to prevent the formation of a crust. This paste should be quite stiff, and requires thinning down with cold water beforc use. It should not be employed thinner than can easily be spread.
For Linoleum. A paste for linoleum is made by mixing the rye flour with cold water to a somewhat atiffer consistency, and adding boiling water. Some glue size is melted down

Passion Flower. The blue passion flower. caeruiea, and its white variety are suitable for planting agains a sunny wall
and added to the paste whilst both are hot. They should be well stirred and allowed to cool, when the paste will he ready for use. The more size that is used, the stronger the paste will be. Alum nay be used as a preservative. In connexion with leather or strong papier mâché work, a paste "hich is similar to linoleum paste is prepared, but instead of employing size, powdered resin is adiled. Boiling should be slow, and the paste should be of the consistency of butter.

PASTE: In Jewolry. A certain colourless llint glars of the hardest and densest kind, known as vitreous paste, is used to initate diamonds: for other stones the glass is melted with various coloured oxides. In the 18th century a Viennese, Joseph Strass, invented a line guality of paste, which has since been known by the name of strass. It possesses almost the brilliancy of diamonds, but as this brilliancy was obtained by a greater amount of oxide of lead in its composition the paste lost some of its hardness. For the best paste jewels, the strass is cut, ground, polished and faceted with exactly the same care as are precious stones.

It is usually set with a solid hacking, as the foil enhances the sparkle of the paste, but some of the finest qualities stand the test of the open setting. This is particularly the case
with coloured strass. So beautiful were the imitations of rubies, sapphires, emeralds and amethysts that in the 18th century some court jewellers preferred to carry out their creations in paste rather than real gems. With the former they could obtain a truer colour in Hawless pieces of exactly the size required. With real gems the design had to be subordinated to the stones, and the matching of Hawless stones of a good colour for a large ornament presented great difficultics, with emeralds almost an impossibility.

Spanish paste of this perind has a great value for collectors, while French and English designs werc also of great beauty. Lovely pieces were made on a background of dark hluc paste with raised Horal designs in diamond paste, a style mostly used in marquise rings and watches. Other beautiful pieces are the miniature frames often surmounted with scroll or ribhon paste work. In the English Georgian paste the stones were cut large and square, well faceted, and often mounted in gold, whereas the French and Spanish designers used silver.

Modern paste is either carried out in replicas of the fashionable jewels, or the old designs are copied for shoe buckles, and other ornaments. In the first case the paste is purely an imitation: in the second, it makes no pretence at being real stones, and if the designs are good it has a heauty of its own. This is especially the case with shoe buckles. The square shapes with large stones well set in straight lines show the Georgian influence; the delicate scroll and spray work, the French.
A paste composition is used to imitate turquoises successfully for fancy ornaments and also for camens, intaglios, and Egyptian scarabs. Paste will not scratch glass as a diamond will, and a test is applied in which an aluminium pencil is drawn across the surface of a jewel to be tested; if paste, a silvery line remains; if natural stone there is no such result.

PASTEBOARD. A form of cardboard composed of layers of thin card united with paste and consolidated under pressure is known as pastehoard. It is a strong material whicli has many uses in the honie, the use to which it is most commonly put heing in maling small boxes and crates for the storage or packing of goods for transit.

PASTEL PICTURE. Although less affected hy damp than are water-colours, pastels should he guarded against it, by using cork disks behind the frames. The effect of fixatives, such as shellac, is always deleterious, and spraying with a diffuser or varnishing with a brush is fatal to the soft bloom of untouched crayon-work. It should therefore be framed and glazed. A grey or stnne coloured mount is most usually suitable, and a narrow black or brown frame should be selected. During the 18th century portrait-pastels were often executed in several media. Thus the portrait might be drawn in crayon on a landscape background in water-colour or gouache, and the detail heightened by the pencil. Mixed drawings of this kind do not hear exposure to strong light with the same impunity as pure pastel, and therefore need special care.
PASTEURISATION. This process destroys nearly all germis. By keeping milk at a temperature between $145^{\circ} \mathrm{F}$. and $100^{\circ} \mathrm{F}$. for not less than half an hour it becomes pasteurised. The milk may be in bottles which are put into a saucepan or a special container, or a double saucepan may be used. It dairies which are nuthorised to supply certified pasteurised milk an approved apparatus must be used. It is to be noted that children fed on pasteurised milk should be given a teaspoonful of grape or orange juice once or twice every day. See Baby; 1)iet : Milk.

# Pastry for Pies, Tarts and Patties 

## Popular Recipes for Plain and Rich Varieties

## Under this heading are included the ordinary pastries pastry are given under their respective headings.  Cream Bun; Patly. etc.

Pastry consists of a preparation of flour, fat and water with the occasional addition of baking powder, eggs, sugar, and lemon juice. The proportion of fat to flour and the methods in which they are mixed make the difference between one kind of pastiy and another.
Flaky pastry is intended principally for covering meat pies, mince pies, sausage rolls, etc., and sometimes ior covered fruit pies. But both flaky and puff pastry are often used to make light fancy cakes with fillings of jam or cream or currants, such as the coses of Banbury cakes, Vanilla cream slices, jam puffs or pattics Short pastry is used for fruit tarts. jam tarts and tartlets, or any sweet pudding where a soft mixture is balied in a pastry.lined dish Hot water pastry makes the correct crust for raised pies, and choux pastry is necessary for éclairs.

Two rules must be borne in nuind for succeasful pastry making. Everything must be as cold as possible, except in the case of loot water crust and the fancy pastries, which are in a class to themselves, and the pastry must be handled as little and as lightly as possible.

An ordinary plain rolling pin is best, not one with revolving handles. The glass rolling pins that can be filled with cold water are excellent for pastry A slah of marble or plate glass or a table with an enamelled metal top is hetter than a wooden pastry board for rolling out the pastry. All baking tins should be thick or they will warp and spoil the shape of small pastries. A thick tin also prevents burning at the bottom of inince pies or pattics.

The best white flour should always be used, and this must he quite dry and cold, and sieved before use. Use a knife for mixing as much as possible, then use the finger tips to finish. Work away from the heat and keep the hands ns conl as possible Margarine alone should never be used for pastry, as it does not contain animal fat, and the oil in it would make the pastry hard and dry. Good lard alone is best for plain pastry, or a mixture of lard and margarine can le used, and butter for puff prastry.

The pestry must be mixed to n soft dough that leaves the sides of the bowl clean. It is impossible to give the exact amount of water required as flours vary in texture. If the pastry is too wet or too dry it will be tough when baked. Use as little Hour as possible when rolling out, as too much spoils its appearance when cooked. Do not press heavily when rolling, but use short, firm strokes. Get the pastry to an even thickness; the edges must not be thinner than the rest
Much good pastry is ruined in baking. A hot oven must be used for ordinary pastry (375 to 380 degrees) and for puff pastry a very hot oven ( 400 degrees). Otherwise the fat will liquefy before the starch cells in the flour have burst to absorb it, and the pastry will be heavy and oily Cold air and sudden draught will cause the pastry to fall and be heavy. The oven door ahould not he opened until the pastry has had time to get woll risen and set. Uncooked pastry will keep fresh for several days if wrapped in greaseproof paper and kept in a cool place. Patty or tartlet tins or pie dishes do not need greasing when good pastry is used, ns it contains sufficient fat to prevent sticking.
Short Pastry. The ingredients required for this are $\frac{1}{2} \mathrm{lb}$. flour, 4 oz . lard, $\frac{1}{4}$ teaspoonful salt, $\frac{1}{2}$ teaspoonful baking powder, and cold water 10 mix Rub the lard into the flour until it looks like breadcrumbs. Ald the dry ingre-
dients and mix well. Mix atiffly with cold water, using a knife Work lightly with the fingers until amnoth, using a little more water or flour until it is quite pliable. Roll out at once on a floured boand and use as required. Flaky Pastry. A good recipe for flaky pastry needs the following ingredients and method of making Take $\frac{1}{\mathrm{lb}}$. flour, 6 oz . lard and margarine mixed, $\frac{1}{3}$ teaspoonful salt, a squeeze of lemon juice, cold water. Mix flour and salt in a basin Divide the fat into four portions. and ruh one portion into the flour. Mix to an elastic dough with lemon juice and water. Roll into an oblong strip on afloured board Flake one portion of the fat down two-thirda of the pastry, leaving the third portion nearest without fat on it. Fold in three from the lower end. Give one-half turn so that open adges are opposite, press these edges lightly with rolling pin to close them, roll nut to an oblong the same as before. Repeat the process until all the fat is worked in, fold up the pastry and set aside for an hour Roll out once nore (fise times in all), cut to required shape and use. Brush with beaten egg and bake in a hot oven. A larger proportion of fat to flour is used for flaky partry, but no haking powder

## is necessary

Puff Pastry. To make this rich pastry take $\frac{1}{2} \mathrm{lh}$. Hour, $\frac{1}{2} \mathrm{lb}$ cooking butter, $\frac{1}{2}$ teaspoonful lemon juice, $\frac{1}{2}$ teaspoonful salt, cold water Press the butter to an even oblong shape in a floured cloth. Rub a small piece of the butter into the flour, add the salt. Mix to an elastic consistency with the lemon juice and water, and work lightly until smooth. Roll out into a square, not too thin. Put the square pat of butter into the centre of the pastry and fold it over, so that there is a parcel of butter wrapped up in pastry. Roll out into a long strip, press. gently at first with the rolling pin so that the butter is gradually ahsorhed into the pastry. Fold in three and roll out again, keeping the open ends to and from you while rolling. Fold and roll out again, then set aside in a cool place for an hour. Roll out twice more and set aside agnin. Then roll out twice more (folding pastry between each time) and use. Puff pastry should be rolled out seven times in all.

Rough Puff Pastry. This is really a simpler form of puff pastry, requiring leas rolling, and less shortening is used. Take $\frac{1}{2} \mathrm{lb}$. flour, 6 oz . lard and margarine mixed, f teaspoonful salt. squeeze of lemon juice, cold whter. Mix the flour and salt, cut the shortening into pieces the size of a walnut and mix then into the flour. Mix to an elastic dough with the lemon juice and cold water. Turn on to a floured board and knead lightly and quickly until sinooth and of an even texture. Roll out and fold four times. Stand aside in a cold place for an hour or longer, then roll out and use. Bake in a hot oven.

Hot Water Crust. Contrary to the general rules for making pastry, this paste must be made in a warm atmosphere, and it aloould never be allowed to get very cool. The ingredients required are $\# \mathrm{lb}$. flour, $\frac{1}{} \mathrm{lb}$. lard, 1 egg yolk, $\frac{3}{}$ teasponnful salt, about a gill of milk and water. Add salt to flour. Put milk and water and lard in a saucepan and bring to the boil. Add egg yolk to flour, stir in the liquid and mix with a knife until smootl. Leave it, covered with a cloth, in a warm place for an hour or so, then knead it for about ten minutes. Keep warm and use for raised piew as required.

Choux Pastry. This delicate type of pastry is used for making cream buns and eolairs.

A good recipe requires 1 oz sugar, 3 oz butter, fi oz. flour, 3 eggs, a few drops of vanilla, $\frac{1}{2}$ pint water Put into a saucepan over the fire the sugar, butter and $\frac{1}{2}$ pint water When these are boiling, stir in the flour quickly, beating the mixture till smooth and cookisg it till it leaves the sides of the pan clear. Then take it from the fire, let its contents cool slightly before beating in the eggs, one at a time, and flavour the whole with the vanilla Spread the mixture on a plate to cool before using it and then bake in a slow oven till it is pale brown in colour.
Pastry Brush. Pastry brushes are used for greasing baking tins and applying raw ogg and other coatings for pastry. They are made of white lirench bristle of various lengths in metal bands or socket handles. For those used in grease it is essential they should not depend entirely on cement to hold the bristles together. Oily substances will penetrate to the roots of the bristles, with the result that loose hairs come out in use. There are various patent or machine-made brushes which claim to be indestructible, and as pressure is employed as an additional security in these, they are to be preferred to ordinary cement-set brushes.

As in the case with all utensils used in the preparation of food, care is necessary to ensure that the brushes are kept clean. Apart from dust and particles of the ingredients used that may adhere to a sticky brush, grease remaining round the roots of the bristles will turn sour, and if in contact with a metal band will produce verdigris. The brush should he thoroughly washed out in a cup of hot water on every occasion after use. Brushes used for egg should not be put into hot water, as it sets the egg. Stand the brush in a jar filled with cold water and ringe under running tap

PASTY. Every kind of meat, fish, or sweet that is enclosed entirely in pastry is called a pasty, if baked without the aid of a tin or dish other than the baking-shcet on which it is laid. The shape is immaterial, but usually it takes the form of a half circle. Pasties make a useful variety of meat pic, especially for picnic open-air luncheons, as knives and forks necd not becarried for service.

The pasty is an economical method of using up, odd pieces of pastry left over from pie-making. A plain whort crust is mont suitable, and the meat or fruit must be cut fine, and well seasoned or Havoured. If the pasty is to be filled with jam or fruit, take care that this is placed right in the centre of the round, so that when the paste is fulded over the jam or fruit juice does not escape through the edges. These should be moistened and well pressed together. See Apple Turnover Cornish Pasty.

PATCHESI. 'This indoor game is a variant of the race game. It is played by fom persons. The board is arranged with the part in which the play takos place in the form of a Greek cross with the home or goal in the centre. The only other implements required are dice. Each player has one arm of the cross, which is divided into squares arranged in three rows, and three counters, which he moves over the squares in accordance with his throws of the dice. Each player must first move his men along one of the outer rows towards the centre, then back along the other outer row, and finally down the centre row to the goal. The one who reaches this first wins the game. See Race Game.

PATCHING. The method used for patching depends upon the article 10 be patched. Usually "patch is sewn on the wrong side, but one made of printed material is best put on the right side. If the patch is to form one with the garment, carc must be taken that the pattern matches and does

wrong side of the hole to prevent the patch For very fine work the hest. The patch
not hreak up the surface This result would obviously be difficult to obtain if the pateh were put on the wrong side of the material
To mend calico articles, cut a patch a little larger than the bole and the worn part round it, and turn down a narrow fold all round on the right side. Place this on the wrong side of the garment, arranging it so that the folds will be inside and the hole in the centre. Pin it in place, tack it all round and then hem it down, taking extra cure at the corners (Fig. 1) Pull out the tacking stitches turn to the right side of the garment and slip the scissors into the hole, cutting it diagonally to within ahout $t$ in. of each corner (Fig. 1). Cut out the worn portion, leaving a narrow edge of uniform width all round; turn this edge in and sew it down neatly. The patch is then finished, and only needs to be pressed with a warm iron.

When patching Hannel, the right and wrong sides of the material should be determined, the former being the more flutiy Each side should be cut straight enough to keep it to the same thread, and herringbone stitch is used for sewing the patch (Fig 2). Fig. 3 shows a good method for thick materials. Iay the patch on the garment, making it 1 in . larger all round than the hole. Turn in and tack a single hem, $\frac{1}{2}$ in. deep, all round the

Patching. Fig. 1. Right side of calico sheet, Fhowing hemming and arrangement of corners. Fig. 3. Overcasting edge to prevent fraying when Fig. 3. Overcastiog edge to prevent fraying when patching thick material
must fit right into the hole and the edges he darned together. See Darning : Mending.

PATCHOULI PLANT. This name is given to one of the varieties of the greenhouse foliage plant Colens, most of which are grown for their begonia-like leaves and their value as summer bedding-out plants. C. aromatica has a leaf, however, from which a one-time favourite perfume was obtained.

# Patchwork and its Decorative Uses <br> Ornamental Designs with Scraps of Silk, Leather, Lace and Paper 

The reader is referred to the articles on Applique and Embroidery for the sitches used in patch work. See also Cushion ; Lace ; Leather Work; Paste; Picture; Pouffe

Patchwork with a suitable assortment of colours and materials and a skilful method of assembling and joining the pieces can be raised to the level of an applied art if a good design is first originated, or copied, and the requisite patches are cut and joined to carry out the definite pattern or pictorial effect selected, The materials cost practically nothing, hut the results can be richly decorative.

Designs must have suitable relation to the objects to be made or partially covered with patchwork. They must also be chosen with regard to the materials that the worker wishes to utilize. It is a mistake to mix patches of heavy weight with thin fabrics: the pieces should be of average substance throughout the work. For instance, leather and stout cloth, velours or velvet, may be used together, and a simple geometrical design should be chosen for their patchwork; silks, satins and lightweight velvets should he assembled for more intricate designs in which fancy stitchery may play an important part; lace should be mixed only with net or openwork embroideries such as hroderie Anglaise; paper patchwork must be entirely of paper, though this may he tinselled or of any colour required by the design.

The completed piece of patchwork made from woven fabrics or leather usually requires to he hacked or lined with a suitably strong piece of material. As paste is employed to assemble paper patches on to cardbourl or strong cartridge or parchment paper, it is
necessary to provide a background when the design is completed

Leather and Velvet Patchwork. Ornamental and durable accessories for the home can be and durable accessories for the leathers or from mixing these with other suitable materials. Floor cushions and pouffes, sofa cushions for lounge or dining mom, and pyjama cases are among the hest articles on which to use leather patch work. Cuttings from leatherwork should he saved or can be purchased cheaply. A good effect is obtained by working light and dark brown leathers in parquetry patterns. Harlequin patterns of diamond-shapel pieces also look well in three or more shades. Netails about cutting leather, sewing and thonging are given in the article on Leather Work. Thonging can be employed for joining larger patches of stout leathers and for making an edging to a cushion or pouffe.

Two excellent cushion designs, which may be adapted to patchwork of leather, velvet and cloth piecea, are given in page 332, Figa 1, 2: whilat
and a similar one round the wrong side of the patch. Fit the patch into the hole and overcast
them together Over. cast the raw edges fraying. and then press the patch well on the right side. a darned-in patch is

Oman or

Patchwork. Fir. 1. Tatle mat of lace natchwork. Many gcraps ol lace are arranged round a central motif帾
the bolster-cushion design illustrated in Fig. 5) could be adapted to amaller scraps of velvet. by making the wide stripes narrower or by changing the colour half way round in each case. Care must be taken not to employ too many colours and to halance any change by a corresponding change in the other atripes
In this style of patchwork patterned materials are hardly ever successful in com bination with other scraps. The only exception would he in the case of some very boldly designed piece of velvet in which the patterin made a distinct motif which could be utilized as a central piece in the same way that a marquetry panel decorates inlay Linoleum, tiles and inlaid wood all may offer useful suggestions for geometrical patterns.

Whether leather alone or with fahrics is used, or velvets and cloths are combined, it is cssential when planning the pattern to have a definite colour scheme in mind. The larger the patches the more important it is that they should harmonize with the room in which the finished article will be used. When patches are intended to match each other they must be cut to exactly the same size. It is a good plan to make a template for each required shape out of cardboard to guide the scissors. The patches should be cut larger than the template to allow for turnings. Pieces of writing paper may then be cut to the exact size of the template and pasted lightly to the back of the leather or velvet patches in order to ensure even turnings.

Templates would be too laborious a method to adopt for patterns except in the case of simple designs requiring only a few shapes. It is advisahle at first to use straight-sided patches. Squares, oblongs, triangles, strijes, diamonds, and hexagons or stars need less skill in joining than curved figures Some excellent designs for suede-finished leather and velvet patchwork for cushions, telephone book covers and tops of floor pouffes can he evolved from stained glass window paper. The lines of the leading can be traced out with the aid of carion paper on an unbleached calico or linen foundation, the colours of the patches carefully selected and cut out from separate transfers of their reapective shapes made from the stained glass window pattern on to tracing paper. No allowance for turnings is needed, because the joins are covered by narrow gimp or a tinsel braid.

Patchwork of Thin Materials. For articlear such as handkerchief or nightdress sachets

Patchwork in lace. Fig. 2. Duchesse cover in preparation, showing bow the different pieces of lace are arranged on a brown paper pattern. The patchwork is finished by an edging of lace
triangular borders will form neat patchwork. poster. Floral designs can he built up from A piece of lloral silk or satin may be chosen scraps of cretomes, cutting out flowers and as a central motif and framed with scraps of ribhon which tone with material used for the rest of the article and with the motif. Fancy stitches may he introduced for joining pieces or for adding interest to designs. Buttonhole, ornamental blanket stitch and satin-stitch are useful: while fenther-stitch (q.v.) or faggoting (q.v.) are very suitable for linen patchwork.

Faggoting may be used to assemble scraps of linen, poplin or casement cloth for runners and mats. Patchwork in four colours such as grey, green, pink and rose, or brown, heige, yellow and orange, is effective for these. The scraps should be cut into squares or ohlongs and arranged so that the colours halance nicely. One shade should be chosen for the narrow horler to lie faggoted to the joined patches, and the embroidery cotton used for

Patchwork in paper. Fig. 3. Example of pictorial patchwork copied from an old Georgian chintz, the design being entirely made from small scraps of coloured paper
the faggoting should match this. A good effect is gained by cutting the central oblong or square also of this shade and larger than the rest of the patches Individual taste will ovolve many ideas on these lines. Borders may be of narrow lace if a remnant is forthcoming from the scrap bag, or edges may be scalloped

Pictorial designs can utilize a number of colours and fabrics. Really line work is done on pieces of canvas with contrasting inaterials and a variety of stitches to outline detail and supply shading. Such work requires very careful planning, and it is best to begin with a simple landscape scene copied from a small leaves to make a panel. Patchwork deaigns should always be conventional when used for large panels. When really well exccuted they form admirable wall decorations.
Lace Patchwork. Oddments of real lace or of good machine made pieces are often to be found in the housewife's scrap bag. These can he turned to excellent account for table mats and runners. A paper pattern of the de sired shape is cut out and the pieces of lace are planned out on it to form a pattern. For a set of table mats a num her of pieces are required. The store at home may be

Fig. 4. Primposes and violets in a bowl, cut out of coloured paper and pasted on a backrround, forma charming picture. Fif. 5. Paper patchwork picture suitable for wall decoration
paper is removed and the mat is carefully pressed. It may be lined with fine washing net to increase durability Directions for washing and further instructions for sewing lace are given in page 6ī. No. 40 white cotton should he used double, as the lace must be strongly sewn together.

Paper Patchwork. The 18th century craft of making patchwork pic tures from scraps of coloured papers has re cently been revived. An easy and far less artistic development of this work was the patchwork from coloured scraps, such as arestuck on the outside of

Christmas crackers and flowers from cards, etc., which were assembled, gummed on to acreens and other articles, and then varnished. Many Victorian screens and papier nâ̂ché boxes and brackets were decorated in this manner.
The exquisitely delicate picture illustrated in Fig. 4 of violets and primroses in a bowl is n return to the 18 th-century method. Nothing but coloured paper is used, each petal, leaf and llower centre is cut out separately and pasted on the hackground, and no drawing is done first on the paper either before or after it is cut. The most beautiful colours can he obtained from using gond coloured advertise inents and cutting out cach tiny section from these in the tint required. The effect is mosaic-like when finished, glazed and framed.
Bolder designs may be executed in foil papers. These are sometimes applied to glass, being pasted on to the reverse side, an idea which is utilized as a decoration for trays, which are afterwards backed and framed with wood The foils in which chocolates are wrapped are used, and any oddments of gold or silver paper to make up the designs.
Some of the most beautifully executed patch. work pictures are done by those who have no akill with the pencil. A sense of colour is necessary and accuracy with the scissors, which in this work are the artist's implement. Figs. 3 and 5 are examples of decorative designs done in this way and copied from 18th-century chintz patterns. Specially prepared coloured papers gummed at the hack can be bought for this work, but the better way is to store up a collection of scraps of every conceivable shade and kind of paper from cuttings of hrown and blue grocery bags to scarlet tea wrappings, and from silver paper to fragments of wallpapers.

PĀTÉ DE FOIE GRAS. The livers of yeese are prepared and sold ns a tahle delicacy under this name. To serve the foie gras on toast. niake croûtes of bread. Pound the foie gras and mix it with a little Worcester sauce and seasoning. Pile it lightly on the croûtes.
Another savoury dish prepared from foie gras is made by melting $2 \underset{2}{2}$ oz. hutter in a frying pan over the fire, putting in $i f$ or 8 water or milk biscuits, and heating them slowly. While they are heating. furn the biscuits frequently in order that they may aoak up as much of the butter as is possible. When they arc ready, lift them on to a dish, dust them with pepper, and place on each a small heap of foie gras, which should first be rubbed through a sieve with $\frac{1}{2}$ oz butter and a squeeze of lemon juice. Put the dish into the oven for a few minutes until the foie gras is thoroughly hot, then sprinkle each hiscuit with a little chopped parsley, and serve them nt once. A small tin of pâté de foie gras is required for this recipe.
Fuie gras may be used for sandwiches and is also served in aspic jelly. Rinse some small dariole moulds in cold water, and pour into them a little aspic jelly to coat the top of each mould to ahout the thiciness of half a crown. Allow this jelly to set, using ice if time is of importance : then decorate it with pretty shapes of cut truffle and chilli, forming a pleasing design in red and hlack. Set this with a little more jelly, and, when firm, place in each mould a small, hall-shaped piece of foie gras. Finally fill up the noulds with more jelly, then leave them to set, when they may be turned out on to a dish. Ahout $\frac{1}{2}$ pint aspic ielly, a small pot of foie gras, 1 or 2 picked chillies and a small truffle would be sufficient to make six savouries.
PATENT LEATHER. New ahoes of patent leather will wear much longer than usual if treated to a liheral application of vaseline and put aqide for a week so that the
grease may soak in. This not only softens the leather, but also prevents cracking.

In cold weather, hefore being placed on the feet, the surface of the leather should be warmed gently before a fire or with a warm hand. The fact that the patent leather will not stretch like ordinary leather should always be borne in mind. If the shoes are tight when bought, no amount of wearing will case then until they crack.

Glycerin and castor oil are good dressings for patent leather, hut only a very sinall smear ahould he used, and that rubhed well in and then rubhed off again. Special transparent dressings for patent leather, which can he ohtsined at most shoe retajlers, are also to be recommiended.

Old patent shoes anmetimes become lincd or covered with crow's-feet cracks. A rag dipped in turpentine and rubhed well over the surface will be found to anneal these cracks, and with a little patience the surface will he restored to its original gloss. See Boots.

PATENT MEDICINE. Proprietary remedies on which duty has been paid, represented by an official stamp affixed to the con-
taining bottle or packet, are patent medicines. In no sense dors the patent medicine stamp indicate an official guarantce of the composition or efficacy of the preparation. The stamp is merely a receipt for the payment of a tax. Patent medicines are generally advertised as a remedy for some form of disease. Some, in fact, are stated to contain, in the one preparation, a "cure" for many and varied diseascs
The danger in using patent medicines is that even although they may relieve some symptom, the patient may be suffering from a disease which requires urgent and thorough treatment, and which would be discovered if a doctor were consulted. It profits a man little to have his cough lessened when this is really due to consumption of the lungs

PATERA. A patera is a circular ornament used on furniture to give accent to rarious parts of the design. It is found on Adam and Hepplewhite furniture. On the carved friezes of hookeases, wardrobes, and secretaires it is separated by lengths of vertical Huting, and is a common ornament at the angles of the panels of cuphoard doors

## Paths and Their Arrangement

## Materials and Plans that Give the Best Results

The reader interested in this subiect is referred to the entries on the various materials used for paths, e.g. Asphalte: Brick; Concrete: Gravel; Tile; and to those on Dutch Gerden: Flower Garden; Lawn and the like. See also Border: Crazy Paving; Ejging: Paving
The constriction of a path depends largely order to give an air of seclusion and distance. upon the location and style of the house and In formal gardens, auch as Dutch gardens, the nature of the subsoil. The materials straight paths crossing each other at right with which it is made may be gravel, asphalt, tar paving, bricks, stone, cinders, tiles, mosaic, or concrete. The path to the entrance door, which will naturally take as direct and straight a course ns possible, should measure at least 4 ft . in width, and be very substantially made. The path to a tradesmen's entrance will generally be taken in as inconspicuous a manner as possible to the rear of the premises. Another form of path is the one that is often found entirely sur rounding a house, this kind heing generally made of concrete.

In the garden the lay-out of the paths is a matter of much importance, especially when space is restricted, as by the careful plan. ning of the paths and the correct disposition of the floral miasses it is possible angles are effective. These can be paved or laid with grass. Grass paths are also attractive in a rose garden or heside a herbaceous horder.

Brick and Tile Paths. The choice of materinls is a matter of individual selection. Gravel is pleasing in appearance, durable, and, if well laid, gives a good dry surface An entrance path will probably be best constructed in brick or tile. This can he done by excavating the top soil and building upa hard, solid berl of gravel, hard core, or rubhle. ramming this well down in the earth and grading it. with the coarsest at the bottom and the finest at the top, not forgetting to provide for drainage according to the sitc.
The bricks, which slould be laid to a fall to drain off eurface water may then be herlded on this foundation, either in sand (Fig. 1), or, if preferred, in cement or lime mortar. If the bricks are bedded in sand it will be best to grout them in with cement mortar (Fig. 2). A liquid mix. ture of cement and water is poured over the surface of the bricks and well hrushed into the cracks
to ohtain a sensation of distance which would otherwise be lacking.

If the garden is of considerable size, a good plan is to make a principal path going direct from the house to some conspicuous point, such as a summer-house or sundial, and from this to take other paths in different directions a nd turn these ahout in

Path. Fig. 1. Making a brick path. The coarser soil is Grst rammed down. and above this the bricks are bedded, either in and, as shown. or in morlar. Fig. 2. The flished path after grouting with cement
with a stiff bristled brusli. The surface is well washed over with water and scraped clean while the mortar is still green
Tiles can be dealt with in a similar manner, but the edge or lierb muat be made sufficiently strong to bear the weight of persons walking on the path, and may take the form of tiles, hull-nose bricks, or other material Concrete may be employed, either in slnbs and in different colours, or broken into pieces, using black coloured mortar in which to bed the concrete. Another variation is the usc of York stone paving, either in hown slabs or in random pieces, laid down like crazy paving.

Mosaic (q.v.) is expensive and more suitable for internal use, as in a courtyard or for the floor in a porch. Where quantities of broken stone are available, or small cules of granite, an excellent composition path is made by lining the sides with bricks and placing other bricks to form a simple pattern, connecting the two side courses of brickwork. The spaces between are filled with lime or cement mortar, the cubes of granite or the hroken pieces bedded into it, and the whole beaten down smoothly with the aid of a rammer and a hoard laid on the surface. After the cement is set, and while it is still green, the surface is well washed with water and scrubbed.
Cobbles. Another style is provided by cobble stones bedded in cement mortar, and usel with a brick or rough-hewn granite edging or kerb. In some districts it is possihle to obtain old granite blocks originally used for atreet paving, and these, if not too badly worn, inake an excellent path, and may be laid as if they were hricks.
A Substitute for Asphalte. Asphalte paths and courtyards are convenient, but difficult for the amateur to lny, unless the arca to be covered is large enough to swarrant the expense of obtaining use of the necessary heating oven and rammers. A convenient sub stitute is to use a mixture of 95 p.c. by weight of stone-dust-obtainable from a mason's yard-and 5 p.c. of tar. The proportion of 5 p.c. of tar should not be exceeded or the mixture will not set hard. In lnying this paving material, the earth must be well rammed or tramped to make it solid. Two inches of the mixture is then applicd, and thoroughly well rolled or tramped. The finished thickness should not be less than 2 in.

The pathways in the garden itself need not necessarily be built up with such hard and impervious materials ns the foregoing, but could he left in the form of natural grass paths, the borders being defined by floral plots. Where much traffic is expected on such a path, stepping stones made of

Fig. 3. Rough boaids set up parallel to each other to form the limitt of a narrow path

Path. Fig. 4. Diggrams showing various ways of laying concrete tiles : hese form a durable material for paths
of odd pieces of brick or stone, etc. The first thing to be done is to mark out $t^{2}: e$ position of the path with a garden line, a number of pegs being driven in as a further guide. The top surface of the marked out path should then be removed to a depth of 2 or 3 in . Into the shallow trench thus formed is put the foundation material, and the whole is firmly rammed in

On ground intended to be turfed the margins of the path may be defined by an elging of rough hoards, between which the path is laid, turf being brought up close to the edging outside (Fig. 3).

The cinders are graded acconding to size; they are placed with the coarser grade at the hotton, gradunlly working up to the finest grade, which should be on the surface. A better result will be obtsined if each layer of the cinders is firmly rammed or rolled dowi. Then give the completed path a good rolling and watering, so as to ensure its being firm, and to prevent it from picking up on to the hoots when walked upon.

Concrete Tiles. Concrete paving tiles in various colours are avail. able, and form a durable and comparatively inexpensive material for paths. A typical product is made in 9 in . square, 9 in. by $4 \frac{1}{2}$ in, and 12 in . by 12 in ., with a thickness of $1 \frac{1}{\mathrm{~g}}$ and $1 \frac{1}{3} \mathrm{in}$. Larger sizes ( 2 ft . 3 in . by 1 ft. 6 in., 1 ftt. 6 in. by 9 in. etc. ) are supplied in a thickness of 2 in.
The diagrams given in Fig. 4 show various ways of laying the abcre A apace of half an inch is left between tiles, which may be laid in mortar or cement. Another method is to spread a thin layer of sand or sifted earth over the prepared founda tions, and then to lay the tiles in position, pressing randoon pieces of Hagstone or granite, sunk them firmly in place The joints are afterin just below the surface of the grass so that the grass may he cut with a lawn mower, will take a goorl deal of wear, and at the same time will look very picturesque.

Cinder Paths. A simple path can be made with cinders removed from the grates and saved until the quantity is sufficient. Suitable material can often be obtained from the local gas-works for a little more than the cost of cartage. The foundation may be composed
wards filled in with earth or sand
A path should require little or nothing in the way of care and attention or repains, except at very infrequent intervals; hut generally all paths composed of rubble. cinclers, clinker. gravel, and the like may wear into grooves and hollows. In such acase breat up the surface, and relay with the old material and a top dressing of clean, fine material, well rolled and watered. and with a nicely cambered surface.

## Patience: Some Games Explained

## A Popular Pastime for Winter Evenings

For the purpose of this article a number of patience games have been selected and the way to play them explained. Those interested incards will And entriez on such card games as Bezique; Bridge; Cribhare; Nap; Piquet; Whist, ete.

The name patience is given to certain card Below these place the four aces as they appear. games which are usually played by a single The reat of the pack forms the stock. The person, although there are a few for two object of the game is to form on each of the people. They are played with one or two aces a sequence in suit up to the king. For packs of cards, but there are a certain number this purpose any tivo is transferred fro:n the for which three packs are necessary. There carpet to its position on the ace, and then a are a great number of these games, but the three, and so on. Vacant spaces in the carpet main principles are the same, to get the are filled from the stock and the game proceeds carda into a certain order. Some of the games are pure luck, but in others there is scope for a certain amount of foresight.

Carpet Patience. Patience games may be divided into those played with one pack and those played with two. Of the former, carpet patience, $\Omega$ very simple game, may be mentioned first. For this lay out, face upward, 20 cards in four rows of five to form the carpet
are filled from the stock and the game proceeds
as long as possible on these lines. When no further progress can be inade the player must deal the stock of cards, face upward, in a heap, known as the waste, and vacancies in the carpet must be filled from these. The top card of the waste can, if suitable, be played on to one of the sequences
Sultan Patience. To play this patience, take ont the four kings and the ace of hearts

Patience. Fig. 1. The nine foundation cards laid out to begin the game of Sultan Patience, with the king of hearts, or sultan, in the middie

Demon Patience. Demon patience requires only a single pack. Having shuflled and cut the cards, deal 13 of them, one on top of the other to a stock Then deal four others out in a row, and another nne to begin a row above them. This serves as a foundation card, and as they appear the other threo cards of the same value as this one are placed with it to form the four foundations. Thus, if an eight is the card first placed there, the other three will also be eights. On these foundations any suit. able exposed card, in ascending sequence of suit, can he played, the exposel cards being the top ones of the four packets on the lower row and the top one of the stock. The ascending sequence goes to thic king and then for loundations on which to build. After the to ace, two, and so on, until the 13 cards remaining cards have been shuffled and the are in place pack cut, four other cards are dealt out to be the foundations of four other piles. The actual building then begins on the nine foundation cards. On the king of hearts, who is the sultan, only a descending sequence of hearts can be built. On the three other kings an ascending sequence of the suit to which each belongs beginning with the ace, can be built. On the ace of hearts an ascending sequence of hearts can be built, and when this is in line with the dcscending sequence on the king, the cards are tra-sferred from the latter to the ace, leaving the king alone. On the four other cards a descending sequence of any suit can be built, and the exposed card can, if suitable, be transferred to one of the live piles of which four kings and an ace are the foundations. Thesc are seen in the illustration nbove.
'Ihe cards not wanted for any of theas nine piles are put, face upward, on a rubbiah heap, and the top one can he used whenever suit able. After the cards have heen dealt, those in the rubbish heap arc dealt out again. They may either, by being unsuitable, block the game, or may enable the five main foundations to work out. If this is done the sultan will be surrounded by four piles, on the top of each heing a queen.
Sir Tommy. Sir Tommy is another variety that is played with a single pack. Ite object is to build up four packs of carrla from the ace to the king, but it is not necessary to follow suit in so doing. The cards, having been well shuffled, are played out. Four of them are put down for the foundations. and there is no rubbish heap. As the aces appear they are placed below the four existing foundations, and the object of the game is to build on them at every opportunity.

If the cards dealt will not go on to an ace pack, they must be placed on one of the four others, and this usually presents a difficulty. It is not easy to decide, for instance, whether a six should go on a five or on a knave, and high carla must often be placed upon, low ones. If the kings and other bigh cards come out fairly late, the patience is almost impossible to accomplish. Some players keep one pack for the high cards, and this is desirable.

Exposed cards can he placed, not only on foundations in ascending sequence of suit, but on to four depots in descending sequence of alternate colour. A sequence of cards, or any portion of a sequence, can be transferred at any time from one depot to another, provided the proper sequence and alteration of colour are preserved. When 11 of the cards in stock have been taken, either of the remaining two may be played. A spacc occurs when all the cards in a depot have been played, and this must be filled by using the top card of the stock. After the stock has been exhausted it may be filled with any exposed card.

The cards remaining in hand after the initial deals are dealt in batches of three face upward to a rubbish heap, and the top card of each then becomes an ex. posed card. Such can be played either on foundations or depots, when the card immediately below it becomes exposed. When only two cards of the pack are left in hand they are dealt separately, and either or both can be played. When all are placed the rubbish heap should be picked up, turned face downward, and dealt out again, the cards from it being played until the patience comes out or is blocked.

Divorce Patience. Divorce patience is played with a single pack. Going through the cards, the player forms of them four

Patience. Fig. 2. The game of Divorce Patience in progress, with odd cards on aces, top row ; even cards on twos, middle row ; rubbish heaps, bottom row

Fous of these packets must have their faces downward and four upward Alter this, deal out eight cards and place this pile in the centre of the eight this centre pile must be placed lace upward. The remaining cards are dealt out, but belore this is done the player should examine the pilcs; il one of the top cards of a pile that lies face upward is an ace or a two, this can be taken out and employed for a foundation card.

The patience is built up on 16 cards, beginning with the aces and the twos, eight of each On the aces all uneven numbers to the king are placed; and on the twos are the even numbers to the queen Whenever an ace or a two appears it is placed as a loundation card. If any exposed card on the piles at the side becomes suitable, it can be taken away and used The top card of the rubbish heap can also be taken, whenever possible, in order to build up a sequence; but if there is a card on the pile and on the heap of the same value, the former must be taken.

At the end of the deal take the eight cards in the centre of the side piles, or as many of them as are left, and spread them out. If any are found suitable, place them in position on the 16 piles. Next turn up the top cards of the four piles that are placed face downward and, if thesc are suitable, use them When no further progress is possible, take up all the side piles and shuffe them with the cards of the rubbish heap. Then deal them out as before. Two of these deals are allowed, by which time the cards should all be in position

Legitimist Patience. Two packs are also required for legitimiat patience Having shuffled them well, take out a king and lay it on the table; then deal out the other cards, placing in a row quecn, knave, ten, nine, eight, seven, and six from nny suit and throwing the rest on to a rubbish heap These eight cards are the foundations, and as the remainder are dealt out they are built upon these in an ascending acale. The carila that cannot be placed go to the rubbish heap, which may be turned over once and suitable cards from it placed in position The object of the game is to get 13 cards on each pile.

Miss Milligan. Miss Milligan requires two packs of cards. Having been shuffled together and cut, eight of them should be dealt, lace upward, in a row to eight depots Any aces that come out at this time, or later, are taken to form eight loundations, which are placed below the depots. The object of the patience is to build on the foundations, eight suits in ascending scquence. Exposed cards, which are the top cards of the eight depota, are played in ascending sequence of suit to foundations, or in descending sequence of altetnating colour's to other depots. A complete sequence of any number of carda may be translerred bodily from one depot to another, provided the proper sequence and slterations of colour are maintained Portions of a sequence cannot, however, be transferred except the top card, which can be moved at any time A apace occurs when all the cards of a depot have been played. Such spaces can only be filled by a king or sequence to a king. If this is not possible, it must be left vacant for the time.
When all available carcla have been taken from the depots, a second eight cards should be dealt to them, and in this way any spaces which may have occurred will be filled The available exposed cards should then be played, after which another row should be dealt out, and this continues until all the cards have been played out. It should be noted that in each round carils must be dealt to all the depots before any one of them is played out.

Quadrilateral Patience. For quadrilateral patience two full packs of cards are also required. Having shuffed both together, deal
six packets out in a row, three cards being in each packet. They should be lace upward. Then lay out six more packets of three each, three on the right and three on the left, in such $\Omega$ lashion that with those already in position they make threc sides of a squarc. The space in the centre will be filled with the eight sequences, the building up of which is the player's aim
The sequences start with tho next card turned up Whatever this is, each sequence will start with one of the same value For instance, if it is a three each sequence will run in suit from the three to the two. The player should first note whether there is among the twelve exposed cards one or more that will serve as foundations, i.e. that correspond in number with the one just turned up. If so, that card is taken away and laid next the original loundation card. The player should next consult the exposed cards to scc if he can pack any of them in descending sequence of suit lor use later. He may be able to place a seven on an eight, or a qucen upon a king.

Having done all poraible in this direction, the player must deal out the remaining cards to a rubbiah heap, laying out any loundation cards as they appear, and whenever possible playing the other cards on to one of the 12 packets or one of the eight foundations. When any packet is exhausted, he can place there a card, either from the rubbish henp or from one of the other packets. The latter is better, as it gives greater opportunities for working off the cards. The cards are only dealt out once, but when this is over the player is allowed to take five cards from the bottom of the rubbish hesp and spread them out. This will help to place furthor cards, and may enable the game to be completed.

Khedive Patience. Khedive patience is not difficult to work out. Having shuffled the 2 packs, lay 25 cards out in 5 rows, 9 cards in the bottom one, then 7, then 5, then 3, and then 1 , the whole resembling a pyramid. From these cards the player chooses onc as the base card. This should be a two, if there is one, or, if not, another low card, say a three or a four This should be placed on one side, and as the other 7 cards of the same value appear they should be placed at one side or the other until there arc 8 altogether. On these 8 cards sequences in their own suit must be built up Any suitable card can be taken from the table and the vacancy made filled up from the pack When no more progress can be made in this way, the remaining cards ahould be dealt out and a rubbish heap, formed from which any vacancies are filled. If the patience works out, the pyramid of carls will totally disappear, as will the rubbish heap which feeds it.

PATINA. In furniture, this term is applied to the metallic appearance of the surfuce of old wood. It is regarded as a sign of age, and therefore is valued by collectors. Patina can not properly be produced by the application of varnish or polish. It comes after years of careful cleaning and rubbing, and as a rule the upper surlaces or those that catch the dust have the finest patina.

The term patina is applied also to the characteristic appcarance taken on by old bronze and copper articles, which is the result of chemical action It is simulated more or less successfully by treating new pieces with various chemical solutions, and can be imitated also by painting such articles with one or other of the special preparations sold for the purposc.

Artiflcial Patina on Metals. A patina can be imparted to bronze and copper in the manner herc described. A green patina is produced on bronze by brushing the article with a rolution made by dissolving 16 grm sal-ammoniac and 4 grin. sodium bicarbonatc
in 1 litre vinegar After this operation the bronze is placed for a time in a box, in which carbon dioxide will be evolved The process is repeated until the desired degree of colour is obtained
A bright green patina can be obtained on copper by preparing 10 per cent solutions of nitrate of copper, sal-smmoniac and calcium chloride A mixture made from 10 parts cach solution is brushed on to the article and nllowed to dry

Another method for copper, which results in an antique green patina, is to lay on the lollowing misture quickly and allow it to dry : $7 \frac{1}{2} \mathrm{grin}$ sal-ammoniac; $7 \frac{1}{2} \mathrm{grm}$. common salt 15 grm liquid ammonia Several applications are necessary. Some carc is necessary in using thesc proccsses, and the worker is recommended to test the solution on an odd pieco of metal before proceeding with a larger job

PATRINIA. This is a hardy biennial plant sometimes called eastern valerian. It bears graceful loliage and fragrant yellow Howers The chief species grown in gardens are palmata, villosa, and scabioscaefolia, which require a sunny position in ordinary soil. Patrinia is raised by seed sown outdoors in spring, or increased by division of roots in March or October

PATTERN : For Dressmaking. Generally a pattern is cut out in paper for one side of the garment only A whole pattern is unnecessary, because the balf can be set on doutile material and a whole shape cut out more casily and quickly. It is only when the two sides are different in shape that it is necessary to have a pattern of the whole garment They are designed to meet seasonal requirements and cut out in various stock sizes; that is to say, the models are made on perhaps 4 or 6 stands of varying average sizes, ranging from sniall to very large
If any alteration is made, whether it is merely a simple one for size, or a big adaptation, the pattern should always be 1ried on after the alteration is completed, so that the exact effect may be judged. One of the rulea of the home dressmaker should be to pin up and fit on a pattern before cutting the material. Only in this way can it be seen whether the desired size and style are there, and so perhaps save spoiling the material.
The best course to pursue when a pattern is to be altered in any wny is to take the parts to be altered and cut them in newspaper, and to carry out the alterations on these newspaper parts first of all, so that the original pattern is still a vailable.
Another essential is to note whether turnings are allowed on the pattern, and, if not, to take carc to leave enough on all the edges for fitting, seams, and hems. It is a good plan, after cutting the material. and before removing the pattern, to chalk or tack round the material close up to the pattern edges, fo as to see exactly what turnings must be taken up everywhere
As a rule, paper patterns can the obtained through pattern services in connexion with fashion or needlework journals and magarines. and through special pattern cutting agencics

Paper patterns of all kinds are supplied by some of the fashion papers published by the Amalgnmated Press, Ltd., especially Home Fashions, Fashions for All, Mabs Fashions, and Children's Dress. They can be obtained, either in person or through the post, from 291a, Oxford Street, London, W. 1

PATTERN: In Metal Work. Patterns are replicas of an object to be subsequently made in metal, and more particularly for the purpose of forming depressions in the moulding box. into which the molten metal is poured in the production of the castings See Casting.

## Pattern Printing on Woven \& Hard Fabrics

Simple Methods for Applying an Effective Ârt Craft

## The reader interested in art crafts will find information relared to this article In the entries on Dyeing; Glass Ware; Lampshade Painting on Textile Fabrics: Stencilling; Transfer

Pattern printing within the limita of simple seen in use and others required for the pattern designs is one of the easiest of the genuine art are on the table ready to hand) has been crafts, and can be used to decorate many objects in the home. Another excellent service which its study can render is the training of school children by cultivating their apprecia. tion of line and colour when forming patterna. Results are accomplished with comparative quickness and at $\Omega$ very small cost. The materials for the craft are simple to use, and obtainable through any artists' colourman.
Two of its advantages are that it can be successfully carried out almost from the first attempt, and that fabrics can be printed with washable and permanent colours. The most delicate georgette scarf can be patterned without injury, while pieces of silk or cotton which have lost colour can be renovated with pleasing results. This is particularly the case with unpatterned window curtains, bedsprends and cushion covers, the fabric of which is not worn out, but the original colours have heen laundered to a drab shade. Ro-dyed and bordered with pattern printing, articles which have been considered unsightly and practically worthless aro transformed into attractive furnishings.
In addition to the articles to be decorated, all that is required to print in almost any colour on woven fabrics, or on hard surfaced ones, such as glass, wood and pottery, are pattern printing liquid colours in bottles and tubes of oil colours; a set of $a$ dozen pattern printing sticks; a palette containing small square pads to hold the colour ; a saucer or white tile for oil colours; some rubber stamps (or these can be cut on ordinary pieces of rubber, as will be explained Inter in the article); pieces of lino; a bottle of copal and one of wood varnish. Bronze powders and gtencil medium can be utilized in this work when it is wished to gain a richly decorative effect.
The liquid colours in bottles are specially prepared for printing on soft materials and are of the exact consistency for immedinte use, while oil colours must be used for printing on glass, wool or potiery.

Oil colours may be used on woven fabrics when thinned with turpentine, but the results are not so satisfactory except for surfaces which remnin liat, such as lampshades or sachets. Soft fabrics tend to become stiff when printed with oil colours, and if the pattern is large the fabric thus trented may not hang or drape in good folds.
Printing on Textiles. Some soft materials are more absorbent after washing, and thus receive colour more easily; this applies to cotton and linen. Silks and other thin woven fabrics need not be washed before printing is done. A few experiments on scraps of material washed and unwashed can be made before starting to print any larger piece. Throughout the work it is advisable to have a small piece of the same material at hand on which to make $\Omega$ few trinls and to eee the effect of combinations of colour. The best way to become accustomed to tho printing process is to collect some scraps of differently textured and coloured materials and make experiments, rather than risk spoiling a piece of work.
The method of working is well illustrated in Fig. 1. An inexpensive tray cloth is being printed in chrome orange, chrome yellow and ivory black. The article is laid on a board which has been padded with sheets of newspaper and a sheet of white blotting paper on top of these. Drawing pins keep the work taut and straight. A little pattern printing colour (or oil colour if preferred) is spread on to the pads in the palette The pattern stick (one is
pressed on to the colour so that the end of the stick is evenly covered and is now being pressed on to the cloth to make the print. The actual process is simplicity itself.
The colours provided-red, orange, yellow, green, blue and violet-are brilliant and pure. Mixed with white or grey as well as with one another, handreds of distinct shades and hues can be obtained, ranging from deep full tones to delicate partel tints. As experiments are made with the printing sticks, and each separaie ahape appears on the fabric, patterns will be found with delightful ense. For those who wish to try experiments before attempting original designs, transfers printed full size on thin paper arc obtainable for scarves, table niats, cushion covers, etc. Possibilities of combinations of printing forms can be scen from the study of one or two transfers.
Although colour is a matter of taste, thero are certain rules which are useful to remember with reference to harmony of tints. Any pure colour will harmonize with black and white or grey, or with itself mixed with black or white to make deeper or paler tones. Two colours will harmonize if grey is mixed with both. Brilliant effects require marked contrasts, such as blue and orange, purplo and green: quiet restful effects can be workel with tones of the same colours, or with those which are closely related, such as blue and vioiet, or vellow and green

A trial border can be quickly printed on $n$ piece of nainsook. First take a pattern stick which prints a half-inch square and place it diagonally and join to it a quarter-inch square. Repeat the arrangenient along the border. This is such a simple pattern that it may seem unintercsting, but it is useful for experiment with oven pressures of the printing sticks, and also for colour coinbination, while it forms a good surround for more elaborato designs. With regard to colour it will soon be seen that the small squares look better in a diarker shade and the large squares in a lighter. With three or four printing sticks, printing different geometrical shapes, a number of simple borders can be worked, and the most interesting experiments can be made in colour.

In Fig. I the simple pattern would not be effective if orange or black had bren used for the large aquarea By keeping these in the palest of the three tones selected they do not overpower the tiny black squares set diagon ally, nor the orangc circles, and thus balance is preserved in the design. It is necessary from the beginning of learn ing this craft to consider not only which colours go well together, but how much of each colou is required, and on which part of the pattern it can most decoratively be em ployed. Most people will want to origi. nate designs after they have practised a few aimple borders and patterns and

Pattern Printing. Fig. 1. Printing a pattern on a white tray cloth by means
 of wooden printing sticks and washable printing cooours
used a transfer, ironed off oll to the object to be printed in the ordinary way. Pattern printing paper is obtainable, which is marked with quarter-inch squares, on which the designs can be worked out with gourche colours. In this way the effect of toncs and shapes can be judged and well ba!anced to suit the particular object.
When conipleted the original design may be transferred to the fabric in one of two ways. (1) If the material is very thin the deaign can be placed underneath and will show through sufficiently to guide the printer. (2) If the fabric is not semi-transparent, $\Omega$ sheet of transfer paper will be required. This transfer paper must not be confused with the pattern printing transfers. It is coated on one side with red, blue or black, and is used in the same way as carbon paper.
At the other end of some of the printing sticks are more fanciful shapes which greatly facilitate the production of elaborate deaigns, and give interest to the patterns, once the simple process has been mastered.

Printing on Hard Surfaces. Wood printing sticks are not suitable for printing on wood, pottery or metal. Such unyielding surfaces require n softer substance, and india-rubber is the ideal material for this purposc. Flower and other shaped stamps are obtainable, or pioces of soft india-rubber can be cut to correspond with the wooden printing sticks. Another way of turning rubber into intercsting shapes is to heat a knitting needle, and when red hot burn round holes with the end, and lines with the side of the neadle, on the pieces of rubber.

For all hard surfaces the oil colours in tubes are used. The colour is squeezed out on to a piece of thick glass or a white tile, a little varnish is used with it, and it is spread evenly so that a palette knife will just take it up when the printing rubber or stamp is pressed into it. When the colour is dry the whole work should receive a cont of vamish.

The application of pattern printing to pottery and wood is illustrated in the various diagrams shown in Fig. 2. Puttern transfers cannot be used for such pieces of work, as it would be impossible on $\pi$ hard and curved surface to keep a transfer in position. After the proposed patterm has bcen sketched out on a piece of paper, the worker will need to make dots with pencil or coloured crayon directly on to the article to be printed. For this type of work the simpler the designs the bettor. In Fiy. 2, $G$ to $N$ show $a$ variety of print forms that go to mako up patterns. In A nothing hut different sizes of squares are used
$D$ shows the formation of the print from the rubber used for printing all but the straight lines on the vase 13. The pattern on the candlestick $F$ was entirely evolved from repetition of print $G$. A collection of articles, including a silk scarf, wooden candlestick, pottery case and papier mâché bowl, are shown in Fig. 3, all of which have been decorated by the simplest of designs in pattern printing.

Printing from Linoleum Blocks. Another way of making printing shapes is cutting them from thiok linoleum This method can be practised on 8 mall pieces. Special cut ting tools are obtain able and comprise dividers, gouges and outline knives of assorted sizes Printing by hand from lino and wood blocks is a more advanced form of pattern printing. The design may be drawn directly on to the linoleum, but usually it is traced on to tissue paper. with Indian ink. The surface of the lino is covered with gum and then placed down on the tracing. The lino block is next turned face upward, and any bubbles on the paper are pressed out with a scrubber or rubleir covered roller.
After the gum is set the block may be cut. With the knife cut round the edge of the design. A clearing cut is then made, sloping towards the base of the first one, lenving a $V$-shaped trench round the design. The portions of the design not required to print are then cut away with a small gouge, or a wider one is used for larger waste picces. Very benutiful results can be obtained from these printing blocks, but such a development cennot be dealt with adequately here. Interesting shapes cut into lino can, however, be atilized to give
freer scope to original idens. These aro mounted with ghe on to pieces of wood and used in much the same way as the printing sticks, but as lino is rather unyielding it is not so suitable for hard surfaces, though good results have been obtained on wood and papier mâché.
PATTY: How to Make. A small pie or pastry case filled either with meat, fish, jam, or some savoury or sweet mixture is knowil as a patty. The cases may be open or coverod, and sometimes they are baked in small, round tins called patto pans. If the case is of puff

Pattern Printing. Fig. 3. Examples of pattern printing on silk, pottery, papier máché and wooden articles
or rough puff pastry it should be cut out of a sheet of pastry about $\frac{1}{1}$ ir. thick with a sharp, round cutter and baked on a steel baking sheet wetted with cold water. When properly prepared and baked in a hot oven, the rounds will rise to the correct height for oyster or any other variety of savoury patty.

The cutter should be rather larger than the size desired, as when the cases rise in the oven they diminish somewhat in circumference. When the rounds are laid on the baking shect, an inner circle should be marked on the surface with a smaller outter, leaving a margin round the cilge. 'This inner portion forms a lid for

Pattern Printing. Fig. 2. Diagrams showing potters and wooden articles decorated with pattern printing executed by ineans of rabber nribts and oil colours. See text
savoury or jam patties, and must be removed as soon as the case comes out of the oven The patty must now be cleared of all loose uncooked paste inside and then will be ready to fill.
Cold cooked chicken, gamo, meat, fish. mushrooms, oysters, shelfish ham, hardboiled eggs, eto., chopped finoly and mixed with a savoury white sauce are used to fill the patty cases, which are then given the name of their contents. The small round of pastry is placed on top of the filling. They can be served hot or cold. For jam patties any kind of jam can be used

Meat Patties. Meat patties inade with plain short or flaky pastry should be baked in patty pans. A round layer of pastry forms the base of the patty, a portion of prepared meat is heaped in the centre of the round, and a secend round of pastry moistened at the edge is placed over for a cover An incision is made in the top, and the patty after being glazed is ready to bake. Add also a little stock or water and bake about 15 min . in a good oven.

Patty Pans. A small round tin known as a patty pan, having a depression in the middle and varying in size is used for baking tartlets, etc. After use they should be wiped out with clean kitchen pajer and should not be washed unless they have become covered with jam, fruit syrup, or mcat gravy. See Prawn Patty.
PAULOWNIA. The hardy summer flowering tree Paulownia imperialis is highly ornamental having very large heart-shaped or lobed downy leaves and violet Howers of tubular shape
The Paulownia likes a deep, loamy soil in a sheltered but sunny position, and abundance of moisture. Propagation is by seeds sown in heat in spring, and by cuttings inserted in sandy soil under a bell-glass or handlight in sumner. This tree is suitable only for planting in comparatively mild districts.
PAVING : Method of Laying. As applied to domestic work, paving is a floor or path laid with large slabs of stone, but in a wiler scnse may include concrete, brick, tile, tar-macadam, asphalte, or any impervious material of a hard and durable nature. Examples are found in the paved courtyard, terrace, or paved entrance path, while in many country homes the foor of the kitchen dairy, and sometimes the living-rooms, are paved with stones. tiles, or brick

Should a stone paving have to be laid, it is customary to make a foundation of hard core, well rammed and consolidated, and then to lay a bed of finer stuff about 2 in. thick, top. ping this with cement mortar or linie mortar, embedding the stones in it, and completing the work by grouting with cement. Bricks or tiles may be laid in a similar manner. The joints should not be too narrow ; $\frac{1}{2} \mathrm{in}$. is not too wide, as wide joints improve the appcarance of such a flow. Smooth bricks specially intended for paving and burnt to the right degrec of hardness are obtainable, but ordinary hard stock bricks or rough bricks are quite serviceable for the purposc.

Care must be taken that the joints are properly broken, that is, that no two bricks stand exactly opposite one another, as if they do the joints will be in line with each other, and the parement would not be so durable. After all the bricks are set in position they are beaten down by laying a board on top of them and hammering it with a rammer or heavy mallet. The whole is then well grouted, thin cement brushed into all the joints, and the bricks cleansed with clean water after the mortar has set. See Concrete ; Crazy Paving ; Path, etc.

PAWL. A pivoted check, known as a pawl, is used in connexion with a ratchet, or similar mechanical device Its function is $t o$ permit rotation in one direction and not in another. A common form of pawl consists of a pear-shaped piece of metal, the broadened
end ol which is pivoted to the one member and the narrow end rounded off to some pointed shape, so that it can engage in the teeth of a ratchet wheel or other device.

A pawl is sometimes made reversible, or double ended, so that in the one position it will permit of rotation in a ripht-handed direction, and when in the other position in a left-handed direction. Common applications are found in machinery, and clocks and watches of all linds, where a pawl is used ns a check or detent to the main spring.

PAYING GUEST. Unlike the ordinary Iodger, a paying guest is a person who sliares the family life of the people with whom he or she boards. The usual arrangement is for an inclusive fec to be charged, and for the person to be treated exactly like a guest, to be given the best of which the household is capable.

Legally, the position of a paying guest is that of a hoarder; for in essence his contract is one for board and lodging. The only difficulty ever likely to arise is as to the length of notice to be giren on either side to terminate the contract; so that both host and guest should he careful to make an express stipulation on this point. There is also an implied undertaking on the part of the loost to provide food and accommodation reasonably adequate according to the sum paid by the guest ; and one by the guest to beliave in a proper manner in the house. Indeed, it would probably he held that these stipulations were conditions upon the breach of which by the one, the other party would have the right to terminate the contract. See Boarding House: Lodgings.

PEA. This is the name hoth of a certain plant (Pisum sativum) and of its seeds that are used, either green or dried, for culinary purposes. The plant is more usually spoken of in the plural, under which heading is appears in this work. Other members of the same family, for instance, the sweet pea, everlasting pea, and glory pen, are grown for their Howering qualities. See Everlasting Pea; Glory Pen; Peas: Sweet Pea.

PEA BEETLE. A little insect that is often very destructive to seed is the pen beetle. It lays eggs in immature pods, and these hatch into legless grubs, which eat their way into seeds and pupate in the cavities. Seed containing this pest usually fails to germinate, imported seed being more likely to be infested than home-grown samples. There is no reliable remedy, and all infested seed must be burnt. See Peas.

PEACH. The peach is one of the most delicions of fruits. In Great Britain it can be grown to perfection out of doors, but only on a sunny wall. One variety, named Breda, may succeed as a standard tree in the open garden in mild districts. Peach trees grown under glass, either in a heated or unheated glasshouse, vield exceptionally fine fruits. The cultivation of the peach tree requires care, otherwise

Peach. Two specimens of the downy-skinned and luscious dessert fruit
Courtesu al Amateur Gardeniny
disa ppointment is almost certain. Unless the soil is naturally loamy old turf soil and decayed manure must be arlded before the trees are put in. Planting should be done in autumm. When the trees are in bloom it may he necessary to protect the flowers from damage by frost.

Pruning is a detail of great importance in the management of peach trees. In spring fresh shoots will develop freely on the old branches, and if all are allowed to remain the tree will be spoilt. All except two shoots on each hranch of the past year's growth should be removed while they are small. One must be left at the top and another near the base: the remainder sliould be time, during a the final pruning takes place : it is done by cutting out the branches of the previous year's growth and tying in the new shoots to replace them. Thus a considerable part of a peach tree is renewed yearly. Shoots which grow one year bear froits the following year and are then cut out. Peach trees grown under glass need similar treatment: if early fruits are required their development may be hastened by maintaining a warm and moist atmosphere in the glasshouse when the fruits are about one third full size. Amateurs will achieve success by ventilating the glasshouse freely during the summer months. Some of the hest

This sum practice is termed disbudding. In late in syrup, then pour them into an earthen ammer, when all the fruits have been gathered, vessel and leave all night. The following mornvarieties are Royal George, Stirling a double variety
arsica. varieties are Royal George, Stirling Castle, Barrington, Early Rivers, and Grosse Mignonne.

Peach leaf curl, a disense which causes hlister-like patches on the leaves, is often troublesonie. It can he prevented bv spraying with Bordeaux nixture in February.

The Fruit. No preserved or foreign peach possesses the delicute Havour of the English fruit, but imported peaches of best quality also appear as dessert fruit. The second quality and preserved or canned peaches inay be converted into many sweets and are not expensive.

Imported or home grown peaches may be preserved as follows: Pare the fruit, which must not he quite ripe,

Outdoor Peach. Cultivation. 1. Planting in loamy soil : a, heavy loam and old mortar; b, original top spit joc, bottom soil opened with brick-bats. 2. Planting on wet soil : a, heavy loam: b. orikinal top spit: $c_{\text {, brick-bats }}$ replaced by good compost. 4. Shallow planting of a wall tree 5. How to distinguish huds : $a$ fruit huds : $b$, growth hads, 6 . Remove front and back distinces be $a$, hais branches. 7. Stopping laterals at base of fruits and keeping to one leas 8. Disbudding : growths at $a$ and $\iota$ to remain unchecked

Peach Gáteau. To make this trifle, a kernels, which should previously have been border ring of sponge cake, a large tin of peaches, cream and flavouring are requircd Put the sponge cake in a glass or silver dish,

Peach Gatean, a trife made with tinned peaches. sponge cake, cream and blanched almonils
soak it with gill sherry and a little of the peach syrup, and then stick into it 2 oz blanched and skinned almonds cut lengthways into thin slices. Round the base of the ring place 2 or 3 peaches cut into quarters; pile the remaining fruit and syrup in the centre, and over them shake pint atiffly whisked cream flavoured with vanilla and aweetened to taste. Garnish the top with a fow crystallized violets

Peach Jam. This is made by peeling and cutting into halves 6 lb . peaches These should be put into an enamel or steel preserving pan with $\mathrm{I} / \mathrm{lb}$. loaf sugar to each lb . of fruit Boil for about an hour, stirring frequently to prevent burning. When almost set add the
kernels, which aliould previously have been
removed from the stones and blanched. Put into jars and cover each witl paper dipped in brandy. See Nectarinc.

PEA-NUT. The pea-nut is valuable because of its oil, and forms the foundation of many nut butters. As well as being eaten as dessert, these nuts are sumetimes ground or flaked and then mixed with fresh mashed fruit, such as atrawherries or raspberries, or sprinkled over the surface of stewed fruit, sundaes or ices.

Pea-nuts lightly browned in hot butter and then seasoned with salt are quickly and simply prepared Shell and akin about a quart of nuts, and toss them gently in a pan containing 2 oz amoking hot butter. When they are of a pale brown colour lift them out, drain them, and coat them lightly with salt to which a little cayenne pepper has been added. Dry the nuts in a cool oven, shake off any loose salt, and, when they are cold, atore in tins till nceded, or eat them hot.

Pea-nut sandwiches are made trom finely ground or grated nuts from which the skins have been first removed. Mix these with hall their weight of fresh butter or whipped cream, season the mixture highly, and spread between thin slices of brown or white unbuttered bread. Pea-nuts are often added $w$ toffee in the same way as almonds. See Almond Toffee.

## Pears: In Garden and Household

## Directions for Growing and Preparing a Popular Table Fruit

This article is on the same lines as those that deal with the Apple, Cherry and Plum; the krowing and cooking of the fruit are described. and then follow the varlous dishes that ca.a be made from it. See further Diet; Fruit; Grafting: Grease: Pruning
The pear is one of the most delicious of all are again pruned, to within about three buds hardy fruits and is eapecially well suited to of the base of the past summer's growth cultivation in the milder parts of England and Wales: elsewhere the choice varieties should be grown on a sunny wall. When budded on the pear stock the tree will reach a height of 20 ft . or more and live to a great age; in this form it is suitable for orchard planting. Pear trees budded on the quince atock are more suitable for gardens, for they are of less vigorous growth and take up far less room: they may be set at 10 to 12 ft . apart. Trees on the pear atock are usually grown in the form of standards : those on the quince stock may be bushes, pyramids, cordons, fan-trained or horizontal espaliers. Those planted against a wall are cordon, fan-trained or horizontal espaliers.

Pear trecs prefer well.drained loamy soil, but they will thrive in ordinary garden ground that is not waterlogged, provided they are planted in a sunny position. In heavy soil it is wise to plant the trees at such a depth that the uppermost moots are covered only by 2 or 3 in . of soil: mortar rubble may be mixed in freely with advantage.

During the first few years pear trees usually make luxuriant growth but bear little fruit; to counteract this tendency it is a good plan to lift young trees (other than standarda) every autumn for the first two or three years after planting, shorten long, thick roots, and replant at once, taking care to keep the uppermost roots near the surface. If this procedure is followed there will be less need for severe branch pruning, with consequent advantage to the trees.

Pruning in summer and in winter is neces. sary. In summer the side shoots on the main branches should be shortened to within about six leaves of the base of the current year's growth : from the middle to the end of July is the best time for this work. Care must be taken not to prune natural fruit spurs-those short stunted shoots on which blossom buds form naturally.

At the winter pruning, which should be done in December or January, the side shoota

Branches which tend to block up the centre of the tree or to cause overcrowding should be out out i this thinning out is important, for fruit buds will not form unlcas the shouts are fully exposed to air and light.

It is necessary to make a careful selection of varieties, for some are more reliable in cropping than others. Some of the most suitable for general cultivation in the open garden are Conference (a very regular cropper), Fertility, Williams' Bon Chrétien, Souvenir dı Congrès, Durondeau, Emile d'Heyst, Louise Bonne of Jersey, Jargonelle, Fordante d'Automne and Charles Erneat. The most delicious pear of all, Doyenné du Comice, is

Pears: thelr coltivation and the insects that attack them. 1. Bow to plant a standard near tree. 2. Planting a dwart. 3. Pear trained as a maiden. 4. As a double cordon. 5. As a triple cordon. A. As an espalier. 7. Showing how a newly planted tree should be mulched. 8. Social samfly. 8 . Vapourer caterpillar. 10. Pear midge. 1-Grab of pear ma
Bu special arrangement wikn

suitable for cultivation as a cordon or espalier on a trellis in the open garden, and as a trained tree or cordon on a sunny wall. Iate varieties of pears such as Winter Nelis, Glon Morceau, Passe Colmar and Olivier de Serres need a warm wall to enable them to ripen thoroughly

Pears auitable for planting as orchard standards are Jargonelle, Williama' Bon Chrétien, Fertility, Conference, Hessle, Lammas, Beurné d'Amanlis and Emile d'Heyst. Good cooking pears are Vicar of Winkfield, Uvedale's St. Germans and Catillac. The hest time to plant pear trees is in autumn as soon as the leaves have fallen, but the work may he carried out between then and the middle of March in mild weather.

Mature trees which are carrying full crops are benefited by manuring from the time the pears have fairly started swelling. Sowage is excellent, but it is wise to use a special phosphatic nianure also, becanse phosphoric acid is essential to fruit development. Mineral superphosphate is one of thie cheapest forms of phosphate fertilizer, and is soluble: 1 oz . to the gallon of water is a suitable quantity. Heavily laden trees are also benefited by a mulch of manure.

Pests of the Pear. The enemics of pears are in the main, those of the apple, with the difference, which is in favour of the pear, that it is on the whole the healthier trec.
Black spot is one of the worst fungus pests of pears. By this is meant the spotting, generally followed by eracking, which affects the fruit. It is worst in badly drained soil, but it may be serious in drained land if the soil is poor. Consideration should be given to the drainage and the condition of the soil. Spray with Bordeaux mixture in spring.

Caterpillars which attack pears in spring should be comlsated by autumn grease banding and spring spraying with arsenate of lead ${ }_{r}$ 1 if . to $2^{5}$ gallons of water. For oyster scale, lime, lime-salt and limesulphur sprays generally am effective, but in bad casea the branches should be scrubbed with a paraflin

Aphides arc often troublesome, especially in dry spells. Paraffin and soft soap, or $1!\frac{\mathrm{lb}}{}$ washing soda and $\frac{1}{2} \mathrm{lb}$. soft soap. in 20 gallons of water, or oz commercial nicotine and $\frac{1}{2} \mathrm{lb}$. soft soap in 10 gallons of water, will check aphides. The last remedy is the best, if applicd very hot where the leaves are badly curled. Pear slug is best fought with nicotine, a wineglaswful to 3 gallons of water.

Injury to fruit by birds and wasps has also to be thought of. Birds may start pecking the fruit before it is ripe. This can be combated with shares to some extent, but netting the trecs is the only sure remedy. If there is not a great deal of fruit to deal with, a strip of cotton wool may be tied loosely round the stalk, and it generally answers; but specially fine fruits may be enclosed in large gauze bags, which baffle both birds and wasps. If wasps are numerous, an endeavour should be made to find their nests and to destroy them at night with hot tar or by other means. Pear Midge. The presence of this pest, which is very detrimental to pear trees,

Pear. The variety called Charles Ernest, a desse
pear of fine fich favour that ripens late
especially the early tlowering varietics, usually first hecomes evident from the rapid falling of the young fruit when about the size of marbles. Upon examination the freshly fallen fruit will usually be found to be deformed and much distorted Upon cutting open an attacked fruitlet, a blackened mass of pulp and excreta with a number of the small, whitish yellow maggots will be found.
In small gardens where only bush fruits are grown the hest remedy is the handpicking and lestruction of all infested fruit, with repeated shallow cultivation of the ground beneath the trees in June and July. In large orchards great benefit has been derived from stocking heavily with poultry in April, May, and June, which is the time when the flies are appearing from the ground, and while the maggots are leaving the fruit.
On light soils an application of kainit, spread very evenly at the time the maggots are falling, is esid to give very good results. Other potash manures will prohably answer the purpose as well as kainit. Spraying the ground or grass beneath affected trees, when the midges are appearing in the spring, with soap and water, 1 lb . soft soap to 10 gallons of water, will kill the midges before they start egg-laying The spraying should be done on dull days or early in the morning. The information given here is taken from Leaflet 5:3 issued by the Ministry of Agriculture
Gathering Pears. Pears are ready for gat hering when the stalks part readily from the tree uniler gentle pressure, even if they are not ripeAs a niatter of fact, most pears should be gathered before they are quite ripe. Sone need to be eaten almost off the tree, but others, including the William and the Jargonelle, are best gathered a few days in advance of full ripeness and laid in a cool room. Gentle pres. sure with the finger near the stalk affords a very fair clue to ripeness. If the fruit is quite hard, and particularly if it has little smell, it is not ready for eating. If it yields a little and has a pronounced aroma it is ready.
lears that will keep till spring are best gathered in the latter part of October, before severe frost comes; a few degrees of frost will not hurt them. If thesc late pears are gathered much before mid.October they are apt to shrivel. The fruit keeps well in a dark, cool, sweet, frost-proof place. As a rule, it improves in flavour if it is kept for a few hours in a warm place before being placed on the table.
The amenable nature of pears, which makes them well adapted for formal training and restrictive pruning, renders them well suited for orchard house culture. They do well in large pots, in a compost mainly composed of
fibrous loam. With support in the form of liquid manure while the fruit is swelling they will furnish excellent crops of splendid fruit.
Uses of the Wood. The wood is hard and lieavy with a short and close grain As it cuts cleanly in all directions it is an excellent wond for carving, but it seasons badly, and without care in the cutting and drying is apt to warp and twist. It absorbs stain well, and as $n$ result most of the dyed stringing and banding material is prepared from it. Mathematical instruments such as rules, tee squares, and set squares are made from it.

Methods of Cooking. For many dishes ripe pears are most suitable, hut for baking or stewing, hard green pears are the hest

To bake pears, wipe 6 hard, green pears, hut do not pare them; lay them on a tin plate and bake them in a slow oven. They will take a long time to cook. When nearly soft flatten them with $a$ wooden spoon, and continue cooking until done. Serve as for baked apples. with sifted sugar sprinkled over.
Stewed pcars can he used as the foundation of many dinner sweets. Peel very evenly 4 large stewing pears, cut each in half and remove the core without taking away the piece of stalk. As they are divided plunge then into cold water to prevent them from turning black When all are finished, take them out of the water and put them into a stewing jar or block-tin saucepan with 5 oz granulated sugar and sufficient water to cover them Add the thinly pared rind of $\frac{1}{2}$ a lemon, 2 cloves, 2 allspice (bruised), and enough cochineal to colour the syrup a good pink. Cover them close and stew for 3 or 4 hours. When tender, which can be ascertained by running a straw through one of them, lift them out and strain the liquor over them. If the liquor is very thin, hoil it sharply for a few minutes.

Pears a la Ricardo. To make this pretty swcet put the stewed pears into a glass dish, pour the syrup over, and then make a small red jelly. Whip a gill of cream till it nearly hangs on the whisk, into it stir $\frac{1}{2} \mathrm{oz}$. preserved ginger cut into small dice, and then blend it lightly with the atiffly whipped white of an

Pears la Ricardo, made with stewed pears and
egg. Heap the mixture roughly over the pears, and decorate the top with lines of chopped jelly and $\frac{1}{2}$ oz. ratafias

Pear Conserve. To make this jelly conserve take 6 lb . ripe, juicy pears, pare them thin, core them and cut them into quarters. Cook them till quite soft, using a little water. Strain all the liquid out of the pulp through a cloth or fine hair sieve ns when making other fruit jellies (see page 647). Measure the liquid and add an equal proportion of sugar Boil the mixture until a jelly is obtained, then strain into glass jars.

Pear Dainty. Stewed pears also form the foundation of this sweet. T'o make it, cut a slice from the top of a round sponge-cake, scoop out the centre to form a case, and in the meantime atew 1 lb . peeled and sliced pears in sufficient sweetened water to cover them When they are tender, leave them to cool, and then add 6 oz ground almonds, putting the minture into the case. Replace the top of the cake and cover with halves of blanched almonds. Prepare some custard with 2 dessertspoon-
fuls custard powder, 3 dessertspoonfuls sugar, 1 pint milk, and some almond llavouring, and, when cold, pour it round the cake. Whisk the white of an egg to a stiff froth, stir into it 1 gill whipped cream, swecten and flavour the mixture with almond essence, and pile it high in the centre of the cake

Pear Mould. To make this, mix dessertspoonful custard powder to a smooth paste with a little milk taken fiom $\frac{1}{2}$ pint. Boil the remainder, add it to the paste, stirring all the time. and then llavour it with a little vanilla.

Pear Mould, the centre of which is olled with tinned pears and whipped cream
While it is cooling, rub a small tinful of peara through a sieve, then add the pulp, together with if dessertspoonfuls castor sugar, to the custard
Fold the stiffly whisked whites of 2 cggs into the pulp, etc., and lastly strain in $k$ oz. leaf gelatine dissolved in $\frac{1}{2}$ gill warm pear syrup. Mix all together, pour them into a horder mould, and leave until set. The centre may be filled with some more tinned pears and whipped cream

PEARL: Real and Artificial. Pearls can be divided into three classes. These are the natural pearls found in certain kinds of shellfish, cultivated pearls which are produced partly by natural and partly by artificial means, and the wholly artificial pearls. The first named are the only ones that may justly be described as genuine, but cultivated pearls are also valuable, and far more costly than the manufactured specimens. Various makes of initation pearls can be obtained, some of them being patented.

The value of real pearls is determined by their freedom from defects and also by their size, shape and colour. The round ones are the most precious, and next to these rank the button-shaped varieties Pear-shaped pearls are cheaper, though large and faultless specimens command high prices. Black pearls are rare and costly. They have two lustres, one being grey and the other green. Black hematite, which is used to imitate black learls, can always be detected by its considerably heavier weight.
Pink pearls are no less valuable than white ones, but they are often peculiarly shaped. Pearls of many other shades of colour can also be ohtained, and are seen in great variety in some famous necklaces.
The best deep sea pearls are liable to de teriorate unless they receive proper care. The brilliancy of colour and the lustre which makes a pearl so attractive soon disappears if it is allowed to come into frequent contact with rough surfaces, or to be dainped by perspiration which contains uric acid. When the outer surface only is damaged, however, it can sometimes be successfully removed. The underlying layers of nacre will be found still to contain the orient tints, though not with the same degree of lustre or brilliancy as the outer surface. The natural lustre of pearls is often lost through keeping these gems for long periods in jewel-cases. A sun hath generally improves them.

The irregular surfaces found on the inside of the oyster shell, mostly semicircular or oval in shape, are known as blister pearls. These are used largely in jewelry in combination with coloured or semi-precious stones, such as amethysts, aquamarines, topazes and tourmalines. The price commanded by seni-
circusar pearls is small compared with the amount that would be realized for a spherical pearl of corresponding size.

Cultivated Pearls. People in Japan cultivate pearls by performing a small operation on the oyster, which enables a bead to be introduced into the flesh, and in the course of time the oyster covers the bead with nacre. There is also another method of introducing a bead. This is by cementing it into the shell and leaving it for a year, or several years, until the oyster has covered it with one or several layers of nacre, thus giving the bead a covering which is the same as the exterior of a pearl that might otherwise have taken many years to produce.

These pearls are usually composed of a core of mother-of-pearl, and, except by expert examination, there is no means of detecting them from the naturally formed pearls. Those pearls which are cemented into the shells of molluscs only receive a covering on the upper side ; consequently, after they are removed from the oyster, they are cut into half-rounds. These are used for mounting into such articles as rinys, bronches and pendants. It has been laid down by Enylish law that these cultivated pearls must not be offered as genuine pearls, notwithstanding that the orient sheen thereon is actually the result of the work of the oyster.

Artificlal Pearis. Really good imitation pearls are artistic productions. These are made by covering a solid bead, either of glass or mother-of-pearl, with a series of layers of collodion: in colour, weight, and outward appearance they are exact reproductions of the best deep-sea pearls. Such pearls can be hardened off so as to give them increased durability and also to enable them to be cleaned by washing with soap and water.

Some artificial pearls are filled with matter obtained from fish scales, and bear an extraordinary resemblance to the real gems. They are made by blowing thin beads or bulbs of glass and then injecting into them a mixture obtained by soaking the scales in water and mixing the sediment that results with some liquid ammonia. It forms a coating inside the bead which gives the latter just the right shade. Melted white wax is afterwards poured in to increase the weight and durability of the bead, and the shiny exterior, in order to hide the fact that it is made of glass, is dulled by the application of chemicals. Such pearls are frequently blown to the irregular shape that distinguishes a great number of the large zenuine pearls.

Imitation pearls in necklaces can be detected by the following simple tests, which, of course, do not apply to cultivated pearla. Gently place the point of a needle on the exterior of the pearl immediately above the point where the hole has been drilled. If it makes a mark, or if by a slight movement of the point of the needle it scratches the pearl, then it is safe to assume that it is an imitation with a core of some solid material with a vellum-like covering.

If the needle makes no impression on the exterior, there is a possibility that it is an artificial pearl which has a glass exterior filled with a mixture of wax and fish-scales. A further test should then be applied by pushing the point of the needle gently into the hole of the pearl. If it is one of the filled varieties, the probing will disclose that the interior has a filling of soft material into which the needle point can be inserted. If the pearl is a real one, the needle will make no impression when pushed against any part of the wall of the hole.

Cleaning Pearls. Pearls may appear to lose their lustre and require cleaning. They can be washed in soapsuds and lukewarm water and then dried. It is important
thoroughly to dissolve the soap before putting a ring or other piece of jewelry. into the lather, and afterwards to rinse it in clean water. It is then dropped into a saucer filled with jeweller's sawdust, which is shaken up and absorbs the moisture on the pearls. The ring is taken from the sawdust and brushed with a camel hair brush or a dry tooth-brush so that no particles of sawdust adhere to the setting. See Jewelry; Necklace

## Peas: Growing and Cooking

## How Gardener and Cook can Secure Good Results

In connexion with this subiect the reader should consult our article Kitchen Garden. See those on other vegetables, e.g. Cabbage ; Carrot : Potato : Spinach; also Coral Spot.
Green peas are the most delicious of all summer vegetables, and by making successive sowings from March to June it is possible to produce excellent peas from June until September. Success depends chiefly on correct cultivation of the soil: this must be dug deeply, enriched with manure and not be deficient in lime. After the soil has been dug and manured a scattering of lime may be applied with advantage, especially on freshly cultivated ground, and on old garden land which has been well manured annually during a period of years. On poor or shallow soil peas are not a success: growth will be poor and the yield small.

The seeds should be sown thinly in a double row in a 12 in . wide shallow trench, 1 to 2 in . deep, taken out on land that has been prepared in the way advised. When the earliest rows are 2 or 3 in . high the soil should be drawn up to them with a hoe as a protection from cold winds and to some extent from birds; it may be necessary to protect the seedlings from birds by using the special pea guards, or fish netting. Tall varieties must be staked in good time, for once the seedlings are allowed to fall over they become bent and rarely do so well as others which were supported early.
The dwarf varieties of peas have been improved so much in recent years that many gardeners now grow them almost exclusively in preference to the tall varieties; the latter, however, still yield the largest crops, and if pea sticks can be obtained cheaply or free of cost it pays to grow the taller peas. If, however, pea sticks are expensive in the grower's locality the dwarf varieties of peas are to be recommended.
Some of the best of these are the following which reach a height of about 18 in .: Peter Pan, Laxtonian, Prince Arthur and Little Marvel. Others which reach a height of about 2 ft . are Daisy, Abundance, Stratagem and

Pearl Barley. The grain of barley stripped of its husk and rounded by grinding is known as pearl barley. See Barley

PEARMAIN: The Apple. This class of dessert and culinary apples is of very old standing. Varieties in cultivation include. Blue, Adams's, Hormead's, Claygate, Herefordshire, and the popular dessert variety Worcester. The latter is an early eating apple of high colour and free bearing. See Apple.

Giantatride. Excellent tall peas are Rent payer. Senator, of whiok an illustration is given in the next page, Prince of Wales and Eureka. Ho a late sowing in June, Autocrat or Gladstone are recommended. The distance between rows of tall peas should be equal to the height of the plants. Catch crops such as lettuce. spinach and radishes can be grown between the rows.

The way to maintain an unbroken succession of fresh green peas is to sow a row every fortnight or so from the middle of March to the middle of May, or even later if necessary. It is a mistake to make one large sowing if peas are wanted throughout as long a period as possible Quite Content and V.C. which produce immense pods, are favourite exhibition varieties.

Diseases of Peas. Peas are subject to a number of diseases. One of these is powdery mildew. The leaves of the peas show yellowishgreen blotches, which gradually increase in size until the whole of the foliage changes to a yellow colour, and soon wilts and dies When badly attacked a now of peas presents the appearance of having been whitewashed, leaves, stems, and pods being equally covered with the mildew.

To control this disease spraying is effective, provided it is begun early enougli. It should be carried out before mildew appears in June and July, using liver of sulphur, 1 oz . in 4 gallons of water

Pea mildew, although liable to be confused with powdery mildew, is really quite different from it and requires different treatment. In it the leaves first become covered with a delicate white mould, which soon changes to a pale pinkish-grey colour, and may pass unnoticed until its presence is indicated by the wilting and yellowing of the leaves. The powdery appearance of the mould, character7. are Dainy, in this case. When

seeds. 6 and 7 . How to sow in pots : a. fine soil ; $b$, good soil ; $c$ leaves
this disease is present the peas should be sprayed with Bordeaux mixture at half strength. This can be made from $1 \frac{1}{2} \mathrm{lb}$. of copper sul. phate or bluestone and lb . of quicklime to 25 gallons of water.
Pea Maggot. This is the name of the maggot that infeats pods of culinary peas. As soon as the maggots are hatched they gnaw their way through the skin and devour the seed When the larva is satisfied it leaves the pod and hides in the soil for its pupal stage, emerging as a moth in June. and immediately deposit. ing eggs in clusters.

Peas. 1. Sowing in old turves : $a$, sowing method ; $b$, seed closed in $c$, seedlings ready for permanent planting. 2. Same in position: $a$, picb soil: $b$, manure or vegetable refuse. 3. Another method : $a$, support for wire : $b$, canes fred to same. 10. Pea thrip. 11. Pea maggot. 12 and 13. Pea weevil and its caterpillar

There is no real remedy for the pest, and all that can be done is to sprinkle soot over the foliage in early June evenings.

Pea Weevil. Weevils will attack peas, and if disturhed will instantly drop to the ground and appear dead. The weevila are about $\frac{1}{1}$ in. long. Seedlings should have sand and paraffin sprinkled round them, or be sprayed with an arsenate of lead wash.

How to Cook Peas. To boil green peas, first put on the fire a good-sized saucepan of water to boil, with sufficient salt, 3 or 4 sprigs of fresh green mint, and 3 lumps of sugar. While the water is boiling, shell the peas, then put them into the water and cook for 20 min ., or according to the age of the peas. Drain them, remove the mint, and dish them in a very hot dish in which 1 oz . butter has been allowed to melt. Stir them lightly in with the butter and scatter over the top, a little chopped mint.

Green peas are frequently served with fried or boiled ham, and makc an appetizing dish. The peas should be cooked as for plain loiled peas, except that the chopped mint is omitted on the top. They may be dished scparately and accompany boiled hain or gammon, or the bacon may be fried and laid on the top of the peas. Gammon rashers ahout $\frac{1}{2}$ in thick are hest for this dish. When boiled ham or bacon is to be served with peas they are sometimes hoiled in the same saucepan, the peas being added about $\frac{1}{2}$ an hour before the ham is done. This method improves the llavour of each. The liam used must not be too salt and no extra salt should be put into the saucepan.

Peas may be steamed by placing them in a jar with a little sugar, salt, mint, and 2 tablespoonfuls water, covering the jar tightly and then putting it into a saucepan of boiling water. Keep the water boiling rapidly for about $\frac{1}{2}$ hour, and add more if necessary.
Cold cooked peas can be used for salad making. Poach 2 or 3 eggs, cut the edges neatly, and leave them to get cold. In the meantime bind a small teacupful of cooked peas with a little mayonnaise sauce, and add seasoning to taste. Place each egg in the centre of a fresh lettuce leaf laid in a salad bowl, put some peas on top, and cover with a little more mayonnaise.

Green pea soup is made by putting 1 quart shelled green peas into a large saucepan with 2 oz raw bacon cut in dice, $1 \frac{1}{2}$ oz. butter,

## top of the soup before serving.

Bottled or tinned peas, when required should be turned into a colander, and washed thoroughly with boiling water. A little mint, butter, salt, and sugar should be added to the pan in which the peas are heated; actual cooking is unnecessary. Packet peas, with which directions for preparing are usually supplied, need to be soaked in hoiling water overnight before they are cooked.
PEASE PUDDING. To make this, soak 1 pint split peas overnight, and in the morning wash and pick them and tie them loosely in a large pudding cloth, giving them plenty of room to swell. Boil them for 4 hours, and when quite tender rub them through a coarse wire sieve or colander. Add to them 2 oz . butter or good beef dripping, and season them with salt and pepper. Mix all well together

Peas. Specimen pods of a popular green pea the variety known as Senator
and tie once more in a cloth, but this time draw it tight round the peas. Boil it again for from 20 to 30 min

Peasgood's Nonsuch. This is a favourite autumn cooking apple of large size and handsome appearance. See Apple.
PEAT : As Fuel. For use as fuel peat is cut in turves from a foot or two below the surface during the summer, stacked edgewisc to dry, and turned every day or two until the drying is complete; this takes 10 to 12 days It is then carted home and piled under cover in an outhouse, or erected into a rick and roughly thatched for winter use

The heating value of peat is a littlc more than half that of a similar weight of coal. It is therefore much bulkier in proportion to the time it burns, and large wooden peat vases, twice the size of the average coal scuttle, are placed in rooms where it is burnt to hold it, and refilled once or twice a day. P'eat makes very much less dirt than coal, and has a pleasant fragrance when alight, but owing to the rate at which it burns it requires more frequent attention than is given to a coal fire.

When lighting a peat fire it should be: remembered that it will not catch from paper. A good handful of thoroughly dry wood is needed to start it, and very little peat should be added until the wond is well alight. Large unbroken turves should never be put on to a newly lighted fire, or they will extinguish it. The proper plan is to break them up small hetween the lingers, and to feed the fire with then gradually, giving entirc attention to it for the first 10 minutes

When the firc has well started the hearth should be piled up with large sods of peat, using plenty of them. They will appear at first to kill the blaze, but it will soon shoot up again. If possible a proportion of coal should be used, starting the firc well with coal, and then piling the peat up high over it. Such a fire will last well, look very cheery, and throw out a great deal of heat. A pair of bellows should never be absent from a pent fireside: they put new life into the fire when it dwindles unexpectedly See Fire; Fuel.
PEAT : For Garden Use. A soil which is made up chiefly of decayed leaves and other vegetable natter is known in gardening as peat. It represents the early stages of the transition of wood into coal. It needs to be mixed with loam and sand for ordinary plant culture.
PEBBLE WARE. This is a term used by Josiah Wedgwood to describe earthenware products in which the effect of erystalline rocks was imitated by means of differently coloured clays. In these materials he turned out llower-pots, basins, plates, inkstands, and candlesticks, but especially vases, all simulat. ing natural crystalline stones.

Egyptian pebble was made of coloured clays, with veining; when spotted with blue it was called variegated pebble. Some of the specific imitations, such as verde antique, agate, porphyry, serpentine, and granite, always bore these names, although they are all varieties of pebble ware The carliest pieces, made by colouring cream bodies, can he distinguished by the light tint of the edges. Afterwards the veining was made to run through the substance by means of bands of clay incorporated in the paste. See Jasper Ware : Wedgwood

PECHE MELBA. A fancy name for ice cream made with peaches is pêche Melba. The peachics are divided in half, stoned, and steeped in liqueur, with a spinkling of sugar added. They are served nith a surround of rich ice cream, and garnished with whipped cream arranged in the centre. See Ice.

PECK. This measure of weight is used for potatcess and other vegetables; also for fruit. Ordinarily, a peck consists of 14 lb ., and four pecks make a bushel. Apples, however, are usually sold 10 lb . to the peck, and onions often 12 lb . See Dry Measure.

PECTIN. This is a substance allied to gum which is found in tipe iruits and causes jams and jellies to sct. Before cooking it exists as pectose, and is converted into pectin by the heat of the process. If too much licat is employed the pectin is changed in character and no longer gelatinizes the jam. On this account too much boiling should be avoided in the preparation of fruit jams.

Apples and gooseberries contain more pectose than soft fruits such as raspberries, strawberries, and plums, and this is why strawberry or other jam often contains a sinali proportion of apple or gooseberry pulp or juice. Unripe fruit contains very lit tle pectose, hence the necessity of employing only rire fruit in jam making. The setting properties of crabapple jelly are due to the largo proportion of pectose contained in crab-apples. A pectin preparation for adding to jams and jellies when making these can be obtained at grocery stores. See Jam; Jelly

PEDIMENT. This word meant originally the triangular finish placed over the cornice that rested on the column of a Greek temple. It thus resembles the gable in Gothic architecture. Its chief use to-day is in connexion with furniture, being scen on English furniture most usually in the form of a broken pediment. The tops of bookcases and cabinets have the sides of the triangle, that would otherwise reach an apex, stopped short of it. This form of pediment was used by Chippendale and is seen in Georgian style rooms over doors and fireplaces. Uccasionally the pediment takes another form; a semicircular one is on the mirror, Fig. 1, illustrated in page 797. Sce Door; Georgian Style.

Pedlar. See Hawker.
FEEL. Peel is a skin or rind, the word being cspecially applied to the skin of fruit. This skin should in most cases be removed before the fruit is eaten. Certain peela, e.g. that of the lemon, have many culinary uses. See Candied Peel; Lemon.

PEGAMODD. This is a substitute for leather, nnd is used for upholstery. It is easily cleaned with soap and water, and kept in condition with ordinary furniture polish. Like all leather surfaces, it becomes cracked with continual use; if treated with one of the specially prepared paints anld for the purpose, the surface can be rendered equal to new. See Upholstery.

PEKINESE DOG. The Pekinese is an affectionate little dog, purely domestic and of engaging manners. Its head is broad and ilat bet ween the long, drooping, heart-shaped ears ; the muzzle short, hroad and wrinkled, and with the broad nose black. The large dark

Any colour is allowable, self or shoots are then cut back, the plants repotted, patched, but the golden-tan, self-coloured and grown in a cold frame until autumn, dogs are the truest to type. The maximum when they should be placed in a slightly weight is 18 lb ., but the smaller dogs are the heated glasshouse. Cuttings made from more desirable. See log; Kennel.

PEIKOE. The fine variety of China tea known as Pekoe is very suitable for mixing with Indian, Ceylon, or other teas. The leaves are picked when the plant is young, and has the down upon it. From the pleasant aroma of this tea it is often called the flowery Pekoe. See Tea.

PELARGONIUM. The two most popular kinds are the ivy-leaved and the zonal pelargoniums, the latter being commonly but erroneously known as zonal geraniums. Both are valued for planting in summer beds, and the ivy-leaved varieties are well suited to filling vases in the flower garden or hanging baskets in a porch, veranda or window box.

They are propagated by cuttings taken from Howericss shoots in August, inserted in pots or boxes of very sandy soil and placed in a cold frame. During the winter the cuttings must be kept in a grcenhouse heated suffi-
ciently to beep out frost : a temperature of 45 to 50 degrees is high enough to ensure their anfety. In autumn or in spring the rooter cuttings are potted singly in 3 -in pots in a compost of sandy loam; they may be repotted in 5 -in. pots before being hardenerl ofl ready for planting out of doors early in June.
The old planta should be lifted early in October: if placed in pots or hoxes of soil and kept under glass safe from frost in winter and spring they may be planted out in June. Old plants are useful for garden vases and for filling the centres of Hower heds. I method sometimes employed by those who have no greenhouse is to shake the roots of zonal pelargoniums frec from soil in autumn and hang them, roots downwards, in a cellar or other frost-proof place for the winter ; it is however less satisfact ory than potting them and keeping them inside a room window.

1 few of the best varieties of zonal pelargonium arc Paul Crampel, red; King of Denmark, salmon; Henry Jacoby. crimson; Queen of the Belgians, white. There are innumerable others. Two favourite varieties of ivy-leaved pelargoniums are Madanic Crouse, salmon-pink: and Souvenir do Charles Turner, carmine-rose.

Certain pelargoniums are grown for the satio of their coloured leaves, but they are less popular than they were some vears ago. Flower of Spring, green and whitc leaves; Crustal Palace Gem, yellowish lenves; and Swanley Bronze, with bronzecoloured leaves, are some of them. Then there are the tricolorlenved pelargoniums, of which Mrs. Polloch is a great favourite.

The show and fancy pelargoniums are still favourite plants for cottage windows where, during the summer months, they may be seen in full beauty in almost any part ol the country. They are valuable for conservatory decoration. When the Howers are over the plants should be partially dried off by giving less water by giving less the fresh shoots will form roots il pots of sandy soil in a frame.
Scented-leaved pelargoniums are rarely seen nowadays, but they are worth adding to a
 collection of greenhouse plants, for they are easily grownina temperature of about 50 degrees if potted in sandy loamy soil.
Zonal pelargoniums will Hower -in winter in a greenhouse temperature of is to 60 degrees if they are
propagated by cuttings in March. During the summer months the plants must be grown in a cold sunny frame and all flower buds should be picked off. In Inte September they should be placed in the greenhouse. The final potting is in $5 \cdot \mathrm{in}$. or $6 \cdot \mathrm{in}$. pots, using a compost of turfy loam with a little sand and decayod manure. See Geranium.
PELMANISM. This game depends largely upon the memory. It is played with a pack of ordinary cards, which, instead of being dealt in the usual way, arc laid face downward on the table unsymmetrically, each card separate. The first player turns up a card, shows it to the others, and lays it down again in the same place, face downward. I second card is treated in the same way. Subsequent players turn up a card, and if a similar card has already been turned up they can pair it off, providing they can remember its position. If they succeed in pairing it the two cards are then removed from the game. This is done by each player in turn, and the one who has most pairs at the end of the game is the winner.
PELMET. This is the furnishing accessory which surmounts the curtains of a window and hides the pole or rod and rings. Woven fabric pelmets are usually of the same material as the curtains, but occasionally a contrasting treatment is omployed by making the pelmet to match an appliqué trimming or border. In such a case the pelmet is often trimmed with applique of the material used for the main body of the curtains. The difference between a textile pelmet and a valance is that the latter is pleated or gathered, while the former is shaped to fit. It may be trimmed with a fringe, scalloped, or stepped and braided, or curved at each end as shown in Fig. 1. It requires lining with the same material used for the curtsins or to tone with them, and often also to be interlined with canvas. The pelmet is fired on to a pelmet board, as illustrated in Fig. 2 below.
Many window treatments now incorporate a glass, wooden or
metal pelmet. Mirror glass is used divided into sections which are held in position with silver-headed nails or glass studs. Coloured glass which matches the colours of the curtains is effective for pelmets. Oak or painted wood moulded pelmets are also seen, while designs in plywood are suitable for bedrooms and modern bungalows. Aluminium and chromium plate are also used for this purpose. The advantage of hard surface fabrica for pelmets is that they do not require to be taken down when the curtains are changed, but are simply cleaned with a damp cloth and polished. Illustrated ideas for pelmets are secn in page 71 , and in the article on Curtain.

Pelmet Board. This name is given to the support which holds a pelmet or a pleated valance in position. It consists of a strip of wond that is sometimes provided with a wide moulding on the front colge and ends. The pelmet is attached either directly to the front edge or behind the moulding. In addition, the rods on which the curtains are hung are generally attached to the pelmet board. An illustration of a pelmet fitted to a board with a moulded front is shown in Fig. 1. The side view in Fig. 2 gives a section showing how the moulding may be attached to the board and the position of the silk pelmet and curtain rod, which is held in position with screw hooks. Small iron brackets are used to secure tho pelmet board in its proper position. See Bay Window: Curtain: Living Room; Mirror

PEMBROKE TABLE. This is a name given to an oblong table with two leares, which may either hang down or, supported by brackets, be raised to the level of the rest of the piece. The leaves may be cither oblong or semicircular, and the table is made in oak and mahogany, ns well as in the cheaper woods. Pembroke tables of the 18th century have fre. quently edgings of marquetry, and on some is the serpentine line favoured by Hepplewhite and his followers. See Table.

PENCIL PAINTING. Pencils specially prepared for this work are known as Aquarello and are obtainable in 24 colours. They may be used ilry, as ordinary coloured pencils, or with water and a brush when pencil painting can be accomplished on paper, textile fabrics, lenther and wood.

Therc are two methods of working the colours. Part of a design is filled in with the desired tint, as if using an ordinary crayon, and then apread and amoothed with a brush dipped in water. This results in beautiful clear wanh effects of non fading colour

Pencil Painting. Outining the design on a parchment spill nolder with a water colour pencil. The boxes have been decorated with pencil colours applied dry
The other method
of application is to damp the paper, or portion of a design on a piece of fabric, slightly with a clean, wet brush and then draw in with strokes of the pencil the colour required. Unless there is an excess of water the colour

will not run, but in this way sliades can be softly blended.

To make a strong outline the pencil itself is dipped in water and used, asshown in the illustration. The conrentional design on a parch-

Pelmet. Fig. 1. Fringed and braided silk pelmet fired to pelmet board with moulded fron!. Fig. 2. Sectional view of board with pelmet attached ant covered spili holder is being drawn before being tilled in
Colours may be superimposed and may be distributed over large surfaces by means of a piece of damped felt wrapped round the index finger.

The simplicity of the outfit will appeal to many people, and pencil painting is a delightful and clean metholl of colouring for childien to use. It is excellent for sketching or for map tinting, and may also be used for colocring photographs on either dull or glossy paper. For this last purpose the pencil is applied dry, and the markings are then gone over with a damped brush. If ton much colour is applied, or it is put in the wrong
white pencil was used over the colour. Leather is pencil painted in the same way as wood. For either work to ensure permanence against wear, spray with an ordinary solution of shellac and alcohol, or brush over with clear varnish, to protect the design. The application of pencil painting to woven fabrics is dealt with in the articlo Painting on Textile Fabrics. See Transfer; Writing Desk Set.

PENDANT. The most valuable of these ncck ornaments are made of gold and are set with diamonds, sapphires, and other precious stones, while platinum and pearls are also used for them. Pendants are also made in rolled gold and enamelled silver.

Yet another type of pendant is of carved or plain amber, jade or ivory. Such pendants often form part of a necklace composed of heads to match, with or without metal chainwork or filigiee connecting links. Other pendants are usually worn on chains which match the metal of which they are made. See Enamelling : Jewchry.

PENDULUM. A clock depends for its timekeeping upon the proper working and adjustment of the pendulum. The motion of a pendulum is controlled by the laws of gravity : if free from friction and atmospheric pressure, it would swing for an indelinite period at a uniform rate The time of vibration of a pendulum depends entirely on its length. It is the same for a given length whether the pendulum swings through a long are or a short one, the velocity being proportionate to the height the pendulum falls in its swing The length is the distance

Pendant. Eiguteenta century piece in rold set rith diamonds
from the point of support to the centre of gravity of the pendulum bob and rod; the shorter the rod the greater the number of the vibrations. Lengthening the rod reduces the speed of the clock, and shortening the rod increases the speed The length of a seconds pendulum is taken as the basis: in the latitude of London this is approximately $39 \cdot 14$ in., and a rod of this length will make 60 vibrations per minute, or. in other words, will take one second to swing from one side of its stroke to the other. Cheap clocks generally run at a speed of 120 or more, hence the pendulum must be shorter than 39 in . in length. The length varies as the square of the time of vibration, hence a pendulum to beat at 120 jer minute will only need to be 9.75 in . long.
The following table gives some of the lengths and corresponding vibration rates:

| Length of I'endulum <br> in. | Vibirution Rate <br> in. |
| :---: | :---: |
| 14.1 | 1190 |
| 11.3 | 110 |
| 6.75 | 1.20 |
| 8.3 | 130 |
| 7.2 | 140 |
| 6.25 | 150 |
| 5.5 | 160 |
| 4.0 | 185 |
| 2.5 | 240 |

The length of pendulum arranged for a clock is governed as a rule by the anount of room available in the clock.case. The clock, through its wheels and pinions geared up to suit the length of the pendulum, transmits the number of vibrations in the form of seconds, minutes and hours recorded on the dial by the hands.

Ordinary pendulums vary slightly with changes of temperature, which cause the metal rods of which most of them are made to expand or contract, thus lengthening or shortening the pendulum, with the result that the clock goes slower or faster Where very accurate time is required pendulums are made to compensate, and there are several ways of doing this.

Modern science has produced a metal known as Invar steel, which requires no compensation and has the lowest known coefficient of ex pansion. This is generally used where very accurate timekeeping is required. A wood rod, well french polished, with a lead bob, also makes a good pendulum, as wood is not much affected by temperature. The spring by which a pendulum is suspended should always be as thin as possible, just of sufficient strength to keep the pendulum from rolling or wobbling.
Regulating the Pendulum. The regulating of a clock consists in getting the pendulum to make the correct number of vibrations 80 as to record the right time. This is done by lengthening or shortening the pendulum In most clocks the bottom part of the rod is fitted with a screw, on which is a knurled nut. On this nut rests the bob which slides up or down on the rod, so that by turning the nut the bob is raised or lowered as required. In doing this, great care must be taken not to buckle the suspension spring, as a distorted spring will very often cause bad timekeeping. A good plan is to hold the bob with one hand and turn the nut with the other.
When a clock requires regulating it should first be noted how much it is out in a given time. The pendulum should be altered accordingly, shortening it to make the clock go faster. and lengthening it to make it go slower. The result should be watched to see what difference the alteration has made over the same period, and from this it will then be possible to gauge exactly what further alteration is required. A long pendulum will require moving a greater distance than a short one for the same error. Some clocks are provided with a means of regulation from the front of the dial.
French clocks use what is known as a Brocot regulator. Over the top of the figure 12 is a
small square, which is turned with a key that works a slide up and down the suspending spring of the pendulum. On account of backlash between the two toothed wheels employed, this device is often not very reliable, and the slide should be observed to see just how much it is moved by turning the key. English clocks use a different method, known as a rise and fall. This is a rocking bar across the top of the clock plates, the pendulum being hung on one end, the other end working on an cccentric snail at the back of the dial, with an arbor through the dial, to which is fixed a pointer or hand. By turning this the bar is moved up or down, by this means drawing the suspension spring between two brass jaws underneath the bar. See Clock: Grandfather Clock.

PENNISETUM. Of these ornamental grasses only one, Pennisetum longistylum, is usually grown in gardens. It is 18 in . high and bears spikes of purplish flowers in summer Seeds are sown out of doors in April where the plants are to bloom.
PENNYROYAL. This aromatic herb (Mentha pulegium) thrives in ordinary soil and is propagated by cuttings in spring. If these arc severed beneath the soil they will possess a few roots and soon become established.

PENNYWEIGRT. This measure is used in Troy weight, 24 grains going to a penny weight: 20 pennyweights make an ouncc. The usual abbreviation is dwt. See Troy Weight.

PENNYWORT. Sometimes called navelwort, and botanically known as Cotyledon umbilicus, pennywort is a succulent plant which may be found growing wild in crevices of rocks and ancient walls in the west and southwest of England and Wales. It has orbicular leaves and bears erect spikes of drooping cylindrical yellowish-green flowers during June. Its rounded fleshy leaves have depressed centres. It is useful for wall-gardening and for outdoor ferneries, but requires mild climatic conditions.

PEN PAINTING. This form of decora tion can be applied to cotton, silk, relvet, leather, papier mâché, wood, pottery, glass and metal. Oil colours are used with a special powder and medium, pens, palctte, palcttc knife, drawing pins, drawing board, and a sheet of clean white blotting paper are also required.
When used on textile fabrics care is neccs. sary to prevent spreading of the oil colour. This may be achieved by removing the work from the drawing board immediately the pen painting is finished and placing it on a sheet of clean blotting paper which has been dusted over with absorbent powder. The back of the silk or other fabric must touch the powder while the colours are drying and this prevents their tendency to spread.

Wooden articles to be decorated in this manner should be lacquered or enamelled first, the design being pounced on when the background is quite dry. Glass and pottery must be washed, rinsed in cold water, and

Pen Painting. Fig. 1. Two of a sot of densert doilies. each of which is decorated with a diferent flower
polished with methylated spirit. Colours will not adhere to a greasy surface Stencilled designs may be outlined in pen painting.

Floral and conventional designs are the most suitable for pen painting. The finished appearance of the work has some resemblance to embroidery as the strokes of the pen by means of which the oil colours are laid on take the form of stitches.
The first step is to trace the design on to the fabric in the case of textiles, to pounce it on for wood or to paste it on the reverse side for pen painting on glass (see page 540) Designs may also be placed under gauze, which is an admirable fabric for pen painting. Black gauze mounted afterwards on satin is effective when pen painted for central pieces on nightdress, glove or handkerchief sachets. In white it is used for des-

Fig. 2. Glags vase decorated D pen painting with design of mimosa in nataral colonrs sert doilies such as those illustrated in Fig. 1. Silk gauze is ob. tainable for the work by the yard or in pieces; also traced gauze doilies and table centres for pen painting.

Special oil colours are sold for this purpose. A convenient method of mixing is to squeezo a little white on to the palette and mix the powder with it till it is of the consistency of thick creant and no specks of free powder are left. The white is then tinted a very pale shade of the colour required and a third of it put aside. The remainder is tinted a deeper shade and hal! of this is put aside, while the part left over is coloured a still darker shade. This gives a medium tone for a flower, leaf or groundwork, a pale tone for high lights and a dark tone for shadows. The various colours may be prepared in this way, and a drop of medium should be added to each before starting work.

The three shades of a colour actually in use may be placed on the blade of an old table lknife. A long, thin piece of colour is then modelled on the knife and picked up with the pen and applied to the fabrio as if making a down stroke in writing, a slight but even pressure being maintained. This is followed by further strokes until the design is filled in; the darker and lighter tones of the colours being used for the high lights and shadows. Practice soon teaches the worker just how to gain good effects from the direc. tion of the strokes. A set of dessert doilies with a different flower on each one is an excellent piece of work to undertake after experiments have been made on a few scraps of silk or cotton to gain someskill with the strokes. English and French makes of pens are obtainable for a few pence a dozen. Bronze and lustre powders can be used to give a richly varied appearance to designs. The former are painted on finely with a No. 1 sable brush, using the quick-drying medium supplied for them. The latter are dusted over portions of the work, while still wet, to
give a raised effect. For instance, they were used to give a touch of realiam to the mimosa leaves and Howers on the glass vase in Fig. 2. The leaves were worked first in greens and while wet covered with green lustre powder. When this was dry enough for the surplus powder to be shaken off, the mimosa was painted in with the pen in chrome yellow and white This was covered with yellow lustre powder to give the fluffy look to the mimosa balls.

One advantage of pen painting is that it can be done rapidly. It takes some time to dry however, one week being the uaval time allowed in winter. Afterwards the work may be hrushed, washed, or rubhed without harm ful results. If the colours fade with time, they can be freshened by a second but light application of paint. See Painting on Textile Fahrics; Stencilling; Transfer.
PENSION. A penaion is rally an annual payment made to elderly or infirm persons in recognition of past services. Officers of the army and navy and civil servants enjoy pensions if they have served a certain period, and many businesses have pension schemes for their employees, among these being the banks and insurance companies. Many local authori ties, such as town and urban councils, have also pension schemes, and pensions are also provided by some trade unions.

Pensions are either contributory or noncontributory. Those given by the state to officers and civil servants are non contributory, i.e. no deduction is made from the salary on this account. Most other schemes are contributory, i.e. the employee pays from his salary a certain amount each week, month, or quarter towards his pension, usually something from 3 to 5 p.c. If he dies before he becomes entitled to a pension, his relatives, in most cascs, receive the amount he has paid in to the fund. In some schemes the firm pays a sum equal to the total contributions of the employees; in others it makes itself responsible for the whole except that part paid by the employee.

The amount given as pension varies, depend ing upon the salary received and the length of service. In the civil service the maximum pension is one-half the salary for 40 years service. In addition, however, a substantial sum is given to the retiring civil servant in the forin of a gratuity. The pension is calculated, morenver, on the salary received at the time of retirement, i.e. when it is highest. Other pensions are usually calculated according to the length of service with a maximum of twothirds of the annual salary. Some pension schemes, but not all. provide pensions for the widows of employees. These may be as much as one-third of the salary

State Schemes. In the United Kingdom of Great Britain and Northern Ireland, and also in other parts of the British Empire, there are state schemes for providing pensions. One of these is the non-contrihutory ocheme for oldage pensions, which, at the rate of 10 s n week. are paid to all persons whose means are below a certain figure on reaching the age of 70 . The other schence provides pensions at the age of 65 for persons who are insured under the national health insurance scheme. These are contributory, combined weekly payments being made for health and pension.
lersons who do not come into any pension scheme can provide a pension for themselves by insurance. They can also in the same wry secure pensions for their dependents. The insurance companies and friendly societies will give information about their terms. An annuity may be described as a pension. Firms wishing to establish a pension scheme should consult an actuary, as only an expert who is acquainted with the conditions of the business in question can eatimate its cost. For purposes of income tax pensions are treated as earned income. See Annuity; Income Tax: Insurance: Old Age Pensions.

PENTSTEMON. This is an invaluable From seeds sown in n heated glasshouse in hardy or half-hardy plant suitahle for the rock January or Fehruary the plants will bloom the garden and flower beds and horders. The same year. A summer sowing in a garden frame

Pentstemon, a showy plant for the rarden border
florists varieties of pentstemon are popular late summer flowers: new onesare raised annually and the sizeand colouring of the blooms have been greatly im. proved : they vary from wh ite through pink to scarlet and through rose to carmine and purple. The plants are abnut 2 ft . high and are very showy from July onwards. Catalogues give long lists of named varicties. The small-flowered section of pentstemon has become popular in recent

Peony: two beautiful varietles. Left, flower of the fragrant white berbaceous albifora; right, rose-shaped flower of a variety of tree peony will yield planta that will flower the following year. 'The florists' varieties of pentatemon are not thomughly hardy, therefore annual propa. gation is advisable. Plants in warm, sheltered places may live thmugh the winter; if they do they ought to be pruned in spring.

Among the species or wild types of pent stemon there are several beautiful fowers. The loveliest of all is the blue heterophyllus, which needs well-drained soil and is suitable for the rock garden. Barbatus, 3 ft., is a good border plant which benrs red flowers in late summer.
PEONY. There are two kinds of peony, one a hardy herbaceous perennial, the other a shruh commonly called tree peony. The former is of chief value in British gardens. There are innumerable varieties with single or double flowers in many charming colours, and well-eatablished planta provide a hrilliant dia play of hloom in May and June. These plants thrive hest in deeply cultivated soil which has been enriched with decayed manure: they must be watered freely in dry weather, and an annual mulch or soil covering of manure in spring is heneficial. The heat time to plant is in September-October. Peonies are often slow in becoming established: they should thereforc be left undisturhed as long as they continue to Hourish. When after some years hruhs soveral feet in arge, hnnclanme blooms in about 18 in . high and hloom freely; a few of early summer. Although these shrubs arc the hest are Newbury Gem, Southgate Gem and Myddieton Gem. The usual method of propagating the named varieties of pentstemon is by cuttings of flower less shoots inserted in a bed of anndy soil in a cold frame in Septen. ber; if the frame is kepte closed for a few weeks they will soon form roots. The plants may remain undis. turbed until April or early May, when they are planted out of doors. A hetter plan is to pot them singly in $3-\mathrm{in}$ pots in spring Pentatemons can be raised from sceds, and those who do not wish to possess certain named varieties will find this method satis. factory if reeds of a good strain are obtained.

Peony Culture. 1. Good soil preparation. 2. First year: planting with Lilies between. 3. Second year: middle plant removed; tulips and libes between 4. How to lift a plant. 5. How to divide. 6. Planting in grass: a, riob
hardy they start growing carly in the spring, and must therefore have a sheltered situation, preferably one facing south or west. They Hourish best in loamy soil. Paeonia lutea is a tree peony from China, and cross-breeding between this and the Japanese tree peony has produced new varietiea Pron. Pee-on-e.
PEPPER : The Plant. The pepper plant belongs to a family of hothouse and greenhouse shrubs of the genus Piper. In Grcat Britain they are cultivated chicfly for their foliage. They require stove culture in a mixture of loam, leaf-mould and sand, and need a temperature varying from $60^{\circ}$ to $80^{\circ}$, according to the period of the ycar Propagation is by cuttings in springtime. The flowers ure insignificant.
PPPPER : The Condiment. Both the white and black pepper are obtained from the seed of the $E$. Indian pepper plant. The white variety, which is less pungent than the other, and is produced by allowing the berrios to ripen more fully, is used as a condiment for the table. but the black gives the best tesults in cookery.

Cayenne and Other Peppers. Cayenne pepper is employed in sauces and for seasoning white made dishes; it is also served as a table condiment it is obtained from the chilli or capsicunt. and the preparation may

Pepper Grinder in painted poruolain and silver. The peppercorns groove at the top, and ground popper is aprintled trom the base in pepper. Long pepper from India, and Neilgherry epper is prepared from a yellow variety grown in the Neilgherry hills. It is usually mixed with cumin and other aromatic spices. Mignonette pepper is a coarse-ground rather whitish variety, mild in character.
Medical Uses. Pepper has various uses in medicine, either as a counter-irritant, a stimulant, or to prevent flatulence, but must be taken in small quantities, otherwise it will set up irritation of the stomach and other organs. It may be used instead of a mustard plaster by steeping black pepper in alcohol, then spreading it on brown paper, covering with muslin and applying it to the skin for $n$ lew minutes.

Where a stimulant is urgently needed, and no brandy, sal volatile, etc., is at hand, pepper will supply the want. Give about 15 gr . of gmund black pepper in milk : it will act as a powerful restorative.

Peppercorn. This is the seed of the pepper plant before being ground, and it is valuable for the adequate seasoning of stock and stews. In order to distinguish the quality, observe that the seeds or corns are not broken They should be whole, firm, and cleanlooking. (See Allspice ; Capsicum: Chilli).

Pepper Pots. Pepper [wts, or casturs, are made of various materials. Cut glass ones, with silver tops, are found in condiment sets, and there are aluminium ones for kitchen use. They are also madc in carthenware, generally as part of a set. For the dining room pepper pots are made of silver, Sheffield plate, and electro-platc, and are usually bought in pairs to match salt cellars and mustard pots.
lepper pots of silver were first produced about 1700. They were cylindrical in shape, with a curved or domed top, which was perforated. Later the vase design was used for them, and, known as castors, they were made to form part of a set of three, two being for pepper and one for sugar. Pots in Sheffield plate were at first made on the same lines as those in silver, but afterwards other features were introduced. Some of the pieces were pierced, and, like the salt cellars, were fitted with glass liners. Bead edging is found on many of the antique pepper pots, which are sometimes called dredgers or muffineers. See Muffineer: Sheffield Plate: Silver: Table Laying.

PEPPERMINT. This hardy perennial herb may be grown in any rich, moist soil, and is well suited for the rock garden, or in rockwork by the side of a sunken walk. The flowers and young foliage should be gathered for the purpose of distillation. Pcppermint should be freely and constantly watered in dry weather.

Essence of Peppermint. Extract of peppermint is used for Havouring certain kinds of swcet meats and digestive lozenges. while the essence is made into cordials. A favourite dessert sweet consists of mild peppermint creams made with fondant and coated with unswectened chocolate.

Medical Uses. The fragrance and stimulating properties of peppermint are due to an essential oil which gives it a value as a medicine in digestive troubles. It is given to infants in the form of peppermint water in doses of

## Perambulators and Push Cars

## Up-to-date Types and Some Notes on Repairing

## Reference should alao be made to the arricies Baby: Nursery; and others dealing with

The shape and design of baby carriages by leather straps, thus preventing any vibrahave changerl of late years, the older high- tion and shock to the baby. huilt type of pram having been superseded by cars having a much lower built body and amaller whecls. The deep, low-built body affords the infant more protection from draughts, and keeps the weight low down and minimises the risk of over-balancing.

The chief requirements for a baby carriage are safety, comfort, and strength. It is essential othee. the beading or othamentation sprung applied hiereto $n s$ in tho case of wiond

Perambalator. Piga. 1 and 2. Two models, both of which have deep, low-built, ateal bodies, and wheela with ball bearingi and ruatleas mporea and babs. The oar on the left in fitted with madguards and a foot brake Courtesu of Dwnkley Safety Prame and of J.ines Bros., Lid
perambulators The surface is finished with carriage dusted inside and out whencver with pliers and bending them until they are
nitso-cellulnse enamel. These prams are casily cleaned. and the surface is not liable to chip. All the bright parts of the chassis can be protected from rust by chromium plating, which is standaid on all good prams

Inatead of the ordinary waist strap, a patent safety strap is hetter ; this costs only a trille more and malice it innossible for the child to fall out of the pram. It. is important that the hood and apron are cflicient. fit well, and are stormproof. Extra tittings are mudguards to lit over the back wheels, a chain guards to lit over the back wheels, a chain perishes rubber cloth and
brake for attaching to tha rim of the wheel spoils painted surfaces. when the car is left atanding, and a holder for an umbrella. The brake should be procured, as it is not safe to leare the pram standing without one. Even on almost level ground, baby can rock or slanke the car and so cause it to start in motion. while on an

Incline the employment of a brake is impera tive if accidents are to be avoided.

The question of size is important in small houses, flats, and in the type of house where the hall consists of a narrow passage. The slorage space must be considered, and the overall length and width should be measured, as in some models the handles extend 1 ft . to $1 \frac{1}{2} \mathrm{ft}$. beyond the carriage body. Folding handles can be had on some models, the levers bcing hinged so as to fold across the top or down against the body.

For two children a well-proportioned double enrriage can be obtained It is wider in the bed, a little longer, and has two hoods, and a special-shaped apron to protect the inmates from rain.

Folding Baby Carriages. In some circumstances it may be difficult to house an ordinary pram, and one of the folding variety must be procured. Great care should be exercised in its selection, and the purchaser should not be induced to buy one of the ordinary lowbuilt folding push cars. This type of car, though it may have an extension and provide a suitable bed length, has not the comfort necessaly for $n$ baby's first carriage, and serious curvature of the spine may result from their use in the upright position in the case of infants. For an older child the push car has its uses, as it is portable and can be taken away on holidays. It is employed normally in the crect position, with thic child sitting up, and can be arranged at will to allow the occupant to rest in n re. clining posture. Good examples of both types of car are illustrated.

Care and Repair. Perambulators wear well and lost a long time if care is taken of them The hubs should be oiled regularly, and the

Perambulator. Fig. 3. Baby carriage witn 1010 lng movement. Fig. 4. The vehicle folded. It can be set un on end for storing. Fir. 5. Push car with body adjustable to three positions and bed extension Courlesil of Tan-Sad. R.1d.

Beeswax dissolved in turpentine or any good wax polish can be applied to keep the pram in good condition. It produces a brilliant polish, feeds the wood and protects the atcel part from rusting and the leather cloth from (racking.
The points that most usually call for attention лre the tircs, hubs, and hood. Pneumintic tires may be treated in the same way as cycle tires; when the ordinary solil tire breaks or wears it must he replaced by a new one. To do this, the lirst step is to remove the old tire. Sometines tircs are secured by cement, and in such cases will have to be warmed. For this purpose the wheel should be taken off from the pram, the dust cap on the end of the nale heing first removed by means of a spanner; when it lias licen taken off it revenls the end of the axie.

In many prams the wheel is held on by a split pin and a washer known as a D washer ; it lias a flat part formed on it which engages on a flat on the axle, the purpose being to prevent the washer rotating. The split pin is removed by pinching the two ends fogether warming the class of lire is fitted by warming the rim of the wheel, laying a little dire cement in the hottom of the rim, immediately inserting the tire in place and springing it over the rim. In the casc of the continuous tiring, the first atep is to measure the length nceded. This is done by coiling the tire round the rim and cutting it off about $1 \frac{1}{2}$ to 2 in shorter than the length round the rim. the amount varying with the dinmeter of the wheel and that of the tire. The next step is to saw the tire naunder with a hacksaw, supporting the tiring in one side of the vice and manipulating the hack-saw with one hand while supporting the other end of the tiring with the other hand Having cut it off, the ends of the wire are joined together hy screwing one end into the other To do this, it is necessary to twist up the length of tiring into three coils and place the two ends of the wire in register. On relcasing the tire, it will uncoil itself, the ends will be firmly screwed into each other, and the tire will be found to le complete.

The next step is to spring the tire on to the

Perambulator Repairs. Fig. 8. Replacing a solid tira: sa wing of length of tiring with hack-saw. Fig. 7. Tire twisted up in coil and wire ends joined. Fir. 8 . Renewing worn-out rivets of a folding perambulator; a heavg hammer is held arainst the head oi the rivet, and the riveting is done with a ball peine tammer
working it on with the thumbs. The fingers and the hands should grasp the rim of the wheel and the.tire firmly, so that it cannot possibly slip and spring off, while the thumbs are pressed over, gradually springing the tire into position on the rim. Before replacing the wheel the bearinga are overhnuled, hub and wheel cleaned up, and the axle oleaned and oiled with light machine oil. After this, the D washer, split pin and dust cap are replaced.

After the pram has been in service for some time it may well receive n thorough overhaul. It should be taken to pieces, commencing at the top and removing the hood, oushions, etc., and taking off the body from the ohassis. The axles, if bolted to it, can be unfastened from the framework or aprings and every part dismantled. The whole should be cleaned, and the metal parts wiped over with a rag saturnted in paraffin oil, which will remove the bulk oi the grease, then they may be finished off with a clean rag. Leather suspension strapa can receive a dressing of harnesa oil.

All metal parts that have been painted should be well rubbed down with coarse sandpaper and smoothed off with fine sandparer, taking care to remove all traces of rust. They may be painted with one or other of the special cycle enamels on the market, which give an excellent result if the maker's instructions are carefully carried out. It is seldom worth while to repaint the bodywork. Many prams now have pressed ateel bodies and are cellulose enamelled, a method giving a hard and durable aurface: Scratched paintwork can be touched up with a paint of the appropriate colour
The upholstery may be renovated with one of the leather revivers on the inarket. The axles and the underframe, or chassis, should then be put together, the wheels refixed, and the straps fixed in their positions. To refix the body will necessitate an assistant, one to hold up the body while the other fastens the atraps to the hangers. The lining of the hood may require renewing, and to do this the old lining may be used as a pattern by whioh to prepare the new one.

## Repairs to a Foldins Perambulator

Folding cars call for somewhat different treatment, as their construction is not the same as that of the ordinary type of pram. The folding car is largely constructed of strips of inetal joined by rivets. The wheels can be removed and re-tired in the same manner as already described. Sometimes the rivets wear and get slack, and the frame may not fold up properly. To remedy this, the rivet should be removed by filing off the shank where it has been burrea over and carefully punching it out. Obtain a new one of requisite size, place it in position and rivet it up, holding a heavy hammer against the head and riveting with a light ball peine or riveting hammer
The bodywork of this class of pram is constructed chiefly with waterproof material and suspended from wooden bars attached to the metal frame. To remove the body it is necessary to withdraw the nails and screws which secure it to these wooden bars. The front part of the boly is secured by rivets to a cross-bar of metal forming part of the franiework, and if this has to be removed the heads will have to be filed off and the rivets punched out. When the body has been removed it can be renovated with leather reviver, or may be re-covered with new material, using the old as a pattern. If the upholstery is sound, but the padding solidified, remove the covering. tease the flock or padding and re-cover as before. When replacing the body, be sure it is securely fixed to the wooden bars and atrongly riveted at the front.
The hood is removed by unfastening the screws which secure it to the wooden bars, as generally this type of hood is made up to give is kind of parallel motion arrangement, on
nickel-plnted metal strips, which allows the hood to fall forward or backwand as desited. When overhauling auch a pram, the hood and body should be removed, all the joints well oiled and all traces of oil wiped off the exterior. The whole of the metal work should be cleaned down and re-enamelled.

PERCH : The Fish. Perch is in season from the end of May till the heginning of the following February. The fish, which varies in size from 1 lb . to 3 lb ., should be cooked and eaten as soon as possible after being caught. It is difficult to scale, and sometimes the scaling is left till after it is cooked; but it is better to plunge the fish for a minute or two into boiling water and remove the scales hefore dressing it. The blanching will facilitate cleaning it

Perch can be fried according to the general instructions given for frying fish.
To stew perch. prepare a large fish and atuff it with a rich veal stuffing, tying it together Put into a stewpan $1 \frac{1}{2}$ pinta good stock, add an onion and carrot prepared and out small, also a bouquet garni. Lay the fish in the pan and pour over it a large wineglassful of port. Season it and stew it in the oven for 20 min . or longer, according to the size. Dish the fish, strain the liquor, reduce it till thick and add some matelotte sauce. See Fish: Matelotte.

PERCOLATOR. 'The apparatus known as a percolator is designed to enable liquid to pass alowly through a porous material, as in a coffee-pot or a filter. In the former a perforated metal or china plate dividea an upper compartment from a lower. In a filter the separator is often made of porous eart henware through which water drips from the upper vessel to the lower and is purified in the process. See Coffee

PERENNIAL. In gardening a perennial is a tree, shrub or plant which persists or lives on from year to year. Herbaceous perennials are those plants of which the stems and leaves die down in autumn but the rootstock lives and produces fresh growth in spring. Familiar hardy herbaccous perennials are lupin, delphinium, peony, and phlox. Hardy shrubby perennials, i.e. trees and ahrubs, are usually increased by cuttings in a frame in August or out of doors in autumn, or by layering in summer ; herbaceous perennials are increased by division in nutumn or spring. Perennials may also be raised from secds.

PERESKIA. A greenhouse succulent of perennial growth, pereskia is alan known as the Barbados gooseberry. Two species are cultivated in Great Britain, aculeata and bleo, and these are grown as stocks upon which to graft the epiphyllum or leaf-Howering cactus. Perfume. Sce Scent.

# Pergolas: In Wood and Brickwork 

## The Construction of a Decorative Garden Feature

> Gardening is represented by a great varicty of articles. These, in addition to those on the Hlowers and plants, will be found under such headings as Areh; Rustic Work; Trellis. See also Flower Garden; Garden; Path; Rambler, etc.

A charming addition to any garilen is a members are similarly mortised and tenoned pergola. It is not only an admirable device and notched to receive the cross-pieces. for displaying the colours of flowering olimbers, They are further notched on their upper side but is a means of providing a shady walk, as it to receive the lighter timbers, which are set is essentially intended for spanning a atraight on edge in the notches and laid longitudinally. walk or path. In its simplest form the Another method is to use rough poles, such as pergola is a skelcton structure, made up from larch, and simply build up the structure by prepared or rough timber, composed of uprights, spaced about 6 ft . to 8 ft . apart, connected together by longitudinal members, and oross-bars apanning the path. These should be at least 7 ft ., and preferably 8 ft ., in height, so that when they are covered with climbing plants there will be still sufficient room to walk beneath them

Oak is one of the beat materials, but any durable wood may be used. Iarch and chestnut are suitable.

Some excellent effects are obtained by the use of rough hewn timber, especially oak, which may be worked somewhat on the lines indicated in Fig. 1. The bascs of the posts ahould be charred or creosoted to preserve them from decay; they will last indefinitely if emberlded in concrete. The posts may be a bout 4 in. square, connected together by horizontal members about 2 ft . 6 in . from the ground, and roughly mortised and tenoned and pegged together The other longitudinal

Pergola. Fig. 1. Good effect obtained by the ase of rough-bewn oak, the uprights and rails being mortised and tenoned to each other
nailing suitable longitudinal and cross nembers to the uprights. This can be done with stout 4 in . wire nails.

A pergola nearly always spans one of the principal paths, the ground being marked out with lines, as in setting out the foundations of a building. Pega are placed on every spot where an upright is to be fixed, and the lines removed. If the poles are of any size, the holes should be dug to a depth of about 2 ft ., according to the nature of the soil, and the first post set up in position, plumbing it to ensure ita being upright. The earth is then filled in the hole around the butt of the post, and well rainmed and consolidated. The butts could be concreted in if desired

The next to erect is that on the opposite side of the path, adjacent to the first ; that is, assuming that the pergola is to be straight, otherwise the procedure will be slightly varied. This is set up in a similar manner, and then the two posts at the opposite ends of the pergola are similarly erected and plumbed. The height for the posts is then determined, a batten being tacked across them at the required height and tested for level, after wbich the tops are sawn off llush with the hatten

The other posts are erected in a similar manner, and as the first and last posts in the line have already heen plumbed and levelled, all that is necessary is to stretch a line tightly
betwcen the two end posts and adjust the remaining posts accordingly.
Having fixed all the uprights, the next atep is to fix the lower horizontal members, nailing these firmly to the uprights, as if this is done securely planks can be laid across them frmm side to side, to facilitate the fixing of the upper nembers, which may then be nailed in position. luring the progress of the work the posts should be sighted from end to end by looking along them to see if any of them are displaced when the error will be immedintely perceived and corrected. Hence when the horizontal and longitudinal members are fixed, and the cross members nailed into position, there will be little fear of the pergoln going out of shape.

Should the ground undulate, the top of the pergola may either be made level or can follow the curvature of the earth. In the former the post on the lowest point of the pergola should he the first to be erected When a pergola is to be erected over a curving path. regular spacing is determined by the use of two batons, one the length of the space between the poles, and the other the width between them

A permanent structure can be made with pillars of brickwork as in Fig. 2, and is often of architectural value to connect the house with some apecial feature of the garden. The brick pillars should be set up on a concrete foundation. Gaps should be left in the brickwork for the reception of the horizontal meinbers, which are slipped into place, or built in while the brickwork proceeds. The work is completed by an open roof of timber. which may be stained to a dark colour.

After a pergola has been erected it is a very: diflicult matter to paint or colour it at any subsequent time, as all the climbers will have to be removed, and re-trained after the paint is dry. Consequently it is most cconomical to use a naturally durable material such as oak or brick, and to treat the less durable ninterial with generous coats of wood preservative before attempting to train the plants around them.

PERIDOT. This deep yellowish-green stone is a species of olivine and is the month stone for September. It can he set in gold or dull silver, and harmonizes well with pink or white topaz, but needs diamonds to display its beauty to the best advantage.

PERILLA. The half-hardy annual perilln. which comes from China and has purplish ornamental foliage. is often used for summer

Pergola. Fig. 3. Charming arrangement at the entrance to a rose garden. The wooden uprights are connected by wires along whish are trained single and double varieties of climbing roses
bedding. It may be raised from seed sown the stomach and other abdominal organs; also in heat during March, the seedlings being infection may result through penetrating transplanted and hardened off for planting wounds, and other causes. out in June.

PERISTERIA. This stove evergreen orchid, Peristeria eluta, is sometimes known ая the dove Hower; the fragrant blooms, white marked with purple, n ppear in summer. It is best grown in well-drained pots or teak baskets, and needs little water during the resting period. See Orchid

PERITONITIS. Inflammation of the peritoneum, the serous membrane which lines the abdominal cavity and surrounds the greater parts of the contents, is called peritonitis. This lining membrane is liable to infec. tion from perforating wleers and ahscesses of

An acute attack generally begins with chilly sensations or violent shivering. The temperature rises quickly, and there is frequently an intense sickening pain in the abdomen Any inovement increases the pain, so thint the patient is even afraid to talk, breathe, or cough, and lies on his back with the legs drawn up and likes to have the shoulders raised to relax the abdominal muscles. The pulse rises to 120 beats or more per minute Vomiting sometimes begins early, and cruses great agony Great distension by gases occurs. Constipation omes on quickly.
To give the patient any chance of recovery an iminediate operation is necessary In the

Pergola. Fig. 2. Permanent structure made with pillara of brickwork and an open rool of timber, stained to a dark colour, over which rosea, clematis, etc., will climb
meantime, in relicve pain, apply hot linsced meal. poultices every 2 hours, covering them with cotton woal or flannels wrung out of hot water and frequently renewed.
PERIWINKLE : The Plant. This name is popularly given to the Vinca, a small family of hardy herbaccous perennial plants They like a shady position and may he planted at

Periwinkle. Star-like blue fowers of the low-growing glossy-leaved shrab that loves the shede
any time between autumn and spring. The flowers are blue or white, and propagation is by division of the roots in springtime The common kinds are major, 20 in high, and minor, 6 in . or so high. Both are suitable for planting heneath trees. There is a variety with green and white leaves. Vinca rosea, a tronical plant. is suitable only for cultivation under glass.
PERMANGANATE OF POTASH. This salt occurs in dark purple crystals, which give a deep violet-red colour to water in solution. Permanganate of potash is a very eflicient antisentio, disinfectant, and deodorizer, removing offensive smells and killing harmful bacterin.

The best way to keep it is in solution in distilled water, dissolving 1 oz in a pint of water. For use this must be further diluted as follows As a gargle, 1 oz . of the strong solution to a pint of water As a wash for ulcers and wounds, 2 or $2 \frac{1}{2}$ oz. to a pint of water.

Discoloration of the hanils or linen caused by potassium permanganate may be removed by a solution of oxalic acid. It may be used as an application for insect bites and stings, and the crystala are rubbed into incisions made over snake bites. In offensive swenting of the feet a weak solution should be used as a footbath once a day or oftencr.

PERNETTYA. This beautiful low growing hardy evergreen shrub, $12-30 \mathrm{in}$. high, is valued for the anke of its large, brightly coloured herries in autumn and early winter. The white flowers are borne in May. The species in cultivation is Pernettya mucronata, and there arc many varieties with berries of various colours-crimann, rose, mauve and purple, as well as white. These shrubs like peat soil, but will thrive in loam that is free from lime; they must be kept moist in dry weather. Propagation is by division in autumn or by cuttings and layers in July-August.

PERNICIOUS ANAEMIA. A very severe form of anaemia, which nearly always ends in death within 3 to 12 months, is termed
pernicious anacmia The disease is most common in people of midale age, and apjears to be associated with poisoning from septic stumps or other septic foci ahout the body. The pallor of the skin has a lemon-yellow tint. See Anaemin.

PEROWSKIA. This handsome shruhby hardy perennial is strongly scented with the perfume of the common sagc Its crect stems, bearing large terminal panicles of violet-blue llowers upon silver-grey growth, arc most attractive during September. There are four species, the chief being P. atriplicifolin, 4 ft . high, which must be planted in a well-drained position where it can get full sunshine. It is best propagated by cuttings planted in light soil, under a handlight, during carly sumimer.

PEROXIDE OF HYDROGEN. When diluted with an equal quantity of water, peroxide of hydrngen may be used as a lotion for wounds and ulcers of all corts. A teaspoonful made up to two tablespoonfuls with water makes a useful mouth wash or gargle for aeptic conditions in the mouth or throat ; and the same may be used for cleansing the nose or ear.

Hydrogen peroxide is a good application for insect bites and atings. A teaspoonful added to the water used for cleaning the teeth not only helps to preserve their whiteness, but alao prevents pyorrhoea. Teeth discoloured through smoking should he rubbed with a piece of cotton wool dipped in uncliluted peroxide. It bleaches the hair to a yellow colour, and is frequently used for this purpose. In the case of dark-haired people bleaching will diminish the disfigurement of superlluous hairs on the face. In speaking of hydrogen pieroxide the B.P. 10 -volume solution is usually meant.

PERRIER WATER. The natural mineral water known as Perrier water is derived from a spring at the village of Vergesc, near Nismes, in France. It contains a sinall quantity of alkaline carbonates and is an excellent table water. See Mineral Water.

PERRON. This is a term applied 10 almost any type of external staircase leading to a house, but it is generally presumed that the entrance door is ahove ground level.

PERRY. Perry is the fermented juice of the pear, just as cider is the fermented juice of the apple; the difference between them is slight, but perry as a rule is lighter in colour. It clocs not 1 aste strongly of the pear; on the contrary, a horoughly fermented pear-juice made from a vintage pear may give a liquor that is indistinguishable from a good dry cider. The pear required for perry making is a hald astringent fruit, that good for eating being unsuitable for perry. When gathered. the fruit should be sufficiently mature and should not be stored for longer than a fortnight before use.

Perry is made in the same way as cider. It ferments better if a proportion, say $\because 0$ per cent, of bitter-sweet apples, or even crabapples, is included among the pears at the timic of crushing. See Cider; Pcar.
PERSIAN CARPET. Peraian carpets and rugs normally have cotton warps and wefts. In some classes the design, made of dyed or undyed yarns, is always fastened to the warp with Selina or Peraian knot, in which the yarn is passed under the first warp, thread and over it and under the next beforc reappearing between them. The Ghiordes or 'Turkish knot, found in all Anatolians and Caucasians, whose warps and wefts are wool, as well as in some Persians and Turcomans, lays the garn over two warp threads, passes it under both, and then brings both ends through between them. The pile or nap is afterwards produced by severing the loops of the knots.
The Sehna knot may be right-handed or lefthanded, so that the nap points either to the
right or to the left top comer. With the symmetrical Ghiordes knot the nap always runs in a forward direction The lustrous sheen possessed by all Persian carpets and rugs is due to the wool being washed in soft running water, leaving the natural grease unaffected. Their durahility is aided by their harmless vegetable dyer. Silk is seldom used, except in some uncominon classes, notably the Kashans, not to apeak of the inodern commercial reproductions done in inferior dyes at Kaisariyeh. Undyed camel hair sometimes appears in field or horder in Hamadan rugs, but a good deal of so-called camel is goat. The gravest defect in modern fabrics is the substitution of the old vegetahle dyes by aniline products, which perish the yarns and cannot be mellowed. It is now the custom in the carjet trade to describe must Oriental carpets as Persian no matter from whence they coine.

Tahriz rugs almost always have florid medallion centres filling the whole ficld. This style they share with Kirmans, whose dyes are always good; but Kirman designs made al Tahriz to dealers' orders are not always guiltless of aniline. Mcdallions, with or without corner-pieces, also characterize the Ghorevan fahrice, which are almost always in carpet sizes only. Pole-medallions, which run in a series with the axes projecting. are a great feature of the Hamadan and Shiraz looms. Birds and animals, diagonal stripes, and other motives are also conimon Shiraz styles.

Very attractive is a diaper pattern of amall repeated objects, carried out in restrained and yet gleaming tones. This is much favoured for small rooms, because it does not dwarf their dimensions, and harmonizes with neutral furnishings and wall-hangings. Of these the most fainous are the Feraghans, which are highly eateemed in the East when made with the Herat design, a rosette between twolanceshaped, fish-like leaves. The field may be dark blue or rose-red and ivory, with ivory and greenish border tones; if there is much ycliow, and the Ghiordes knot is present, it should be noted that the piece cannot jossibly he antique. Saraband is usually diapered with the pear or cone design, arranged with the stems in opposite directions; in the style of Khorasan and Herat the pears all face the same way. The inost cliarming of Sarabands have borders of small conventionalized flowers linked up by a trailing vine, notahly rich rose or blue pieces with ivory horders.

Some clarsos have fields of large lloral designs without uny medallion suggestion, especially in the extensive output of the Sultanahad district. From bere come showy carpets with florid horlers of a type much affected for Ixminster squares. The mechanical sym. metry of these reproductions lacks the appeal of the unsjoiled native craftamanahip. Other better Persian designs are copied freely in the British factories, and such carpeta, whether Wilton or Axminster, are a good choice for dining room or living-room. See Carpet; Dining Room: Rug.

## Persian Cat. See Cat.

PERSLAN CYCLAMEN. This is the popular name for Cyclamen persicum, an attractive winter- and spring-llowering plant for the amateur's greenhouse some varieties of this cyclamen have prettily fringed petala, whilst others bear quaint huttertly-like flowers. See Cyclamen.

PERSIAN LAMB. A fur often confured with astrakhan, which it somewhat rescmbles, Persian lamb is a curly black skin of remarkable softness and durability. Kain does not affect it, and therefore, unlike most furs, it mak be worn with rafety in wet weather. Its natural colour is a rusty black, hut it is dyed to a much deejer shade.

PERSIAN LILAC. This is the popular name of Syringa persica, n graceful hardy shrub. It grows to a height of 4 ft ., and bears lilac-coloured fragrant blooms in May.

PERSIMMON Of the several kinds of persimmon the best known is Diospyros kaki This is a small leaf-losing tree which, if grown in large pots in a sunny, airv greenliouse, will vield its orange-vellow, plum-like fruits. In mild districts it may be grown on a sunny wall out of doors
PERSPIRATION. The sweat glands, the essential purpose of which is to extract water from the blood and pour it out on the surface of the skin, are scattered all over the body They are especially numerous on the soles of the feat and the palnis of the hands. Perspiration, although we are insensible of it, is continually flowing. The average amount of perspiration, sensible and insensible, in the - 4 hours is about 2 lb ., but exercise or heat increases the amount to an enormous extent.

The chief function of perspiration is to regu Iate the heat of the hody. People who do not swent easily are very liable to heat stroke if they find themselves under conditions which provoke this Perspiration, therefore, fulfils an exceedingly important function, and care should be taken, by keeping the skin clenn, to give it free cxit.

Excessive perspiration chiefly affects the armpits, groin, and feet, and is sometimes associated with an offensive odour. The parts should be washed once a dny at least with cold water and soap, dried thoroughly, and powdered freely with boric acid. In the case of the fect the powder should go well in hetween the toes, and the inside of the soclis should also be powdered. Shoes should he worn for the sake of coolness. The following powder could be used instend: Salicylic acid 15 gr . powder starch 50 gr , powdered talc to 1 oz For the armpits the following pouder may be dusted on several times a day after washing the parts and drying then thoroughly

l'owdered starch

| 1 |
| :--- |
| 3 |
| 3 |
| dran |

3 oz.
3
For the feet these lotions are useful, applied daily: 1 oz. formalin in 2 pints water, or water coloured red with permanganate of jotash, or a 2 per cent ointment of salicylic acid in vaseline may lic used. Those who perspire freely should always wear woollen underclothing

Perspiration stains on clothes should be treated promptly with fresh lemon juice and then washed in warm soapy water. If this treatment is not successful at first it nay be repeated, but the lemon juice should not be allowed to remain on for more than a few minutes, otherwise it may itself injure the colour of the material.

PERUVIAN BALSAM. Known some times as balsam of Peru, this is the exudation from the trunk of a Central American tree. Externally, it acts ins a disinfectant and as a stimulant when applied to a raw surface. Its chief use externally is as a parnsiticide in the treatment of scabies, nits in the hairp etc. It exerts a stimulant and antiseptic action on the lining of the bronchial tubes, and is therefore often included in expectorant mixtures in the treatment of chronic bronchitis.
When poured upon a fresh wound and covered with a bandage, Peruvian halsam has a healing and antiseptic action, and the balsam need not be changed for many days.

PERUVIAN LILY. This is the popular name of Alatrocmeria, hardy tubcrous-moted plants which grow from one to three feet high and bear showy, amaryllis-like Howers in summer. In some gardens, especially those having well-drained soil, they give no trouble, and in fact sometimes become rather a nuisance by spreading rapidly In others

Poruvian Lily. Bulbous plant of vivid hue well suited for growing in a sungy border or rockery

Courtesy of Amateur Garden'ul
where the soil is clayey it must be made suitable by adding leaf-mould and sand very freely The Peruvian lilics need a sumny place and appreciate such shelter as is provided by $\pi$ wall or fence. The roots should be planted 5 in. or $\mathbf{~} \mathbf{j}$ in. deep in spring. Some of the best kinds are aurantiaca, orange Hushed with. red. chilensis and its varieties in many rich colours, and psittacina, crimson marked with brown and green. Propagation is effected by lifting and dividing the roots in spring or by sowing seeds under glass in early spring
PETASITES. The winter heliotrope (petasites fragians) is useful for planting in the wild garden or woodland for the sake of its white fragrant flowers, which open in February, when few other plants are in bloom It grows 12 in . or so high and sprends so rapidly as to become a muisance in small gardens

Peter's Pence. In certnin Incalitjes this name is given to the honesty ( $q \cdot \nabla$ ).

PETROIL. This is the name given to a system of lubrication in internal combustion engines in which the lubricating oil is mixed with the petrol in the main tank of the machine. See Internal Combustion Engine ; Lubrication.

PETROL, or Gasoline. Thesc names are used for the lighter distillates obtained from crude oil. Petrol is highly inflam. mable, and its vapour, when mixed with air, is explosive. Special regulations govern the storage of the spirit in any considerable quantity. It must be kept in motal vessels of not more than 2 gallon capacity, pro vided with a screw stopper, so that leakage cannot take place. Not more than fio gallons may be stored in one place, or at any one time, exclusive of petrol actually in the tank of a motor car or motor cycle If the building used for storage is within 20 ft. of any other huilding notice must be given to the local authority in January of each year, and the authority may inspect the premises. Inflammable gords staclied in dumps, such as timber, are considered to be a building. The place of and intention to store must be notified to the local authority.

Apparatus or material for extinguishing fire must be provided in any place where pictrol is stored, and this applies to a privato garage if petrol is left in the tank of a motor vehicle housed therein The filling up of the petrol tank should never he done in the mesence
of a naked light. An electric light or some form of safety lamp only should be used One or two pails full of sand should be kept handy in case of fire, or a better plan would be to install one of the chemical fire extin. guishers. Small fires can usually he smothered with a damp cloth or sacking.

Water should not be used if petrol takes fire, as the petrol will floal on lop and thus be distributed over the floor of the building.
A point to remember is that insurance companies will not accept liability should it be proved that even as little as one tin of petrol is kept on the premises in which the car is garaged, unless the amount and incthod of storage are stated at the time the policy is effecterl. This does not apply to pietrol in the tank of the car or motor cycle at the time.

Cleaning Uses. As a cleaning agent for clothes, petrol has few equals. Sergc, silk. satin. felt, and velour garments of all kinds, provided that they are not of too light a colour, can be cleaned with it. It should be noted that the petrol vapour may travel a considerable distance and be ignited by a lire or lamp. Many fatalities have been cansed thus

This uork is best done in daylight, oul of doors, and the petrol in any case must be kepl a sulfe distance away from a fire or naked lighl. Niee Iry Cleaning.
Petroleum. See Parallin
Petrol Gas. See Air Gas
PETSAI. The Chinesc cabbage or petsai resembles a cos lettuce in appearance with pale green leaves and thick midribs The former are eaten like kale, and the latter. with sauce, like seakale Seed may he ohtained from specialist sccismen, and is best sown during July. See Scakale.

PETUNIA. This half-hardy llowering plant is suitable for cultivation in the greenhouse nod for planting in llower beds out of doors in summer. Though they are perennials and can he increaserl by cuttings under glass in spring, if it is wisherl to perpetuate named or spiccial varieties, it is usual nowadays to treat then as half-hardy annuals and raise them every year foms seeds sown in a heated glasshouse in February. Those which hear

Petunia Favourite greanhouse plant bearing fowers ranging from pink to crimsou and purple
double flowers must be propagated by cuttings: is finishod by polishing in these are more suitable for cultivation in pots under glass than out of doors. A compost of loam, leaf-mould, decayed manure and sand will ensure fine plants.

PEWTER: The Metal. A silvery-grey metal, very soft and ductile, pewter is oomposed of a similar group of metals to those known as Britannia metals, or alloys which contain a large amount of tin. Peuter is used in the form of sheet, and can be cast in a ladle or in a simple furnace In some typical compositions of pewter the percentages of the metals are as follows:

| Tin | Anti- <br> mony | Copper | Z.nc | 1ead |
| :---: | :---: | :---: | :---: | :---: |
| 91.5 | 6 | 1 | - | 1.5 |
| 88 | 8 | 2 | - | 2 |
| 88.5 | 7 | 3.5 | 3.5 | 1.5 |

If bismuth is added to the extent of 5 per cent the melting-point of the alloy is lowered Copper and antimony both tend to harden the
 alloy. With lead there is the danger of lead poison. ing. Pewter melta at about $400^{\circ}$ F., a temperature only one third of that necessary to melt aluminium or brass ; it can, therefore. be fused in a ladle over a gas.ring or fire. Articles to he made in pewter in the forin of enstings are Pewter. Fig.
pot. dating from $1740-50$ the lathe.
Suitablesolders for pewter are composed na follows: lparteach ol bismuth and tin, melts at. $286^{\circ}$ F.: 3 parts tin. 1 part lead, melts at $334^{\circ} \mathrm{F}$. 1 part bismuth, 2 parts tin melts at $336^{\circ}$ F.: I pari hismuth, 3 parts tin, meltr at $392^{\circ} \mathrm{F}$. A commonly used solder alloy consista of 1 part of bismuth, 1 part of tin, and 2 parts of lead The larger amount of lead may be aafely used on out. side work. Of the Huxes for pewter work Gallipoli oil, tallow, resin, and chloride of zinc are the most used. The oil is to be preforred, and can generally be purchnsed from firsi. class supply shops. This is aimply applied to the work and the solder run on in the usual way

To get a bright finish on peuter the piece should he first cleaned with benzoline to remove any fingermarks and then rubbed all over, both the worked and unworked parta, with ornot up and down

PEWTER COLLECTING The great dinary knife powder until the necessary polish attract whera. mould is prepared with moulding sand or will do well to study the collection in a good Jacohean Hagons are dignified and of aterling
plaster of Paris. The latter must be well museum, and make uphis mind to specialize quality as a rule. Georgian church plate is dried before the metnl is poured. The casting in one hranch of pewter, not necessarily to the henvy and rather dull Church plate is some.

Pewter tor the Collector. Fig. 3. Left to right : Frenct lidded measure, c. 1690-1710; Englisn porringer of Charles II period : \&cottish tappit hen, 1750 ; English bleeding bowl, Stuart period. French lidded measure of about 1710. At the back is an English dish, 1780-80 Courtesu of 11 \& A. Kimbell
ne necesary polish attract others. scribed then after cleaning as de-well-known maker are worth picking up if a snt the owner desines what is known as reasonable in price. Dishes fetch far more, satin finish to his pewter, he should obtain and a boar's head dish 24 in . in diameter is some very fine powder, such as is used by worth many pounds. Jugs are effective pieces dentiata, and use it on a flannel to polish the for diaplav, and so are chocolate and coffee pots piece. The flannel should be rubbed mund. Somo collectors may feel drawn to the collect charm of peuter is the pearly grey colour and Angons and patens may be follnd in the there is no other exactly like it. The beginner there is much faked church plate in the market. will do well to study the colleotion in a good Jacohean Hagons are dignified and of aterling

Pewter, Fig, 2. Pair of Flemish candle Fik. 2. Pair of Femish tinies made of Rritannia metal which the collector must avoid

A sinall collection of pewter may be diaplayed to advantage on a Welsh dresser or an antiquo style oak sidehnard or buffet. Tho plates will look well placed on edge, and the table portion will serve for a fow choice exhibits, such as tappit hens (see Fig. 3) or Inrge tankards A fow small cups may bc permitted on the shelves in front of the plates The drawers in the dresser, or the cuphoards at the sides, may be used for small exhibits, such as spoons,

For those who specialize in small articles such as snuff-boxes or sponns, the only satisfactory method of display is in a curio table with a glazed top.

It is no use to put pewter with brass tobacco-boxes, steel candlesnuffers, china and Sheffield plate, all mixed up together. Pewter also suffers from being placed in a room where decoration and furniture are of too ornate a description to make a gond setting. It looks hest with oak or plain mahogany furniture and in the rather old-world type of living-room, dining room or hall. To realize the effect of pewter properly displayed, a visit to the Victoria and llbert Museum may be recommended. If any specimens of pewter are imperfect through age, accident, or carelesaness. they may
be displayed in a cabinet just as specimens, or they may be restored by a careful reatorer. to render them capable of the ordinary handling to which they may be aubjected.

It is possible to lacquer the pewter, when it has once been jroperly cleaned, with an acctone varnish. which is transparent and not offensive in appearance. It is, however, far more satisfactory to clean the pewter to a certain point of brightness, not too silverlike. then smear it over with a rag which has some vaseline upon it. Rub it well with n clcan. soft velvet cloth, and afterwards at intervala, as the Japanese are asid to do to their wonderful metal work, polish with an old silk handkerchief

PHACELIA. The most beautiful flowering plant in this group or genus is Phacelin campanularia This annual should he sown out of

Phacelia. Bell-shaped flowers of the species known as campanularia of this American annual
doors in April where the plants are to bloom in summer; it grows 9 or 10 in high and bears bell-shaped flowers of rich blue colouring. It thrives heat in a sunny place and in well. drained soil.

PHATUS. This is a very old type of terrestrial orchid requiring cultivation in a stovehouse, and it is, therefore, beyond the scope of most amateurs. There are several species in cultivation, all of which grow some 2 ft . in height, and bear hlossoms of various colours See Orchid.

PHALAENOPSIS. This is a most graceful orchid with Howers on long arching stems It is grown in baskets or susjended pots in a warm greenhouse in a compost consisting of sphagnum moss and a little orchid fibre. A minimum winter temperature of about (io degrees is necessary. They need moist, shady conditions in summer and a good deal of water while growing freely, but drier conditions in winter. The flowers are white marked with various shades of colour Schilleriana and sanderiana are two well known ones, but the newer hybrids are now chiefly grown

PHARYNGITIS. Inflammation of the pharynx, the cavity behind the nose and mouth, is of three main varieties: acute simple pharyngitis, commonly called sore throat : chronic pharyngitis, frequently occurring in singers, speakers, street hawkers, and uthers who overtax their vocal organs; and acute phlegmonous, n serious but rare affection.
In acute simple pharyngitis, or sorc throat, the inflammation is superficial. The common cause is exposure and catching cold. The patient has a feeling of tenderness, dryness, and tickling in the throat. He sneezes, coughs, has a headache, and loses his appetite.

Usually the inflammation lasts only a few days or a week. The patient should remain in bed if he desires a speedy cure. To relieve the congestion and discomfort in the throat,
give ice to suck, and apply a llannel wrung out of hot water to the throat. Inhalations of steam give relief. A good application to the throat is glycerin of borax. When, the inflammation has subsided the patient should use a gargle of a $\frac{1}{2}$ teaspoonful either of glycerin of tannic acid or of alum, in a wine glass of water; or the glycerin may be painted on. He should keep to a liquid diet.

Chronic pharyngitis, or clergyman's sore throat, is cansed most frequently by over use of the voice. The patient should give his voice a long rest, and go to live in a warm, dry climate if possible. He must give up smoking and drinking alcohol if these habits are practised. The pharynx may he sprayed with a 1 per cent solution of carbolic acid once or twice a day. An excellent gargle is made of $l$ dram each of common salt, bicarbonate of sorla, and borax in a pint of tepid water. See Throat Pron. Far-in-ji-tis.

PHEASANT. Pheasants are in season from Oct 1 to Feb. 12, and should be hung for 12 to 15 days. Pheasants may be tested for age by examining the wing feathers and the spurs in the cock bird. The spurs in an old bird are Jong and sharp; in a young bird they are short or round and blunt.
In preparing a pheasant for cooking it is trussed like a chicken and stuffed and roasted as described under the heading Game I medium-sized bird takes $30-35 \mathrm{nmin}$. to roast, but the time varies according to the size of the bird and the heat of the oven.

Pheasant and Macaroni. Roast pheasant larded and served with macaroni affords a change from the ordinary method of dressing. Only young pheasants are suitable for this dish Lard closely the breasts of a brace of pheasants with small strips of larding bacon, using about 6 oz . ; cover with thickly huttercd paper, and roast for 25 min . in a inoderate oven. Then remove the paper and return the birds to the fire or oven for 10 min . longer.

While the birds are cooking prepare the inacaroni. Cook 1 lb . small niacaroni till tender in plenty of boiling salted water, strain it and return to the stewpan with 2 oz . butter and I teacupful tomato sauce and the saine of brown gravy. Mix well and let all become very hot, then season with white pepper and add 3 oz grated cheese. Do not stir the ingredients to mix them, but toss them over and over with a fork. Arrange the macaroni on $n$ dish, sprinkle over a little more cheese and pour over another teacupful of gravy, then serve the pheasant on the top of the inacaroni.

A Pheasant Entrée. An excellent inethod of cooking pheasant as an entrée is called the gipsy way. Truss the bird as for boiling and put it into a stewpan or casserole with 6 oz. bacon cut in dice; the bacon should not be too lean. Add 2 oz . butter and a tooth of garlic, and fry all together until the bird is brown. It must he turned over while frying, so that the breast may become as well coloured as the back. Now pour away the surplus fat and add 2 peeled and aliced Spanish onions, 4 peeled and sliced large tomatoes, and 2 wineglasses sherry. Season to taste. Put the lid on the stewpan, see that it fits well, and stew gently for $\frac{3}{2}$ hour, giving the pan every now and then a gentle ahake When cooked add a dust of pimento pepper, and dish up with

Pheasant. Roast pheasant. garnished with tail
feathers and served on a bed of watercress
the gravy and vegetables poured round it on the dish. The remains of cold pheasant may be used up in any of the methods described under the general heading of Game in this work. See Casserole; Chicken: Fowl: Game: Partridge.
PHEASANT'S EYE. This is the popular naine of adonis, a genus of spring-flowering hardy herbaceous perennials suitable for the rock garden. The best known is Adonis amurensis, which grows 12 in high, has deeply cut, almost fern-like leaves, and large yellow buttercup-like tlowers in March-April Vernalis, 9 in bears amaller yellow flowers in spring. Loamy soil $w$ ith which leaf-mould has been mixed suits these plants The annual kinds, autumnalis, bright red flowers in late summer, and aestivalis, red Howers in June, July, are raised from seeds sown out of doors in April in a sunny place in light soil.

PHLEBITIS. Inflammation of a vein, or phlebitis, may be of a septic or a simple character Septic phlebitis may be caused by organisms circulating in the blood, or by such organisms being introduced through a wound or making their way into the vein from septic tissues which surround it. It is a very dangerous condition, as clotting, or thrombosis, occurs in the vein, and the clot becomes infected
Simple phlebitis is more prone to occur in the gouty and in those who are anaemic. It is more likely also to occur in veins that have been in a varicose condition for a long time, or in veins in which the circulation has been sluggish for a long time

The occurrence of phlebitis is marked by pain and tenderncas in the line of the affected vein, which is felt to be firm and cord-like. If the vein is superficial the skin over it is reddened and somewhat swollen. If a large deep vein of a limb is involved, the limh below the site of the mischief becomes progressively swollen and brawny to the touch.
A person suffering from phlebitis should rest in bed, and if the affection is in one of the veins of a lower limb, as it inost commonly is, the limb should be swathed in cotton wool and elevated on a pillow. Pain may be relieved by smearing glycerin of belladonna along the line of tenderness. The weight of the bedclothes should be taken off the limb by using a bed-cradle. Large doses of sodium or potassium citrate are sometimes given in order to lessen the risk of thrombosis. See Varicose Veins
PHENACETIN. Phenacetin is a colourless, tasteless, crystalline substance which is only slightly soluble in water. Its chief use in medicine is in the relief of pain. In the treatment of severe neuralgic headache, migraine, dysmenorrhoea, the lightning pains of locomotor ataxia, phenacetin in 5 gr . doses every hour until 3 or 4 doses have been taken often gives great relief. Further, to safeguard against the possibility of heart depression following on the drug's action, phenacetin is often prescribed with caffeine, as in the following powder: caffeine citrate 2 gr., phenacetin 5 gr .

In poisoning by an overdose of phenacetin an irregular, Huttering pulse, slow breathing, blueness ahont the face, profuse perspiration, and a general condition of collapse, which may even lead to death, are the commonest symptoms. Treatment consists in applying warinth to the body by hot-water bottles, warm blankets, etc., and in administration of some stimulant, spirits or sal volatile. The patient should reinain in bed for a day or two after the symptoms of poisoning have passed off, to avoid all risk of heart failure.

Philately. See Stamp Collecting.
PHILODENDRON. The hothouse plant called philodendron has heart-shaped or arrowshaped leaves, usually of a very vivid green
in colour. The plants require a mean average temperature of $60^{\circ}$, in pots in a mixture in which leaf-mould and peat predominate. They are useful for training up pillars and onvering ugly walls, but their llowering properties are negligible. Propagation is by cuttings at any senson of the year. Wnter should be given freely daily.

PHLOMIS. This is a shrubby or partly shrubby plant of sage-like appearance which Hourishes in sunny places if ret in well drained soil. The most handsume of all is the Jerusalem sage (Phlomis fruticosa), a shrub $4-5 \mathrm{ft}$. high with grey lcaves and bearing yellow llowers in sumnier. It is increased by cuttings placed in sandy soil in a frame in July and Iugust.

PHLOX. The herbaceous perennial phloxes are invaluable border plants which are in full beauty in July and lugust. They Hourish remarkably in the cooler northern districts, and in southern gardens are best suited by heing planted in slight shade. They must have decply dug soil enriched by manure; they are not a success in poor, dry ground. If the plants are allowed to remain undisturbed for 2 or 3 years they form splendid clumps.

Propagation is by division in early autumn or by taking cuttings of the young shouts in spring and setting them in sandy soil in a slightly heated glasshouse. The finest heads of hloom are obtained by lifting a fow plants in autumn, placing them in boxes in a slightly heated glasshouse, and inserting the fresh shoots as cuttings early in spring. If put out in April-May each plant will bear one splendid head of bloom.

Many new varietics of phlox are introduced almost every year, and for them the nurserymen's catalogies should lie consulted. A few beautiful ones am Le Mahdi, Europa, Rijnstroom, F. A Buchner, and E. Danzanvilliers. The half-hardy annual phlox Drummondi, of which there are varieties bearing llowers of various colours, is an excellent summer bedding plant, for it blooms for many weeks. It is raised from seeds sown in n heated glasshouse in February-March, the seedlings being planted out of doors in May.

The dwarf trailing phloxes suitable for the rock garden are charming plants which sonn spread into wide masses if plantel in slight shade in a compost of loam, leaf-mould and sand. They are increased by cuttings inserted in sandly soil beneath a handlight as soon as the plants have finished llowering. The favourite is the moss pink (Phlox subulata), of whioh there aro several beantiful nanied varieties, e.g G. F. Wilson, mauve; the Bride, white; and Vivid, rose. Phlox amoenn hears large rose-coloured llowers III these dwarf phloxes bloon in spring

Phlox. Flowers of the herbaceous phlox, a splendid border plant which blooms in Joly-Auguat

PHOENIX. Of this palm, which is not hardy in Great Britain, the chief specics is the date palm (Phoenix dactylifera). It is less decorative as $n$ pot or tub plant when grown under glass in this country than Phoenix canariensis, a tall graceful palnı for large conservatorics. Phoenix rupicola is another attractive kind and Rocbelini, a less vigorous palm, is particularly useful. These palms thrive in a compost of half lonm and half peat with sand added freely. They need moist shady conditions and a minimum winter temperature of 50-55 degrees. Propagation is by mearis of seeds sown in pots of soil plunged in libre in $n$ case in the hot house.

## Phormium. See New Zealand Flax.

PHOSPHATE: In Medicine. The salts formed by the union of phosphoric acid and bases arc called phosphates. They are used in medicine as tonic remedies, in the syrup of iron phosphates, the compound syrup of iron phospliates, B.P.C., or chemical food, Enston's syrup and similar preparations. Sudium phosphate and effervescing sodium phosphate are used as aperients.

## PHOSPHATE: In Gardening.

The fertilizers known as phosphates are essential in the garden for the well-being of plants, as their action directly affects fruiting and llowering. These phosphates consist of various jiroportions of phosphoric acid combined with bases of organic mineral sulastances such as potash and lime.

One of the most valuable combinations is superphosplate of lime, which, in good commercial samples, contains about 25 per cent of soluble ploosphates. This phosphatic manure is best applied during spring, lightly forking it in 2 or 3 weeks before sowing or planting. It is most suitable for land with tendency towards lightness. On heavy, clayey soil another phosphoric manure, basic slag, is to be jreferred.

Bones are valuable for the phosphates they contain, and arc commercialized in a substance
known as steamed hone Hour, which is a great acquisition wherever phosphatio food is required. Other phosphatic manures are phosphate of ammonia and phosphate of potash, hoth purticularly valuable as liquid stimulant for pot plants, and used in the proportion of $\frac{1}{2} \mathrm{oz}$. to a gallon of water. See Fertilizer; Gardening, Manure

PHOSPHORUS. Ordinary phosphorus is n peculiar waxy solid substance "hich, when exposed to the air, rapidly oxidizes and readily bursts into llame. It therefore must be kept under "ater, in which fluid it is insoluble Phosphorus has the characteristic of being luminous or glowing in the dark. There aro several kinds; the white or yellow is virulently poisonous, and the red or amorphous is not poisonous. Poisonous phosphorus is present in some matehes and inamany rat poisons.
Poisoning by Phosphorus. One of the first symptoms of acute phosphorus poisoning is a burning sensation, or a taste something resembling that of garlic, in the mouth Then a burning pain may be felt in the thmat and stomach. The patient vomita, and if the matter brought up is examined in the dark it may be seen to glow. Purging occurs in some cases.
The doctor must be sent for without delay. Meanwhile, give a very weak solution of permanganate of potassium, or oil of turpentine. the Fiench variety for choice It may be given in closes of thirty minims every halfhour. The patient should be given soothing drinks, such ns barley-water, linseed ten, and gum-water. He must not be given castor oil. or any other oil, butter, fat, milk, or eggs, for three or four days.
PHOTINIA. Of this genus of shrubs the moat valuable in gardens in this country is the Chinese hawthom, photinia serrulata, an evergreen which will reach a height of 10 feet or more : it hears white Howers in June and the reddish-tinted young leaves ane attractive. This shrub is not very hardy and except in mild districts alould be planted against a sunny wall.

## Photography: How to Get Good Results

## Hints and Suggestions for Snapshots and Advanced Work

## For advice about the choice of a camera and the details of photographic processes the reader is referred to the specific headings Camera; Developing: Ennarging; Fixing: Negative ; Printing: Washing, etc. Ses also Landscapc Photography ; Lens: Panchromatic

Amateur photographers may, roughly, be divided into two classes-those who regard. consciously or unconsciously, the camern as a machine in which all that has to be done is to press the button, while the camera and the chemist do the rest: and those who regard photography as a hobby without limit in interest and knowledge.

For those in the class first mentioned the principal considerations are the methods of obtaining the resulta they want with a minimum of trouble, and the complete exclusion of the chemienl side of photography. So limited, photography can nevertheless he made an interesting and valuable hobly if the limitations are frankly acceptel, and a fow rules atudied and intelligently applierl. Photography of this kind is generally spoken of as snapshot pliotography.

Plotographers of the second type develop out of the lirst, hecause they find that the hest way of learning how to improve their resulta is to make somie study of each hranch of photographic work, and, in particular, to develop their own negatives and to make their own prints and enlargements Waeh of the scparate operations is dealt with in detail in other parts of this Encyclopedia Here will he given an outline of the subject in two sections, one for the taker of snapshots and the other for the amateur with wider aims

For the heginner the simplest, and in many ways the nost satisfactory. type of camera
is the lwox-form or other type of fixed-focus roll-film camera provided he accepts its limitations and does not expect a camera which is designed for smapalota in strong outdoor light to produce indoor portraits.
It is still a comnon delusion that a really good photograph can only he ohtained by the use of a first-class camera with a very explensive lens. It is far more probable that the lieginner will produce good photographs with the simple hox-form camera than with a more elaborate camera possessing an expensive lens It is simply a question of knowing what the camera and its lens can do

The Camera. Two things which the heginner should bear in mind from the first time he uses his camera are, first, that it is not a jress-the-lutton machinc, but a tool which requires practice for its proper use ; second, that $n \mathrm{~s}$ it is $n$ snapahot camera to be held in the hand. successful snapahots can only be obtained in stmong light out of doors. Although the simplest box camera can be used on a stand or stendied on a wall or a chnir while a time exposure is given, which means any exposure lasting longer than its to $\frac{1}{2} \frac{\text { sec., the beginner }}{}$ will generally wish to snap everything.

Whether he has a cheap camera or an expensive and clahorate une, it is imporsible to overconie the difficulty that a large number of subjects are not sulficiently well lighted to permit successful snapshots. This does not mean of course, that no results at all will
be obtained, but that the photograph will subject. The ordinary view not be a good one; it will cither give a finder is too small to show grey, flat pint with poor detail or where detail, and the only way to shadows are included, harsh and unnatural contrasts will appear

Roughly, it may be said that with a fairly cheap hand camern. having a lens working at about 1:12 (Kodak 1), sunshine, or sunlight reflected off large white clouds in a blue sky is necessary for a successful snapshot, and this only in summer time. This applies to cameras with shutters marked ns working at a speed of ${ }_{2}^{2}$ 's sec., which usually means between of and ${ }_{3}^{10}$ sec. With better lenses wo:king at $f / 8$, as found on the slightly more expensive types of roll film camera, successful resulta may be obtained in slightly dull summer light and midday winter sunshine. It is clear, therefore. that the leginner is limited in his snapshots almost entirely by the question of light.

Light is very deceptive, and when it appears bright to the eyes it may be weak from the point of view of the camera, as, for instance, sunlight under trees. The only thing that will show definitely the strength of the light is an exposure meter (q.v.), and the heginner is atrongly advised to make use of one.

The lind of camera referred to is known as the lixed-focus type, i.e. there is no trouble with focussing; so long as the camera is held more than a mininum distance away from the object to be photographed everything will be in fucus and shown sharply in the resulting photograph. This distance may he taken

Photography. Fig. 1. The optipod, a substitute for a frinod, holding a camera to a fence, walking-stick, or other object to permit time exposures Courtesy of Kodali. Lid
normally as about 4 yd It is only necessary to ree that no object nt a shorter diatance comics in the picture as seen in the viewlinder. If it d!oes it will appear hlurred and disproportionate in size in the photograph. spoiling it accordingly.

Securing Good Snapshots. The following simple rules, if carefully attended to, will do much towards securing successful snapshot photographs
See that the object to he photographerl is included completely in the view-finder. Photographs in which the top of a person's hat. or the feet, or the top of a building or other object is cut off are bad. All that is necessary is to get farther away front the object. A little practice at judging listances, experimenting on a friend or an inanimate ohject at distances from 4 to 12 or 15 yd ., will be very helpful.

Hold the camera firmly with both hands and perfectly level. If it is pointed upward, persons and buildings will look as if they were falling backward: pointed downward they will appear to be falling forward.

Look at the object squarely. Practise looking in the view-finder before exposing: but when exposing, fix the eyes on the be cetail, and the only way to be certain of snapping at
the right moment is tolook at the object.

Take a breath before snap ping, and hold it as the shutter release is pressed: this prevents movement of the camern during the instant of exposure. Exposure should be made by a firm and deliberate movement and not sharply, which may mean jerkily. Do not take a snapshot with the sun shining on the lens. With the box-form camera the lens is set inside the box, and is fairly well shielded. but with the folding camera the lens mount is shallow nnd affords little shale for the lens. Sunlight shining into the lens will lie found to give flat, misty results.

While perfectly clear photoyraphs are olitained picture, which will improve it.

Do not attempt to take distant views and wide Inndscapes with a snapshot camera They are beyond its scope. directly into the camera. The hest sna pahots are obtained when the subject is not aware that he is being photographed. This hint applics particularly to groups and strect scenes by the ses. At least (M) per cent of amateurs' failures are due to under-exposure, though it may not alvags be recognized. Use an exposure meter occasionally.

When the tilms or plates have been developerl and prints minde there is usually a chance of im proving the photograph by trimming it. With a small camera not possessing a focussing screen it is not possihle to ensure that nothing but the picture required will appear on the print, particularly in the case of snapshots. In fact. the small view-linder usually provided with roll-film cancras makes it dangerous to attempt to give the whole lilm to the subject or person smapped, for if this is done there is a prob. ahility that something will he missing in the photopraph. See, therefore, that sufficient matgin is given, hut cut it off when the print is made. Many photographs are greatly iniproved hy trimming off unnecessary sliy or fore. ground, or cutting out in. truding objects. Examples are given in Figs. 3 and 5.

These photographs, taken more or less by chance fiom an amateur's collection of snapshots containing many succesaful pictures. show several faults common to a large proportion of snapshots One is insulticient care in choosing the view-point. getting too far from or too near to the obiect of the picture Often a movement of a few feet to one side or forwards will obviate dilliculties and prevent

Fig. 3. Improvemant by trimming print. Building is falling backmard
because camera was tiffed upward
foreground objects bulking too - largely or getting ton much foreground. Another fault is not holding the camern straight
If the printing of the suapshots is left to the chemist or photographic dealer he can be relied upon to make the prints on paper hest suited to the particular negatives. A matt or semimaft surface paper gives softer and more pleasing results than glossy paper (unless the sharpeat rletail is requircd, is when thic photograph is to le reproduced ill a newspaper or hook), and the amateur will do well to ask for his prints to lic made on these mntt papers.

Do not hlame the chemist if the photographs turn out badly Grey and flat prints are almost invariably duc to badly exposed negatives. The modern husiness of devetop. results will sun shining from hehind, lictter ing and printing amateurs negatives is so whed with well orgalized and cartied out on the scientific one side or a little towards the front, principles of time and temperature develonfor then some shadows will be included in the ment that properly exposed negatives will

As far as possible, prevent people staring

Do not he afraid of over-exposure, except

Photorraphy. Faults in amateur snapshots. Fig. 2. Camera ot beld straight, too much foreground, unwanted piece
development until the correct methody seiniautomatically obtained by the tank have familiarized him with the appearance of good negatives. Even if he uses plates or flat films he should employ a developing tank in the same way hefore he attempta dish development by the dark room lamp

No written deacription can convoy a olear idea of the appearance of a correctly exposed and developed negative. and the amatcur without this knowledge who attempta development hy the aid of the dark room lamp is almost certain to go wrong With some films and plates and developers the image flashes up quickly in the developing bath and there is the consequent temptation to take the negative out lest it be over-developed. whereas the truth is that after the ininge has a ppenred time is required to build it up in the negative. A negative which looks bright and full of detail under the red lamp will! give fat and grey prints after fixing, herause it has been removed from the develojer before development is complete. With other films, plates. and developers the reverse is the case, and the imange appeara slowly. The safest rule is to folluw the scientific methods of development by time and tempernture accorrling to the tables giren with most developers.
Do not make any attompt to correct either over- or under-exposure ly varving the time of development of "dodges" lor correcting faults in exposure, hut modern scientifio working has proved them to be uselces. at leagt as far as the nmateur is concerned.

While still using his camera largely as a hand cainernthe amateur can en large its scope greatly by pro. viding a stand or tripod for it, so that time exposures may be kiven under the many conditions when smapshots are bound to be failures Even without a tripod a little ingenuity will find support by pressing the camera firmly against a post, tree, fence, or wall, or placing it on top of a wall or post packed level with small stones. A simple device for fixing the carnera is the Kodak Optipod, shown in Fig. 1, by means of which any convenient tree, fence, or even a walkingstick may be used. With the latter it is quite possible to hold the camera suff. ciently steady to give $t$ or $\frac{1}{8} \mathrm{sec}$ exposure.

Next, the use of different shutter speeds marks At the same time, if he is properly bas to be studied. If the camera has only ambitious he will consider the elementary one apeed, usually marked $\frac{1}{2}$ sec, but actually somewhat slower, this can be overcome to, some extent by olosing or opening the dia phragm By closing the diaphragm, i.e using a smaller stop, as explained under $\mathbf{F} /$ numbers the exposure is ahortened, and vice versa.

The beat way of increasing the range of photographic possibilities is to invest in a camera with a fairly good lens with an aperturo of about $1 / 6.8$ and, perhapseven more im portant, a really good shutter giving accurate speeds of from 1 sec to $\frac{1}{6} \mathrm{sec}$. It is the lack of a slow shutter speed that is the greatest a slow shiter speasure. The camern sces all and records fault in cheap hand cameras With the all with a fidelity that may have a disastrous slower speeds, say $\frac{1}{3}$ or $\frac{1}{2}$ sec., good photographs can often he obtained, the camera heing steadied, when a snapshot would mean bad under exposure

The amateur must practise the technique of his hobby until he can obtain negatives fully exposed and fully, but not over, developed. sharply focussed, clean and without stains, clean nd without stains, holes, raph in artistic arrangement of his photo graphs in the posing of the original subject, whether personal or natural, and in the production of his pirints.

Pointing the comera at a beautiful scene and pressing the button will not necessarily produce a beautiful photograph. The camera does not see as the eye. Its range is linited and it is far leas selective Looking at a scene that impresses one, the unimportant and perhapa unpleasant items are passed over and hardly noticed in the general impression result. Some selectivity result. Some selectivity
is therefore essential. A lamp pust can be avoided by moving the camera a foot or two to one side Similarly, obtrusive objecta which would fill the foreground of the photograph are often reduced in inpmortance by moving back.

Some Useful Hints. Following are a fow hints which will help in the pmduction of satisfactory photographic pictures even of the simplest and most unambitious lind.
Do not get ohjects of different or opposing interest in the picture In other words, concentrate on the subject to be photographed, and let the hackgmund be no nore than background. In most cases it is the foreground that makes the photograph.

Do not have the most intereating object in the middle of the picture. The centre is the weakest point. Keep the principal sulijert alightly to one side, or alightly aloove or slightly below the middle. On the other hand, do not arrange the picture so that the eye is led out of it towards the side. A river. for instance, should come out of the picture at the buttom right or left corner, not at the side.
Avoid bare expanses of sky or flat foreground. Trim oñ the print at top and bottom to reduce these defecta. Plain white skics do not exist in nature, and if panchromatic plates or films are not used, so that sky and clouds are inoluded on the negative, either print in clouds from a special cloud negative, taken at the same time as the particular landscape, or trim the print down so that the minimum amount of sky is shown.
In phetographing buildinga, nuch better and more interesting pictures will be oblained if parta, details such as doors, windows, glimpses down aisles or thmugh arches, are taken, rather than if the whole, inside or outside, is attempted. This rule frequently applies to landscape subjects, particularly wooded scones, as explained under Landscape Photography.

PHOTOGRAVURE. Photogravures that have been damaged by expusurc, dirt or greane can he cleaned by immersion for several hours in benzine in a Hat, shallow photographic dish. The dish mist be kept covered and no naked lights permitted in the ronm, owing to evaporation of highly inHammahle vapour Afterwards dry and brush over with clean, soft linen. This removes grense and dirt held by it. Other discolorations can tie got rid of by hathing in hydrogen peroxide, 10 vols strength diluted with 1 part of water, in a photugraphic dish. the photugravure being exposed to strong daylight while in process of immersiun.

An alternative method is to follon the henzine bath with a prolonged immersion in
sodium carbonate solution, 2 oz . of washing soda to 8 oz . of water, finishing by thorough washing in running water to remove all soda. See Carbro Process : Printing.

## Phthisis. See Consumption.

PHYLLOCACTUS. The phyllocactus has large flat stems, no leaves, and red, white, or pink flowers borne chiefly in summer. It is one of the favourite cacti for cultivation in pots under glass. It should be potted in well-drained pots in a compost of sandy loam with which hroken brick or mortar rubble has heen mixed. A sunny, airy greenhouse suits this plant best ; it must be safe from frost in winter. Propagation is by means of cuttings. During summer the phyllocactus needs a good deal of water, but little in winter. There are numerous named varieties with large showy flowers.

PHYLLOSTACHYS. Of this hardy bamboo several species are of considerable ornamental value. A position sheltered from cold winds is most suitable, and deep loany soil that does not dry out in hot weather is required. Bamboos do not flourish in poor, dry soil. Some of the most decorative species are aurea, which has yellow stems, fastuosa, Hexuosa, henonis and the blackstemmed nigra. All are of tall and graceful growth. The whangee cane for walking purposes is furnished by these bamboos. The old canes or stems ought to be cut out in April. Propagation is by lifting and dividing the clumps in September or May.

PHYLLOXERA. Also known as the vine louse, this small insect is very injurious to vines, and although more prevalent in America and upon the continent of Europe than in Great Britain, it is scheduled by the Ministry of Agriculture as a notifiable pest. An attack may be recognized by the warty or knotty appearance of both foliage and roots. As a rule the remedy is complete destruction of infected vines, thorough cleansing of the vinery, and the introduction of new border soil. The Ministry of Agriculture must he notified at once of the appearance of the pest, failing which a heavy penalty may be imposed.
PHYSALIS. This is the botanical name of a hardy herbaceous perennial known as Chinese lantern or winter cherry. It is grown for the sake of the enlarged, orange-coloured lantern-like calyces which enclose the true fruits: they are in full beauty in late summer and early autumn and are cut for decorative use indoors in winter. The leafy stems die down in autumn, and at that season the plants may be increased by lifting and dividing the clumps. The sorts with the finest "Ianterns" are Franchetti and Bunyardi. Physalis edulis is the Cape gooseberry.

PHYSIANTHUS. The evergreen green. house flowering, climbing plant Physianthus alhens attains a height of from 10 to 15 ft . It has red and white flowers, borne in ear!y summer. It should be planted in a large pot or tub. in the ordinary potting mixture, and placed in such a position that it can be trained up walls. rafters, or pillars Propagation is by seeds or cuttings in spring. In some parts of the country it is known as the white bladder flower, on account of the downy and bladder-like appearance of its

## blossoms.

PHYSICAL TRAINING. Systematic training for the promotion of health and the development of the body can take many forms. One of the most convenient, because it is practised without apparatus, is the Swedish system, often referred to as free movements. It was an important part of the training of the British soldier during the Great War. and forms the basis of the syllabus of physical exercises for puhlic elementary schools issued by the Board of Education. It is divided into groups, each concentrating
on a certain part of the body. and in this way muscles are brought into play which have hitherto been dormant, or nearly so.

One result of the system is to develop the chest and increase its measurement. To do this the gymnast takes deeper and more complete inspirations, filling the lungs with fresh air to their maximum capacity. This habit of adequate respiration, which is one of the main features of the system, tends to
improve the general health and fitness It cannot be too strongly emphasized that correct breathing is a vitally important factor in all branches of physical training. Much benefit may be derived by taking 10 to 15 ninutes' Swedish drill night and morning. If performed indoors a window should always be opened to permit of good air heing breathed. See Breathing ; Drill ; Dumb Bells; Exercise ; Gymnastics: Indian Club.

## Pianos: Mechanism, Choice and Care <br> With Instructions about Doing a Few Elementary Repairs

Owing to the presence of a Piano in almost every home this article is one of the most important of those dealing with musical matecrs. Others are Flutc: Harp; Player Piano: Violin. See further Gramophone etc.

A piano is $\Omega$ percussion instrument having steel strings struck by felted hammers which are set in motion by the depression of keys. The keyboard consists of a recurring series of long (white) and short (black) levers or keys, scven of the former and five of the latter in each octave. No pianos are now made of less compass than seven octaves $A$ to $A$, while most modern instruments have this compass extended to C .

Parts of the Instrument. To each note there are three strings (trichord), except in the lower part of the compass, where spun copper covered strings are userl, two to each note as a rule, but in the lowest octave of all only one. All these strings of varying thick. ness and length are stretched from the wrest pins over upper and lower bridges to other pins on the frame. and are subjected to a very high tension, the pull of which in a concert grand amounts to some tons, to withstand which there is a frame of iron or steel.

In most modern pianos the strings are made to cross one another so that the greater length thus obtainable in a smaller case may produce more sonority This is called overstringing. Behind or under the strings lies the soundboard, usually of Swiss pine or fir, joined up and varnished. The action consists of several independent but co-ordinated parts, which move on a key being struck and impel the hammer against its string, at the same time providing that it recoils instantly. An inıportant plart of the action consista of the dampers, which are small pads of felt lying upon the strings to prevent them vibrating. They are lifted off in the process of playing, and remain off so long as the key or keys are held down. Upon the latter being released, the

damper falls upon its string and stops or dampa its vibrations. In the very highest part of the compass they are not necessary, as the extreme shortness of the strings renders the sound very evanescent. The whole of this action is contained within a wooden frame. enabling it to be removed bodily.

Lastly, there are the pedals, of which there are usually two. The right or sustaining pedal, when depressed, suspends the whole of the damper action, irrespective of the fingers. In a grand piano the left pedal shifts the action, so that the hammer escapes striking one string of the three The unstruck one, however, vibrates sympathetically, thus producing a different quality of tone. But in most uprights, either the hammers are shifted nearcr to the strings so as to lessen the force of impact. or else a strip of felt is interposed between the ham. mer and the strings. This last is called the celeste pedal. In both instances the very characteristic una corda effect is lost.

When the strings are horizontal the instrument is either a grand or a square. the latter being very rare in Great Britain The mote usual form of instrument is that in which the stringsare stretched from top to bottom, known as an upright; if of larger make, an upright grand; if of smaller, a cottage piano ; or smaller still, a pianette. Naturally, the larger the instrument the fuller and stronger the tone, because more sonorous strings can be used. As regards the case, this is sometimes of solid oak, mahogany, or American walnut, but as a general rule it is either stained in imitation of ebony or rosewood, or else it is veneered in walnut.

There are other terms connected with the case which need explanation. The lid is the top of the instrument. It is usually divided
into two halves, the front half working on a long hinge The front panel is immediately below this, and upon it are fixed the music rest and the sconces. The bottom panel is just above the pedals The fall covers the lieyboard, and is joined to the hollow by a long hinge. In some pianos there is a nome board bearing the maker's name, though this is generally placed upon the fall. The 1 russes are the nore or less ornamental supports under the keyboard on the right and left

Choosing a Piano. In choosing a riano the purchaser should be prepared to spend as much as he can athord, as cheap pianos are seldon good investments. To the uninitiated eye the instrument may appear as highly finished as a inore expensive one, and its tone may even seem as good, but it is unlikely to wear well. It is thercfore advisable to go to a maker or dealer of reputation, and to avoid places where pianos are n mere side line to other articles. It is best to pay cash down if possible, as most firms are then ready to niake a substantial concession. If this be not possible, there is the instalment system It is usual to liave an agreement, and it is well in make sure that it is not one-sided and wholly against the purchaser if he should, by any chance, fall behind in any of his payments.
The first test of a piano is that of the tone Everybody has his own personal preferences, but, in general terms. the tone should be full, mellow, and powerful, without any trace of hardness or harshness. A good tone has depth and richness, whereas a poor one, despite apparent brightness, seems shallow and all on the surface, lacking singing quality. Avoid a brittle high register, like playing on glass, and what is called a tubby bass, i.e. weight of tone without richness. If the buyer is also a player, he can judge for himself, but otherwise he shonld onlist the help of a friend. The tone should exhibit perfect evenness throughout the compass, without a single break. This evenness can casily be tested by playing scales in single notes at various speeds up and down the piano.

The repetition should be perfect. Try several different noter, high, medium, and low, by playing each as rapidly as the fingers can move. Test the damper by playing passages and staccato chords-without pedal, of course -and listen for the insiant cessation of vibra tion. What is termed an underdamper action will be found to give the best results, as the damping is quicker and more effective. 'l'ry the peda!s and see that they are doing their work well. Pay particular attention to the touch, which should respond to the wishes of the player as expressed through his fingers. Persons nccustomed to an old. well-worn piano rometimes think that the touch of a new one is stiff, wherens it really is better regulated and more calculated to produce all shades of tone Notice whether the white lieys are ivory or celluloid. The latter substance is more generally used to-day. Ivory is greatly to be preferred, but it adds to the cost. As to the case, the best makes are distinguished by good taste rather than by assertive ornamentation, which in a wellfurnished room is apt to prove an eyesore.
It is quite possible to pick up a bargain in the shape of a second-hand piano, especially when one hears of it privately; also, most makers and dealers have such instruments either returned from hire or taken in part payment for new ones. But the purchaser should be wary of pianos included in cntalogues of after-season sales, especially if they are by obscure makers. A second-hand piano should be tested in the same way as a new one, but it is ndvisable to see, at the same time, if the hammers arc much cut by use, and whether moth has attacked the felt, bushes, etc.

A piano is very susceptible to changes in the atmospherc and temperature. It is best placed
against an inside wall, at a fair distance (rom it; if possible, a cross position is preferable. In no case should it be near the fire, close to a window, or next a door through which there is a strong current of air ; all these will cause it to go out of tune

It is not ndvisable to place objects such as books, ornaments. or vases of flowers on the lid of the piano. They lend to disngreeable jarring or buzzing. and if water is spilt more damage may be done in a minute than can be remedied in a month. Open the lid frequently ro as to ventilate the interior Condensation of moisture on cool surfaces is common in every roons, and this can as easily happen inside the piano as outside it. So-called ominmental covers should also be taboo. The use of insulators or glass cups, though sometimes neccessary to proteot the instrument from damp, may not only cause inconvenience to the player hut also putundue strain on the pedals through raising the piano too high. A foot rest should therefore be uscd in such cases.
It is the custom for the firm which sells the piano to tune it for 6 months free of charge, after which it is the duty of the purchaser to see that he gets a competent tuner. It is false economy to rave a few shillings a year by employing an inferior man. The piano should be tuned at least four times a year, or oftener if it is much in use. Sometimes little defects will develop which should be left to the tuner to remedy.

Cleaning the Plano. Once a year the piano should have a spring clean, for dust and Huff will find their way into the best-cared-for instrument, and cannot but affect the tone. First open the lid back, and then remove both top and bottom panels by undoing the hooks, buttons or stavs by which they are kept in place. Next take of the fall and hollow, which will be quite easily done. To take out the action, turn back the catches on each side, firmly grasp the frame at the sides, give it a alight pull forward, and the whole can be lifted out. It should then be placed upright on the floor in some position where it will be in no danger of falling
Now remove the keys in regular order from the bottom to the top, and place them on a table. They are all numbered, but it will he convenient to preserve the proper sequence. In removing them, ease them gently off their pins. With a light brush of soft hair, or of feathers, dust down the strings, and then remove all dirt from the bed underneath the keyboard and from the base of the instrument, bring carcful not to damage any of the baize bushes. On no account use a duster unless it is perfectly dry. When the cleaning is over, replace all the parts in the inverse order to which they were taken out.
Ivory has a natural tendency to turn yellow with age, but this discoloration may be retarded, even if it cannot be wholly prevented, by cleaning the keys frequently from the dirt and perspiration which fingers are bound to deposit. They can be well rubbed with a chamois leather wrung almost dry; the rubbing is done with the tip of the finger, so as to avoid any damp coming into contact with the wood at the side of the key, each key being immediatcly dried with a soft cloth.
Very occasionally the ivory may be rubbed over with a little uncoloured methylated spirit; this will help to keep it white Another recipe which has been recommended is to use lemon juice instend of spirit. If the keys are very discoloured it is best to seek expert advice. The case should be dusted lightly with a soft cloth; hard dusting with harsh material rubs the dirt into the polish, thus destroying its lustre. Never use furniture cream; use, instead, a soft cloth, very slightly damp. sprinkle a few drops of paraffin uloon it; a nd apply it lightly. To prevent any damage f́rom moths, camphor balls may be employed.

Simple Repairs. While the services of п competent tuner should be utilized regularls to keep the piano in playable condition. small breakages sometimes occur in the interva! between his calls and cause considerable annoyance by putting the instrument out of use for the time leing. Although interference with the mechaniasm of a piano by an inexperiencel person is to be deprecated, there are certain minor repairs that can be undertaken by the handyman. The following hints are intended more particularly for the bencfit of those in remote districts who cannot call in the expert at a moment's notice

Broken Strings. One of the most frequent troubles is the hreaking of a string. In the case of a steel string this may affect either one note or two aljacent notes. The portions of the wire that has suapped should be cut off as close as possible to the tuning pins in the wreat-plank and the loose portions carcfully drawn out. This prevents any jangling noisc in playing the instrument. but it reduces either one note to a monochord or two adjacent notes to bichords, and conserpuently decreases their volume

This procedure should be followed in regard to the covered strings. except that the bottom portion need only he eased off the hitch pin and drawn out. In the case of a bichord there will still be one string playable. but a single string note will be dumb. In the latter case care should be exercised, when playing, either to miss the corresponding key or to touch it as lightly as possihle to avoid breaking the section of the action. Since there is nothing now to stop the travel of the hammer, breakage of the tape or of one of the flanges of the action may result. The liroken pieces of wire or string must be retained to scrve as』 pattern for replacement.

Broken Hammer Shank. Another occa sional mishap is the breaking of a hammer shank. If the tracture is a finirly long one, the two pieces can he jointed together with seccotine and hound round with strong silk or linen thread. If. owing to shoit grain in the wood, the breali gives insufficient glucing surface, it can be apliced temporarily by means of a thin piece of light wood glued on immediately in front of the shank, so as to resist the force of the blow, and this splint should be atrengthened as before with si!k or thread wrapping. Care should be taken, however, not to increase the weight of the shank more than can be avoided since this, in turn, will affect the weight of the touch.

Where a permanent repair is desired. the procedure is to remove the broken pieces of shank from the hammer head and butt. This is done loy melting the glue in both joints by means of a small blow lamp. or, failing this, a petrol filled cigarette lig! iter which does not give off smoke. Whatever form of heat is applied, care must be taken not to scorch the wood. When the glue is sufficiently softened. the pieces of shank can be twisted or pulled out. Where the application of heat is ineffective, the shank nust be cut off at the point where it enters the head or butt and the remaining piece drilled out. Care must be taken not to enlarge the diameter of the original holcs, and the drill must follow the original direction of the looles This is particularly necessary in regard to the head, and the need for this caution will be appreciated by noting the angle at which the head is fixed on the shank

Making a New Shank. Before cxtracting the broken shank it is better to shape the new one 'This should preferably be minde of the same wood as the rest of the set-mahogany. cedar maple, etc.-but if this is not readily obtainable a shank can be made from a piece of thin dowelling. The grain shou!d run in the direction of its length to lessen the risk of
the shank snapping under the force of the blow. A piece onger than will be necesanry should be cut from the dowelling and glass papered down to the thickness of the original ahank It should then be slightly filed at one end to fit into the hole in the hammer head When filing, the shank must he kept turning in the hand to ensure its being perfectly round An alternative method is to use two long files. One file is laid on a bench or other flat surface and the tip of the shank to be inserted in the heal is placed on it. With a stroke o the other file the tip is made to travel under pressure between the two and the fibres of the wool are thus compressed until the diameter is sufficiently reduced to allow the shank to enter the hole and fit tightly but without having to be forced in.
When'a satisfactory fit has been obtained a small groove is made with a marking gauge along the tip to allow the surplus glue to escape. To fix the shank to the head a blob of seccotine is dropped into the hole and the shank is turned in the fingers as it is preased home so as to form a ring of seccotine at the dge of the hole. The other end of the shank is prepared and fitted into the butt in the same wry, but the shank must first be cut to the correct length. It is essential that the ength aliould be exact, otherwise the hammer will not hit the strings at the correct nodal point and impurity of tone will result.

To arrive at the correct length, the measurement of one of the adjacent hammors is taken from the small centre pin in the flange (to which the butt is hinged) to the centre of the wooden portion of the hammer head. This measurement is usually about $5 \frac{1}{8} \mathrm{in}$. but it may be slightly more. The new hammer shank is then roughly tipped to allow it to enter right down to the bottom of the hole in the butt 'The measurement of the new shank s then taken from centre pin to centre of head, and the difference between this and the first measurement cut of the new shank. The latter is then re-tipped and fixed in the butt as alrendy deocribed. To allow the liammer to be turned to form the ring of seccotine the tape should first be carefully laken off the check wire
Replacing the Hammer. In replacing, care must he taken to sce that all the parts of the rection are in their correct position. When forming the ring, the hammer head must be lelt in correct position, and to ensure this the hammer is carried forwarl to its note and the nose of the hammer placed in contact with all the strings forming that note
In many pianos, especially overstrungs, the hammera are on the slant, and the new haminier must be in line with its neighhours to prevent fouling. To olstain this slant the tip of the shank that enters the butt, after being prepared, is filed slightly on the side opposite to that to which it inclines. Should the hammer nfter fixing not be quite in correct alinement it has to be "cast." This is done by henting the shank-the petrol lighter will serve for this purpose-and bending it either with the finger or pliers in the required direction The hammer should be held in position till the shank has cooled and set This operation must be performed gradually and repented till the required position is attained. The butt whould be held firmly while casting, to prevent strain or breakage, and the casting should not be done til! the seccotine has thoroughly iardened. Should $\Omega$ hammer head becone ooqe this can be easily refixed with seccotine, care being taken that the head is in correct position in regard to its neighhours and its note as already mentioned. A broken tanc can be temporarily repaired by fixing the broken ends with seccotine to a hacking of narrow tape
Repairs to Keys. In regard to the keys, n soraping or creaking noise is sometimes caused
by a chip or shaving on one key rubbing against another. This should be renoved with a chisel working the wry of the grain. Should two keys rub together at the front the piano has to be opened out and the faulty key taken off the pins. Underneath the front of the key will be found an oval-shaped pin This should he very slightly turned with the pliers. so that its flattened side inclines to the front only just sufficient to give clearance If turned too far, or if the pin is roughened with the pliers, the key will stick. If clearance hetween two keys cannot be obtained in this way it means the key has warped and requires the tuner's attention

Where an ivory or celluloid front or head has come off a key these can be readily refixed with seccotine after the old glue has been care fully removed from both surfaces. Ordinary glue should not be used for fixing celluloid, as it is apt to cause discoloration.

The Pedals. In regard to pedal troubles, an annoying squeak sometimes occurs. This may siniply mean that the pedal hinge requires oiling, but it may also arise from two rockers rubbing together or the front rocker fouling the inside of the bottom door. Where this occurs sufficient wood can he removed with a chisel from the offending rocker to give clearance. The replacement of a broken pedal is better left to the tuner.
PICKLE. Foods stceped in'a preservative, auch as salt, ןrepared brine, vinegar, or some similar acid, are known as pickled or pickles. Vegetables such as onions; beetroot, red cabbage, and cuoumber are either pickled separately or together. Fish or meat may be pickled, as, for example, salmon, herrings, pork, or beef. Walnuts or tomatoes also may be pickled, the former alone, and the latter usually as an ingredient in a mixed pickle.

An excellent pickle is made with celery and tomatoes boiled with vinegar, sugar, and spices in the proportion of 2 heads of celery broken small to 9 tomatoes, 1 brcakfastcupful sugar, $\mathcal{l}$ breakfastcupful vinegar, 1 tableapoonful salt, and $\frac{1}{2}$ teaspoonful each cloves, allspice, cinnamon, and mustard All the ingredients should be brought slowly to boiling point in a preserving pan and simmered for it hours. While hot the pickle should be poured into jars or bottles and sealed up.

Some vegetables require a more highly spiced vinegar than others. Cauliflowers pickled separately should be cut into sprays, sonked for 9 daya in brine, blanched for 10 min., dried and put into jars with spiced vinegar poured over them. To make this allow $\frac{1}{2}$ oz. mixed pickling spice to 1 pint malt vinegar, boil, add 1 teaspoonful salt, boil again for 5 min . Strain over the cauliHower and allow to grow cold before putting into jars. Ilways tie pickles down very closely, and after a week or two, if the vinegar has been absorbed, fill up the jars with a further supply. For French beans, lay in brine as for cauliflowers, then hoil them in the liquor, adding a tableapoonful of vinegar until they acquire a good green colour. Usc the pickle vinegar hot.

For cucumber pickle use very small cucumbers. Rub them all over with salt. then cover them and lave them for 9 days, turning them each day. Drain and cut them into oubes, and lay them in a basin lined with well. washed and dried cabbage leavea Pour over them enough boiling vinegar to cover them; lay over the top more leaves, and leave them n a warm place all night. Next day strain off the vinegar and drain the cubes. Preparc the basin again, using fresh leaves; arrange the pieces in it and pour the vinegar over them again, after boiling it up. Cover as before with leaves and set to stcep. This process must be repeated for 2 more days, when the colour of the cubes should be much improved. Now put the cuoumber into jars, boil up the
vinegar with pickling spice, let it go cold, and fill up the jars

Onions should not be used for about a month after pickling. Peel a pint of the pickling variety, sprinkle with salt and leave overnight: then put them into some boiling apice-flavoured vinegar. The latter may be prepared from 1 pint white wine vinegar, oz. allspice, $\frac{1}{2}$ oz. white peppercorns, 1 or cloves, and 1 teaspoonful salt. Let them boil, and then simmer for a few minutes and skim the top before putting in the onions. The whole should cook for about 5 min . bcfore being poured into a jar and tied down

Piccalilli. This mixed piokle is composed of various vegetables cut into portions and favoured with hot spices. It is made as follows: Prepare a small cauliflower and cut the flower part into neat pieces, peel $\frac{1}{2}$ pint button pickling onions, string 18 French beans, peel 12 small shallots, then cut into cubes 4 oz. vegetable marrow, also prepared, and wipe 12 gherkins.

Sonk these vegetables in brine with 3 or 4 capsicums for 9 days, but dry them well before pouring on them the following pickle ; also add 3 cloves of garlic. For the pickle, to 1 quart white wine vinegar add oz. salt, $\$$ oz. sliced ginger, $\&$ oz cloves, 1 dram each mace, black pepper, and white pepper, and $\frac{1}{d}$ dram cayenne pepper

Steep the spices in the vinegar, letting it remain in a warm place for 3 days, then boil it up alowly. Mix 2 oz. dry mustard and $\frac{1}{2}$ oz. turmeric to a thin paste with a little cold vinegar and add to the boiling spiced vinegar. Now add the vegetables and boil all together for 5 min , then set to cool, and when quite cold put into jars. If very hot pickle is not desired, lessen the amount of cayenne pepper.

If all these vegetables are not obtainable at one time, make up the pickle with those which can bo had, and add the missing in gredients as soon as available. This pickle improves with keeping, so that a little delay in finishing it will not harm it.

Pickled Herrings. Soused or pickled herrings can be bought in a prepared form and are then ready to eat immediately, or may be soused at home (see page 593). Dutch pickled herrings are imported in flat tubs To prepare these wash thoroughly and suali for 2-3 hours in milk. Cut off the heads and tails and divide the fish into fillets about 1 in . thick. Pour vinegar over them, or a sauce composed of 3 tablespoonfuls salad oil, 2 tablespoonfuls mixed vinegars, such as chilli, tarragon, herb, or tomatoes, and I teaspoonful each chopped parsley and shallot, and a seasoning of pepper
The herrings may be garnished with.slices of hard-boiled egg, but root chicory, or sonie suitable salad herb, or a well-mixed plain salad, may be served with them Salt should be sprinkled to taste. Salted herrings make a good luncheon dish.

Pickle Fork. These forks are usually made of silver or electro-plate with bone, ivory or mother-of-pearl handles, or entirely of the metal. A variation is a telescopic pickle fork. This fork lengthens so that when piciles are low in the containers they can he easily reached. A substitute for a pickle fork, and one which is useful for such varieties of pickles as walnuts, which might split it pierced with a fork, has spoon-shaped ends. Thesc open and close by manipulation of the spring top. See Beef; Herring: Marinade : Pork; Red Cabbage; Walnut.

PICK-UP. This is a device for reproducing gramophone records electrically, and is used in conjunction with a wireless receiving apparatus. The pick-up is the clectrical equivalent of the sound box used in the ordinary gramophone, and in its elementary form may comprise a permanent magnet having an
armature arranged so as to pivot freely bet ween the magnet pole pieces．The armature may have a chuck for holding the gramophone needle，or alternatively the needle itself may form the armature．A winding of silk or enamel covered copper wire surrounds the magnet pole pieces or the armature．

In operation the needle and therefore the armature vibrates in sympathy with the undulations of the sound channels on the record，thus causing changes in the magnetic field produced by the permanent magnet These changes are communicated to the coil winding and voltages arc set up across its ends．These voltages are then applied by way of the pick－up leads to the grid and nega－ tive filament，or grid bias negative，of a low frequency amplifying valve，and magnified up to a strength sufficient to work a loud speaker

A pick－up requires careful and skilled design in order to avoid unpleasant resonances and undue wear of the record．A good pick－up employed in conjunction with a properly designed low－frequency magnifier and a cone or moving coil loud speaker will give excellent reproduction over the range of musical frequencies covered by the record．

The average pick－up is highly sensitive，and in many cases two low－frequency amplifying stages will give ample volume for domestic purposes．In the case of the less sensitive piok－ups the detector valve of a wireless receiver employing two low－frequency stages may be arranged so as to act as an additional amplifying valve，the pick－up being switched directly into the grid circuit of this valve．

## Switching in the pick－up

A single pole change－over switch is required， the connexions being as follows：The lead joining the grid condenser and one side of the grid leak to the grid of the detector valve is disconnected from the grid terminal on the detector valve－holder and transferred to one side of the change－over switch．The centre or common terminal of the switch is connected to the grid of the detector valve，and the remaining terminal on the switch is joined to one side of the pick－up．The remaining side of the pick－up is connected to the $1 \frac{1}{2}$ or 3 －volt grid bias negative socket on the grid battery

Thus in one position of the f⿴囗十介itch the set functions as a wireless receiver in the normal manner，whilat in the other position of the switch the piok－up is connected in oircuit with the low－frequency magnifier，the high－ frequency side of the receiver being discon nected．This switching scheme may also be employed in sets which incorpornte only one low－frequency stage

If a volume control is not already included in the low－frequency circuit of the receiver， it is advisable to connect a potentiometer having a suitable reaistance value dircetly across the pick－up itself．This method，in addition to providing an efficient control of volume，also prevents overloading of the first amplifying valve．
The pick－up leads should not be permitted to trail across the set or to become entangled with the loud speaker leads，since this is liable to cause instability．It is frequently heneficial to earth the pick－up tone arm．See Gramonlunle．

## Picnics：Suitable Fare and Accessories

## How to Plan，Pack，and Serve in Appetizing Fashion

Suggestions for menus and special pienle ware are given in this article．See also the entrles Luncheon：Salad；Sandurich

Whether $n$ picnic is at the bottom of the garden，in a hut on the beach，or in some far－ diatant heauty－spot．its essential character－ istio is lack of formality．In summer，when sunny days permit，tea，luncheon or supper out of doors can be a delightful form of entertaining guests，or of varying the monotony of home meals for the family，eapecinlly during holiday times．Succesa in all cases though mainly dependent on a factor outaide the control of the organizer or hostess，namely， the weather，is also subject to good planning， good fare，and a suitable location
The meal selected is a matter of choice， though tea－picnics are the most usual．largely hecause they are the easiest to arrange．When the entertainment is simply and solely a pienic for children，where ten is served and games played nfterwards，woods are popular for the actual meal，but there should be an open space near for the games．Rounders is often part of the programine，and sporta with prizes are sometimes organized．The ideal place may be some distance away，and means of locomotion have to be studied．A small party may pack into a car ：a larger one may have the use of cars which are loared ry friends；but where a number of children are being enter－ tained，hrakes or a private omnibus may be hired，a method which usually gives great enjoyment to the guests

The food need not be elnh orate for such a picnic：but there must be plenty of it． It is astonishing how hungry people get in the open air This does not mean that any thing is good enough to offer the guests．The breand used for the fish－paste，egg and cress，mustard and cress，and cucumber sandwiches should be both brown and white and as freah as is consistent with neat making．Crusta are better left on，both for reasons of economy and also because the sandwiches keep a better shape．Bridge rolls，alightly sweetened brioches，and cur－ rant bread are all excellent for children＇s tes picnics， whether only buttered of sandwiched with jam，honey and sliced banana，walnuts and raisins or lemon curd Butter ahould be creamed before apreading， and fillings should be generous enough to prevent any reproaches of dry or du！l fare， but not so generous that they ooze out uncomfortably at the first bite．Bought sandwichea are seldion the success that nicely home－made ones are．To keep the bread freah wrap） them in waxed grease－ proof paper first，and then fold up in wet butter－muslin．

Very rich caker are not only too expensive，but out of place nt such a pienic．All the sponge inixtures are liked including jam sponge sandwiches．Swiss rolls， simple layer cakes and sponge fingers．Rock cakes，dough－nuts and the various plain and

Picnic．F／R．1．Luncheon and tea outht for lour persons．The gaily－coloured ware is non－fragile，very light，and easily packed Courtesy of Messrs．Beall

Picnic Luncheons．The same type of fare can be taken for the fanily lunclieon on the beach．or when 1 laskberrying some distance from home，if the sandwiches have more substantial fillings or home－nade Cornish pasties，veal and ham pie or patties（these last are convenient because they do not necessitate knives and forks）are added to the menu．Anchovy or any other sa voury hard－ boiled egg dish and individual salads packed in cardboard cases with a box of amall gruyère or other cheeses to be eaten with buttered bread．rolls，or biscuits are also simple to prepare．Home－made potato and onion salad with ham and tongue or beef sandwiches make a favourite meat course．Creams and jellies may be taken in their moulda Tomatoes and soft fruit can be carried in punnets． Jaspberries or strawberries should be well covered with cabbage leaves and placel so that they will not be crushed in transit．

When a picnic is given with a view to entertaining gueats in an informal manner．

a slightly more elaboiate equipnient and menu may be required and prepared. Where practical, it is a good plan for the hostess to name in the invitations an hour when she will ring up the various guests to contime arrangements. This obviates the had weather uncertainty. Often if all preparations for food have bcen made and the ensuing day proves wet, the party can be given in the house, and the guests will enjoy a helpyourself cold luncheon almost as much as the proposed pienic. A good menu would be either anchovy eggs or prawns in aspic, chicken and ham (in portions), or veal and ham pie or chicken sandwiches, salad, fruit-jelly and cheese biscuit sandwiches or cheese straws and a variety of small genoese pastries. If fruit salad is taken it may be packed in a container with a screw lid, and cream is better whipped before starting, and taken in a glass jar with a screw top. Mayonnaise dressing for the salad can be packed in the same way: Coffee may be carried in a vacuum flask either hot or iced. A jar of pickles may be added and condiments must not be forgotten.

For a grown-up party a cocktail is sometimes necded. This is best carried in a shaker containing a vacuum for freezing mixture. A pleasant non-alcoholic drink to vary lemonade is jinger ale punch, made from 3 oranges, 3 lemons, 2 grape fruit, 1 pint ginger ale, 4 oz. castor sugar and 1 pint water. The juice is squeezed from the fruit and the ginger ale, water and sugar added and allowed to stand. Some prople take a large jug, squeezer and ingredients and make this punch on the spot Menus for picnic suppers are exactly the same as for luncheons. For moonlight parties hot soup and hot coffee are generally appreciated.

The case illustrated in Fig. 1 contains a One effective type of picot edging is shown complete outfit for luncheon and tea for in Fig. 1. It consists of a series of small four people, and is very light in weight. loops of embroidery thread, between each The plates, tumblers and cups are of non- two loops a simple oversewing or buttonhole fragile ware in brilliant colours, and food. stitch being made in the material, to ensure containers, flasks, spoons and knives are all that if one loop is accidentally dragged, it packed into a conveniently small space will not pucker up the rest of the loops. 'lumblers in the same ware are obtainable in a Although this cdging is easy to work, care has separate leather case, and plates. cups and to be taken to make the loops of an even length, saucers may also be purchased singly as otherwise the effect will be spoiled. It should required. A useful accessory is a combined also be noted that the edge to be trimmed must corkscrew and stopper opener.

Tea if carried in vacuum flasks should have milk and sugar packed separately. An excellent ideat invented for use with a thermos flask is a tea-infuser. This simple but ingenious device provides a method for brewing tea when required. The flask is filled with hoiling water, tightly corked until tea is wanted. when the requisite number of spoonfuls are placed in the infuser, which is provided with a hook for attachment to the rim. When put into the flask the beverage is quickly ready to serve freshly mede. Should ice cream le a part of the menu, a general-purpose thermos jar is obtainable with wide opening to permit easy filling, emptying and cleaning. Separate containers can be stowed inside such a jar when it is wished to take several iced or hot dishes, the food being retained hot or cold for several hours. Another method for providing ice cream at a picnic is to take a half-minute freezer (see page 488).

The vacuum jug shown in Fig. 2 is particularly useful for carrying hot coffee

Picot. Fig. 1, How to make an ornamental looped edge. Fig. 2. Buttonholed picot used in openwork embroidery Fig. 3. Substitute for picot formed by a cut line of hem-stitching
first be neatly faced in or hemmed. Com. mence at the left-hand end of the edge by pushing the needle through the material from the back to front. Carry the needle a little farther along towards the right, and ngain push it through the edge in the same way, and draw through the cotton or silk until a loop of the size desired is made ; then make a tiny buttonhole stitch in the material inmediately to the right of the loop. Continue in this way along the edge, and fasten off on the wrong sidc.

Another type of picot is shown in Fig. 2. 'This is a buttonholed picot, and is much used in Richelieu work to decorate the many buttonholed hass or strands which form the open-work part of thís embroidery. A trimming for collars, cuffs, or house linen can be made by buttonholing the material cdge and working these picots at frequent intervals. The edge that is to be decorated in this way need not be proviously neatened, hecause the buttonholing will itself make it quite neat.

Commence by buttonholing along the edge of the material, beginning at the right-hand end; then when the position at which the first picot is to be made is reached, work 3 more buttonhole stitches. Carry the needle back to the right, and slip it through the head of the first of these 3 stitches, and draw through to leave a tiny loop of the cotton or silk. Buttonhole stitch along this loop in the same way as a loop is made for fastening purposes, and when the left-hand side of the loop is reacherl, procced to buttonhole the edge ns before, until ready to make the next loop.

If desired, the loop can be made thicker by earrying the needle back to the left side before buttonholing it, slipping it through the
last stitch, and then carrying it back to the right-hand side, as before. In this way there will be 3 strands of cotton in the loop over which to buttonhole. If the loops are set fairly closely together, the edging is a pretty finish for table mats.
Imitation picot edging is formed of $\Omega$ line of hemstitching which is worked by machine, and afterwards has the outer coril cut away, to leave the out bars of the hemstitching forming a serics of cut ends, as in Fig. 3. To obtain this picot, simply run a coloured tacking along the edge that is to be trimmed, anci take the fabric to $n$ sewing-machine shop to be hemstitehed along this ine: then cut the outer cord of the hemstitching away. With this edging there is no nced to hem or face in the edige of the material.

There are many other picot edgings. length of crochet chain, for instance, sewn along the edge of a tray cloth or runner in a series of loops is very effective, or it may be worked directly on to an open-meshed material, passing the crochet-hook through the edge after each loop of chain is made, and making it secure by means of $\pi$ double crochet. Picots in crochet arc chiefly used to form a background or filling for Irish crochet and to make a picot edge on narrow edgings and Inces. See Crochet ; Embroidery ; Richelieu Work.

PICOTEE. This old type of border carnation has a narrow band of colour at the edges of the petals. There are two types of picotecs, the white ground and yellow ground, the edge being of various coloursrose, red, purple, or scarlet. Picotecs need the same cultivation as border carnations.

## Pictures and Picture Frames <br> How to Hang and Frame Prints and Paintings

This article is one of those that deal with decorative accessories for the home; others being Curtain: Mirror; Rug. See also Cornice: Drawing Room; Living.Room; Panelling; Passe Parlout: Queen Anne Style; Vic:orinn Style

A picture is onc of two things, either sinuply a decoration upon the wall, or else the illusion of a landscape or figure subject seen through a hole in the wall Frames for the first type of pictures should be nieraly borders or part of the whole acheme of the picture: for the second type they should linve some solidity or depth which gives them power to divide the pictures front their surroundings
The earliest frames were architectural in design Most pictures being painted for churches, altarpiece frames were in the asmo character as the arches of Gothic huildinga. The Italian frames of the Renaissance period were made exactly like doorways and windows enclosing painted portraits and clnssical figures with an illusion of reality. The frames had the same upright columns, lintels, sloping hase lines and pediments of the windows and doors of the period.

With the introduction of landscape painting pictures became popular and enclosure for protection was necesaary. Metal frames finely decorated with leaves and festoons were produced in France Gilded and carved wood and geaso decoration followed, and many beautiful frames were designed in England. At the beginning of the nineteenth century it became the fashion to frame everything from a miniaturc to a huge landscape in gilt frames to match, irrespective of style of picture. Later in the century the walls of living. rooms were completely covered with pictures, the gilded frames of which were usually of more importance than the paintings.

To-day framing varies from the strip mouldings, cut in lengths and mitred at the corners to the specially designed carved frames taking into consideration light and shade effects and period of pictures. The art of framing and hanging pictures is governed by three things -place, picture and period. With regard to
place, there should he general ngreement with surroundinga. In modern ronnis a fow prints and pictures of the decorative typo look well when framed or re-frumed to suit the furnishing schemes relected. Flat frames of harmonious colour are the hest choice. Old f́mies do not mix happily with inodern ornamental nccessorics.
lictures of the recond type of interest, historical, port raite, landscapes or figure pieces, nust be considered on their own claims. Sometimes they are too heavy for the living. roons, hut may look well in the hall or on the staircase. Oil paintings require well recessed and not flat frames. Carving is added so that light and shade shall play on the surface of the frame. In this atyle of picture such framing does not detract from the interest, but adds to it. 'The frames should alan possers such fentures in their designs as connect them with the school to which the painting belongs in style and period These features may be studied at big picture galleries with representative collections. Another intereating thing to note is that inould. ings and ormaments will correspond with those in use on furniture, etc., of the period and the influence of Chippendale, Robert Adanı, and other grent designers can be scen.
Generally speaking. a better effect is gained by hanging pictures, with the exception of one over the mantelshelf, at the eame level all round than by arranging them at different levels. An example of such good placing is seen in the illustration of a living-room in page 734, Fig. 4. On panclled walla such as are there shown, any haphazard hanging or mixture of frames would spoil the decorative scheme of the roon. The tendency is to hang them too high; the lower edge of the picture itself, not of the frame, should in most eases be on the eye-level of the beholder when
standing. By inclining the frames slightly forward the reflection of the glass is avoideal and also the ascumulation of duat
Care of Pictures. Old frames should never be regilded without discrimination, especially as much modern gilding is far from being durable. The brass hooks uscd on picture rails tend to disintegrate where gna is used, and may cause pictures to fall. Heavy frames should be supported by three vertical wires or chains, hecause this minimizes the risk attending the slipping of one of them. When the glass is being cleaned pads may be placed behind the upper edge of the frame, to keep the pioture rigid; otherwise the supports may become dislodged. Fly-marka may be removed by a damp cloth or brush, the spot being dried immeliately after. Nildew will usually hrush off. If for any reason a canvas is unglazed, it may be kept in condition by means of a dry feather and a silk handkerchief

The task of cleaning or restoring pictures is best entrusted to an experienced person. If they arc antique canvases, covered with the grime of generations, they mny without much risk be sponged over with warm water. Soap should not be applied without experience, and acid and alkaline fluids are risky. The darkened condition of inany pictures is due pither to the cxcessive use by the artist of siccatives, or to the action of time. Such pictures cannot be properly renovated, and when they are retouched or repainted the monlern pigments may not age in the same way as the original ones, so that the picture conies to look pratchy and unplensing. Sometimes thic original can vas has been so weakened that it nerds rebacking. All these vicissitudes demand nuch skill in their treatnient.
Hanging Pictures. Pictures should be suitably framed and liung against a barkground that will enhance their beauty. A picture rail is a convenience where large pictures are to be placed, except in a panelled or period roon, when, unless the pictures can be themselves trented es panels, they must be placed with great discretion and hung so that neither wires nor supports show.
It is not a difficult matter to fix a picture rail. The succeeding article on this subject should be referred to. Brass hooks for the picture rail can be obtained with a stamped decoration (Fig. 1), or plain.
The beat way of hanging pictures on walla not providel with rail or rods is by means of onc of the picture suspenders which can be obtained from the ironmonger. That shown in Fig. 2 is attached with long fine steel pins driven into the wall at a slight inclination, and will hold a picture up to 50 lb . in weight. Another form of hook shown in Fig. 3 is fixed with a single pin, and is made in sizes to hold weights of $30,40,70$, and 100 lb ; the method of fixing is shown on the right. These pins are intended for plaster walls; for brick-faced wills the beat method is to use an ordinary stout brasshended nail, but the wall should be plugged first. This may be done by using n manall cold chisel and then filling the hole with a wooden peg, or by the fibre plug method.
Ordinary cord is convenient for hanging small pictures, but it is not advised for heavy ones. Stranded picture wire is much more

Pictnre Hanging. Fig. 1. Brass hook for picture rail. Fig. 2. Banger for wall with no rall. Fip. 3. Hanger fred ithasingle steel pin. Fi
Brass dicture cbaln
suitable for general use. Brass picture chain as shown in Fig. 4 is known as patent chain, but ordinary brass jack chain with plain round double links can be used. Stout brass screw eyes should be fastened in the back of the frame about half-way down the width of the top piece. Pictures that require a tilt ahould have the screw eyes about a quarter of the way down the sides of the frame.

In hanging a picture, sufficient wire or chain should be provided to support it at the approximate height ; the final adjustment is made by shortening or lengthening the wire at one of the screw eyes at the back of the frame. Although a single length of wire attached to two screw eyes and supported on one hook will be sufficient for pictures of ordinary size, it will be necessary to use two separate lengths for heavy oil paintings or large engravings. Stout screw eyes should be driven in the frame, and the chain carried vertically to nails or hooks on the rail.

Picture Framing. Although the maiority of picture frames are put together with the mitre joint, one which is usually regarded as troublesome to deal with, there is nothing specially difficult about it if proper tools are used. A fine backsaw is the first requirement. It is almost useless to attempt to use a coarse one, as it is sure to splinter out the grain, and will probably ruin the mitre block on which the mitres are cut. The mitre block is a device for cutting mitres accurately without elaborate marking out. The important point about it is that on no account must the saw be forced in it. It is purely a guide for the saw, so that the latter must run frecly in it.
A useful appliance, though it is not an absolute necessity, is a mitre cramp. This holds the parts of the joint firmly together whilst the nails are being driven in. A hammer and punch are also needed. The Warrington type hammer is the most convenient, but practically any kind of carpenter's hammer can be used.

Materlals. It is usual to buy picture frame moulding ready made, as it is so cheap and cleanly finished that it does not pay to attempt to make it. All sorts of patterns are obtainable. Some are in plain wood, oak or some other hardwood, and may be just moulded or te partly embellished with an embossed design. The latter type looks attractive, but calls for extra care in mitreing because the pattern must be balanced.

Another type of moulding has a highly polished surface of composition. Here, again, care is needed in order to avoid chipping. A
Fig. 1
Rebate
third kind of moulding is gilt. This usually has a fine, smooth finish and
gives a different effect from those frames in which gold paint is applied after the frame has been put together. All picture mouldings have one point in common in that they liave a rebate at the back in which to accommodate the picture and glass.

Other materials include cheap thin wood backing. Practically any thin wood can be used. Plywood is excellent for the purpose.

A good quality glass should be used, one of a good clear transparency, which will not give the picture a distorted appearance due to inequalities in thickness. Some brown paper to back the whole, screw eycs to hold the cord. and a few picture sprigs are the only other requirements.

As the picture has to fit in the rebate of the moulding, the size of the frame must be based on the rebate size. Fig. 1 is a section through a pictur moulding and shows the rebate clearly. As a practical example, assume that a picture measuring 10 in . by 7 in . has to be framed. Whilst the rebate size is all-important it is necessary to ascertain the overali size because, when the moulding is placed on the mitre block, the back edge touches the kerf in the block. This back edge necessarily represents the overall size.

Fig. 2 shows how the calculation is made. The moulding should be measured on the under side from the rebato to the back edge, not the complete width. In this case it measures 1 in . Consequently, the overall length is 10 in . (the picture length) plus 1 in . at each end (the moulding), giving a total measurement of 12 in . To this it is advisable to add, say, it in. to allow clearance for the picture. Similarly, the height bocomes 9 in. full. The rebate causes a margin of the picture to be hidden all round. If this is to be avoided the picture must be stuck on to a slightly larger sheet of paper so that only the projecting part of the paper is hidden.

Cutting the Mitres. Place a piece of moulding on the mitre block and, holding it firmly against the back, cut one mitre as shown in Fig. 3. Notice that back of the moulding touches the kerfs in the mitre block, not the rebate side. The reason for this is that the saw is not so liable to split out the grain as would be the case if the
moulding were reversed If cut carefully no trimming is necessary.

From the point of the mitre mark the overall length along the back of the moulding. Place it again on the mitre block with the mark slightly to one side of the kerf in the block. In this way the mark is just left in when the second mitre is cut. If this were not done the frame would te a trifle under size.

Proceed similarly with the opposite side. but take the length from the piece already cut, this is because the opposite pieces must be exactly the aaine length When the two remaining sides have been cut the four pieces can be tried together on a flat board. Somc workers prefer to trim the mitres on a nitre shooting hoard, but this should not be nccessary if the work has been done carefully.

Assembling the Frame. There are various ways of doing this. Those who have a mitre cramp will find this a qreat advantage. The mitres of two adjacent pieces are glued and placed quickly in the cramp. When the members of the moukling coincide exactly the tightening screws are turned, and two nails are driven in, one in each direction Fig. 4 shows the r.rocedure. In the case of extra tough wool it is $\Omega$ good plan to first drill fine holes.

Next the two opposite pieces are put together in the same way, so that the work at this stage is in the form of two letters L. The moulding can be taken out of the cramp immediately after the
in and punched honc. nails have been driven in and punched honc.
It is now merely a matter of joining together the two parts, and this is done in exactly the same way.
If a mitre cramp is not available the bench vice can be used to hold the one fiece whilat the nails are being knocked in. In this case it is essential to drill a hole in the upper piece and drive in a nail so that it just projects at the mitre. Otherwise the blows of the hammer simply cause the upper piece to slip, down. In any case a small amount of slipping is to be expected, and for this reason it is necessary to placethe upper piece a trifle lugh, as shown in Fig. 5. The hammering soon brings it to the correct position. Fig. 6 shows the work in the vice.
A point always to be remembered is that nearly all picture mouldings are

Fig. 5. Upper plooe of moulding is placed slighty high to coanteract downward alip thinner to. wards the rebato. Consequently the nails must be so placed that they go into solid wood. Nothing looks worse than for a nail to emerge at the surface of the moulding. If this should happen the nail should be tapped back and withdrawn, and another nail driven into a more solid part of the moulding.

When assembling the snitres in the vice the left hand should alwavs hold the upper picce
ol mouldingapartly to steady it and partly to prevent it from turning on the nail. It may be found g.fter all four sides have been put together that the frame "winds" slightly, that is, the four pieces are not in a true plane. 'This is easily ascertained by laying the frame on aflat hoard If it is not true.

Picture Frame. the two diagonally opposite corners will stand To hold it in position a few picture sprigs are up a trific. This is casily corrected by placing the frame face downwards and tapping the corners lightly with the hanmmer, care being taken not to break the joints.

A third method of putting together a frame is shown in Fig. 7 It has the advantage that no nails are driven in until after the glue has set There is thus no danger of the joints

Picture Frame. Fig. 8. Back ol picture, showing sprigs and paper backing
slipping. All the mitres are glued and the four parts are laid in position on a flat board. To squeeze out any surplus glue the parts of ench mitre should be rubbed together. A piece of strong string is then tied around the whole, thus binding the sides together. T'o force the joints tightly together eight small pieces of wood are cut out, and two are passed between the string and the moulding at each side near the centre. By sliding the pieces towards the corncrs the string is tightened. At least twelve hours must elapse before the string can be taken off and the nails driven in.
No matter which method of assembling is adopted, it is important that any surplus glue is cleaned of before it hardens. It is difficult to remove hard gluc cleanly, and it looks most unsightly in a joint. If the glue is used carefully and sparingly it will not be squeezed out on the surface of the moulding. If it should ooze out it can be wiped off with a swab damped with hot water.
Putting in the Glass. If the worker has a glass cutter he can easily cut his own glass.

Probably the majority, however, will prefer to take the frame to a glazicr, who will cut a piece of glass to size After the glass has been thoroughly cleaned and polished it should be laid in the rebate, care being taken not to finger-mark theinner side. The picture is laid over this and a piece of backing prepared. If thin wood is not available a piece of stout cardboard can be substituted. It should be of such a thickness that the back is level with the back of the frame.
driven in all round as shown in Fir 8 These are headless and can be tapped down so that they scarcely project. A piece of brown paper is pasted down over the whole. This gives a neat finish and excludes all dust Small screw cyes can be put in at the sides to hold the cord.
To hide the nail holes plastic wood or was should be pressed in. If the latter is used it should be heated and dropped in from a pointed match stick. When it has cooled it can be levelled down with glass paper. If the frame is to be stainel or painted this should be done before the glass and picture are inserted.
PICTURE RAIL. As a rule the wooden moulding or rail incorporated into a wall surface to support pictures and other omaments should be at a height equal to the architraves on the door, but space may require this to be raised or lowered. Several typical sections are illustrated.

In new work the picture rails are generally fixed to rough grounds embedded in the plaster, oval brads being used which are punched helow the surface, the holes being made good with putty or hard stopping. In a room devoid of a rail the picture rail inay be fixed by the use of wall plugs and screws, the holes for the latter being carefully stopped

Occasionally the picture rail may have to be cut and removed to permit a wardrobe or other article of furniture to stand Hat against the wall. This is accomplished by sawing the moulding across with a fine-toothed tenon saw, placing a piece of card above and below the moulding so that the saw will not damage the plaster. To repair such a moulding will require a new piece of the same section, which is cut to fit between the existing ends of the picture rail and painted or stained to match the existing work.

Metal picture hangers are used which are curved in such a way that they fit sccurely over the edge of the moulding, thus doing anay with the necessity for nails, and allowing the position of the pictures to be changed at will, without any disfigurement of the walls.

PIE. In some parts of the country the words pie and tart are interchangeable, but usually there is a distinction het ween them, a tart being open and baked in a shallow tin, while a pie, with few exceptions, is deeper and has a covering of pastry. See Apple Pie; Fish; Game; Pastry, etc.

PIECRUST : On Furniture. In furniture design this term is used for a certain kind of edging sometimes found on small tables. It is waved or scalloped and is raised above the flat centre because the latter has

Picture Rail. Fig. 1. Typical examples of simple picture rail mouldings shown in section
been worked down with the tool. It is chietly scen on mahogany tables of the time of Chippendale style.

PIER : In Building. As used in domestic building construction a pier is a stone or brick pillar, or a projection built out from the face of $n$ wall to strengthen it or to carry any excess of local weight. A small portable building is often arranged to rest on a number of low brick piers. Timber plates are

supported by the piers, and the Hour of the to build the four corner piers first and then building rests on these plates (see Garage). level them, if necessary laying one or two The piers will be proportioned to the size and weight of the building, but for most erections in connaxion with the home the piers will suffice if built in 9 in . brickwark

The first step is to excavate the soil until a sufficiently firm bottom is reached; a bed of concrete about 18 in square and 6 in. to 9 in . thick should be laid at the bottom and as soon as the concrete is set the brick piens can be crected upon it. The simplest plan is level them, if necessary laying one or two
courses of tilcs, but getting the heights uniform The intermediate piers may then be built. levelling them by stretching a line tightly between the corner piers and resting upon the tops. The remaining piers can then be built up, and the line will serve to keep, them uniform both as regards direction and height. After the mortar has set hard the timbers may be bedded on the top of the piors and the building completed. See Bric:k; House.

## Piercing in Metal Work

## Directions About a Graceful Form of Ornamentation

Th.is contribution is one of those dealing with the decorative working of metals. See also Bent
Iron Work: Meral W'ork; Napkin Ring; Repousse
For the $h$ me craftaman, pierced metal carbon paper and is transferred to the metal work offers a very attractive occupation. and many of the articles which the amateur metal worker producos can be ornamented by piercing. It does not cost a great deal for the apparatus, neither does it require a work bench. the only real essentials being a good, firm table and a stendy light. The tonls are few and inexpensive, the most important being a metal.

Piercing. Fir. 1. Design 10 pierced metal napkin ring laid fiat. and ghowink the measurements of the piece of metal necessary for the work
piercing salw, a work tahle known as a sawing table, and a cramp to affix it to the table.

The table can be made from a piece of 1 in. deal with a $V$-shaped piece cut from the front part. This open portion is th allow the saw to move while the jaws or side pieces support the meta!. The width and shape of the opening can be modified to suit the work in hand. The material used for pierced metal work is thin shect metal, either brass, copper, zinc, or pewter, and genernlly No. 24 gauge. The thickeat metal that can be cut by hand is a bout No. 16 in copper or brass.

As a task for the beginner the napkin ring shown in Fig. 2 can be cut in copper, brass, or pewter, about No. 20 gauge in thickness. It is a 1)-shaped ring ornamented with a monogram The
file or cleared away unless this is done projertion catching sawing table and breaking the salw blade. It will save trouble to make all the holes at the start. so that the sawing can continue with. out interruption.
The piercing-saw is clearly shown in Fig. 4. The saw clamp nearest the handie is fixed to the latter, and the one at the end of the frame is free to slide in and out of a square hole in the frame. This clamp is adjustable by means of a smal thumb nut ; its pur. pose is to tighten the blade when it has been fixed in the clamps.
The effective length of the frame can be altered by sliding the back of the frame in or out after loosen ing the locking serew. To fix a saw blade in the frame, first see that the teeth are pointing downward. that is, towards the wooden handle. For exterior work, fasten the raw into the top clamp, then press the
end of the frame against the edge of the table, thus cansing the frame to spring a little; keep the frame in this position and fix the blade in to the lower clamp. and screw the thumb nut tightly. The spring of the frame will tighten the blade, and further pressure can be brought on it by tightening the thumb nut at the end of the frame, thins drawing the clamp and the saw very tight. When the saw is twanged like a harp string, it should give out a decided musical note. It is very important that the blade be tight, or it will not cut properly and will specdily break

On internal work the saw has to be passed through the hole in the metal, as shown in Fig. 3 when it can be tightened as described, although some workers prefer to fasten and unfasten the top clamp, as then the work can rest on the left hand while the right is employed in clamping the blade

The next stage in the work is to fasten the saw tahle to the work bench with screws or with the clamp, and rest the work on the top, of the saw table with the part to be pierced over the hole therein, and with the edge of the part to be cut as near to the sides of the table as is possible. Then with the left hand hold the metal lirmly to the table, and with the right conimence the sniving.

The whole of the cutting is done on the down stroke, and on the up stmke the saw blade should pass as easily through the saw cut as possible. Keep the saw perfcctly upright. ns in Fig. 4, and make about 2 strokes per second. Maintain this rate of progress, and continue the cutting steadily with an even pressure throughout the whole of the time the blade is at work When the blade is working on a straight line there is not so much risk of it breaking; when cutting curved parts the blade must be kept going steadily all the while, as if it is twisted in the hole it will be almost certain to break. Should the blada show the slightest tendency to stick, it can be lubricated with $a$ little oil or tallow.

When the first hole has been cut the others can be dealt with in the same way. The
expanded design is ${ }^{\mathrm{givec}}$ Fig in leading dimensions being indicated. In cutting the desired monograin it is essential that the letters be

Fif. 2. Napkin ring, tue making of which is described here

formed by removing the metal around them, and that they have sufficient support from the framework The articles on Initial, Lettering, and Monogram will form a guide in making the design.

A full-size design should be prepared on thin paper, and the sheet of metal is cut with a pair of tinman's snips to a rectangular shape with overall dimensions a little larger than the design. The metal is then flattened and cleaned up on the surface with fine emery paper. The design is placed over a piece of
going over it with a blunt pencil.
The next step is to cut the nutside of the metal to shape, doing this with a pair of snips or sawing it with the piercing saw if the outline is at all intricate. A pair of cutting snipa with bent jaws would be a useful addition to the tool kit, and is employed for cutting curved outlines. A small hole must be made through the metal just inside one of the lines that define the outline of one of the larger holes. This may be done either with a small drill in a handdrilling machine, or, in the case of thin materials, with an awl. The rough enges of the metal on the under side of the hole should be filed flat with the end of a small with a countersink, as there is a risk of a on the surface of the spoiling the cut or

Fig. 3. Threading the gaw for Internal work. Fig. 4. How the saw and work Cable are used. Fir. 5. Filing the edges true with a jowelier's needie file Fig. 6. Shaplng the ring on a wooden block, after which the joint is brazed or silver soldered, and the ring finished by polishịng. plating, or lacquering
saws are made in various grades, or numbers of tecth to the inch, and as $n$ general guide it oan be taken that the harder the metal the greater the number of teeth per inch will be needed
After the pattern has been cut out in this way, the edges may be a little rough, and it will be advisable to clean them up with fine fics The work can be held in the hand, as in Fig 5 , or the metal can be grasped in the vice between two pieces of hoard. When filing, watch the progress carefully, as a few careless al rokes with a file will destroy the appearance of the whole design. The metal is fashioned to the desired curvature by bending it over a shaped worren block with the hands, finishing hy gentle hammering with a repoussé or other llat-faced hammer, as in Fig. 6. The joint is afterwaids brazed or silver soldered, and the work is then cleaned up. Finally it is polished, laequered, or plated, whichever is found to be most suitable to it.

PIER GLASS. Strictly speaking a pier glasy is a mirror of such shape and size that it can be fixed between two windows, the name bring due to the fact that the word pier in one of jts senses means the wall space between two openings. l'ier glasses were seen in the great houses of the 18th century, and often pier tables were made to match them. Their principal features were their size and the richness and elaboration of their carving and gilding. The phrase, however, is now used somewhat loosely for a looking-glass suitable for the dining room, drawing room, or one of the other irception rooms of the housc. See Cheval Glass: Dressing Table; Mirmer

PIERIS. This is an evergreen llowering shrub belonging to the heather family. It liears panicles of white blooms in the spring

Pieris, a bardy evergreen shrub with beather-like flowers in apring and early summer
and early summer months. It likes peaty soil, but will flourish in lonmy soil which is free from lime. Planting should be done in September or in April-May. The hardiest kinds are floribunda and japonica, which grow 3-4 ft. high and Hower in April-May. A more vigorous and less hardy kind is Pieris formosa, which is chiefly suitable for planting in mild districts Little pruning is needed, but the shrubs should be clipped lightly when the period of llowering is over. Propagation is by sceds and layers

PIER TABLE. This is one of the several forms of the occasional or side table. The name was first given to a table designed to stand against a wall between windows, the reason heing that the wall space there is sometimes called a pier. Seen in the inore affluent houses of the 18th century, many of them had marble tops and were designed in the Louia style, although they were

Pier Table. Antique example veneered with satinwood and other woods. English, about $1770-80$ R"l special permiasion of the Director, Victoria
a pier table is a light table, the marble top having given way to a wooden one, made to stand at the side of a room. Its usual form is a reproduction of the antique example illustrated See Table
PIETRA-DURA.
This is a form of Italian inlaid work in which marbles, agates, or other liard atones are inlaid in wood or inarble and known as pietra-dura Used in the decoration of隹 glass benesth which they were placed. To-day proper, which is embedded in cement.

## Pigs and Pigkeeping

## The Feeding and Housing of These Profitable Animals

Country readers, in addition to this contribulion, may consult with advantage such articles
as Duck: Goat; Poultry. Sec also Bacon; Ham; Pork
It is essential that before entering upon same time. Water should be added, or prepig keeping persons ahall make themselves ferably a little skim milk, to give the whole acquainted with the regulations of the local the consistency of gruel A newly weaned sanitary authority These vary from place pig will usually require about 2 lb of food to place, being more stringent in urban arens per day, irrespective of added water, and, in than in rural ones.

Making a Start. When this matter has been atisfactorily settled, the next point to consider is the type of pig that should be kept Before making a choice the pig keeper should decide whether he intends to breed from it or to keep it as a store or a fat pig; in the latter cise he should decide whether he intends to convert it into pork or bacon. Whichever his intention may de, he is advised to select the breed or type of pig that is most popular in his district for the purpose for which he requires it Whatever breed or cross is selected. it is advisable to choose the offspring of a well-bred dam of good conformation. It is also important that the sire should be purebred and that the sire and dam should not be too closely related.

It is advisable to start pig lieeping with a newly weaned pig, about eight weeks old, care being taken to secure as good a specimen as possible. An extra shilling or two spent on a good pig will be amply repaid. At the same time, the buyer should not devote too much attention to fancy points. Above all. he must have an animal with a vigorous constitution ; a greedy, lusty fellow, active on his legs, lengthy and round in shape, with a clean and plinble akin, covered with a fine coat of soft, glossy hair.

Feeding the Pig. For several weeks after weaning the pig should receive its fool in $n$ moderately sloppy condition, slightly warm if the weather is cold. The food should be easily digeatible and may consist of potatoce, turnips, and other vegetables, together with table scraps and grease from the kitchen and a little middlings or sharps. The roots and vegetable matter should be boiled together and afterwards well mashed nnd mixed, the mea! being incorporated at the

Pig. Berksbire plg, a proftable breed, producing fine hams

Sow of the Middle White breed, a prolific variety that matures early
objects to black porkers."

If carefully fed from the start a pig should weigh from 170 lb to $180^{\circ}$ ib live weight when about 5 or 6 months old. It is then reanly for killing. The dressed carcasa should then weigh from 130 lb to 140 lb . The nmount of food re. quired at this stage will be from 5 lb to 6 lb of meals or their equivalent each day If kept alive beyond this stage the rute of increase gradually slackens, while the amount of food neces-
could well be spared for this highly nutritious forage plant. Rape, vetches, and rye supply highly nutritious green food at times when such material is scarce. For the supply of the necessary succulent food in the dead of winter recoursc must be had to potatoes, furnips, mangolds, sugar heet, artichokes, paranips, etc. Of these, potatoes and sugar beet are the most valuable, 4 lb . of each being considered equiva. lent to 1 lb . of cereal meal.

For the first month or two the pig should be allowed a moderate amount of exercise. An occasional run outside its sty will tend to promote a healthy uppetite and will also encourage growth. When the pig reaches about 100 lh . in live weight this should be curtailed, and feeding should be rather more forced. Wheat offals, accompanied by a little rice meal, maize meal, or harley meal. may be given more frecly, and the supply of the more bulky vegetaile food should be reduced.

The pigkeeper should note that the method of iceding pigs is most important, if the best quality meat is to be obtained In a good carcass the flesh should be solid, of uniform consistency, and fine texture evenly streaked with fat and lean, of a bright fresh colour, and not watery. The fat should be firm and white and remain hard at ordinary temperatures, while a thin, smooth and mellowskin is desirable.
'lo obtain the above qualities a proper food ration is necessary; anyone situated near milk. butter and cheese factories, who can obtain the waste by-products and use them with meal, has the ideal ration for producing good quality pork and bacon. An unbalanced ration consisting chiefly of oily foods, with maize and rice meal, produces dark coarse Hesh and soft spongy fat. A suitable carcasa for the fresh pork trade has the following characteristics:
Head, Inght and medlum size. Shouldera light and tine Back, frim and level; ribs well sprung. Helly, straight underline, nicely lined with Hair. llanis, plump, deep and well let down. Flank. thick and at reaky. Bone, Hoc

The Ministry of Agriculture give the following conformation which the Wiltshire bacon trade requires:

Buck, long and level, with ribs well sprung. sides, level and inoderately dee $\mu$ Hams, hroad. WIde, and deep to hock; tail set high Belly and lank, thick w/th straight underilne. Shoulders, light, and on a line with forelegg below, and with wides laterally, free from wrinklea and coarscness. Flank, alined with the gides. Head, neck and jowl ight. Legs, aliort and set apart ; the pip alould tand well up on the tips of the toes. Bone, fine
The pork section of the National Federation of Meat 'raders' Associations states, in sumInarising points to be borne in mind by pig hreeders, that "Iarge and middle white and Welsh breeds, or pigs produced by crossing large black or Berkshire sows with these breeds, are suitable for the pork market. The loar should not be black, as the trade stronglv
sary to produce each additional lb. of pig becomes greater. Fat bacon and fat pork, however, are more useful as food than are their lean equiralenta, especially in winter, and the person who only fattens one pig for his own use will be well advised to keep this factor in mind He may prefer to feed his pigs to a heavier weight than 180 ll . In the absence of straw, dried bracken, grass and leaves make a thoroughly satis factory bedding for pigs Every effort should be made to provide an abund ant supply, especially in cold weather, when the pig prefers to curl up in bed, and is content with the minimum of exercise When it is remembered that food is more expensive in winter than

Fig. 2. Pigsty shown below, giving details of door, brick floor, surrounding wall, etc
promotes the general health of the animals, prevents chills and rheumatiom, and minimizes the risk of discase.

The foundation must be dry and, if condi. tions permit, it should face south Access to a small paddock is a distinct advantage Openings in the wall and roof, through which the passage of air can be easily regulated, should oe provided in order that the temperature may be kept as even as possible throughout the year. A close, stuffy atmosphere destroys the appetite and is as harmiful as a cold sty. Provision for suitable lighting may be made either in the walls or in the roof

A simple type of sty is illustrated in Fig. 1, which indicates the general arrangement of the structure The total area occupied by the double structure is 15 ft . by 18 ft . The covered portion is 6 ft from front to back, leaving an open space of 9 sq. ft. for each enclosure. Details of the outer walls and door as well as the brick floor to the pen are shown in Fig. 2. Such an ercction provides accommodation for two sows and their litter In this case the sty is located in the angle of a wall and the roof plate resta on the wall of the adjoining building. The same lines of treatment may be followed if the pigheeper prefers to build an independent structure, when. of course, four walls will be needed.

The first step in construction is to mark out the ground with pegs and lines and excavate the top soil, digging a shallow trench, which is filled in with concrete and the top surface levelled off. The whole surfaceshould be covered with concrete at least 9 in. thick. A fall is preferably arranged to the front of the pen and an outlet provided to any convenient drain: that it takes more food in winter to produce in its absence $\Omega$ sump should be built a lb. of pork, the supreme importance of and drain pipes taken to a cesspool, or some comfort during the coldest season of the other sanitary arrangements made for dealing year is apparent.

Building a piggery The mun easention of a pigsty are comfortalle and clean condi- prefer sufficiently, the walls may be put up, of a pigsty are comfortahe and clean condi- preferably in 9 in work, hut in the case of
tions. A dry bed, combined with suit. sinall pens it may he possible to utilize $\frac{1}{d}$-brick able ventilation and the absence of draughts. thickness, that is, walls only $4 \frac{1}{2}$ in thick,

Pigsty. Fig. 1. An easily constructed pigsty in brickwork with a felt-covered timber roof. It is situated in the angle formed by two walls, and will provide accommodation for two sows and their littera
using strong cement mortar made of I part head in two, removing the bones Season it to

Portland cement and 2 parts sand The brickwork should be continued to plate height and the roof furnished with stout rafters or other roofing material.

The floor should be floated off with at least 1 in. thickness of strong cement mortar, unless it is finishod with regulation stable tiles. The surface should be brushed over with in stiff-bristled broom as soon as the cement is steady, or partly set, to roughen it, so that the pigs can maintain a sure footing on it. A stout wooden rail raised on posts 9 in . high and 9 in. from the wall will prevent the sow crushing the young ones when she lies down. The walls are rendered with cement and finished with limewash as desired. A strong door of substantial pattern must be provided for at some part of the pen, and is needed for the covered part or house as well. Provision should be made for light and air in the way of small windows, which can be merely openings, or else they may be partially closcd with wood shutters or with perforated inetal. Pigs must not be liept in such a manner that they constitute a nuisance, and in most places there are by-laws which must be complicd with by those who kcep them

Cooking Hints. When pickled, dried and cured, pig's check is known as bath chap, but it is also sold simnly pickied Bath chap needs to be soaked before being cooked, but pickled check usually requires a thorough washing. Both are cooked in the same way.

Pig's Feet There are various ways of cooking pig's feet, but broiling and frying are perhaps the best. 'To do this, wash two feet thoroughly, scraping the skin with a knife, then cut them in two and let them soak for about an hour in salted water. Wash them again in fresh water, tie them together and put then into a pan containing I pint water and $\downarrow$ gill vinegar which have been previously heated over the fire.
Boil up the whole, and after removing the scum from the top put in a small onion, a bunch of herbe, and salt to taste. Cover the pan and cook its contenta very slowly until they are tender, then take out the feet, hone them and season them to taste. 'Hev can be eaten hot or cold. If they are to be fried spread a little pork sausage ment over the cut sides of the flesh, and fit the pieces together again to form their original shape. Roll then lightly in Ilour, coat them with egg and breadcrumbs, and fry them in a pan of hot fat.
'To broil, cook and hone them, brush them over with melted butter, coat with breaulcrumbs, and cook over a clear tire. Apple sauce (q.v.) makes a good accompaniment
Pig's Head. The most usual method of cooking this is to steep it in a salt pickle comprising 1 lb . salt and $1 \frac{1}{2}$ or saltpetre and then to boil it, and serve it hot with cabbage or beans; or to boil it in a clotlo, press it between two weights, and serve cold'

For pickling, scald the head in boiling water for a few minutes, scraping off the hinirs with a knife, then cut it open and remove the brains, eyes, and snout Wash it thorough!y, leave it overnight in a pan of atrongly salted water, and then rinse it in fresh water. Rub it all over with the salt mixture and leave it thus for a bout 6 days, turning and basting it daily. Before boiling, wash the head again to remove the surplus brine, then put it into a pan containing just enough water to cover it. Boil this up, removing any scum from the top, and then cook the head slowly until it is tender. Serve it garnished with the cooked tongue, skinned and neatly sliced.
To prepare the cold dish boil up a salted pig's head in a pan containing sufficient warm water to covel it, take the scum from the top, and then let the whole simmer for about 2 hours. When tender, take it out of the pan to cool, skin and slice the tongue, and split the
head in two, removing the bones Season it to
taste, and on one half of the head place the slices of tongue putting the other half on top to form a sandwich. Tie the whole in a pud ding-cloth, cook it again for the same length of time as before, and then press it between two weights, leaving it to get cold. It should then be served thinly sliced

PIGEON. Anyonc wishing to keep pigeons should think carefully before securing stock The climate and the available accommodation must be considered. If one is living in a town many of the most beautiful and picturesque pigeons cannot he licpt. Birds such as FanTnils, Jacobins 'I'runipeters, Fairy Swallows, Muffed-legged Tumblers are sorrv-looking objects when they are forced to live in the atmosphere of an industrial district like Manchester or Leeds, but in the open country they will do well.

Birds of delicate-coloured plumage and markings are also unsuitable for town life Dragoons, Antwerps. Snow Homers, Carriers, Scandaroons, and English Owls thrive liest in the country. Of those which thrive in almost any climate may be mentioned dreh. angels, Tipplers, Flying Homers, Magpies. Nuns, Short and Long faced Tumb!ers. Borbs, 'Turbits, African Owls, Poutera, Pigniy Pouters, Norwich and Holle Croppers, lỉrummers, Swifts and Modenas. The best breeds for a beginner to choose from are the short, hardfeathered birds such as Archangels, Long faced Tumblers, Exhibition Flying Homers, Mag. pies, Nuns and Modenas.

Before deciding upon any particular breed the novice should visit one of the shows which are held in all parts of the country from September till Fehruary and select one which is the best adapted to the environment in which the birds will have to be kept.

Feeding the Birds. As to food, maple peas, tarea, dari and wheat in equal proportions make good feeding for the smaller breeds. The larger ones may be given beans, and amall maize in addition Green food in the form of lettuce, cabbage, or some of the succulent

Pigeon: lour breeds that are general lavourites. 1. The nun, an attractive loy pigeon. 2. Norwich cropper, a pouter pigeon. 3. Homer or homing

甘" courlestl of Piyeons and Plie Placon World
weeds found in the garden, chopped up tine and given in a bowl twice or thrice a week will be muchappreciatel. A handful of mixed small seeds and rice may be given ns a tit-bit once a week.

The hreeding scason extends Irom February till July. It is unwise to prolong it, as it interferes with the proper casting of the feathers in the moulting season. Unless a bind noults freely its health will be impairel.

Young pigeons are cared for by their parenta for the first month. After that the old birds leave them to themselves, and set about raising another family. A hen pigeon when she goes to nest lays her first egg at night. and the second about noon on the second day nfter. The period of incubation is 18 days

The Pigeon House. Before purchasing any birds a house in which to keep them is needed. The papers devoted to pigeons contain advertisements of many such. The majority of pigeon keepers use home mide erections. chiefly because they can adapt the house to its surroundings. The best form of building for the purpose is a strongly mule wooden whel built of 1 -in. tongued and grooved boards. The roof should be covered, on top of the boards, with either galvanized iron slieets or asphalte felt. The outaide walls may be covered with either tar or paint. The ?ormer is more lasting, the latter morc pleasing to the eya Dark-green paint with the window and door frames in white is attractive. The insidr should lie painted light blue or whitewashed.

Each house should possess a wiredl-in aviary. or llight, extending the whole width of the front. and about 10 ft or 12 ft . long. Stout 3 -in. wire netting should lie used, which if tarred every summer will last many ycars

If success is to be attained and a race of strong, healthy birds built up they nust never be overcrowded A shed 8 ft. by 6 ft . with a span roof 6 ft . 6 in . at the eaves will give accommodation for eight pairs of the smaller breeds or six of the larger. The floor of the house should be covered to the depth of 3 in . with coarse sn wdust, which should be renewed frequently. It will last much longer if the droppings are removed from the top every weel: The floor of the aviary should be dug out to a depth ol 2 ft ., and filled with broken bricks, or clinkers, to within 4 in. of the top. This should be covered with conrse sand, which should be rolled hard, the top swept or scraped every week, and the whole of the and rencwed every six months.
Ordinary hracket perches fixed to the wall will suit any of the breeds recommended to tha beginner. Good nest boxes may he made from the ordinary sugar boxes which are sold by grocers. These should he laid on the floor. Glazed earthenware nest pans should be used. The hox should contain sawdust to the depth of 1 in., and the nest pan also ; short pieces of soft straw 4 to 6 in. long may be given to the birds for nesting material. Large open pans of earthen. ware or zinc are best for
baths, and fountains for drinking water. Never let the birda drink the bathing water if it can be avoided. Drinking water should be given fresh daily. The bath water should lee rencwed twice a week. See Dove

How to Cook. Wild or wood pigeons should always be roasted, but the house pigeon may be served in a variety of ways. When buying these birds, select those with comparatively small eyes soft red and tender feet, and necks covered with bright, neat-looking feathers of much the same colour as those on the rest of the body The spurs of the male bird should be short and round
'l'o roast pigeons, pluck, draw and singe then, then wash and truss then. Ierve the feet on, but scald and scrape them. Iay a shallot inside each bird, dust with pepper and salt then tic over the breast a rasher of fat bacon Roast for 20 to 25 min ., and baste frequently using clear beef dripping or butter Just before dishing, dredge the birds with flour, then baste and return to the fire or oven to finish cooking. Bread saluce and a good brown gravy should be served with them, and the stock with which the gravy is made should be finvourel with the giblets If liked, roast pigcon may be stuffed with pigcon forcemeat
'lo broil pigeons, split the birds down the back, spread them open, rul) them with butter season and broil them over a clear fire or under a gas griller before dishing. rub then once more with butter, sprinkle over them some chopped parsley and a few grains of cayenne pepper

Pigeon Forcemeat. A good stulting for pigeons can be made from the livers of these birds Parboil 2 of these, chop and mix them with $\frac{1}{2}$ dessertspoonful chopped shallot, ( 6 dessertspoonfuls breadcrumbs and こ oz. chopped fat bacon Scason the mixture with pepper and salt and a little grated nutmeg, and bind it with the yolk of an egg and, if needed, a little milk

Pigeon Pie. 'T'ake 4 young pigcons and 3 lb . rump steak 4 oz . prepared and chopped mushrooms 4 shallots, also peeled and chopped, I dessertspoonful chopped parsley 2 hard-hoiled eggs, and seasoning. Cut each bird in halves and fry the pieces sharply for 2 or 3 min . to colour them. Cut the steak into slices, roll them and dip them in pepper, salt. and thour. Lay then at the botton of a piedish, then sprinkle over half the mushroom, parsley, and shallot. Arrange the pieces of pigeon over the steak, sprinkle on them the remainder of the mushroom, etc., and senson.
'l'he egge must be cut in quarters and fitted in among the portions of pigcon: moisten with d pint good stock. Cover with rough puif pastry (see Past ry) in the usual way, decorate the centre with pastry leaves, egg the top ol the pic. and batic about is hours. Before serving, fill up the pe with gravy and replace the pastry ornament with the fect in the opening on tho top of the !id The feet of the birds should be senlded, scraped. Blanched. and glazed with meat glaze

Pigeon Ragoût. 'l'o nake this ragoût, bone and stuif 4 pigeons with veal stufting (see Forcemeat), but ald to this 2 oz. chopper fat bacon and the chopped livers of the birds Flour the pugeons and fry them a good brown in hacon fat Then put them into a casserole cover them with stock, aulding 4 oz. preparal mushrooms cut in strips. I carsot cut in dice, and a sliced onion. Pour in a wineglassful port and a tablespoonful orange juicc. Season to taste, boil up and stew gently about 1 hour. Garnish with crouttes of fried bread or of puff pastry.
Pigeon Soup. Nake 2 quarts stock well llavoured with vegetable. and add the giblets of the birds to be used. Truss 4 old pigcons hrown them in a frying-pan, using butter to fry them, and turning them in order to brown
then allover Drain them from the fat and add them to the stock, which must be ready hoiling on the firc. Cook all gently for one hour, then remove them from the soup, shim it free from fat after straining it, and thicken it with brown roux. Serve with dice of fried bread. Fillets cut from the birds may be served in this soup, or tho pigeons may be laid aside whole and used up for some made dish. If the soup ia too pale, colour it with a little browning.
PIGEON BREAST. The serious de formity of the human chest, in which the ribs are llattened so as to throw forward the breast-bone, is known as pigeon breast. It occurs in rickety children who suffer from some bronchial affection, which prevents the free entrance of air into the chest, and is then due to the clfect of atnospheric pressure on the softened ribs. See Rickets
PIKE: The Fish. This large fresh-water fish requires careful cleansing or it is apt to retain its muddy flavour

When the pilie does not cxcecd 4 or 5 lb . in weight it is known as a luce or jack. Large pike are considered better than small ones. The flesh when cooked should look white and firm, but it will improve by keeping for about two days in a cool lasler before it is dressel The roe of the pike should be thrown away. When scaling the fish lay it on a dish in the sink and pour hoiling water over it
To bake a pike whole, choose a tish weighing about 8 lb Wash, scale, and draw out the gills, trim off the fins, and then wash the fish again before wiping it dry Fill it with a well-scasoned veal stufling (ser Forcemeat) and sew it up, then truss it in the slonpe of an $S$; score the fish each side in several places and lay it in a rather deep baking tin. Add not less than 6 oz butter or clear beef dripping, 3 pecled and chopped shallots, 2 oz prepared and chopied mushrooms, 1 small onion stuffed with 4 cloves, a honquel garni, and pint good stock to which has been udded a wineglassful of sherry. Cover the fish with a well-buttered paper and bake it for an hour in a good oven, basting frequently.
As soon ns it is ready dish it, removing the trussing strings. Pour olf from the pan all surphis fat and stir in $\frac{1}{2}$ pint stock. Have ready $\frac{1}{2}$ pint well-flavoured brown sauce, add it to the stock, mix all together and cum the whole into a stewpan, boiling it till it is reduced to the right consistency Skim it free from fat or scum, add 1 oz. butter, a little anchovy casence, the juice of $\frac{1}{2}$ a lemon, 2 wineglasses sherry, and scasoning of cayenne pepper Strain this sauce over and round the pike

Cold Pike. Prepare the fish and truss it as in the preceding recipe, and then make the following broth: Fry for 10 min . in $\frac{1}{2}$ gill salad oil 2 onions and a carrot, both prepared and sliced, 2 rashers bacon cut in strips, a bouquet garni, 3 allspice, and 4 cloves, and when the vegetables are ready pour into the pan 2 quarts white atock, add some white wine if liked and 1 dessertspoonful salt Simmer for an hour, and strain. Boil the fish in this until tender-about hour for an average sized fish. Let it lay in the broth overnight. Then drain it, remove the trussing strings, and dish it. Coat it with mayonnaise sauce. A pike of 9 lb is sufficient for from 10 to 12 persons. The fish may be reheated in the broth and served hot with tartare sauce. Like all fresh-water fish, pike is better boiled in prepared liquor than in water The liquor need not be thrown awny, as it can be used up for making fish soup or sauces. If liept more than three days boil it up ngain. See Fish.
PIKELET. These are sometimes known as Lancashire girdle cakes. The ingredients arc $\frac{1}{2} \mathrm{lb}$ flour. $\frac{1}{2}$ teaspoonful salt, $\frac{1}{2}$ teaspoonful
bicarbonate of soda, l teaspoonful creain of tartar, 2 teaspoonfuls castor sugar, one egg, $\&$ pint water and $\&$ pint milk. Mix flour and all dry ingredients, beat in yolk of egg, milk and water. Beat well, then fold in the stiffly beaten white of egg. Pour in tablespoonfuls on a hot greased girdle. Cook until brown underneath, then turn with a knife and brown on reverse side. Butter and serve very hot. If left to go cold before using toast then on both sides before a clear fire. See Girdle.

PILASTER. This term is used in archi tecture to describe a form of pillar paitly embedded in a wall. It is a fcature of many buildings, and examples are also found in shop fronts and as decorative features of chimney pieces and furniture. In panelled rooms symmetry is often attnined by the use of a pilaster to balance some other feature; the face is panclled or moulded and carved to harmonize with the other decoration. See Panelling.

PILCHARD. The small salt-water lish known as pilchard somewhat resembles the herring in appenrance and taste. but it is more oily and it has a tin in the centre of the back and not near the tail. Pilchards are caught in large quantities off the coast of Cornwall, and are in scason from the middle of July till the end of November. They deteriorate rapidly after being caught, and usually are at once salted and kept in harrels or tinned in oil.

Pilchards may be cooked according to most of the methods employed for herrings, and in some parts of Britain they are made into pies They must he soaked overnight nad then placed in a pie dish with alternate layers of lecks and covered with short pastry 13ake about 30-40 min. See Herring ; P'astry

PILE : In Textile Fabrics. Velvet and velveteen are eloths with comparatively short pile, whereas plush has a longer pile. Other pile fabics are in common use, one of them being Turkish towelling, in which the pile consists of loops. The imitation fur fabrics, such as astrakhan, are piled, and so are many carpets. In Genoa velpet, as used in furnishings, there are two heights, and often colours, of pile forming a decorative pattern. Pile fabrica are generally warmer than cloths macle without pile The wear conses not on the sides but on the ends of the tibres, and for this reason properly made pile goods are durable A beauty, depth, and richness are obtained for carpets, furniture and hangings in velvet piles which cannot be obtained in non-piled materials Pile surfaces have their disadvantages, for sometimes their surface is a clinging one, and they harbour dust The pile can be pulled out of new carpets by careless use of carpet-sweepers. The longer the pile in fabrics of any kind the greater is its tendency to beconie laid. See Carpet; Velvet

PILES. Congested and varicose conditions of the veins at the lower ends of the bowel are the cause of piles. Thero aro two varietics, external and internal, but hoth miny be present.

Anything which produces an obstruction in the circulation of the blood in the abdomen is a predisposing factor. Constipation is one of the most frequent causes. Congestion of the liver acts in the same way, and piles are common in beer and spirit drinkers, and also in those who eat largely, or live a sedentary life. Sitting on the grass, a stone or a cold seat may bring on an attack by chilling.

External piles form dark brown folds of skin running out from the anus. They are soft, but when filled with blood large and hard. Friction and want of cleanliness may cause them to inllame. With internal piles the first symptoins may be a little blseding As a rule, they give no pain, but cause
a sensation of fullness in the bowel. and they may cnuse straining at stool.
Constipation must be preventerl. Eat wholemeal bread, stewed pruncs, apples, and other fruits, and plenty of vegetables. Violent purgatives of any kind are bad, while nloes are particularly to be avoided Regular, modernte exercise should be taken, the hest form being a brisk walk of two miles a day. The sufferer should take great pains to avoid much standing about and cold feet; he should never sit on the ground or on a cold scat; lie should take little or no nlcoliol, strong tea or coffee. Another important rule is to lieep the affected parts perfectly clean by washing and aponging. When piles become inflamed the patient slould keep his bed and send for the doctor.
When the acute atage of the inflammation has passed off, the official ointment of gall and opium may be used applied on lint, or witch hazel ointment. When internal piles come down or prolapse at stonl, they should be gently pushed back with the fingers. Should bleeding occur thoroughly smear a small plug of cotton wool with witch hazel ointment and gently push it into the bowel.
PILLAR. In architecture a pillar is a rigid upright support capable of stnnding alone and siupporting an object or part of a building. liilars may be employed for a portico or entrance porch, for a pergola, or as part of the structure of a house. Pillars have a definite decorative value, and the architect rmploys them in this way as well as to perform some useful purpose. Unlike a column, a pillar does not of necessity conform to any defined rules of proportion or period, but the claracteristics of the recognized periods of architecture are generally talien as the basis in preparing a deeign. See Porch.
PILLAR ROSE. This term is used to distinguish varietics of climbing or rambling roses which are suitable for training on polea or pillars from 6 to 8 ft . in height. For the taller pillars some of the rambler roses are suitablc, e.g. Fraicheur, Hiawatha, Lady Gay, Sander's White, Lady Godiva, Blush Ramililer and Dr. Van Flect. Some of the best climbing roses for pillars 6 ft. or more high are Scarlet Climber, Mme. A. Carric̈re, Lemon Pillar, Climbing Ophelia, Climbing Lady Hillingdon and Iady Waterlow. See Rose.
PILLION SEAT: On Motor Cycle. This is an auxiliary seat attached to the carrier at the rear of a motor cycle or side rar combination. Two types are here illustrated. It is against the law to carry mome than one passenger on the pillion seat of a motor cycle, and the person carried nuist sit astride on a properly secuied seat. This law does not apply to a motor cycle with side car. Side saddles may be used only when a motor cycle is attached to a side car.
An extra premium is generally charged by insurance companies if a pillion passenger is to be carried, and an ordinary policy not having this extra cover may be invalidated if such a passenger is carried. See Motor Cycle.

PILLOW. The ordinary pillow is made of goose teathers or of down, enclosed in a corer or tick of white fustian, which must be firmly and strongly sewn, so that no feathers can escape. A pillow requires to be unmade. stoved, picked over, and remade from time to time; but this need not he done so often if it is sewn into a plain linen underslip, and kept thoroughly well shaken and heaten.

Down pillows are nearly twice as expensive as gond fentlier pillows, but they have the disadvantage that they nre very hot. and many penple like them to bc replaced in suminer by feather pillows. The ordinary English pillow is oblong in shape, a bout 27 in. by 18 in. But the square pillow, which may be as large as 27 in . by 27 in ., is most comfortable if it is used with what is known as a wedge bolster. This is like a tiny mattress, about 5 in. deep at the back and sloping down to $a$ bout $\frac{1}{\frac{1}{2}} \mathrm{in}$. in front.
Children must have pillows thinly filled, so that the head is only very alightity raised. Low pillows are better for adults, too, and the modern tendency to do away with the bolster is a recognition of this.

Pillow Case. Pillow cases, or, as they arc sometimes called, pillow slipa, are obtainable in cotton and linen. Linen is much the best, for it not only wears and washes extremely well, but is smoother and cooler, and therefore more comfortable than cotton. The cases vary in size, so that hefore buying a pillow case the pillow it is to cover should be mensured. If a pillow case is too small the pillow will be hard and unyiclding; if it is too large the pillow will be untidy.

Frequently the alip is a plain bag, fastened at one end with linen buttons or tapes. It may be decorated with a hemstitched barder or a frill. or with lace and rows of hemstitching. Unless for fancy pillows for day time use or ornament, embroidery should be nbsent or kept to the corners of the case only. When making a pillow case, it is best not to fasten the buttons directly to the end, but to make a flap of double material, about $2 \frac{1}{2} \mathrm{in}$. wide, that will fold down over the end of the other side of the pillow. The buttons are then sewn inside the flap, so that they are invisible when the case is fastened. See Linen; Quilt.

PILLOW LACE. Lace made with many threads on a cushion or pillow is popularly known as pillow lace. This term is somewhat mislcading and such handmade lace is more correctly termed bobbin lace, as many needlepoint laces, in which a single needle and thread are used, are made on pillows. See Lace

PILOCEREUS.
This is a genus of greenhouse cacti, without leaves, and with fleshy, spiny stems. A familiar example is old man cactus. The genus properly is classified under the name cereus. See Cactus.

## PILOT CLOTH.

Other colours can be had, but pilot cloths are commonly blue. They are heavy woollens intended
originally for pea-jackets, such as ship pilots wear as a protection from wind and rain.
The cheaper kinds are thick but hard, and in looking at them carcfully the blue colour is seen to be cloudy and lighiter on the surface of the short nnp than in the hody of the material.

PIMENTA. This evergreen shrub necils grcenhouse treatment as far as Great Britnin is conecrned. [sfaring white nnd red flowers in early summer, Pimenta acris is vigorous nnd needs a lot of space. It should be pruned in the spring, and propagation is by cuttings.
Pimento Pepper. This is an alternative name for Jamaica pepper, better known as allspice (q v.).
PIMPERNEL. One of the prettiest of British wild flowers is the scarlet pimpencl (Anagallis arvensis), a common weed in gardens. Of others grown for their decorative effect in flower beds and borders the prettiest are Anagallis linifolia, of which the varietiea Parksii, red: and Phillipsii, blue, are the best. They grow only about 6 in . high and are useful edging plants. Seeds are sown under glass in April and the seedlings are planted nut of doors in May. The bng pimpernel (Anagallis tenella) is a pretty pink-flowered trailing plant suitable for moist places in the rock garden or bog gardon

PIMPLE. Papules, which are small, solid prominences of the skin, are popularly called pimples. They vary in shape, and may be pointed, round, or llat on the top. Common examples are the eruptions of chicken-pox, acne, and boils in their earliest stages. They should not be ruhbed. In many caser a little boric ointment removes pimples, but more energetic treatment

## may be necessary:

PINCERS. An indispensable tool in the home is a pair of pincers for pulling out nails and other purposes. The ordinary type has a pair of broad jaws and two handles, one with $\pi$ knob and the other with a fork or claw end. This is inserted under the head of the nail and used to prize it up sufficiently to enable the jaws to get a firm liold under the head, after which the pincers arc closed together and pressed over sideways, thus withdrawing the nail, which may subsequently be pulled out. The cost of a good tool is so little that it is worth while to get a really serviceable and well made pair of pincers.
Shoomakers' pincers have grooved and serrated jaws, with an upstanding block formed on one of them They arc employed for pulling leather into shape, and the block is used to got a good pull, being rested ngainst some firm part to obtain a good purchase.

PINCHBECK. From its resemblance 10 the precious metal, pinchbeck has been popularly termed Brummagem gold. It was to the mien and women of the 18th and early 19th centuries what rolled gold and gold! filled articlea are to those of to day, with this difference, that the supply was much moro limited. Consequently, it has a distinct value to the collector of antique jewelry.

Modern inventions, such as gold-filled pro ducts, have superseded pinchbeck in Great Britain, but a variety of it is in use in Switzerland and other continental countries, for cheap jewelry and articles made to imitate gold.

The collector should beware of the modern imitations of old pinchbeck, many of which are difficult to distinguish from the genuine
article, but, as a rule, are not so carefully made and are distinctly inferior in artistic quality. Examples of old pinchbeck that are worth acquiring include snuff-boxes and patch-boxes, with slips of onyx or agate forming the top and bottom : vinaigrettes, various kinds of buckles, bracelets, and other articles of jewelry set with tortoiseshell, mother-ofpcarl, amethysts or topazes. Ring and jewel caskets can occasionally be picked up which are a valuable addition to any colloction; these are beautifully ornamented with agate, onyx, cairngorm, or lapis lazul. See Jewelry.
PINC:INNG. This is a gardening term which means cutting off or pinching off the tips of shoots or branches to force the development of others and thus ensure well-branched trees or planta. See Pruning.
PINCUSEION. The simplest form is a littlo bag stuffed with bran and sewn up at the end. Bran is the best material to use, as it is much lighter than sawdust and has not its tendency to absorb damp. The covering material should be strong and closely woven, so that the pinheads cannot pass through and the bran cannot come out through the pinholes For this reason it is always best to make a bag for the bran, then to cover it with another material such as silk or velvet and edge with a narrow cord. The daintiest dressing table pincushinns have detachable, washable covers of embroidered muslin, the cushion being covered with pink, blue, or mauve satin.

PINCUSBION FLOWBR. This is the old name for scabious, a plant much in demand for cutting purposes. There are annual, biennial, and perennial kinds. The finest of all is the Caucasian scabious, which is popular not alono for garden decoration, but as an exceedingly beautiful florists' flower. See Scabious.

PINE. The word is often ased loosely to describe various cone-bearing trees, but correctly it is the popular name of those contained in the genus Pinus. Some of the pines are of great value as a windscreen for the protection of choicer trees and plants: they are particularly useful for planting in exposed soacoast gardens. They are evergreen and rather slow growing.

It is wise to plant small trees about 2 ft . high, for they become established more quickly than larger ones. The Austrian pine (Pinus laricio nigricans) is a most valuable wind break tree. Pinus insignis, which is chifly suitable for mild districts, is also a gond shelter tree. The most familiar of all is the Scots pine, Pinus sylvestris, a tall handsome tree which reaches a height of 80 ft . or more and will thrive in very exposed places. It furnishes the timber known as deal

Some of the pincs are suitable for planting as ornamental lawn trees in large gardens One of the most distinct is the umbrella pine (Pinus pinea), a flat-topped tree of distinctive growth which can be recommended for gardens in the milder counties. Others are the blue pinc (excelsa), with grey-green lenves, and the Corsican pinc (laricio), which flourisies in poor soil The pines are propagated by seeds sown out of doors as soon as they are mature

Uses of the Wood. The name pine is applied to several varieties of timber, the produce of trees which grow extensively in Europe and N. America. The Scots fir, which is common all over the north of Europe, is called northern pine, or red, yellow, or white deal, according to its character. It is the wood commonly used in carpentry, in housc-building, for outdoor work. and rough work generally It is cheap, not heavy or difficult to work, and durable, varying in character according to locality and conditions of growth.

Other varietics of pine come from North America; an important one being yellow pine It is a pale honos-yellow in colour, light, soft.
straight-grained and uniform in texture, easy to work, has very few knots, and shrinks and warps very little. For these reasons it is the wood preferred by pattern-makers. It is not employed for outdoor work, but in joinery and cabinet-work it is the best kind of softwond, and in furniture it often forms a ground for veneer. Mouldings, panels, and frames are made of it.

Another Amorican wood is pitch pine, highly resinous, strong, and heavy, and is therofore much used for piles, struts, and the like. Reddish-yellow in colour, it has strongly marked annual rings that show as alternating light and dark streaks in the grain, sometimes with a wavy figure, and is rather difficult to work owing to its resinous character. Being clean and attractive when varnished, it is sometimes used for bedroom furniture and also for flooring purposes. In general, however, it is unsuitable for indoor work, especially when close joints aro needed, as it shrinks badly. Pitch pine takes varnish much better than it dnes paint. See Deal ; Wood.
PINEAPPLE: How to Grow. Mainly owing to the great quantities of this fruit which are imported the pineapple is now rarely cultivated in Great Britain, although for delicaoy of Havour the home-grown pine is unsurpassed. The best method of cultivation is to prepare a bed 3 ft . in depth of fresh leaves in a deep garden frame or pit, which is heated, cover the leaves with a 12 -in. layer of loamy soil, and plant the pines in this at about $2 \frac{1}{2} \mathrm{ft}$. apart. Considerable artificial warmth is required: the winter temperature should be about 65 degrees. If only a few plants are grown thoy should be potted in large flower pots 10 in . or 12 in . in diameter. Pmpagation is easily effected by suckers or offshoots, which, if potted and kept in a moist hothouse, will form roots. The leafy top of a ripe fruit may be made to form roots in the same way.

The botanical name of the pineapple is Ananassa sativa. A variety named The Qucen is best for cultivation under glass in Great Britain (See Greenhouse)

Serving the Frult. To prepare the fresh fruit for the table, dut it into slices with a silver or stainless knife and cut off the rind, taking care to remove all the woody part. When canned, pineapple retains much of its flavour, and can be served alone with the syrup poured round it, mixed with other fruits to form a compote or fruit salad, or cut up to mako pineapple flans, fritters, ctc. Crystallized or glace pineapple may also be bought in rings or chunks.
Pineapple jelly is made as other table jellies. described in page 648. For fritters this fruit is used either fresh or tinned, and the batter is the same as that given in the recipe for Apple Fritters (q.v.) Tinned pineapple is used for a flan, which is made as described in page 464. It can also be used as a filling for turnovers and tartlets and to decorato small cakes or layer cakes though glacé pineapple is more often used for cakes.
Pineapple Cup. Peel a small pincapple and cut it in thin slices. Sprinkle it well with castor sugar and let it stand 6 hours. Put the trimmings of the fruit into a bright stewpan. cover them with cold water, and then boil up, skim, and simmer them till the flavour is extracted. Strain this cssence over the fruit. add the juice of 2 oranges, 6 oz . castor sugar, and 11 pints white burgundy. Stir and then cover over, and keep in a cold place. When required add a syphon of soda or seltzer water
Pineapple Mould. Mix a dessertspoonful chocolate powder to a smooth paste with a little milk taken from $\frac{1}{2}$ pint; boil up the remainder of the latter and stir it into the chocolate. When it has cooled slightly, add it to a beaten egg, strain the whole into a jug
placed in a saucepan of cold water over the fire and cook it until the custard thickens. Then take it from the pan, add 3 dessertspoonfuls castor sugar, and leave it to get cold

Rub the contents of a small tin of pineapple through a sieve, and mix the pulp with the chocolate custard. Put $\frac{1}{2} \mathrm{oz}$. leaf gelatine in a saucopan with $\frac{1}{2}$ gill pineapple syrup, let it dissolve slowly, and then strain it intn the whole. Pour the mixture into a wct border mould, leave it to set, and after turning it out fill up the centre with a gill of stiffly whisked cream sweetened and flavoured to taste.

Pineapple Pudding. To make pineapple pudding, 3 oz . crystallized pincapple should be used, but the fresh or tinned fruit will do quite well if the juice is drained away. Put intu a stewpan $\frac{1}{2}$ pint milk with 3 oz . sugar, and as soon as it comes to the boil draw it back from the fire and stir in quickly 4 oz . fine sifted flour. then return it to the heat and beat it well. As soon as the paste ceases to adhere to the saucepan it is done. Let it cool slightly and mix in the well-beaten yolks of 3 eggs, add also the pineapple, chopped, and then fold in the whipped whites of the egga. Pour it into a buttered mould and steam for $1 t$ hours Serve it with sweet sauce. If crystallized pineapple is used, flavour the sauce with a few drops of pineapple essence. If fresh or tinned fruit, make the sauce with the juice or liquor in the tin. See Fruit Snlad: Marmalade ; Salarl.
PINEAPPLE FLOWER. Alternatirely known as Eucomis, the pineapple flower, which belongs to the order Liliaceac, is $n$ half-hardy bulb, succeeding in sandy loam in a cool house. As a rule it is grown only in pots in the greenhouse, but in mild districts and in

Pizeapple Flower, bulb suitable for pot onltivation sheltered positions it will sometimes do well out of doors. It reaches a height of about 2 ft., and flowers in August. Pro. pagation is by offsets in spring. The species punctata, green and rose, is usually grown.

PINE WEEVIL. Sometinces known as the conifer beetle, this is a pest which de vours the bark of such trees as pinc, firs and spruce Eggs hatch out into fleshy white larvae, about $\frac{1}{2}$ in. long, pupating in autumn, and emerging as wecvils in June. All old stumps of the trees mentioned should be cleared away and all branches of infested trees well shaken to cause the pests to fall upon sheets of paper spread beneath; they are then collected and burnt. See Inscc. ticide.

PING PONG. This game is an indoor form of lawn tennis. Rules were drawn up and an association
formed, but after a time the game began to le called table tennis. The ping pong association was therefore dissolved and the game is now governed by rules drawn up by the Table Tennis Association. See Table Tennis.

PINGUICULA. Butterwort is the common name of this group of low-growing hardy

Pinguicula alpina, a hards pezennial bearing yollow-
tipped, white fowers, suitable for the bog garden plants. They form rosettes of leaves, bear violet-like llowers on slender stalks in May and are suitable for planting in the bog garden or moist spots in the rock garden. One of the pretticst of these flowers is srandiflora, with violet-bluc flowers; the bloonis of alpina are white marked with ycllow. The plants can be propagnted by division preferably in the autuinn.
PINHOLE PHOTOGRAPHY. A minute hole in a light-tight box forms a substitute for a icns. The apparatus is simple, and no focussing is requircd. It may easily be improvised for testing purposes from any rectangular light-tight box at one end of which is fitted a very thin metal plate, such as a piece of copper foil, and at the other a photographic plate kept in place by a clip. A small hole is made in the copper foil with the point of a needle, and kept covered until exposure is made.

Mr. Alfred Watkins, of Hereford, has prepared a table for sizes of pinholes based upon the use of sewing-needles which are standard in size: metal disks piorced with standardsize holes for pinhole camoras can be obtained from him which can also be fitted into the ordinary camera in place of the lens. While the distance between the hole and the plate does not affect focussing, it does affect the size of the image thrown on the plate, the greater the distance between hole and plate the larger the image.

The sizes of holes to give the best definition for any particular distance between hole and plate, and a means for calculating the approxiinate exposure, are given in Mr. Watkins' table as follows :

| Neerle | Diameter | Best Dlatance Hole to Plate | Calculate Exposure as for |
| :---: | :---: | :---: | :---: |
| No. | In. | In. |  |
| 1 | 2 | 40 | 1/80 $\times$ cu |
| 4 | 4 | 910 | 1/80 $\times 1 / 5 \times$ |
| 7 | \%11 | 10 | 1/60 $\times \ldots$ |
| 8 | ! | 8 | 1/56 $\times$ \% |
| 10 | ${ }^{1 / 4}$ |  | 5/30 $/ 35 \times$ |
| 12 | 1 | 34 | f/35 $\times$ " |

Thus, if the pinhole is to be used in an ordinary camera with a total extension of 8 in., the hole should not be made with a needle larger than No. 8. The actual exposure is then calculated by referring to an exposure meter or table. Having calculated the exposure according to the speed of the plate and actual lighting conditions at the aperture or $f /$ No. given in the table for thesize of pinhole in use, it is multiplicd by 00 , the resulting exposure being in seconds.

Alternatively the figure obtained may be reckoned as minutes. Thus, for instance, on a bright summer day, using No. 8 pinhole, the meter may give $\frac{1}{8} \mathrm{sec}$. for $\mathrm{f} / 50$ : this is reckoned as $\frac{1}{f}$ min., or 20 sec . The hole made by the needle must be perfectly clean, and any burr marle in piercing the foil carefully rubbed down with emery paper or file. Only in a very bright light can the image be seen on a focussing screen. Therefore a good view finder is cssen-
tial. The larger the plate used in a pinhole camera the larger the angle of vicw, and this property makes the pinhole very valunble in crampéd places, such as buildings in narrow streets or interiors where it is impossible to get sufficiently far away with an ordinary camera to include the whole subject. For landscape purposes with an ordinary lens the angle of view may vary from $20^{\circ}$ to $50^{\circ}$. With a pinholc it may be anything up to $100^{\prime}$.

Another useful property of the pinhole camera is that its image is mathematically correct, and may be used for calculating heights and distancos. The size of the image depends upon (1) the size of the object ; (2) distance from object to pinhole ; and (3) distance between plate and pinhole. It is directly proportional to (1) and (3) and inversely proportional to (2), so that if two qualities are known the third is casily calculated. Thus, to find the size of an object, the distance (2) being known, multiply the size of the image on the photograph produced by the camern by (2) and

Pink: two beantiful varieties. Loft, fine flowers of Dianthus Herbertii : right, blooms of the variety known as Queen Mary
profusion of fragrant flowers in spring. There are two chicf classes, the border and the alpine or rock garden pinks. The border pinks Hourish best in well-drained rather light soil; clayey soil can be made suitable by adding leaf-mould, sand and grit. Planting may be done in autumn or spring.
Propagation is by cuttings taken in June or July and inserted in sandy soil out of doors and covered with a bell glass or handlight. In four or live weeks the cuttings will be rooted and the covering can be removed : they may be planted out in autumn. Two kinds of cuttings are used-the piping, which is the top of a shoot pulled out, and the ordinary cutting, 3 in. or so long, made by severing the shoot just beneath a joint and renoving the lowest leaves. Pinks can also be increased by layering. The double whitc, named Mrs. Sinkins, is still the favourite border variety. but others are listed in catalogues. There are some beautiful flowers in the Herbertii strain of pinks. The old laced pinks are seldom grown now, but varicties may be obtained from specialista

In recent years the perpetual floworing or Allwoodii pinks have been raised and have become very populas. There are many named varicties in rich and varied colours. They are increased by cuttings or by layering in sunsmer. Border pinks are very easily raised from seens sown in boxes of light soil in a frame in May : the seedlings will be large enough to plant out of doors in autumn
The alpinc pinks are exquisite rock garden flowers suitable for planting in gritty soil in divide by (3). If the size be known and the sunny places. The most popular of all is distance required, divide (1) by the size of the the Cheddar pink (Dianthus caesius), which image and multiply by (3). See Exposure : forms a wide low tuft of leaves and bears small F/Numbers: Lens.
PINION. A small cog wheel that engages with another cog wheel usually of a greater dianteter is termed a pinion, and is constructed of either stecl, cast iron, brass, phosphor bronze, or even vulcanized fibre
Apart from its use in transinitting rotary motion the pinion is cxtensively used in conjunction with a rack, as for example in the focussing arrangement of a microscope. Very small pinions, such as are used in clock and watch making, are generally machined from pinion wire, which is manufac. tured in lengths, diameter, tooth sections, and numbers of teeth according to require. ments. See Gear.

PINK. The pink is one of the most delightful of all the old-fashioned garden Howers and unsurpassed as an edging plant for beds and borders. Its grey leaves arc attractive all the year round, and it yields a

How to grow Pinks. 1. Layering an old plant : a, fine soil over lagers. 2. Rooted layer. 3. Same transplanted to shallow drill with sand at base 4. Cutting or piping. 5. 8ame propared with lea! tips romoved (b) and properly clanted : $a$, very sandy compost. 6. Propagation nader handlight: a, fae sandy soil ; $b$, sand ; $c$, soil ; $d$, crocks ; $e$, handlight: $f$, boz
soil containing lime These two, together with glacialis, should be tried in the moraine. See Border; Carnation
PINKING. Pinking is a good method of finishing the cdges of material that is not suitable for the usual double turning. The edge is acalloped in small triangles or half. diamond shapes. This is done to prevent the material from ravelling along the raw cdge, and to nenten the appearance.
To pink an edging, ordinary sharp scissors may be used. A line of tacking should be run along the edge where the head of the acallops is to lie, or a sealloped transfer can be ironed on to the material to act as a guide. The material should then be folded between each scallop, and a slanting cut made to the depth required or to the line of tacking. If the pinking is to be carried out on oilcloth or leather, the points can be faintly drawn in with chalk or pencil.
PINS AND NEEDLES. The prickling sensation, popularly termed pins and needles. is one form of paraesthesia, or a disturbance of sensation. which may be experienced on parts of the body in nervous and other discases. These may be due simply to debility, and an iron tonic may cause their disappearance.
Pint. This measure is used for milk, beer, and other liquids. It consists of 4 gills, and 2 pints make a quart.
PINTAII: The Duck. A pintail is a type of wild duck that derives its name from its long, pointed tail. It is almost invariably roasted, and, except for the fact that the feet are usually left $n n$, it should be prepared and trussed in the same way as an ordinary duck Abnut 20 min is the time required for ronsting, and because the flesh of the pintail is rather dry it should be basted frequently. Serve it with some sharp sauce and garnish it with watercress and cut lemon. See Duck

PIP. The kernel or seed of fruit, $a s$ of an apple, pear, or cherry, is known as the pip Although plants and trees may bc raised from pips the process is not advocated for practical purposes, because most of the scedlings would be worthless, and the trees are slow in reach. ing the fruit-bearing stage unless budded on other stocks. For those who nevertheless desire to experiment in the propagation of fruit from pips the following information will be useful

For apples and pears the pips may be sown when fully ripe, in pots of sandy lnam, and placed in a cold frame. Watering must be very moderate until the seedlings have grown 3 or 4 in ., and then they are transplanted to open ground. Further periodical transplantings will be required as the trees incrense in size, and they will probably bear fruit in 6 to 10 years after the original sowing. Apricots, cherries, damsons, and plums, as well as apples, pears, peaches and nectarines, may be raised in a similar manner. Amongat other fruits likely to give results from pips are raspberries and atrawberries. See Apricot: Cherry: Pear

PIPE : For Smoking. Wood of various kinds is used in the manufacture of pipes. Briar is the favourite, but Australian myallwood, ebony, cherry, and other kinds of wood are alm employed. A good pipe is made from thoroughly seasoned wood, and the harder it is the hetter. It should have a nice straight grain, without knots or flaws of any kind. The colour varies from rich shades of chestnut or walnut, with a tinge of red, to the glossy black, which many smokers prefer.

For the mouthpiece vulcanite, made or finished by hand, is the material chiefly used. A silver band or mount at the end of the stem is a customary ornament.

Regular sminkers usually keep one or tivo good briars for everyday use, reserving the
meerschaum, should they possess one, for occasional enjoyment together witli such varieties as the cherrywood or the corn-cob. The two latter are amongst the cheapest and simplest types, consisting of the hollowedout bowl of cherrywood or cob, into which the stem is thrust. Patent varieties are on the market, the object of which is to collect or get rid of liquid accumulations of nicotine.

When smoking a pipe for the first time, shred some tobacco well and pack about a third of a charge smoothly and evenly in the bowl, heing careful not to ram it right down to the bottom of ${ }^{*}$ the pipe. Light the tobacco carefully, making sure that the whole top of the surface is aglow, and smoke it indoors, very slowly. If the tobacco burns down one side, as a result of bad packing or a strong draught, the new wood is bound to suffer from the unequal distribution of the heat. It will suffer equally from excessive heat developed by too rapid drawing at the pipc. A new pipe should be cleared gently of all unconsumed tobacco each time it is smoked. Never refill and relight it; nor, indeed, any pipe while it is still hot from a previous smoke.

A pipe should not be knocked against the heel or the hob or mantelpiece, or, when out of doors, on a wall or post or railing, to get rid of the unconsumed residue of tohacco, as this very often results in cracking the pipe. All such remaining tobacco should be removed by scraping it out gently with the blade of a pocket-knife. See Tobacco.
PIPE : For Gas, Water, Steam. Pipes of all kinds play an important part in the home. Water is brought into the house through a lead pipe and taken to a cistern or receptacle in the roof. When it is intencled to fit a hot-water supply the pipe is generally of iron and may be plain or galvanized, tho latter resisting the attack of rust. In some cases the water is supplied through $n$ copper pipe, especially in connexion with hot-water supply in districts where the water has a corroding action on iron. Gas is conducted through a rough iron pipe known as gasbarrel, which is made of wrought iron and is measured by the nominal bore of the pipe Thus a $\frac{1}{2}$ in. gas pipe means that the pipe measures $\frac{1}{2}$ in. internal dianeter, while the nutside is about $? \mathrm{in}$. diameter. Hot water barrel and steam pipe or barrel, stronger varieties, are measured in the same manner

In contradistinction to gas-barrel, brass and copper pipes are measured by the outside diameter and are purchasable in various thicknesses or gauge sizes. The higher the number the thinner the tube; a normal thickness for gas fittings is No. 16 gauge, nominally $\frac{1}{18}$ in. thick This class of
 Pipe Joints. Pig. 1. Remonng plug from T-piece. Pig. 2. Cutting pipe to correct length by means of a hack-saw. Fig. 3. The end of the pipe must be gled up before screwing is begun
pipe is made in two grades. The one most generally used is made with a seamed or brazed joint; a superior tube is known as seamless and is made from the solid. The latter, or triblet drawn, as it is sometimes called, is usually more accurate to size and forms a stronger tube than the seamed Larger diameters such as 2 in and upward are made in thin gauges

Pipes are jointed in various ways, according to their nature and purpose; for example, gas and hot water pipes are connected by means of fittings with screw threads cut on or in thens. and screwing to corresponding threads cut on the pipe. Lead and compn pipes are joined by a soldering process, and the joint is known as a wiped joint. Brasa and copper pipes are joined with screwed fittings, and also by brazing and soldering to suita ble fittings.
Joints in Gas or Hot Water Barrel. In. atructions for manipulating lead piping are given in the article on Plumbing. The amateur shou!d be verv chary of doing anything to the gas service pipes, as there are many snags for the inexperienced Gas barrel, however, has many other uses than its most common one, and can be employed in conjunction with certain stock fittings to make atanchions, handrails, etc.
The home worker may at some time or other wish to alter his hot water supply system, or, for example, talie a branch from the existing water pipe to a fresh point. This may be accomplished by unfastening one of the joints of the existing pipe, after having turned off the water, or isolated that part of the pipe so that the water cannot escapa.
 in a convenient position and the outlet from the T.piece hss been plugged, the best plan is to commence the new work from it. In Fig. I such a pipe is shown, the plug being removed with a spanner or pipe wrench.

A piece of pipe has to be cut to length, as in Fig. 2, the ends of the pipe rounded off with a file, and the scale, or hard
outer surface, removed by filing, as in Fig. 3. The pipe is set vertically in a strong vice, or horizontally in a proper pipe vice, and a thread cut upon it with stocks and dies, as in Hig. 4. To test the thread, a socket or other standard screwed fitting should be tried in place, to ensure that a perfect fit results : if necessary the die is adjusted and run over the pipe again, so that the fitting screws on evenly and firmly. Both ends of the pipe should be treated in the same way. The next step is to screw the pipe into the $T$ and to make the joint water or gas tight with a mixture of red lead and gold size or a good thick paint.

This is smeared on with a brush, a few fibres of hemp twisted into the screw thread, and the pipe screwed into the T.piece (Fig. 5). To prevent the pipe sagging it inay be supported temporarily with a nail, pipe hook, or a strut of wood. If it is desired to terminate the branch at one end of the length of pipe, this can be effected by screwing an elbow on the end of the pipe and screwing a plug into it, but if it is necessary to carry the pipe upward or downward, a sufficient length of it must be screwed into the elbow and $T$ or branch fitting.

A great point is to make the screw threads a good fit, to make them tight with the aid of red lead. and to cut the lengths correctly at

they have rooted, when they may be planted out. Pipings may be taken at any time during July and August. See Carnation: Garden : Layering: Pink.

PIPING: In Needlework. A length of piping cord encased in a tube of material is employed in dressmaking and in making covers, cushions, curtains, etc., to finish off

Piping in Neodiework. How the cord is onclosed in a tube of material
the edges, in an ornamental manner. If these edges are curved, the piping is made separately, and applied afterwards.

To make it, take a crossway strip of material $1 \frac{1}{2} \mathrm{in}$. wide or more, according to the thickness of the piping cord, which may be had in many different sizes. Fold one of the longer edges over nearly duwn to the other, and slip the cord up into the fold; then tack along close up to the cord to keep it in position. Lay the piping over the right side of the article to be piped so thot the narrower of the two strip edges faces this, and the cord lies in. ward; then stitch the strip down to the article close up to the cord. Roll the cord upward so that it lies along the top of the article, and hem down the wider of the two raw edges. If the edge that is to be piped is
the start. Another point to bear in inind is to work progressively from one end upward, otherwise it will be necessary to use connectors. These are long sockets, and to usc them one of the ends of the pipes to be jointed must be screwed for a sufficient length to allow the socket to screw right on to it. The ends of the pipe are then drawn as close to one another as possible, the socket unscrewed from one and partly on to the other. both of them being secured with locknuts tightened up on the ends of the socket, as in Fig. 6. The nuts have to be fitted before the socket is screwed on. A sound joint is made with twists of hemp soaked in a mixture of red lead and gold size.

When an iron pipe is to be joined to a lead pipe it is necessary to use a brass union fitting and to solder the lead pipe to the tail of the union; otherwise the fitting work may proceed as described. See Overflow.

PIPE CLAY. White clay resembling potter's clay is used for making tobacco pipes and other purposes. The peculiarity of this variety of clay is that it is soft and greasy to the touch and very tenacious. When used for whitening leather parts of military accoutrements its adhesiveness is increased by adding white of egg to a thick cream made by rubbing pipe clay with water.

PIPING : In Gardening. This is the name given to a special kind of cutting used in propagating pinks; it consists of the top of a shoot pulled out instead of being severed with a knife. To take a piping, the top end of a shoot is held in the right hand, while the leit hand grasps the stem. The right hand gently but firmly pulls the stem apart, showing a hollow pipe, like a quill or tube.

These pipings, when taken, are planted in a mixture of silver sand and finely-sifted soil, watered and covered with a handlight until

quite straight, it is just sufficient to turn the edge of the material itself in over the cord. and to run alorig close up to it; but this cannot be done if the piping is to be of a contrasting colour, as often happens. Piping can be used in rows as an ornamental trimming, by taking up a tuck in the material and setting the cord at the back of the fabric, so that this may be picked up inside the tuck, which is then stitched. Sometimes the material is pushed along the piping, to give a rucked effect. This style is used in making cushions.

PIPPIN. A popular type of apple is known by this name, well known examples being Cox's Orange pippin, Allington, Kerry, King of the Pippins, King's Acre, Sturmer, Normandy and Summer Golden pippin. The first named is the finest dessert apple known.

Normandy Pipplns. Dried apple rings are sold as Normandy pippins, although they
are sometimes known as biffins. They mny be used for winter fruit salads and puddings, but require to be washed thoroughly before use and to be steeped in cold water for 24 hours. See Apple; Dried Fruit.

PIQUÉ. A material often used for making detachable coat-slips, collars and cuffs, pique is generally white or light-coloured. The surface is ribbed into cords, and in true piqué these run crossways on the cloth, although lengthwise cords are often sold under the same name. The cloth is a strong cotton one which wears and washes well. A silk material ribbed to look like this cotton cord is known as silk piqué.

Piqué cinbroidery is a form of white stitchery upon a strong foundation. The outlines are traced by a cord made in crochet chains or overcast, while the fillings are in different stitches to imitate a figured material, such as linen damask.

PIQUET : How to Play. Piquet is a card game for two players, and is played with a pack of cards from which all from the six to the two have been thrown out. The 32 cards rank as in whist, and the ace is high in cutting and play. There are no trumps.

The dealer deals 12 cards, 2 or 3 at a time, to his opponent and himself, face downward. The remaining 8 cards are placed on the table face downward in a pack of 5 laid across a pack of 3 . The object of the game is to score for certain combinations held in the hand, and afterwards by the winning of tricks. First of all each player examines his 12 cards, and begins to declare, beginning with the dealer's opponent. If the latter finds that he has no king, queen or jack in his hand, he calls out carte blanche, and scores 10 points. If the dealer also has carte blanche, he does not announce it until his opponent has discarded.

The dealer's opponent may discard any number of cards from 1 to 5 . and at least one. Whatever number he discards he takes a corresponding number from the top of the pack. If he does not take 5 , he may look at those he leaves. If he takes 3 , for example, he may look at the next 2. The dealer then discards and draws a corresponding number of cards from the pack. He is bound to discard one card, and may take all the cards which remain, if he wishes. He may look at any of the cards he leaves behind, but if he does so his opponent has the right to look at them as well, either after playing his first card or naming the suit that he intends to play.

The hands being made up, the dealer's opponent begins to declare his hand. He first calls the point. This is the suit which has the greatest pip value. The player first of all announces how many cards of his longest suit he has. If he has more cards than the dealer, the latter says Good, and his opponent scores the point. If he has less, the dealer says Not good, and scores the point. If the number of cards is equal the pips are counted, aces counting as 11, court cards as 10 , and the other cards at their face value. If the pips are cqual, ncither player scores the point. The point cards must be shown to a player's opponent when demanded.

Each card in a point scores one. A point of six counts 0, for example

The second call is sequence, three or more cards of a suit in order. The plaper with the longest sequence counts it. If the number of cards in the sequences are equal, the highest sequence scores. The player with the best sequence also counts all other sequences he may hold, his opponent counting none. If the best sequences are equal, neither side scores. A sequence of 3 cards counts 3 points; of 4 cards, 5 points; and of any greater number, 10 points plus the number of oards in the sequence.

Thus a sequence of 0 counts 10 points As with the point, sequence must be shown when demanded. The third call is triplets or fours. These are 3 or 4 cards alike, as 3 kings or $\mathbf{4}$ aces, and the hest scores. Three of a kind counts 3 points; 4 of a kind, 14 pmints. The player with all higheat triplet or 4 counts all others in his hand, his opponent counting nonc. The hands must be called in the regular order : point, sequence, triplets or fours
How to Score. Each card led counta one point, and as each point in declaring and afterwards is made, the players announce their total score. If the ilealer's opponent scones 30 points by declaring his combinations and by the cards he leads before the dealer scores, he scores an additional 30 points. known as pique. If either player reaches 30 before playing a card and before his opponent scorea, he acores an additional fiO points for repique The dealor's opponent leads and adds one point as he does so, and the dealer must follow suit. If the winner of a tick also led, he counts one for his next lead. but if the other player wins the trick he counts one for winning it, as well as one in the usual way for his next lead. The winner of the last trick always scores one extra point, no matter which player led.

If each player wins 6 tricks it is a tic; the player who wins more than (i tricks scores 10 points for cards, and the player who wins every trick scores 40 points for capot. This acore includes the point for the last trick. The game is 100 or 101 points up, and scoring is in the following order, since each player may actually he able to make sufficient points to score the 100 or 101 , and so the order of scoring becomes important. Carte blanche is scored first, and then point, sequences, fours and triplets, points made in play, and finally the cards.
In Ruhicon piquet there is no definite scone Fach game consists of $\mathbf{i}$ deals, and the player making the highest aggregate wins. The winner deducts the loser's score from his own and adds 100 points If the loser fails to reach 100 points the winner adds the loser's score and 100 points to his own. Pron. Pik.et.
PISE-DE-TERRE. This is the name given to the building of walls and structures with earth. Shuttering is erected to the thickness of the wall, and the earth is fillod in and rammed thoroughly. Sometimes the base is marle of several courses of brick or stone, to protect the piséde-terre from dampness.
PISTACHIO. The small green kernel of the pistachio nut is used in cookery as a decoration for either meat or siweet dishes In galantine these nuts are often introduced into the forcemeat stuffing, forming a contrast in colour to the red tint of the tongue or ham or the black of the truffle. Pistachios enter into the composition of various dinner sweets much in the same manner as almonds. Pounded or chopped pistachios may be made into sauces for puildings by employing any method adapted to almonds.
Pistachio Cream. To make this cream, blanch and peel 2 oz. pistachio liemels and pound them in a mortar with a few drops of rose water. Make a ich custard, using $\$$ pint
milk, the yolks of 3 eggs, and $2 \frac{1}{2}$ oz. castor sugar. Cool the custand slightly, then mix in by degrece the pounded nuts and, in order to heighten the colour, add, if neceseary, a little spinach-green or sap-green colouring.

Dissolve 1 oz. leaf gelatine in 2 tablespoonfuls water; and after the custard and the nuts have been passed through a sieve add the gelatine. Last of all fold in lightly ${ }^{3}$ pint whipped double cream, and pour at once into a mould rinsed out with melted jelly and decorated suitably. Set it on ice and turn it out of the mould when the crenm is to be served. The custard must not be quite cold when the gelatine is added, or it will begin to set before the cream can be mixed with it.

PISTON. In an engine the piston is a mov ing part that has a free reciprocating movement in the cylinder and takes 1 he pressure of the

Piston. Fig. 1. Diagram showing types al piston used in internal combustion engine design: $A$, cast iron : B, alumlniam : $O$, aluminium and bronze

Piston rings are always made of close grained cast iron, machined all over, and ground to a fine limit so as to ensure a perfect fit in the groove. There are several methods by which a perfectly uniform expansion of the ring is assured, so that it oxerts an equal piressure on the cylinder wall over the whole of its diameter. By the first method the inside diameter of the ring is machined lightly eccentric to the outside diameter, and slotted or cut through at the thinnest part: by this means the beuding moment will be equal from any point, thus allowing the ring to keep a perfect circle when closed to the diameter of the cylinder.

By the second method the rings are turned a little larger in diameter than the cylinder, slotted to leave a gap, and sprung into the cylinder. The gap must be laige enough, when the piston is in place, to allow for proper expansion of the ring.

In anothermethod, the inside diameter of the ring is machined from the same centre as the outside diameter, and slotted. It is then pertianently expanderd. so as to give tho necessary tension when closed to the diameter of the cy!inder. by means of hammer blows at close intervals
oxpanding gas, thus transforming it into round the inside diameter mechanical motion, via the connecting rod and the crankshaft.

The piston of an internal comibustion engine as used on motor vehicles is of the type known ns trunk piston, being long ns compared with that of a steam engine. It serves as a guide for the small end of the connecting rod to which it is connected by a gudgcon pin.

Pistons for petrol engines are constructed of cast iron, machined as light as possible, of aluminium alloy, and of aluminium and bronze (Fig. 1). Generally the top, or piston head, is llat, and bevelled at the edge. although sometimes a slightly domed head is eniployed. In the majority of 2 -stroke engines the piston is provided with a specially shaped deflector on the head. The purpose of this is to direct the path of the burnt gases, as well as to retard the moment at which the fresh gases will unavoidably come in contact with the tail-end of the burnt gases
The fitting of piston in a cylinder is not sufficient in it self to prevent leakage of compression bet ween the two surfaces, and forthis reason what are known as piston rings are fitted in grooves machined round the piston, which by expanding against the cylinder wall prevent a leak age at this point.

The rings are arranged so that the gaps do not fall in line. In order to obtain as perfect a compression as possible, some makers fit two thin rings in one groove, placing the slots on opposite sides; by this arrangement loss of compression via the slots is greatly reduced. This has led to the introduction of the donble twist piston ring shown in Fig. 2, which presents an unbroken surface to the cylinder wall over the whole of its diameter.
Methods of shaping the slots so that as little compression as possible shal! get away at this point are shown in Fif 2. Scraper rings of various constructions are fitted to remove surplus oil from the wall of the cylinder, one being located usually at the lowest of the groovem, just nbove the gurlgeon pin. Small holes in the pis. ton wall carry the oil thus removed to the inside. The ring is grooved, chamfered or stopped, and has a sliarp edge for scraping off the oil (Fi.g 3)

The removal of the cast iron ringe from the piston is a job thateallsfor con-
Fir. 4. Removing piston rinks by meaus of string of tio inserted and worked round
siderable care, and is best carried out as follows : Obtain 3 or 4 strips of sheet till about in. wide, and insert them all side by side at one point hetween the ring and the piston. Next work them round to the positions shown in Fig. 4. By so doing it will he an easy matter to remove the rings without fear of breakage. Never attempt to remove more than one ring at a time. To replace the rings, it is a good plan to use the strips as a means of keeping the middle ling, where three
nre used, from contering cither the top or bottom groove.

On examining the ringe one or more may be found to have extensive brown marks on the face. This will mean that the ring so marked is a bad fit to the cylinder wall Theonlycure is to fit a new ring. In the case of one ring only being so marked, a varying degree of porosity of the cast iron, causing unequal heat distortion, will be the most likely reason; but where all the rings are affected, then a badly worn cylinder is responsible After a considerable mileage the ringa may be found to be slack in the grooves The only remedy is to have the grooves turned true, and a new set of rings fitted

It is essential to the proper functioning of piston rings that all carbon deposit is removed from the bottom of the grooves, and a blunt instrument only that will not damage the rvalls of the grooves should be used for Internal Combustion Engine; Notor Car.

PIT : A Card Game. Pit is a card game plaved by 3 to 7 people with a special pack of cards, and is so called from the slang name for American corn exchanges, which are known as pits. The cards numiber 63 , and contain 7 suits of 9 cards each. The number of suite used must correspond with the number of players. The cards are named after the cercals wheat, corn, oats, barley, ctc., and the object of each player is to obtain a complete set or corner in one cereal before any other player.

The cards are shuffled and clealt one at $n$ tine in the usual way. The suits are of varying values, which are indicated on the cards. Thus, wheat may be 100 , corm 75 , and an on. The game is won by the plaver who first succeeds in scoring 500 points by the corners he makes in any cercal. A minuite is allowed players to sort their cards and the pit is then opened. Each player tries to exchange cards he does not want for an equal number of cards he does, but without naming the actual suits he wants. Every player shouts out the number of cards he wants, and tries to shout down the opposing players. "Trade two," shouts one player: "three," cries another; "four," yells a third, and so on. The cards traded must be all of the same suit. Immediately a suit is complete the player shouts out "Corner in wheat," or whatever cereal it may be. After each corner the player is credited with its value, and the cards are shuffled and denit afresh.

PITCH. Pitch is the black residue in the distillation of tar. Vegetable pitch is produced in Sweden, and mineral pitch is obtained in large quantities from gas-tar. Damp walls are effectively treated by painting them with melted pitch. Another method is to paper the walls with paper impregnated with soft pitch. Other uses to which pitch is applied are as a component of briquettes, for making black varnish, as a waterproof coating for roads, and as a protective paint for iron.
Yellow Burgundy pitch is used in making plasters whieh are applied to the chest in affections of the lungs. The pitch is melted and spread on thin leather by means of a hot ircn The plasters are also applied to the loins in lumbago and for relieving rheumatic pains.

PITCHER PLANT. The peculiarity from which the pitcher plant obtains its name is the fact that the mid-ribs of the leaves extend beyond the ends, and each forms a sort of jug or pitcher, with a lid When a Hy or other insect happens to fall into the pitcher, its slippery mouth, which is also furnished with stiff hairs or bristles, prevents the escape of the insect. The leaves are green, sometimes with brown or red blotehes, and the plants should be grown in a hothouse, in baskets of peat and sphagnum moss, suspended from the roof of the house. They require plenty of moisture, and should be shaded from the sun
The botanical name of the pitcher plant is Nepenthes, but there is another genus with the same English name and of similar habit. This is Sarracenia, the side saddle plant, or Ainerican pitcher plant. It flourishes in peat and moss, and will thrive in a cool house. There are
th Howers of various colours. cally as Nepenthe several sorts, with Howers of various colours.
The Sarracenia requires very little water in the winter-time. The pitchers are richly marked, and possess the same insect-entrapping qualitics as Nepenthes. One kind, S. purpurea, is hardy, and may be grown in the bog garden, or in a moist comier of the rock garden, in a peaty soil. The surface of the soil should be kept covered with moss. All kinds are increascd by division in early spring.
PITCHFORK. The sharp-pronged instrument known as a pitchfork is chielly used in farmwork, for forking hay or manure and for other purposes. The common type has two slightly curved steel prongs about 1 ft . in length and spaced from ( 5 to ! in. apart. At the back end of the prongs two lugs are formed, and to the inside of them is attached a long handle, usually of ash or hickory. The length of the handle is about 5 ft ., with a diameter of $1 \frac{1}{2} \mathrm{in}$. to 2 in . The ends of the prongs are often turned out slightly at the ends to enable the fork to retain the load it has picked up.

A common use of the pitchfork is in the construction of hayricks, the tool being used to toss the sheaves from the hay cart to the top of the rick. Another application is in the distribution of manure over a field. The pitchfork is almost exclusively used for farm and small. holder's work

## Pitch Pine. See Pine.

PITTOSPORUM. This group of evergrcen shrubs or small trees is hardy only in the milder parts of the country. They thrive in sandy, loamy soil to which a little peat may he added with advantage. In other districts they should be planted against a sunny wall, or in tubs, and kept under glass safe from frost in winter. Tobira and undulatum, with white sweet-scented Howers, and eugenioides, with pale fragrant blooms, are some of the best. Propagation is by cuttings placed in sandy soil in a frame in August.
PLACKET. The slit or opening in the side of a skirt is usually known as a placket. It should be just large enough to enable the skirt to be put on and taken off with ease, and is prepared by opening the seam from the waist downward. 'Two pieces of material, each about $\frac{1}{2} \mathrm{in}$. longer than the opening and 4 in . and 2 in . wide respectively, are then required. The uider piece serves as an underlap, being doubled over and sewn to the left side of the
skirt, while the remaining piece is faced to the right side. Press studs arc generally used o fasten.
PLAGUE. The acutc infectious disease known as plague, bubonic plague, or black denth, has spread over the world at various periods, causing a heavy mortality. It is endemic in E. Asia It is due to infection with the bacillus pestis, which may gain access to the body in food, by inhalation, or by the bites of fleas or other wounds. Rats are mainly responsible for its spread Preventive measures include isolation and disinfection the destruc tion of rats and other vermin. Curative measures include various sera.

PLAICE. The treshness of plaice can be determined by the orange-coloured spots with which the fish is covered. These should br. bright, any tendency to dullness being an indication that the fish is stale. To prepare stuffed plaice, wash, olean, and dry the fish, remove the fins and head, and slit the fish down the centre to the bone, making the incision on the side covered with black skin. Lift the Hesl, with the knife on both sides of the bone, and fill as full as possible with forcement, and then lay the plaice in a tin containing a little inelted butter or margarine. Brush some of the fat over the top of the fisl, sprinkle the latter with brown breadcrumbs, and bake it in a warm oven for a bout $\frac{1}{2}$ hour, basting it occa sionally with the fat. Sprigs of parsley and alices of lemon may be used as a garnish. A suitable sauce such as maitre d'hôtel or tomato sauce should be served in a sauce-boat Com plete instructions for filleting and frying plaice are given under the heading Fish (q.v.) on page 462.

Plaice au gratin may be prepared by wash. ing a plaice, trimming the tail, and removing the fins, eyes, and dark skin. Put it in a gratin dish, place over it 1 oz. butter cut into small pieces, and add also $\frac{1}{2}$ gill milk and salt and pepper to taste. Put the fish in a moderately hot oven, cover it with a plate, and bake it for about 20 min . Pour what remains from $\frac{1}{2}$ pint of milk into a saucepan, heat it up with 1 oz . butter and seasoning to taste, and when it is warm pour it over 1 oz. Hour previously mixed to a smootl, thick paste with a little water. Put the whole back into the saucepan, stir it well until it boils, continue boiling for 6 min., and then stir in 1 dessertspoonful grated cheese. Take the fish from the oven, pour the hoiling sauce over it, and on top sprinkle another dessertspoonful grated cheese Return to the oven or place under the grill until the cheese melts and browns.

Fillets of plaice may also be served thus: Mix together 3 tablespoonfuls white breadcrumbs, 1 dessertapoonful grated cheese, a finely ohopped shallot, and a skinned and mashed tomato. Season them with pepper and salt, add sullicient egg to bind thein, and spread the mixture over the fillets. Roll them up, stand thein in a buttered tin or pie-dish, and put any of the mixture that remains on top. Cover the lish with a buttered paper, bake it in the oven for 15 min , and when cooked lift it on to a dish, pouring some hot tomato sauce and sprinkling a fow browned crumbs over each fillet. See Fish; Food: Force. meat ; Frying; Maitre d'Hotel

PLAN: Of a Building. A drawing giving details of construction and arrangement of the parts of some object or piece of work is known as a plan, and refers more particularly to architectural drawings of buildings. Plans of machinery are senerally termed working drawings, and similar drawings of boats are called the lines. Plans of buildings are prepared to a uniform scale of $\frac{1}{\frac{1}{2}}$ in to 1 ft . for the general arrangement drawings, the elevation of the exterior and the disposition of the rooms. Urawings on a larger acale of $\frac{1}{2} \mathrm{in}$. to 1 ft . are employed for the purpose of constructional details. See -Irchitecture: House

## Planes: Varieties and Their Uses

## The Care and Manipulation of these Important Tools

The amateur woodworker may te reminded that this Encyclopedia is full of articles giving detailed directions about making various items of furniture, for many of which a knowledge of planing is essential. In addition there are articles on the varlous types of plane, e.g. Jack Plane: Ovolo; Plough; Rebate Planc; Router; Smoothing Plane. See further Amatcur Carpentry; Tools

The carpenter's plane is used for producing the sole, or bottom of the plane. If sloort a smooth flat surface on wood. In its simplest whitish lines are visible, known as medullary form it consists of a steel blade which is rays, thesc should be as nearly as possible at passed through a wood or motal block, the right angles to the sole of the plane, as such a cutting edge projecting slightly below the tool will wear better than one in which these botton. The blade, which is inclined at an lines are at another angle. If the plane angle, is secured in its place with a wedge or has been made by a reputable maker, it can sone other device, and in the larger varieties a handle is fitted to the tool. In some planes the blade, or plane iron, is single; in others it is composed of two separate portions, the cutting iron and the back or covering iron.
The bottom of the hole where the blade protrudes is known as the mouth, and the upper portion as the throat, and it is important that the mouth should be just wide enough to allow the shavings to cone away freely and pass through it; if too wide this will not press down the fibres of the wood in front of the plane iron, which consequently will have a tendency to tear the work badly. The principle on which any plane works is that the cutting iron is so ground and sharpened that the shavings are chiselled off with $n$ regular and uniform motion working with the grain and not against it. The function of the plane is to guide the direction or course of the plane iron and to regulate the depth of the cut. In inetal-bodied planes with screw adjustments, etc., the principle is the same.
The amateur should possess n jack plane, trying plane, and
 reasonably be expected to be true and free from warp or twist; but this can generally be told by holding the plane horizontally on a level with the eyes, and looking along the level of the sole. The body of a new wooden plane the first time iron, that is, the side that is not ground

The blade is replaced and held as if taking the plane apart, while the wedge is tapped lightly in position with a hammer sufficiently to hold the iron. The plane is tilted at an angle, and the edge of the iron will be seen to protrude slightly. If it does not, it may be tapped out gently by tapping the opposite end with the hammer, or be adjusted by the screw device on an iron plane. The iron should project slightly less than $\frac{1}{10}$ in from the sole of the plane, and should project evenly over the whole brendth of the blade. except the comers, whicl will be slightly rounded off in the grinding process. The wedge should be secured tightly, and the plane is ready for use.
A smoothing plane is adjusted in the same way, except that to loosen the plane iron, the back of the plane is struck with the hammer
should be soaked in raw linseed oil before using it for

To remove the iron of a jack plane, or trying plane, grasp the plane in the left hand, the thumb pressing upon the iron, and the fingers grasping the bottom or sole of the plane. With the aid of a hammer strike a sharp blow near the end of the plane, as in Fig. 1. This will loosen the wedge, which can be with. drawn and the blade lifted out. The two irons aresepar. ated by laying them on the bench, holding them firmly in the left hand, and manipulitting a scrowdriver, as in Fig. 2. The plane iron should rest on or be firmly held by some support such as the hench. When the screw is loose the back iron is slid along the slot cut in the plane iron until the screw is opposite a large diameter hole, when it can he lifted out of its place. The iron is sharpened in the manner described in the articles on Grinding and Oilstone. The cover iron is then replaced; the edge should be about $\frac{1}{n}$ in. or less from the cutting edge of the plane iron. The cover rests upon the front of the plane
(Fig. 3) In the case of motal planes the various adjusting devices are opcrated. Fig 4 shows a metal trying plane with the location and purpose of the various adjustments indicated.

Manipulation of the Tool. Most planes are held and used with both hands; in general, the right hand grasps the handle of the plane, such as a jxck plane, or the back part of a smaller plane, such as a smoothing plane Some very small planes may be held in the right hand only; they arc used for chamfering the edge or cleaning up any little roughness on the end of a piecc of wool, or for work on curved surfaces, but are seldom of usc in making a really flat surface. The correct method of using a smoothing plane is illustrated in Fig. 5 , which shows the disposition of the hands and the style of shaving that should be produced. Rebate planes and similar planes used for making mouldings are held in the manner indicated in Fig. 6, which shows a fillister plane employed making a rebate.

Figs. 7 and 8 show the heginning and ending of a planing movement with $\Omega$ jack plane The top front of the plane is grasped hetween thi lingers and thumb of the left hand, and the handle held in the right. The object should be to thrist the plane forward in a straight line, keeping it level. A ten. dency to roll the plane may he detected by the tool inclining to lift at one corner, and this may be
 smoothing plane
checked by control with the hands and arm
If the edge of a board is to be planed, the tool is grasped in a different manner. It may be held as in Fig. 9, the first finger of the right hand being extended as shown, and the left hand reating on the top of the planc. With this grip it is possible to judge whether the plane is being held level or not.

Planing to thicknessos and widths is simply a question of gauging The principle is to establich a flat surface, or face side, then one edge. These are inarked off and gauged to the desired thickness, for which purpose special hardwool gauges can he preparel, or, as in gauging the thickness of a panel, grooves can be ploughed into a small piece of wood, and this is applied to the edge of the panel to correct the planing.

When planing curved surfnces, always work downhill; never attempt to plane uphill against the grain of the wool When rlaning

Fig. 4. Typical iron plane with principal parts named

Plane Fir 5. Tsing grain, hut work from each side across the end grain to the middle; or slightly bevel one corner of the board and plane across the end grain to this bevel ; or clamp it to an odd piece of wood on the far side of the hoard, and plane right across. If theae precautions are not ohserved, the wood will split Another

aid is to hold the plane diagonally, or slanting, neross the board, but to push the plane bodily in a straight line.

Before attempting to plane woord it is essential that the plane iron is very sharp, and it must be rubbed up on an oilatone when this becomes necessary For rough work the planc iron should project considerably; for smoothing, a less amount, and for a fine finish the least a mount it is possible to set it at. When the plane is cutting properly, the slinving sliould come away with a clear. decided sound.

PLANE: The Tree. The hardy summerleafing plane tree, ranging in height from 60 ft. to 80 ft ., will thrive in the gardens of smokeladen towns and oities when all other trees fail as the bark is slied annually. Many fine examples are to be seen in London and other cities in Great Britain. Acerifolin (London plane) and orientalis are two of the chief kinds: they llourish in ordinary soil and may. if it is necessary to keep them within bounds, be pruned hard every few years. They are not, however, suitable for small gardens. The planes can be increased by cuttings set out of doors in late autumn.

PLANK. This is the name given to sawn timber 11 in . or more widc, and from $2 \frac{1}{2} \mathrm{in}$. to 6 in.thick, but the word is commonly applied to all sorts of hoards. Examiples are seen in planks of a platform, in planks used in scaffold. ing and general building purposes, and in bont building.

For cabinct nıaking it is very often cheapor to purchase a plank and have it sawn into boards, the charge for the saw cuts being a few pence. An objection, however, is that the boards may wind or $t w i s t$ after sawing from the plank, so that a period of seasoning is

Fig. 6. Using a fillister plane to form a rebate
end grain, do not plane straight across the desirable before using the stuff for anything important. Care should be taken in selecting
a plank for conversion, and an end grain showing the heart should be avoided unless several thin boards of narrow width are required. In planning the number of boards due allowance must bo made for the thickness of the saw cuts. For example, a 6 in . plank can be sawn into four lin. and two $\frac{1}{2} \mathrm{in}$. boards, each leing full in thickness.

PLANT. Some authorities define a plant as a living organisın, diversified in structure and possessing organs of nutrition and reproduction. The former comprise root, stem, and leaves, functioning for purposes of respiration, circulation and growth The latter include the flower, with its calyx and corolla, and stamens and anthers, the malc organs: pistil, stigma, and ovary, the female organs. Male and female organs may be contained in one llower, or they may be borne on different
important. Care should be taken in selecting

Plane. Fig. 7. Start of the stroke with a jack plane. Fig. 8. How the plane is held at the finish of the stroke.
Fig. . Shooting the edge of a board with a jack plane
plants; some examples carry male and female llowers separately on the same plant.
PLANTAIN: The Fruit. The plantain is a fruit belonging to the banana family, of which the scientifio name is Musa. The very Iarge outsize fruits, often attaining n curved length of 8 or ! in ., which are sold in Great Britain as bannnas, are really plantains. They may also be distinguished by their thick, tongh skins Real hananas are much smaller, softer, and have thinner, velvety slins. The culture of plantains is as for bananas ( $\mathrm{q} . \mathrm{\nabla}$.).
PLANTAIN: A Garden Weed. Two plantains (Plantago major and $P$. Innceolata) compel the attention of the gardencr because
they are common weeds of the lawn. They spread rapidly by means of self-sown seeds and should be uprooted with a bent-pronged weeding fork while small. A little sulphato of ammonia or lawn sand, if placed on the plantains in settled dry weather, will destroy them. Or they can be killed by means of a special weed eradicator which liberates a supply of weed killer when thrust into the plantains.

PLANTANN LILY. This group of hardy herbaceous percnnials, 2 ft. or so high, is valued for its largo ornamental leaves and spikes of small white or lavender colourcd lily-like flowers in summer. They flourish cither in sunny or partially shaded places in well drained loamy soil and are increased by division in spring. Snails are very fond of the leaves, and if not deatroyed often apoil the beauty of the plants. Thie plantain liliea are first-rate for cultivation in tubs and develop into large handsome plants in n few years; the varieties with coloured leaves are particularly well suited to this purpose. The chief kinds are Fortunei, glauca, which has grey-blue lenves, Sieboldina, and subcordata. Two low-growing kinds suitable for edging or for cultivation in pots are lancifolia and tnrdiflora.

PLANT HOUSE. A glasshouse built for the cultivation of plants and fruits which are not sulliciently hardy to be grown out of doors or are improved by the shelter thus afforded. The stove or hothouse is for tropical plants; its ininimum winter temperature is a bout 65 degrees. The greenliouse or conservatory artificially warmed to maintain a minimum temperature of a bout 50 degrees is for the cultivation of half-hardy and subtropical plants. In the cold or unlieated greenhouse many hardy rock and border plants can be grown in pots, ns well as grapes, peaches and tomatoes, either in pots or planted in a border of soil. During the spring and summer months half-hardy flowering plants, e.g. fuchsia, tuberous begonia, zonal geranium and gloxinia, may be grown.

There are two chief types of glasslıouses, the span roof and the lean-to, the latter being built ngainst a wall. A garden frame is indispensable to the possessor of a glasshouse; there the plants are propagated and kept until well developed. A pit is a frame or small glasshouse the Hoor of which is below the ground level; it is often uscd for the oultivation of melons and cucumbers Special glasshouses are constructed for the various classes of stove, intermediate and coolhouse orchids. See Greenhousc.

PLANTING. The best times to plant are autumn and spring, the former period being preferable for hardy perennials and lenf-losing i rees and shrubs. Evergreens may be planted in September-October, or in April and May. Farly planting, either in spring or autumn, is sound practice, when preceded by thorough preparation of soil.

The method of making holes just sufficiently large to accommodate cramped roots should be avoided: they must be opened enongh to provide ample space, with a little to spare, when roots are spread out horizontally. The value of trenching land before planting is great. See Digging; Mulching; Trenching.

PLANT LICE. The name is applied to the various types of aphis, such as the grcen tly, which do great harm to all kinds of plants by sucking sap Infested plants out of doors should be syringed, during a dry evening, with an insecticide, or with a homely remedy made of soft soap and quassia chips in solution. In the greenhouse fumigation with a suitable fumigating compound, such as $n$ nicotine preparation, miny be found to be necessary.

The best treatment for apple, plum, and other trees infested with lice is to spray the lower leaf
surface rrequently with an insecticide. Certain garden insects, including the ladybird, ichneumon fly, etc., are voracious devourers of plant lice. See Insecticide.

PrAQUE. Ornamental tablets of metal, porcelain, majolica ware, ivory, plaster, marble, etc., usually carved or decorated in some manner, are known as plaques.

With the exception of polychrome enamels, such as the lith century masterpieces of Limoges, metal plaques aro usually wrought in low relief. They may be hammered out in repoussé, or cast and chased, ns in the case of ormolu or gilt bronze, being sometimes oval portraits in the manner of large medallions, sometimes round or oblong scenes of classical or local interest. If they are of actual value,
as examples of antique work, they should be protected by appropriate glazing.
Ceramic plaques of value usually take the form of old delft, either Dutch or English, of majolica, or the jasper-ware plaques introduced by Josiah Wedgwood.
PLASHING. This is a method of repairing or confining a liedge by bending shoots tnwards the roots and cutting the stems half through. In this way the sap is still allowed to circulate, the stcms remain alive, and unruly ones bccome pliable enough to twist a mong others. Care must be taken that the plashed stems, or branches, are not cut more than half through, ol herwise they will die. Proper trimming and attention to hedges in season will generally e, obviate any necessity for plashing. See Hedgc.

## Plaster and Plastering Methods

## The Effective Treatment of Walls and Ceilings

For further details ahout work of this kind the reader should turn to the article House Sce also Ceiling; Cornice; Float: Frieze; Hawk; Lath; Mortar; Partition, ctc.
Plaster is the name given to calcareous here is prepared from pure chalk lime compounds with a base of calcium sulphate. In the general use of the word, as applied to building operations, it refers to a mixture of lime, sand, and water, gencrally with the addition of plaster of Paris, or some other material to accelerate its setting. The genera! use for plaster, as far as the amateur is concerncd, will be in the plastering and repair of wall surfaces.

The plaster for a wall is applied in 2 or 3 separate conts. The first, or pricking up coat, is applied with coarse stuff coniposed of a good chalk limo, coarse, clean, sharp sand, and clean ox hair. For the mix-up the sand is arranged in the form of a hollow basin, preferably rested on boards (Fig. 1); but if the ground is impervious, such as a concreted floor, it can be set direct upon it. The lime should previously bave been thoroughly slaked, and is used in the form of a putty with a consistency not unlike that of thick cream.

This is sifted through a sieve, which may be rested upon a couple of poles or hoards upon the surface, and water is run through it, if necessary, to ensure that no lumps of the lime are prevented from being inixed with the sand, which should previously have heen sifted for a similar reason. The hair, when purchased, is in a clotted state and all lumpy. It is separated by placing some of it on a bonrd and beating it with two sticks, one held in each hand, so as to separate the hairs without breaking them. The hair when heaten is disposed over the slaked lime, and the whole of the sand and lime turned over and thoroughly well mixed with larry and shovel. The mixture should be just wet enough to mix evenly. The larry is a broad bladed tool resembling a hoe. In the blade is a large hole, which aids the mixing of the plaster.
The mass that is thus prepared should be is left to temper, the nore satis. factory the plas. ter. The usual proportions are 1 of lime, 3 of sand, and 1 jb . of hair for every cubic font of coarise stuff. The object of mixing the hair is to bind the plaster together and make it more tenacious.
The plasterer's putty or lime. putty referred to
heaped up and left to temper for as long as possible before using. Coarse stuff made in this way can be used at once, but the longer it

Plaster. Fig. 1. Preparing tho llme plaster in the centre of a crater of sand
measuring aloout 14 in . across, with a small round handle underneath. Stuff that is being applied to the wall or ceiling is conveyed from the mortar hoard to the hawk and laid on with a trowel. The latter is an oblong tonl made of steel, having a handle attached, and is used for applying the first coat of material, known as the coarse stuff The hand float, similar in shape, but made of wood, is em. ployed for applying the linal or setting coats. The scratch consisty of 3 or 4 laths nailed together in the form of a fan, the ends being pointed. It is used for scratching over the surface of the accond coat, so as to form a key for the succeeding coat.
The pauging trowel resembles the ordinary thowel used by bricklayers, except that it is tapered, and does not terminate with a sharp point, but is slightly rounded off. Its use is for mixing small quantities of material, such as putty and plaster. The margin trowel is for work where it would not be possible to use a float. In shape it rescmbles a small shovel with the sides turned up ahout $\frac{1}{2} \mathrm{in} .$. and is made of steel. The stock brush is for sprink. ling small quantities of water on to the work to keep it to working consistency.

Thore are other tools used by the plasterer which require professional skill and much practice to handle ; they arc used principally in the formation of mouldings and cornices. For example, the running horse is a tool cut to a particular shape to form a certain section moulding. These tools are generally specially made for the particular job, in conjunction with small moulding tools of different shapes. Another tool is the joint rule (Fig. 3) for working in the angles on cornice work. All thesc implements may he obtained from any good tool store.
Plastering a Brick Wall. Supposing that a rough brick wall is to be plastered, then the work will he carried out in the following manner: First, with a garden syringe or a bucket and brush, thoroughly wet the bricks Having placed several buckets fill of the coarse stuff on a mortar board in a convenient position, as, for example, on a box adjacent to the wall to he plastered, take a hawk in the left hand and the laying on trowel in the right hand, and, with a swinging, circular movement apply the plaster to the brick. work, pressing it firmly into contact and making it about $\frac{1}{2} \mathrm{in}$. thick. Fig. 4 illustrates the method of application. Only sufficient of the wall should be covered at a time to permit of convenient working.
The next stage is to tako a derby float, and work over the whole surface to Hatten and even it. If, however, tho wall surface is to he got up in any style, a screed lvill be necessary. This, in the case of 1 room having a picture rail and skirting board, may be wooden strips about 2 in. wide and $\frac{1}{2}$ in. thick, securely nailed to the wall, and backed up when necessary with rough grounds, so that their surfaces are in line and repiesent a level surface. A traversing rule or long batten is worked up and down, levelling off the plaster and making its surface uniform with the level of the grounds.

When the plaster begins to set, a wide, flat, mugh wood float, having a nail driven through it, the point of which projects through the face, is applied to the surface of the plaster, producing a series of scratches ; this provides a key or hold for the second coat. For all ordinary partitions a second coat may be applied the next day; it may be composed of fine stuff, gauged with a proportion of Keene's cement, or some similar hard, quicksetting material. It is applied with a wooden float, this coat not being so thick as the former.
Fig. 5 shows the mortar hoard in position in the centre of the room and the second coat in course of application. It is brought to a
true and that surface by the aid of a traverwing rule, with a metal float and a liheral application of water. The great point is to prevent the plaster from setting ton quickly, and this can generally be accomplished by moistelling the work, and keeping it damp as the job proceeds, both with the first and second couts All small blemishes are carefully worked out with a laging-on trowel, or hand tloat. as illustrated in Fig. 6 , and the corners linished off. They may

Which tutie the form in general of cnst plaster enrichnents, the plaster of which they are composed heing reinforced with fibrous material, such as hair, coconut fibre, and the like. In many cases canvas is used as a backing, and

ling it Hat, true and level with the surface. To ensure a good joint the edges of the old work must be kept saturated with water. On all angles or corners liable to sustain extra wear, the first coating of plaster should be composed of Portland cement and sand in equal proportions. Sometimes in a lath and plaster partition or ceiling the laths are broken, or they fail through age or some defect, in which case all the affected laths should be cut out and replaced by new. The process is descrihed and illustrated under the heading Ceilings.
PLASTER: In Medicine. The value ol
be finished aquare with the aid of a special thin strips of wood are employed as a reintmwel virtually having two faces, which work forcement These are siniply cemented in place simultaneously at the juncture. A different with plaster of J'aris. treatment, and one that is very effective and hygienic, is to cove the corners, that is, mund them off, using a wooden float more or leas triangular in section, with one of the angles rounded off to the desirel curvature. The appearance of such a corncr, in course of completion, is illustrated in Fig. 7
Great care must be taken in reducing the linishing coats to a sinooth and level surface in every part. It is important in this connexion to work the lirst layer as evenly as possible. Equal care should be taken in linishing the arrises, or edges, of projecting corners, particularly the edges of chimney breasts.

Ceilings. Similar methods are employed in the case of ceilings. These are often decorated with applied fibrous plaster ornamentations.

If the cornice is large and consequently too heavy to he made solid, it is usunlly cast in pieces and then fixed into position. An alternative method is to fix blocks of wood, either triangular in form or of a shape ap. proaching nore nearly to the outline of the comice, so that strips of wood or laths may be nailed on and thus provide a strong foundation for the first layer of coarse work Full instructions for repairing a damaged ceiling are given in the article on Ceilings (q.v.). Plaster work on walls is liable to surtain damage, in which case any dents or bruises can he lilled in with neat plaster or a mixture of lime-putty and plaster of Paris. The general procedure is to hack out the plaster over the damaged area, thoroughly wet it and work
in the new plaster with a small trowel, trowel- plasters applied to the skin may depend on the support and pmetection they give, or on the Jrugs they contain.

A plaster should not be used indiscriminately for closing akin cuts and slight wounds, as there is always a risk of microbes thus being enclosed in the wound. The wound should first be protected by a thin layer or pad of antiseptic gauze. Strips of plaster should be used with spaces between to allow of the escape of discharges. Plastery are usunally so made that the heat of the borly melts them suflicient.ly to allow of them clinging to the skin. Sce Adhesive Plaster: Corn ; Mustard.

PLASTER OF PARIS. Calcium sulphate, known as plaster of Paris, is used for the production of casts of many varieties of small atatues and ornaments, for mouldings and interior decorations. It is employed in making

Fig. 4. Using the layingion troweí io appiy urst coat ol plaster. Fig. 5. Applying the finishing coat. Fig. B. Hand Hoat finishing the coat. Fig. 7. Rounding off a corner with a wooden float which is triangular in section with one of ita angles suitably curved
numerous applications in surgery. It is finely ground and is obtainable in several grades, and should invariably be kept in a dry place.

Plaster of Paris has the property of setting into a hard white subatance when it is mixed with water. The best proportion to use is water I pint to plaster 2 lb . When the plaster sets, it expands slightly.
Plaster figures are made by pouring mixed plaster into moulds. The figures are generally hollow, the residue of plaster from the centre being poured out before it has had time to set. If a small proportion of Portland cement is added to the plaster the time of setting is delayed. The hardness of the plaster is increased by using alum solution instcad of water in the mixing prucess Plaster of Paris is useful in the household for mending broken tiles and for filling up crevices in walls.

If only a small quantity is wanted, a good plan is to fill a bowl about of with cold water and pour in the plaster with a circular motion, distributing it evenly over the water and nt the same time stirring with a circular motion using a wooden spoon or smooth stick. The surface of the water will exhibit air bubbles, and the plaster should be stirred until these bubbles no longer appear The stirring should be steady, and the water should on no account be riolently disturbed, as the air bubbles will be imprisoned and the work will be imperfect The mixture speedily gets thicker, and it required to be poured into a mould to make a cast, this should be done just as the plaster is in the thickening stage, approaching the consistency of thick cream. If required for moulded work, pour the plaster in steadily so that the air in the mould can escape. See Casting ; Modelling.

PLASTIC WOOD. This is the name given to a preparation of word in paste form. It is used as a filler in woodwork and for a variety of other purposes. It can be moulded by hand or modelled, dries and hardens in a short time, and takes stain or polish readily. When using plastic wond to fill nail holes, knot holes, or shakes, the stopping should be left a little above the surface level and the surplus chiselled off when dry. Any moisture or grease on the surface to be treated will provent the filler from adhering properly, and i a considerable area is to be dealt with it is as well first to apply a little of a special softening preparation, which can be had from the maker of the plastic wood.

PLATE: The Utensil. As used in the household a plate is a tlat, shallow dish used for holding food at the table and elsowhera Plates are made in cvery possible kind of china and earthenware, in enamel ware, aluminium and pewter. In dozens or half dozens they form an essential part of break. fast, dinner, dessert and tea services. Plates of four sizes are usually part of a dinner service, those for the soup having deeper bowls than the others. With breakfast and tea services there are larger plates for bread and butter, cakea, etc. Plates are also sold singly or in odd numbers, and plates of metal are used for cooking and other purposes.

Plate Rack. Usually of wood in the larger sizes, smaller plate racks are often in metal. Teak wood plate racks with accommodation also for cups and saucers are convenient fittings for the scullery or kitchen sink when there is a good deal of washing up to be done for the household.

When fixing a wooden plate rack, stout ear plates (or mirror plates) are screwed to the back, and plugs are fixed in the wall at suitable places to coincide. If fibre plugs are used (see Plug), screws must be employed which are threaded close up to the head, so that the screw can be driven right home into the plug and properly grip the countersunk portion of the ear plate. When attaching the plates sce that the countersunk side of
the bole in projecting top portion faces the proper way (i.e. outwards into the room).
Plate Warmer. Any apparatus that is used for heating plates or dishes may be described as a plate warmer. A type used mainly in large establishments somewhat resembles a miniature oven. and has separate shelves for plates, vegetable and meat dishes.
In the home, the iron rack nbove the stove is often used as a substitute for a warming plate, the dishes being left there while the meal is being prepared. A small metal standard plate rack is useful for this purpose, and it accommodates a number of plates. Electric warming plates can be obtained in various sizes, fitted with flexible cable and wall plug.
A less modern kind of plato wariner still used consists of a deep dish which contains a trough for holding hot water. The plate is placed on top of this trough, and the water as it becomes cold is poured away, fresh hot water being put in to replace it. See China; Dinner ; Sink: Tea; Washing (T).
PLATE : In Photography. A plate is a piece of thin glass of standard size coated with light-sensitive emulsion for exposure to light in a camera. After exposure and development plates are called negat-ivcs. When the sensitive cmulsion is coated on a celluloid support the combination is known as a film.

There is a somewhat greater variety of glass plates than of films, both in the matter of speed or degree of sensitivity to light, and of the kinds of emulsion used. For this reason many amateur and professional photographers prefer glass plates to films, in spite of their greater weight and bulk. Nevertheless the use of flat films in addition to roll films has so increased that one company, the Kodak Co., has abandoned the manufacture ol glass plates.

Varieties of Plates. The varieties of plates which are of use to the amateur are stated in the following paragraphs.
Ordinary plates made uncler this title by most plate manufacturers are coated with plain emulsion and moderate in speed, and are very suitable for all-round amateur work if sufficient exposure can be given. They have a finer grain than faster plates, and therefore give good contrast and make excellent enlargements and lantern slides. They are not fast enough for snapshot work. Orthochromatic or panchromatic emulsions include dyes that give more accurate response to colour values than the plain cmulsions.
The plate sold as ordinary has generally a speed of about 70 H . and D. (Hunter and Driffield system). Other ordinary plates, i.e. with plain emulsion, but of higher speeds, are sold under such names as Rapid, Special Rapid, Ultra Rapid, Speedy, etc., and have H. and D. speeds of about $100,125,170,250$, 300, 400, 500, and 600. Even higher speed emulsions are now gvailable. Unfortunately not only are there different systems of calcula. ting plate speeds, but there is great difficulty in obtaining results which are scientifically consistent. Thus a batch of plates marked 200 H . and D. by one maker is not necessarily of the same speed as another maker's plates also marked 200 H . and D. This is the principal reason why the amateur is always advised to keep to the brand of plate whose qualities in working he knows by experience.

A speed number is not a reliable indication of the quality of a plate. As a general rule medium speed plates are more likely to be of high quality than very fast ones, although some of the most rapid plates give very good results. Experience can be the only guide in the choice of a plate, but for general use an extremely fast plate should be avoided. The slower plates have thicker emulsions than the faster, and are therefore freer from liability to fog, give better contrasts, and a wider range of tones. The faster plates have much thinner emulsions, and there is consequently greater
difficulty in manufacture to ensure freedom from fog, and to avoid lialation owing to the surface of the glass support being nearer the surface of the film. Fog is due to scattering of light over the sensitive surface of the plate with the result that a general greyness is observed in the negative which consequently gives a somewhat flat, grey print.

Many plates are now available designed to overcome halation troubles. One method is to coat the back of a plate with a black nonreflecting substance, such as caramel. Thesc plates are sold as backed plates. Another is to coat the plate with a matt emulsion. When developed, the negative has the appearance of being coated upon finely ground glass. For interiors with window-lighting, light coming through tree foliage, polished metal articles. and similar subjects which cannot be satisfactorily reproduced on ordinary plates on account of halation. thesc plates are very useful. Other anti-halation plates are available in which a special light-absorbing coating is placed between the emulsion and the glass plate.

For amateur purposes the sizes of plates best suited are the $3 \frac{1}{2} \mathrm{in}$. by $2 \frac{1}{2} \mathrm{in}$., the $\ddagger$ plate, and the $\frac{1}{2}$ plate, the favourite being the $\&$ plate. A better-shaped plate for general use, particularly for landscape work, is the standard continental plate, 9 cm . by 12 cm ., or a bout $3 \frac{1}{\frac{1}{2} \mathrm{in}}$. by $4 \% \mathrm{in}$. The following are standard Iritish, and continental sizes.

STANDARD SIKES OF PLATES

| Name | Size | Diggomal |
| :---: | :---: | :---: |
| - |  | 3 ln . |
| - |  | $41 \mathrm{ln} .$ |

The diagonals given in the above table serve as a guide to the size of condenser required if the plates are to be used in an enlarging lantern. All the sizes given are also standard sizes for bromide and gaslight papera and the sizes up to whole plate for P.O.P. See Developing; Film; Negative ; Panchromatic.

PLATE GLASS. In the processes of its manufacture plate glass is finished with a flat and true surfacc, and, being transparent and free from irregularities or surface niarkings, it is used for good-class windows. In the home plate glass is also used as a protective covering for washstands and the tops of tables. The surface is easily kept clean, and docorative material can be placed beneath the glass to add colour to the room. In the same way a well-polished piece of furniture or tray can be protected, and the grain and colour of the wood revealed.

Another application of plate glass in the home is as shelves in the bathroom, or for pastry making in the kitchen. Nhelves should have rounded and polished edges, and they aro generally supported by clectro-plated wail brackets.

Plate glass can be purchased from builders' merchants or first-class ironmongers, and has to be cut to size by the manufacturers. In ordering it is well to give the exact dimensions, or a full-size pattern of the piece required. The thinnest plate glass measures $\frac{2}{18}$ in thick. A usoful thickness is $f \mathrm{in}$., and this will generally be supplied if no thickness is mentioned at the time of ordering. Sec Glass.

PLATE MARR. Articles of gold and silver plate are marked with a set of symbols by certain recognized guilds or assay offices in the

United Kingdom, as a guaranten that the metal is of stinndard purity, and also to indicate the date. Thesc hall-marks on plate are a greater saleguard than pottors' marlis on chisa, and are always taken into account by rollectors Thry have no relation to the artistio inerits of the plate.

From 1784 to 1890 in Great Britain, and from 1807 to 1890 in Ireland, the sovereign's head was punched on all plate to denote that duty had been paid The duty marks of the three kings faced to the right, Qucen Victoria's to the left Duty-free pieces, intended for export, were identified by a figure of Britannia to prevent their being sent out of the country duty free and then inmediately brought bacl ngain. In $187 \%$ all imported plate marked at an English office wins required to bear the letter F, to indiente its foreign origin. In 1900 distinctive symbols for imported plate were prescribed, such as the constellation Leo for London, of Libra for Sheffield, and a triangle for Birmingham. See Silver.
PLATINOTYPE. In this process of printing pictures from photographic negatives tho final picture is composed of platinum, and is therefore of the highest degree of permanence.
When exposed behind the negative in a printing frame the picture gradually appenis as a la int brownish image on the yellow paper. Alter some practice it is ensy to judge when the paper has been sufficiently exposed; the detnil of the picture requires to be visible everywherc except in the highest lights, suclı as the sk.y. The paper is much more rapid than P.O.P., so that in bright daylight only $\longrightarrow$ or 3 min . are required for exposure.
The paper must be kept perfectly dry both before and after exposure and during printing. It is sent out by the makers in sealed tins containing calcium chloride, which keeps it absolutely dry. Unless the prints are to be finisherl off as soon as they have been made, they sloould be put in one of thesecentainers until the time arrives for development. The paper should be backed up in the printing frame with a sheet of thin rubber or oileloth or a piece of celluloid, in order to prevent moisture getting in.
Several varieties of platinotype paper are made, some for prints of black colour and others for sepia; different surfaces are also available. The former are developed in a cold solution, but for the sepia papers a warm developer is necessary.

The handling of the paper after exposure is exceedingly quick and simple. The print bearing the finint picturo is floated face down on a developing solution, which immediately causes the picture to flash up to its full depth. The print is laken off the developer for an instant and a picce of glass rod run over the surface, so as to ensure that every spot is covered by the developer. It is then allowed to remain floating on thic developer for a further half minute or longer. The developer consists of a saturated solution of oxalate of potaah, and it is important that this cliemical should the pure A specinl form of it is supplied by the Platinotype Company in packets requiring ouly to be dissolved in hot water.

## Washing the Print.

$\qquad$ As soun as develop. ment is complete the print is transferred, without washing, into the lirst of three baths of weak acid made by mixing 1 part of pure hydrodhloric acid in tio parts of water. Three lots of this solution are put in white porcelain dishes, and the print is nllowed to remain in each of the threc for about 5 min . The object of these baths is to remove the yellow iron sensitizing salts from the paper; unless this is done the prints will retnin a certain yellow stain. The teat for complete removal of the iron salts is that bath No. 3 remains perfectly water-white alter the print has bern
in it for 5 min If at the end of this time any yellow tint can be seen, bath No. I should be thrown away and its place taken by No. 2 . The latter is in turn replaced by No. 3, and a fresh lot of acid poured out for the third bath.
In working off a considerable number of prints it is best to allow them to remain for longer than is min., say 15 or 20 min., in bath No. 1 This will do no harm so long as there is plenty of the solution, a nd it will a void the necessity of replacing the third bath by fresh. Even in their weak state these acil baths render the paper somewhat tender, and care must be taken not to trar the prints nor to rub onc over another.
From the last bath the prints are translerred to running water and aro washed for about $1 \overline{\mathrm{~J}} \mathrm{~min}$. They are then laid out or hung up to dry, or can be pressed dry between blotting paper, or even dried quiokly hefore the fire, since there is no golatine coating on the paper.
With sepia papers the developer must be heated to a temperature of from $160^{\circ}$ to $170^{\circ} \mathrm{F}$., by putting it in a porcelain developing dish placed over a small gas ring. Sepia papers must be treated separately from those for black prints in the acid baths, otherwise the pure black colour of the latter will acquire a sepia tinge. For the sance reason black and sepin papers should never be kept together in the same container, nor should a dish used for sepia developer be afterwards used for the black papers. See Photography: Printing.
Platinum : The Metal. Of whitish. grey colour, platimum is generally to be found in tho native state, although it inay be alloyed with other platinum minerals It is used extensively for the manufacture of jewelry and objects of art, for various dental and medical appliances, and for several forms of clienical crucibles. Owing to the fact that platinum has nearly the same expansion rate as glass, it is employed in making many forms of electrical contact points and connexions for lamps and other fittings, especially wherc the conductor has to pass through the glass.
Platinum is used in jewelry chietly as a setting for diamonds. On account of the high cost of this metal, such a setting is usually backied with gold. Platinum needles, or points, as they are called, forin a part of every pokerwork outfit, and their uses in this connexion are described under the heading Polierwork.
PLATYCERIUM. This plant, which is commonly linown as the elk's-horn fern, is epiphytal in form and practically provides its own nourish mient. Its horn-shaped fronds are

Platycerium, or elk's-horn fern, a greenhouse fern with curioasly shaped fronds
fertile, but in addition to these it throws up tlat, broad, barren fronds, which spread upon thic surface; these decay, and provide substance upon which the plant survives.
Plants are best arranged upon blocks of wood, covering their roots with pent and inoss, and binding the whole firmly with copper wire. Thus prepared they may be suspended from the roof or other parts of a warm, shaded greenhouse, keeping them moist at all times, and top-dressing every year with peat and fresh moss Propagation is by offsets, with rootlets, thrown off at the base of the plant. and planted during March.
PLATYSTEMON. The common name of Californian poppy ( $\mathrm{q} \cdot \mathrm{v}$ ) is applied to the hardy annual, Platystemon californicus, and to various other tlowers The platystemon, which is raised from sceds sown out of doors in April where the plants are to bloon in summer, grows from 10 to 12 in . high, has grey-green leaves and bears pale yellow poppy-like tlowers.
PLAYER PIANO. The terms player piano and piano player are often used as if they were synonymous, which is not the casc. When the idea of playing the piano by means of a mechanical adjunct first became practicable, it took the form of a cabinet containing the mechanisin, which was moved to and from the piano as required This was the piano player. It had drawbacks in the way of adjustment, which inventors overcame by finding room for the mechanism in the hody of the piano, thus making the adjustment invariable. This is the player piano. Apart from certain differences connected with the altered positions, the principles of construction and management are the same.

The Mechanism. The principle of the player is pneumatic. The motive power is supplicd by a pair of treadles like those of the harmonium, whioh fill the bellows, the action being made to operate on the keys of the pianoforte. The notation for the player piano consists of a roll of paper having perforations in it. This roll is attached to the spool, and when the treadles are worked, it unwinds and passes over a tracker bar picrced with $8 \overline{0}$ or 88 holes corresponding to the notes of the ordinary or the extra compass pianoforte. When a hole in the roll coincides with a hole in the tracker bar, the note on the piano corresponding to it is made to sound.

Below the keys are if or more levers, or sometimes buttons, for various purposesrolling and re-rolling the music ; controlling the tempo: kassening the tone on either or both balves of the compass; and working the pedals of the piano; to which may be added one for controlling the melocly.
The player piano is an ingenious device for rendering pianoforte music without the aid of fingers (in a pianistic sense), but there is, however, not only ainple scope, but an absolute necessity, for individuality on the part of the operator if the elfect is to be musically satisfactory. The player piano has to be studied just the same as any ot lier instrument, and the first thing to be learned is how to use the treadles, for on this depends the various degrees of tone from pianissimo to fortissimo.
The possessor of a player piano should always buy good rolls, not only ns to the music cut on then, but also as to the quality of paper, for if this be poor and soft it will take up moisture from the air, swelling to such an extent that exact tracking and accurate playing will be out of the question. The roll can be dried. but it is hetter to buy the best only. It is cheapest in the long run, as with careful use a roll should last a long time. In buying a second-hand instrument it is best to get someone who unclerstands players to test it thoroughly before clinching the bargain. See P'iano.

PLAY PEN : How to Construct. Suitable either for in or out of doors, a play pen is useful for assisting a baby to walk. For convenience in carrying it about, the pen should fold up in a small space, and, although it should be strong and rigid, the method of construction must allow of the use of comparatively thin material.
The play pen illustrated in Fig. I has 2 long and 2 shorter sides, the latter being hinged together in the centre and nlso linged at each end to the long sides, so that they fold inwards and allow the sides to closo up. First prepare four 48 in . lengths of birch or whitewood to $1 \frac{7}{8}$ in. by $1 \frac{1}{8}$ in., and, if the materin is purchnsed especially for the purpose from a timber yard, order some 2 in. by 1 i in . mnterial to be machine-planed on all sides, which will bring it to the approximate size. In addition, nbout 53 lengths of 8 in. birch dowels, 24 in. long, and another 12 ft . of the $1 \frac{1}{8}$ in. by $1 \frac{1}{8}$ in. wood will be sufficient.
Place 2 of the 48 in . lengths together, and, beginning at the centre, set off $1 \frac{1}{2} \mathrm{in}$. each side, and follow with 3 in. marks across the edges, making 16 marks in all and leaving a 1 d in. space $n$ t each end. Draw a line along the centre of the whole length and bore centre or twist bit holes to a depth of $\frac{3}{3}$ in., but first make sure, by testing, that the hole is a tight fit for the dowels. The total height of the pen is to be 24 in . over all, so that the depth of holes and length of rods must be carefully gauged throughout the job. On the remaining 2 lengths draw a line along the ventre. Place them together, and this time commence marking 3 in . spaces $7 \frac{1}{2} \mathrm{in}$. from the centre, which will give 12 centre marks for the holes. In one length, which will be the bottom one, set out 2 minks 4 in . from the centre; the corresponding space in the top piece is left plain. Bore holes as before Then plane off the corners of top lengths and at top of bottum lengths, round the ends and finish quite smooth. The 2 lengths with the 16 holes nre now glued up, the dowels being cut off to 218 inches.
The section at Fig. 2 shows the shape of the top pieces with the dowels in position. When the round rods of the other long side are in position, there will be a space of 15 in between the 2 inner ones, this is to allow for the bead frame. The method of making this part is to trim the ends of a $15 \frac{\mathrm{~g}}{\mathrm{~g}} \mathrm{in}$. length of dowel for the horizontal piece, A, as in the section at Fig. 3, and three 11 ? in . lengths for the vertical rods at B. Holes of $\ddagger$ in. diameter and $z_{8} \mathrm{in}$. deep are bored in the 2 up. rights ilt in. up, and others corresponding to those at the bottom in the horizontal length, and the trimmed ends of rods fitted in.
Three 158 in. lengths of $\frac{3}{16} \mathrm{in}$. brass rod are next fitted in the upper part of the inner uprights ns at C Fig. 3 and 18 coloured glass or wooden lends threaded on, 8 on the top. 6 on the centre. and 4 on the lower rod. The side can now be glued up, provided all corners have been rounded and smoothed with glass paper.
An alternative method of securing the short lengths of dowel is to file $n$ hollow on the ends and screw them together as in Fig. 4. Instead of using round wood for the uprights and centre bar. $1 \frac{1}{8}$ in. square wood can be mortised and tenoned together.
For the ends, cut off 8 lengths of $16 \frac{7}{8} \mathrm{in}$. by $1 \frac{7}{7} \mathrm{in}$. by $1 \frac{1}{8} \mathrm{in}$. wood,
place them together, and set off 3 in . marks from one end; these will fit next
the side. Draw centrc lines and bore the holes for the dowels as before, ench length having five holes. Round the top lengths to match those of the sides as shown in the scetion at Fig. 2, nnd take the corners off the underside and on top of the bottom lengths. Dowels can then be fitterl and glued to give a total height of 24 in ., as with the sides.
Before the corners are hinged together, ns at Fig. 5 , with $1 \frac{1}{2}$ in. by 1 in. back flap hinges, the 2 halves of the ends are hinged with similar hinges on the outside, ns shown in Fig. 6. In addition to the hinges, it is necessary to fit locking plates on the top bars; these are made from shect iron or brass 5 in. by 1 in . by $\frac{1}{d}$ or $\frac{3}{8}$ in.
The screw holes are drillell at one end, and a $\frac{1}{4} \mathrm{in}$. bolt soldered to the other through a hole drilled $\frac{1}{2}$ in. from the end, the end of the plate being rounded as in Fig. 7. The plate is screwed to one half of the rail, and the bolt fits in a hole in the opposite half, being held by a wing nut as in Fig. 8. The centre for the hole should be accurately marked from the plate and bored right through the top rail; but to allow the bolt to enter, the wood is cut away with a chisel at a slant on the inner edge of the hole, as shown in Fig. 9.
In order to prevent the loss of the wing bolts, a groove should be filell round each, and a length of brass wire with an attached loop fitted on, the ends being soldered, so that it will move but not slip off. A length of chain is attached to the is attached to the
loop, as in Fig. 10,
and fastened to the top rnil. The woodworls if quite smootl should be sized and varnished, or it may be enamelled white. The metal fittings, with the exception of the rods in the bead frame, should bo conted with black enamel, but care must be taken that the rough edges of the hinges and locking plates are taken off with a file and smoothed up with emery cloth. See Baby : Nursery.
PLEATING. One or more folds of material pressed flat and held in usually at the upper end only, allowing the lower one to open and give extra fullnes 3 when required, is called pleating. The arrangement of folds to form pleating is used extensively in dressmaking.
Different kinds of pleating arc suited to heavy or light materials. Kilting and boxpleating are gencrally employed for the former, while a finely woven material should be chosen for accordion pleating, as otherwise it is diffcult to keep the pleats in place.
Inverted pleats or box pleats are made as shown in Fig 1, quite close together. In the case of plealing for a skirt a piece of binding or taps is usually placed at intervals of about 6 in. ncross the inner side of the pleats, nnd tacked to each one to prevent them opening and coming out of shape. Crêpe-de-Chine, georgette, or any light woollen fabrie can be accordion or knife pleated with success. Accordion pleats are rather difficult to keen in place. Knife pleats (Fig. 2) may be tacked into position and pressed flat.
Pressing the Pleats. When pleats become creased or lose their shape, the garment should

Pleating Fig. 1. Inverted and bor pleating. Fig. 2. Knite pleating
painted with a mix. ture of equal parts of the tincture and the liquor of iodine. Drugs such as potas. sium iodide, the salicylates, etc., are usually given. Aspiration, or removal of Huid through a hollow needle inserted by the physician into the pleural sac, is a common remedy in this disease, notably in the chronic form. Exercises to expand the lungs ahould be practised. Iron tonics and cod liver oil are useful, and a few months' residence
tacked into place, and the whole covered with a clean, damp cloih. Press this heavily and evenly with a hot iron unt 1 it is dry and the steam ceases to rise, and the pleata will then be found neatly pressed. If the pleats are many, the process should be done in stages, two or three pleata being pressed at a time. The jron should not be too hot, otherwise the covering cloth may be dried before the pressing is finished, or the garment beneath may be badly singed. If the result is not satisfactory, the cloth may be damped again and the process repented. Box pleats are the easiest to press, but the finer kinds and sunray pleating, in which the pleating widens towards the base of the garment, need to be arranged skilfully, and in a great number of cases are best sent away for professional treatment.
Pleated frilling in net, ninon, and voile becomes $\operatorname{limp}$ and shapeless when washed, and requires special skill in ironing to restore the original pleats. Some of the laundries specialize in dealing with pleated and frilled garments and return them in an almost new sondition. See Accordion Pleating; Box Pleat.
PLEIONE. To-day classified as Coelogyne by botanists, this genus of orchids includes some very pretty species. One of the best for cultivation in a cool greenhouse is maculata ; its flowers are fairly large, with attractive markings of yellow and orimson upon white, and these are borne in autumn, appearing while the plants are leafless. See Orchid
PLEURISY. Pleurisy, or inflammation of the pleurae, the membranes which line the chest cavity and cover the lungs, often follows a chill, but this is only a predisposing cause. The active agent is the germ of such diseases as diphtheria, typhoid fever, pneumonia, and especially tuberculosis. The attack may be of the dry type, or fluid may accumulate in the pleural cavity.

In dry pleurisy a severe cutting, stabbing stitch is felt under the armpit or around the nipple, but it may be above the collar bone or on the abdomen. Any movement of the chest greatly increases the pain. Vibration may be felt wherp the hand is laid on the chest. The patient lics on his back, or very often on the healthy side, because pressure on the affected side causes pain; when the pleura becomes filled with fluid he usually lies on the affected side so as to have full use of the healthy side.

Pleurisy with effusion, being commonly caused by the tubercle bacillus, is often fol lowed by consumption of the lungs. much fluid fills the pleural sac, it may causc bulging of the spaces between the ribs, and the heart and the abdominal organs may be displaced.
In the dry stage the chief aim of treatment is to relieve pain. For this purpose apply linsced meal poultices, hot fomentations, turpentine stupes, or a mustard poultice. In the effusion stage the affected side is often
at a mountain resort is very beneficial in most cases. See Lung.

PLEURO - PNEUMONIA. This term means, with reference to human beings, a combination of pneumonia and pleurisy. The term is more properly applied to a disease which is very fatal to cattle but does not affect human beings. See Pneumonia

PLIERS. Of the many patterns of this tool there are 3 that should be found in every amateur's tool kit, and these are: side cutting, gas and round-nosed pliers. The first, generally made with Hat jaws and with cutting edges at the sides, are used for snipping of wire. Gas plicrs, made with serrated, circular, internal jaws, are for gripping pipes and rods. Round-nosed pliers with tapered jaws are indispensable for forming eyes at the end of wire and for other purposes, such as bending wire and thin sheet metal.

Electricians' pliers are made with heavily insulated handles to protect the worker from electric shock. Small flat-nosed pliers are bandy for bending thin metal. Cone pliers, which resemble gas pliers, are used for tightening cones on a bicycle. See Leather Work.

Plimsolls. This word is sometimes used for the rubber-soled shoes worn by children and known also as sandshoes.
PLINTH. As employed in architecture a plinth is the base or alab on which a column rests. The term is also applied to the same part of the construction of a base for a statue or pedestal. In another application the word is used to describe the upper projecting course, or cornice, of a wall The word is also used in a similar sense by the woodworker. See Chest of Drawers: Cupboard.
PLOUGH: The Plane. A plough is a woodworking plane designed to make a groove on the face of a board parallel to an edge. The bardwoorl body of the plane is furnished with a stcel sheet, or blade, projecting down-

Plougb Plone. Simple type used for making a groove to tate isid in. plywood Inset, right, sectional view of the plane Courlesy of Handicrafls, Lid. cress and cut lemon.
ward, which is divided so that the cutter, or iron, can pass through : the blade is thinner than the width of the narrowest iron to be used. Two bars pass transversely through the body of the plane, and carry a hardwood block, or fence, adapted to bear against the edge of the board.

In use the bars are pushed through the planc body and locked by wedges, so that the distance from the centre of the iron to the face of the fence is equal to the required distance from the centre of the groove to the edge of the board. The width of groove depends on the size of the iron chosen. The amount cut at each stroke is regulated by the amount that the edge of the cutter projects below the bottom of the blade: the iron is locked by a wedge aftes being adjusted as required. The total depth to which the groove is ploughed out is regulated by an adjustable stop below the plane body.

The tool is pushed along the work repeatedly till it reaches the required depth. when it

ceases to cut owing to the operntion of the stop. While cutting is in progress the fence is kept up against the edge of the work so that the groove comes in the right place. The tool must be so held during the cutting process that it is kept level laterally. Two useful types are illustrated. Ses Planc.

PLOVER. Plovers arc almost invariably roasted, the directions being the same as those given for rousting game. While cooking, they must be kept well basted, ot herwise they will he found too dry. They may be drawn or left undrawn, but whatever the method adopted, the livers must be left inside. The time required for cooking is about 20 min ., and the bird should be served on small rounds of fried bread Garnish with water-

Plovers' Eggs. The eggs are of a rich flavour, and are regarded as a delicacy. Though sometimes eaten hot, they are better cold, and, ufter being hard boiled, should be left in cold water until they are to be served. They may be served on small ovals of bread and butter, and garnished with cress or salad and maitre d'hotal butter. If the egga are preferred hot, they should be reheatel in some suitable sauce and served in it. See Game.

PLUG: In the Wall. Before any fitment can be attached to a brick, breeze block, or plaster wall, holes must be made to take plugs in which the naila or screws can be driven home. For many of the jobs about the home the patent. fibrous plugs offer the most convenient means of doing this. The plug consists of a short piece of specially prepared fibrous material, through the centre of which is a
small hole. In the material in which the scmiv is to be inserted a suitably sized hole is made with a drill or jumper, the plug pushed into it, and the screw driven into the plug. The effect is to cause the fibre to open and expand, therehy firmly grippinge the walls of the hole in the walls, etc The plug can be applied to brickwork. atone, or plastet, and is a practical means of fixing a great number of articles in the home. Some care is needed in miaking the hole. A jumper of the proper size for the plug should be employed, and the latter must be the one intended to be used for the particular gauge of screw employed. Do not attempt to drive the tool straight into the wall, or the outside edges of the wall will probably be cracked and break off, leaving an unsightly mark. Hold the jumper lightly in the left hand and strike the tool a series of sharp, light taps, slightly turning the tool in the hole after each tap. In this way a perfectly round hole can he formed in the wall without damage. The tool should not be forced, and it should he held straight out from the wall, or perpendicular to it, as in Fig. 1.

Having prepared the hole to a depth suited to the screw, a plug of the required length is inserted in the hole, so that the end is flush with the wall surface. The length of the hole, and consequently the plug, will vary with the article to be fixed. Suppose, for instance, the fitting is $f$ in. thick. If the article were not very henvy, a $1 \frac{1}{2}$ in. acrew would probably he sufficient, leaving 1 in . of the screw to fit into the hole in the wall. In this casc a plug 1 in . long, fitted into a hole about the same depth, or alightly more, would be needed. The next step is to insert the screw through a suitable hole dilled through the article, and into the hollow centre of the plug fitted into the hole in the wall. The screw should then be screwed up tightly with the aid of a suitable screwdriver

The holes for a rail or other like article should be bored in the wood and the positions of the holes carefully inarked on the wall. The plug holes must coincide exactly with these, and the screws must enter the plugs accurately, centre to centre, or the plug may split. The screw must be of wuch a length that it can be driven home, and thus hold the

Fig. 4. Rough bole chipped out with cold chisel Fig. 5. Driving wooden plug into hole

Plug. Fig. 1. Making bole for flbre plug with borer. Fig. 2. Inserting f bre plug in bole made in plastered wall. Fig. 3. 8howing bow screw enters the bollow centre of the plag
ahorter in length than the screw, and to drive the plug in so that it is below the surface of the wall. This preventa the unthreaded portion of the screw from entering the hollow of the plug, and thus facilitates the screwing-up operation. An alternative is to use screws which are threaded right up to the head, when the plug can be fitted flush to the surface of the wall as usmal. This type of screw is required in fixing thin metal fittings, such as brackets, mirror plates, and hangers.

It is often necessary to plug a brick wall to provide a fixing for rough grounds, henvy shclves, etc Where the joints between the
bricks are visible it is generally possible to cut out the mortar Prepare a hardwood plug equal in width to that of the hole and about 3 in long, and drive it into the joint along the way of the grain, so that the end grain is facing out of the hole. The wood should be tapered, and is driven in tightly with a hammer. The joint may then be made with neat cement.
If it is necessary to place the plug in the brick itself, or in a plastered brick wall when the joints of the bricks are not visible, the hole must firat be ohipped out with a cold chisel, or brick boner, as illustrated in Fig. 4. The rough hole thus formed is drilled out smooth, and a softwood plug driven into the brickwork, as in Fig 5. If the plug is niade to proper length, which is slightly less than the depth of the hole, it will only have to be driven in flush with the wall, otherwise the protruding end may be sawn off with a hand saw, interposing a piece of zinc between the aide of the saw and the wall to prevent scratching the latter

In plugging a concrete wall it is necessary to chip out a hole in the concrete, making the hole wider at the bottom than at the mouth. The plug should be split at the top and provided with a wooden wedge, which is first placed in the hole; the plug is then introduced so that the wedge goes into the slit, and the whole is driven into place. The wedge will expand the wood plug at the back and cause it to grip the concrete. As an extra precaution, the hole may be loaded with plaster, or, priferably, cement, hefore driving the plug in, so that every crevice is filled with cement.

When making holes in walls for plugs, care must be taken to avoid gas and water pipes, or the casings of electric light cables that may be embedded in the plaster work. When plugging into brickwork, especially near the fireplace, the hole must not go too near a Hue, or the plug may takefire. See Gas.

## Plums: The Garden Varieties

## The Growing and Cooking of a Delicious and Serviceable Fruit

Thls article deals firstly with the growing of plums and with keeping the freces frec from insect pests. This is followed by entries that describe the making of various plum dishes. Sec furiher Fruit; Grafting: Pruning: the articles on other popular fruits, e.p. Apple; Cherry: Pear; also Bottling ; Bullace; Cordon: Espalicr; Grcengage ; Jam ; Silyer Leaf; Spraying, etc.

The plum is one of the most useful of late summer and early autumn fruita, and if correctly managed will yield satisfactory crops unless climatic conditions are very unfavourable when the trees are in blossom in spring. Many of the dessert plums are self-sterile, and unless other varieties are planted near them they will not bear fruita freely. A mixed plantation is indispensable to success

Plum trees may be grown in the open garden in the form of hushes or standaids, or as trained trees on walls; they are also grown as cordons, but are not an suitable for this method of training as apples and pears.
During the first few years after planting plum treos usually grow very vigorously but hear little fruit. Orchard standards, which eventually form large trees, must be allowed to grow freely and much fruit cannot be expected from them for several years. But by correct manageroent bush and trained trees can be made to yield in their early years

Plum trices thrive hest in well drained loamy soil, especially that which overlice chalk. In preparing sites on clayey land the sub soil should be broken up to provide drainage, moitar rubble should be added very
frecly, and lime ahould be applied Manure
ought not to he mixed in and the trees must be planted with their uppermost roots 2 or 3 in . below the surface. Every autumn for the first three or four years it is a good plan to lift young plum tiees. shorten the thick roots, and replant at once. On light land, loamy (turfy) soil should be placed about the roots at planting time.

The following are some of the best cooking plums Although all are sclf-fertile varieties it is, nevertheless, safcr to have a mixed plantation than to rely on onc or two varietiea only Czar, blue-black, August; Gisborne's, greenish yellow, August; Monarch, large, dark purple, Sept. Oct : Pershore (yellow egg plum), vellow. August: Victoria, rose-red, Septeinber Other cooking plums to bc recommended for a mixed plantation are Pond's Seedling, a large reddish fruit ripe in September, and River's Early Prolific, small purple, late July.

There arc some delicious fruits among the desnert plums, but as a rule they do not bear so frecly as the cooking varicties and ought always to he interplanted with the latter. Some of the most reliable are Coe's Golden Drop, vellow, September, which does best on a wall facing weat ; Comte d'Althan's Gage,

Plom. The variety $\begin{gathered}\text { Victoria, as a a } \\ \text { bearlog large pink frult }\end{gathered}$ reddish, Sepicmber; Denniston's Suplerh Gage, greenish, Auguat ; Early Transparent, Gage, yellow and crimson, August; Jeffereon, yellow and red, September: Ou'lin's Golden Gage, yellow, August : and Stint, small, yellow and red, August.

Pruning the Trees. Plum trecs need very little pruning; indeed, they are usually worse for much cutting. One reason is that they are addicted to gumming, and nothing is more likely to bring a bad attack of this, particularly in a mature trained tree, than severc pruning. The pruning necessary for the training of the tree should therefore be done at a very early stage, and nifter they have become established they should be pruned as little as possible. Repeated bard shortening should never be practised with open-healed trees, whether dwarfs or standards, as auch pruning is apt to result in the production of a large number of soft, whippy shoots, none of which will be found suitable for an extension branch.
Summer pruning may be applied to the new lateral shoots of plums. Matured trees
need little pruning, an ve the occasional removal of $n$ branch here and there if the head threatens to become too thick Trained trees, whether cordons, fans, or horizontals, will produce a certain ainount of breastwnod from the main hranclies, and the course of pruning in this case is the asme as with similar trees of applos and pears, namely, summer pruning and winter spurring
Pests and Diseases. The plum, in conmmon with other fruits, has numerous enemies. It escapes the canker which is often so deadly in apples, but falls a victim to the still more destructive silver leaf, which attacks trees at all ages, but is most dangerous in old trees There is no relinble remedy. The trees should he grown in well.drained, substantial soil containing lime, proned little, and maintained in as healthy a state as possible, according to the circumatances and the means at disposal. Beyond that, prompt burning of badly affected trees is desirnhle. Everỳ bit of deail wood should he burned, as it carries the spores which spread the disense.

Caterpillars are sometimes injurious, and in the presence of an attack the trecs should be promptly sprayed-but not while the trees are in bloom in case of injury to the treeswith a solution of arsennte of lead, 1 lb . in 25 gallons of water.

Gumming is liable to cause trouble in plums. as in other stone fruits, esplecially if the soil is undrnined and very loose and rich, or if much winter pruning is done. But trees grown in well-drained, fertile soil, and pruned by summer pruning or branch thinning in summer, instead of winter pruning when there is very little sap moving, ecldom gum. Grcen and blue flies (aphides) sometimes chock plums severely. especially in dry aprells, and curl the lenves One of the general winter sprays, such as lime, limesalt, and lime-sulphur. tends to keep down aphides; but if an attack has to be fought directly, a paraffin and soft soap emulsion is excellent, and the lest remedy of all is $1 f$ oz. of commercial nicotine and $i \mathrm{lb}$. of soft roap in 20 gallons of water. To be efficacious this mixture must be used very hot.

How to Cook. To stew plums, remove the stalks and wipe the fruit : then put them in a stewpan with $6-8$ oz sugar and $\frac{1}{2}$ pint water to 111 . plums The amount of sugar varies with the kind of plum employed and the degree of ripeness. Let them simmer until soft.
Another way of preparing nlums is to bake them in $n$ jar. First skin the plums. If they are ripe, the skin will peel off; if not. they will first require scalding. A fruit knife should be used to draw off the skin. Put them in a stone jam jar or crock, with the sugnr on the top and just a little water, and bake until tender

Except that plums are used instead of spples, the method of making plum charlotte is exactly the same as for apple charlotte (q.v.). For pie, flan or tart pluins should be ripe or partly stewerl first with sugar and allowed to get cold Otherwise the pro. cedure is the same as for other fruits when making these dishes.

## Plum Jam. To every

 lb. of plums used in jam-making, 3 lh. sugar is required. Wipe andstalk the fruit, put it into a precerving pan with the sugar, nnd cook slowly until the Inatter has dissolved. Kcep the jam well stirred so that it will not burn, and when the sugnr has melted bring it to the boil, boiling it for 3 hour or moro. In the course of cooking most of the stones will leave the plums; these should be taken out as soon as they appear. and if they arc cracked, the lierncla hlanched and then put back, the jam will be improved

To make plum and apple jam peel nad core 4 lb apples. cut them into rough pieces, add $7 \frac{1}{2} \mathrm{lb}$. sugar, and bring them to the boil in a preserving pan. [ut in 6 lb . plums. Boil fast, removing the scum, until the syrup jellics when coolod on a plate. This should take about an hour. Pour the jam into jars and tic down the jars when the contents are cold.

Plum Solid. This sweet can be made with any kind of ripe plum. For it take 4 oz . granulated sugar. a lemon. I oz gelatine. and 8 fint water

Plum Two specimens of Orpington Prolitic purple dessert plum of delicious flavour
to ench lb. plums. A glass of claret and a stick of cinnamon an inch long may be added, or instend of the cinret almond essence many be used for flavouring.

Having wasled and stalked the plums, put them into a pan with the water, the sugar, the cinnamon and the rind of the lemon thinly peeled. Simmer them until tender, strain off the liquid and rub them throughasieve Melt the gelatine in the plum liquor, straill this into the puree, ndd the clarct or essence, and reheat the mixture. It should then be poured into a basin and stirred frequently until cool.
When cold turn the mixture into a mould that has been rinseal out in cold water, and Icave it until it is sct. Then turn it out into a dish and decorate it with chopped almonds or pistachio nuts and some Devonshire cream.
PLUMBAGO. This group of climbing half-hardy shrubs is suitable for cultivation under glass and of herbaceous perennials for the garden. For the former purpose the chief favourite is the Cape leadwort. Plumbago capensia n lenf-losing climbing shruh for the

Ylumbago sarpentae, a cuarming blue-Howered plant for a sunny place in the rock garden

Plumb Bob and Line in pase simply a smooth piece of string or cord, fairly thin and of aven texture, to the lower end of which is attached a plumb bob. It is used by surpending it and allowing it to hang down freely. It will then naturally assume a perfectly vertical position as soon as it has come to rest.

It is used for comparing upright parts of a structure, udjusting them to the line so that they thenselves will be upright or plumb. All such operations as setting up doorposts, comer posts of buildings, nnd so forth, should be checked by the plumb ling to make sure the vertical members are perfectly upright. When not in use, the line should be coiled up on a reel, wound on to a spool, or wound around a stick, and preserved in the tool chest or other convenient place.

There are various patterns of the bob, rang. ing from simple ones which are merely plain lead costings to instruments made of brass and filled with lead, accurately machinel and finished. The illustration shows a typical pattern in use and indicates the method of handling it.

A plumb line is easily extemporised from a piece of smooth string to the lower end of which is attached any weighty object of nymmetrical form. A henvy lead sinker, as used by anglers, could be employed, or a large hexagonal nut with the string passed through the hole in its centre.

A plumb level comprises a combined plumb rule and spirit level It has a vertical bubble tube for plumbing upright work, in addition to the usual tube in horizontal position. Another type can be used with a plumb hob for vertical work. See Brick; Plumb Rule.
slightly hented greenhouse: it bears bunches of lovely pale blue flowers in summer. It is usually planted in a border of lonmy soil. but may be grown in a fub or large flower pot; it should be pruned in February. Cuttinus can be made from the fresh shoots in spring. Plumbngo rowen, which bears rosc-coloured Howers in winter, needs the temperatuie of a hothouse
Of the herbacenus perennials the best is Plumbango larpentae. n beantiful plant 12 in. or more high, suitable for a sunny spot in the rock garden or at the foot of a low wall ; it needs sandy, loamy soil The rich blue lowers open in August-September, and the leaves colour well. It is increased by division in spring.

## PLUMBAGO: The

 Mineral. This is another name for graphite, a form of cartion. It has many applications as a lubricant Plumbago is a conductor of electricity, and in electro-plating work it is used as n preliminary conting on non-conducting materinls, such as india. rubber, which have subsequently to be electroplated. Crucibles are made of plumbago. as they stand the hent of the furnace, and are extensively used for the melting of metals.PLUMB BOB AND LINE. 'l'he plumb line is piece of string or cord,
2
lin line are used for measuring and setting chall work I wrench hammer and gas pliers are required for dealing with nuts and collars, cspecially those found on hrass or iron pipes.

Plumbing. Fig. 1. Plumber's tools. A, dresser. B, gas tongs. C, wood blocks. D, saips. E, wrench.

 branch pipe to main pipe. Fig. 8. Building up solder around joint. Fig. 9. Finished wiped joint
pipe is to form a round hole in the pipe wall. After filing, the hole is scraped into a funnel shape. Fig. 7 shows the branch pipe fitted into the main pipe. The meeting and joint faces of the pipes are acraped clean with the shave hook, and subsequently the solder is melted around them, as in Fig. 8, and allowed to run on tho joint. About 1 lb . of solder is required, nnd when it is being applied the final shape of the joint is borne in mind.
The main pipe is secured by a nail and a piece of string to a temporary block of wond, so as to raisc the pipe from the wall or other backing. The main pipe should be bent or closed up ao as to grip the branch pipe. Fig. 9 illuatrates the saddle joint complete. The inain pipe has been straightened; but at least 20 min . must be allowed hefore straightening to permit of the joint cooling uufficiently. The pipe is straightened by careful bending with the hands and lightly atriking it with a wooden mallet.

This class of joint is employed when it is required to run an additional branch, as for exainple for the supply of water to a tap over a copper, or some other position. Where it is necessary to make several bends in the branch pipe thesc should be worked beforc it is attached to the main pipe. Fig. 10 shows the
firmly in the groove,
plumber's dresser, which is resting on top of a trestle to allow free movoment and space in any direction. Care must be exercised not to distort the section of the pipe to any extent. This is avoided by careful manipulation of the pipo, gently hammering the sides wherever it exhibits any tendency to flatten. The hammering is done in order to drive the pipe back from an oval section to the proper circular shape.

When a sharp) bend is to bo made, the amateur may get good results by the method illustrated in Fig. 11, where a sharp bend in a pipe is made for a square corner of $n$ rough piece of wood, in which a groove has been cut to the width of the pipe. The walls of the groove should be upright and exactly the diameter of the pipe, so that the latter is gripped and this tends to

Plumbing. Fig. 10. Bending a pipe over the dresser. Fig. 11. Showing how a sharp bend is made in a pipe
cad as the work proceeds, rendering a lurther heating of the joint unnecessary.

There are one or two pointa that the amateur plumber should bear in mind. The water supply companies have stringent regula tions governing piping ard fittings connected to their mains, and only materials and fittinga of an approved specification may be employed. Local authorities also have regulations which must he complied with, especially as regards any work connected with the sanitation system. Some require that the work shall be done by a registered plumher The advice or assistance of a competent person should be obtained before undertaking any task other than that dictated by cunditions of emergency.

Plumb Level. See Plumb Bob.
PLUMB RULE. The plumb rule is employed for testing the uprightness of a structure. It comprises a piece of board with a pear-shaped hole at the botton of it A line is scribed down the centre of the board, and near the topa nail or peg is fixed, to which is attached a strong, smooth, and tine string, the lower end of which is weighted with a pearshaped piece of lead, which ewings clear in the pear-shaped hole cut in the boaril. To prevent the string of the plumb from dangling about, a strap of leather or some other material is fixed acrass the board just above the opening, and is so arranged that the string can swing clear, hut not to too great an extent

The illnstration shows the method of use. which is in hold the board against the object to be tested, and to judge its uprightness. or otherwise, by the line of the string in

Plumb Rule in use to test uprightness of door lining relation to the line scribed on the board. If the structure is out of plumb, that is, not vertical, the upper end of the bonrd will lean outward. or in. ward, and the hoh will tend to swing over, and the string will not coincide with the scribed line. In testing a curner of brick. work, or when orecting a corner post, a timber structure, or a door pust, it is neccssary to test in two directions, npplying the pluinb rule to hoth faces of the work, as it may he up,tight in one direction but not in another. Adfustmentsarc made to the work until the string hangs exactly in register with the sctibed line on the board

A plumb rule can be made up by any amateur from a piece of board about 4 ft . long, 6 in. wide and $\frac{1}{2}$ in. thick The line must be ecribed in the centre of the board, exaotly parallel to hoth

Plumbing: repairing a gutter. Fig. 12. Cracked gutter beforo repair. Fig. 13. Gutter cut across and raised, and groove cut in gutter board. Fig. 14. Melting lead solder iuto groove and joint. Fig. 15 Surface of molten metal being levelled flush with the lead
the outside edges. The hole is cut out with summer. They thrive in ordinary soil in a sunny a pad saw or keybole saw, and the edges place and nre increased by division in autumn. smonthed off with a gouge or sandpaper The favourite kind is Bocconia cordata.
The line is twisted into three saw cuts made in the topi end of the rule, one central and the others at convergent angles. as shown. See Plumb Bob.

Plum Cake. Cakes containing raisins are often sjoken of as Plum Cakes See Calie.

PLUM DUFF. Tomake this plain hoiled pudding, which is also known as spotted dog, chop up very finely $\ddagger \mathrm{lb}$. suet and mix it thoroughly with $\frac{1}{2} \mathrm{lb}$ flour to which $\frac{1}{2}$ tenspoonful baking-powder has been added Add also $4-0 \mathrm{oz}$. well-cleaned currants, 1 oz . sugar, and a pinch of salt. Mix together with a well-beaten egg, adding a little milk if neccseary. Scald and tlour a puclding cloth, put the mix. ture into the centre of it, andeither roll it and tie it at either end, or tie it on top. In cither case leave plenty of room for the pudding to swell Drop the pudding into boiling water and boil for 2-3 hours.
PLUME POPPY.
This is the popular name of bocconia, a group of vigorous hardy herbaccous pereminials, 6 ft. or more high, with decorativegreygreen leaves and plumes of small pale tlowers in late

Plymouth China coflee pot, dating from 1763-70 Brltish Museum

Plum Pudding. See Christmas P'udding
PLUSH. A longer pile distinguishes plush from velvet. Mohair plush is cheaper than silk plush and is sometimes used for covering large pieces of furniture. Teddy-bear plush is obtrinable a hout 50 in wide.
Linen plushes can be had for making curtains, but their pile is more easily flattened down than that of silk or hair plushes Hatter's plush, made with a laid pile instend of an erect pile, and intended for covering silk hats, is a distinct variety. See Upholstery.
PLYMOUTH CHINA. The interest of Plymonth china for the collector lics in the fact that it was the carliest true or hardpaste porcelain to be produced in England of English materials. As it was being made for a few years only before 1770, when its inventor, W Cookworthy, trans. ferred his activities to Bristol, it is not easy to come by, and is also sometimes difficult to distinguish from Bristol ware. The sides of the vessels from both factorics frequently show n spiral ridge, due to a defect in the throwing. But Plymouth ware can often he identified
by a characteristic amoky atain in the glaze, comparatively free from risk of warping as well as by its high polish, and also by the cold, grey tint of the underglaze blue.

The pieces to look for arc cups with folinge reliefs, statuettes, shell-shaperl salt-cellsra, and oyster and pickle stands. These are cither plain whito or with blue decoration, which was alan done on mugs, arucers, sauceboats. and full services Ennmelled designs were painted on plates, teapots, vascs, and ligures, those comprising birds and llowers having been done sometines by a French nrtist from Sevres.

The usual mark, in underglaze blue or cnamel colours, resembles a combination of 2 and 4 , being the alchemists' symbol for tin This appears in gold on some of the finest pieces, which perhaps belong to tho Bristol perind of Cookworthy's work. Sce. China.

PLYMOUTH ROCK. One of the most popular breeds of poultry is the Plymouth Rock, which is generally spoken of ns tho farmer's fowl. This bird has a large frame which carries plenty of meat. It is $n$ good, especially a good winter, layer. The hena are most excellent mothers, and the chicks am hardy and quick in maturing.

The Plymouth Rock is bred in 6 coloursbarred, white, black, blue, buff, and golden barred, the latter being tho lateat to appear The barred has a greyish, bluish-white ground colour with glosay steel-blue bars running across. These bars must be distinct, even, and narrow. The chicks are greenish grey with pnle cream under parts, or very dark, almost black, top colour, with a small apot of a light colour on the head

Whites are pure white right through, the chicks creamy white. Blacks are a rich lustrous beetle-green black, the chicks black and white. Buffis are a sound even shade of soft lemon buff, the chicks buff. Blues are of an even slaty blue throughout, the chicks bluc and hlue and white The golden barred are as the barred, except that the ground colour is two shades of golden buff, the chicks buff. See Fowl; Poultry.

PLYWOOD. Made of thin layers of wood glued together at right angles or diagonally and then placed under considerable pressure and then placed under con in large sheets or panels, and in thicknesses from $\frac{1}{\frac{1}{2}} \mathrm{in}$., increasing by $\frac{1}{\text { or }}$ in to $\frac{1}{1}$ in. These thicknesses are generally of 3-ply, but additional layers of wood are commonly used up to 5.ply to a thickness of

Various kinds of wood are used. Birch, whitewood, satin walnut, and pine are softwoods and suitable for backing or staining. Of the com monly used hardwonds. oak, mahogany, teak, black walnut, and bird's eye maple are obtainable in plywood. The more expensive woods are made with $n$ core of cheaper wood.

The main feature of plywood is the strength it affords in a thin board. It is estimated that a piece of plywood is four times atronger than solid wond of similar thickness The method of manufacture, which places the grain of the layers at right angles to one another, prevents aplitting and renders the miaterial

cause lowers the vitality and enables the germs to multiply. One of the most powerful predisposing causes is intemperance. No other factor assists "recovery so much as plenty of freah air. The pationt should have a large well-ventilated ronm.

High temperature is one of the greatest dangers as it may lead to failure of the heart If necessary, sponge the patient with cold or tepid water, uncovering only a small part ol the body at one time, and drying it hefore sponging another part

Pneumonia In Dogs. Pneubionia is a com mon sequel to distemper, or it may follow bronchitis or a severe chill. There is a high temperature, breathing is quick and difficult, and a characteristic symptom is blowing at the lips The patient should be kept in a tempera ture of about $60^{\circ}$, with plenty of fresh air.

Envelop the chest in gamgee wool with a flannel coat over it. Apply compresses to the side as hot as can be tolerated. Place a piece of flannel in a length of linen and insert it in hoiling water onntaining $n$ little methylated spirit. It can then be wrung dry without hurting the hands. Place it well at the sides, at the hack of the elbows, and under the chest Cover with flannel, and then tho gamgee wool Do this severnl times a day. Feed little and often with strengthening foods See Dog

POCRET BOOK. A pocket book, in one meaning of the term, is not, strictly speaking, n book at all, but a wallet, usually of leather, provided with compartments for holding letters, papers, notes, stamps, etc. It usually folds down the middle and is of a convenient size to carry in a man's pocket In another sense a pocket book is an ordinary printed book made in a small size. Pocket editions are obtainable of most of the classics and a greal number of other well known works.

A third meaning of the term is almost synonymous with note brok, except that the latter has n wider significance, embracing books of almost any size, while the size of a pocket book usually varics between about that of a post card and that of a playing card.

POCKET KNIFE. Strictly speaking, the blades of n pocket knife are placed side by side at one end of the case while those of a pen-
knife are at upposite ends, but for practical chiefly to poas, beans and uther members of purposes the distinction is no longer marle, and the term pocket knife is applied to both.

The ordinary pockot knife is usually about 3 in to 4 in. long. Blades are mounted between two plates, usually of brass, a brass rivet fitting a hole in the shank of the blare holding them in place. The rivets embrace the covering of horn. bone or other material, as well as the brass plates. A steel spring riveter in the centre presses against the shank ands of the blades, causing them to open and shut with a snap. A shoulder on the back of the knife blade fits the top of the spring and takes the strain of the blade when in use. Each blade is provided with a thumb-nail groove in order to lacilitate its extraction from the casa.
A well-made pocket knife is a long-wearing tonl, and it is only rarely that it needs attention. The most easily worn parts are the brass rivets. Constant opening and shutting the blades in time wears away theso parts until the rivet either snaps or wears 80 thin that the apring loses its effect. While the parts are separatod to put in new rivets the knife can be thoroughly oleaned and reconditioned

The method is as follows : The blades, or blado if the knife has only one, are opencd and clamped between two pieces of wond held in a vice. Using a very small drill about the size of a rivet head and a hand brace the burrs of the rivets on one side only are drilled avay. This process is shown in Fig. 1. The knife is then removed from the vice, into which is tightly clamped a small hexagon nut. A small rivet punch is improvised from a piece of stcel knitting needle of rather smaller diameter than the rivet itself. The knife is placed on the nut so that the ivet comes over the hole in the nut, and the rivet is then punched out. (Fig. 2.)

The parts should be cleaned by dipping them in petrol and rubbing them with a rag. A short length of stout brass wire is obtained of a diameter to fit the rivet holes, and the blades and apring are reassembled as shown in Fig. 3. The coverings are also fitted and the brass wire cut off to within $\frac{1}{10} \mathrm{in}$. of the cover ing plates. A Hat hammer head is fastened in the vice to form an anvil for riveting. The rivet is held against the hammer head while a series of gentle taps are given to the other end in order to spread it.

Fig. 4 shows the burring over of the new rivet, which should be struck on its edge in order to create as large a burr as possible. When a substantial burr has been obtained on one side, the knife is turned over and a munded burr knocked on the other side. All the rivets are treated in this way. The next step is to file off the rivet ends flush with the covering plates, taking care not to remove too much of the rivet head in the process or the rivet will not hold.

It occasionally happens that one side of the scale or covering of a knife cracks across. A suitable material is chosen, and a new scale cut and filed to shape to replace the broken one. Rivet holes are drilled to correspond, and reassembly is proceeded with as above. The life of the rivets is considerably lengthened by a drop of oil on the moving parts from time to time.
POD. The botanical definition of a pod is a dry fruit (possessing several seeds) which is dehiscent, i.e. which when ripe opens to let the seeds fall. It is popularly used in reference

## the Laguminosse family.

PODOPEYLLUM. This hardy herbaceous perennial posscsses largo, deeply lobed leaves and bears chicfly white flowers in sunimer. They should be planted in damp leafy soil. Propagation is by division in spring. Two of the chief kinds are peltatum. 12 in. high, with pale flowers and small green fruits (hence its popular name May apple), and emodi, 12 in . high, with bronze-green leaves and white flowers followed by red fruits.

The dried root of the May apple is used in medicine as a purgative and stimulant for the liver, preparations in common use being podophyllin, dose to to gr. : tincture of podophyllin, 5 to 15 minims. It is usually taken in the form of a pill, which inay be made up from 3 gr . of podophyllin resin and 21 gr . of extract of hyoscyamus. This is divided into 12 pills.

POET'S NARCISSUS. This is the common name of Narcissus poeticus, of which See Narcissus. with a free nddition of sand. During the summer months a cool, airy greenhouse or frame nuits them, but in September they must again be placed in warmth.

POINTER: The Dog. Besides having a good nose to find the game, a pointer must have endurance and pace, and he should be built on lines which indicate the two latter. His forelcgs should be straight and strong, the thighs long and musculsr, the shoulders long and sloping, chest deep and not ton wide bodv well ileveloned
there aro many beautiful varieties. The perianth is white and the crown or centre is of various rioh colours.

POINSEMIA.
This
hothouse plant is grown for the sake of its scarlet bracts, which are in full beauty in winter, the true flowers being 8 mall and inconspicuous. When the plantg have finished flowering they should be pruned and kept rather dry at the root for a few weeks. Then if kept moist and warm they will atart into fresh growth, and the young shoots are taken off and inserted as cuttings in pots of sandy. soil in a propagating case Subsequently they must be potted in small pots and finally in those 5 or 6 in . wide, in a compost of loam two thirds, decayed manure one third, the pointing material is still wet a grooving tool is pressed into it and, when set, there is a recess to receive mure jointing material, usually of a contrasting colour.

In repointing an old building the joints have to be raked out to about 1 in . in depth and in the procces the

Pointer. Champlon of this broed of sporting dos
and powerful, loin slightly arched, broad ard muscular. In fact, he should be symmetrical all through, giving the impression of being able to gallop and stay. White usually predominates in the colour, and the markings may bo lemon, orange, or liver. Wholecoloured black or liver are occasionally scen. See Dog.
POLNTING: In Building. Pointing is the process of finishing the face of joints in brickwork or stonework. giving it a better appearance and offering resistance to rain at the joints. It may be done as the building work proceeds, which is the strongest form of pointing, or it may be done at the completion. working from the top downward and striking the scaffold as the work is finished. The lattel method gives the better and cleaner appearance, but it is not as strong as the other and it is more costly, becausc the joints have to be raked out to at least $\frac{1}{1} \mathrm{in}$. deep so as to receive the material that is used for pointing.

The struck joint is the best and strongest kind of pointing. It consists in pressing the mortar tightly into the joint with the tmwel. forming a smooth face splayed back at the top edge so as to weather the joint, or in other words so as not to hold the rain that might drive on to the wall.

Flat pointing or flush pointing is carried out on the interior of walls that are not to be finished in any way other than limewashed: it consists in flushing the wet mortar off with the trowel, so as not to encourage the lodg. ment of dust. Flat pointing is sometimes used on external work, but it is then what is terned jointed, that is, while

Pointing: four lypes. Fig. 1. Straok joint the top edse bolaz splajed back Pointiag: four lypes. Fig. 1 . straok joint, the top odge boing spiaged back
to weather the joint. Fig. 2 Eeyod pointing, in whioh the mortar is grooval Fig. 3. Flat or finsh pointing. Fig. 4. Tuor pointing, a more orammenta form, bat jess. easy for the amatear
edges of the bricks often become very dam aged. They are first flush pointed so as to make sound the damaged edges, then a grooving iron or jointer is drawn along the wet pointing, forming a recess, into whioh is put usually a white pointing. The flush pointing is first coloured, however, to match the brickwork.

In keyed pointing the pointing material is pressed into the joints with the trowel in the usual way, then a gronving iron is placed into the joint and drawn along, thus forming a semicircular recess. The grooving tool is made generally from a pieco of $s$ in. round iron. set up so as to form the handle at one end. There are other forms of kicyed pointing, but thesc need professinnal skill and are used principally where rendering of the walls is to follow

The tonls required for pointing consist of a pointing trowel-i.c. onc having $n$ blade a hout 4 in. long and a straight-edge-a piece of wood about 3 ft . long, $2 \frac{f}{\mathrm{f}} \mathrm{in}$. wide, and $\frac{3}{3} \mathrm{in}$. thick An old table-knife ground off to a point is used for trimming the edge of the joint that has heen pointed, so as to cut olf any surplus inaterial there may be.
The material used is, as a rule, cement mortar, made up of equal proportions of Port. Ind cement and clean, sharp pit sand The materials are mixed together dry. then aufficient clean water is added to make them plastic On!y as much of the material is mixed as can he used. The inortar is pressed into the joints, and brought in a smooth face by drawing the Irowel along it, cutting the edges straight with the knife and straight-edge

If old brickwork is being pointed, or new work at the completion of the ordinary bricklaying, then, in addition to raking and cleaning out the joints. water must be copiously employed. On no account should pointing he done during very frosty weather, becauso the material will ultimately fall out of the joints

POISON. Certain substances are statutory poisons. They are enumerated in the Schedule to the Poison Act. Any preparation which contains a statutory poison must he labelled as "poison." A medicine prescribed for internal use may be thus inbelled. but this fact need not alarm the patient : care must be taken, however, to adhere to the instructions.

Poisonous substances nust be dispensed in containers which are ensily distinguishable by colour and shanpe, and on no secount should they be transferred to plain containers in the home. All poisons should be kept under lock and key. It is illegal to send poisonous substances by post, except such as arc contained in medicines prescribed by a registcied dnctor and dispensed by a registered chemist and druggist. Opium, its alkaloids and cocaine are classed as dangerous drugs, and dealings in them, by preseription or nther!vise, are suliject to strict regulations.

POISONING. In few emergencies can angacious first aid be of such service as in that of pisoning. The nerd may arise in a variety of circumstances. It may be definitely known that pmison has heen swallowed or otherwise may have got into the body, and the nature of the poison may even be known. Without this knowledge, however, the probability of poisoning would be recognized when a person becomes ill shortly after taking food, drink or a dose of medicinc.

Some poisons destroy tisaues with which they come into contact, and are known as corrosives. There is evidence of destruction of the lining of the mouth. and possibly marks oil the face and clothing. Such poisons cause an immediate burning pain in the mouth, throat and stomach, also vomiting, and perhaps purging There may he difficulty in breathing. The patient is collapsed.

Amongst the corrosive poisons are the strong mineral acids, such as ail of vitriol : the caustic allialics, such as strong ammonia,
corrosive sublimate, formalin oxalic acid certain metallic salts, etc Carbolic acid and crensote also cause a burning pain, but vomit. ing is uncominon, and there is a sense of giddincss and intoxication, followed by un conscionsucss

Irritant poisons may or may not occasion a hot fecling during swallowing, but they causc nausea, vomiting, abdominal pain, purging, and more or less collapac Some cause diffi culty in breathing, and some cramps in the legs. They include antimony, arsenio, copper, lead: mercury, zinc, croton oil and other strong purgatives, arum, cantharides, etc.
Narcotic poisons may, like opium, cause immediate somnolence, decpening into slcep and coma: or, like belladonna, there may be pronounced delirium and then coma: or, liki alcohol and nitro-benzenc, they may cause signs of intoxication, followed by coma
Some poisons, including aconite, diluted oxnlic acid, prussic acid, elc., cause great dopression of the heart, while others. such na

TARLE OF COMMON POISONS GROUPEI ACCORDING TO
TIIEIR ANTIDOTES

## Polson

Oxalic acid (salt of sorrel or lemon)

Sulphuric acid (oil oi vitriol)
Hudrochloric acid (spirit of sult)
Nlerle acid (arjua fortis)

hemlock, calabar bean and curare. cause mus. cular paralysis Nux vomica and its alkaloids trychnine and brucine. cause convulsions without impairing consciousness or producing igns of irritation of the alimentary tract
In the event of poisoning $n$ doctor should be sent for at once, and should be told what poison his heen taken, if this faet be known In the meantime, first aid should be rendercel promptly If the nature of the poison is known, instructions as to its trcatinent will be found under the appropriate heading in this book, but, if not, treatment should be along the !ines to be now laid down:

If the poison be a corrosive, on no accoun: should an cmelic be given, as vomiling might cause perforation of the stomach, bul in all other cases, if the putient can suallow, an effort should bc mule to empty the stomach
To this end a tablespoonful of mustard or two tablespoonfuls of common salt may br arm water Vomiting may he hastened by tickling the back of the throat with a feather or a paper spill, and when it begins the patient should drink large draughts of tepid water in order to washout the stomach

In the next place, or in the first, when dealing with a cor rosive poison, something should fe given to neutralise the activitics of any drug remaining in the stomach: a list of the appropriate antidotes to use for each poison is given hace A strouk infusion, or decoc tion, of tea is usually a good thing to Live as not only does it stimulate, but the tannic acid which it contains is an anti dote for nllinloids. the active principle of most veretable poisons, and for some metals

The irritation caused by a corrosive or irritant poison may be less cned by hiving demulcent drinks such as nilk, thin gruel, thin cornflour or arrowroot, olive oil, or white of ege in water Oil should not be giren, how ever, in poisoning by cantharides or phos phorus and as littlc water as possible in poisoning by oxalic acid or lysol When poison has been itl the stomach for some tinue sornc ol it may hare passed into the howel, in which case one ol t wo tablespoonfuls of castor oil, or a tablespoonful ol Epsom salts in s
tumbler of warm water, should be given For difficulty of breathing caused by corrosive poisons, hot cloths sliould be put on the neck, and the air may be noistened with steam by means of a bronchitis kettle (q.v.), which can be improvised, if necessary. Pieces. of ice should be given to the patient to suck.

Faintness and collapse are treated by keeping the patient lying down in bed and promoting warmth by blankets and by putting hot-water bottles, covered with llannel, at the feet and by the sides. Stimulants should be given in the shape of sal volatile, a teaspoonful in a wineglass of water, whisky or brandy, a teaspoonful or more, according to age, cto., well diluted, or strong tea or coffee. No alcoliol should be given in poisoning by aniline, nitro-benzene, or related poisons Pain or cramps are treated by placing large hot fomentations over the affected parts.

Any bottles found near the patient, or any vomited matter, should always be kept for the doctor's inspection. See Artificial Respiration; Emetic ; Fainting; Food, Poisoning by ; Ptomaine Poisoning; Shock; and under the headings of all the principal poisons

POKER. Pokers are made of iron, steel, brass, copper, oxidized silver, and other metals. The cheapest are little more than iron bars, but more expensive ones are made with a certain amount of ornament, and are usually part of a set of fire irons. Omamenta tion is confined to the handle and upper part.

Poker Gas Burner. This is a burner used for igniting a coke or coal fire. It is connected to a plug point at the fireplace, the gas lighted, and the burner thrust into the firc amongst the coke or coal. When the tire is well alight the burner is withdrawn and disconnected. See Fire Irons; Gas
POKER : The Card Game. Poker is a card game for any number of players less than seven. There are several varietics of the game, the commonest being draw poker, and the rules differ greatly in minor details. This game is played with an ordinary pack of 52 cards, and the cards rank as at whist ; the ace can count high or low as required, but not botli at once.
One player usually acts as banker, and sclls counters to the othiers, redeeming them as required. A limit usually is set to the amount that any player may raisc a bet In one general variation eacli player begins with the same number of counters, and when he loses all or is frozen out, he drops out of the game. Any player may quit the game when he wishes, receiving from the banker their value for any counters he may still hold. No hand may be shown until betting has ceased. The players cut for denl, the lowest dealing, and aces count low. In some forms of deciding the opening, player cards are dealt round, and the first to receive a jack deals.
The Hands. Five cards are dealt to each player, one at a time, and these five cards constitute a hand. There are 10 varieties of hands, as follows: The hands are given in the order of their importance, beginning with the highest possible hand that can be held. A Hush is 5 cards of a suit. Royal flush consists of the ace to the 10 of any suit. Straight flush is any $j$ cards of a suit in sequence, excluding royal flushes. Four of a kind consists of 4 aces, 4 kings, etc., and one ordinary card. A full house consists of 3 cards of a kind, as 3 tens, and a pair. Three of a kind is 3 cards of the same denomination, as 3 tens, 3 fours, etc., and 2 ordinary cards. Two pairs are selfexplanatory. One pair and 3 ordinary cards s the lowest hand but one. The lowest hand contains none of the above, and consists of all ordinary cards.
The royal flushes tie, since the suits do not rank at poker. Some players, however, rank the suits as at bridge, so that a royal flush in
hearts beats one in diamonds, etc. If 2 plavers hold hands of the same class the highest denomination wins, e.g. 3 kings beat 3 fours. If 2 hands tie, except royal flushes, the highest card wins. In a sequence a top card, for example, decides, as does the top card in a flush, though in some forms of poker flushes are always equal. If each player has equal pairs the highest ordinary card settles the winner. If a hand has no scoring cards the highest card wins. If the highest cards tie, the second highest wins and so on. If hands tie throughout, the pot is divided. The player to the dealer's left is known as the age, and before the deal he places a counter or counters in the pool. This stake is known as the blind or ante, but must not exceed one-half the limit. Since this stake is a compulsory one on an unknown hand, it is invariably made as low as possible, usually a single counter.

How to Play. Each player is dealt 5 cands each in turn, and after looking at his hand he may do one of three things. He may pass, in which case he throws his cards face downward on the table, and takes no further part in that particular hand. He may go in, that is, decide to play, in which case he puts in the pool double the amount of the ante. He may put in the pool double the ante and then raise the stake to the limit, or any less he chooses.

Any player who wishes to go on then must put in the amount of the raise. One player may raise the contributions one counter, the next by 2 or 3 counters: and so on; but every player who decides to play must contribute the full amount of the highest raise plus double the ante. Any player who has already contributed before a player who raises, may decide to throw in his hand and lose the counters he already has in the pool rather than risk losing more on a bad opening hand.

When all players have decided to go in or pass, each player may discard any number of carla from his hand up to 5 , and receive an equal number from the dealer. The discarded cards are thrown face downward on the table, and must not be looked at by any player. This drawing of cards is known as filling the hands, and the object of each player is to improve any hand he may have. A player may have a pair, for example, and he discards 3 cands and draws a fresh 3 in the hope he may get another card to pair, or otherwise increase the value of his hand. A player who draws no cards is said to stand pat
The drawing is all important; for by it each player tries to decoive the others as to the cards in his hand. A player may hold 4 fours and an ordinary card, for example, when the pot is opened. If he stands pat the other players may suspect the cards he holds, or assume he has in any case a flush or full hand. If he discards one card, however, and draws another,
though the latter in any case cannot help him, his opponents are not sure whether he is drawing to 2 pairs, trying to complete a Hush or a sequence, or even trying to make a full house when holding 3 of a kind and 2 odd cards. In the same way a player may hold 3 of a kind, and throw out only one card.

A player on the other hand may hold 4 cards of a suit and draw one card to try and get the fifth for a flush. If he fails, it does not necessarily follow that he throws his hand down at once. For all his opponents know he may have obtained his flush, or he may have been drawing to ? pairs to try to get a full house, and so on. He may decide to bluff and boldly raise the stakes, frightening other players into the belief that he has a good hand. and inducing them to throw their bands in. If players throw in their hands the winner is not bound to show his cards, and it is therefore not known whether lie was bluffing or not It is this' fact which is important in the game, for if a player is a good one, it is never a certainty whether he is bluffing or not.

The players having filled their hands bet in turn or pass out. Any player may raise tho bet of the last player or decide to see him, and all cards are exposed in the last case, unless a player still to bet decides to raise. But when the players decide to see tho highest bet, the cands are exposed, and the best hand takes the pool.

Other Games of Poker. In straight poker the hands are not filled as in draw poker already described, each player retaining the 5 cards originally dealt him. Each puts in the pool the same amount as ante or blind, and players pass or come in as at draw poker. If all pass the pool is added to afresh, as for a new deal, the deal passing to the left. In atud poker one card only of each hand is dealt face downward, the remaining four being dealt face upward. The betting is as in draw poker.

Jack pots is a well-known variation of poker. In this form of the game each player puts an agreed stake into the pool, which cannot be opened, that is, played for, unless some player holds either a pair of jacks in his original 5 cards, or some combination which is better than a pair of jacks. Such a player may or may not open the jack pot as he pleases. If he does so he may open it for any stake ho pleases up to the limit, and each player must stake a similar amount or throw in his cards. The stake may he raised up to the limit by any players. If no player comes in except the opener of the pot, the latter takes the pool, and shows the necessary cards which are equivalent to or will heat the pair of jacks required for opening. If no player opens there is a fresh deal, each player once more contributing to the pot, and so on until the pot is opened

## Pokerwork in Various Forms

Appliances, Tools, and Methods for this Decorative Handicraft
This contribution explains the methods for decorating suitable materials by means of pokerwork. Other artistic crafts treated on similar lines include Enamelling; Gesso; Lacquer: Leather:
'Ihe ornamentation of wood, leather, and velvet by tracing the pattern with a hot platinum point or needle is known as pokerwork or pyrography There are various appliances for this purpose. One of these, an electrical apparatue contained in a box, is illustrated in Figs. 1 (left) and 3. A small plate screwed on to the front panel merely needs reversing to change the voltage. The machine can be fitted with either an adapter or plug-piece, and used on any ordinary fitting.

A simple appliance is shown in Figs. 1 (right) and 2. Instcad of an ordinary union, a pyro top is fitted into the neck of a bottle which is charged to two-thirds of its capacity with benzoline. It is adrisable to leave the ben-
zoline in the bottle for half an hour, if possible, before putting in the top. There is a small tap on the pyro top. When first heating the point, this should be vertical. Press the bellows slightly and light the little jet at the top of the union. Hold the platinum point in this until red hot. Then turn the tap horizontally and continue pumping to force the gas generated from the benzoline through the tube on to the point. Care must be taken never to touch any metal with the point when hot, as this will greatly damnage it.

When burning wood, the point should be kept hot, so that as it burns along the outline it produces a tiny flame whioh will consume the smoke. There is a small attachnent sold
which can be fitted to the cork handle. This makes an excellent whicalle man is called $n$ smoke diffuser. When working on workbox, powder or leather or velvet, the point must only be a dull red, as the method is to acorch a line and not actually to hurn it. In velvet the pile only should be touched, and it is advisable to use a small, light point. For general use where only one point is available, an ordinary flat point is best, תs the outlining can be done by holding the point almost upright and sideways. For the broader work, the point may be used as a modelling tool. A horn noint is useful for outlining, and burna n good clear line, cutting deeper than the flat point. Shading is done by means of a shading point, or the flat point held over the wood to scorch it.

Pokerwork on Wood. The surface of the wood ahould he carefully prepared by rubbing over with a piece of sandpaper, and then the rleaign is traced on it or transferred by placing the pencil side of the tracing next to the wood and going over the back with a hard pencil Pokerwork tranafers are obtainahle in variety, but an original design is to be preferred where possible or one that is adapted to the shape of the purticular piece to he decorated. The worker next pokers the outlines. He must use the point as $n$ pencil and draw with it, avoiding any uneven pressure, which menns a hal line. As soon as the point touches the surface the work must be continued or a hole will be burnt. It is wise to practise on a piece of wood, making lines, curves, etc., and in this way to determine the correct heat for the point. When the end of a line is reached, take up the point. Avoid pressing ton heavily on the wood, as $n$ line can always be deepened if necessary. The point of the needle must not be too hot if the wood is soft. If it is intended to colour the work, the outline and main sharing only should be pokered.

The cabinet illustrated in Fig. 5 is an example of surface work. The denign is first traced on the wood, previously prepared, then the whole of the outline is posered, using a horn point. For the fine lines a small horn point is used. The work is then lightly rublied over with an old piece of sand papar to remove any charred wood or grease, and atained with water atains. The doga and the clothes of the figures are coloured in liquid ensmels. (Se Enamel: Flower Designs on Wood, n. 424.) An tique gold bironze colour s employed for the archer of the cabinet. a round box decora.

Pokerwork. Fir. 1. Two forms of apparatus used. In that abown on the left the point is heated by electricity. The right-hand one consists of a bottle of benzoline surmoanted by a pyro top. Fig. 2. Showing the platinum point being heated in the benzoline flame. Fig. 3. The electrically heated point in use. Fig. 4. Tools nsed in 10 me forms of this handicraft. Reading downward amall rouge, Guter, and bent-knite point for relief work

Paint it in oil colours, using megilpas a medium Make all the colours as bright as possible and outline some of the flowers in gold. Stain the edge and the reat of the box walnut colour using two coats of stain, and was polish.
Velvet and Leather. Silvel pokerwork on velvet, Fig. 6: produces a good effect. Thi silver sheen is olitained by means of a sheath which is fixed over the point. Heat the point in the ordinary way and then try the sheath on a piece of the velvet. Most velvet pokers hest going with the pile: but there are exceptions. The whole of the outline should first be silveled and the design then coloured in with spirit atains or pastels. Spray with silvel fixative to make the work brighter.
Pokerwork may he used on heavy cloth to outline stencilling, and forms a decoration for the tops of floor cushions. The stencilling should be done with a strong brush to ensure n clear outline.
To use pokerwork on leather the worker should select a suitable design, and when working, the point should be kept a dull heat. as only surface burning is required The whole of the design should be pokered and the necessary colouring then done. To make important parta of the deaign atand out use lacquer and bronze colours. The reat of the leather should be stained a dark colour to tone, and the whole should be wax polished.

Relief Poker Work. Relief-burning, which is an advanced form of pyrography, has the appearance of carving when tinished and can be used to decorate furniture A different point is needed, called a bent-knife (Fig. 4). The work aliould he cramped to a tahle.
The point must he made very hot, and after the design hins been traced it should be out. lined as at A. Fig. 8. The line should be burnt to about 1 in deep, holding the bentknife almost parallel to the surface of the wool. It should not he allowed to lean to either side, and is held more upright in going round a curve. It is essential to have a cleancut outline, and it is best to cut the outline outside the design. A little methylated spirit rubbed lightly over the surface to be burnt will prevent the wood from charring too much. Should there be an angle in the design, begin each line from the corner.

The next thing is to sink the background This can be hurnt out with the point, but it uses the points a great deal and causes exces. sive smoking It is much quicker and easier to use a small gouge, as in Wig. 4. For large spaces a larger gouge can be eniployed. Carve out the wood across the grairr as far as possible to prevent tearing it, and do not cut too deeply at first. Be careful not to damage the design. It is most important to keep the tool well sharpened. Fig. 8, B shows the background ourved out.

Before attempting the modelling study a similar subject, and determine which portions of the design require to be sunk. The elges are left and the portions of a leaf on

Pokerwork. Fig 5 Cabinet in surface poker, the finer lines of the design being worked with a born point, and the whole falsbed in stalas, gold bronze colour and enamels. Fig. 8. Sllver work on black velvet coloured with spirit stalng
breakfast dish To prepare it, boil up 4 teacupfuls milk and water mixed in any proportions, adding salt to taste; sprinkle in 1\} teacupfuls maize meal, and stir the whole over the fire for about 10 min . Then draw the pan to the side of the fire and cook its contents slowly for about 1 hour, stirring them occasionally.

When cooked, spread the mixture on a plate, allow it to get cold, and then cut it into squares. Fry the latter in a pan of fat or bake them in the oven until they are crisp Serve the cakes with a slice of liver and bacon on each, and some good grary.
either side of the centre vein It is a good The plant will grow in any ordinary soil, but plan to start from the centre of the leaf, can only be recommended for the eflect whioh using the flat side of the bent-knife, and is produced by its berries. The roots of the gradually to work almost to the edge, pressing a little heavier to make a depression. This is often done by means of the gouge in order to save the point (Fig 8, C).

A fluter, another carving tool, shown in Fig. 4, is used to make a groove for the centre vein The point is used to smooth a way any irregularities and put in the finishing touches. The veins must be put in, using the edge of the point, and the background burnt even It is necessary from time to time to brush over the work with a wire brush to remove the charred wood; and if the work is not sharp enough after this operation, touch it up again with the point. An uncoloured leal is shown at D, Fig. 8. The colouring should be as soft as possible, merely to enhance the value of the carving, not to supersede it. The background should be stained to match the other furniture Marquetry stains are best.

When polishing a large surface or an elaborate piece of work, coat it all over with liquid wax polish, using a soft brush. Allow this to become dry. Then smenr a little wax polish on a piece of wood. Take a soft brush and brush this over the wood, up and down, until the polish is spread evenly over the yuriace of the brush. Then brush over the work, following the direction of the grain of the wood Do this several times, leaving the work a few hours between each rubbing

POKEWEED. The hardy perennial pokeweed (Phytolacea decandra), sometimes called the red ink plant, is suitable chiefly for the shrubbery or wild garden. It forms a large bush 5 ft or more high, with white Howers, allcceerded by purple berries during autumn.

## plant are poisonous.

Pole : The Measure. See Rod.
Polemonium. See Jacob's Ladder (q. $\nabla$.).
POLENTA. Served with liver and bacon, polenta makes a good supper, luncheon, or

POLISH. Any preparation that is used to produce a glossy surface on wood, leather, plate, linoleum, etc., is known as a polish. It is sold in liquid and paste form, and is usually applied on a rag or brush. Various kinds of polishes, such as those used for cleaning boots, brass, and furniture, are employed regularly in the home. See l3oot Polish; Floor Polish ; Furniture Cream and Polish; Metal Polish.

## Polishing: Finishes for Various Surfaces

## Effective Methods of Treating Wood and Metal

Reference may be made to the article on Furniture and to those on the various pieces of furniture
that can be treated in this way, e.g. Tuble. See also French Pollshing; Labour Saving Staln
The process of french polishing is described left in ridges. This may be avoided by using in a separate article under that heading. a wide eamel-hair brush, but practice will As a substitute for french polishing the process enable the largest surfaces to be succesafully known as glazing will be found useful. Glaze treated with the rubber, which is by far the can be purchased realy made, but is easily better method prepared by dissolving 3 oz of gum henzoin in f pint of methylated spirit. The mixture should be allowed to stand for several days before use, as it improves by keeping. The surface of the wood should firat be filled and rendered perfectly smooth with fine glass paper. A body of ordinary polish is then applied, as described in the article on french polishing

The glaze can be applied with a brush, but it is customary to use a rubber and paint it on, applying it in the direction of the grain The method is to dip the rubber in the glaze, which should, be placed in a saucer, and wipe it over the work quiokly, lightly, and evenly, taking care not to go over the surface twice until the first application is dry. With wide surfaces some experience is necessary, and unless great care is used the surface will be

Eggshell finish can be obtained with a glaze finish by adding about one-third of sandarac to the mixture of benzoin and apirita; the finest finish is obtained by rubbing down the finished polished surface with pumice powder, applied with a piece of felt slightly lubricated with raw linseed oil. Dip the felt into the oil, place on it some pumice powder, and rub well over the work with an even, circular motion The nreasure applied although not light must not be heavy; the rubber must be kept supplied with powder and enough, but not too much, oil. Wien the surface has been dulled evenly all over it should be rubbed down with a clean rag and wiped over with benzoin Small mouldinga or carvings can be rubbed with a brush

Oil Polish. Oil nolishing has several advan tages over other forms of eurface finishing,

Pokerwask. Fig. 7. Lid of bor with simple flower design in colours. Fig. 8. Panel In relief burning, whiob gives the offeot of carving. A. traced design outlined. B, background sunk by means of a rouge. $C$ modelling of the leaf begun. $D$, the finished leaf belore colouring
and is particularly effective on oak. It doee not crack or blister, neither does it show marks made with water, but it requires time and a considerable amount of friction. Prepare linseed oil by placing a quantity into a vessel, surround it with water, and allow it to simmer on a gas stove for about $\frac{1}{2}$ hour. Pour it into a bottle, and add one-eighth the quantity of turpentine. Apply the oil with a felt or flannel rubber and rub it thoroughly into the wood. It is possible to apply too much oil, but the amount of rubbing cannot be overdone. The work should be carricd on over a period of 2 or 3 weeks at least; a little oil and plenty of rubbing every day or every other day. When a suitable polish has been obtained and the work shows signs of sweating, a little methylated spirits can be rubbed over the surface, as this will dry it without spoiling the polish Further applications of oil can be applied if required, and the spirit finishing will not affect it in any way.

Floors can be polished with oil polish applied with a pad made by wrapping some flannel round an old brush; by applying the oil polish to a stained floor and thoroughly rubbing it in, a lasting polish will result.

Wax Pollsh. Wax polishing may be used on any kind of wood and gives an eggshell gloss which is most effective on oak, mahogany and walnut. Either white or yellow wax should be shredded, placed in turpentine, and left to dissolve. The consistency of the mixture should be that of cream. It is applied with brush or rubber, and must be evenly distributed and thoroughly well rubbed in. A dry rag should be used for finishing, but a good body of polish must be applied if the finish is to last. The finest effects of wax rolishing are obtained by giving the surface a body of french polish, rubbing the surface down with pumice powder, and then applying the wax polish; but if ordinary wood is properly filled and thoroughly cleaned down with fine glass paper a satisfactory polish can as a general rule be quite easily obtained.

Carved and Pierced Work. The treatment of carved work depends mainly on its surroundings, and generally a high polish is not desirable. The most suitable method is to cover the work with raw linseed oil, allow it to stand for a few hours, and wipe it off with a soft rag. After 2 or 3 applications, followed by vigorous rubbing, the groundwork will remain dull, nut a soft polish will appear on the raised parts. Although a body of french polish can be applied to carved work, and some portions brought to a high polish, the better medium for woods like oak, walnut and

Polishing. Fig. 1. Rabber for waz or oil polishing. Fig. 2. Pounce bag of maslin for holding pamice. Fig. 3. Rubber made of rag for ase in suriace alling. Fig. 4. Method of using rabber by meat. Fig. $\delta$. How the rabber is held
mahogany is a creamy mixture of beeswax, a rag, or brushed and rubbed down.

Fretwork and pierced woodwork are more difficult to polish owing to the broken surface With wax or oil, it is mainly a matter of working into the crevices, but with french polish, a particularly light touch is required. The edges of large pierceal surfaces, especially the end grain, should be filled with size or a prepared filler, and well smoothed down. The polish can then be applied on a small pad made by wrapping a little cotton wool round a thin stick and covering it with soft rag.

Treatment of Stains and Cracks. The repolishing of surfaces which have become stained usually means the removal of the old polish, in many cases right down to the surface of the wood. If the surface is dented, it may mean planing, or, at least, filling the surface to bring it up smooth and level. Special preparations for removing old polish can be obtained, but the usual method is to soak the surface with methylated spirit to soften the shellac, and rub it with a coarse rag. Glass paper will then be sufficient to take the top surface off. Unless the work is dented or cracked, or the stains go too far down, it is better to leave the original body so that a fresh surface of polish can be applied. With veneered surfaces, the greatest care must be taken. If the veneer is damaged, repairs can often be effected by the application of a hard filler, or by the use of wax.
Defects in polished surfaces do not always show at once, but when they do, they should be remedied as soon as possible. The commonest defect in french polishing is known as sweating, and is caused by the excessive use of oil, which breaks through the hardened surface It is difficult to treat, as any further hardening of the surface will be affected in the same way. Continual application of furniture crean will keep the surface bright, but until the surplus oil embodied in the polish has worked out, further french polishing will do no good. Cracks which may have occurred on a french. polished surface can only be removed by rubbing the whole of the surface down with pumice powder, and then repolishing in the ordinary way.
White marks on a french-polished surface may be caused by defective inaterials, or by water or spirit stains on a glazed or poorly finished surface. The best way to remove them is to take off the top surface and repolish; to put a new coat of polish on the old one, without removing the stains, is not advisable. Jight stains can be taken out by wiping the surface with lin. seed oil and then rubbing it lightly with a rag dipped in methylated spirit. If the stains are caused by hot plates, the only thing to do is torubthe surface down and repolish.

Polishing Metal. The polishing of metal surfaces can be done in many cases by purcly mechanical means or alternatively by hand. Polishing wheels of various kinds can be fitted to the lathe or arranged separately on a special bench fitted with a polishing head
and a fly-wheel. A useful polishing head with a drill chuck, etc, can be bought for a few shillings. Hand polishing. essential for some work, is done with rifflers, emery cloth and buffing sticks.

In machine-polishing, turned work is first rubbed down with emery cloth, finishing with the finest grade. The surface should be left free from scratches, for all subsequent work depends on the quality of the emery finish. As a rule, the emery cloth is used in conjunction with a piece of wood.

The next process is to apply pumice powder by means of a buffing stick, made by glueing strips of basil leather to wood strips of convenient size. For iron and steel it will generally be sufficient to complete the polish. ing with pumice powder, but a high finish can be obtained by using flour of emery and oil. 'lo obtain a good surface on turned brass in the lathe, first use emery cloth, then pumice powder, and finish with powdered rotten-stone and oil.

By the use of a polishing head, with wire scratch brushes and polishing mops-and these can also be attached to a lathe-much more rapid results are obtained The scratch brush is made of hard brass wire and used with vinegar and water or stale beer to produce a lather so that a scouring effect results.

For further finishing, brushes made of bristles, leather, calico and swansdown are suitable for applying pumice, rotten-stone and other polishing powders. As a rule the brush is revolved towards the article and the workel, and the highest speed is used for the final polish. The highest possible finish for brass and copper articles is obtained by the use of crocus powder applied with a calico mop Silver can be scoured with a scratch brush, then treated with rotten-stone and oil and finished with rouge and water, the higheat gloss being obtained by burnishing.

POLRA. The polka is danced to 2.4 time, and consists of light, springing, semicircular movements of three steps each. The original movement was to start off with a little spring, so that counting in teaching is spring $1,2,3$, and not 1, 2, 3, spring. See Dance; Dancing.
POLLACE. Known in Scotland as lythe, the pollack is a large fish of the cod tribe with protruding jaws, and is rich in oil. It is cooked by the same methods employed for cod. Plain boilcd or steamed is perhaps the best way to cook it, but it requires a well-flavoured sauce. Large fish of this description can be baked with advantage. They should be out into slices or steaks, laid in a deep dish well lined with butter, sprinkled with seasoning and lemonjuice, covered with buttered or greased paper, and baked until cooked through to the bone. Pollack should be served accompanied by piquant or shrimp sauce.
Occasionally the name of pollack is applied to the coal fish, also to some descriptions of fresh-water fish; but these are of a different species. A small fish of delicate flavour found in some of the Scottish lakes is called a pollack, but has, however, no relation to the other varieties of fresh-water pollack. See Cod; Fish; Sauce.
POLHINATION. In gardening pollination is the process of self or cross fertilization. It means the placing of pollen on the stigma of the same or a different flower whence it was taken There are three natural methoda and one artificial, the first being effected by insects, self-agency, or wind ; the latter by the hybridist, with the object of securing fresh varieties of flowers, fruit, or vegetables.

When the pollen is placed on the same Hower, or another upon the same plant, it is termed self-pollination; but if transferred by insects, wind, or hybridizer to the Hower of another variety, it is called cross-fertilization.

POLONY. A description of dry sausage known as polony, and first made at Bologna.
js a sausage which has been either boiled or smoked, and is fit for consumption without further cooking. The polony is a mixture of finely minced meat, highly seasoned and spiced. In the best varieties lean beef, ham or pork is used as a foundation, with portions of fat bacon interspersing the lean. The sausage is Havoured with chives or onions, spiced with mace or nutmeg and scasoned with salt and black pepper. A large clean sansage akin is then filled with the mixture, and it is bciled for 2 or 3 hours, or smoked for several weeks. If boiled the skin must be frequently pricked with a needle to keep it from bursting In some parts of the country the skins are dyed a bright red This skin is not edible. Sometimes strings of dricd or smoked sausages are called polonies

POLYANTTHA ROSE. The dwari poly. antha, or baby rambler roses, as they are popularly called, vary in height from 12 to 36 in . and bear bunches of single, semi-double or donble flowers in summer and autumn. They are useful for planting in Hower beds or as an edging to large horders and for cultivation in pots under glass. They need the same treatment as ot her low growing roses. Piruning, done in early April. is severe or light according to whether small or large bushes are wanted.

The older type of dwarf polyanthin rose is of low growth, 12-18 in., with bunches of small Howers. Some of the newer varicties are taller and more vigorous and hear larger blooms. I few of the best are Alice Amos, rose and white, Eblouissant. bright crimson, Ellen Poulsen, rose, Elsc Poulsen, light pink, Gloria Mundi, orange salnion, Katherine Zeimet, white, Kcrsbergen, dark red and Mrs Cutbush, pink.

POLYANTHUS. The bunch-flowered primrose callod polyant hus is one of the loveliest of spring llowers. The modern strains are

PQlyanthus. $\begin{gathered}\text { Blassom beads of this many-coloured } \\ \text { smring flowering primula }\end{gathered}$
distinguished by vigorous growth and large clusters of bloom of rich and varied colouring -crimison, orange, yellow, and cream. They are invaluable for spring berlding. Seeds are sown in boxes of fine soil or on a prepared seed bed out of doors in May. The seedlings are grown on a reserve border during the summer and in October are planted where they are to bloom in April-May. Another method of propagation is to lift the plants after they have finished llowering, separate them into pieces cach with a few roots attachel and re:
plant them on a reserve border for the summer A slightly shady place suits them best at that season. The old gold-laced polyantlus is now little grown excejt for exhibition purposes.

## POLYANTHUS NARCISSUS.

The buncli-flowered or polyanthus narcissus (tazetta) is valuable for cultivation in pots under glass, in bowls of fibre indoors and in beds and borders out of doors. They need the same treatment as other forms of narcissus. The old sulll-flowered varieties have been superseded by others raised by cross-breeding between them and the poets' narcisans (poeticus); they are called poetae narcissi. These are more vigorous and altogether finer plants with large bunches of
fragrant show'y flowers: they are also hardier than the old type. Some of the best of them are Aspasia, Elvira, Jaune a Merveille, Klondyke, and Orange Cup: they have white, creamwhite, or yellow perianth, with cup or centre of yellow, orange, or orange-red See Narcissus.

POLYGALA. These are hardy or half hardy shrubs with small leaves and pealike tlowers in various colours in sumıner: the popular name is milkwort. The favourite hardy species is polygaln chamaebuxus, which is of low growth and suitable for the rock garden : it needs sandy peaty soil and bears pale yellow blooms in spring. Polygaln myrtifolia, which will reach a height of 8 ft . or more, can he grown out of doors in mild districts and elsewhere in pots in the cool greenhouse; the flowers are reddish-purple $J$ compost of loam, peat, and sand is suitable Pruning is done after the flowers have faded, and propagation is by cuttinge at that season
Polygonatum. This is the botanical name of Solomon's Seal (q.v.).

POLYGONUM. Knotwend is the common name of this group of hardy plants, some of which are valuable for the rock garden or border. Others spread very rapidly and may soon prove a nuisance in gardens of moderate size. The most familiar is a rampant climbing plant, Polygonum baldschnanicum, which is uscful for covering a trellis or arbour, while it looks well if allowed to clamber over all evergreen. It bears bunches of small white Howers in early and late summer

Two pretty little planis for the rock garden or front of the border are altine, is in., and Bistorta, 24 in., both bear mse-coloured flowers in late summer. Cuspidatum ani sacchalinense, which grow 8 or 10 ft high and bear white Howers in late summer, spread quickly, and it is difficult to get rid of them. They look well in the wild garden or shrubleery. A half hardy silvery-leaved plant, Polygonum lanigerum, is often used for summer bedding

POLYPODY. This is the popular name of a genus of ferns, called botanically polypodium. The common polypody (vulgare) is a hardy evergreen fern, 12 in or more high, which fikes a shady place and soil with shich leaf-mould or peat and sand have been mixed. There are many attractive named varietics of this fern. The beech fern (Polypodium phegopteris) and the oak fern (Polypodium dryopteris) are other popular kinds. Many polypodiums need to be grown in a warm, moist atmosphere under glass and must be shaded from sunshinc. A suitable compost is made by mixing loam, leaf-mould and peat
in equal proportions. and adding sand frecly. Some of them are Knightac, nigrescens, Smithinnum, Mayi and schneitlerianum
POLYSTICHUM. The preenhouse and hardy evergreen fern polystichum is known as shield fern from the curious shape of its leaves. Culture is not difficult if protection from the rays of the sun is afforded, whether in the heated house or open garden. See Fern.

POMEGRANATE. This is a flowering. and fruiting shrub (Punica Granatum) which is suitable only for planting in a well drained border of loamy soil at the foot of a sunny wall in comparatively mild districts Only in exceptionally favourable seasons arc fruits

ears. The neck and body are short and compact, the body rounded and deep chested ; legs straight, fine boncd, and well feathered; feet small. There are two coats, the under soft and fluffy, the upper long and rather harsh, standing out straight like a frill around the neck, shoulders, and chest. The tail, too, which is carried flat over the back, is profusely covered with long stiff hair. All colours are admissible, either selfs or parti-coloured in patches ; but the selfs are preferable. Except white selfs, no pon should have white feet. Most poms were pure white until pure blacks became fashionable. See Dog: Kennel: Mange; Rabies, etc.
POMPON : In Dress. This soft, fluffy ball is used for fancy dress, especially for pierrot costumes, and also for finishing the ends of a girdle for a dressing-gown.
To make pompons of wool or knitting silk, cut two rounds of cardboard a little harger than the required pompon. In the centre of each cut a round hole, about a third of the diameter of the whole round. Plate the two card board rings together, and wind the wool, which can be all one colour or many different ones, mund them, passing it through the hole in the centre. If the pompon is to be a small one, the wool must be threaded through a necdlo; and even if it is to be large, a needle will be required when the hole is nearly filled.
Only when the hole is completely full has enough wool been ased. Then thread a bodkin with several strands of wool, and slip it all round the circumference, under the edge of the wool, so that the two ends of wool come out in the same place. Pull them carefully but tightly, so that the strands passing round the circumference slip between the two cardboard circles. Then put the point of a pair of scissors just between the cards, and cut the wool all round. 1raw the strands as tightly as possible and tie them firmly, leaving the two long ends for attaching the pompon. Then cut the cardboard away, and the pompon is finished. A woolly ball for a child can be made in the same way.
POMPON: In the Garden. This name is given to certain varicties of chrysanthemum and dahlia which bear small, round blooms. Sce Chrysanthemum ; Flower Garden.
POND. A pond is a pool of standing water. Ornainental ponds are found in a number of gardens, in which they form a picturesque feature. The pond should always be made in the open clear away from trees. Board fences close to the pond are also objectionable. becauso they hinder the continuous circula. tion of warm and cold air. The exact top of a hill is always chosen in preference to other sites, as it affords ideal conditions for the downward How of constantly fresh supplies of air. The pond should be quite shallow; in shape it should resemble a saucer rather than a bowl.
The Soll. If the soil is well drained and of a dry nature, such as the Sussex chalk or tho Surrey gravel, all that is needed is to select a site on level ground to preclude the possibility of disaster being caused by small surface rivulets in time of heavy rain. Given such a site the pond can be dug out, thickly lined with strav or reeds, covered with a gond crust of carefully puddled clay, extending well out over the nargin of the straw to keep it dry. and the clav protected by a thick layer of stones or pebbles.
If the soil is lowland clay or loann, a pond sunk below ground level is doomed to fail, and it is better to have the whole of the prond above ground. This may be arranged by building a low skirting wall with drainage holes through it at intervals round the base, forming the surface of the ground inside to a slight rise in the centre, paving the bottom with concrete or otherwise to prevent interference by earthworns, and then putting in the
lagging, puddle, and stones. - Dew ponds do not require artificial flooding when constructed, as they commence work from the dry of their own accord.

A Dew Pond. This is an artificial basin with a layer of material that is a good nonconductor of heat below. It has the remark. able property that dew forms on it in greater quantity than on surrounding objects, and that it will also collect dew on nights when tho country in general gets none. The supply of dew at night during a dry summer is adequate not only to compensate for evaporation by day, but also to afford a valuable supply of water; for instance, in the otherwise waterless parts of the down country of the south of England, all stock are watered at dew ponds.
The reason why a dew pond supplies itself with water is really very simple when it is properly understood. On a calm and cloud. less night the air which has been warmed during the day tends to conl rapidly by radiation of heat out into space, while at the same time the warm earth radiates heat up into the air; the result is that the air, which is losing heat above, but receiving some compensation from below, cools slowly, so that dew is likely to be dcposited on the ground in small quantity towards the end of the night when the air temperature has dropped low enough to cause condensation of the water vapour in it.
Now a dew pond, with such water as it contains already, may be considered as a patch of land over which a shallow surface layer is cut off from all heat communication with the decper-seated levels of the soil; hence the dew pond gets quite cold by radiation quite early in the night, after which it ceases to keep the air above it warm by further supplies of radiant heat. The consequence is that the air above the pond becomes so cold, by itself radiating its heat upward, especially at the bottom where it is in contact with the cold pond, that it deposits dew in the pond basin. Again, the coldnoss of the column of air above the water causes it to descend on to the pond surface, deposit its dew, and flow away horizontally. See Dutch Garden ; Lily Pool.

PONGEE. Unbleached, brownish, handmade silk fron N. China is the original pongee. It is plain, but has irregularities in the thickness of its threads. The material has a crispness which softens a little after repeated washings.

PONY: How to Keep. In many country houses a pony is kept either for the children to ride, for pulling a lawn mower, or for light road work in a governess cart. Being smaller than a horse, it costs less to feed: it is also much hardier, and can therefore be run at grass in a small paddock during the greater part of the year. There are several distinct breeds in Great Britain, the main varietics being the Shetland, Welsh, New Forest, 1)artmoor, Exmoor, and the Hackney. Next to the Hackney the Welsh is probably the best, but for real hardiness the Shetland cannot be surpassed.

A good pony should have short legs and sound fcet. Too many have narrow feet, contracted at the heels. It must be surefooted and free from tricks. If required for saddle work it must have an oblique, not upright, shoulder.

As for colour, the best ponies are light and dark bay, blue roan, red roan, brown, and grey. There are good chestnuts, but cliestnut is not a hard colour, not is black. A pony may be kept in a shed if left unclipped, but a stable is preferable. A pony stable may be built cheaply out of wood, with a galvanized iron roof, but whatever the material it is cssential the floor should be sound and well drained.

Feeding the Animals. As a rule, ponies are less dainty than horses, and therefore less difficult to feed. A pony at regular work will require 6 to 8 lb . of oats or similar food daily, but if not required for work may be run out nt grass. It is we!! to bring the animal in at night and give it $n$ small amount of hay If turned to pasture for some considerable time, it is a good practice to remove the shoes, but tips should be fixed to the forcfeet in order to prevent the horn from becoming broken. A good supply of fresh water must be arranged for. In summer a pony will require some 5 gallons a day.
In the matter of feeding, $n$ mixed diet is best. It can consist of oats, beans, maize, bran, and chaff In buying oats it is necessary to avoid those which are broken or dusty. Good oats should be plump, not too dark coloured, and quite free from any musty smell. Some horses and ponies do better on crushed or braised than on whole oats. Maize is useful for a pony in poor condition, because of its fattening qualities. Beans form $n$ strong and stimu lating food, but should be at least a year old before being used. Barley is inferior to oats as a food for horses or ponies. If a ration of lentils is given it should not exceed $\frac{1}{2} \mathrm{lb}$. daily A little bran is useful for an animal that is not getting green food.
As a rule, a mixture of oats with chopped hay is the stnple food for nll ponies kept in stables. Condiments may be given at times, but any excess of treacly or sugary natter is not good. A little linseed is bencficial to the animnl's coat, and a bran mash should be given 2 or 3 times a week. The best hay is that from upland pastures. Hay that is burned or mowheated is always a poor investment. Good hay can be told by its unmistakable fragrance. All ponies are fond of carrots, $n$ few of which should be given at intervals. Swedes form a good substitute if carrots are unobtninable. Under no circumstances should $n$ pony be fed while hot from exercise. A good driver, how. ever, does not bring in his animal in a state of perspiration, but allows it to go quietly for the last mile of the jonrney, and so to come in cool.

Grooming and Bedding. In the matter of grooming it is essential to remove mud as soon as possible from $n$ pony's fect and legs. The feet of an animal standing in the stable must be cleaned with a hoof pick at least twice a day. Shocing must be done with care. Many smiths are prone to cut away too inuch of the horn in shocing, with the result that the animal soon goes lame. A pony that is kept clipped will require to be covered by a blanket while standing in the stable.

Good bedding is essential, but for a pony it is not necessary to go to the expense of straw. In most country districts bracken is obtainable, and forms a uscful substitute; it is cut usually in September, and can be drial casily and stacked. Bracken is distinctly preferable to saivdust or pine needles. The bedding must be forked over daily, and, if possible, tumed out in the air to dry. If a pony is allowed to stand on wet and fermenting bedding its health and feet alike are certnin to suffer. See Horse ; Stables.

POODLE. This dog is not so well fitted to be a home companion as most other domestic breeds, as he is neither so affectionate nor so reliable in temper. Moreover, to keep him in good companionablo condition may involve considerable work. His coat is the chief trouble ; though the very long hairs are hard, they are much disposed to tangle, and the daily use of the comb and brush is a necessity. This is the reason why most poodles have a great part of the coat clipped closely or even shaved, leaving tufts at certain points, which give the animal a grotesque appearance.

Without constant grooming the hair twines up into long cords which trail along the
ground and require oiling. which soon renders the dog unpleasant company indoors Regular combing, by getting rid of the shed hairs, reduces the length of the eoat, and this curls instead of cording. Even so, the Poodle Club recommends that a third of the hody should be clipped or shaved. The colour of a good poodle should be unmixed, that is to say, all black, all white. all red. or all blue. See Dog; Kennel;

## lange, ete.

POOL. This ball game is played on a billiard table by a number of persons. For it special balls are provided, each of these heing a different colour, white, rd, yellow, green, brown, blue, pink, and then, if necessary, the same colours in the same order, spotted. Each player has his own ball, and they play in turn, the sequence of the colours being set out on the scoring board in the order mentioned above. The game is for each player to play at the hall of the previous player in order to pocket it.
Method of Play. The players must first determine by lot, or by some other convenient method, the choice of the balls. Each player starts with three lives. The owner of the white ball places it on the spot, the owner of the red ball plays at it, and at the end of his breal: the next in order follows. The st riker's ball must hit the one at whieh he is playing. If the latter ball is lawfolly pockeled its owner pays a forfeit, loses a life, and his ball remains in hand until his turn arrives again. The one who pockets a ball continues to play, aiming at the ball nearest to where his own rests. If he can continue to play until all the balls on the tahle are pocketed, he piaces his ball on the spont, and the next player plays from hand if the striker fails to score or makes a foul, the next in thrn plays.

In pools of less than four players, the game continues until all the players but one have lost their lives. The surviving player then takes the whole pool. In pools of four or more players, when only two players are left in with an equal number of lives, they divide the pool. If they have an unequal number of lives, the game is continued until the number becomes equal, when they divide, or until one loses all his lives, when the survivor takes the whole pool. It is provided, however, in all cases that a striker who has lawfully pocketed a ball has the option of either continuing his theak or dividing.
Starring. The first player who loses his three lipes is entitled to purchise a star by luying into the pool the value of three lives, for which he receives as many lives as therc remain to the player or players with the lowest number. The player, however, must decide whether he will star or not before the next stroke is played. If the lirst player who is out refuses to atar, the second may do so ; if the second refuses, the third may do so, and so on until two only are left in the pool, in which case the priviloge ceases.

If before a star two or more balls are pocketed by the same stioke, including the ball plaved at, each having one life, the owner of the ball first struck has the option of starring. If he refuses, and more than one remains, the jersons to whom they belolig must draw lots

for the star. If the balls pocketed do not inclucle the ball played at, thoir owners must draw lots for the star.
Only one star is allowed in a pool of six players, hut two stars are allowed in a pool of seven or more players. The player taking a second star pays double the amount of the first star. Thesame player may take both stars.
No convenient method of handi. capping at pool has becn devised. The handicap of starting with two lives in. stead of thice is a very severe one. The best, player, however, may arrange to divide, in the proportion of their remaining lives, at the reguest of the player who survives with him to the end of the prol. The best plaver may alsn agree not to star. This information is token from the rules of the Billinirls Association See Billiards: Russian Pool: Snooker
P.O.P.: In Photography. Printing-out paper, or P.() P., is used for the printing of pictures fiom photographic negatives. It is so called from the fact that when the paper is exposed to daylight behind $n$ negative, the picture gradually prints out until it attains its full depth. It is one of the ensiest photohraphic papers, but is less popular since a still simpile variety, namely self-toning paper, has largely taken its place. P.O.1. prints require to be toned in order to give them a pleasing colour; prints on self-toning paper, however, have only to be fixed, since gold contained in the coating produces the toning action when the prints are placed in the fixing bath.
P.O.P. is made by almost every manufacturer of photographic papers in several varieties, differing chictly in surface. There are trice desciptions of the paper, matt, semi-matt, and glossy, the last-named being chielly used, as it gives the utmost detail in the pictures Sensitive P.O.P. postcarls are made for the production of photographs of this size. P.O I'. is used almost exclusively for printing from small negatives on account of its rendering of detail. It cannot be used for enlargements or for printing by artiticial light, since the low sensitiveness of the paper makes it necessary to use daylight in printing.

When exposing the paper behind the negative, it is necessary to allow the light to act until the picture is very much darker than it is required to be when finished. The print is, thercfore, examined from time to time by turning back one half of the printing frame. The correct degree of printing is reached when the shadows of the picture have a choked-up, appearance, and when the highlights (the sky) are perceptibly of rleeper tone than a pure white. In ordinary good daylight, printing will he completed in from 5 to 15 min ., according to the density of the negative. Some practice is needed in hitting the cxact degiee of over-printing correctly ; more over-printing is neerled when a negative rrints quickly, say, in 5 min., than when printing occupies a longer time.

A number of prints having heen made, they require to be toned and fixed in orler to change the reddish colour of the prints to an agrecable purple or purplish brown. The most satisfactory method for the beginner is to tone and fix at the same time, in a single salution which
contains gold chloride for the toning and hypo for the fixing, with other chemicals necessary for the process This combined bath, as it is called, is hest purchased in liquid form, or as a powder requiring to he dissolved in the requisite quantity of water.

The prints, without any previous washing, are placed one by one face down in the combined hath. and kept on the move. When the prints have taken on all agrecable purplish tone, transfer them to a dish of water and give them a thorongh washing by allowing the water from a tap to run into the dish for a bout one hour. During this time the prints must not be allowed to clot together, otherwise the water docs not obtain free access and the chemicals are not removed

As a safcguard and particularly if prints tone quick!y, e.g. in less than 5 min ., it is advisable to use an additional solution for extra fixing. This is made by dissolving 3 oz of hypo in 20 oz . of water. Prints are trans. ferred clirect to it from the combined toning bath, and kejp moving in it for ahout 10 min . After the washing process the prints are laid face up on blotting paper, or clipped up on a line to dry. On no account must they be put face down on anything, or heated, as the sticky gelatine surface will be spoilt. See Printing: Self-Toning Paper
POPCORN. This is an American dish made with maize or Indian corn. The unripe grains are parched over the fire until the heat bursts them open and the centre of the grain is exposed. In this condition it is caten and considered a great delicacy. The best inaize to use for popcorn is that with a smallish grain

Poprorn is also sold as a sweetment. The grains are poppel, and coated with cither piik or white sugar very much in the same manner as is n sugar plum.

POPE JOAN. This card game is played with a special hoard, which consists of a circhtlar tray or hoard revolving on a central post or stand. The tray is divided by lines running from the centre to the circumference into 8 compartments, each of which will hold 100 or 150 counters. Each division has n name, these being pope, king, matrimony. queen, intrigue, knave, ace, and game. Popic is the nine of diamonds, matrimony is king and queen in the same hand; intrigue is queen and knave. The ace counts the lowest.

The game is played with a full pack, save that the eight of diamonds is withdrawn. This card, and also the four kings, are stops, i.c. a sequence stops when one of them is reached. The cards are dealt round to the players, and the last is turned up for trumps. An extra hand is dealt to the centre of the table, and the cards thercin are stops, as are those just before the ones that have heen already led in play. Wach player contributes an agred number of counters for the stake, and these are distributed among the several compartments of the tray.

The elder hand, i.e. the player on the dealer's left, leads any card lie likes, at the same time naming it. The next to play is the person who holds the next highest card in that suit, who also names it. This continues until no one can play a higher card, when the one who played last leads again, and the process is repeatcil. When the sequence is thus stopped, the cards previously played are turned face downward.

During the game a player who plays king, qucen, ace, or knave of the trump suit or pope takes the counter or counters in the corresponding compartment of the board. If he plays both king and queen of trumps, he takes those from the matrimony compiart. ment ; if he takes queen and linave of trumps. those in intrigue. If the card turned up for trumps is ace, king, queen, knave, or pope, the dealer takes the counters in the comprimment
concerned The aim of each player is to get rid or all his cards, and the onc who doen this is the winner $H e$ is entitled to the counters from the game compartment, and adso to one counter from each of the other players. The holder of the pope, if the carl is still in his hand, dnes not pay this counter If, however, he has played it, he docs.

If, as is usually the cusc, counters remain in some of the compartments, when the game is over, the cards are lealt round face upward in order to see who shall take the spoil. Those who obtain ace, king, quoen, and knave of diamonds take the counters in those divisions, if there are any: pope entitles its receiver to the counters in that division. The counters in matrimony, if any, are divided between the holders of the king and queen of diamonds, and those in intrigue between the holders of qucen and knave.

POPLAR: The Tree. Few treen grow more quickly than the poplar and it will flourish in damp low-lying land unsuitable for many other kinds. The best known is the Lombardy poplar (Populue nigra pyramidalis), a tall tree of columinar form : it makes a good windbreak or acreen if pollarded to make it spread when the desired height is reached The white poplar (Populus alba) and the aspen (Populus tremula), which is distinguished by the possession of leaves which quiver in the alighteat hreeze, are other kinds Mnat of the poplars are easily increased by cuttings set out of doors in autumn The aspen is usually propagated by suckers.

Uses of the Wood. Poplar, although not a wood of much cominercial value, nor nlways obtainable from timlicr dealers, is useful for numerous purposes. It is used for sugar and herring barrels, packing cases, inatches, clothes pegs, ehurns, pails, clogs, and wood wool or shavings for packing; also for brake blocks, the bottoms and sides of carts, wagons and barmu's, and sometimes for field hurdles. It is soft. light and porous, casily dented, but does not aplinter so easily as most woods and does not burn readily. It shrinks a great deal and is not very strong or durable, but is casy to work and seldom split by nails, though it holds nails well In colour it is light grey or pale yellowish brown. See Wood
POPLIN. Irish poplin is a combination of silk and wool, slightly ribbed, firm and warm without being atiff and heavy.
Cotton poplina, plain-coloured or striped, are the chief poplins in use for ourtains and light upholstery fabrics. They are obtainable in a wide range of coloura and guaranteed fadelcss.
POPPY: The Flower. Three kinds of poppy are invalunble hardy garden llowers the oriental, which is perennial, the Iceland, which is biennial, and various types of annual poppies. The oriental poppy (Papaver orientale) thrives in ordinary well-tilled soil and bears large handsome blooms in orimson, scarlet, rose, salmon and other colours in May and June. It dislikes being disturbed and should not be transplanted unneccssarily : it is increased by rowing seeds in May or by taking root cuttings in autumn There are many named varieties.
The Iceland poppy (Papaver nudicaule) is grown in gardens ns a biennial, seeds being sown in bores of tine snil or out of doors on a prepared seed bed in May to producc flowering plants the following year. The seedlings must be transplanted before they become crowded and put out in autumn or spring where they arc to bloom. The Coonarn is an improved type of lceland poppy. The chief favourite among the annual poppies is the Shirley; but the Jarge double varieties of the grey-leaved opium popply are very handsone. All these are raised from seeds sown out of doors in March-April where they are to bloom in summer. The flowers of

Poppy Flowers and buds of the Ryeburgh poppy
poppies are very fleeting, but if cut before the buds liave expanded they last well in water indoors. See Iceland Poppy; Nepaul Poppy; Opium Poppy.
POPPY ANEMONE. This is onc of the most brilliant of garden llowers : its botanical name is nnemone coronarin. There are many strains or types, the St. Brigid being the favourite: the fowera are large and of brilliant and varied colour-scarlet, crimson, purple, nose, etc. The roots ahould be planted on a sumny sheltered border in September to provicle blossoms in spring: they are set 3 inches deep and 4 or 5 inches apart in well drained friable soil of loam, leaf-mould and sand. Planting in February will ensure a later display of bloom

PORCELAIN. Porcelatn is a fine, thin transparent ware, practically the same as china. See Chelsca China: Dresden; Plymouth; Sèvres, etc
PORCR. A porch is n covered entrance to a house, either built on to it in fmnt of the door or part of the house itself. Whether it is a successful adjunct or not depends on its harmony with the architectural style of the house. Porches are sometimes added to exiating dwellings with bad reaults because they completely spoil the frontages deaigned by architects in planning the main buildings. A porch inust be an important feature; it is therefore essential that it should be an attractive one.

For our first illuatration a quaint brich porch with a tiled and pointed roof is selected. Both brickwork and tiling accord with the style of the little liouse, the walls of which have been partially whitewnshed with so thin a coating that the outlines and colour of the bricks show through it. The porch is ceiled and has an electric light fitting which illuminates the entrance and the naine on the door

Very different in oharacter is the other small porch illustrated in Fig. 2. This some what formal entrance belongs to $n$ house in a town strcet. The classical character is sug geated by the pilanter effect at each side and by the projecting roof. The paintwork of porch and doorway gives distinction to the front of the house. Glazed bricks nre used for the step, and there is an electric light fitting:

Half-timbered houses and country cottages are often designed with picturesque porches. A combination of herringboned brickwork and oak for the timbers and side balustrades is employed to construct the porches of some modern houses with excellent old-world effect. For a whitewashed cottage the simple roomy porch illustrated in Fig. 3 is a charming architectural feature. The door and timbers are of old onk, and the tiles of the porch ronf match those of the house. The side windows are glazed to aforl better protection from the weather. The rafters are exposed, as a ceiling would be out of place in such an entrance.

A dignified porch is illustrated in Fig. 4, with its semicircular formation, domed

Porch. Fig. 1. Quaint bick parch with pointed tiled root which sults this modern type of country cottage. Fig. 2. 'Shis tormal porch for a small town hous? is painted to harmonize with the door

Humplirell \& Dera Joel

Porch. Fir. 3. An attractive porch made from old oak beams rooted with tiles, set outside a whitewashed cottage. Fig. 4. Domed and pillared entrance in the angle of two walls of a brick-built house No. 4 bu courtesy of Our Homes and Gardens
roof and pillars. It is an attractive feature for the "angle house" designed with two wings to catch as much sun as possible. In such a porch there is room for a white painted seat at either side of the door, or for green tubs containing hydrangeas or other suitable flowering piants. The ronf is ceiled and finished off as a part of the interior of the house. It has a central enclosed electric light fitting.

An attractive porch for a bungalow can be constructed entirely from light timber. The uprights, 3 in. square, are connected by short cross-pieces of timber. 2 in. deep and 1 in . thick, mortised or dowelled into place. At the top the uprights are framed into place with timber 4 in . in hreadth and 3 in . in thickness, finishing flush with the tops of the posts The roof rafters are brought down on to this plate and the roof tiled The eaves are finished with aoffit and fascia board, faced with O.G. cast-imon guttering, the down pipe for the rain water being provided in the most convenient position adjacent to the rainwater Irainage aystem. Such a porch should be made in prepared timber, and looks well if oak stained to contrast with whitewash or rough cast and brick. See Lnggia : Lych Gate ; Name Plate; Path.

PORK. The season for pork should he confined to the winter months, or from the end of September to the beginning of April. When salted, especially in the form of bacon, pork is more wholesome than the fresh meat. This is the only salted meat which is superior in point of digestibility.

Particular attention should be paid to the condition of the meat, and to sce that not only is it free from taint, but that the fat is devoid of kernels. The best joints for roasting are the leg, loin, and fore-loin ; the spare rib, also, may be roasted, but it is not so thrifty. Roasted joints should be stuffed with sage and onion stuffing, served with thickened brown gravy and accompanied by cither onion or apple sauce If it is not desired to atuff the joint the stuffing may be formed into balls and cooked in the tin along with the meat.
To prepare the leg for roasting, saw off the shank bone and make an incision between the rind and the fleah just bclow the knuckle.

Fill the cavity with the stuffing and sew it in securely, or it will ooze out and be partially lost in the pan. Then, with a sharp-pointed linife, score the surface on the rind in even lines about $t$ in. apart. Cut well into the rind, but not deeper than the outer skin. Pork should always be well basted with plenty of good dripping, and be exposed to a good solid heat, especially at first ; but on no account must the crackling be scorched. Allow 20 $\min$ to the lb . for masting the leg, and 20 $\min$. over.
All solid joints require longer to cook than thinner pieces, and the time for cooking meat should be measured rather by the compactness of the flesh than the actual weight, after considering the average. The crackling of pork is improved if, when nearly cooked, it is rubbed over the surface with butter, drerlged slightly with flour, and then basted before being returned to finish. The directions given apply to all joints of pork, but for loin and fore-loin saw off the chine For loins or spare rib make the incision where convenient well under the skin. Before roasting these, and after the chine bone is removed, just separate the rib hones. but be sure that the joint is left whole.

The gravy should be served in a gravyboat. Any trimmings should be added to the stock from which the gravy is made : also the dregs remaining in the pan in which the joint has been roasted should be addled, after the dripping has been poured off. Pork dripping should never be mixed with that from other ments. It is always rather highly flavoured and will have absorbed the taste of the stuffing. Pork dripping can be used for basting poultry or game.

To boil a leg or hand of pork, saw off the shank bone and put the leg into a saucepan with a large onion stuck with 3 cloves, 1 lb . carmots, and the same of paranips. Cover it with cold water, boil up, skim, and continue boiling very gently for about 3 hours, or a little over or under according to the size of the leg; 20 min to the lb . is usually allowed for thick joints, but pork must invariably be cooked right through to the bone. For pork and beans add $\frac{1}{2} \mathrm{lb}$ soaked haricot
beans 30 min before the pork is cooked. Drain the beans and serve separately with parsley sauce. The spring or belly of pork is usually salted and boiled, but if not too thin it can he roasted Care must be taken not to over cook it. Make up some sage and onion stuffing into balls, fry these, and dish with the pork
The ears and feet can be cooked together Purchase them ready cleaned, and soak them for 12 hours. then rinse and boil them til tender. Let them get cold, and then soak again for 1 hour in a little vinegar, 2 cloves, 1 bay eaf (bruised), and seasoning. When ready to cook, dry them and cut the ears in slices and bone the feet, cutting the flesh in neat pieces Fry the slices and pieces in butter after egging and crumbing them ; or they may he dipped in batter hefore they are fried
Pork chops should not be cut more than in. thick. They should be neatly trimmed beaten with $n$ cutlet bat, and fried in hot butter. To dish, sprinkle with a little chopped onion and powdered sage Pork cutleta are cut from the neck bones, and should not be more than $\frac{1}{3} \mathrm{in}$. thick. They should be egged and crumbed, and a little minced shallot and powdered sage may be mixed with the egg. The cutlets are fried on both sides in hot butter until thomughly cooked.
Pickled Pork. To pickle pork, cut the meat into joints of $n$ convenient size and, after wiping it and removing all kernels and pipes, rub it well with common salt. Let it stand for 12 hours, then drain off the brine, and the following day steep it in a pickle prepared from $1 \frac{1}{2} \mathrm{lb}$. common salt, $\frac{1}{2} \mathrm{lb}$. bmown sugar oz. raltpetre, and a gallon of water. Boi these ingredients together for about $\ddagger$ hour, remore the scum from the top, and then strain them. The pickle should be allowed to cool hefore being poured over the meat, and the latter should remain completely immersed in it for about 12 days.

Pork Pie. To make a raised pork pie, weigh out 1 lb . neck of pork, freed from skin and hone, cut it up finely, season it to taste, and then add $\{$ tablespoonful chopped onion and I teaspoonful powdered sage. Make 6 oz .
hot water crust (see Pastry), turn it out hot on to a floured board, and knead it until it is perfectly smooth Cut offthree quarters of it and roll it out to acircle about $\frac{1}{4}$ in. thiok, keeping theedges even and the strip itself of uni form thickness. The remaining picce of pastry should be wrapped in paper and kept hot over
 raised pie monld like the one illustrated should be used for baking a pork pie. Line the mould evenly with the large piece of pastry. If no mould is available
the pastry may be shaped over the hottom of a round cake tin Stand the tin in the centre of the circle of pastry. nnd press pastry evenly up the sides, kceping the top edge level Remove tin and tie a bnnd of grenseproof paper round paatry case

Put in the pork mixture, moistening it with a little stock or water, and press it well in, leaving a narrow rim of pastry standing above it all mound Roll out thinly the smaller piece of pastry, cut from it a sound for the top, hrush the edges of it with cold water and then lay it on top of the pie pressing the edges together. A ridge of pastry standing about of higher than the pie should be left all round, and this should be trimmed and decorated with a pair of scissors. A hole must be left for steam to escape. Any scraps of pastry may be used to decorate top of pie.

Brush some beaten egg over the whole pie, und bake it in a moderately hot oven for 1!-2 hours, or until the pastry is lightly hrowned and the meat tender. When the pie is cooked. pour through the hole in the top a little warm stock in which a sheet of gelatine has been disalved, and then allow it to get cold. See Apple Sance; Bacon; Pastry; Sage.

PORRIDGE. The preparation known as porridge is made by stirring oatmenl, whentmeal. Quaker Onts, or some similar patent food into boiling water or milk, or a mixture of both. It is eaten for breakfast either with sugar and hot milk, with cream, or with salt, and is hoth heating and nourishing.

To make oatmeal porridge boil up 1 pint water, then sprinkle in 3 oz . ontmeal, stirring all the time to prevent burning. Continue stirring until the mixture is smooth and creamy, then add salt to taste and let the porridge cook slowly at the side of the fire for about 45 min . Stir occasionally to prevent sticking, and add more boiling water if necessary. Serve in porridgo plates or soup plates. Porridge made with whenten meal requires about $1 \frac{1}{2}$ handfuls to each cup of water. The meal is sprinkled into boiling water, salt leeing added to taste. Stir until smooth, then allow to cook gently 40 to 50 min . Porridge is also made with harley meal and ontineal. The method is similar, the oatmeal being aprinkled into boiling water, allowed to boil for 10 min ., then the barley is sprinkled in finely thmugh the fingers and tuble salt added. This form of porridge is hest taken with cream. As it helps to purify the blood, it is said to be good for the complexion.

PORRINGER. A porringer wiss originally a vessel used for holding porridge. Though it is sometimes known as a caudle cup, strictly apenking a caudle cup has a lid and is bellied,
or rather squat, in slinpe. A porringer proper is lidless, with fairly straight sides. Porringers were made in silver, pewter, and Sheflield plate, and good examples are much sought by collectors. They are known to have existed in the 16 th century, nnd the lion and unicorn pattern appeared after the Restoration

The hest porringers were made from 1660 to the time of Annc. Examiples are freely decorated with acanthus and roses Repoussé is used for decoration with, in some eases, a little chasing by way of relief. 17th century specimens are found with fanciful devices of animals, birds, and Howers therenn; hut with the accession of William III, Dutch influence was exercised in the direction of simplicity, and the flute and tho gadroon appeared. See 「ewier; Silver.

PORTABLE WIRELESS SET. This is a self-contained receiver. It is usually built into

a cahinet of the suit-casc type and is designed for use with an enclosed frame acrial

Four or tive valves are normally employed and the low sensitivity of it frame acrial renders high-frequency amplification essential. A well-tried circuit should be chosen owing to the restricted layout of the components in a portable set. The use of more than one stage of tuned high-frequency amplification calls for skilled design. otherwise stable opera. tion may be impossible It is therefore common practice to employ either one tuned screen-grid high. fiequency stage or one luned and onc chokecoupled stage.
Careful screening is necessary in order to avoid interaction between the frame aerial windings and the high-frequency coupling coils. In the casc of choke-coupling the
high-frequency chokes should have a high inductance value and a low self-capacity. l'oorly designed chokes will result in a loss of amplification, and may possibly cause instahility. It is advisable to decouple the screening grids of the screen-grid valves with resistances having a value of (i)0 or 1,000 olims and 1 mfd . by-pass condensers to lowtension negative.

The low frequency stages may comprise either one stage of resistance capacity amplification followed by a trancformer or two transformer coupled stages Tho transformers should have low ratios

The risk of instability may he minimized by inserting a $\mathbf{2 5 , 0 0 0}$ ohm decoupling resistance in series with the detector high tension positive lead, and a 2 or 4 mfd by-jass condenser to low tension nogative.

The limited space available prohibits the use of large-capacity high-tension hatteries, and therefore it is highly important to apply negative grid bias to the high-frequency valve or valves, and also to adjust the grid hias on the low-frequency side with care Failure to apply the correct grid bias will considerably shorten the life of the high-tension

Portable Wireless Set. Lett. Reneral lagout of receiver, showing valves and batteries. Above. typical erample of a q-valve portable set, showing loud speaker and controls
battery. The low-tension accumulator should be of the unspillable type.
In the case of portable sets which are only intencled to be moved from room to room the lighting ninins can be employed, and the high tension can be ohtained from an eliminator, a suitable unit being one which has also a switch for trickle charging. Such eliminators as these are readily ohtainable, and are designed to till the space normally occupied by the high-tension battery. In use the eliminator mains plug is inserted into the socket of a lamp holder in the room in which the set is to bo worked.
The toud speaker usually comprises a balanced armature cone unit, and is inserted in the lid of the cabinet The frame aerial winding for the long and medium wave bands may be wound around the framework supporting the lid, and in a home constructed receiver the most at raight forward scheme is to employ two separate windings for the medium and long wave bands respectively. Wavechanging can be carried out with the aid of a double-pole change over switch, a second switch of the anme type being utilized for wave-changing the high-frequency coupling coils. See Frame Aerial.

PORTER: The Drink. This name is given to the dark-coloured malt liquor similar to but thinner than stout, and not so fre quently used. Sep Stout.

PORTLAND CEMENT. Poitland cement is so named hecause of its resemblance in colour to Portland stone. It is made by the intinate mixing of calcareous and argillaccous innterials such as limestone and clay, in certain definite proportions. Portland cement should always he of the British standard specification. See Brick; Cement; Concrote; Rendering

PORTRAIT ATTACHMENT. A small lens known as $n$ portrait attachment, or magnifier, is attached by screwing to the lens
mount of a Kodali or other foiding cainera to increase the focal length, for taking portraits. With the ordinary lens alone nothing nearer than about 15 ft to 20 ft is in focus, so that portraits of sufficient size on the film or plate cannot be obtained The portrait attachment, by lengthening the focus of the lens, allows the camern to be hrought within 8 ft . or 10 ft (not nearer) of the person to he photographed.
Another use for the portrait attachment is to get photograplis of huildings and ohjects in confined spaces where it is impossible to get the whole of a building within the limits of the focussing screen without tilting the camera, and so producing distortion See Lens: Swing back

## Portraiture: In Photography

## Simple Rules for Good Results in Amateur Work

Continuing the sequence of our photographic articles, our contributor dcals here with the taking of
portralis. Other entries that hear upan this subiect include Orthochromatic: Panchromatic. See portralis. Other entries that hesr upon this subiect include Orthochromatic: Panchromatic. See also Camera: Enlarging: Lens: Pholography: Spot-liphe
Of all branches of amateur photography consisting of two separate lenses, nne of which portraiture is probably the most difficult. Much can be done with the ordinary snapshot camera, particularly if it be clearly recognized that it is not designed for portrait work, and its use is mainly confined to out-of-doors portraits taken with the subject some distance from the camera. For indoor work a stand camera is cssential. To get sntisfactory results with a fixed-focus camera an extra lens, called a portrait attachment (q.v.) or magnifier. should lie used

With the ordinary lens the figure will he too small on the plate or film, even for enlargement, since if the sitter is brought near to the camera he will be out of focus and the perspective will he distorted. Even with a portrait attachment the sitter should not be less than 8 ft . or 12 ft . from the cannera This will give a somewhat small image on the plate, which. however, can be enlarged antisfactorily

To obtain a large image on the plate, such as is seen in professional portrnits. a lens with n long focus is necessary. For a $t$-plate camera an 8 in. or 10 in. lens will give gond results. Its definition miny not be perfectly sharp, and its deptlı of focus will be sinall if, as should he the case, it is of fairly large aperture. These qualities, however, are advantages in portrait

| xs |
| :--- |
| 日C | work, giving soft, rouniled pictures. Thus an old single landseape lens will serve excellently. If the lens of the camers in use is what is known as a doublet,

can be screwed out, it will he found that using the back lens only will give the extrn focal length required, i.e enlargement of the image. although it will have the effect of reducing the aperture, and therefore increasing the exposure.

The next consideration is ahortness of exposure. Naturalistic portraits cannot be obtained if the sitter has to keep $\Omega$ rigid position for inore than a fraction of a second. This is one of the reasons why the aninteur snapshot portrait is often more pleasing than some professional portraits. Short exposure is obtained by using a fast lens, i.e. working at an aperture of $f / 6$ or less, fast plates or films (such films as the Kodak 'Verichrome' used with a pale filter can be made to give good resulta), and strong light. Outdoor light is the strongest, and therefore hest for minateur portraits, although it has the disadvantage that it cannot be controlled.

For outdoor work avoid full front lighting, and place the sitter ao that the light is stronger on one side than the other. With the sitter facing the st rongest light squarely. all model ling in the face will be lost and the portrait consequently untrue and uninteresting. For similar reasons full sunlight is nsually un satisfactory, rpart from the fact that it makes

the subject screw up his eyes and wrinkle the forehead. A tree, wall, fence, or other object on one side of the sitter will help to give the necessary side lighting and greatly improve the modelling. Lighting from above also needs consideration, for if it is too strong the eyes will he shadowed by the forehead and hair and give a scowling effect.

If the top lighting is too harsh a screen can be rigged up with an old sheet stretched horizontally 2 or 3 ft . above the subject's hcad A camern with $\Omega$ focussing screen enables all these effects to he studied. Much can be learned if a good-sized sculptured bust or plaster cast is used for experiments and for trial exposures.
Great care is necessary in the choice of a background. It must not be full of detail sharply rendered, or the interest will be divided A neutral background should le chosen it possible If it is in deep shadow without high lights, the portrait will be thrown up well A simple and effective background is provided by a sheet stretched on a clothes horse Whatever its nature it should be well out of focus

Another foint is to see that there is no incongruous object, such as a bush or tree trunk, immediately behind the sitter.

Whenever porsible use orthochromatic or panchromatic plates or films. Apart from questions of colour in the dress, freckles or slight rednesses or other hlemishes in the skin, hardly noticed by the eye, are greatly exag. gerated by ordinary plates on account of their insensitiveness to red. With colour sensitive plates these characteristics are reduced to their proper proportion, and retouching, n matter hardly within the capacity of the nverage nmateur, is avoided
The pose of the sitter should he attended to carcfully, but without making him adopt unnatural or uneasy positions which will give the effect of strain. Do not let him sit in a slovenly attitude, but reasonably upright, with the chin held up $a$ little and the cyes looking very slightly to one side for a full-face portrait. The camera should he so arranged that the lens is about level with the chin. The face should he studied to ascertain whether full face, side face, or profile gives the most characteristic and pleasing likencss.

Indoor portraiture ©s somewhat more diflicult 1 han outdoor work. Much more careful control of the lighting is both necessary and possible, and

Portraiture. Fig. 1. Result obtalned with lighting from one window. Fig. 2. Reflecting screen added, wlth improved lighting ot iead and iace moieiting. Fig. 3. Picturesque lighting effects obtained with background screen and arrangement, of reflector and camera. Fig. 4. Good effect with lighting from t windows and reflector. The diagram above each photograph shows the arrangement of camer
Specially pholographed by $E$. Hoppe

Portugal Laneel. Evergreen flowering tree attrac tive for the garden shrubbery
effects can be obtained which are impossible outdoors. Longer exposures are required, but this difficulty can be partly overcome by the use of very fast plates, or of panchromatic plates without light filters.
The tendency with indoor anateur portraits is towards harshness of lighting. This is a acoided by using a room with a good-sized north window, or, better, with two windows, the lower part or the whole lightly screened with lace or muslin ourtains, or other white translucent material, to soften and diffuse the light. The subject should be placed near, but not too close, to the window, and a reflector on the other side (Figs. 2 and 3). This lights up the portions of the face and figure otherwise in shadow. A reflector can be contrived with a large sheet or white paper hung on a clothes horse or a line that can be moved about. The positions of screen und camera are best found by experiment. Suggestions are given in Fig. 1-3, which show three possible arrangements in a room with one window. and in Fig. 4 for a room with two windows. Very interesting effects can be obtained with the reflector placed in front of the sitter, the camera lens pointing through a bole cut in the reflector.

If the top light is too strong, it can be regulated by short curtains on rods hung at the top of the window.

The background in an ordinary room should be carefully considered. It is usually best to contrive a simple background out of some un. patterned material not too light in colour hung on a line stretched across the corner of the room and kept out of focus. If the ordinary room furniture constitutes the background take care that no prominent lines of furniture, picture frames, etc., pass directly lehind the sitter's head, and also that the glass of piotures, or other bright objects, do not eatch the light, thereby making a glaring white blob in the photograph

The head should not be central in the plate unless a full-face front-figure portrait is being made. With side face, or profile, much more
pleasing results are obtained with the head on either side of the middle line of the plate.

Exposure should always be cherked with an exposure meter, except when artificial light is used, when actual experiment alone can decide, according to light, lens, and plate used Development should be deliberately on the thin side, either using the ordinary developer diluted with one-third the amount of water extra to the ordinary amount, or by shortening the time of development. Over-development will entail loss of modelling and harshness without any gain in detail. For most portraits rather broad effects are best, and these are given by thin negatives, which are printed or enlarged on matt or rough papers.

PORTUGAL LAUREL. This vigorous evergreen (Prunus lusitanica) forms an attrac tive tree if allowed to grow naturally and bears white flowers in summer. The best time to plant is in September or early May, and it is wise to put in small trees as large ones can rarely be transplanted successfully.

PORTULACA. The dwarl-growing portu laca is a S . American annual flowering plant of low growth. It is raised from seed sown in pans in $a$ cold frame in carly spring and planted out in June. Sowing may be made in the open grmund in May. The flowers are crimson, pink, white. and yellow. They need light anil and a sunny place.

PORT WINE. There are three classifica tions of port : vintage, ruby, and tawny, of which particulars are here given.

Vintage Port. Vintage port is wine of a particular vear, shipped, as a rule. from 2 to 4 years after it is made, bottled in Great Britain, and allowed to mature in cellars. It matures slowly and improves with age. Only those years in which conditions have been favourable to the perfect ripening of the grapcs are known as vintage years.

The purchaser of vintage port should take care that the wine has been shipped by a reliable shipper in the first instance, and bottled by a good wine merchant. The pur chaser should always assure himself of the bottling date before taking delivery. The most economical plan is to buy vintage port carly, as soon as the wine merchant has bottled it. The wine should then be laid down in the cellar for keeping purposes. Ten ycars in bottle is a fair age, although the wine may improve up to 20 years or more.
Vintage port is hnown by its character, full, fruity Havour, colour, and fine bouquet. In the process of maturing in bottle a crust is formed, and the wine should be carefully decanted, the white splash on the end of the bottle being kept uppermost. The decanter should be perfectly dry and clean. The bottle must not be shaken, nor the sediment allowed to pass into the decanter: If the cork breaks. the wine should be poured into the decanter through a strainer or piece of muslin.

Port bought for immediate use from wine merchants should be stood upright for 24 hours in the dining room to enable the crust to settle, and so that the winc acquires the temperature of the room. Port should be decanted at least 2 or 3 hours before drinking, as the wine develops in bouquet and Havour.

Other Ports. Tawny port is not a wine made from any one apecial year's grapes, but a blend of wines of a number of years. It is matured at Oporto in wood instead of in bottle, and conscquently loses its deep red colour. It is a lighter wine, both in colour and body, than vintage port.

Ruby port is a compromise between vintage and tawny. It may be a wine of a particular vintage kept in wood for some time before being bottled so that it has lost some of its depth of colour and strength ; or it may be a blend of wines of different years blended at Oporto or in Great Britain by wine merchants.

The percentage of alcohol in port wine is from 15 to 20 per cent. When more than 15 or 16 per cent. of alcohol is present. the wine has bcen fortified, that is to say, spirit has been added to it. Much cheap wine sold under this name may be nothing but a mixture of potato or grain spirit coloured and fla voured with dycs and essences. Natural port is a wholesome beverage, but the artificial compounds may be extremely injurious. Port wine is combined with malt or malt extract in some tonic preparations. See Alcohol: Wine

Port Wine Mark. See Birthmark.
POSITIVE. In photography a positive is the reverse of a negative, and may be made, as is most usual, on paper or on glasw, when it is seen by transmitted light instead of by reflected light, as in the case of n print. A glass positive is generally known as a trans parency It may be for use as a lantern slide or a colour transparency
Ordinary transparenciea are made for the purpose of copying negatives by contact A alow plate is best. See Colour Photography; Negative.
POST. A post is a picce of timber, metal, or other material usually lixed in a vertical position and used as a means of support or attachment.
The majority of fences are constructed of posta made in wood. cast or wrought iron, or concrete, set at a distance apart, the intervening space being filled with rails, palings of wood, chains, stout galvanized iron wire, or barbed wire. In the latter two cases a stouter post, called a atraining post, is often placed at certain distances, incorporating a drun with a ratchet device for tightening the wire. An example of a concrete atraining post braced with a atrut is illustrated in the article on Fence, at page 451.

A gate post has to carry a heary weight, and often needs a support on the opposite side to the gate. Since a gate sinks if the post falls even slightly out of the vertical, it

Post. How a corner post is erected in the course al constructing any small building
is advisable when erecting the post to ensure a perfectly sound foundation. Where the gate post is of wood, it should be well creosoted or treated with some other form of wood pre servative, to prevent rotting. See Clothes Line; Fence; Gate.

## Postage: Rules and Regulations

## A Concise Guide to Matters of Everyday Concern

This article contains information about the dispatch of letters and postal packets of all kinds Branches of the subject are dealt with under the headings Money Order: Parcel Post: Post card. See also Letter; Parcel: Telegram

The cost of sending letters, papers, cards, for the first year after removal is done without newspapers, etc., through the prost is met by charge. For redirectionduring the second and purchasing stamps and fastening them to the letter, card, or wтapper. Parcels, not exceeding a certain weight, can be sent in the rame way. The postal rules and charges are divided into three main classes, which refer respectively to inland postage, i.e within the British Isles: to postage to British possessions and the U.S.A and to postage to other foreign countries.

The communications that are sent through the post may be divided into four classes: letters proper, this including letter cards: postcards; newspapers: printed papers of other kinds.

Letter Rates. A letter may be sent to any part of the British Isles, including the Irish Free State, for $1 \frac{1}{2} \mathrm{~d}$. provided it does not exceed 2 oz . in weight. If it does exceed 2 oz . in weight, it will cost an extra $\frac{1}{d}$. for every 2 oz or portion of 2 oz . Thus a letter weighing 3 oz . will cost 2 d , and one weighing 5 oz . will cost $2 \frac{1}{2} \mathrm{~d}$

The prepaid rate of postage on letters from the United Kingdom to other parts of the British Empire generally, mandated territories, except Iray and Transjordan, the United States of America, Egypt and the British Post Office at Tangier is $1 \frac{1}{2} \mathrm{~d}$. for the first ounce, and 1d. for each additional ounce or fraction thereof. The rate to all other places abroad. including Iraq and Trans jordan, is $2 \frac{1}{2} \mathrm{~d}$. for the first ounce and $1 \frac{1}{2} \mathrm{~d}$. for each additional ounce or fraction thereof.

A letter if posted unpaid is charged on delivery with double postage : if posted underpaid, with double the amount of the deficiency. No letter may exceed two feet in length, one foot in width, or one foot in depth ; or, if inade up in the form of a roll, 30 inches in length and four inches in diameter. There is no limit of weight.

Postage stamps can be bought from any post office. They are sold in the following values: $\frac{1}{2}$ d., $1 d ., 1 \frac{1}{2} d ., 2 d ., 2 \frac{1}{2} d ., 3 d ., 4 d ., 5 d .$, $6 \mathrm{~d} ., 9 \mathrm{~d} ., 10 \mathrm{~d}$. 1s., 2s. 6d., 5 s ., and 10 s . A took containing $181 \frac{1}{2}$ d. stamps, 6 penny ones and six halfpenny ones can be bought for 3 s Letter cards, stanped with a $1 \frac{1}{2} d$ stamp, can he bought. The charge is 2 d . for one, and goes up to 1 s . $6 d$. for a packet of 10 .
Envelopes embossed with $1 \frac{1}{2} d$. and $\frac{1}{2} d$ stamps, envelopes for registered letters and newspaper wrappers, are also sold at the post offices. These embossed envelopes are in two sizes, $4 \frac{3}{2} \mathrm{in}$. by $3 \frac{1}{16} \mathrm{in}$., and $5 \frac{5}{18} \mathrm{in}$. by $3 \frac{1}{8}$ in. Of the former a packet of 11 bearing $1 \frac{1}{d} d$. stamps costs 1 s . 6 d ., and of the latter a packet of 15 costs 2 s .

Newspaper wrappers bearing 1d. stamps cost 2s. for 22. Registered letter envelopes with stamps for 4 d . embossed thereon are sold in four sizes, $5 \frac{1}{2} \mathrm{in}$ by $3 f \mathrm{in}$. 6 in. by
 These can he used for foreign postage, pro vided the extra stamps are affixed. In rural districts stamps for $\frac{1 d}{}$., 1d., and $1 \frac{1}{2}$ d., and also envelopes with a $1 \frac{1}{2} d$. stamp, can be bought from a postman.

Redirecting Letters. Any kind of postal packet can be redirected to the same person at another address under certain conditions. This privilege is necessary when persons remove from one house to another. It is also very useful when families go away for the summer holidays, and during other absences from home. It can be done either by someone authorized by the person to whom the letter is aldressed, such as a relative or caretaker, or by an official of the post office. The redirection of letters
thind years a fee of 1s a year is charged After that 5 s. a year is charged.
The postal authorities only undertake to re direct letters, postcards, etc., when such cannot be redirected at the place of addrcss. They do not, for instance, redirect postal packets addressed to a person who has temporarily left his house, unless the house is left unin habited; or those addressed to clubs, hotels hoarding houses, or lodgings.

Notices of removal and applications for redirection must be signed by all the persons to whom any packets to be redirected are to be addressed. Thus, in case of a removal, all the members of a family who have any reason to expect letters must sign, not the head of the house only. Printed forms for this purpose can be obtained from the local post office or from a postman, and when filled up and signed should be sent to the postmaster or handed to the postman.
Registered Letters. Letters which contain money or artioles of value should be regis tered, and if this is done compensation will be paid by the Post Office in the event of loss. Any letter, parcel, or other postal packet can be registered. Anything intended for registra tion must be handed to an official of the post office, and a certificate of registration, bearing an acknowledgment that the necessary fee has heen paid, must be obtained. Nothing intended for registration should be dropped into a letter hox
The fee for registration is 3 d . exclusive of postage This insures the-packet up to $£ 5$, so if it is worth more than that sum a higher registration fee should be paid. The fees and limits of compensation are as follows, this applying obviously to inland postage only. No compensation in excess of $£ 400$ is paid.

A packet intended for registration must he made up in a reasonably strong cover appropriate to its contents and must be fastened with wax, gum, or other adhesive matter. It is not sufficient neerely to tie a packet with string, but if it is tied with string in addition to the fastening, the string need not be sealed.

If it is desired to secure compensation in the event of damage to a packet not sent in a parcel, the packet must bear the words fragile, with care. These words should appear on the face of the cover, above the address. Any official to whom a packet is tendered for regis. tration is instructed to refuse to register it if the packing is, in his opinion, obviously inadequate. Compensation will nevertheless be refused if, though acoepted, the packet is afterwards found to have been imperfectly packed. When several packets are sent for registration by the same person it is desirable for a list of the addresses in duplicate to be sent with them; one copy is kept by the post office and the other is signed and returned to the sender. The sender of any registered postal packet may arrange at the office of posting, either at the time of posting or subsequently, for an advice of its delivery to be sent to
him The fee is 3 d , payable by means of stamps affixed by the sender to a form provided for that purpose.

Packeta that contain coin or jewelry, and also all packets for inland postage bearing the word Registered or any other word, phrase, or mark to the like effect, written or printed on the cover, are, if posted otherwise than in accordance with the regulations, subject to compulsory registration and are charged on delivery with a registration fee of 6 d . less any mount prepaid in excess of the postage.
Any packet which is found open in the post or cannot be delivered, and which is found to contain an uncrossed postal order in which the name of the payee has not been inserted, a cheque or dividend warrant not crossed or made payable to order, a banknote, currency note, postage stamps, or any article, other than coin or jewelry, of a value in each case of 10 s . in coin, will be subject to registration and be charged with a registration fec of 3 d . No compensation will he given for any postal packet that has been compulsorily registered.

Compensation in respect of money of any kind, coin, banknotes, money, postal orders. cheques, stamps, etc., will be paid only in those cases in which the money is enclosed in one of the registered letter envelopes sold by the post office, and the packet is tendered for transmission by registered letter post. The compensation paid in respect of coin, which must be packed so that it cannot movo about, will in no oase exceed $£ 5$. . Compensation for damage to a packet sent by registered letter post will be paid only in cases where the packet is marked with the words fragile, with care
Printed Papers For printed papers the prepaid rate of postage is d d . and an additional dd. for every 2 oz . or fraction thereof up to a maximum of 2 lb . Printed paper includes all documents that fall into the following six classes. Such documents must consist of a printed form and any writing on it must refer solely to its subject matter or must consist of formulas of courtesy or of a conventional character, not exceeding five words or initials.
(1) Commercial or business papery of a lormal character, namely, invoicea, orlers for gomds or for work, confirmations of orders, advice notes of the dispatch or receipt of letters, documents, goods, or money, wnybills, bills of lading, receipts for ronds or money, statenients of account, price lists, prices current. market reports, delivery and shipping notes, tenders for zooxds or for advertisementa, quotations or gonds, estimates for work, inyluiriew for quotations, outract noter, conffimations of contracts, share transfer notices and applications for employnient. Notices oi assessments and applications for payment of mites, notices relating to the registration of votera, notices, certificates, reports, and returna aiven or made to or by public bocdiea. lista nuld bular statements.
(2) Proposals and policies of insumnce, powers of attorney, proxy papiers, llcences, voting papers,

## (3) Circuliss thut is printe

4) Printed Christmas, printed notices and letters. picture, greeting and visiting cards. (including information for insertion in printed proofs and sinilar publications) with corrections and enstructions.
(f) Educational exercises and examination papers ith comments, corrections and instructions.
As overy printed paper is subject to examination, it must be posted in a cover that can be easily removed for the purpose of examination without breaking any seal, tearing any paper, separating any adhering sulsstance, or cutting any string No printed paper may contain or bear any communica. tion in the nature of a letter.

No paper money may be posted or conveyed or delivered by post in a printed paper. A stamperl proxy paper or a stamped and addressed card, wrapper, label, or envelope forwarded in order that such card, wrapper, label, or envelope may be returned through the post is, however, permitted. A packet prepaid as printed paper, but which contains
an enclosure of any kind, is not admissible at printell paper rate.
Newspapers. Newspapers can be sent through the post at special rates provided such newspapers have been registered at the general post office. If this has been done, the words Registered for transmission through the post will usually be found thereon. The rate of postage on publications registered in this way is ld for every copy not exceeding 6 oz., with a further charge of $\frac{1}{2} \mathrm{~d}$. for every additional 6 oz . or fraction of $6 \mathbf{~ o z}$.

The rate is per copy; so if two or more copies are sent in a single packet each is liable to the same postage as if posted separately. But in no case will a copy or a packet of such copies be chargeable with a higher rate than that chargenble on a printed paper of the same weight. A copy or a packet of copies posted unpaid or underpaid is chargeable on delivery with double the deficiency at the newspaper rate or printed paper rate, whichever involves the lower charge. No copy or packet of copies may weigh more than 2 lib or exceed 2 ft . in length or 1 ft . in width or depth, or, if made up in a roll, 30 in . in length and 4 in . in diameter.

Every newspaper sent through the post should he so folded and covered, if a cover is used, as to admit of the ready inspection of the title. Every copy or packet of copies must he posted either without a cover or in a cover open at hoth ends, which can be easily re. moved for the purpose of examination. No copy of a newspaper sent by post at news. paper rate may hear on the paper itself or on the wrapper any writing except the name, address, and description of the person to whom it is sent, the name of the sender, the words With compliments, and a request for its return in case of non-delivery.

No unregistered publication and no article that is not part of a publication registered as a newspaper or a supplement thereto may be enclosed in any packet sent at newspaper rate. No supplement to a publication registered as a newspaper is admissible at the newspaper rate unless it is sent through the post with the publication to which it is a supplement. If any of these regulations are infringed, the packet will be charged, either as an underpaid printed paper or an underpaid letter, or is transferred to the parcel post and charged with a fee of Id. in addition to any deficient parcel postage, whichever involves the lower charge.

Other Points. If a letter, postcard, or newspaper cannot for some reason be delivered at the place to which it is addressed, it is returned direct and unopened to the sender, provided it hears on the outside his or her name and address. If this is not thereon, the packet is opened by an official of the post office, and if it contains the sender's address it is returned thereto. An undelivered postal packet which cannot he returned to the sender and contains no enclosure of importance is destroyed.

Any person who desires proof that a letter, letter card, postcard, printed paper, or news. paper has been posted to a particular person, should hand in the letter or card at a post office and ask for a certificate of posting. The fee for this is $\frac{1}{2} d$., payable by means of a stamp, which must be affixed by the sender to the certificate. A letter which contains anything of a fragile nature should be lahelled fragile.

In towns, where post offices or pillar hoxes are found in almost every street, the postmen are not allowed to accept anything for the post, hut in country districts it is different. There, subject to certain conditions as to weight, etc., a postman must accept any letter, parcel, or other postal packet handed to him on his round, whether intended for registration or not.

Railway Letters. In Great Britain the rail. way companies will accept and convey letters, both on weekdays and Sundays, by the next
available train or ship, either to be calsed for at the station of address or to be transferred to the nearest letter box. Such letters are called railway letters.

A railway letter must not exceed 2 oz . in weight and must be taken to a passenger station of the railway company over whose line it is to be sent, and tendered, during such hours as the station is open to the public, to a servant of the company. Postage at the inland rate must be prepaid by putting stamps on the cover in the ordinary way. In addition, a railway fee of 4 d . is charged, which must be paid in cash to the railway company's servant. Nothing further is payable on delivery.

Mails by Air. Any kind of letter packet may be sent by air mail, that is, letters, postcards, printed papers and commercial papers. and samples. The limits of size and weight are the same as for similar correspondence sent by ordinary post. Air mail letters can be accepted for registration, hut insurance is limited to letters and boxes for Holland and Switzerland. A special hlue air mail label anust he affixed to the top left-hand corner of every air mail packet. These labels may be obtained free of charge at any post oflice.

Stamps to the full value of the cambined postage and air fee must be affixed at the top right-hand corner of the address side of the envelope. If the proper fees are not piepaid, the packet cannot he sent by air mail. The combined postage and air fees for correspondence for countries outside Europe are for a weight of half an ounce.

POSTAL ORDER. Those who wish to send small sums of money through the post may do so by purchasing one or more postal orders from any post office where this kind of husiness is transacted.
Postal orders are issued for various amounts between 6d. and $£ 1$ ls. The charge is 1d each for those of 2 s .6 d . and less, $1 \frac{1}{\mathrm{~d}} \mathrm{~d}$. for those between 3 s . and 15 s .; and 2 d . for those above that amount. If odd sums of money are required stamps can be fastened on to the order, if they do not exceed 5 d . in value.
To obtain the money for one of these orders the recipient must take it to a post office and sign his name thereon, or pay it into a bank where he has an account. If, however, it is crossed, it can only be paid through a bank. Persons wishing to send larger sums of money through the post can do so by means of money orders. See Money Order.

POSTCARD. A postcard is a card on which a message is written and which is sent through the post. Postcards are sold ready atamped at all post offices for a little more than the cost of the stamps, while unstamped cards suitable for posteards can be bought and stamped by the sender.
In Great Britain and Ireland the rate of postage is a penny for every card. A postcard, if posted unpaid, is charged double postage on delivery ; if posted underpaid it is charged double the amount of the deficiency. The prepaid rate of postage on every reply post. card is 2 d . As regards size, a postcard may not exceed $5 \frac{1}{2} \mathrm{in}$. in length, by $3 \frac{1}{2} \mathrm{in}$. in width, or
 If private carcls are used as postcards, their material must be ordinary cardhoard or paper not thinner than that sold at the post offices for use as postcards. Picture postcards, il containing not more than five words, will go for $\frac{1}{2} \mathrm{~d}$. as printed papers. (See Postage.)

Nothing may be attached to a postcard except the stamps: a completely adherent gummed label or slip that folds back, hearing the name and address of the person to whom the card is sent; a similar label, not exceeding 2 in . long and $\frac{3}{3} \mathrm{in}$. in width, bearing the name and address of the sender of the card; and engravings, drawings, photographs, and printed matter on very thin paper and com-
pletely adherent to the card These additions may be affixed either to the back of the card or to the left-hand half of the front. The right-hand half of the front must be reserved exclusively for the address and the postage stamps. If these rules, which are intended mainly to allow picture postcards to go through the post, are not observed, the postal authorities may refuse to deliver the card, as they are officially entitled to do.

A postcard may not be folded, nor may it be hent or altered in such a way as to reduce its size below 4 in . by 23 in . It must not be fastened against inspection in any way, nor enclosed in a cover of any kind. If these rules are brolien the card will be treated as is letter and will be charged accordingly.

Postcards can also be sent to destinations outside Great Britain. Gencrally speaking the rules are the same for these as they are for inland postcards. The rate of postage for one of these foreign cards is $1 \frac{1}{d}$., and for a reply posteard is 3 d . A postcard from a place abroad, if unpaid, is charged with a postage of 3 d . If it is partially paid it is charged with double the deficiency, with a minimum charge of $1 \frac{1}{2} d$. Any card can be stamped and used as a postcard for the foreign and colonial post provided it is of cardhoard similar to, but not thinner than, that used for the cards sold at the post oflices for use as postcards. They may not excced $5 \frac{1}{2} \mathrm{in}$. in length by $3 \frac{1}{2} \mathrm{in}$. in width, or he less than 4 in in length by 23 in. in width.

Postcards for abroad must bear on the face the heading Carte postale, or the equivalent of the heading in another language. Thia heading, however, is not obligatory for single postcards that have been manufactured privately. Reply paid postcards must bear on the face in French, as a heading on the first half, the words Carte postale avec réponse payee; on the second half, Carte postale réponse. Each of the two halves must, moreorer, comply with the other conditions laid down for single postcards. One half should be folded over the other, and they must not be closed in any way.
Official postcards sold for inland postage may be used for destinations outside the United Kingdom if they bear a postage stamp for the additional postage required. This concession does not apply to reply paid cards. A postcaril must be sent unenclosed, that is to say, without wrapper or envelope.
Although it is forbidden to join or attach to postcards samples of merchandise or similar articles, yet illustrations, photographs, stamps of any kind, address labels, and cuttings of any kind may be affixed to them, provided that these articles are not of such a nature ns to alter the character of the postcard ; that they consist of paper or other very thin aubstance, and that they adhere completely to the card. With the exception of address labels or slips, these articles may only be affixed to the hack, or to the left-hand half of the address side. These details are sufficient for ordinary purposes, but fuller ones will be found in the Post Office Gıide

POSTE RESTANTE. This name is given to a post oflice where postal packets of all kinds may be addressed and left until called for.

When letters, etc., are addressed to a person at a poste restante, the words, To be called for, or Poste restante, should appear in the address. The post restante is intended solely for the accominodation of strangers and travellers, who, however, must not use it for more than three months consecutively. Postal packets addressed to initials or to fictitious names, or to a Christian name without a surname, are not taken in at a post restante.

Postal packets may not be re-directed from one poste restante to another in the same
town, or from it private address to a poste restante in the same town For the purpose of this rule the various postal districts of London are considered as different towns. All persons applying for letters at a poste restante must furnish sufficient particulars to prevent mistakes and to ensure delivery to the proper person.

Postal packets from abroad will he kept at a poste restante for a period of two months, and those from within the United Kingdom for a fortnight. Letters addressed to a post office at a seaport town for a persun on board ship expected to arrive at that port are kept for two months. At the expiration of these periods postal packets will be treated as undelivered If, however, one bears a request for its return within a specified time, not exceeding the official period of retention, it will, if not delivered, be dealt with in accordance with such request. See Postage.

POT. A pot is a general term for a vessel for holding foorl, both when cooking and at other times. The word, however, has been superscded largely by the special names given to the various utensils, although it remains in mustard pot, pepper pot, and stock pot, and in the words pot-hook, potherb, and pottery. Another pot is the Hower pot, and potting is a familiar tern among gardeners. (See Flower Pot; Mustard; Pcpper; Potting ; Stock Pot.)
Pot Plants. Plants grown in flower pots arc chiefly relied on for the decoration of the conservatory and greenhouse, and by making a selection of suitable kinds a succession of bloom can be assured all the year round
Those of chief value for summer and autumn flowering in the amateur's greenhouse are tuberous begonia, yellow arum lily, fuchsia, zonal geranium, begonia semperflorens, campanula isophylla, herbaceous calceolaria, petunia, chrysanthemum, hydrangea, mar guerite, heliotrope, lilies, nerine, Scarborough ily or vallota and various annuals.
For winter and spring Howers reliance must be placed on daffodil, hyacinth, paper white narcissus, tulip, Chinese and other primulas, Persian oyclamen, stoclis, azalca, nrum lily, cineraria and perpetual Howering carnation, together with various shrubs which may be forced into bloom. Suitable foliage plants are ferns, palms, indiarubber plant (ficus elastica), aralia sieboldii, araucaria excelsa, hlue gum (eucalyptus), grevillea robusta, isolepis gracilis (a grass-like plant for edging), ophiopogon variegata, panicum (also suitable for edging) tradescantia, aspıaragus Sprengeri, and smilax.
Seeds of hardy and half-hardy annuals should be sown in pots in September for spring and early summer bloom and in March to provide a succession. Several secds are sown in $5-\mathrm{in}$. or $6-\mathrm{in}$ pots and the seedlings are thinned out, not transplanted. The buttertly flower (schizanthus) is one of the best for sowing in September, but many annuals can be grown in pots.
Watering is one of the most important details in the management of pot plants : most failures are due to incorrect watering. The secret of success is not to moisten the soil until it is moderately dry, and then to fill the pot to the rim. Water should not be given again until the soil is fairly dry.

POTASH : In Medicine. Applied externally in concentrated form, potash acts as an irritant and caustic. In medicinal doses internally the action of potassium salts resembles practically that of the corresponding salts of sodium.

The sulphate, tartrate, and acid tartrate of potassium are all commonly used as saline purgatives or "salts," and may be employed in habitual costiveness. The best way to take these salts in this ailment is dissolved in half a glass or more of warm water, slowly sipied,
hefore breakfast. The acid tartrate is one of impurities that sometimes harm active roote the ingredients of Imperial drink (q.v.), often prescribed as a cooling beverage in slight feverish states.

Potassium chlorate is commonly uscd as a mouth.wash or gargle, the drug exhibiting an antiseptic, curative action in all kinds of sore throats, tonsillitis, and similar conditions. It should be discontinued, however, after a few days' use. An aerated water containing hicarbonate of potash makes a palatablc diluent of other drinks, and is feebly antacid.

As a Fertilizer. l'otash is an essential element of plant food, producing quality and Havour in fruit, tubers, and roots. The form used is kainit, an easily soluble salt containing about 15 per cent potash, but embodying

## Potatoes: Cultivation and Cooking

## Successive Steps in Preparing this Vegetable for the Table

Other articles that contain something usefulabout potatoes include Black Scah; Cutworm; Digging: Division: Forcing: Kitchen Garden; Manure; Trenching. See also Burgundy Mixture; and for the cooking, Chips: Frying; Hot Pot; Irish Stew; Salad; Shepherd's Pie, etc.
For garden purposes the most suitable soil kinds. A space of 12 to 15 in should be left in which to grow potatues is a rich loam, a between the sets, and the rows should be from trille on the sandy or chalky side, well drained, 2 ft to 2 ft .6 in . apart. If plenty of ground is and in a sunny situation. If the soil is heavy available. the potatoes may be inserted at it should he thoroughly dug over during the 3 ft ., and catch crops grown in between the autumn and winter. Couch grass, docks, rows. They may be planted either whole or nettles, and uther perennial weeds should he in pieces, according to the number and quality forked out; if there is any reason to suspect of the eyes or shoots that leather jackets, wire worms, or millipeles are present, the eriil should he turned over.

When the soil is sandy or open in texture it can he improved, as far as potato growing is concemed, by adding dead leaves of decaying vegetable matter. Impoverished land should be enriched with stable manure, which may he dug in during the antumn or winter or before planting in spring. Lime, say 7 lb . to the rod, is beneticial to rich garden soils.

The selection of the beat varieties of potatoes for planting purposes is a matter of great importance. Some which do well in one district prove disappointing in others, and an actual trial is often the only means of proving whether a new variety is worth planting.

Planting, Early potatoes can lie planted early in Narch. Affer the surface of the ground has been levelled, the sets should be put in about !) in. apart, at a depth of 6 in There should be a span of 18 in . between the rows If the soil is heavy, the potatoes should not he huried so deeply.

The end of March or the beginning of April is the hest time for planting the ordinary.

Potato. Method of preparation for planting. 1. Large tuber divided. 2 and 3. Divisions ready for liming. 4. Well-sprouted tuber with supertluous eyes removed. 5. An ill-sprouted tuber with weak useless shoots. 6. How the tubers are arranged in a baz for sprouting

When the potatoes are about 9 in . high they should be earthed up. Sufficient soil is hanked up to cover any young tubers that may be growing near the surface.
Growing Under Glass. Iotatoes may be grown under glass where hottom heat is available. A frame or pit should be prepared early in January, with a $\leq$ ood hed of manure or leaves. This is covered with ahout 1 ft . of soil, and the potatoes planted about 6 in . deep Plenty of fresh air should he given in mild weather, and tepid water. No earthing up is required. The potatoes will he ready early in May. A few radishes may he forced in hel ween the rows, if desired, in which case the turnip-rooted sorts are the best to employ.

Digging. As regards the digging or lifting of potatues, growers are prone to lift early ones too early and late ones too late. The bulk of the earlies ought not to be lifted until the tubers have got at least to the size of a hen's egg and the tops have changed colour. If they are lifted too early the crop will suffer from loss of weight or of starch, the sub. stance which gives the tuber its nourishing value. Exposure on the ground for a few hours is desirable, as it allows for setting the skins. There are few cases in which potatoes lose by being lifted before Michaelmas, and there are many in which they gain. It is well, if jossible, to lift them when the soil is comparatively dry, as they will then come up fairly clean. Late potatoes lifted in September may, as a rule, lie on the ground for 20 hours, provided the weather is not too wet.

Potatoes for Seed. For seed, potatoes of a suitable size can be bought, or they can he saved from a previous crop, provided it is a hoorl one. It is not desirable to plant the
very small potatoes known as chats, or the largest tubers, except in the case of first early varieties, when cutting should be avoided As potatoes lose their vitality if grown continuously in the saine locality, frequent change of seed is recommended; experience has shown that it is desirable to obtain seed tubers from a district farther north than that in which they are to he planted. Some growers ohtain new seed tubers every second year from Scotland. In the warmest and driest districts of the country a change of seed is advisable every year.

Growers who wish to provide their own seed tuhers should set aside a portion of the crop for this purpose, lifting it before the tubers are fully ripe, as immature tuhers make the best seed. They should then be selected Clean tubers, having been selected, should be allowed to lie on sacking or on the ground for a few days, and should be turned occasionally so that they become greened. This will improve their keeping quality. In winter they sbould be placed with the crown uppermost in shallow trays or boxes, or on shelves one layer deep. These should be laid in a cool, frost proof place where they will get as much light and air as possible. Tubers boxed in this fashion develop 2 or 3 strong green sprouts instead of a large of doing this is to scatter litter lightly but number of weakly shoots, which they pro thickly over the heap.
duce if they are pitted or kept in the dark.
Manuring. A good system of manuring consists in the application just hefore the time of planting of a mixture of superphosphate of lime, 5 parts, and sulphate of ammonia, 3 parts, at the rate 3-4 oz. to the sq. yd. If sulphate of ammonia is applied after the shoots have come above the ground, it should he mixed with soil so that the growing plant does not come in contact with it. The addition of a small quantity, $l \mathrm{oz}$. to the yd. run, of wood ashes as a dressing to the soil before the sets are planted is also to he recommended. If potatoes are cut into sections before being planted, the wounded parts should be dipped into alaked lime.

Storing. For potatoes stored on a large scale a clamp or pit is almost a necessity, but other methods are possible with small quantities. A dry, frost-proof shed makes an excellent store. In this the potatoes ahould be spread in layers on the floor, either directly or on straw, bracken, or sacking. The rlepth of the Inyer must not he more than 21 ft . or the tubers may become heated and liegin to sprout. They should be covered with straw, litter, or sacking to keep out the light, unless they are intended for seed.

They should be inspected 10 days after they have heen put in store. and diseased potatoes removed. The shed should be ventilated whenever possible or desirahle. A watch must he kept for rats and mice. and every care taken against frost. One effective method

Potatoes in various stages of growth, illustrating bow the tuberation is effected Courtesil of Amateur Gardening

Where there is no shed suitable for storing, and the quantity is not too great, the tubers may be placed in thick baga and left in a larder. Quicklime or lime and llower of sulphur sprinkled lightly among them will help to keep down the disease. During the late autumn season they should, if possible, be looked over once a fortnight, and diseased tuhers removed. In winter old sacking thrown over the sacks will protect the potatoes from frost. In very severe weather extra covering should he put on at night and removed in the morning.

If no suitable place is available, potatoes may be atored in a cellar, careful attention being paid to ventilation, particularly during
the first months of storuge.

For growers who are in a prosition to store their potatoes in a clamp or pit, the following hints may be helpful. The condition of the potatoes at the time of clamping is most important They should he putaway in a dry state, and as free from soil as possible.

Irge clamps are lin ble to develop more heat than small ones. As a general rule it is unsafe and inadvis. able for the base to exceed 7 ft., while smaller clamps are often seen. The site should bedry and well drained, and the base, if anything, should be alightly above the generalle vel of thesoil.
Having been placed in a heap, shaped like
a pyramid, the potatocs must next be covered First cover them with a layer of straw ahout 6 in thick A plank about 1 ft . broad and from 8 to 10 ft . long should be placed along the top or ridge of the heap, and the sides, to the edge of the plank, covered with an inch or two of soil. The plank is then moved along. and another length covered with soil. In this way the top of the clamp is kept free from soil. thus providing for the necessary ventilation.
The covering soil should not be put on at once. If the weather is fine and severe frost is not threatened, $\Omega$ full fortnight should elapse between putting on the straw and closing in with the first covering of soil. as this allows much of the hent that is produced by respiration to escape. In very wet weather the soil may be put on sooner, as it is inadvisable to close in when the straw is sodlden It may be neccasary to add more soil to the sides later in the year

Adequate top ventilation must be given. The straw should be left exposed along the ridge and not closed in completcly

Potato Diseases. Potntoes are subject to n number of diseases. The chief one is known sometimes as potato blight and sometimes as potato disease The first sign of the disease visible to the naked oye is the appearance on the leaves of dark brown or blackish spots of irregular size and shinpe, on the under surface of which $\Omega$ delicate white mould may be secn, esperially round the margin of the diseased areas. If weather conditions favour the fungus the dark-coloured patches spread rapidly, and the whole of the foliage, and sometimes the stems also. soon become blackened Potato plants badly attacked by blight give off a very distinct and disagreeable smell.

If the weather is wet after the haulm has heen attacked, the tubers soon begin to be affected. Infection of the tuhers is brought about by spores which, liberated from the surface of the lenf, are washed into the soil.

By the use of Bordenux or Burgundy mixture in June and July the spores of the fungus are prevented from germinating and producing threads which grow into the tissues of the leaf, and hence the haulm, instead of withering, as it does when attacked by blight, remains healthy and green. Spraying must be done in good time, and if heavy rains have washed the spraying material from the leaves, the operation of spraying must be repeated.

Potatoes in store are liable to diseases. One of these is dry rot, which uqually develops from December onward, becoming more severo as the spring advances.

Potato Leaf Curl. Probably no diseare is more directly responsible for weakly potato plant and light crops than that termed potato lesf curl. In the lighter soils in the southern and drier part of Great Britain it is very pro valent and is particularly abundant where the practice of using locally grown seed is followed. A marked symptom is curling of the leaves.

As the disease is perpetuated by means of the seed tubers it is of the utmost importance that they should not he saved from affected plants. Not only should tubers from dwarfed or distinctly curled plants le rejected for seed purposes, but also those from all plants showing curling of the lower leaves and, at all events in the south, those in immediate proximity to diseased plants.

Potato Scab. Common potato scah or brown scal, is one of the most widespread disenses affecting the potato. It is particularly pre valent on light gravelly soils poor in hunius, and on other soils where ashes, lime, and other alkaline substances have been used freely. The diserse is also caused by a minute fungus which attacks the surfaces of the tubers and gives rise to the production of dark scnttered scabs, or large eroded patches. The scabs increase in size with the growth of the tubers, and they may in bad cases cover almost tha

Potato. Doufle row dug up showing number of tubers produced Courtcsu of Amateur Gardening entire surface of them. For eating. the and serub the required number of potatoes put sound part of a scabbed tuber is not injured. The nost important preventive, according to Leaflet 137 of the Ministry of Agriculture, is suitable trentment of the soil. To sandy or gravelly soil organic matter of a vegetable nature should be applied. In gardens ancl amiall holdinga, decaved lenves, spent hops and grass mowings may be used.

The application of lime, ashes and soot should be temporarily suspended on alkaline soils, and their alkalinity counteracted by the use of superphosphate of lime and sulphate of ammonia in apring. Scabled potatoess and peclings from nffected potntocs must not be thrown on the manure heap, neither should they be given to piga unless they liave previously been boiled.
Sclerotinia and Sprain. Potatoes are also subject to a number of other diseases, although these are neither so widespread nor ao frequent as those already mentioned. The aclerotinia disease is most destructive in the northern and damper parts of the country, and is eapecially virulent in the west of Ireland. To eradicate it the most important step is promptly and syatematically to collect and burn all diseased portions of the plant in order to prevent the disease from spreading and the sclerotin from reaching the soil. The sterilization of the soil by ateam is also recommended. Unless this has been done, potatoes and other plants liable to this discase should not be grown in infected soil until at least three years have passed.
them into a pan containing enough hoiling wate to cover them, adding a dossertspoonful of anlt to every quart. Bring them to the hoil. then ainmer them gently until they nre soft but not broken. Drain off the water, peel the potatoes, and then put them back into the pan, covering them with n clean cloth and placing the lid so that it half covers the top Put the pan over gentle heat for a few minutes, shake it occasionally, and then turn the potatoes into $n$ hot vegctalile diah. If preGerred, the potatnes may be served in their skins, water being drained off and the potstoes left to dry thoroughly in the covered pan. The time required for cooking is 20 to 30 min .

To boil potatoes with out the skins. they are washed and peeled thinly, the eyes and any damnged or discoloured Mortions being removed. Potatoes of large aize are cut into halves or quarters of uniform proportions. They are then put into a pan of asalted boil. ing water and conked in the amme way as potatoea boiled in their skins. Some varieties of potatoes conk better if placed in cold water, so should

The disease known ля eprain is not gen erally distributed, but it in troubleanome in certain localities where the soil conditions nppear to favour its development. It may be recognized by the appearance of dark brown blotches or streaks on the flesh of the tubers. The disease known as pink rot is common in parts of Ireland, capecially in the west, and has slso appeared in Great Britain. The fungus causes a wet rot the tubers, and the disease owes its name to the fact that the cut surfaces of infected tubers turn pink when exposed to the air. It commences when the potatoes are still in the ground.

Cooking Potatoes The potato is alinost pntirely a starchy food. It contains ureful sults, but these nre mostly ost unless it is cooked in its jacket. To support life it must be combined with fats, gravy, for exnmple, improving its fond value: and proteins, meat, fish, milk, or chcese. New potatoes are less starchythan old ones.
To hoil potatoes in their akins, wash
resulte not be successful by the method \%iven try this. Potatoes need careful watching to prevent them hoiling into the water. Some do this quicker than others, therefore it is impossible to give a definite time for cooking Stenmed potatoes cooked in their skins ahould first be waslied and then placed in a covered steamer over a saucepan of boiling water. Cook them until the skins begin to crack and the potatoes themselves feel soft when tested with a fork; then take the lid olf the steamer, move the pan to the side of the fire and let its contents dry. Peeled potritoes may be atenmed in the asme way. This method of cooking takes about $\frac{1}{2}$ hour

Potatoes baked or roasted with a joint should first be parhoiled, drained nad sprinkled with aalt. Lay them in the pan under the meat, basting them frequently, and when they are brown on one side turn them and brown the other. They mav be served on the dish with the joint or placed in a hot vegetnble dish. 'These require sbout 1 hour's cooking.

Gloves for acraping new potatoes are y useful invention. Those illustrated have a metal attachment for removing eyes The potato skins are rubled off by means of the wired surface on the fronts of the gloves.
Now potatocs, aiter being washed and acraped, are put into a pan of boiling aalted water with a sprig of mint, and simmered gently until they are tender. The water is poured off. the pan returned to the side of the firc, the top half covered with the lid, and the potatoes left to dry. A small lump of butter or mar garine is placed in a hot vegetable diah, and the potatoes served in it, with the mint re moved and a little chopped parsley sprinkled on top : $20-30 \mathrm{~min}$. is the time required
Fried Potatoes. Fried or chip potatoes are served with grilled chops and steaks, fish, etc. Old potatoce are more successful than new ones. The starch cells in new potatoes are undeveloped, so they do not fry a good brown They can be used, but care must be taken not to over-cook them in the effort to get them as brown as old ones. Slice some washed and peeled potstoes into finger-shaped pieces with a knife or potato cutter, or cut them into straws, cubes or thin oval-shaped slices. Put them into a bowl of cold water until they are required, and in the meantime heat rome fat in a a aucepan until a faint hlue smoke rises from it. Drain the potatoes in a clean cloth, and put them into a frying basket, placing the latter in the fat. Shake the bnsket occasionally so that the potatoes may cook on hoth sides, nnd when they are brown and crisp lift out the braket. let the fat drain from it into the pan, and then empty them into a dish lined with crushed tisaue paper. Stand in a warm place until potatoca are drained thoroughly, then serve in a hot vegetable dish with salt sprinkled over them.
Fried potatoes that can be enten hot or cold, known as potato crisps, are prepared by

Potato. Gloves for scraping new potatoes. The fronts are made of fine wire and the potatoes are rubbed between them. Note the attachment on the right-hand plove for removing eyes, etc.
slicing the potatoes as finely as possible with the special cutter illustratel in this page or with a very sharp knife. Put the pieces in cold water and let them stand as long sa possible. Heat a pan of derp fat until it is past the blue-smoke stage: it must be perfertly still and no sign of smoke arising. Dry the potatoes well, and put them into a finemeshed frying hasket. Reduce the heat under the frying fat. and lower the basket in carefully. The fat will bubble up in the pann. and must be withdrawn from the heat if it shows signs of boiling over. Allow the potatoes to cook for about two minutes-until they are transparent looking but not browned at all.
Then take them up, and let them drain in the basket in a warm place while the fat is rehented to the same degres as before Then put in the basket of potatocs again They will lecome crisp and brown almost immediately, and muat then be taken up and drained well on tisaue paper. Sprinkle with salt and serve, or if required cold they should be stored in an airtight package The two fryings take every scrap of moisture from the potato slices so they remain crisp indefinitely
Other Methods. For sauté potatoes, cold hoiled potatoes are required. Chit 1 lb . of these into slices $\frac{1}{2}$ in thick, and fry them in a pan containing 1 oz smoking hot fat When they are pale brown on one side turn them over and cook them on the other Serve them hot. sprinkled with salt and fincly chopped parsley.

Boiled potatoes may also be served au gratin. To do this, cut fi large cooked potatoes into sliccs, place these in layers in a fireproof dish with a little grated cheese and salt and pepper sprinklal hetween each layer. Ahout 3 oz . cheese will be requised for this. Pour $\frac{1}{2}$ pint white sauce over the whole, sprinkle a littlo moro cheese on top, and hent the mixture in a morlerate oven or under ia griller. Serve the potatoes in the dish in which they were cooked

Potatoes that are to be mashed should first he boiled or steamed, and then put through a sieve, beaten up with n fork, or pounded with a potato masher. The potatoes are placed in this and are forced through a wire mesh by pressing down a handle Add \&oz. butter or margarine nod a tablespoonful of milk to each lb of potatocs, season to taste. and then put them into a hot vegetahle dish Mark tho top with a fork and then place the dish under a griller or in the oven so that the potatoes mny become lightly browned on top

For notatoes in la Jucherse, melt 2 oz . butter in a saucepan, and when hot add 2 oz . grated checse. and the yolk of one egg. Mix all well together over gentle heat, and season to taste with salt and popper and a dust of nutmeg. Turn out on to a floured board, and spread out until $\frac{1}{}$ in. thick. If the mixture seenss too soft, add a little flour. Cut out into rounds with a pastry cutter or make into 3 -in. squares. Mark the tops in a lattice pattern with the back of a knife. Brush over with beaten egg, nut the pieces on a greased baking sheet, and hake in n molerate oven until a delicate brown. The samp misture as the foregoing may be shaped into potato balls, egg and breadcrumbed, and fried in deeps smoking fat.

Potato scallops are also made with this mixture put into buttered scallop shells. the tops sprinkled with grated cheese and baked in a hot oven till slightly brown.

Cold cooked potatoes may be used to make potato fritters. Nelt a lump of butter a little lews than twice the size of a hen's egg in a saucepan, stir in ? lb . cooked potatoes rubled through $n$ sieve, the yolks of 1 or 2 eggs, $\Omega$ dust of nutmeg and seasoning to taste. Mix in also 2 stiflly whisked whites of rgg, and in the meantime heat up a deep panful of fat When the latter hoils, drop in the misture a teaspoonful at a time, snil cook the fritters until thev are a golden brown. Then drain them and serve them garnished with parsley.

Potato Cake. Cold hoiled potatoes may tre on a Houred baking sheet to prove. Bakic employed to make these cakes Prepare them them in a hot oven. They should be eaten
by rntibing 2 oz . butter into $\& \mathrm{lb}$ flour, adding 2 oz. castor sugar, $\frac{1}{2} \mathrm{lb}$. mashed colll potatoes and 2 oz sultanas. and mixing the whole with a beaten rgg lioll the mixture out to a thickness of about $t$ in., cut it into round cakes. and bake these in a hot oven for about 20 min . When they are cooked, slice them through the midule butter them and

serve them hot $1 f$ swect notato cakes are not liked the sultanas and castor sugar may be omitted

Potato Croustade. Snvoury croustales can be made from 2 lb cooked potatoes, 1 egg and 3 extra yolks, some bread crumbs and seasoning. Rub the potatocs th:ough a sieve. then mix them with the 3 yo!ks and salt and pepper to taste, and shape the mixture into flat round cakes. ahout if in high and the same in diameter.

Brush these over carefully with beaten egg and coat them with fine breulcrumbs: repeat the operation, and then with a small cutter mark a small circle in the centre of each cake Fry the croustades in hot fat, drain them on kitchen paper, and with a sharp-pointed knife take out the centre pieces. Scoop out as much as possible of the potato without damaging the sides and fill the hollow with minced poultry, ganie, or fish, seasoned and mised with thick sauce.

Potato Dumpling. Potato dumplings for serving in soup can be male in the following way: Boil 6 dry mealy potatoes in their akins and, after removing the latter. rub them through a fine sicve. Beat I oz. butter to a cream, add to it the yollis of 2 or 3 egge, and then mis in the sieved potato. $t$ oz Hour, and seasoning to tuste. When the mixture is firm, divide it into small, even-sized pieces, shape these into dumplings and cook them for about 5 min . in a pan of boiling stock
Potato Rolls. Stearn two good sized potatoes, and while still hot pass them through n wirc sieve into a basin and mix with them $1 \frac{1}{2}$. sifted tine Hour and 1 traspoonful salt Cream oz. veast with sugar and add to it $2 \downarrow$ gills of warm water. Make a well in the centre of the Hour and potatoes and pour in the yeast and water. Sprinkle a little Hour from the sides over the top, cover it over with a thick cloth, and set it to rise in a warm place.
When t is quite light knead in 2 oz . butter and the well-heaten yolks of 2 egga , and work up into a dough as for bread (q.v.), adding with the eggs $\frac{1}{4}$ teaspoonful carbonate of soda dissolved in 1 tablespoonful warm water. Divide the dough into equal parts and make each into long-shaped rolls. Place these hot after being pulled apart with two forks and buttered.

POTATO CUTTER. There are various kinds of potato cutter on the marliet, one of them being a cylinder-shaped tin with a perforated top. The potato is forced through these holes with the hand and comes out in long linger-shaped pieces. This cutter is

Potato Cutter which outs fancy shapes, mainly for purposes of garnisbing. Above, left, device for slicing potatoes finely and quickly for notato crisps
specially designed for chip making. The cutter illustrated on the left is used for slicing potatoes finely for crisps. The other is for cutting fancy shapes.

POTATO PEELER. There are various kinds of patent potato peelers, differing both in size and design. The most effective type consists of $n$ straight piece of wood about 4 in . long, into which is fitted a convexahaped projection of cast iron. The latter, in turn, is fittel with $n$ blade which reaches just below the edge of the iron
The blade is drawn sharply over the potato, with the result that the peel is drawn up) ward and outward through a slit in the iron. This pecler can also be used for peeling ot ber vegetables as well as fruits. Its chief recommendations are that it can he used without danger of cutting the hands and it jeels the skin off without waste.

POTATO RING. In silver and Sheffield plate the potato ring is now chielly a curiosity valued by collectors. It was first made in Ireland early in the 18th century, and Irish specimens fetch high prices. The rings were used as stands for the wooden bowls in which the potatces were brought to the table.
The conventional shape is a band of metal about $2 \frac{1}{2}$ in. deep, bent to form a circle something like a large napkin ring. This was swaged to present a concave surface, and was decorated by piercing or embossing; sometimes by chasing or engraving. Most rings were larger on one side than on the other, the reason being that they could be used for bowis of different sizes.

Potato rings are occasionally found fitted with glass bowls. Several beautiful examples are in existence. One in Sheffield plate is ornamented with foliage, and has Hat chasing rith ogee mounts round base and rim. See Sheflielil Plate ; Silver.

POTENTIAL DIVIDER : In Wireless. that illustrated is from walnut, 1 in . thick. This is a tapped resistance, which, when connected across a source of potential, enables voltages to be obtained which are a known fraction of the total voltage across the ends of the resistance. Thus a potential divider joined across a 6 -volt battery might have tappings at one third, one lialf and two thirds of the total resistance. The voltages between each tapping and the negative end of the resistance would be four, three and two volts respectively.
Potenti:, dividers may he employed in mains eliminators when it is desired to tap off voltages lower than the maximuni available value. The resistances used in this case should preferably be wire wound and capahle of carrying the anode current consumed by the valve or valves
Potentioneters, i.e potential dividers having continuously variable tappings, are used in wirelcss receivers for controlling volume or for adjusting the potential applied to the grid of the detcctor valve.
Volume control potentiometers, when incorporated on the low frequency side of a set, should have a value of not less than 500,000 ohms, and may take the place of the grid leak in a resistance capacity coupled stage or be connected across the secondary winding of a low frequency transformier.
Detector grid potentiometers may have a value of 400 ohms and are joined directly across the positive and negative low tension leads. The end of the detector grid leak which usually goes to low tension positive is transferred to the slider or moving arm of the potentiometer. The use of a detector grid potentiometer frequently results in an improved control of reaction, and is often beneficial in sets designed for short wave reception. The most suitable position for the moving arm of the potentionieter is determined by experiment.

POTENTILLA. The cinquefoil or poten tilla is an old hardy herbaceous perennial of which there are several improved varieties with large showy flowers. The plants reach a leeight of $18-36 \mathrm{in}$. and hear single or semidouble strawberry-like llowers in summer. They can be increased by division in autumn or by sowing seeds out of loors in May. The varietics Gibsun's Scarlet, Yellow Queen and William Rollinaon, red and orange yellow, are a few of the best Potentilla nitida is a beautiful little rock garden plant with grey leaves and pink flowers: it needs gritty soil and should be protected by a raised piece of glass in winter.

POTHERE. This name is used for any plant the leaves and atalk of which are used for food, more especially for such herbs as thyme, marjoram, etc., used fur flavouring. Vegetables that are served in stews, such as carrots, turnips, parsnipa, onions, etc., arc often known as potherbs. See Asparagus; Balm ; Masil; Cabbage; Spinach, etc.
POTLID. Owners of picture potlids, which were sold in such large numbers between 1848 and 1859, and are now valuable, often complain of there being no really satisfactory method of displaying them. Thic pictures require no covering of glass, being upon carthenware, glazed, and absolntely permanent. The illustrations show the system of framing.

To make the rim, it should be turned about 1 in . in width all round, and of an inside measurement ahout $\frac{1}{3} \mathrm{in}$. less than the potlid in dinmeter. The front may be moulded, but the outside circular edge and the back are kept Hat. No rehate to take the lid, as an ordinary frame takes glas8, is necessary, but one may be turned out of the back if desired. Any convenient wood may be used, one of thic hardwoods being desirable:

The rim is shown in section at $A$.
The backing consists of a ring of common wood-soft white deal is suitable. The ring is turned of an outside diameter like that of the irame ring, or, if preferred, a tritle smaller, but in any case, not larger, than the frame. The inner circular a perture in the backing ring is of a size to fit tightly over the outside rimı of the potlid. This backing ring is shown at $B$.

The potlid, C, is adjusted in the frame, $A$, the convex or picture side of the lid being outward, and thus visible through the frame. The ring, $B$, is then slipped over the rim at the hack, and the ring screwed, with not less than 2 and not morc than 3 screws, to the frame. One screw is shown at D. The potlid is thus held most securely in the circular frame, and
both the front with its picture, and the inner por-
Potlid. Sectional tion of the lid with jerhaps its makers marks, are visible as desired. A picture ring, E, permits of the framed lid being exhibited upon a wall. The best plan is to arrange them along the top of a set of shelves, or an oak dresser

POT POURRI. There are various recijes for making pot pourri from mixtures uf sweet-scented flowers, herbs and leaves, preserved with salt and spices. It is necessary to gather the flowers or leaves to be used on a dry day as any danipness on them causes mould. The stalks should be removed and the flowers, etc, dried for at least two days in the run The old-fashioned roses with strong perfume are the best to use.

A simple recipe is made from rose petals and a powder composed of equal quantities of musk, storax, cloves, orris root, Jamaica pepper and dried lemon peel. A layer of rose leaves is put into the jar, then bay salt and next a layer of the pounded and powdered apices. Repent these layers till the jar is full. Cover closely and leave for a month. After that the contents may be mixed and stirred and placed in ornamental jars or muslin hags. Jars are better for preserving the scent of pot pouri. They should be provided with well fitting lids, which may be removed to allow the fragrance to escape into lie room hs required.
Another recipe requires a linndful each of lavender llowers, rose petals, sweet briar leaves, jasmine, rosemary and half a handful each of sweet geranium leaves, mint, thyme and lemon verbena. Put layers of these in a wide mouthed glass jar with bay or rock salt hetwcen each layer Cover for a month and

Potlid. Front and back view of the lid with frame completed
after turning out tho mixture add 1 oz. pow dercd orris root. a few dmps each oil of neroli, oil of musk, oil of cloves and oil of cinnamon. The bay salt which is ohtainable in lumps is roughly pounded. It may be mixed with an equal quantity of common salt.
POTTED FISH. Almost every kind of fish may be potted, but those usually preserved in this way are salmon, shrimp, and lobster. They may be bought in small glass jars or tins, but can also be prepared at home according to the following directions.
Potted salmon is hest made from cold boiled fish. Remove all skin and bnne from the latter and pound it well in a mortar with enough hutter to malie a smonth paste. Add seasoning to taste, then turn the mixture into clean, dry jars, and cover it with melted butter bcoore tying it down.

To make potted shrimp, remove the heads and tails from a pint of shrimps, and then pound the latter in a mortar with a little butter. The shells also should be pounded with butter and then pressed through a finc hair sieve before they are added to the fish Season to taste

Melt a lump of hutter about the size of a hen's egg in a pan, and stir the shrimp mixture into it. When the butter has been absorbed, move the pan to the side of the fire and add a little powdered mace. Let the mixture cool before joiting it as deacribed in the previous recipe. Prawns may be potted in the sanie way, and so nay the remains of any conked white fish. The latter, however, should be favoured with anchovy and well scasoned.

POTTED MEAT. Almost any cold cooked ment may he potted First free the meat from skin and gristle, then mince it finely and put it into a nortar with seasoning to tastc. To every $\& \mathrm{lb}$. meat allow a little more than 3 oz. melted butter, adding it gradually and reserving a little to cover the meat when it is potterl. A little tomato sauce or Worcester sauce added to cold mutton or heef is an improvement. Pound the mixture well then ruh it through a wire sieve and put it into pots, pouring the remainder of the butter over it to kecp out the air.

Two different kinds of meat, such as veal and ham or chicken and tongue, may be used together. Ham. from its salt nature, makes a good addition to most fresh meats, but should not be used in too large a proportion.

Potted chicken is especially tasty when mixed with ham or tongue. To prepare it, take $\frac{1}{2} \mathrm{~b}$. cooked chicken and $\} \mathrm{lb}$. cooked han or tonguc, mince thesc thoroughly by putting them through a machinc 2 or 3 times, and then pound then in a mortar with a little more than : 3 oz . butter, previously melted. Scason the mixture to taste, rub it through a tine wirc sieve. and then put it into small glass pots, putting a little more melted butter on the top of each.

Rnw meat inay also bo potted, but should be as lean as possible. Boke 1 lb . of this in a jar to which is alded a tablespoonful of butter. the same quantity of water, a lew cloves, a pinch of allgpice, and some aalt and pepper. Cover the jar well with buttered paper and a close-fitting lid, and place it in a tin of boiling water in the oven. or in a saucepan of hoiling water on the stove. Cook the whole gently for 2 or 3 hours, then take the meat out of the jar and make into a paste by pounding it in a mortar. Finally, aub it through n sieve and put into jars covercd with clarifind fat.

## Pottery and Pottery Collecting

## How to Recognize Typical Pieces of Many Periods

This contribution is concerned with decorative carthenware pleces, and the reader is especially referred to the article on China. Other branches of ceramics are deale with under Faience; Terra Cotta; Tiles. See also the separate entries on kinds of Pottery, e.g. Saısuma Warc; W'edgwood: Whicldon Ware
used on Bristol 18th-century ware While Chinesc, Persian and Indian styles of deroration werc copied in the Staffordshire potteries, several firma apecialised in views of cathedrals, cast lcs and country houses. These were mostly on dishes and plates; figures also received much attention from the designers.

In cottage homes, apart from lustred ware. the taste for chimney-piece ornaments was catered for by the Staffordshire factories with the so-called china toys. These earthenware figures were in part based upon the Chelsen tradition, in part upon the uninstructerl work of local modellers. Their figures were art less, but they carried on the 18 th-century work of the Woor family. Fig. 6 illustrates a statuette of a girl modelled by Ralph Wood about 1760
The productions of John Walton, ncarly all in ensmel colours, such as his shepherdesses with a foliage background, and his scriptural groups, mark a degeneration of type which Iltimately led to the spotted dogs and woolly sheep of Ralph Salt. The figures of these and a score of other potters, who turned out farmynrd incidents and portraita of celebritics. are to he found, genuine or forged, on many $s$ farmhouse mantel. Most of this class of image-work is unmarked, and indeed a marked piece should be suspecterl. With these may be ranked the jugs and mugs portraying historical events, with other memorial ware.

Leeda ware includes Egyptian basalt (matt black), glossy black, white ware which is blue printed, and lustre printed pottery.
Like the willow pattern at Canghley, lustre ware was introduced, at Spode's, in the later years of the 18 th century. The large output of Newcastlo and Sunderland lustre wase of a less interesting and artiatic character covered with scenes, rhymes and texts in black transfer work and enlivened by patches of pink or purple lustre fell within the earlier years of the lath century. When the design itself was lustred the effect was less crude, hut this north-country ware at its best seldom John Dwight. and the delft, which wa wrought at Iambeth, Bristol and Livel pool. Astbury ware also included pottery statuettes an example of which. dated 1740. is shown in Fig. 5.
For about eighty years of the 18th century the Frank family ware producing pottery of a refined delft type at Bristol. This earthenware hal a clear greenish-blue glaze, and many of the designs were tranaferred by printing. Some of the pieces had grounds of bluc or purple dots surrounding a printed or painted panel. Characteristio also of Bristol ware was white ornament over the ename! glaze The initials of the painter, sometimes the word Bristol, the date or occesionally two strokes crossed diagonally with two others were marks

Pottery. Fig. 3. Example of Palissy Ware, a 16th-century dieb with cupids set between the sunk portions Brilish Muxeum

Pottery. Fig. 4. Quaint salt glaze group, dating from about 1730 British Museum
reached the level of that made in Lecds, Swansea and Staffordshire. As it was mostly unmarked, its origin is usually determined on the dubious evidence of the potting.
Some of the best Staffordshire lustre was made by Wedgwood's, whose founder himself did some good work in this method. After 1831, a silver lustre made with platinum was introduced at Longton by Charles Allerton, and for 40 years his products attained such distinction that they were in constant demand by collectors. In contradistinction to the Sunderland lustred mugs are the salt-glazed brown wares produced at Brampton and Chesterfield, inaccurately called Nottingham ware. This inclutes complimentary tankards, jugs with hunting scenes, and animal figures for the mantelpiece

Victorian Pottery. With the Great Exhibition of 18.51 there was insugurated a revival, which profoundly influenced the pottery crafts. Many of these pieces have an old. fashioned rather than an antique air. Victorian pottery should be chosen for its decorative merit, whether it seeks to simulate ancient styles or is the outcome of the creative thought of its own age.
The task of emulating the gleaming hues of the medieval majolica was approached in the mid century at Minton's, and afterwards at Wedgwood's. The two methods of reproduction were quite distinctive, the former using dark clays with opaque enamela, the latter white bodies with coloured glazes. Later on the accomplished work of William de Morgan, who successfully rivalled the glories of the old Gubbio as well as the Persian lustre, remains quite unsurpassed.

A profound influence has been exerted upon the ceramic industry by the faience and other art fabrics for which the Doulton works at Lambeth are famed. Dating from the Great Exhibition, they present distinct qualities of make and design, and as moulds are but sparingly if ever used each piece possesses its own individuality. Even when the work is deliberately reminiscent of early pottery, as in the case of Miss Crawley's studies in the old Persian and Rhodian manner, the same observation applies.

Another great development of this period was the invention of Parian ware (q.v.), whose ivory-white body, unglazed or slightly glazed, ensbled statuettes to be moulded which
reaemb.led marhle Mesides Copeland's, Minton's, and Wedg. wood's, there are other works, such as Bootes' in Burslem and the Irish factory at Relleck, which did admirable Parian figures. A polychrome effect was also secured by majolica pigments ait Stoke especially by Poole, Stanway and Wood. The smaller examples are often desirable and, like other Victorian products, will assuredly attract in due time the attention of collectors. 'The larger figures and groups are often of poor design and pretentious.
Demanding at their hest no less care in modelling, are the terra-cotta figures and groups of the same period. Notablo among these are the clasaical statuettes turned out at the

This was founded by
Dale Hall pottery. a potter of another name in 1790 , and a mark embodying this date was adopted late in the 19th century. It is one of several instances of a mark with an errly date actually attesting not the antiquity but the modernity of the ware.

Modern Pottery. Much rustic pottery is turned out to-day in Sussex, Devonshire and other districts. Some of it is made of common brick clays with blended glazes, others have a fireclay hody. Specimens of the best work of the Ashtead Potterios are most desirable acquisitions. Their table ware is excellent in shape and design. In the productions of the Wedgwood, Minton, Copeland, Cauldon and other Staffordshire potteries, besides the Doulton in London, there is great variety Individuality is a vital clasacteristic and the pottery of to day has attained a standard of popularity on its own merits. In some of the designs there is a note of the bizarre in brilliant colour and geometrical forms. In others rich soft tones are finely blended, as in the modern versions of pehble ware (q.v.) and of "Peach bloom." Whito ware is perhaps the most beautiful, and two examples of fine design and glaze are illustrated in Figs. 7 and 8.

Modern Pottery. Fig. 7. Duck and drake in highly

This white ware is sometimes faintly tinged with colour where the pottery shows through the paste surface. Very benutiful book-ends are modelled in it, while candlesticks made of white Poole pottery show fine designs. A lovely branched pair for the mantelpiece or for the dining table have a conventionalised bunch of grapes on each stand. Book-ends in creamy crackle, which serves to mellow the appearance of the pottery, show genmetrical designs, and are a change from the animal and cherub figures so often seen. Other decorative book-ends are made in polychrome pottery, in a great variety of shapes, designs and colours.
The modern vases shown in Figs. 9 and 10 rcly on shape for their simple beauty and for

Fig. 5. Grenadier in Astbury ware, c. 1740. Fig. 6. Statuette of a girl, modelled by Ralin Wood, c. 1760
their usefulness, as they are both entirely charming and adequate for flower arrange ment. Fig. 9 is in brown earthenware of the classical amphora shape. while Fig. 10 is of rose-pink lustre shading to deep wine red. Ashtead and Poole pottery vases showing multi-coloured designs on white grounds provide many examples of decorative modern English ware, while French pottery is well represented by pieces which have excellent designs of sporting character, the development of sport having greatly increased of late years in France. Modern deaigns, whether

Pottery. Fig. 8. Brown earthenware amphora, a graceful and useful pottery onse for tall flowers or foliare. Fig. 10. Example of modern !ustre marestading from rose pink to wine red

Holiday makers oftell bring home תง souvenirs of continental travel individual pieces of local pottery which have attracted their attention. Favourite objects of this kind are initutions of Cologne atonevare tankirds, Dutch delft-often not delft at all in the sense of being tin-enamelledItalian majolica, and Spanish luatre. The homely wares of North Africa with their brilliant and strikingly orienta designs are gry in certain rooms Modern Italian pottery also is much favoured on account of its wealth of colour and plessing shapes

The nost popular rival of British pottery that is procurable without foreigntravel comes from Japin. Of its earthen. ware fabrics, not to he confused with the true English or French, arc characterized by sug. porcelains, the most famous are those of gestion: the amount which is left out being Satanna 'Jhe tawcliy platters and vascs as important as that which is detailed. There are most certsinly outstanding potters to day whose collected work will increase in value
which are turned out mechanically in Japanese factories for the purposes of export trade should lie avoided

## Pottery: Making Simple Pieces

## An Outline of a Pleasing and Useful Handicraft

This contribution explains how simple articles can be modelled, fired and glazed, at home, and concludes with a brief description of methods for vecorating pottery

There are two methods of forming the Before being used, the clav must be worked shapes in pottery; one is by building up the clay by liand on n potter's wheel, the other by casting and pressing Apart from the potter's wheel and $n$ muffle furnace, the tools are simple and inexpensive. The clay used for making bricks or Hower pots can be used if properly sieved and evaporated down, but for good work it is advisable to employ common C.C., or cane-coloured earthenware. China clay forms the main hody of porcelain; blue clay, known also as hall clay and hlack clay, is very strong and plastic. Felspar, flint which flock clay and driven in with a mallet or has heen calcined and ground, and bone ash flat hoard (rig. 3). The result is seen in the are mixed with clay to bind the material cut edge, small holes being formed by the air together and render it translucent.
How to Mix the Clay. Ordinary clay can be refined hy mixing it with water to form a thin crenm, passing it through a No. 40 sieve. The mixture is placed in a shallow pan and alowly evaporated. The dried clay is mixed with fine sand and powdered flint- 8 parts of clay, 2 of fint, and 1 of sand. This body, ulthough not so safe in use as the properly prepared C.C. Lody, is quite suitable for such objects as candle. sticks, small trays, or thick bowls for bulbe, but it wolild not do for circular forms on the wheel, or for casting.
The clay being hard at first is moistened with water; the lumps should be reduced to powder by pounding, water being then added until the clay is soft enough. It is of the right consistency when the fingers easily make an impression in it without picking any of it up. It can be kept in this condition for a long time if placed in a tin or zinc-lined tox: small quantities will remain plastic if kept in a tin biscuit box and covered with $n$ damp cloth.

Pottery. Useful articles which can be modelled in clay, and fired and glazed at home. The photograph shows, amongst other pieces, a candlestick, an ash tray, and a vase ornamented with a conventional flowaph pattern

the mould; and when sufficiently thick, the slip should be poured out and the mould left in n warm place for about $\frac{1}{2}$ hour. The mould should now be taken apart, using every possible care; there should be no difliculty in removing the vase, as the clay shrinks on drying. The lines and the waste at tho top should be trimmed off with a sharp knife : then leave the shape to hecome quite hard

To complete the work, rub the base on glase paper to level it, rub the sides down with tine ginss paper, mund off the edges at the top, and finish by riping over the whole of the shape with a damp sponge. Throughout these linishing operations the clay shape must be handled very carefully, as it is very fragile, and will continue to be until it is fired. The 1 -piece mould is done in the same way, but as only those objects that can slide out of the mould, after the casting has set, are suitable, all that is necessary to take the casting from the mould is to place it upside down. The same methods of cleaning up apply

Pressed Shapes. These are easier, but it is not so easy to make the ware thin Proceed by flattening a lump of clay, using if desired a hatter as in Fig 14. this being a thick disk of plaster with a stout handle. The clay is placed on a piece of linen or calico and pressed out llat with a rolling pin to a thickness of $\frac{1}{4} \mathrm{in}$. or 80 . Sponge the surface of the mould, place the thin slab of clay on it, and press carefully to the shape.

When hoth sides of the mould have been done in this way, smooth the edges, coat the joins with slip, place a thin layer of clay along the join, and then place the parts together. The joins are pressad to the sides of the mould from contrasts in form To make one, first set out on the pattern a line that will divide it into 2 equal parts. Place it on the board and build up a bed of c!ay to the halfway line, extending $\frac{1}{2} \mathrm{in}$. at the topand $f \mathrm{in}$. at the bottom. Shape the sides of the clay and attach a border of cardboard, as in Fig. 10 : then fill up the space with plaster, allowing at least $1 /$ in. of plaster noove the pattern. When set, carefully remove the walls and the clay and work out semicircular depressions at each corner of the half mould, as shown in Fig. 11. These recesses, which should be quite smooth, are necessary in order that the two halies of the mould may be accurately keyed together.

Coat the surface of the plaster with olive oil, replace the walls, the half mould heing at the hottom, as in Fig. 11, and fill up, with plaster again. When set, the walls should be removed. Then smooth the bottom of the mould and cut the recesses in each half at right angles to the join, as shown in Fig. 12. Oil this surface, place walls round the mould and fill up with plaster to give a thickness of about $1 \frac{1}{2}$ in., thus casting the third member or hottom piece of the mould. When set, the two halves of the mould should be prized apart, the pattern removed and the mould placel together again to dry, the final drying taking place with the parts separated

Casting a Vase. The methorl of casting allows considerably thinner pottery to be made. First prepare a large howl or small pail, which should be perfectly clean. Place a few lumps of clay in it, and pour water in to more than cover the clay. Next squeeze the clay between the fingers, and thoroughly mix the clay with the water until it forms a creamy

liquid. The liquid, termed "slip," is passed through a No. 40 phosphor bronze sieve, a stiff bristle bruah being used to assist it. The mould is sponged lightly with water and tied together with string, onc or two wooden wedges being used to tighten up tho parts, as in Fig. 13.
The mould is now tilted, and the slip should be very carefully poured into it so that no bubbles are formet, as these mean holes on the surface of the finished casting. The liquid or slip should he watched, and it will be seen that the level gradually falls. Keep refilling it, and give the mould a revolving movement from time to time to prevent the clay settling at the hotton. As the sides absorl, the water from the slip, the clay becomes deposited on

Fig. 13. Mould tied together with string tightened with wedges
the inside and wiped over with a damp We illustrate a special gas muffle turnace sponge fitted to the end of a piece of stick If for pottery It is made in a number of sizes. the mould is placed in a warm room for an but the amateur potter will need n muffle size hour the shape inside will have shrunk of at least 14 in . wide, 8 in . high, and 18 in sufficiently for the mould to be taken apart. deep, if vases and similar ohjects are to be when it can be treated like a casting.
Much pottery can he made without moulds by building the shape or throwing on the wheel, but in inaking spouts and handles, either pressing or casting should be followed Âny additions can be made to a piece of pottery while in the clay atage by scratching the parts to be joined, coating them with slip, and holding in position until set Handles or projections is obtainable in

Pottery-Making. Fig. 14. Disk of plaster with handle attached, used for flattening a lump of clay
applied in this way should not be touched before firing, and must he carefully fixed, or they will come apart When making pottery, it must not be allowed to dry out, and if the piece cannot he finished at one sitting it must be kept covered with moistened cloths.
There are many ways of decorating pottery. Line incision is the earliest and the easiest; it is done with a modelling tool, and for smali work there is considerable oppmrtunity for artistic treatment. Another method suitable for the pre-fired stage is to use slip formed from different coloureal clays: n number of

plensing effects can he worked in this way by applying the slip with suitable brushes.

Firing the Clay. Before poittery can be glazed or painted it is necessary to subject it to great heat and to tranaforn it into what is known as biscuit. This is the most critical part of the work. If a small furnace is used, the work must be placed in a muffle, supporterl on slabs of fireclay or sand. The shapes are conveniently arranged, the air inlet almost closed, and the dampers $\ddagger$ open. Light up gradually if using a gas muffle furnace, close the lower door, and after the muffle has got sufficiently hot-in ahout half hour-the lower door should he pushicd in close and the interstices covered over with clay
When the work has finished steaming turn on more gas, leave for ahout an hour, plaster up the top door, and give full heat until the interior, judged from the spy hole, is white hot : this will take ahout an hour. The work can now be allowed to cool. To make quite sure, the placing of suitable trial pieces so that they can be removed during firing will help; if the trial piece can be scratched on the surface it is a proof that the firing is not complete. Small piecea of clay, known as Seger cones, can he placed inside; these will bend over when the correct temperature is reached Common C.C. requires a tempcrature of $1,100^{\circ} \mathrm{C}$. and ahout four houra in the furnace.
he filled up with a cement made of 3 parts fired clay, 1 part damp clay. and $t$ part of No. 8 flux, ground to a powder, sieved, and mixerl with gum. Biscuit pottery can be coloured without firing by applying colour diluted with gum arabic, dextrine, and water to the moist surface of the clay. A fine surface can be applied to unglazed pottery by using ordinary wax polish.

Cloisonné Decoration. Another method is to apply cloisonné enamels.
is obtainable in various colours, and may be applied with a diffuser or a brush. A glaze firing at ahout $800^{\circ} \mathrm{C}$. will be found most convenient, and if the article is to hold water it will he necessary to glaze the interior as well Coloura can be added to a plain glaze by mixing them with boiling water, passing through a 200 sieve, and mixing with the glaze; only a small amount of colour is required. Before the underglaze paint is applied the surface of the pot must he stoppal by coating it with a solution composed of gum arabic and water. The paints employed for the work are metallic oxides or oxy-salts, and give their true colours when combined with the glaze
Shapes that are not quite perfect need not generally he thrown a way, for small defects on the hiscuit pottery can be removed with glass paper, and amall holes, cracks or nhips in the article can

Fig. 1b. Muttle furnace tor tring pottery Fletcher. Russell \& Co.. Led., Warrinoton

A simple outfit of these contains 6 enamels. gold and silver powder, medium, varnish, 1 flat brush and 4 camel-hair brushes. The design is incised on the plastic surface of the pottery with a modelling tool before the clay is fired. Fig. 17 shows the pleasing and simple type of design which lends itself admirably to this kind of decoration. Pieces of pottery can he painted in sets to harnonize with any colour scheme. This style of decoration is particularly suited to pottery book-ends of simple or geometrical shapes. For those who are unable to make their own pieces, a variety of articles can be olitained with designs already incised. The procedure is very simple. First coat the whole of the article with the special varnish, which dries in about half an hour. Then a coat of gold or silver enamel is applied, taking care that this flows into the incised lines of the design; this, again, is allowed to dry for ahout an hour and the decoration

Pottery Making. Fig. 16. Painting on unglazed pottery with cloisonné enamels alter the design has been incised, as shown on the plate. The Fig. 17 been gilded but not coloured, while the jar is ball comped Fig. 17. The finished pieces. Fig. 18. Jar with lid decorated in
in colours is proceeded with. Fig. 16 shows rammed firm, but not articles in three stages of decoration. The plate is merely incised with the design, the vase has been gilded, and the small jar has been half coloured. The design is pioked out in various tints, using $a$ separate fine brush for each tint employed on the piece Figs 17 and 18 show the pieces finished
Care should be taken not to let the colours run intu the incised lines, or the effect will be spoilt. Therc is no need for subsequent varnishing, as the enamels are durable and have a brilliant finish They can be thinned if desired with a special thinning medium.

The larger brush used for the varnish should be cleaned with methylated spirit, while the brushes for the gold, silver and coloured enamels should be cleaned with turpentine.
POTTING: In the Garden. Success i the potting of plants is acquired only by practice and experience: ignorance of its elementary principles is the cause of ninetenths of the sickly anaemic-looking plants seen in many greenhouses and in moms. For successful potting attention must be paid to the cleanliness of the crocks and pots, the drainage, the ingredients for composts and correct planting.

Pots and crocks sliould be well soaked and cleansed with water, even if quite new. Proper drainage is essential Take a fairly large piece of curved crock, and place this, hollow side downward, over the pot hole. Incidentally, an oyster shell is admirable for the purpose. The next layer of crocks must be determined by the clasa of plant being potted If this is a hard-wooded suliject, crocks should be broken up quite sinall. but if the plant is softrooded, as, for example, the geranium, then larger pieces will be required.

The larger the pots the larger the crocks, allowing deeper drainage to plants remaining in pots for a considerable time, and leas to those having a shorter stay. Indeed, for foreing stuff, such as spirens, one large curved crock is often sufficient. On top of the drainage place a little rough of leaves, moss, or fibre, to prevent loose compost dmpping amongst the crocks and choking drainage
The chief ingredient in potting composts is lonm with plenty of fibre, such as is obtained from old pastures, where the roots of grass are several inches deep. Cut turres in autumn, atacking them grass downward, and placing light facings of well-rotted manure and a sprinkling of lime between layers. In twelve months this will become n stack of loam in suitable condition to form a base for most potting composts.

Other indispensable materials for the potting shed are leaf-soil, pent, silver sand, charcoal, wood ashes, mortar rubble, and bnnemeal These are not all required at one time; but with supplies to draw upon, practically any combination for many different kinds of planta may he made up at vill. Whatever combination is in preparation, this should be well mixed and turned with the spade, damping it when necessary, until a gripped handful will hang together, yet separate at slight touch.
A good general compost is formed of 3 parts loan, 2 parts leaf-soil, and 1 part sand. For seeds and cuttings only use equal parts of loam, leaf-soil, and sand, finely sieved and mixed.
The placing of the plant is no less important than the contents of its pot. Do not drag, or lift by the stem, any young plant fiom its early receptacle, but spread it upside down upon the fingers of one hand and gently rap the rim of the pot on the potting bench, so that the pot itself may be lifted clear. Carefully remove any old crocks with as little root disturbance as possible.

A few inches of soil, made firm with a potting stick, should be placed in the larger pot, and the new plant artanged upright in its centre. Suitable compost should be worked round and filled within in of its rim, a necessary apace for watering. When ramming, be carelul not to touch the old ball of soil. but only the filling of new compost. Various plants and hulbs require potting at different depths

A potting bench or table is desirable for the amateur gar dener, the construc. tion of which may be on the lines sug. gested in the sketch Labels, too. should not be ignored if choice plants are to be duly identified. A potting stick is easily constructed from an old broom handle. rounded at one end and cut chisel-shaped consisting of 4 pints. culosis. old-fashioned footstool. radius, or half the diameter.
at the other. Different sizes of pots should he stuckerl and boxes of graded crocks ready to hand. A mistalie is to use pots that 3 in. from its lower end, is called Pott's fracture are too large. ## Pouffe Ottomans or Humpties

## Materials and Methods for Making Attractive Floor Cushions

The reader of thls article should turn for furtner information to the entries on Box Ottoman; Cushion: Leather Work: Patchwork: Upholstery

A pouffe or humpty is the name given to a length to the circumference of the circle, and variety of Hoor cushions varying considerably in size and shape, from small circular pouffes to large square or oblong box humpties which possess well sprung and upholstered lids.

Pouffes are suitable for use in small rooms as they take up little floor space, and when not required as seats they can be placed out of the way in a corner or under a table. The box type is a useful addition to bedroom or sitting room, as it can be used either as a slipper, hat or work box. 'The rofter type of solid pouffe floor cushion is a cony accessory for the nursery, while invalids and elderly people find them more comfortable than the

Solid Poufles. The solid pouffe is the simpleat kind to make. It can either be circular or aquare in shape, and is made by stuffing a calico cover with sone suitahle filling. Decide a pproximately the size required, then cut out a pattern in strong paper. This can be pinned up, and gives a good ider of what the size will be when the floor cushion is completed: 16 in . diameter each for top and bottom, as in Fig. 1, makes a mediunsized circular one with a band of 16 in . deep between, as in Fig. 2. It is import. ant to get a true circle, or the finished shape will not be good. A circular tray can be used; or if this is not available, take a piece of fine string, tic a small loop in one end, and fasten the other end to the centre of the piece of paper with a drawing-pin. Place a pencil in the loop, stretch it tautly, inoving it in a circle: the lenkth of the string gives the

To make the case, cout a strip of unhleached calico, preferably selvedge way, equal in
length to the circumference of the circle, and
allowing $1 \frac{1}{2}$ in. for turnings. Tack the top of the band to one circle and the hottom of the hand to the other circle; the case then resembles a short bolster, as in Fig. 3. Machine on the wrong side, leaving about 6 in . open on one side

As a quantity of filling material is required when making large floor cushions, the centre can be filled with cuttings of woollen or cotton materisks. For the new filling necessary, imitation hair, filbre, flocks or brown rugging wool, with wood wool right in the centre, is the most suitable. For a medium size pouffe about 10 lb . of wool is necesary
As the filling is a dusty process, it sliould be done in a roon with little furniture, and preferably in one with a linolenm floor covering. Each handful of filling should be Huffed out before it is put into the case. Use a wonden spoon or stick for forcing the wool into tl edges. When as much as possible has bet.l forced into the case, take a piecc of flat wool and beat it evenly all over.

Unless the cushion is well stulfed, after it has been in use a short time it becomes flat and loses its shape. When it is impossible to add any more wool, the seans can be sewn up securely. Take some atrong string and, using a slip-knot, cord the waist as tightly as possible, Fig. 4. Place a piece of flat wadding cut to size over the top of the case before covering with the upholstery fabrio.

For a pattern of a square-shape poutfo cut two pieces of paper about 30 in . by 30 in , as in Fig. 5, for a medium-sized nouffe. Fold each piese in half lengthways, and then width-wrys-this gives a small square of 4 thick. nesses. as in Fir $\mathbf{6}$; curve of the top left-hand

Attractive round pouffe floor cushions can
comer (Fig. 7) and the shnpe will resemble lig. 8. These two pieces form the top and hottom of the pouffe.

Having out out the unbleached calico for the case, sew the curves at each corner together as in Fig. 9, and when all the curves are joinal the cap-shaped pieces are formed which make the top and bottom of the pouffe. Place one ahove the other and join then together, leaving one of the four scams open for filling (Figs. 10 and 11 ).

There are two ways of making the outer covering for pouffes : either by making the material into a bag-shaped case, leaving one side open into which the cushion is dropped, or by stretching the material and scwing it securely along each waist-line. The former is less trouble, but the latter allows the covering material to be stretched more tightly. Place the weft edge, with a 1 in . turn, aiong one side of the waist, and stitch securely with strong thread. Then pull the finbric tightly round the cushion, atitch it firmly along the opposite waist-line, again along the first side, and attach the material to the two remnining sides of the waist, cutting off any surplus. Gather the comers of the niaterial to form ears, and neaten the waist with cord to match the cover ; if the cord is thick the ears can be sccured by being slipped through the twisted cord. A pouffe of the above description is illustrated in Fig. 12. he inade by using velveteen for the sides and bottom and introducing patchwork of leather and velvet for the top. Such a pouffe can be finished without the corded waist if made 20 in . in diameter, the outer covering being cut in the shapes shown in Figs. 1-3, and the top and bottom finished with a piping or fancy cord. The side strip (Fig. 2) may lee cut 10 in. deep (less turnings). Fancy stripsd material inay be used for the top and bottom of such pouffes with a plain fabric for the sides; or terry cloth with an appliqué design in a contrasting colour will make a good cover for a nurserv floor cushion
A two colour schome may be devised for a square floor cushion by mounting a square piece of brozade oi damask cornerwise on upholstery satin which matches the groundwork of the figured material, and finishing off the edges with narrow gold braid or coloured gimp.

Pouffe Ottoman. The pouffe ottoman shown in Fig. 13, makes an attractive piece of furniture, as well as a convenient receptacle for music, needlework, or newspapers. A strong woolen box should he procured, if possible with dovetailed sides. No lid is necessary. A box 18 in . long, 12 in . wide, and 12 in . deep is a convenient size : one of smaller dimensions, when upholstered, would not have a very roomy interior. Divide the

Pouffe. Fig. 12. Solid pouffe upholstered in small patteraed brocade. Fig. 13. Pouffe ottoman, which can be made from a wooden bor, with sprung and upholstered top
bos in two pieces, cutting off a section 4 in . deep; but if the box is too shallow to allow of this, a narrow box having the same length and width can be utilized by knocking out the bottom, or a wooden frame can lie made by using four 4 in . battens; this should be atrengthened at the corners. The bottom part of the hox will form the container or ottoman, and the 4 in . frame, when fitted with springs, will make the lid and seat of the pouffe
The two parts must be upholstered separately, the fixing of the hinges being the linst step. First upholster the bottom part: if nccessary, acrub) and dry the hox, preferably out of doors. When dry, rub the inside first with coarse and then fine glass paper. Cover the sides with any suitable faloric, such as casement cloth or hessian. Messure the distance round the box and the depth; allow $\underline{\imath}$ in. for turnings. Tack the hessian firmly along the top edge and the bottom, keeping it as tant as possible. The reason for covering the wooden sides is that it is impossible to fix hair or wool filling on to wood.
Stitch 3 or 4 rows of strong twine loops into the hessian, using a sacking needle and lenving about 2 in. hetween each row. Each loop should measure about $2 \frac{1}{\mathrm{in}}$, and a back stitch is necessary between the loops, otherwise the filling, when forced under, causes them to slip. Fig. 11 shows the lower part of the box covered with hessian, and the rows of twinc loops ready for the stuffing.

Wond wool is a very cheap tirst stuffing end rugging wool, fibre, or imitation hair are all suitable for the top layer. Arrange the stuffing as evenly as possible under the string loops, giving the corners extra pacding, so that when finished they will be well rounded, as in Fig. 13. Cut off a length of unbleached calico, allowing for the padding and for mitred corners, and tack it in position along the bottom of the box; standing over it, pull the cover up tightly over the padded sides, as in Fig. 15, rearranging and adding more stuting if needed. Tack the covejust inside the box. Line the inside first with lavere of cotton
wool and then with casement cloth. A straight piece of material about 2 in . deeper than the sides of the box and long enough to go round it is necessary. Use small brass tacks to fix the lining along the inside of the top edge. Cut a piece of stiff cardboard to fit the bottom of the inside tightly ; cover it with the anme material, and place it in position. A piecc of plain American clotly to match the upholstery fabric in colours should be tacked over the hottom of the box that comes next to the lloor, to prevent the edges of the material fraying and to neaten. The bottom of the pouffe should be fitted with castors or glides. If the latter are used, 4 small stained blocks of wood should be screwed in position nt ench corner. in which the prongs of the glides ahould be fixed! : this raises the pouffe off the ground and improves ita gencral прpearance.

To upholster the licl, first st retch the frame with good quality webbing bands length. ways as in Fig. 13, and then interlace them at right angles in basket fashion. A webling strainer or small piece of wood used as shown enables the bands to he stretched vory tightly. Procure five or six 8 in. copper springs, arrange them in position on the web-
bing, and stitch them firmly, using twine and a packing needle. When all the springs are fixed nt the bottom, tack the outside ones tightly to the frame, and tie euch one to the adjacent springs. When all are lashed down, cover the springs and sides of the frame with hessian, make twine loops and pad in exactly the same way as the lower part. Extra padding must be piled on to the top of the springs or the sent will become flat after being in uec a short time. Keep the stufling in position with a cover of umbleached calico, tacked to the lower edge of the frame.

Tapsestry, rep, velveteen or phish miay be used to cover the humpty; with a patterned material a more professione! appearance is given if an oblong panel 10 in . by 14 in . is piped on to a length of fabric. The panel must he arranged so that it comes in the centre of the lid, and the piping sliould be of one of the colours incorporated in the pattern. Nitre the comers ncatiy, maling any surplus material into small rosettes, Make a small tab of covering materinl about 2 in. long, and tack it to the middle of the front edge of lid, to facilitnte owening. Linc the inside of the lid with casement cloth over cotton wool, tacking it on to the wooden rin. Attach the bottom of the pouffe to the lid by two sminll brass hinges. Two chains screwed inside to the sides of the bux nnd to the rim of the lid may be added to keep the id from falling back:

POULTICE : How to Make. As a means of applying moist heat to any part of the body one may make use of a poultice. Poultices increase the flow of blood to the part which they cover, withdrawing it from deeper, congested areas: hence they are useful in deep-sented pain, as in cheat affections, inflammatory pain in the abdomen, or in the painful swelling of joints. In the case of boils, poultices relieve the tension and bring the boils to a head more quickly. The unaterials used are crushed linseed, brend, vatmen!. starch, etc. Crushed linsecd is

Pouffe. Fis. 14. Lower part of ottoman covered with bessian, also four rows of string loops and some of the wool in position. The last plece of webbing of lid
better than linseed meal, becanse it contains more oil, and therefore does not so readily stick to the slin. Mustard and various antiseptics can be combined in the poultice. Bread, linseed and mustard poultices are described under their own headings, while directions for making one of starch ure given in the niticle on Eczema.

Poultices large enough to cover both the back and chest of the patient arc sometimes
ordered. For children, these can usually be made in one piece, the poulticc being wrapped right round the body and escured with snfety pins; but for arfults it is generally necessary to make two separate poultices, large enough to meet at the sides. These cannot be pinned satisfactory and are there. fore held in place with a special binder or a wide strip of matevial that will serve the same. purpose. I warm, close-litting jacket, such as that sometimes worn by pneumonia patients, is also useful for confining these poultices.
l.inseed and other poultices, to be effective, must be smooth, soft, and as moist as possi ble, without being sloppy. They should be thicli enough to retain heat and moisture for some time, but not so thick as to be uncomfortably heavy. As their value lies principally in the warmth they supply, it is necessary to make them quickly, and to apply them at once before they have time to cool. For this reason everything that is required should be got ready before commencing to make the poultice, and the patient should nlso be prepared. Poultices on any part should be removed hefore they becomc cold. The skin should then be dried with n soft cloth, smeared with vaseline, and covered with a piece of flannel. Sce Bread Poultice; Liczema; Fornentation ; Linseed ; Mustard, etc.

## Poultry and Poultry Houses

## How to Rear the Birds Successfully in Town and Country

[^8]The facilities for those who wish to keep the run should be about from 20 to 24 fect a few fowls are much grenter than they were long and as widc as the houso. If the house a few yeurs since, ns stock is so much more can be placell on grass the larger portion of easily obtained. Many now buy pullets of the run shuuld he open. and the house and run various ages from three to six inonths. This should he moved from one spot to another each menns that the small poulty kecper avoids the tiouble and time spent in brceding and rearing and therefore needs less nccommodation.
These young pullets may be hought, kept until they have completed their first reason of laying and then sold to a dealer, or clac fattel and killed for the table. Tt pinys hetter to buy what is known as gunranteed stock, that is biris bred from stock which has heen tiap-nested, and whose production is known. Tu-day poultry farmers are catering for such buyers as they never did before. Many are breeding cross-bred birds, known ns sexlinked, that is the union of two pure hreeds which hare progeny of such colour and marking that the sexes are dissimilar as soon as the chicks are hatched. This method of brecding reluces the breeder's costs, as he is saved the expensc of rearing his cockerels.

The Poultry House. For suhurhan or town poultry kecping, a bouse with a covered run is best. The spnce given in the house to each bird should bo three to four spuare feot. and
year. If grass is not possilile, the run shoukl he well brushed and scraped each w'cek, also dug over about once a month, and giveu a gond covering of lime.
The floor of all poultry houses should he boardel and covered with peat moss or chaff. Such a lloor is more sanitary and there is less trouble from tats and mice. As soon as the litter on the floor shows signy of lecoming damp, or there is a musty smell it should be swept cut and a fresh lot put in The perches should be fixed from 18 in to 2 ft . fiom the lloor so as to avoid injury to the legs and feet when the birds fly down from the perches, and so as to miss the draughts which are a fiequent cause of colds when the perches are lival too high.

If the houses are kept clean, the perches and their holdery brushed over with paraffin or turpentine every fortnight (except in the height of summer), when once $n$ week is to he preferred, there will lec little trouble from red mites, or lice. 'The best aspect for a houso

Poultry House. Fig. 1. Combination house and scratching sined, which will accommodate six or eight birds Courtess of Boulton \& Paul. Ltd
is southeast. The birds then get the early house with a span roof The building is morning sun, and avoid its heat during the mounted oll stming cast-iron wheels. In adlatter part of the day in the summer months.

The manufacture of poultry houses has now become a great business, and the poultry appliance builders can supply any sized house that may be required from one suitable for 5 or (f) birds to one for several hundred Strongly built, well lighted, efficiently ventilated. yet draught proof, are the points of a good serviceable house. The ready made houses are sent out in sections and are quickly and easily holted together. They are fitted with all the necessary locks and bolts, and windows.

Three common types of poultry house are illustrated. Fig. I shows a combination house and scratching shed for six or eight birds. The simplest type of house consists of four walls of timber covered with a timber or felt roof and possibly provided with a hoarded floor. Half of the finnt is usually devoted to a door, of which the one part may be hoarded up or the upper part can be made with wire netting. The other half of the front may take the form of a window covered with wire netting and provided with some kind of adjustable screen or shutter, as shown in Fig. 2.

A development of the same type of building is illustrated in Fig 3, and comprisea a small

Poultry House. Fig. 2. Strongly built bouse, small enough and light enough in weight to be easily portable Courtess of T. Ball d Co.. Ltd
dition. perches, dmpping hoard, and outside nest boxes are providerl, and so arranged that the birds can enter them from within and the attendant can remove the eggs from the exterior. This type of honse is suitable for birds that are kept on open range, as the building can be moverl about from one place to a nother and the birds enabled to run on fresh pasture

Larger and more pretentious huildings used for mosting and scratching sheds arc often used. By another method, an extension of the main building consisting of a long run with a back and side wall and open front is enclosed with wire netting. and is used for scratching purposes, the main building being reserved for roosting and laying. One jortion inay he utilized for breeding and incubation purposes. Another plan is to use the main building for egg production and to have separate buildinga for incuhators, rearing. and the storage of foodstuffs. Provision should be made for keeping the grain and other foodstuffs in a dry location and free from attack by rats and sparrows.

For the benefit of the poultry kecper who wishes to build his houses and runs we give at the end of this article constructional details of two or threc useful types

Feeding the Birds. In feeding a sinall flock the table scraps mixed with equal parts of brall and middlings will give them good feeding, in fact all they need, except for grain and green food. The latter may be the refuse of the vegetables used in the house, such as the outer leaves of lettuce. cabbage and broccoli, the tope of carrots, parsnips, beetroot. and turnips. The rinds of vegetable inarrows and melons may lie boiled and mixed with the household scraps. The grain feed, wheat and onts, should be given at night, a good hig handful for each hen It is advisable that the
house scraps and neal mash should he given warm in the early morning.
By way of a change harley meal, or Sussex ground oats, may be used occasionally instead of the middlings Fresh clean water should he provided every morning, and in the summer time at midday as well. Flint grit and oyster shell is also neederl. If the run jo not very large the birds may be exercised by lianging the green food in a net bag and suspending it just out of their reach, thue compelling then to jump for it.

Kcep the nest boxes very clean, supply them with fresh hay, and dust them once a week with a good insect powder. The houses should he whitewashed inside twice or thrice a year. This not only liceps the house sweet, but alan makes it lighter than when it is creosoted. A lew drops of carbolic may be added to the whitewash when it is mixed. The outside may be painted, tarred, or creosoted as desired.

The Breeds. The hest breeds for a small household llock are the non-broody or light hreeds such as Leghorns, Anconns. Anda. lugians, Minorcas, and Campines. The Leg. horns and Anconas lay egge about 2 oz . to $2 \ddagger \mathrm{oz}$. in weight. The Andalusian and Minorca eggs are generally from $2 \downarrow \mathrm{oz}$ to 23 oz ., and sometimes a bit more. The Campines eggs ate from 1/ oz. to $20 \%$ The Hanlourgh family are also non-sitters and prolific layers, whilst they are among the most beautiful of all fowls, hut their eggs are sinall. All these mentioned lay white eggs

For town and suburban lovers of poultry. whose accommodation is limited in character and who only need the birds as a hobby,

Fig. 3. Useful poultry house, with outside nest boxes, the whole set on wheels for easy transport

Bantams are useful. The hreeds to be recominended are the Sebrights (gold and silver), Black Rosecombs, Minorcas, Leghorns Old English Game, and all the Wyandottea, except the whites and Columbians which are not suitable for town rums. The feather legged breeds like Pekins and Brahmas are suited for the show man only, and the same may be said of mudern game bantams.

Those who have a field, or paddlock, in which to keep their birds, may indulge in breeding with consequent pleasure and profit. They have a much larger field from which to select their birds. Among the hirds they may choose fiom are all the sitting breeds such as Wyandottes (Whiten, Blacks, Blucs, Buffs, Columbians, Gold and Silver laced, Paitridge, and Silver-pencilled); Australorps; Orping. tons, Dorkings; Plymouth Rocks (Barred Butf, White, Columbian, nud Partridge) ;

Barnwelders, Suscex (Light, Red, Speckled, Buff, Brown, and White); Croad Langshans Rhode Island Reds; Indian Game: Old English Game (Black.reds, spangles, Brown reds, Birchens and Piles) ; Houdans; Faverolles; also any of the light non-sitting breeds. The non-sitting breeds lay white-shelled eggs ; the sitting breeds tinted or brown, except the Dorking. which is white Breeds like the English modern game, modern Langshans, each very long in leg, Brahmas and Cochins with their heavy body and leg fenthers are not to be recommended to the ordinary amatcur. They are fancy breeds entirely and require special care and treatment.

One breed which is most useful and at the same time handsome is the latest comer from Holland-the Welsummer It is the only light breed which lays a brown egg, but is is not safe to stylc it a non-sitter becanse many of the hens do go broody.

Of the heavy breeds the best layers are the White Wyandottes; Rhode Ialand Reds, Australorps; Barred and Buff Plymouth Rocks and Light Sussex. None of the light breeds are good table birds. The best breeds for table poultry are Dorkings, Sussex, Orpingtons, Croad Langshans, Houdans, Faverolles, Indian and Old English Game. The best of the general purposes breeds, that is fairly good egg proflucers and table poultry, are the Wyandottes, Plymouth Rocks, Rhode Island Reds, Barnwelders and Croad Lang. shans.

Crossing is not advisable when egg production is the ohief thing to be considered because it induces broodiness and loss of production, but for table purposes crosses between Indian Game on the one side and Dorking, Sussex, Buff or White Orpington, or Faverolles, on the other are to he recommended, eapecially Indian Game and Faverolles, the progeny of which are very quick growing, Crosses between the Old English Game and any of the birds mentioned as suitable to the Indian Game. are good, but generally not quite so large when matured as those from the Indian Gaine.

Fattening for the Table. In fattening poultry the following procedure is adopted. The birds that are to he fatted for the table should be penned in a small place for about a fortnight hefore being killed. During this period they are fed upon mashes maile of Sussex ground oats and barley meal in which about two ounces of mut!on fat is mixed per bird daily. This fat may be ohopped fine, or it may be melted

Poultry. Fig. 4 Portable poultry run and roosting house, made to accommodate eight or nine birds Bu arrangement with Evans Bros, Lid.. L.onion

milk can be used the flesh will be whiter and more succulent. No grain or grit should be given during the fattening period. When the time for killing comes the birds should be starved for 24 hours. as the flesh keeps better.

Killing the Birds. The most simple and humane method of killing is to bold the bird with the shanks closely gripped together in the left hand. place the bird across the knce, head down wards, grasp the head with your right hand, and give the neck a swift jerk and twist at the same moment The bird should then be hung hend downwards to allow the blood to drain down into the nock. If this is not done the blood will remain in the body and cause the flesh to be discoloured. The feathers should be removed whist the body is still warm, they will then come away quickly and easily. Always draw the feathers in the direction they lie with a downward movement and so avoid breaking the skin.

Final Hints. The chief things neerled to ensure success in the keeping of poultry is to purchase sound bealthy stock, house it in buildinge which are waterproof, light, and well ventilated. Everything about the house and run should be kept scrupulously clean so as
Fig. 5. Method of joining framing in making poultry house shown below

to avoid disease and attacks from vermin. such as red mites and lice. The food should be sound and fresh and given regularly. Regularity in feeding has much to do with good health and egg production. A bird that is unhealthy is not a good layer. Crushed oyster shell and sharp flint grit are as necessary to the bircls' welfare as is food. Water pots

Poultry. Figs 6 and 7. Interior and exterior views of a bygienic poultry hoose, showing the covered run, with food honpers, nest boxes, perches, ete clean. Never let the water which the birda are to drink stand in the sun. Sun-warmed water is a frequent cause of diarrhoea.
Making a Poultry House. A portable run and roosting house suitable for 8 or 9 birds is shown in Fig. 4. The whole of the timher consists of white deal framing weather hoarding, and tongued and grooved flooring boards. A method of framing is shown in Fig. 5. Here the cross-rails are halved and nailed to the uprights, and by using corrugated fasteners mortise and tenon and bridle joints are avoided. The cent:c upright rails of the run (F, Fig. 4) may he nailed on the inside of the top and bottom rails, as shown. The small feeding.door (G) is made by nailing tongued and grooved flooring boards on two battens, and hinging it with a pair of stamper steel butt hinges costing a few pence.
The top part ( E ) is boarded so a.s to provide a shelter to the stock at times when it may not be desirable to nllow them access to the interior of the pen. The shelter, on account of expense, may be omitted if desired, and it is left to the discretion of the builder as to covering it with tarred roofing felt. The out side and the top of the run is covered with wire netting, which is secured to the framing by small galvanized wire staples.

The pen is made by constructing two end frames, the joints of which are constructed similarly to Fig. 5. These frames are connected together by nailing weatherboarding ( $C$ and $D$ ) on the back and front; and in matchtolrding (lettered H) on the end. For the opposite end ( B$)$ a battened door is male and hinged to the upright rail (R). This door will allow easy access to the interior of the pen and permit the removal of the egga. An arrangement such as this is essential to a good poultry run The nesting arrangements are shown by the shelf ( $N$ ), the upright partitions ( $\mathrm{P}, \mathrm{P}$ ) and
the 2 in . by 1 in. rail which is provided to keep the nesting material in it place. The exit and entrance ( $M$ ) at the front of the pen is

Poaltry. Fisa. 8-10. Constractional dotails of the arse wire ran shown in Fis. 7

The bottom of the pen (A) is an important part. It is self-contained and should be made by nailing 1 in . tongued and grooved flooring boards upon the four battens (K), which are 5 in wide and 11 in . thick. This floor portion should be tarred, and whilst the tar is soft it should be liberally sprinkled with sand and fine grit. The floor is not fastened to the pen, and it is therefore casily removable for cleaning purposes, etc. For the perches three langths of timber, $2 \downarrow \mathrm{in}$. wide by $1 \frac{1}{2}$. thick, should have their corners rounded off so as to give an octagonal section. Holes 18 in . in diameter should be bored across the front board just under the roof for ventilation.
A wire run suitable for 50 laying birds should measure about 75 ft . long by 40 ft . wide. The poultry house could be of the type illustrated in Figs. 6 and 7, and being located at the north end, always faces the sun. The run is built up by mak. ing holes in the ground with a crowbar or a jumper and erecting 2 in . by 2 in. deal posts, 7 ft. 6 in. long and 10 ft apart, the corner posts strutted with aimilar material. They are preferably coated with creosote or some other preservative prior to their erection. Some galvanized iron wire, 16 gauge, is then strained through holes drilled at the top and near the ground.
level of the uprights, and drawn up tight with an eyebolt or strainer, as in the method adopted when erecting a wire fence.

For this run 10 lb . of the wire will be required. The object is to provide support for the poles, which it does in an economical and effective manner. The run is completed by fastening galvanized iron wire netting to the poles, using staples for this purpose and further securing the netting by wiring it to the straining wires. This netting must be at least 6 ft . high, and may be all 3 in . mesh lf young birds are to be allowed to run. the better plan is to begin at the bottom with a length of 1 in . mesh wire 2 ft . high, and complete the work with 3 in. mesh wire. The wire netting is fixed to the ground with wooden pegs cut as shown in detail in Figs. 8 and 8. A panel of the run is shown in Fig. 10. Alter natively the bottom can be boarded up to a height of 2 ft . with rough wooden planks. This latter method is necessary if the run is used as a breeding-pen.
The Semi-Intensive System. 'Fig. 11 is a block plan showing the lay-out for a poultry farm handling 200 laying birds on the semi-intensive system. The houses have been designed with a view to economy in material, ease of construction and erection, combined with greater comfort and durability than is generally the case in the housing of poultry. The houses are made in sections, each of which is 10 ft . in length and provides accommodation for 25 laying hens, and includes nest boxes and a covered scratohing-shed or run all under one roof. Any number of birds in multiples of 25
can be accommodated by constructing the requisite number of back, front. and end sections. Each two sections have a separate outdoor run 75 ft . long and 40 ft . wide.

The following is the method adopted in constructing the houses. The necessary details are given in the diagrams at Fig. 12. In the first place the ground was inspected, and the best position for the house determined, having regand to the contour of the land, which falls away from the house on the south. The house faces due south-west, receiving the full benefit of the sun, morning and evening The ground was then marked out and trenches 9 in . Wide and 2 ft . deep dug out and filled in with concrete and brickbats as a protection against rats
The top surface of the concrete was then levelled to receive the building. The building consists of a framework of 2 in . square deal, covered with in. tongued and grooved matchboards, those with a damaged bead being set aside for use as dropping boards or elsewhere than on the external ualls, as the latter must be weatherproof. The joints at corners are mortised and tenoned, and the door parts are similarly jointed, all the others boing halved and screwed or nailed. The accompanying working drawing give all dimensions and details. All material was first cut to length, then the joints prepared, the matchboarding nailed on, and the whole creosoted inside and out. As soon as this is dry, the work of erection proceeds.

A start is made at one corner, setting up the end section, and holding it in place with

$$

battens fixed to the top and secured at the bottom to pegs driven into the ground. The front section is then put up in place and similarly supported. Every care must be taken to get this corner square and perfectly upright, otherwise the house will always be lopsided and insecure. A plumb rule proves the latter, while a stout cord, 10 ft . long, attached to hooks fixed exactly 6 ft . from the corner in the end section, and 8 ft . from the corner on the front section, ensures the squareness of these two sections. The corner is bolted together with 5 in by $\frac{3}{3} \mathrm{in}$. coach bolts and nuts, with a washer beneath the nut. Then the back section is crected and bolted in place. The remaining front, brek, and end sections are tlien erected and bolted together, temporary cross pieces heing nailed from side to sside, while the internal stretcher section and the ridge pole and struts are nailed in place.

The roof is covered with 3 in. mesh gal. vanized imn wire netting stretched very lightly, and a covering of tarred felt securely nailed to the top of the section with clout nails. The roof is completed by laying the 6 ft . lengths of galvanized corrugated iron, completing the work with a standard galvanized iron ridge capping securely nailed into the ridge pole. This ruof costs very little more than an ordinary hoarded and felted roof, and is much more durable. The tarred felt lining is essential, as otherwise the condensation would make the interior of the house very damp and uncomfortable. The fonts are enclosed with 2 in mesh galvanized wire netting, and portable screens made of waterprooferl canvas in a wooden framework are provided for use in very wet and cold weather.

Nest Boxes. The nest boxes (Fig. 13) are made to project on the back of the house, and constructed with a weatherboarded hinged top providing easy access for egg collecting. Perches made from 2 in by $1 \frac{1}{2}$ in. deal with rounded edges are carried in thearers, and can be lifted out for cleaning. Dropping bnards, supported on bearers and legs, are provided with cross hattens and lift-out for cleaning. A sliding hen door is fitted at each outside end of the section, and the intermediate section has double folding doors normally closed and bolted. Exterior doors are ledged and braced, hung on 18 in . cross-garnet hinges and fitted with a lock and key, and also a turn-button on the inside to enable the attendant to close the door while working inside the house. The floor is left in its natural state and covered with a deep hed of litter wherein the hens can scratch for grain This is good for the birds and keeps them healthy and contented.
A large "aler vesse!, feeding t.rough and hopper, and a dust bath huilt in one corner complete the house. Access to the runs is obtained by framed doors covered with 2 in. mesh galvanized iron wire netting, hung on simple hinges and provided with a hook and eye fastener. The combination of run, sciatch-ing-shed, and roosting house has always pioved satisfactory. In fine weather the hirds can be outdonss in the run: in wet weather they are conlined in the seratching-shed. On extremely cold and wet days the screens are put up, and the birds are warm and comfortahle, and ahle to seek their food in daylight and also in the dry. with satisfactory results in egg production.

POUNCE POT. Also known as n sand botle, the pounce pot in silver and Sheftield plate is sought by collectors. It was made for holding sand, which was used hefore the general employment of blotting paper to sprinkle over writing in order to dry the ink

POUNCING. Patterns may be pounced On to metal, glass, or pottery by means of a Jinen bag containing blue chalk. By ponneing is meant that the bag will be dabbed all over the surface of a stencil and will thereby
transfer to the surface of the article itself the outline of the design cut in the stencil paper. See Stencilling

POUND. This standard English mensure of weight is divided into 16 ounces, and consists, strictly speaking, of 7,(100) grains; 14 pounds go to the stonc, 28 to the quarter, and 112 to the hundredweight. There are $2,2 f()$ pounds to a ton. The usual abbreviation for pound is lb ., which is used throughout this work. See Avoirduprois Weight.

Pound Cake. This is n rich sultana calic usually baked in a spuuare or oblong, fairly shallow, cake tin. See Calie.
POUT: The Fish. The pout possesses a membrane covering the head and eyes, and which it has the power of intlating. The best known is the whiting pout. $n$ member of the haddock tribe. It makes excellent eating, bul must be consumed very shortly after being caught to be in good condition. Largo specimens attain the weight of 5 lb ., but the smaller fish have the best llavour. They can be cooked by the same methods ns are used for haddock.

POWDER. A powder may be described as any substance reluced to fine particles. Powders used in the home may be divided into those used for the toilet, e.g. face and tooth powders. those used for various cleansing purposes, and those takell as merlicines.

For the complexion, ponders can be had in white, cream, pink, and tlesh tints, variously perfumed, and either in solid or loase form. They should be carefully sclected hoth for texture and colour. Many women hlend their own by mixing two or three shades until the desired tint is ohtained Other hinds of toilet powders include rice. pearl. violet. nud talcum powders.

Cleansing powders include those for cleaning silverware and cutlery; there are also sanitary powders and vermin destroving powders. Powrered soaps are used in washing clolhes. while another jowder used in the houschold is baking pouder.
The powders uged in medicine are reluced to very small particles by a mill, or with pestle and mortar. To give bulk where a small quantity of the drug is to be taken, sugar of milk is frequently included. Powders may be taken by sprinkling on the tongre or in jam or syrup.
Powder Puff. Puffs for applying porder to the skin are made chiefly of swansiown, lambs' wool, and beaver fur: for hygienic reasons no puff should be used too long.
To make a powder puff, cut out a circular piece of swansdown or fur, turn in the edges to the wrong side, and then cover the hack with a circular piece of white or coloured silk. If a bone button and ring or some other type of handle, are altached to the centre back, the puff will be found easier to use. Large puffs intended for powdering the neck, shoulders, and back are fitted with long handles of wood, bone, or tortuiscshell, and are backed with ruched satin narrow ribbon, or lloral trimming.

A usual kind of powder puff is a handlierchief puff. Small pieces of coloured swansdown can be purchased and neatly sewn on to the middle of a creppede. Chine or georgette handkerchicf. This may be decorated by painting or pattern printing (q.v.).

On large powder puffs the usual hone button and ring may be substituted by a handle made from a lonk of satin ribbon or a small bunch of parlded silk-covered flowers and fruit. See l3abv; Baking Powder; Beauty; Emery Powder : Make-up; Scent: Talcum : Terth, elc

## Power Grid Detection. See Detector.

PRAIRIE SUNFLOWER. The fine species of perennial suntlower, Helianthus rigidus, is a good plant for the garden or for vielding cut Howers. Inproved varieties of this prairie

Prairie Suntlower, a tavourite species, with Howers ranging through all shades of yellow
sunflower, as it is called, include Miss Mellish, Miss Willmott. Daniel Dewar, and Rev. Wollev Dod All are !n varying shades of ye!low, the tlowers being borne on slender crect stems, 6 f1. or more high.
PRATIA. licing a dwarf plant of trailing habit. pratia is suitable as a creper for a slightly shady place in the rockery. It belongs to the harebell family. The chief kind is Pratia angulata, which grows up only 3 in. high, and during summer hears white llowers; repens has white flowers followed by red berries. It is hest plantclin March, and may be increased by division during the same month. See Ruck Garden.
PRAWN. In appearance resembling the shrimp, the prawn is la giger and more delicate in Havour Like the shrimp, it is hought ready boiled, and if fresh it should he firm and a good pink in colour. P'rawns can also he oblained preserved in tins, in which case they are not only cooked hut also shelled

Preparing Prawns. To shell prawns, take the head and tail in the two hands and pult tho prawn straight, giving it a little twist at tho same time. In this way practically all the shell will come off with the head and tail: the piece hat remains can quite casily be removed
Cut some large tomntoes in slices, and on each slice place a thin slice of cl:cumber and then 2 prawns. Prepare some thin bread and butter, spread it over with anchovy pasle, mixed if liked with tomato sauce. Cut the bread and hutter into strips, roll them up, and place them on the dish hetween the tomato slices. Another way is to place the prawns on a thin slice of lemon, and garnish them with parsley or sprigs of watercress.
'To prepare prawns in aspic, line some sinall dariole moulds with aspic jelly, and leave them until the jelly is nearly set, when some finely chopped olives, or pickled gherkins, and some chopped lobster coral is sprinkled over it. Then put 2 large prawns or 3 small ones into each mould, fill them up with more aspic. and

Prawns in aspic served on croûtes of fried breal spread with green butter
put in a cool place or on ice to set. Meanwhile inatie as many croutes of fried bread as there are dariole moulds, and spread them with green butter. This is made by placing it oz inixed and wished herbs, comprising parsley, tarragon, chervil, and chives in a saucepan of cold water and boiling them; dry thonoughly with a clean cloth and pound in a mortar with 3 oz butter a little anchovy essence and seasoning, afterwards rubbing the mixture through a sieve.

When the prawne are to be served, a mould is turnerl out upon each prepared croutte. and one is served to each person

To preserve prawns whole in butter, shell 1 pint of prawns and pack them closely in shallow china pots Crush the shells roughly. and put them, with $t \mathrm{lb}$. frosh butter, into a stone jam-jar in a pot of bniling water When the buiter is thoroughly melted strain it free of shell, Havour it with cayenne, nutmeg, and a little salt, and pour it over the prawns. Mure inclted butter should te added when this is cold, if the pots are not full. Tie them down, and store them in a cool, dry place.

Prawn Patties. While the puff partry (sce page 812) for these patties is cooking. the filling may be prepared Make a plain

Prawn Patties, consisting of pof pastry cases, with a filling made frow whlte sauce, small pleces of prawn and some grated cheesa Dinner Party ; Etiquctte. months, and disappears.
their elder brothers and before their younger brothers' wives Daughters of peers marrying peers of lower degree take the snme order of precedency as their hushands; thus the daughter of a duke marrying a baron degrades to the rank of baroness, while her sisters married to commoners retain thioir rank. Mere official rank on the husband's part does not give similar precedence to the wifc. See

PREGNANCY. The fact of conception may be shown, or at any rate suggested, almost at once by nausea, sickncas, or an ill-defined sensation of some sart, but much more commonly it is not suspected till the failure of a menstrual period. Morning sickness may appear very early in pregnancy, but as a general rule it appenrs towards the end of the first month, lasts two or threc

As soon as a woman finds herself pregnant she can generally, by consulting a doctor, find out within a week or two the probable date of her confinement. She is thus ablo to engage a doctor and a nurse. The duration of pregnancy is about 40 weeks, that is to say, 10 lunar months or 9 calendar months. Thicre are various methods of calculating the 10 days. white sauce, and add to it $\frac{1}{2}$ gill shelled there is prolonged standing. prawns cut into small pieces Nake tho mixture thoroughly hot in a pan over the fire, then stir in 4 tablesponnfuls grated cheese and salt and pepper to taste. When the cheese has melted, fill the pastry cases with the mixture, and garnish the top of each patty with a prawn's head.
Prawn Sauce. This sauce can be served with any white fish. To make it, prepare 1 pint melted butter sauce, season it to taste, and add $\frac{1}{2}$ a teaspoonful lemon juice and a few drops anchovy essence. Then drop in $\frac{1}{2}$ pint shelled prawns, and the sauce is ready. See Aspic: Curry; Hors d'Oeuvres; Patty ; Silad.

PRECEDENCE. Precedence is the order in which individunls follow one another at state and other public ceremonies. There is also an order of precedence for private gatherings, nlthough this is not so rigid. There precedence is usually given to the guests in order of their rank and social standing.

For state ceremonies there is a regular order of precedence for peers and officials. The king comes first, then the prince of Wales, and the other male members of the royal family. Next come the archbishop of Canterbury, the lord Chancellor, the archbishop of York, and the prime minister. in the order named. Other high officials follow and then come the peers, rank after rank. After the peers come a number of other persons, sons of peers, baronets, knights, and other members of the various orders.
Women take the same rank as their husbands or as their eldest hrothers. Daughters of peers rank immediately after the wives of

She should take open-air exercise every day, and should live in well-ventilated rooms. She should have a sufficiency of rest at night, and as her pregnancy advances whe will, as a rule, find it desirable to lie down for a little several times during the day. It may be a comfort to her and make exerciac more easy if she wears a properly fitted obstetric belt. Her dress should be loose. She should have plenty of plain food. In most cases she is better without alcohol. It may be well to sup. plement the ordinary diet with a frec allowance of milk.
Constipation is apt to be troublesome, and an attempt should be made to obviate it by including porridge, brown bread, vegetables, and fruit in the diet. Shnuld an aperient be required a teaspoonful or more of castor oil at bedtime may be sufficient, and may be taken every night if necessary ; or liquorice powder or cascara may equally serve the purpose. The use of strong purgatives is dangerous.
The drawbacks of morning sickness may be avoided by having a light breakfast in bed and an hour's reat before getting up A woman
date of a confinement.
One is count back 3 months from the beginning of the last period, and to add

Pregnancy does not, and ns a rule need not, interfere witl the ordinary routine of a woman's life and duties. She should be careful to avoid physical strain or shock, such as is in. volved in lifting weights, in journeying in jolting vehicles or in occupations in which

Preserving and sterilizing outnt, comprising
combined bolder and stand, and glass jars
should keep in touch with her doctor throughout her pregnancy. See Baby; Childbirth.
PRESERVATIVE: In Food. The use of chemical preservatives for food can hardly be dispensed with, as so much food is importeil and hoth this and home-produced food require to be stoied, sometimes for considerable periods Some chemicals used for preserving are harmful if taken in the amounts which might well be ingested in the course of ordinary diets containing a fair proportion of preserved food Boracic acid, once used extensively, is an example.

In Great Britain the Public Health (Pre. servatires, etc., in Food) Regulations, 192?., prescribe the articles which may contain chemical preservatives, the approprinte preservative and nmount in each. The onlv preservatives allowed are sulphurous acid and benzoic acid. See Adulteration; Food.

PRESERVING: Of Food. Fruit, legetables, meat or fish may be prescrved and sterilized by a simple method and the use of the outfit illustrated. This is an economy to the house wife, as foods may be purchused when pirces are low, or home-grown vegetahles and fruits may be preserved during the plentiful season. The shelves of the lariler may be stocked with jars of chicken, fish, game, soups. fruit or vegetables which, have been preserved, and will keep for years owing to efficient sterilization without the use of chemicals.
The Process Described. Tho process is simple and fuel saving. The jars are first filled. placed on the combined holder and atand as shown in the illustration, and then put into the sterilizer. When the water at the bottom of the sterilizer reaches the correct temperature the jars are bernetically sealed. No screwing covers are needed, the glasa covers are self-sealing and the contents can be preserved for years. The natural juices and vitamins are retained, and the food kept pure and wholesome. With the combined holder and stand all the jars can be placed into the sterilizer or taken out with one operntion. The stand is supplied with six clips for holding jars securely in position. Shallow jars can be placed one on top of the other. The thermonieter is protected by a steel sheath and is clearly charted to show the cormet temperature for sterilizing various foods, milk, etc. The special jars can be obtained in several sizes and are guarantecd against breakage by heat.

Preserving Pan. This shallow pan for making jam or inarmalade is usually made of brass, copper, or aluminium, but cheaper kinds can
be obtained in tin, iron, and enamelled ware. The iron ones are not to be recommended as they often discolour their contents, while the tin and enamel pans quickly become overheated and so cause the jam to burn unless the latter is kept well stirred. Enamel pans are also liable to chip.

PRESSED BEEF. To prepare this procure n picce of brisket of beef weighing from 5 to if lb. ; see that it is well covered with fat and nent-looking, also perfectly frec from the slighteat taint. Wipe it and lay it on one side whilc preparing the brine. Nix well in an carthenware pan 2 lb . common salt, 1 oz . saltpetre, $3 \frac{1}{2}$ oz. raw sugar, 1 bay-leal bruised, 1 small teaspoonful mixed sweet herbs, which have been sifted, 1 blade mace, and 4 cloves.

Bonc the meat, immerse it in the pickle in the pan, and rub it well with this mixture all over, doing this for about 5 min. Kecp it in a conl place, and every day for 5 days turn the meat and rub it as on the first day, taking care that it is left on the side which has been turned over. The joint must remain in the salt for from 12 to 15 days, but after the first five days it need not be rubbed, only turned each day. The saltpetre gives the red tint.

To cook the meat, wash it free from salt in cold water, then lay it in a saucepan large enough to give it plenty of room. Cover it with cold water and boil it up, skimming it very carefully. Add 20 peppercorns, 3 carrots, 2 onions, ench stuck with 2 cloves, 1 head of celery, and 2 turnips. All the vegetables should be prepared and cut into pieces of convenient size. Simmer the whole gently for 4 or 5 bours, or until it is very tender, akimming occasionally. When cooked, take up the meat, drain it and lay it on a deep dish, quite flat. Corer it over with a second dish and arrange on the top sufficient weight to pross the brisket into an oblong shape.

When cold, remove the weight and covering dish, and trim the neat ; then glaze it and dish it, garnished with parsley. The bones removed from the briskct can be added to the contents of the stock-pot, or boiled down separately with a little vegetable and converted into glaze The stock left over from cooking the meat may either be served as a hroth, with the addition of suct dumplings, or it may he used as the foundation of a brown soup. Brisket is too fat for some tastes, and a piece of silverside or round of becf may be sub. stituted.

ISrisket can be bought ready salted and cooked in the same wry. See Beef.

## PRESSING

 Of Clothes. Pressing is one of the most inl. portant items in the care of clothes, as it prevents them from losing their shape. When pressing is done systeinatically by means of at clothes press, it is seldom necessary to resort to othier treatment ; but with garments where this method is not practioablc, steam pressing is usually effective.

Pressing. Suord iron, heated by electricity. for pressing

Steam pressing can be done at home with the aid of a hot iron and a damp cloth. The latter should be of linen or calico or some similarly thin material.

Press heavily on the iron so as to remove any creases, and continue pressing until the cloth is dry, taking care that it does not become singed. If the garment itself is wet when pressed, the cloth that covers it should not be damped. The iron must not touch the garment itself, otherwise a shiny appearance may quite likely develop.

Any cleaning that is required should be donc before pressing. A special iron for pressing men's ties is shown in the illustration. The "sword" is hented by electricity in the ordinary way and the tie is atretched on to it after the silk has been slightly damped. See Clothes; Ironing.

PRESSURE COOKER. Fond cooked by steam pressurc in a pressure cooker requires only a very short time owing to the high concentration of the steam inside the cooker.

Pressure Cooker consisting of a casserole with lood contalners. The food is cooked by steam pressure, which is rerulated by a special device Courtesn of Ilarrods, Lld

There are scveral makes of pressure cookers on the market, but the principle is identical in all cascs. The cooker is really a strongly made casacrole with food containers and a lid which fits internally into the cooker. This is held in position witls a locking bar. When the lid is in position no steam can escape: the greater the steam pressure the more securely the lid is held in position, and the lid cannot be removed while the stean pressure remains The lid is fitted with n whistle device, the function of which is to ragulate the cooking of the food, and when sufficient pressure lins been generated this whistle blows and warns the user to remove the cooker from the gas or other heat. The whistle is marked with numbers on the movable top half and with a red line at the base, and one of these numbers is set to the red line according to the kind of food which is being cooked. There is also a safety valve on the lid.

Inside the cooker are basket containers for vegetables, also a combined lifter grid and strainer. It is possible to cook a complete meal in a pressurc cooker, as ench fond kceps its own flavour, and locs not affect that of others. Gteens retain their colour, and dried vegetables can be coo'ved in a few minutes without soaking. There is very little shrink age or loss in cooking, and all the natural juices and valuable salts are retained. For stewing or boiling, cold water is put into the cooker to the depth of 1 in . to $1 \frac{1}{2} \mathrm{in}$. ; for roasting, boiling fat is put in.

Below are a few exainples of the time taken for various foods to cook in a pressure cooker. Ronst chicken, 6-10 minutes instead of $40-60$ minutes. Roast joint, 12-15 minutes instead of 2 hours or longer. Stewed meats, 12
minutes instead of 2-3 hours. Potatoes, 8 minutes instead of $20-25$ minutes. Green vegetables, 7-10 minutes instead of 25 minutes. Dried vegetables, 20 minutes instead of 2-3 hours. See Digester.
PRICRING-OUT : Of Plants. The process of transplanting the seedlings as soon as possible after they have made their first tirie leaf in addition to the seed lcaves is termed pricking-out. It requires care, and where the seedlings are very small a thin, Hat stick notehed V-shape at one end, should be used to lift thein from the sced-pan or box.
Tender seedlings raised under glass should be pricked out into pots or pans, at distances apart according to their hahit of growth: they will require careful shading and wateringo for some time after pricking-out, and must be kept under glass until establiahed Outdoor plants raised in heat must be hardened ofl before permanent planting.
Seedlings raised directly in the open may be thinned out instead of pricked out, and, where necessary, transplanted when 3 or 4 true leaves have formed
PRICKLY HEAT. In the tropics Europeans frequently suffer from the skin disorder known as prickly heat. It produces intolerable tingling, pricking, and itching, and is due to obstruction of the sweat ducts. Small red pimples, no larger than it pin's head, cover the arms, breast, neck, shoulders, and thighs.

Rest in a cool, slindy place, if practicable, is one of the best measures Iced and hot drinks, spirits and wine, are to be avoided So are hot baths, especially with the "ise of soap. Many remedics are recommended, of which the best appears to he a mixture of 8 parts of olive oil and 1 part of lanolin rubbed into the skin night and morning.
I tepid alkalinc bath has sometimes a very soothing effect. It is made by ndding 1 oz . of bicarbonate of sodn to each gnllon of water Or a tepid bath of plain water may be taken. the skin bcing afterwards rubbed with lemonjuice, or carbolic lotion (1 part carbolic to 60 parts water), or calaıninc ointment ; or dusted with a powder made of equal parts of oxide of zinc, boric ncid, and starch.

PRICKLY PEAR. This is the common name of opuntiu, one of the cacti It is usually cultivated in pots under glass in a collection of cacti, but a few, notably monacantha and vulgaris, can be grown on a sunny, welldrained rockery at the foot of a wall.

PRICKLY THRIFT. This is the popular name of a rock garden plant, acantholimon, which forins a low civergreen tuft of spiny

Prickly Thrift. Rose-coloured flowers of a rockery olant which requires a sunny position
leaves and bears rose-coloured Howers in soil therc are some summer It needs well drained sandy loam remarkable plants and a sunny position, and is increased by cuttings in a frame in Alrgust Acantholimon glumaceum and venustum are the chief hinda: both have rose coloured tlowers

PRIMING: For Painting. As applied to house painting and similar work, priming is $n n$ undercoating or groundworli for sub.

Priming paint applied as a groundwork to raw timber sofuent conts of paint or onanicl Pio. nrietary brands are made up spe. cially for woodwork metal. or stone The amateur can make his own by mixing red lcad in paste or powder form with white lead and linseed oil thinned with turpentine, and a little driers added This is brusherl well into the word. work imme. diately it has heen pre pared. The adrantage of a priming coat is that it
works well into the wood and acts as a durable busc lor the paint that follows, which would otherwise neel off after exposure to wind and weather Sec Paint

PRIMROSE. This is the popular name of the spring-llowering I'rimula vulgaris and its varieties Primroses arc natives of hodgerows, banks. woods, and the sides of streams, and when found wild they may be dug up and hrought into cultivation 'Tley are increased by division after flowering or by sceds sown in spring in a frame The blue priniruses are great favourites and the double varicties urc charming llowers Primruses like slight shade in moist. loamy soil. See Auricula Evoning Primiuse Himalayan Primrasc.

PRIMULA. This groupl of bardy and greenhouse plants is of the utnost importance to the gardener, for many of the specics and varieties are invaluable for spring and summer hlooming out of doors or for provid. ing a show of thowers under glass in winter and spring

There are two chicl t vjes of hardy primula, those which lluurish best in partial shade in deep, invist soi!, and others which thrive when planted in erevices of the ruck garden Among those which need deep, moist

Primula. Lelt, tult-llke Hower beads of the species denticulata, whica needs a moist situation. Rigbt, P. varlabilis, a rock-rarden flower

Primula. 1. How to sow: $a$, crocks; b chopped old turl; $c$, fine soil : $d_{\text {, }}$ seed sown on top ; $e$, Rlass. 2. Seedings ready for pricking out. 3. Seedings pricsed out in box. 4. First notting. 5. Second potting. 6. Plants placed in coldrame. propastion by shoots slit at greenhouse: $a_{\text {, moist shingie. 8. Method of }}$ beaped with mosi to make roots firm. 10 Rooted sboot potted separately

Bu specia: arrangement with Amatcur Cardening
As regards planting, this should be carried out in early autumn or in spring.
Several of the primulas are charming winter and spring-flowering grecnhouse planta which can be grown to perfection in a minimum temperature of 50 degrees The Cbinese primulas (sinensis and stellata), of which there are numerous varicties in rose, crimson, salmon and other colours, aro the most valuable The yellow-flowered Kewensis and flaribunda, the pale yellow verticillata and the fairy primrose (malacoides) in blac. mauve and rose are others to be recommended. Primula obconica is a showy kind with blush. ruse or crimson Howers Gloves should be worn when handling the plants or the hairs on the leaves may cause irritation of the sk in.

Seeds of primulas sinensis and stellata should be sown in pans of fine soil in a frame in May. During summer the plants must be grown in a cool, shady frame, and in September they should be placed in the greenhouse. A suitable potting compost consists of loam two-thirds and leat-muuld one-third, with wand alded freely l'ots 5 to $\mathrm{B}_{\mathrm{in}} \mathrm{in}$. wide are large enough for the final potting.
Seeds of primulas iloribunda, Kewensis and verticillata should be sown in April; thuse of malacoides in April and June to maintain n succession of tloom P'rimula obconica should be sown in March in order to provide plants in hlowm in winter. These need the same treatment as the Chinese primulas. See Flower Garden: Potting : Pricking Out: Rock Garden.

PRINCE'S FEATHER. This is the common name of a half-hardy annual (Amiaantus hypochondriacus), which bears spikes of crimson Howers on stems 3 ft . or more high in summer. It is raised from seeds sown in a heated glasshouse in Jlarch, the seedlings being planted out in May. Other favourite allied plants are love-lies-bleeding (Amarantus caudatus), and Josepli's Cont (Amarantus tricolor).

PRINT : The Material. Many kinds of cloth are printed with designs, but the name print is most often given to simple cottons, usoful for aprons, working overalls and dresses, or for dust shects. Print enn be pasted down as a lining to wooden boxes or cupboards, and it can be omployed as a backing to curtains made of washing niaterial Old print dresses can be cut up to make capital dusters, and when these are worn out they are still use. ful for wiping grease from machinery or for polishers for floors furniture, or boots.

PRINT : How to Choose. Print collect in colour or finish. Some of them bear the $n$ m ing is still a hobby open to people of moderate means. Most old print shops have hundreds of prints put away in portfolios through which the would-be collector may look and find treasures, ranging from a few pence to a few shillings apiece.
The collector's first business is to learn to identify the different processes of engraving and cutting by which the print is evolved. The broad distinction between an etching and a mezzotint or a lithograph is fairly evident at sight. But it is not so easy to tell the differ ence between an engraving on steel and one on copper, or to know at a glance the mixed processes employed to produce a certain kind of etching. Only by watching an operator at work on a plate through all its stages can absolute certainty be gained as to the way it is done.
Londoners have access to some of the finest prints in the world at the British Museum, at South Kensington, and the Guildhall; but all over the country there are plenty of good prints to be seen. Yet the most valuable experience is that gained in the shop For prints of all descriptions the inexperienced collector's safest guide is an intelligent and honest printseller.

It should be remembered that prints of views, topical events and sports, if good in themselves, are bound to increase in value. Anyone who specialises in prints of one town or district, of naval and military subjects, yachting, motoring, or aviation, may probably form an interesting and valuable collection.

While etchings by great masters, such as Rembrandt, Albrecht Dürer, and Whistler, and colour prints after Morland, Wheatley, and other artists are beyond the reach of the ordinary collector, there are many decorative prints in colour or monochrome which can be picked up for comparatively small sums.
The collector's Japanese prints form a class in themselves and are nearly always pleasing and those by the less known names may often be bought cheap. One should, however, remember that the Japanese produce a large class of prints solely for export, and they are not of the best quality.

Plate Marks. Fivery collestor is warned against the purchase of prints lacking the slight indentation that shows where the plate has been pressed on the paper; yet a print without a plate mark is not necessarily a fake. Absence of the mark may simply be the result of printing from a plate larger than the paper. The illustrations, for instance, to Scott's novels and Rogers' poems were printed from plates larger than the pages of the book, and there are hundreds of similar cases where the plate mark has disappeared for this reason.

False margins can generally be detected by holding the print up to the light, just as the most cleverly exccuted repair of a hole or tear in the specimen betrays itself if the light is strong enough. Touch can often determine the age of a print by revealing the texture of the paper. Modern paper is hard and harsh compared with 18 th century and older paper. This test, however. is not infallible.

A finger passed lightly over the surface of a print should show whether it is genuins or a clever photographic reproduction.

Baxter Prints. Genuine Baxter prints, the work of George Baxter, are valued by collectors. Baxter illustrated a large number of books, producing frontispieces and vignettes in addition to separate pictures. Many of these were used to illustrate pieces of music, and valuable Baxter prints have been discovered in this way, especially portraits about $4 \frac{1}{2}$ in. long, into which he put some of his best work. Some printing firms were afterwards licensed to use the Baxter process, which consisted in building up beautifully coloured prints by the use of many blocks; but the work of these licensees never equalled the originals either
in colour or finish. Some of them bear the name
of Baxter, and collectors are very liable to be misled by theso. Genuine examples bear the name of the artist and one or other of his various addresses in London; they have good mounts and are generally clean and unfaded, Baxter's brilliant and lasting colours being one of the principal secrets of his remarkable success.
There was no 3-colour process in Baxter's day: each colour in a picture had to be applied separately. and in this Baxter excclled. He started with an engraving, originally on wood, later copper, and then steel, printing in black, brown, or purple. This was the

Photographic printing processes are divided into two classes. The first and oldest, and apparently simplest, is the printing-out method in which daylight is allowed to act on sensitive paper behind a negative, the action continuing until all details of the image are visible. The paper which is used in this process is called printing-out paper or P.O.P. (q.v.).

In the second method, called the develop ment method, artificial light is used, and the exposure of the sensitive paper is very much shorter, no visible image being produced unti the paper is treated with a chemical developer
In both P.O.P. and development papers the negative is held in a printing frame for exposure. since it is essential that the sensitive paper should be closely and evenly in contact with negative and also that light should not leak in through the edges of a glass negative. Printing frames can be bought cheaply; if a number are required, they can be made a describel later.
When printing films it is necersary to place a piece of clean glass in the frame first, then the film, followed by the paper, the sensitive side of the film being in contact with the paper or the image will not be quite so sharp and will also be reversed. A waste negative glase of the right size for the frame, carefully cleaned, will serve best for the film support. keeping it flat and in close contact with the printing paper. If glass negatives are being printed see that the glass sicle is thoroughly cleaned and without smears or finger marks. for any marks will appear in the print, particu larly if it is on gaslight paper. Care must also be taken to see that the ncgative is thoroughly dry, or it will adhere to the sensitive paper, spoiling the negative and causing silver stains on it, which are extremcly difficult to remove. Take great care to see that the paper itself is not handled with moist or dirty fingers.

When printing in daylight on P.O.P. the frame should be filled in dull light or shadow and the printing should be carried out in diffused light, never in direct sunlight, except perhaps in weak sunlight from November to February. Too strong a light reduces the contrasts even in a good negative, and gives flat, dull prints. Weaker light, well diffused, increases contrasts and brightens the prints Place the frame on the window-sill out of the sun, but with an uninterrupted view of the sky. After a short time the print is examined in a dull light by opening one half of the hinged back of the frame.

See that the paper is not pulled or disturbed in any way, or a double and blurred image will appear on the finished print. Depth of printing varies somewhat according to the paper and toning bath used, but as a general rule it should be carried on until the whites of the picture are well coloured and the
foundation. After that he applied his colours with a series of wood blocks. letting one impression dry and then adding another

The variety of colours is always a striking feature of his work, from 8 to 20 different colours or tints being found in a single print. The register is always perfect ; that is to say each colour is fitted exactly into its place. This is one of the characteristics of a Baxter print ; another is the beauty of the colouring Baxter ground and mixed his own colours, and was very particular in his choice of paper He engraved the plates himself, and personally superintended every stage in the production of his prints. See Picture

## Printing and Printing Frames

## The Best Methods for the Amateur Photographic Worker

For the photographer who carries out the technical processes of his hobby clear instructloas are given under this and the relative headings, Developing; Enlarging: Flxing; Negative

Washing. See also Gaslight Paper; P.O.P.: Self-roning Paper
shadows begin to appear solid. Fixing and toning should be carried out as soon as possible after printing, as P.O.P. tends to discolour if kept after printing and will not tone so well

All prints, whether on P O.P., gaslight, or bromide paper, are much more effective if a white margin appears round the photograph proper. This is obtained by the use of a mask, best cut to fit the particular photo graph from opaque paper. flat and uncrumpled, such as the black paper used for wrapping sensitive plates. A sharp knife or a mounted razor blade must be used to cut the mask, since clean, straight enges are essential. Sets of masks may be bought, but those of oval shape or with rounded corners should not be used, for their effect is most inartistic.
To get clouds visible in a negative to print properly on P.O.P. paper it is necessary to shield the ground portion of the negative for part of the time during printing by placing a card over the frame, and so allowing the sky portion extra time for printing. The card should not touch the glass, but should be about $\frac{1}{2} \mathrm{in}$. to 1 in . away from it, and moved occasionally, or a sharp line will appear in the print In a similar way, when there arc no clouds in the negative, the sky portion being opaque, the print will be improved if, insteal of appearing a blank white, it shows some tone of varying density.
To do this, expose the paper first in the frame through plain glass, covering all but the topmost (sky) portion of the negative with a card as before, gradually moving the card downward so that the top of the print has the iongest exposure and shows a decided tint. The finished picture will show a graduated sky of much more natural appearance than if left blank. This process is called sunning-down. When printed P.O.P. papers are toned and fixed together with self-toning papers the two operations of toning and fixing are combined in onc.

Printing Frame. Several kinds of frames for making photographic prints and suitablc for all sizes in negatives, are obtainable. Although generally made in wood, some are made of metal, two kinds of the former being shown in Figs. 1 and 7. The framework of the first is shown in detail in Fig. 2, and for sizes up to whole plate the material can be the same size in section.

Taking the dimensions of a 1 -plate frame as a guide, the two sides $A$ should be 6 in . by 1 in . by $\frac{3}{} \mathrm{in}$,, and the ends 5 in . by 1 in . by $\frac{1}{2} \mathrm{in}$. In order to reduce the thickness of material close to the negative, the top edge of the wood should be planed to a chamfer, as in Fig. 3, and the mortise and tenon joint cut as in Fig. 4. The thickness of the tenon is 1 in., but, before cutting, allowance must be madc for the chamfer and also the rebate, this being $t$ in. deep and $t$ in. inward. The

Printing Prame. Fig. 1. Prame with mortise and tenon corners. Fig. 2. View showing joint and rebate. Pig. 3. section of side. Pig. 4. Detail ol joint. Pis. 5. Alternative joint. Fig. 6. 8pring. Fig. 7. Another methoj ol mating trame. Fis. 8. Soction showing apring and ataple. Fig. 9. Binged beviz
rebate is cut in order to leave a projection at the ends; Fig. 2.
'The simplest way oi making the frante is to chamier the two lengths ${ }^{-} A$, cut out the recess to leave $f$ in. at each end and to cut the mortise to a depth of 1 in The ends B are first notched on the side so that the bottom of the inclined shoulder is I in. from the end. After glueing up, the corners can be rounded as shown. An alternative method of forming the joint is shown in Fig. 5, the top chamfer being made after the joints are cut. The spring should be of hard rolled brass, hammered to form a curve, as in lig. 6, a suitable width being in., the length for a $d$-plate being 40 in Staples as at $S$ should lo mate from $\frac{1}{8}$ in. hard brans wire and driven in the wood.

For the plywood frame in Fig. 7 the bottom piece C should be for a frame of the same size as Fig. 1, 6 in. by 5 in., the tol pieces 15 in . by 1 in . by $\frac{1}{1} \mathrm{in}$, and the end pieces $E$ it in. by 1 in. by $\frac{1}{1}$ in. Cut the sloping recesses in the sides 1 to a length of about 2 in . and a clepth of $\frac{t}{} \mathrm{in}$., and then glue on, with end pieces $E$ butted against then.

The springe are now prepared and screwed on as in the section in Fig. 8, and a staple fitted to each spring. The hinged back for the first frame is made from $\ddagger \mathrm{in}$. wood, each portion being $3 \frac{t}{t}$ in. by $2 \frac{1}{8}$ in., hinged together with small brass butts The bach for the second, shown in Fig. 9, is made from two pieces, one to fit in the recessed portion and the other beyond it. Brass hinges can be used, or a strip of linen cloth glued on.

PRISONER'S BASE. This game can be played in a garden or playground by any number up to about 40 players. The ground should be markel into two equal portions, and at each end a base established. If played in a yard these can be marked with chalk, the base being $5-0 \mathrm{ft}$. each way.

When tho players have been divided intu two equal parties the game begins. At first they risk capture by venturing into the enemy's ground, or remain on the watch for those who onter their uwn. Those who are caught by being tagged are placed as prisoners in the lase, but can be relcased if touched by a free member of their own side. Buth prisoner and rescuer can be tagged anil brought back to
prison before reaching their uwn ground. A gane is won when one side has made prisuners of all its upponents, or when a free inan enters his upponent's prisun when it is empty
PRIVET: The Shrub. Thin is the commonest of all hedge shrubs and it is scarcely surpassed for forming a close liedge quickly. but it needs to be clipped frequently during the summer inonths and impuverishes the ground near by. The plants should be set in autumn at $1 \overline{\bar{j}} \mathrm{iu}$. apart; a thick hedge is assured most quickly by planting a double row. the plants in one row alternating with thuse in the other. In the following spring they should be prunol to within 12 in . or so of the base to make them branch out. The common privet is Ligustrum vulgare, but the oval. leaved privet (Ligustrum ovalifolium) is a better shrub with mraer leavion which arealnume

privet. Spraye of Ligustram valgare, the common privet
evergreen. The golden leaved privet is a favourite hedge shrub: it varies a good deal in colour and it is wise to chouse the plante in a nursery.
Several of the privets are worth cultivation as decurative shrubs: two of the best are japonicum, t-5 ft., and lucidum, ij $\mathrm{ft}_{\mathrm{t}}$; both bear white flowers in summer. Privet is easily increased by cuttings inserted out of doors in October or in a frame in August. See Hedge: Quick.

PROBATE: Of a Will. When a man diek leaving a will his executors cannut liandle his eatate until they have proved, or taken out pmbate of, his will. This is accomplisbed by takind the will either to a local registry or to Sumerset House, lugether with a copy : leaving the original there, and receiving frum the officials a copy written on parchment and sealod with the seal of the probate division of the high court. This is called a prolate colly, armed with which the executor can collect. the eatate and deal with it.

Any person who wisher to dispute a will must enter a careat on a form provided by Somerset House in London or a probate registry (fee $2 /(3)$. 'This form is to the effect that no will of X Y deceased is to be admitted to probate without notice to the objectur or his solicitor. The cavcat remains in force for six months and may be renewed. Anyone who wishes to prove a will of X Y deceased must first search and see if there is a caveat If he finds one, he must give nutice to the objector called a 'warning summons ' (foe 2/6). Unless the objector enters an appearance to the warning summons the caveat cxpires. If an appearance is entered by the ubjector it will be necessary to prove the will in solemn form by litigation.

The action is heard in the probate division of the high court, when the witncesses to the will come and give their evidence on nath : the objector is allowed to call evidence to show cither that the will was not executed according (1) law or that the testator was of unsound mind or subject to undue influence or the like. If the will is pronounced valid, it is then said to be proved in solenin form.
The ordinary probate of a will is called proof in common furin. The fullowing documents are required: (1) un affidavit according to the form which can be obtained from Sumerset House or the lical registry containing all particulars of the leceased's estate: (2) an oath of executors proving the cleath, will, dtc. . (3) renunciation by any exccutor where necessary ; (4) engrossment of the will and any rudicils on official engrossment sheets of special paper: (5) where neccssary an affidavit of due execution of the will; (6) a certificate of reasun of delay where the application is made after a lapse of 3 ycars from the testator's leath in order to enable the eatate duty to be assensed. If the deceased left a will but either named no executor or the executor whom he named is dead, then the person who would be entitled to administration if he had died intestate is also entitled to be administısto with the will annexed. As a rule, administra. tion is granted to the residuary legatee, because it is clearly wh his interest that the deceased's estate should be properly administered, he being entitled to what is left after paying debts and the various legacies devised under the will. See Executor; Legacy ; Will.

PROGRESSIVE PARTY. A pmgressive party may be held in one's own house, or, if it is desired to invite a large number of people, it may be oqually well held in a hall hired for the occasion. Whist is the must suitablo game, as bridge is too scientific to admit of the casual play and constant change of partners and talks which occur during the evening's entertainment. It is impurtant that the tables should not ise too cluse tuget her, and that circulation should be easy. Also that une or two people should be in rescrve in case
some player disappoints. Each table should have its number clearly marked
The best time-table is as follows: Allow $\frac{1}{2}$ hour for the questa to arrive, to serve coffee or any light refreshments, to hand out acoring cards. and for the arrangement of partners play mav last for $1!$ hours ; and another hour will serre to circulate refreshments and present the prizes It is a great mistake in allow the play to last too long, as after a certain time things may begin to drag.
It is heat to lcave the arrangement of partners to chance, and to let them find each other by one of the ordinary methods, such as the pairing of words. Ench man's card should have the table number written on it, and there should be two men for each table.

Ilay must start with the ringing of a bell : it should continue from 5 to 10 min .. and cease when the liell rings again. The winning couple, when the scorcs liave been tilled in, then move to other tables. Usually the woman moves to the next highest numbei and the man to the lower one. This ensures that the majority of perple shall meet ench wther in the course of the evening. The losing couple remain at the same tables as before. hut when the new arrivals come they ohange partners. When pliny ceases the scoring cards should he handed in to host or hustess, and the plavers go into another room for refresh. ments while the results are checked and graded. These will then be announced and the prizes presented. There should be at least one prize for the first woman and one for the first man leyond that, the matler is left to the means and digeretion of the host and hostess See Evening l'arty; Whist.

PROHIBITED DEGREE : In Marriage. In the Book of Conimon Prayer of the Church of Enyland there is printed a table of kindred and aflinity showing whom a man or a woman may not lawfully marry.

It is now permissible to marry the sister of a lecensed wife, but it is not lawful to marry the sister of a divorced wife who is still liring. A clergyman is not $t_{0}$ be subject to noy penalty for refusing to marry a man to his decensed wife's sister, because this sorl of marriage is still contiary to the law of the Church of England.

One of the prohibited degrees was removed, us far ds the civil law is concerned, when an Act was passed in 193! allowing a man to marry his nicce by marriage. See Marriage.
PROMISSORY NOTE. I y y the Rills of Exchange Act, 1882, a pmmissory nute is defined as an unconditional promise in writing made by one person to another. signed by the maker, engaging to pay on demand or at a lixed or determinable future time a sum certain in money to or to the order of a specitied person or besrer. The form of a promissory note is as follows

August 11931
Thiree months after date I promise to piy to Mr Arthur Smith or or :er the simm of One Hundred pounds with interest at, 0 "\% (Six per cent) for valuc recelved
£ 100 .
£100 (Signed) Jobn Jones
In this note John Jones is called the matier and Arthur Smith the payce. The payce of the note can negotiate it, i.e. by endarsing it on the back with his signature lie can transfer it to anybody he pleases, with or without consideration. It may he negotiated in the same way by the holder as often as he chooses. In this way the note can pass through any number of hands and the holder at the end of the 3 monthe has the right to present it for payment to John Jones.

If John Jones ducs not pay it, the holder can call upon any of the persons or all of them whose names are on the back of the note ns endorsers to pay. Any of such endarsers who dnes pay can in turn call upon anyone whose name was upon the note before his own to pay
him until it gets hack to. John Jones, the maker. It is no lefence to John Jones or any of the other people, it sued, that they received no consideration. If anybody in the whole series of transaotions has given any value at all, eithel in money or moner's worth, the note hecompa one fur valuable consideration in his hands, and also in the hands of anvone who rakes it after him
The value of a promissory note is that it is negotiable, i.e the holder of it has a good title to the money quite independently of the title of anyone from whon he took it.

As between the original partics, i.e. the original maker and payee of the note, the maker may have a good defence on the ground either that there iras no consideration given for the note or that it was obtained from him by fraud or for some illegal consideration. But if the note gets into the hands of someone who is a holder in due course, i c a holder who received the note atter consideration has been given for it by somebody and who talies it without receiving notice of any fraud or illegality at its inception, the holder call sue upon it.

If in the note set out John doner receiverd no value from Arthur Smith, that is a gond defence of John Jones if Arthur Smitl sues him upon it. But if Arthur Smith sells the note to William Brown for £is, William Brown can sue John Jones for the Llos. He can, of course, also sue Arthur Smith. Again, suppose John Jones was induced to sign the note by some frand on the part of Arthur Smith, Johnl Jones can set this up as a defence against Arthur Smith, but if Arthur Smith sells the note to William Brown, who had no notice of fraud, then John Jonesi inust pay William Brown if he is naked.

A note is only fully negotiablesolong as it is current, i e. until it hecomes overilue. The note is ovcrdue after the time when it is stated on the face of it to be parable. Thus, the note alove is overdue after the expiration of the three months. It can still be transferred osen after that date, but anyone who takes the transfer takes the risk of the note having been had at its inception. In other worls, it becomes like an ordinary contract or debt, and the maker may set up any defence or fraud against any holder, and it will then lie upon the holder who took the note after it was overdue to show aflirmatively that he had no knowledge of such fraud See l)ebt. : I.O.U.

PROPAGATION: Of Plants. The chiel methocls of propagating plants are by sceds: outtings : division; layering . bulhils; offerts: grafting; inarching leaves, as in gloxinia runners, as in straw herries: stein-ronting, as in the castur oil plant, eyes as in vincs ; and by pipings Most of these are dealt with under separate headings.
Aide to propagation are pota, pana, and boxes, a fine sieve, some pance of glass, 2 or 3 cloches, a finerosed watering pot, a good syringe, a keen budding hinife, and a few minor appliances, such as bust; clean crocks, etc. To these may be added a propagator and a garden frame. A propagator can be made from an ordinary box, with sheets of glass from old picture frames, or fronl a pot with char conl and fibre. and
covered with glass. Suitable soil is required and, generally any good light soil opened with a little sand will suffice, but certnin othor combinations will often be called for, including rich loan, anally peat well rubbied down. decayed leat-mould, silver sand and charcoal.

A few hints on preparation for sowing may be of value Pats, boxes, or pans must be well crucked with clean potsherds. over which a thin layer of moss or fibre is placed. This is followed with compont to within \} in of the top, the whole then being made moderatcly firm tiy pressure, and gently watered. Fixcess water should he allowed to drain well away, then the secols are sown thinly and covered with mil put through a fine mesh sieve.

After sowing, sced reccptacles should be covered with a sheet of glass to conserve moisture. Should the soil show signs of dryness, immerse the pot gently in tepid water and moisten the plunging niaterial. It can be sliaded from sunshine with sheets of beorn paper when the tirst rough leaf is formed it should he removed to a naturally shady place until ready for transplanting, every precaution heing taheil to avoid clamping off.
There are varions kinds of cuttings Shoot cultinge should always he takell with a hee or cut at the base of a joint, the lower pair of leaves being removed. Other types are root cutting and leaf-cutting. Receptacles with soil should he prepared in the mannel already devised, hut instead of the fine top covering of soil, well-waslied sand ahould he used. Tlif cuttings are inserted with a dihber, and thri bottoms must touch soil at the lase of thein holes. the soil is pressed firmly round them, and they are removed to a propagator.

Most hardy herbacous perennials are casily increased by division, i.e by liftiny the clumps in autumn or spring, separating them into pieces and replanting the latter Only the young outer pieces should be chosen. Border carnations, various shruhs and straw. herries are propagnted by layering in sumimer: The shoots or stems are slit and the slit por tion is pegged into the soil and kepit inoist Budding is practised in July-August, chielly for the purpose of raising a stock of fruit trees and inses. Grafting is carried out in spring buth out of doors and under glass Raspherries, chrysanthemuins. and some shrubs are propagated by suclioes, i.e shoots which grow through the unil from the parent rootstock See Bedding: Cuttings: 1)ivision: Edging

## Grafting; Pruning.

PROPELLER SHAFT. Tnis (also known as cardan shaft) is the driving shaft placed between the grar box and the back axle in a

Propagation : the various methods employed. 1. Budding. 2. Grafting. 3. Inarching. 4. Multiple layering. 5. Stem rooting. 6 . Rootlet of monks8. Crinam ofiset
10. Root propagation. 11. Hardwood cutting

motor vehicle, and may be classified under two heads-open and enclosed. With the open type a universal joint is employed at each end, one of which is capable of longitudinal as well as universal movement. The reason for this is that the radius of the axle movement is governed either by the point of the spring anchorage to the frame or, where fitted, by the point of anchorage of the torque stay. The object of the torque stay is to relieve the springs of the twisting tendency of the axle, which is created by the driving and braking stresses.

Unless the centre of the universal joint next the gear box is the same distance from the axle as the other centres that govern the axle's movement (e.g. the spring or torque st-ay anchorage), the up and down movements of the axle will cause the length of the propeller shaft to alter slightly, and this sliding movement must be provided for. Thercfore one of the universal joints is made to permit longitudinal movement. The open shaft is usually constructed of large diameter steel tubing, which affords rigidity and strength.

With the enclosed shaft, the difficulties of centres do not exist to the same extent, because the casing for the shaft is also a rigid part of the back axle, and acts as the torque stay with its forward end anchored close up to the gear box by a ball and socket joint.

Apart from the attention to lubrication which all universal joints require, there is one other point which may be mentioned in connexion with the propeller shaft, namely faulty alinement. This may be detected by a regular rhythmic whining noise when the car is running quietly. The trouble can be put right by any service garage, and is not an expensive job. See Brake ; Motor Car.
PROPGRTY TAX. This name is given to that part of the income tax which is derived from property. This is paid by the occupier of the house or premises, and if he has a landlord he is entitled to deduct the amount from the rent. See Income Tax.

PROTEIN: As a Food. In animal and vegetable tissues there are found complex organic compounds of carbon, hydrogen, nitrogen, oxygen, and sulphur, which are known as proteins. Food must contain a certain proportion of these nitrogenous substances, because they are absolutely necessary for the building and repair of the tissues. White of egg, serum albumin, fibrinogen, peptone haemoglobin, and casein are examples of proteins.

The patent food sold as protein food is used largely in vegetarian cookery, but may also be served as a breakfast or supper drink. To prepare this, put 3 tablespoonfuls of the food in a jug, mix it slowly with half pint of hot water, milk, cocoa, tea, or coffee. Grated nutmeg, cinnamon, or ginger Havouring may be added to taste. See Diet; Food; Vitamin.

PROTRACTOR : For Measmring, Used for measuring angles, the protractor is generally made in brass or celluloid, the commonly used pattern having a base of 4 in . The method of using the protractor is here illustrated. The two ends $A$ and $B$ are placed on a line with the centre. point $C$ exactly at the place where the required angle is to start from. If a mark is made at the point 60.as indicated at D and the point $D$ joined to the centre point $C$. the angle made by the lines A C D contains (: $6^{\circ}$. In the same way an angle of $25^{\circ}$ can be set Jff from the point E, and the angle con. tained by the lines FCB is $45^{\circ}$. Other
angles are $55^{\circ}$ at $\mathrm{G}, 77^{\circ}$ at H ; the right angle is at K and an angle of $115^{\circ}$ is contained by the lines LCA. See Drawing.

PROUD FLESE. The flabby, unhealthy tissue that sometimes projects from the edges of a wound or ulcer is popularly termed proud Hesh. It may result from an excessive use of poultices and ointments. The remedy is the application by the surgeon of an astringent, such as a solution of sulphate of copper or nitrate of silver
PROVENCE ROSE. One of the oldest garden roses, this is commonly called the cabbage rose because of the shape of the blooms, which lack the graceful contour which is characteristic of many modern varieties The Provence rose, which was derived from Rosa centifolia, beara rose-pink fragrant blooms It forms a fair-sized bush, flowers in summer only, and should be pruned in March by cutting out old worn-out branches and shortening the previous year's shoots slightly.
PROVERBS: The Game. There are various games of this name. One of the best known is as follows: One person is sent out of the room. The others select some proverb which contains as nearly as possible the same number of words as there are people present. The words are then given out in order and the person outside is summoned in. He proceeds to ask a question of each player in turn, and the answer must contain the word of the proverb which has been given to that player. When all have been questioned the newcomet must guess the proverb
Should there be insufficient words to go round, the people for whom there is no word must keep silence. If there are more words than players some of the playera must be responsible for two. Obviously the proverb chosen must have as few distinctive words as possible if it is to present difficulties in guessing. "It is never too late to mend " is an example of an easy one to disguise, while " a rolling stone gathers no moss "' is remarkably difficult. There are few ordinary questions an answer to which would naturally contain "rolling" or " moss" ; the latter word alone would identify it.

A Variant. In another form of the game a list is made of as many proverbs as are considered necessary, the number being regulated by the number of guests expected. Fach is then written out in separate words on separate pieces of paper. The key word of each is kept out, and the others, having been well shuffled, are pinned up in different places all over the house. This must be done before the guests arrive. It is advisable to keep the original list as a reference in case of questions.
The guesta are each given a key word and are set to complete the proverb which it suggests to them. They must be shown which rooms may be included in the search, and must all start at the same moment. Each proverb when completed nust be brought to the hostess, who will then issue

Protractor. Instrament used by the draughtaman for measaring angles
the largest number in the time given receives a prize.

This is an excellent game for an afternoon or evening party and the less formal type of at humc. At least three proverbs should be allowed for each player, but the larger the num ber the more difficult they are to find and the keener will be the interest. See Children's Party.

PRUNE. The dried fruit of the many varieties of plum is known as prune. Prunes form a health giving addition to the diet because of their content of carbohydrate, and alan because they increase the palatability of cornflour and other starchy dishes. They have a mild laxative effect, and are taken with advantage by those who have a marked tendency to constipation.

Before stewing, wash the fruit thoroughly and suak it for 12 hours or more in a covered basin containing sugar and water. To 1 lb . prunes, $\ddagger \mathrm{lb}$. or a little more sugar and enough cold water to cover them should be allowed. After soaking, put the fruit and syrup into a pan with a little lemon rind and juice. Stew these slowly until the prunes are tender, and serve them with the syrup.

Prune Fritter. Cold stewed prunes may be used to make frittors Take out the atones, and in their place put some blanched almonds Then coat the prunes with frying batter and fry them to a golden brown colour in a pan of boiling fat. Serve the fritters sprinkled either with castor sugar and grated chocolate or with sugar alone.
Prune Mould. This sweet is made by washing lb . prunes, covering them with cold water, and letting them soak for 12 hours

Prune Mould, a jelly awee! which can be made richer
by the accompanjment of thickly whiaked cream
Dissolve a $\frac{1}{\text { p }}$ pint packet of lemon jelly in hot water, and pour about 2 tablespoonfuls of it into the bottom of a mould previously rinsed with cold water. Put the prunes, together with their liquor, into a saucepan, add 3 dessertspoonfuls sugar, 1 oz . candied peel cut into small pieces, and the grated rind of a lemon, and cook all gently until the fruit is tender. Take ont the prunes and stone them; boil up the syrup for a few minutes until it thickens, and then set it aside to cool.

In $\frac{1}{2}$ gill of it dissolve $\frac{1}{\frac{1}{2}} \mathrm{oz}$. leaf gelatine, put the prunes back into the remainder of the syrup, and add the atrained juice of a lemon, \% oz. blanched almonds cut up roughly, gill sherry, and the rest of the jelly. Strain in the gelatine, atir all tugether until they thicken, then colour the mixture with a few drops of cochineal and pour it into the mould. When it has set, turn it on to a dish, and with an icing bag force round its base 1 gill thickly whisked cream. sweetened and Havoured to taste. Sprinkle the cream with some pistachio nuts which have been blanched and chopped.

A prune and rice mould can be made by soaking \& lb . prunes as already described, and then putting them into a saucepan with the water in which they have been soaking. Add also a dessertspounful Demerara sugar and 1 oz . candied peel cut into small pieces, and cook them until the fruit is soft. Then take out the prunes, stone them, and boil the syrup rapidly for about 5 min . The candied peel may be left in the syrup or strained out. W'as', 3 nz . rice, put it in a saucepan with
$1 \frac{1}{2}$ pints milk and 2 dessertspoonfuls sugar, and conk it slowly until it has absorbed the milk. Then stir the prunes into it, turn the mixture into a wet mould, and leave it to set.
Prune Pie. A pie can be made from pruncs by preparing 1 lb as already deacribed and putting them in a deep pie-dish. Cover with a lid of short pastry and balie in a hot oven half an hour. Six oz pastry will be required.

Prune Pudding. To make a pudding with prunes they should tee stewed and then rubbed with a little of the syrup tlirough a fine sieve. Mix together $\& \mathrm{lb}$. Hour, the same quantity of breadcrumbs, a little less than 1 lb sugar, 4 oz. suet, a teaspoonful baking-powder, and a little salt. Form a well in the centre, and into this put a well-beaten egg, a brealifastcupful of the fruit pulp, and a little milk.
Mix these gradually, adding more milk if necessary, and then turn the whole into a greased basin. Cover it with a piece of greased paper, and steam the pudding for

Prune Pudding, a wholesome steamed pudding which might be served with hot custard
about 3 hours. Hot custard makes a good acoompuniment. See Batter; Custard; Pastry. PRUNELLA. This dwarf growing perennial, commonly known as self-heal, is suitable for carpeting bare ground. The hest form. Webbiana, has crimison-purple flowers.

## Directions for an Essential Gardening Operation

The gardening reader may be referred to such headings as Apple: Gooseberry : Pear: Plum : Rose. Sec also Disbudding: Grafting: Kitchen Garden : ctc.

Pruning is the process of cutting trees and with small, fairly wide tecth. A pruning hook bushes in such ways and at such times as will is useful for cutting high branches. help their productive qualitics. Pruning is chiefly enployed for trees and bushes that bear fruit and Howers.
Dealing with fruit trees, the objects of pruning are scveral. One is to form the tree, as trees are grown to certain forms for certain reasons, and these forma are secured by piuning. Another is to secure for all parts of the tree their due share of air and sunlight, so that they will perform their functions properly. Pruning is also necessary to induce fruiting and to improve the quality and quantity of the fruit ; to facilitate cultural functions, such as tillage, spraying, and finally gathering; and to remove dead and diseased fruit.

Knife and Other Tools. The pruner needa several tools. The first is a good knife, which he should keep thoroughly sharp, particularly towards the tip, of the blade. The reason for this is that long, slicing cuts, finished well through to the tip, are the sufest and best. Such cuts can be drawn boldly on to the thumb with the kcencst of edges on the knife without the slightest risk of injury, whereas short, jerky cuts are unsale. The knife is the best tool for use on small trees, hut for larger trees secateurs or pruning shears nay be used. especially if the pruner is working on a ladder, because he can steady and cut the shoot with one motion. For heavy pruning a saw is necessary. The beat is a tiny one with a blade not more than 5 in . long and an inch wide,

Pruning : some of the necessary tools. Top, strong folding knife for the amateur gardener. Centre, pruning shears. Bottom, pruning saw, which has a row of teath on each edge

Saw cuts and large wounds should be trimmed to smonthness with the knife and sealed over with whitc lead, oil paint, or carpenters' knotting.
Two Groups of Trees. To enable pruning to le done correctly some knowledge of the way in which trees and whrubs bear their flowers or fruits is essential Fruit trees and bushes fall naturally into two groups so far as their proning is concerned: those of one type produce fruits chiefly on spurs-short, sturily shoots which bear blosson buds; those of the other type yield the beat fruits on shoots or branches of the previous year's growth. The fruita of the spur-fraiting type are apple, pear. plum. sweet cherry, apricot, gooseherry, red and white currant and vino.
Briefly, the way to prune these fruit trees is to shorten the side shoots of the current season's growth in July or early August, and to cut them back still further in winter. At the latter season weakly and crowded branches must also be cut nut. Plum, gooseberry and apricot are most fruitful under is modified form of this treatment ; in the management of apricot and plum trees care should be taken to preserve pronising young shoots and to cut out parts of old branches to make room for them. The pruning of gooseberry bushes is done principally by thinning out the branches to such an extent that the hand can be passed between them, though the side shonts may he pruned in the orthodox way. luring the summer vine sinoots must he pruned; if this is not done it will liecome overcrowded and weakened.

Fruit tiees which bear chiefly on the branches of the previous year's growth are peach, nectarine, black currant, raspberry, loganberry, blackberry, and other allied berried fruits,

Pruning. 1. Comparison of \&ruit (a) and wood (b) bads. 2. Pruning cuts : $a$, correct, $b$, incorrect: snag left above eye : $c$, altogether wrong: $d$, cul too deep. 5. Principle of pruning busb apple. f. Pruanag a rose busb black parts to be cut away. 7. Pruning side shoots to encouraqe iruit spurs
-those which have still to develop-which will yield the flowers Familiar kinds which need this treatment are the rose, mauve bud dleia all varicties of clematis of the Jackman type, hydrangea paniculata (not the common hydrangea hortensis), hypericum or St. John's wort, late summer spiraeas and hardy fuchsia

There is atill another type of ornamental tree or shrub-that which needs no regular or systematic pruning. They inust be looked over oncasionally for the purpose of thinning out crowded branches or shortening straggling ones which spoil the symmetry of the hush These include flowering cherry, crab and plum, magnolia, rhorlolendron, azalen, viburnum or guelder rose, orange ball tree (Buddleia glohosa!. hawthorn and lahurnum

PRUNUS. This is the botanical name of one of the most important gmups of hardy flowering and fruiting trees It includes the almond, peach, nectarine, damson, aprical and plum. The common and Portugal laurels are also classed by the botanist as Prunus.

PRUSSIC ACID. Hydrucyanic or prussic acid is found in oil of bitter almonds, peach kernels, apple pips, cherry laurel leaves, and other vegetable products. When separated or prepared it occurs as a colourless liguid with a characteristic odour. Potassium and sodiun cyanide are used in the extraction of gald from ores and in photography

Prussic acid and the cyanides are extremely poisonous In poisoning by prussic acid there is rapid unconsciousness, but if there be time an cmetic of mustard and water should be given. An attempt should be made to rouse the patient by dashing cold water on the face and cheat, or cold and hut water alternately. Ammonia smelling salts shnuld be held to the nose, and warmth promoted by lont Hannels, hot-water bottles, and chafing the limbs. If breathing fails, artificial reapiration ahould be at once begun Stimulanta should be given when swallowing is possible See Artiticial Respiration: Poisoning.

PSITTACOSIS. Disease of parrots. is due to a filtrable virus and may be communicated to man. Even healthy birds may serve as carriers After a serious outbreak of the disease in 1929, in 1930 the import of parrots into Great Britain was forbidden

PSORIASIS. The skin disease known as panriasis is characterized by Hattish, dry patches of varying size covered with white or silvery-grey scales. The backs of the elbnws, the fronts of the knees, and the scalp are the favourite sites. but the trunk and other portions of the body ane not uncommonly involved as well. As a general rule the patient does not complain of symptoms beyond itching, and the patches can generally be made to disappear under treatment. Relapses are common, and the disease is subject to sudden increases in its rate of speed, If untreated this skin discase may last for many years.

The drugs used include arsenic, potassium iodide, thyroid extract, ctc. The first step in lucal trcalsnent is to scrub the patches with hot water and soff soap, or bathe them in warm olive oil. An ointment consisting of tar ointment, $2 \frac{1}{2}$ drams, and lanolin, enough to make I oz., is applied night and morning after the patches have been thoroughly clearod of scales. Another useful drug is resorcin, which may be used in an ointment composed of resorcin. 15 gr . ; lard, 1 oz . Pron. So-ri-as-is,

PSYCHO-ANAIYSIS. A method of investigating the subconacious part of the mind, which has proved of great value in the treatment of certain forms of neurotic disurders, is known as psycho-aralysis. The method was devised by the Viennese physician Prof. Sigmund Freud, and, with its applica. tions, has led to the development of a schnol of thought which recognizes the influence of
the aubconscious in a large number of menta prooesses

Speaking broadly, the paycho-analyat regards the mind as composed of two parta, the conscious, which appeara to control our thoughte and actions, and the aubennacious, which, without our heing aware of it, does in fact exercise a powerful intluence upnn our motives and conduct. The aubeonscious becomes the repository of painful memories and primitive tendencies which are described as being suppressed or repressed. and often date from early childhond

The exigencies of civilization and ancial life clearly demand a very considerable deцrec of inhibition of the primitivn instincts and impulses. Abnorinal tendencies present in infancy and childhond are by painful experience and education (in the bmadest senac) gradually eliminated from, or prevented from ever entering, the conacious part of the mind no normal growth and development procead

It is clear that very often the impulses to action of the conscious and subeonscious must be in direct opposition to each other. In the norinal individual these two parts are so adjusted that no conflict of which he is aurare arises. In the hysterical individual, however, the adjustment between the two parts of the mind has not been satisfactorily effected, and the result is the appearance of the various symploms which are characteristic of hysteria

The ultimate object of treatinent by prychoanalysis is to effect an adjustment between the conscious and subconscious, and thus bring about a resolution of the conflict which is responsible for the symptoms For thin purpose, by means of a special technique, the patient's immediate and free assnciations with eventa in his life which have had an ennotional cffect, slips of the tnngue, prrors in writing. etc., are nbtained, and furnish a clue to the underlying cause of the tmuble. In particular, dreams provide material of great value for investignting the subconscious

Litule by little under this treatment the patient comes to understand the warring mental processes which are going on within him : the aymptoms gradually disappear, and in favourable cases a complete cure can be effected. The patient who seeks relief by this method is advised to place himself only in the hande of a akilled physician

PTARMIGAN. A amall specien ot grouse tound in mountainous regions, the ptarmigan is alao known as the white grouse, because of the colour of its plumage in winter it needs to be well hung, and is cooked in the same way as ordinary grouse. Ptarmigan is best eaten young, otherwise it may be found to have rather a bitter flavour These birda make an excellent salmi and game pie See Game Pron. Tar-mi-gan.

PTERIS: The Fern. The bracken (Pteris aquilina) is the commoneat of all Rritish ferns and a familiar feature of the landscape in many parts of Great Britain, especially in wondland districts. It is acarcely suitable for planting in gardens of moderate cxtent. Bracken fronds provide useful material in winter for the protection of roses and tender shrubs. Several of the pteris ferns are admirable plants for the alightly heated greenhouse and room window : they are easily grown in pots in a compost of loam, leaf mould, and sand. Tremula, serrulata, serrulata cristata, cretica and cretica albo-lineata are some of the most attractive. They need a good deal of water in suminer hut inuch less in winter. They arc propagated by sowing apnres in pots of soil covercd with glass in the greenhouso.

PTOMAINE POISONING. By their action on animal and vegetable matter,
called ptomaincs, some of which are poisonous It would appear, however, that in the great majority of cases of food poisoning this is not duc to ptomaines, or to the producte of putrefactive organisms generally, but to discrse-producing bacteria and their toxins. A poisonous ptomaine may nccur in cheese pork. ice cream, and other commodities

Almost any kind of food may give rise to poianning. but some kinds are more dangerous than others. and should be eaten with caution in hot weather. These are veal and pork pies made from salale neat or kept some time after cooking. cold veal, pork, and badly cured ham, sausnges, mussels and othce shell-fish, mackerel, crab, canned fish, and contaminated ice cream To these may he added goose and veniaon kept ton long

Buth the liviny inicrobea and the chemica! aubatances they pruduce in the food may be puisnnous. The microhes are killed by thorough cooking, hut the poisonous substances within them may not be affected. Consequently conking is not always a protection

It should be remembered that cooked food is as liable to infection by microbes as raw food. Meal may be quite wholesome when first used and then, when put away in a dirly or ill-ventilated larder, it may become conlaminated. This very oflen occurs, poisoning being frequently caused by cold or re-heated meat that has been kepl some lime after cooking.
One of the great dangers arisea from the fact Chat the meat or fish may contain a fatal dose of prison without having any apperance o! odour or decay.

The symptoma may set in soon after a meal or be delayed for twelve hours, or even longer. The patient suffers from violent pains in the abdonnen, with nausea, vomiting, and purging. His pulse beata quickly; he has a severe headache, is very weak, and in a state of extreme nervous depression. There may be cramp in the calves of the legs, alcepiness. dizriness dimness of sight, difficulty in breathing, and finally collapse and death.

At the outset give an emetic of a tableapnon ful of mustard in $\frac{1}{2}$ pint of warm water. Follow this with a quickly acting purge, anch as a large dose of salts, 1 oz . of castor oil, or 5 gr . of calnmel For weakness give stimulants, and keep the patient warm with blankets and hot. water buttles. Any of the following stimulants may be used : whisky or brandy, in doses of 2 th 4 teaspuonfuls fre:puently repeated; sal volatile, a terspoonful in a little warm water: or hot, strong tea Pain may be relieved by hot prultices or flannely wrung out of loot water to the abdomen. When the patient recovers sufficiently to take food, it should consist at first of boiled milk only See Food: Poisoning.

PUBERTY. The critical age when the sexual functions become active is usually ic. ferred to as puberty. In Great Britain it occura in girls betweon the ages of thirteen and fifteen, but may be a year or two carlier or later in exceptional instances. In boys the average age of puberty is between fourteen

## and sixteen

Profound changes take place at this periud, and parents should exercise great care and watchfulness over their children's health. bodily, mental, anil moral. The physical and mental change is very sudden, and there is a great expenditure of energy on the quick development. It is not uncommon, therefore, to have signs of nervous diaturbance and exhaustion showing themselves at this. time There is a great increase in glandular activity, and the effect of this on the skin glands is a reason for the onset of acne at puberty. The whole outlook of life becomes altered, the feeling of sexual difference asserts itself, emotion deepens, and the bny or girl may
become very impressionable, selt conscious and perhaps shy and awkward in manner
Plenty of nourishing food and outfloot exercise and abundant time for sleep are essential. The following shows the minimum of sleep required as a rule :

13 ycars old
$10!$ hourn
Do not let a boy or girl be overworked in hody or mind If schonl-work seenis too much it should be cut down. With regard particn larly to girls, their management at the a ppear ance of menstruation (q. $\nabla$.) will influence their henlth for life
PUDDING. Puddings may be boiled. steamed, or baked, according to their in gredients. These made of suet are bniled or steamed, being wrapped in a scalded and lloured cloth, or turned into a greased basin and covered with a cluth or a piece of gronsed proper. Batter and custard puddinge, as well as those made with a covering of pastry, are baked in a deep dish. Ice puddings come into a different catcgory, as they are made by a freezing process

Pudding Cloth. The calicn cloths in whioh boiled puddings are cooked should be sprinkled with llour hefore use They need to be kept scmupulously clean, and after use any of the mixture adhering to the cloth should be scraped oif, the cloth washed in hot water to which a little soda has Lcen ndded, and, if ncopssary, boiled. Rinse it well to remove the sorda, and dry the cloth in the open air. No soap should be used either in washing or boil. ing. Cloths used for tying over the tops of puddinge cooked in basing are treated in the same way. See Apple, Batter: Beef Stenk Pudding; Cherry; Chestnut: Chocolato: (lhristmas Pudding; Cuconut: 1)ried Fruit: Gonseberry: Ice; Jam; Lemon; Macatoni: Dlarmalade ; Pastry ; Pineupple, etc

PUERPERAL FEVER. Quite shortly after labour a woman mily liecome feverish for a few hours, from some slight cause, or she may become seriously ill from septio infection of the womb or other neighbouring part. The name puerperal fever is popularly given to this condition.

Symptoms of infection may appent a few hours after the birth of the child, but most frequently the first symptoms manifest themselves about the third day. Fever is usually the first sign to attract attention ; it may be accompanied by a chill and headache Puer peral fever is a notifin ble disease and immediate inedical treatment is required.

PUFF PASTRY. The most delicate of all baked pastries is puff pastry. It is made with equal quantities of butier and Hour, a little lemon juice, water, salt. The method of mak. ing puff pastry is given in the article on Pastry sometimes an egg is ndded to the other ingredients to enrich the colour of the pastry, which requires a steady but brisk oven. See ['astry.
PUG: The Dog. The pug is a quiet ${ }_{1}$ clean, and affectionate dog. His strong attachment and faithfulness to his master or mistress, his docility and good behaviour, make him a very attractive homo companion, eapecially when it is not desirable to spend so much time over the dog's toilet as is requiwite for pets with long, silky coats. Short, thick, and rounded in body, with a smooth, short coat, the pug has well-developed hindquarters, straight, short logs, and a tightly curled tail. The head is rather large, with square, wrinkled face and a short black muzzle. The eyes are large and black; the small, silliy cars hang close to the head. Pugs were formerly all fawn-coluured, with a hlack line down the middle of the back,

Pug, a favourite variety oi short-haired toy dog
a black siot in the centre of the forchead and one on each check: the toenails were black. Thesc points are no longer insisted upon. There is now an entirely black race, and the fawns vary from silver grey to apricot colour The weight should be from 13 lb . to 17 lb . See Dog; Kennol.

PULLET. From the time when she enierges from chickenhoud until she becomes an adult the female fowl is known as a pullet. In the past a forl was considered a pullet from the day she was hatched until Jan. 1 in the vear following. lhut with the advance of egglaying properties, nud the institution of egg. laying competitions in which the birds are entered as pullets, it has become customaiy to speak of the number of egge a bird laid in her pullet year. To avoid confusion, a bird is con-
sidered a pullet until she has comipleted her first laying year, which is termed her pullet vear, though strictly speaking she became a hen on the previous Jan. 1. For exhibition purposes the old detinition remains, and a pullet becomes a hen on Jan 1 following her birth See Chicken; Fowl: Incubator; Poultry.

PULMONARIA. These hardy herbaccous plants of the borage family are suitable for the rock garden or border. The flowers of inost wf them are blue on opening and change to ruse colvur as thicy fade, and the leaves have white markings The common name is lungwort. The best suits are angustifolia, 12 in , arver nensis, 10 in ., and rubra, 12 in ., roddish. The Howers open in spring and early summer Propagation is by dividing the plants in autumn See Border: Rock Garden.

PUMICE. There are a number of uses for pumice It is employed in the form of a powdet in soaps and cleansing mixtures of many linds, and is also present in a number of polishing compositions. Pumice is chielly employed in the hoone lor clenning purposes. A small lump is rubbed on the fingers to remove stains and paint markings. The prowder. wrapped in a linen or muslin bag, ean be employed for rubbing down a painterl surface. especially if worked with a little water to act as a lubricant. In addition pumioe is employed as an ingredient in a certain liind of soap known as pumice soap.

Pumice stone is usually greyish white in colour, but can also be ubtained in gellow, brown and black. It is eapecially effectivo in removing obstinate ink stains from the lingers. and is also used to produce a gloss on un. polished marble, and for rubbing down-papier mâché articles bcfore painting them See Lubrication , Marble

## PUMPS FOR THE SUPPLY OF WATER

## A Household Necessity in Country Districts

This article is one of those that desl with the important subject of the water supply. Sce that entry: also Frost: Pipe: Rainwater: Ram: Well
In country districts, and also to some extent harrel, lifting the font valve that divides the in towns, households are dependent for their two. Then cones the down struke caused by supply of water, or at least for some part of the upward movement of the handle. the water it, upon a pump, which may be situated either below the bucket being trapped by the closing inside or outside the dwelling. Such pumps of the foot valve. This, therefore, forces are of two main kinds. The one more fre quently seen is known as a reciprocating pump; but the otlier, the chain pump, is also used. There are three main kinils of reciprocating pumps: bucket or lift pumps, piston or force pumps, and combined bucket and plunger pumps.
The principles of the buokot or lift pump are fairly simple. A buckot works in a barrel, being raised or lowered by the movement of a bandle. When the bucket is first raised a partial vacuum is creatod in that part of the barrel that is below it, and water rushes in through the suction pipe which is bensath the open a valve nearer the top of the barrel, or one in the bucket itself, and the water gets above the bucket. The bucket then rises again and carries with it the water above the upper valve, which is discharged through the mouth of the pump. Simultaneously, more water is sucked into the barrel through the lower valve Tho sequence s illustrated in Fig. 1. In Fig. 2 a typical lift pump is seen, the valves heing shown separatoly. The latter may valy in type, but the working principle is as above describerl.

The lift pump is useful for raising water from a well to the surface. and is recominended

Pump. Fir. 2. Bucket or lift pump. with valves shown separately. A, plunger, showing mushroom shown separately. A. plunker, showink mushroom
for suction liftes up to about 25 ft . Trouble associated with this pump is usually restricted to incorrect valve seating owing to the material used being perished or worn, or to a badly fitting plunger, also due to wear. New leathers can be had quite cheaply, so that it is not worth while to continue using defoctive ones. Where considerable pumping is required before water is drawn, indicative of faulty valves, the operation may be considerably quickened if a quantity of water is poured into the top of the pump before pumping is commenced.
Lift and Force Pumps. When, in addition to lifting water from a well, it is desired to force water into an elevated tank a combined lift and force
 puinp is used The pnttern illus. trated in Fig. 4 has an air chamber on the delivery side, and
is provided with a draw-off cock, permitting water to be obtained at the pump if desired. A hose may be attached to the nose of the cock. The principle of Pump. Fir. 3. Mechanism of the force pump is common type of lorce pump shown in Fig. 3, which illustrates what is known as a ram type, used for working agninst considerable pressurc.

An excellent pattern of force puinp is that known as a semi-rotary, illustrated in Fig. 5. The internal construction comprises a rocker or movable plate, which oscillates within a circular cast-iron casing. The water enters at the bottom, is forced to the upper side of the rocker through a simple flat valve, and then through the upper chamber into the delivery pipe, other valves serving to check the return of the water.
This type of pump is very ensy to work, n nd will lift water from a depth of 10 or 12 ft .
without the need of a holding-up valve. It will lift from greater depths if such a valve is fitted to the suction pipe. but no pump will lift more than ahout 27 ft. It can force water to a great height, depending largely upon the energy with which the handle is operated and the amount of friction in the pipes

Another good pump for domestic purposes, quite inexpensive, is the diaphragm pump shown in Fig. 6, which at 60 strokes per inin will deliver $4 \frac{1}{\text { gal, water per minute. With }}$ the addition of a foot valve and atrainer it will lift from 25 ft . and force water to a vertical height of 50 ft . In this class of pump a flexible diaphragm of leather or rubber replaces the piston or plunger.
Chain Pumps. The chain pump (illustrated in Fig. 7) consists of an endless chain, passing over a pulles which is driven by a crankshaft mounted in suitable bearings in a framework or casing situated over the well head The lower end of the chain should reach well below the surface of the water, which is raised when the crank is turned. The water clings to the rising chain and is flung off into the casing by centrifugal force as the chain passes over the pulley
The turn of the chain must be at least 2 ft . below the surface of the water in the well The spout should deliver the water over a barrel or into a shute or pipe, whence it can flow to any desired point. The only attention necessary is an occasional cleaning of the chain and irequent lubrication of the crankshaft bearings. This type of pump is specially adapted for lifting thick fluids, such as liquid manure, sewage, etc. Normally it is arranged for a depth of 12 ft helow the spout, but can be made for any depth not exceeding 25 ft . At 45 revs. per minute a 2 - in . pump will raise 650 gal per hour with a depth below spout of 12 ft .

Deep Well Pumps. In these the working barrel is located at or near the normal water level. The suction pipe projects down into the water, and terminates in a foot valve with a strainer to exclude dirt and other foreign mntter. The de ivery pipe extends to the well. head and thence to a cistern or storage tank. The pump is actuated by a well-rod made of wrought iron, or sometimes of wooa, which is guided by rollers in metal brackets fixed to the well.side, as in Fig. 8, or mounted on a central staging.

Fig. 7. Endless chain pump for thick liquids
Joscph Evans \& Sons. Led

Power Pumps.
The well.rod in the pump illustrated is worked by a whee and crank type of pump motion.

A deep well pump of a simpler kind is shown in Fig. 9 A branch for the delivery pipe is pro. vided 18 in helow ground level, and a draw off cock 3 ft ahove surface level This type is adnp. ted for wells up to 80 ft . dcep, and for delivery to an ele. vated tank about 20 ft . above the well top Asmaller pump has the lever inotion worl attached to a plank (Fig. 10), the working barrel-not illustrated - being fixed helow near water level and connected by iron rods with the motion

As a mule a pump for the domeatic supply is not required to wark continuously, and therefore a hand-operated apparatus which is employed for an hour or lesa per day usually suffices to fill the overhead cistern However, we give hrief particulars of a horizontal double acting power pump which can be driven by an oil engine.

The Petter pump shown in Fig. 11 is coupled to a paraffin-petrol engine of the type illustrated on page 633 , one rated at $1 \frac{1}{2}$ B.H.P. being used. Such an equipment will deliver ahout $3 \overline{5} 0 \mathrm{gal}$. water per hour under a total head (including friction) of 150 ft . Suction must not exceed 25 ft . A foot valve and strainer are supplied with the pump.

A mininture pumping plant is sometimes employed to operate a small fountain in the garden. An underground rain-water tank can be arranged as the snurce of aupply, the water from the fountain falling into an ornamental pool, whence the overflow drains back to the rainwater tank. A suitable plant might consist of a small centri. fugal pump operated by means of a $\ddagger$ horse power electric motor.

Useful Data. A pump in theory should lift water from a depth of about : 33 ft ., but owing to various causes the average pump will not work with a vertical suction of more than 27 ft ., reduced in the case of decp wells to about 20 ft .

In the case of some rotary and semi-rotary pumps the suction depth is much less. Factors governing the output of the reciprocating pump are the length of stroke and the inside diameter of the working barrel. Taking, for example, a single. acting pump with a 2 in.

Pump. $\underset{\text { wik. }}{\text { well }} \begin{aligned} & \text { 8. Saction of a deep } \\ & \text { force pump }\end{aligned}$
barrel and a 6 in stroke, operated by hand at 30 strokes per minute the apparatus should deliver about 120 gal water per hour This is the theoretical quantity from whichan allowance of from 10 p.c. must be made for slip. etc If the number of strokes per minute is in orensed or diminished theoutput will be correspondingly affected When the source of sup ply is at ground level, as in the case of a spring or stream, and a fall can be arranged, it is often possible to use a ranl (q.v.) to raise the water.

PUMP: For the Motor Car. Pumps of various types arc used in motor cars and motor cycles to inflate the tires and to circulate the oil in the engine and the water in the cooling system. The cylinder, piston connecting mod and crank of any internal combustion engine form a pump: the piston will draw air into the cylinder vin a valve on the down stroke and following this the air will be expelled on the up atroke
This is the principle adopted in the case of most mechanical pumps such as are used in garages, but the ondinary hand-operated tire inflator carried on the car consiats of a plunger on a rod working in a tubular cylinder. A thind type of pump consists of one or more vanes working in a disk eccentrically disposed in a

Fig. 8. Deep well pump, showing standard (left) and working barrel. Fir. 10. Smaller pump with lever motlon atfached to a plank Courtesy of Joseph Evans \& Sons, Led
circular chamber of a slightly larger diameter. so that as the disk and the vanes revolve in the chamber the space betwcen the vanes is constantly increasing and decreasing.

Oil Pumps. For circulating lubricant in an engine various applications of these principles are adopted. The plunger pump comprises a cam which is rotated by the engine and depresses a plunger (returned by a spring). oil being drawn in on the up stroke through a amall ball valve and delivered on the down stmke through a similar valve. In the gear pump two small gear wheels arc arranged within a casing which fits them fairly closely One gear wheel is on the end of a shaft usually driven from the camshaft by skew gears, and the other whec meshes with it. As the engine mtates, therefore, both the gear wheels turn also A hole in the pump casing admits oil, which fills up the spaces between the teeth on the gear wheels and is carried round by the he gourd an teeth to the other side of the casing There as larcely grown in Great Britain as in $\mathbf{N}$.

America Culture is the same
definite supply of oil only a little in excess of the actual amount required by the engine, as motor cycle engincs-except on some of the most modern types-do not carry a supply of oil in a sump. Those motor oycle engines, however, which have been designed to earry oil in the sump employ methods resembling those used in a car engina

Pumps for Water Circulation. Engines with water circulation on the thermo-siphon aystem do not require a pump, but in large and mediuns. sized cars $n$ centrifugal pump is used Con water from the bnttom of the radiator flows into the centre of the casing, and the vanes of the rotating member carry the water round with them so that the water is caused to flow thmugh the outlet pipe on the periphery of the casing to the cylinder jackets

PUMPKIN. The pumpkin is $\mathrm{a}_{\text {f }}$ fruiting plant of the Curcurbita fanily. to which the pourd and the marrow also becong it is not
as for narmws

Pumpkins, like marmws, have their uses in cookery. and can be made into soups. pies, and other dishes. They may also be served ns a vegetable, when they should be prepared according to the directions given for cooking marrow For soup making. old pumpkinsmay be used, but for all other purposes they should be young and tender.

Pumpkin Pie. This pie is made by cooking some thin slices of pumpkin in hoiling salted water and when tender, rubbing them through a sieve, Measure out 3 pint of the pulp. and to it add 3 well-beaten eggs, $\frac{8}{4}$ pint milk, $1 \frac{1}{2}$ terspoonfuls lemon-juice, and sugar and spice to taste

Mix these well, then turn a pipe is provided along which it is forced at them into a pie-dish lined with short-crust considerable pressure.

In the vane pump the shaft is eccentric to a circular casing. In a slot in the end of the shaft there slides $n$ vane consisting of two flat pieces of metal with small springs between them. As the shaft motates it forces the vane to turn within the casing, and accordingly the spaces betwcen the shaft, vane and casing alternately increase and decrease in size. A hole admits oil to the space which is increasing in size, and $n$ pipe conducts oil from the space that is decreasing in size. In most cars the oil pump is attached inside the crankease, projecting downwards into the sump. The pump is then sub. merged in oil, and there is no clance of its failing to begin work as soon as the engine is started When the pump is attached to the outside of the crankcase above the oil level it is usual to arrange the suction and delivery pipes en that when the engine stops the pump remains full of oil and is ready to start again. If a pump fails to work it may require priming, ie. filling with oil

On motor cycle engines similar principles are employed, but the oil-circulating pumps are usually run at a slower speed and are smaller. They are called upon to deliver a

Pump. Fig. 11. Self-contained power pump driven by a 1 : B B.P paraffin-petrol engine pastry, and bake the pie for about 40 min or until the pastry is golden-brown in colour and the filling of a firm appearance Serve it either hot or cold, and sprinkled witlı cnator sugar
Pumpkin Pudding. To make this dish take a pumpkin, 2 oz butter, $\frac{1}{2}$ pint milk, 2 or 3 eggs,

Courlesy of tha Autoeal

3 oz moist augar, $\downarrow$ teaspoonful powdered mace and a little grated nutmeg. Peel the pumpkin, remuve the seeds, and steam or boil it until it is soft. Drain the pulp well, pass it through a sicve and measure it. One pint is required for the quantities mentioned; if more or less is used they must be varied accordingly.

Beat in the butter and apices: add the sugar and the inilk, which should be made hot : beat (1) the jolks of the eggs and stir them in. Mix these all together, put them into a greased pie-diah and bake the mixture in a moderate oven for an hour or until it is firm when touched. Whip the whites of the egga to a stiff meringue, sweeten this to taste, favour it with vanilla and pour it over the pudding, which should then be put back in the oven to get brown and set. It can be served cither hot or cold See Gourd ; Marrow ; Pastry.

PUNCE : The Tool. In the domestic sense a puncli may be considered as any small wood or metal bar used for intervention between the hammer and the object to. be amitten The nail punch is a piece of mild steel bar. either hollow or flat at the small end, and slightly rounded at the upper end. This is applied to the head of the nail, and the upper end is struck with the hammer to drive the head of the nail below the surface of the wood, or in order to prevent the wood being bruised.

Punchics of various kinds are used for the perforation of leather The wad or saddler's punch has a hollow, tube-like cutting end, with the hollow carried upwards and increased in diameter at its mouth. A smart bluw with a hammer drives the punch through the material, leaving a clean, round hole. The part cut out is driven up into the hollow portion of the punch, succer ding cuts gradually forcing the dinks out at the mouth. Other small, hollow punches are used lur making reund holcs in leather. A hand-tool can be had with several punches of various sizes, and is used like a pair of pliers. Matting punches are made of ateel, and are used by wood and inctal workers for working up a diaper pattern. One end is shaped to produce the pattern, the other slightly rounded off. Soft punches are used by metal workers for many purposes.

A centre punch is for making an indentation on a metal surface (e.g. when starting to drill a hole). A similarly shaped punch with a sharp point is used for picring holes in corrugated iron. A bell centre punch has a conical shroud surrounding the point and is used for centreing the ends of cylindrical rods. Sjring actuated punches are made which need only a gentle prewure to operate the marking point. spacing punch has an ad. ditional or quide point which can be set at varying distances from the marking point.

Name or Ietter punches are employed for punching names or inonograms. Buttonhole punches are used by dressmakcrs and tailors for cutting cloth. Eyclet punches are used cyelets on sails and the sails and the
like. Pinking

Punch. Uuing a nail punob to drive the nail head below the surtace of the wood
punches are about 1 in in diameter and are employed for cutting soft malerial with a semated edge. Automatic, incchanically actuated minchea are made for cutting cardboard and paper for filing purposes Leather W'ork; Nail, Repoussé Work.
PUNCE: The Liquor. Five ingredients, lemon, sugar, apices, spirits, and water, are usually employed in brewing a bow! of punch. which was originally an Indian drink.

In making punch the juice of several lemons, together with one lemon cut into slices, is put with sugar intu boiling water, allowed to stand for half an hour then atrained into the bowl, and the spirits added, rum. biandy, gin, or whisky. with some grated nutmeg. The recipes vary, the quantities of cach ingredient required being more or les a matter of taste: the proportion of water to apitits may be 2 to 1 , or less. Rum and brandy may be mixedisometinen milk takea the place of water, or champagne is used instead of spirits. Elg punch is mnde by adding 4 eggs 10 each pint of whisky, brandy, and rum in equal proportions
Punch Jelly. Rum, sherry, and kirsch an used to Havaur this jelly. Put the thinly peeled rind of 2 lemons into a pan with $\frac{1}{2} \mathrm{lb}$ loaf augar and 1 pint water; boil the whole to a syrup, and then add It oz. leal gelatine, the atrained juice of the lemona, a wineglassful each of rum, sherry, and kirsch. and an inch atick of cinnamon. Iet the gelatine inelt slowly, then boil up the whole and add a cruslicd eggahell, toget her with the stiffly whisked white of an egg. Whisk the contents of the pan over a fire till they boil up, let them settle for a few minutes, and then atrain thein through a cloth until they arr clear Pour the jelly into a mould to set, and serve it in small glasses, with a teaspoonful of whipped, sweetened cream on top of each. decoratu:d with half a glacé cherry and atripa of angelica. See Mill: L’unch: Rum.

Punch Bowl. Very capacious punch buwls were at one time a recognizad art icle of house hold equipment. To-day when one is possersed it is sometimes used on Now Year'm Eve and other special occasions when punch is brewed. The briwla were usually of polished oak or other wood, plain or with ailver mountings. The bowls were also made of silver, and soine fine pieces date from the latter part of the 17th century, when they were introduced into England. A few existing specimens are of Sheffield platc, but this metal was not much used for them. They are sometimes provided with a ladle, inade of whalebone or wood, in the bowl of which a coin was inserted. The monteith, sometimes classed as a punch bowl, differs from the latter in that it is notched at the rim so that the glasses may hang by the foot down into the bowl. The rim could be removed when the glasses wore required for use.
lorcelnin was employed in making lighter and more delicate forms of punch bowl, and decorated vensels of this kind are atill made in Japan for ornamental purposes, and form an article of export. There are some annual cuatoma and ceremoniea at which a punch bowfilled with spiced ale is passed round.

PUNCTURE : Row to Mend. When a leakage occurs in a cycle or notor lire, it is well to make sure the valve is not at fault. A glass of water held up to the valve will reveal a leakage by the presence of air bubbles. If the valve passes the test, take out the inner
tube, attach the valve, and pinmp up again. If the leak is a bad one, it will be sufficient to run the hands over the tube to detect the atream of eacaping air If the leak is a mmall one, the inHated tube should be inmersed by 13 to 8 in. lengths in a bucket of water. Air bubblea will locate the puncture, and its position can be marked with an indelible pencil.
The patch had better be a prepared one, as sold with the puncture outfit. The surface ol the tube near the puncture shonuld be thor oughly cleancd with glass paper and a little petrol. The solution should be rubbed well into the surface of the tube on and round the place of puncture and on the patch until the two surfaces are tacky. The prepared surface of the patch is protected by linen, and shoulis] not be touched with the fingers after the linen han been removed. The patch sloulal be held firmly on to the tube until it is dry. In dealing with a large putcil care must be taken that air is not inl. prisoned between tube surface and

Punch Bowla in antique ailver. 1. Engraved bowl originally need an montelth; period of Jamea II. 2. Oneen Anne panch bawl with ombassed shield mank handlet and cantellated loose rim: maker
the patch. 'Jhis cun be avoided by first pressing the middle portion into contact and then slowly working down the remainder.

Plenty of time should be given to let the patch dry thoroughly, and it should be dusted with french chalk to dry the sticky edges. If the inner tube has punctured on the lim side and not on the tread side, the wheel sim should be carefully examined while the patch is drying. The puncture may have been caused by the nipping of the tube between the cdge of the cover and the rim, or by chafing on the spoke heads, which may not have been filed down properly, or the tape which protecis the tube from direct contact with the heads has slipped or worn through. Perhaps the tube is not the correct size for the cover, or it has not been propeily intated. The cover may be a bail fit on the rim, or the rubber may have perished

A common cause of punctures is nipping of tl.e inner tube, owing to lack of care in replacing it. The detlated tube should be placed inside the cover on the wheel, the cover having one free edge. Fit the valve and pump up the tube just sufficient to make it round. The cover can then le levered on the rim with little danger of the tulse being pinched. In any case, when the ec ver has teen finally placed on, the rim should br examined
all round, to make sure, before the tube is finally hlown up
Before replacing the tube, the inside of the cover should be carefully examined to locate the nail, scrap of flint, or other object that causell the puncture This may he hardly visible, but unless removed will caus trouble again Any conaiderable fash in the cover should te sealed up with one ol the patent compounds sold for the purposer See Motor Car Mntor Cycle. Tire: Valve
Purgative. See Aperi ent; Cathartic.

## PURLIN : Of a Roof

 The purlin is the horizontal member of the runf that supports the common rafters between the idgr and the wall plate The purlin is supported by the principal rafters, u hich nre the tol members of the truss of the ronf; the ends are supported by the "alls at the end of the huilding, or, in thin case of a hipped roof, they are framed to the hip limbers See House : Luft : Rouf.PURPLE CONE FLOWER. This is the popular name of a hardy herbaceous perennial, Echinacen purpuren, which grows $2-3 \mathrm{ft}$. high and benrs large reddish-purple finwers with a raised cone-like centre The newer varicties should the grown in preference to the old one; two of the beat are Taplow Crimson and The King, which have reddiah tlowers. Propagation is by division in autumn

PURSE. leather is the material princi pally employed in purse-making, pigskin in particular being favoured for men's purses hecause of its hard-wearing qualities Suelle purses, though attractive in appearance, are less durable Venetian lenther furses, orna mented with medieval designs in colours, are sometimes carried by women inside large purse bags Velvet. silk, and satin, elahotately beaded and embinidered, are also farourite materials for small parses to be used with inrious even ing dresses.

To make a brocade puise, as illustrated, cut out a circle of brocade 7 in. in diameter. and a circle of sill: or ot her lining of the saine size. Sew the two together neally around the cdge with a running Parse. Brocade pursa the gilk a running
being gashered to an ivory top stitch, then up and attach them to a bone or ivory pursetop Trim the inside, where the materin mects the frame, with a little rose-trinming or ribbon ruching. Bone, meta', and tortoise. shell purae-tops can he bought at drapery stores Sec Bag: Beads; leather.
PURSLANE. Puralane is an annual plant (Portulaca oleracea) grown for the value of its leaves as a summer salad. Seed must be sown early in April, the scedlings being thinned to 6 in apart. As soon as the shoots are about 3 in . in length they should be cut off close to the ground. If desired, a succession may be had until the late autumn See Calandrinin.

PUSH-PULL: In Wireless. This is a system of low-frequency magnification in

Which two similar output valves are coupled to a specia centre tapped secondary low-frequen oj transfor mer. The grids of the two valves are connected one to rach end of the second. ary winding and the centre puint
s juined to grid-hias negative. The anorle circuit crimprises an output tiansformer laving a centio-tapped primary winding This centretapping is connceted to ligh tension positive, and the two ends of the primary winding are joined respectively to the ro output valves The secondary winding of the out put translormer is connected to a loud speaker in the usua! way

In operation one valve deals with the positive half cycles of alteannting current, and the other valve with the negative half cjeles Thus two valver in push pull will handle ap proximately twice the grid swing of one similar value having the aame high tenaion voltage applied to its anode and connected in circuit in the normal manner. The method is advantagenus in cases where it is desired to deal with relatively large grid inputs on comparatively low high-tension voltages

PUSS MOTH. Thic arva of this moth is one of the most peculiar lound in the garden, the caterpillar bearing a curious resamblance to a kitten, whilst the parent moth ib covered with soft down The caterpillars hatch out from eggs de ןresited on the leaven of such trees as jop. lars and willows, feeding

Puss Moth upon them and gnawing the shoots. In duc course they form a cocoon, under cover of which the chrysalis stage is rached, from which they emerge as motlis during Juno The caterpillars shonld be picked off by hand and destroyed, or the trees sprayed with l'aris green was!
PUTLOG. On a builder's acafiold putlogs carry the boards that form the floor. They are filaced at right angles to the wall lint is being built, with one end resting on the ledger of the scaffold; the ollier end is let into a hole specially left in the wall to receive them

Putloga are about 5 ft . long and 3 in . square They are made usually of birch, and they are split and not cut, in order to obviate injuring the fibres of the wood, thus affording greater strength. The putlogs are as a rule placed about 4 ft . apart along the ledger See Scaffolding.

PUTTEES. Worn at times by men round the lega, puttees consist of long, narrow bands of material usually cut from woollen cloth, hut they may be specially woven fabric bands. They are warmer and more comfortable than leggings, and in addition they have the advantage of giving substantial support to the legs, thus acting as n preventive of varicose veins leing spirally wound from the ankle to just
below the knee, the leg is protected by at lenat a double, and mostly by a treble, thick. ness of the materinl, so that there is little danger of ecratches and othet iniuries heing auffered by the wearer They are. therefore, very suitable for farmers and others engaged on the land, and for thase who go out shooting and walking Thev are usually made in khaki molour, but navy blue ones are occasionally seen Great care and some skill are necespary in winding them round the leg, as, if lindly wound, they will look untidy.
To obtain a smart offect putices should be lirmly and closely wound, but this must not interfere with the circulation The method is that of ordinary bandnging, a reverse being made in the puitee whenever necessary sn that it may be llat to the shape of the leg. The uanal procedure is to begin at the inside of the ankle and wind upivard but the artillery method is to start below the kneecap and wind downward to the ankle

PUTTING: On the Lawn. Putting ean be practised on a lawn too small for croquet nr lawn tennia Apart from the land. the only requirements are a few balls and two or three putters

Putting resolyes itself into the playing ol two kinds of putte, a long appronch putt and a short putt, which drops the ball into the tin with a definite click. The approach putt involves two ideas : first, the imagination of the line to the hole, and the ability whit the ball alning the imagined line : and, secundly, judgement or instinot, horn of habit. of the strength necessary to make the ball traval firmity to a spot close to the hole The hall lies, say, 10 yd . or so away a putter is taken, and the linc of the putt inspected. It is vall not to muve either head or body until the putter is still and the stioke is quite finished.

The short putt is of a diflecent eharacter, and is apparently a simple businces which requires little more than confidence Many players see the ball and the hole, and, holding themscives quito stendy, tup the hall firmly yet smartly towards the back of the hole. and are successful

Making a Green. A golfer can obtain putting practice anif also a good deal of quiet reoreation on an ordinary lawn. One way of doing this is to make the hawn into a mininture golf course, say. one of nine holes. although any other number can be substituted Suitable holes can be minde in the ground and a small Hower-pot put in each, or, if preferred, a metnl cup can lie bought for the purpose
The holes should be dispused so na to give the greatest possible variely in the leneth and dircction of the atrokes One will he made as long as the ground will allow, and the otbers arranged to give putts. each shorter than the other. 'Jhe diagram offers a suggeation as to

Putting Green. Diagram showing how to lay out a lawn as a miniature roll course of nine holes
the laying out of the ground A simpler way of obtaining practico is to make a single hole in the lawn and to aim at this from various distances See Clock Golf: Golf, Midget.

PUTTY. As generally uscd in the liousehold, putty is the material known as glazier's putty, and is composed of whiting and linseed
 is The word plastering to rlescribe the fine stulf consisting of lime and water; it is also the name of a powder used in pulishing
glass and steel $S m a l l$ quantitics of glazier's putty can boob. tained from any oil shop or from an ironmonger :
but if a quanity is re quired, it is inore cono. mical to purchase a 7 lb keg; when not in use, the lid sbould bokept on tightly. It is sometimes advocated that the top be covered with a small quantity of linseed oil to provent the putty hardening.

Should putty when purchased be very soft and sticky, a very amall quantity of wbiting inay be added, by taking a lump of the putty in the left hand, sprinkling it with powdered whiting from the right hand, then ralling and knending the putty This process should be continued until the putty is an evon paste, perfectly fiee from lumps.

Whon putty is tho dry, the same operation is performed with linseed oil, which softens the material. Should it be ahort, or tend to crumble, it is an indication that it requires linseed oil, and the process can bo hastened by slightly warming the putty. In soine cases the putty may te prepared by placing a quantity on a clean board and beating it with heavy pieces of wood, one in cach hand, much as if heating up butter. Usually, however, the beat method is to knead the putty between the hands, as by this means its consistency can be judged When exposed to the air, putty gradually gets hard, until finally it becomes alinost as hard as soft stone.

A putty knife is a thin, broad bladerl knife with a word handle, the blade somewhat pointed at the end and more or losa jear shaped It isanindispensable thol for applying putty, stopping up small holes in wood. work prior to paint. ing, and for other purpuses. See Enainel: Glass: Line.
PUZZLE JUG. This name is given to a type of jug which has some unusual and unexpected feature. For instance some

Puzzle Jug. Quaintly fashioned jug in Wrotham slip ware British Mluseum
have a serics of hollow tuhes running round the ritn of the jug and through the handle The tubes contain the liquid, and the spouts, which project from the rim, are so arranged that the drinker will be drenched unless ho knows exactly which of the spouts to cover with his firgers and thumb.
These jugs have always a suggestion of rough humour about them, and many waro made for the use of ale houses Today they ale sought by collecturs. A few puzzle jugs were made in England in the 1 fith century Later they werc made in large numbers. especially by the Staffordshiro putters, but also at Leeds, Liverpual and Bristol. Some were imported from Holland They are often found with humorous inscriptions upon them

## Pyaemia. See lloond Poisoning

PYORRHOEA. Pyorrhoea is a discase commencing at the margin of the gum where this encircles the neck of the tooth. In the carly stages it may be recognized by a redness of the gum margin, and a tendency to bleed when rubbod, eg. with a toothbrush It is caused by stagnation of secretions, which barbour multitudes of microbes.
The natural method of preventing the discase is to eat or masticate the foods which neccasitate or stimulate mastication, and which rub, cleanse, and promote movement in the secretions surrounding the necks of the tenth. The foods which do this most effectually arc senerally of a somewhat fibrous nature, such as meat, fish, and particularly uncooked vegetablcs. The mastication of fresh fruit alan is very suitable for preventing the stagnation of matter around the necks of the teeth, and the type of fruit which is most useful is such as is of a firm consistency, and sumewhat acid or tart, such as apples.

Artilicial incthods follow the same principles. A toothbrush is generally used to supply the friction necessary to keep the necks of the tecth clean, and should be used with an up and down motion, rather than across the tecth. As the toothbrush cannot be forced between the tecth very far without injury to the gum, a mouth wash of a slightly acid nature should be used to rinse the inouth, and this should be done fairly vigorously. A pinch of cream of tartar to ahout a wineglassful of water may be used. The importance of preventive mcasures may further be emphasized by recognizing that as ago relvances the predisposition to the disease increases See Tecth.

PYRACANTHA, This is a favourite evergreen shrub which bears white hawthorn-like flowers in spring and red or yellow fruits in autumn. It will thrive in the open, but is more commonly planted against house walls, whore it forms a decorative covering in spring and autumn, and is pleasant to look upon al the year round: the common kind is Pyracantha coccinea ithe firethorn), which beare red fruita: the variety Lalandii has orange red fruits, while those of angustifolia and rogersiana are orange yellor.

Pruning, which should be done in winter or early spring, takes the form of thinning out crowded or weakly branches, or if the shrub is on a wall of keeping it within bounds. Propagation is by sowing seeds out of doors is soon as they are ripe.

PYRAMIDS: The Game. The gamo called pyramids is played on a tilliard table with 15 coloured balle, usually red, and the white ball which is used as the striking ball The coloured balls are arranged in the form of an equilateral trianglo, and the object of the players is to atrike one of them with the white ball in such a manner as to pocket a coloured ball, points being seored accurdingly. The balls ued in pyramida are slightly smaller than ordinary billiard balls

Pyramids is usually played by two persons, but it can be played by four, or by any other convenient number forming sides. It is a game of winning hazards exclusively, cannons being ignored

When the 15 red balls are placed on the table, practically everything, between players of appuoximately equal skill, who strike a good winning liazard, depends on getting an opening for a break. Safety play is so greatly the deciding factor that first-class plavers often

Pyrethrum, the variety B. Roblngon. See below.
make stroke after stroke without the least intention of pucketing a ball. But when at last the desired opportunity does present itnelf, 4 or 5 balls are almost sure to vanish, and it is by no nean unusual to see a break of 8 balla made, which ends the game at once.

Shell-Out. It is different when playing shell-out, a game often confused with pyramids. because it is played with the same number of balls and points are scored in the same way. But there is the important difference that sliell-out is a round game for a number of players, whereas pyramids is a game between two players. When playing shell-out, a man draws a stake fiom each of the other players for evory red ball he can pocket, and it is consequently the game to concentrate on every possible chance of taking a ball. The trouble is that while safety may close the game up for the next player, it is lung odds againat a bout of safety lasting until a man has another chance at the balls, a circumatance which makes sufety the exception rather than the rule when playing shell out. See Billiards.

PYRETHRUM. The most valuable planta in this group are the Horist's varieties of Pyrethrum ruseum, which grow from 18 to 24 in . high and bear single and double long. stemmed flowers in rose, crimson, blush and other colours in May and Junc. They are hardy herbaceous perennials which thrive best in well-drained soil. The way to propagate the plants is by lifting and dividing the clumpsas soon as they have finished flowering.

Seeds may also be sown under glass in oz of developer. Forunderspring, the seedlings being grown on a re- expusures take 1 part of serve border in summer and planted finally in $\mathrm{A}, 1 \frac{1}{2}-2$ parts of B , and add autumn. There are numerous named varieties. The noon daisy (pyrethrum or chrysanthe. mum) uliginosum grows 5 ft . high and bears largo white daisy-like flowers in late summer. It flourishes in ordinary soil, even on a shady border, and is increased by division in antumn. Pyrcthrum aureum is the well known golden feather sometimes used as an edging to flower beds ; it is raised from seeds sown in a heated glasshouse in spring. See Border: Carpet Bedding: also illus. p. 1022.

PYRIDINE. It is believed that the benefits derived in asthma from burning various fumigatory powders are due to pyridine. For use in asthma pour a dram on a plate and allow it to evaporate in a small room in which the patient remains for half an hour.
Pyridine is used with soap as an insecticida. Leaflet No. 330 of the Ministry of Agriculture gives the following formula for the treatment of apple aphis:

Pyrldine
Soap (soft)
402.
116.

10 cma.
See Asthma : Insecticide: Nicotine
PYRO or PYROGALLOL. Often, but wrongly. known as pyrogallic acid, pyro, as it is known to photographers, is more widely used than any other devcloper. Mixed with an alkaline substance or another developing agent, it produces negatives of fine quality, showing the characteristic yellow stain of pyro, which, however, often improves the printing value, especially of thin negatives.
Dissolved in water, pyro quickly oxidizes the solution, turning dark brown and losing activity as a developer accordingly. It is best kept in strong solutions containing an acidifying agent, potassium or sodium metabisulphite being added, when it will keep for several months. Pyro is sold in two forms, compact crystals and light feathery crystals, easily soluble in water. It is very poisonous, and must bo kept in well. corked bottles.
Pyro is never used alone, but combined with an alkali, sodiu $m$ carbonate or caustic soda, or another developing agent. In making up any formula the quantity of pyro in grains per ounce of developer mixed ready for use gives a useful indication of the strength of the developer. When weak, pyro brings out the first details in a negative quickly, but requires a comparatively long time to build up proper density: when strong, the image appears slowly, but density is rapidly gained, so that development is complete soon after the image appears.
Following are formulae for standard pyro combinations :

For normal use lake 10 minims $A$, 10 minims $B, 5$ minims $C$, and 1 oz . water.
A. Pyro .. Pyro-Caubtic Soda

Sodium sulphitc, 1 oz. (or $1 \frac{0}{1} 07$. .) Water
.110 gr. io 10 ör B. Caustic boda .. .. .. .. .. .. 35 gr . Water io 10 oz .
For use take 1 oz. of $A$ and $B$ and 102 of water. This is a quick acting and very economical developer.
A. Pyro

Metol
Potassium metabisulphite
Potasslum bromide
Water
B. Sodlum carbonate, crystal. Water
and B. This will contain 2 gr . of pyrs, to the

A, $1 \frac{1}{2}-2$ parts of $B$, and add
2 parts of water. T'his developer combines the characteristics of strong pyro and metol, and gives hoth detail and density quickly, the negatives being slightly greenish black. It is a good and reliable developer for the snapshot photographer.

The Watkins' develop. ment factor for pyro varies with the number of grains per o7. For the pyro-metol formula given above it is 9 . See Developing: Photo. graphy ; Pyro-Soda.

## PYRO-SODA. The

 must commonly employed of pyro developers, and perhaps the most economical of all photographic developers, is pyro-soda. this decorative shrab When used without potassium bromide re. strainer, which is quite unnecessary, it gives brownish or greenish black negatives of very good printing value, without the risk of fogging.

Pyro-soda is so called because the alkali which it contains is carbonate of soda, though ordinary washing soda is liable to contain impurities, and the photographic quality should be obtained. There are many pyro-soda formulae differing principally in the proportions of the preservative and alkali, but that which follows will mect the amatcur's requirements. The developer is always made up as two stock solutions, which are mixed and diluted when required for use. One contains the pyro with preservative, and the socond the alkali. First make up the following : Ten per Cent Pyro Stock Solution

> Pyro iü inetabisulphite Potassium

10 Oz
Water .. inetablsulphite .. .. $\quad$ io.$_{0} 20$ gr.
A half-pint stoppered bottle is required. The water is boiled briskly to get rid of dissolved air, which would cause oxidization of the pyro, and allowed to stand until cool without being disturbed. Crush the metabisulphite, the preservative, and dissolve it in the water. Pour it carefully into the $\frac{1}{2}$ pint bottle, add the pyro, and leave it to dissulve, the bottle being kept atoppered. Do not shake the bottle, or oxygen will be reabsorbed. This solution will contain almost exactly 10 per cent by weight of solid pyro. That is, every 10 minims of solution will contain 1 gr . of pyro. Made up exactly as described, it should keep for two years or more.

No. 2 Alkali Stock Solution
Sodium carbonato
802.

Sodlum sulphite
8
to 40
The carbonate and sulphite are dissolved in about 1 pint of hot water, which has boiled for some time, and the total made up to 40 oz . Keep it in a large corked bottle; a glass stopper is liable to stick on account of crystallization in the neck. It should keep for about a year. For use make up in the following proportions: Pyro-Soda Developer
10 p.c. stock pyro solution, 20 minims (or dropes) No. 2 soluthon
(or Uropes)
$\cdots \quad 102$.
Water
to 1 "
This developer will then contain 2 gr . of pyro per tluid oz., and will be suitable for practically any plate or film. For tank development 20 ninims of the 10 per cent solution and 1 oz . of No 2 may be used for each 4 oz . of developer, then containing $\frac{1}{8} \mathrm{gr}$. of pyro per oz. When pyro is used for tank development it is essential to pour off the whole developer from the tank and return it once or twice to avoid uneven development. Merely shaking or tilting the tank is not sufficient.

The Watkins' development factor for pyrosalmon, red and bluish.

(D)behind for the cighth returning. repeat this figure. however, it may be planted. The way to induce it to blossom freely is to prune the side shoots in summer and again in winter. There are several named varieties. In a favourable summer Pyrus japonica bears large quince-like fruits which do not ripen, but may be used to make an excellent jelly. In recent years a new race of Japanese quinces, called Cydonia Maulei, has become popular: there are many varioties with flowers in UADRILLE: The Dance. In quadrilles the set is composed of 4 couples, who form a square, each couple facing the centre, the men standing on the left of their partners. In the first figure, the leading couple and their vis-a-vis start by crossing over and returning. In each case 7 walking steps are used and the left foot is brought up

This movement is called half right and left. because each dancer passes on the right-hand side of the first person met in crossing and the left-hand side of his own partner. They cross and return to the first 8 bars : setting to partners in the next 8 bars. This is passing on the right-hand-side, using 3 steps forward and the left forst brought behind and 3 steps back, bringing the right foot up to the left to finish, giving the right hand to partner and

Then comes the ladies' chain, in which the women cross giving the right hand to each other and the left hand to the opposite men and the same back to place, while the men move round behind their partners giving the opposite woman the left hand and repeating the same movement to meet their own partners when they promenade holding hands, over to the place of their vis-d-vis, then return and perform half right and left to finish. There are 16 bars of music. The side couples now

In the second figure, the woman of the leading couple, and the man of the vis-a-vis, advance and retire, using 3 steps and the forst brought behind, and then move to right and left, cross to each other's place, advance and retire. This is danced in 16 bars. Then all return to place, set to partners, and turn in 8 bars. This movement is repoated by the other couple, each woman dancing with the partner of the opposite woman.

The woman of the leading couplo and the opposite man change places in the third figure, giving the right hand, and return, giving the left to each other and then tho right to their partners, so that the 4 dancers form a chain. They take a step forward together and one back, do this twice, then cross over to the

गpposite couplea' place The two people who started the figure advance and retire twice giving the nearest hund to their respective partners. All 4 advance and retire and then icft and right tu places. This is danced in 32 bars The figure is repeated in the same order 38 the preceding one.
In the fourth figure, alao 32 bara, the leading couple advance and retire again advanion and thewoman remaina on the left of the man of the op prsite couple. while hes bartner re. turns tu place The 3 advance from the other sideand retire, then cross over, give hands round, cross to their original places and half right and left to inish. The side couples then repeat the figure.
The fifth figure starts withell 4 couples join-
 ing hands.

Quaman. Bulb of the lily fa mily with blue or white flowera
and huttom couples pimmenade to each other's places and turn. These two movements are performed in 16 bars Then the ladies' chain follows for 8 bara and final promenade th places and turn for another 8. This figure is irpeated, being started by each of the four couples in turn and sometimes again by cach of the couples.

Another form of this danco is known an the Caledonian quadrille. In this the set is $;$ iom. posed in exactly the same way as in the ordinary quadrille and there are 5 figures. The chief difference between the two is that reel time is used throughout the Caledonian quadrille. The finst figure is danced in the asme way as in the quadrille, but there are slight differences as regards the others. The finale of the dance is a promenade all mund. See Lancers: Reel.

Quaigh. Shallow Righland drinling oug in wood with two handlea
QUAIGR. The Highland drinking cup known as a quaigh or quaich was rarely seen south of the Grampians until towards the close of the 17th century. It is in the form of a shallow bowl of oak or other wood, with two small oars or handles, and usually without ornamentation, being one of the simpleat of drinking vessels and probably of very ancient origin. It was alsu made in pewter and horn, and some were of silver, but the earlier quaighs were all carved from blocks of wond and made with ataver and houps.

In the 18th century the quaigh found its way to the lowland houses, and was embellished with silver mountings. Other uses werw found for it, and quaighs were utilized as alms dishes and served in some Scottish churches as communion cups.

Quail. These hiris may be cooked in the same ways as pigerons See Pigeon

See Grass.
QUAMASE. This is A hardy bulb belonging tos the lily family. It gmiva fmen 12 t.1 24 in . high and bear apikes of white or blue Howers in May and June. They thrive in urdinary well tilled suil and shiuble be planted in :utumn about $\overline{\mathrm{z}} \mathrm{in}$. deep. The bolanical natne of fllamash is Camastin. The chiel species ane esculenta, bluc and its white valisty leitchlinii, Cusickii, pisle blue and Fruseri, palc blue. I'ropagation is by offsets taken off in autumn or in carly apring or by sce-ts sown as soon as ripe in boxes of soil in a frame.

QUARANTINE. The period during which a ship on which an infectious discase has occurred is kept out of port, or, at any
rate, from free personal communication with the ahore, is callel the quarantine periol. The word quarantine has, however, also come to menn the period of isolation of persons suffering or convaleacing from an infectious disease, and of others who have been in contact with such perauns wherever they may be.
'I'he question of quarantine. in the general experience, mostly arises in comnexion with the attendance of children at school. In the table herewith the dates at which a convalea cent or contact may return to sehoos are duly set out, but children who have actually been ill will probably require a little holiday beforr going back to school.
