The date from which the quarantine of eontarts is to be calculated is that of the last expmasure to infection. A rertificate of litness (w) attend school should be got from a donetor. both for patients and contacts. Mort of the above particulars do not apply to adulte. See Infectious Disease.

Quarantine for Dogs. Nudog can he landed in Creat Britain without a licence, which muat be obtained from the Ministry of Agriculture, 4 Whitehall Ilace, Iondon. S.iV. When landed, the dog must go into quarantinc, that is, it must be detained and isolated for $n$ perind of six months from the date of landing on the premises of a veterinary surgenn.

Thi following premises, which can accommodate large numbers of doga, have been approved by the Ministry for the reception of all classes of imported dogs :

1. J. Braln, M.R.C.V.S., 5, St. Licurge's 'Turpace Cheltenham.
F. Brodley, M.R.C.V.S., Keka Dum, Hesald Hull. . S. Brooksliznka, M.R.C.C.S., 18, ('ouper stmet Buington, Manchestir.
W. Burt, M.R.C.V.s., 2, Eilward strent, Brluhtom Potton, Berls.

The owner or importer of the dog at the time of inportation muat pruville the manager of the quarantinc atation at which the dog is detained with a permanent address at which any neceasury commonications will at all times reach hirn

Severe penaltiea are inflictel upon persons who bring dngg into the country, by aeroplane or otherwise, in urler to avoid sending them to a quarantine atation. See I)ug.

QUARRY. This name is given to a square or lozenge-shaped piece of glass sometimes set in leaded lights. Quarries are painted with figures or patterns and inserted in otherwise plain lights. They are also seen as plain squares set diagonally in 15 th-century church windows to divide panels or roundels painted with pictorial subjects. See Staineđ Glass.

Quart. This measure is used for milk, beer, and other liquids. It consists of two pints ; and four quarts make n gallon.

QUARTER : The Measure. This measure or weight is the fourth part or quarter of a hundredwcight, containing therefore 28 lb or 2 stone. As a measure of capacity, used for grain, etc., the quarter contains is bushcls. From it has aprung the words quart and quartern, used in measuring food and drink. See Avoindupois Weight.

QUARTER : Of Meat. This word is used for the parta of a beast when it is cut up for luman ford the idea being that it is quartered or divided into four. The parts are known from their position on the animal as the fore quarters and the hindquarters. Sce Beef Carving ; Joint; Lamb: Mutton.

QUARTER DAY، Quarter days are clays on which are due the rents of houses taken by the quarter and certain other payments. In Eingland, Wales and Ireland they are March 25 (Lady Day) June 2.1 (Midsummer Day), September 29 (Michaelmiss Day), and Decem her 25 (Christmas Day). In Scotland they are l'eb. 2, May 15, Aug. 1, and Nov. 11. Sec Rent

QUARTERING: In Woodwork. Quar. tering as a furm of decoration in woodwork consists of the division of a surface into 4 parts, the grain of each portion running in a dircction contrary to that ne.rt to it. Its most general use is in furniture, as a decuration for panels. table topy and other llat surfaces See Grain ing; Oak; Veneer.
Quartering : Of Timber. This term applicd to timber means timber baving scantlinge from 2 in syuare up to 6 in . squarc.

QUARTERN LOAF. A loaf of bread weighing 4 lb ., which is known as a quartern loaf, is not a fancy bread, but a household quality, and inust be sold by weight. In making a batch of bread the dough for each loaf should be weighed olf before baking. or it will be impussib!e to obtain equal-sized luaves See Bread.

QUASSIA. The wood of the quassia tree in thic furm of chips is ased both as a tonic in medicine and in gardening to destroy insects. The chiel medical preparations are infusion of quassia, dose $\frac{1}{2}$ to 1 fluid oz, concentrated solution of quassia, and tincture of quassia \& to I Huid dram. Quassia is frequently combined with iron in bitter tonics prescribed for anaemia and delility The infusion is often made at home by letting the chips stand overnight in cold water, or by leaving water in a bowl made of quassia woorl. The action of quassia is mainly in the mouth. where it stimulates the gustatory nerves; the gastric vessels are reflexly stimu!ated, with the result that the gastric juice pours out. 'This secretion is temporarily diminished when the bittes saliva itself passes into the stomach. It is sunctines empluyed to kill threadworms, \& to $\frac{1}{2}$ pint of it being injected int, the rectum

Garden Uses. In the garden quassia is uscful for clearing gooseberry or currant bushes of caterpillars in spring. The chips are boiled in the proportion of 1 oz to a quart of water; a similar quantity of soft soap is added, and the bushes are sprayed with the mixture thus obtained. See Insecticide: Spraying.

QUARTREFOIL. The quartrefoil is a conventional treatment of a llower form with four lobes which is employed in stone and wood carving, and is a common feature of Gothic ornament Like the trefoil and the cinque. foil, it is based on a geometrical construction. See Stone; Wooldcarving
Queen Anne Style : Decoration \& Furniture

## The Graceful Elegance of the Walnut Period

> Pieces of furniture made in this style are referred to in a number of articles in our work. The reader may therefore consult suchentries as Chair: Drawing Room; Sercen Settee: Tapestry. Sce also Furniture: Lacquer: Marquetry: Mirror: Silver: and the articles on the immediately prece Jing und subsequent period styles, William and Mary: Georgian

In England the end of the 17 th and begin the walls and had thick sash bars. The win ning of the 18th century were marked by a period of great beauty in furnishing and interior decoration. At the end of the reign of Charles II walnut had superseded oals for finer pieces; by the time of Queen Anne the age of oak had practically finished except for strictly useful and farmhouse furniture. In the main her period was distinguished from those of the Restoration and of William and Mary by greater comfort and less stateliness, by elegance and grace rather than opulence of ornainent and the grandeur which made the best furniture of the preceding periods only suitable for the homes of the magnificent.
Queen Anne furniture is also simpler than that of the Georgian styles, including Chippendale, which followed. It is this simplicity of line combined with exquisite beauty of work. manship, the lovely use of colour in lacquer and needleworl, omamental china and ntirrors, impoted Oriental carpets and rugs, which inade her perind style at once compaob and homely and yet richly varied. It was open to Easlern artistic influence and the comforts which commercial overseas trade were making more generally possible.
The architecture also underwent a change, largely brought about an the result of fresh ideas from Holland during the previnus reign moulded and reproduced by wnch distinguished men as Sir Christopher Wren and Sir John Vanbrugh. The last named was responsible for the most famous house of the period, Blenheim Palace. Dutch architects also did much work in the royal palaces and had a great influence on Queen Anne style in build. ing, as also had the carvings of Grinling Libbons on the interior decoration.
The smaller houses were of brick, and built for the most part on rectangular plans The shaping of the gables with scrolled outlines was one of the most characteristic Dutch features. The winduw frames were llush with
the walls and had thick sash bars. The windows had comparatively amall panes. The hoorl or perliment, and flanked by futed colunns. while hlacli and white marble was userl for the curverl steps.

Interior Decoration. As the principal ruoms of the house became co-ordinated in design, the
upper and lower parts of the chimney prece were designed to harmonize as a whole instead of as separate features. Internal doorways were made decorative by the introduction of boldly moulded architraves and pediments Carving was employed in the decoration of mouldings on the panels, but was on the whole sparingly used and with good effect.

A beautiful drawing room or parlour of this period style is illustrated in trig. 1 The panels are 3 ft . wide and reach fom dado to cornice. The dado shows a projecting moulding running all round the room, while the pancl mouldings are enriched with carving and pediments, the detail of which forms part of a co-ordinated scheme enhancing also the fireplace and the door (not seen in illustration). Over the fireplace is a picture let into a panel arranged for its reception. Swags of carved fruit and foliage surmount it. pilasters are employed at either side.

Bolection moulding is characteristic of this style. Up to this time it had been usual for the pranels of a room to be recessed below the level of the stiles and muntins which surmund them, the intervening moulding being practically an elaboration or agreeable modification of the square section of the edge of the board. But the bolection moulding became a feature in itself and projected in front of both panel and stile.

Walnut was employed in some cases for panclling, but less expensive was the pine panelling, which was usually painted cream or light green. Occasionally it was lacquered and painted in Chinesc or Indian style with coloured decorations and raised and gilded portions on the panel designs.

Wallpapers were imported from China and a few were manufactured in England with hand-blocked and part stencilled designs showing Oriental influence, but these were rare, and the most general form of interior decoration was painted panelling.

The plaster ceiling of a Queen Anne room was "sually panelled out in a large way in conformity with the walls. The mouldings would he prominent, and the decorative enrichment, although bolll, wou!d be contined to suitable positions and not scattered indis. criminately. The floor would be of oali boards

Queen Anne Style. Fig. 1. Drawing room or parlour decorated in typical Queen Anne style, with large panels surrounded by broad raised moulding enriched by carving. The chimney piece bas a panelled picture and pilasters, and the carpet is Oriental

Courlesti of lVifle Allom \& Co
or parquet The fire basket grate for burning coal was speedily ousting the open heartls for logs.
Typleal Furniture. Domestic furniture of the Queen Anne period was chiefly of walnut, although heantiful pieces are existent made of other fruit woorls such as pear, plum and apple, and much fine work was lacquered, especially cabinets and chairs. Oak, cliestnut, cedar, and other woods were used for constructional or foundntion work, and walnut for the outer parts of the pieces. The bulk of this walnut furniture was veneered, probably as much upon deal as upon oak, although naturally the existing pieces are mainly the oak ones

Queen anne Style. Fir. 2. Cbair covered in retit point needlework and having cabriole legs with club feet Courtesy of M. Harris of Sons walnut, acacia, olive-wood, and laburnum side tables, however, are in existence. enloyed, and finely grained walnut loga were set aside for oyster grain veneer. in Fig. 4. This knee-hole dressing-table is furniture does not rely on ornament, but on exal like the knee-hole writhetable the perfection of grain, line, and proportion. The be noted as they are typical of Queen Anne varnish used cannot be initated by the acid style. Bureaux of the hureau-bookcsse type bleaching preparations employed to simulate the effect of period walnut

Inlaying and marquetry were as nuch used in Queen Anne's time as they were in that of William and Mary, and this is a feature of many picces in those styles. Cross-banding, featheredging, and herringboning were used upon bureaux, chesta, and grandfather clocks. A characteristic feature of the marquetry of the time was its enclosure in panels outlined by parts of circles, and frequently combined with oblongs having rounded ends The grounds of these panels were of wood differently coloured from that of the rest of the piece. The escalloped shell is a characteristic detail of the period It is shown above the panels in Fig. 1 and also on the chair decorated in lacquer work, Fig. 3.

The general lines of furniture became curvilinear instead of vertical and horizontal, and the cabriole leg was now first introduced and reached the form in which it was standardized for the next 50 years, with variations in knee ornaments of shells and acanthus leaves, and in scroll, club, hoof, claw, and claw and ball feet. Stretchers disappeared from chaira and settees during Queen Anne's reign and reappeared in some of Chippendale's pieces, expecially in the Chincse style.

Queen Anne chairs, settees, and stools had upholstered sents. Moreen was employed as an upholstering fabric, velvets and brocade sometimes, but the bulk of these pieces for parlour use were covered in needlework. Cross-stitch and petit and gros point were employed in coloured wools on canvas. A winged or grandfather work is shown in Fig. 2.

Some of the chnirs were marle with pierced, scrolled, deep rails, and with turned or scrolled legs; while others, more typical of the period, were without the piercing and scrolling, but had hoop and splat backis Settees in the form of two linked chairs were also products of Queen Anne's day. The broken pediment and also the lunette or semi. circular shapen pediment observed in architecture were scen in mirror frames, bureaux, and china cabinets.

Drcasera on cabriole legs replaced the heavier ones of thic 17 th century ; sideboards and large dining.tables

A representative piece of furniture is shown exactly like the knee-hole writing-table of the
period in construction. The handles should Courtestl of Countru Life and Gill \& lleigate. Lid
style chair covered were made in great variety and also double in beautiful needle. chests of drawers or tallboys. Built-in cup-

baking-powder and mixed with the grated rind of a lemon, \& lb clean currants and $1 \& \frac{\mathrm{oz}}{2}$ candied peel, all cut into small pieces. Turn tho mixturo into some sinall greased fancy cake tins and bake the caker in a hot oven for 20 min
QUEEN LILY. Three species of the queen lily. phaedranassa, a S. American half-hardy bulbous plant, may be grown in Great Britain in a warm sheltered border out of doors, or in the greenhousc. Some of the best arc the scarlet ventricosa, vermilion-shaded schizantha. and yellow chloracea.

QUEEN OF THE PRAIRIE. This is a herbaceous species of meadow sweet botanically named Spirea lobata, about 4 ft . high, producing heads of rosy carmine Howers in June it should be planted in a shady, moist torder during autumn

QUEEN POST. In building, this name is given to two posts in a roof truss used for supporting a large roof with a span of from 30 to 45 ft It is not so generally employed as the shorter king post truss, but is suitable for a small roof with a Inntern light.

The roof truss comprises at least 9 elements. The horizontal member, called the tie beam, reaches from onc side of the building to the other, and rests on the walls. The queen posts are tenoned into the tie beam, and the principal rafters are framed into the latter and the top of the qucen posts. A straining beam is fitted between the two queen posts, and struts are placed between the latter and
mixture, and bake it for $\&$ hour When it is nearly cold spread on it a layer of jam, and on top of this pile the stifly beaten whites of eggs. Put the pudding back into the oven until the meringue is a good biscuit colour See Meringue: I'astry.

QUEEN'S WARE. This term wan first adopted by Josiah Wedywood about 1765 th describe his improved cicnm-ware, of which he presented a breakiast service to Queen Charlotte. Cream ware was the Lasis of all the earthenware fabrics produced at an carlies dato by Whicdon, even when the nature ol the body was concealed by agate and other decorations The paste was a mixture of flint and clay, as used for Staffordshire saltglaze

The mprovements made by Wedywood tesulted in an earthenware ol liglit texture, in various ahades of cream, straw. and salfron, well potted, with a soft glaze His final improvement was to introduce Cornish growanatone The effect was such that delft and salt-glaze were driven out of the market Wedgwood's own services of dinner, dessert, and tea ware were usually made in this material, which is stil! produced at Etruria. He decorated it in hand-painted designs, and a sparing use of fire-gilding, and sent large quantities to Liverpool to be transfer-printed. Gold lustre was also employed.

The collector may usually identify this ware mainly by the Wedgwood mark, hecause some rivals attained a very close imitation of its

Queen Post. Wustration showing the emplogment of two uprights in a rool truss
the rafters. A straining sill is fixed hetween qualities, notably Elijah Mayer of Hanley the queen posts to prevent the stress from Queen's ware was produced in most of the the struts shearing the tenons of queen posts
Iron stirrup straps connect the queen posts and the tie beam, and three-way straps are secured on each side of the rafters, queen posts, and straining beam. A typical example of a queen post roof truss is illustrated See King Post

QUEEN'S CUSHION. The popular names of quecn's cushion and doredale muss aro given to one of the nossy saxifrages named hypnoide. This is a hardy low growing plant which forms spreading moss-like tufts and hears white flowers in May It flourishes in the rock or wall garden, or as a border edging. in well drained soil in sunshine or slight shade The varicty Kingii is of particularly dense growth and makes a delightful moss-like cushion though it does not flower freely.

QUEEN'S FLOWER. This is one of the names of the Indian crêpe flower, Lagerstroemia indica, a shrub or amall tree suitable for cultivation in a greenhouse having a minimum teniperature of abnut 50 degrees It bears beautiful rose-coloured flowers which have prettily curled or crimped petals, hence the name cièpe flower. It may be grown in large pots or in a burder; a we!! drained compust of loam, peat and sand suits it.

QUEEN'S PUDDING. To make queen's pudding, boil up $\frac{1}{2}$ pint milk with 3 oz . castor sugar, a little lemion rind, and 1 oz butter, then pour this on to 3 oz breaderumbs. Allow the whole to cool slightly, and mix in the yolks of 2 eggs and the juice of a lemon. Line a piedish, with 3 oz . short pastry, and put a strip of pastry around the edge. Fill it with the
styles already mentioned at Lecds, while at Stockton, down to about 1848, a reproduction of the Etruria fabric was made by Smith and marked W. S. \& Co.'s queen's ware See Pottery: Wedgivoud.

QUENELLE. The rich white forcemeat known as quenelle is served sometimes as an entíe, but is also used as a garnish for soups and inade dishes. Quenelle may he made either with meat or tish, but the meat must consist of veal, poultry, or game, and the fish of some delicate varicty that can be pounded very finely.

When quenelles are served as a garnish for clear soups they are made up with teasponss, then are poached and laid at the bottom of a hot soup tureen, the soup being poured over then gently.
Chicken Quenelles. For these put 10 oz . cold chiclien through a tine mincer and pound it well. Melt $\frac{3}{}$ oz butter in a saucepan, add twice as much Hour, and mix the two nutmeg. Mix these ingredients with the ingredients well before adding gill white flesh of the fish, shape the quenelles and foach stock. Bring the whole to the buil, cooking as for chicken guenelles. it until it ceases to adhere to the sides of the pan, and keeping it well stirred. When the mixture has been allowed to cool slightly, add the minced chicken, ssason the whole with pepper and salt, and beat in an egg. lound all these ingredients together, then rub them through a sieve.

Shape them into quenelles in the following way Well fill a tablespoon with some of the

Quenelle. Quenelle of chicken served with white sauce and garnished with green peas
ficsh of the fish, shape th
as for chicken guenelles.

A very simple tish quenelle mixture nay be quickly prepared by pounding the flesh of : large whiting in a mortar with the hardhoiled yolks of 2 cggs, 2 oz bread panada (the bread to the soaked with builing millk, hot stock or water), 3 oz . (resh butter, and acasoning Separate the yolks and whites of the egga, and steam the yolks in a cupl or jar by thenselves, leaving the whites raw. When

Queen's Ware. Cup and saucer bearing the Wedgwood mark: the transfer was printed at Liverpool Brithsh Museum
mixture, shaping the latter with the aid of a knife dipped in hot water to form the quenelle into an oval Then dip another iablespoon into hot water, and with it remove tise quenclle from the first spron into a well. greased frying-pan filled with boiling water or ntock. Punch the quenelles for a hout 12 min , keeping them basted with the water

When they are cooked, take them out ol the pan, drain them well, and arrange them on a dish, afterwards coating them with some white sauce made from 2 oz each Hour and butter, 3 gills milk, 1 gill good, flavoured whita stnck, a squecze of lemon-juice, and a suffi. ciency of seasoning.

Quenelles of veal and rabbit aĭu made in exactly the same way. They may be varied by adding equal quantities of lean ham or bacon, and a little tinely chopped onion In making all quenellea, scasoning is important. Care nust be taken to prevent then being insipid. Garnish with green peas, or chopped French heans, or sprigs of parsley.

Fish Quenelles. For these use whiting for choice, as it is casier to work with: but most lish can be used. Skin 3 large rock Whiting and remove all the tlesh from the bones. then pass it through a wire sieve. The back of a wooden st:oon is hest to use for this purpose. Allow for each whiting 40 oz bread or Hour panada, 2 eggs, and ecasoning of cayenne pepper and salt, also a little mace or
other ingredients are well mixed work in one tablespoonful chopped parsley and the whites of the eggs whipped to a stiff froth. When all are incorporated the quenelle meat is ready

QUICK. The hedge plant quick, or hawthorn, may be planted during late autumn, winter, and early spring in soil which has been dug over to the depth of about 2 ft . The plants should be put in about 6 in . apart. A double row will make a much stiffer hedge.

Qüickset Hedge. This is a very old term signifying a live fence or hedge set with quicks, a name generally applied to Crataegus Oxyasantha, the common hawthorn. For the production of a quickset hedge thorough soil plecparation is essentia!, the ground being deeply trenched and allowed to settle down before planting either in Oct. or early Nov.

Four-year-old plants of quick are to be pieferred ; they should be planted about 8 in . apart, and cut back to about 6 in of the ground tevel. Cutting back in drastic fashion induces strong growth from the basc. Some growers prefer a double row of plants. Hedge bottoms should always be kept clean, and the soil regularly forked over. See Hawthorn; Hedge.

Quicksiüver. This is an alternative name for the chemical element mercury ( $q$ v.)

QUICKSTEP : The Dance. The fundamental steps of the quickstep are the natural and reverse turns, from which all variations ale built up The natural turn is generally used on corners, the reverse (usually a section only) on the straight. As in the Fox Trot (q.v), a slow step (S.) takes two beats, a quick step (Q) takes one; the latter is danced on ball of foot. Only one walk or, at the outside, two should te done between the steps. The weight of the body should be forward (without leaning forward) towards partner.
The natural turn, counted S.Q.Q.S.S.S., is danced as follows. The man steps forward with right foot (on heel first, but going immediately on to ball) turning on it to R. (S.); steps to side with left foot (Q.) and closes right foot (R.F.) up to it (Q.) ; steps back with left foot (L.F.), turning on it to R. (S.), closes R.F. back to L.F., turning from L. heel to R heel (S.) and steps forward with L.F. (S.). (See Fig. 1) The girl (see Fig 2) steps back with, L. $F$, turning on it to $R$, to side with
R.F., still turning, oloses LF. up to R.F., The girl's quarter turns are executed by steps forward with R.F, turning on it to R., stepping back with L.F., turning on it to R.. tc side with L.F, and brushes R.F. through' (close to L.F.) as she steps back with it.
A three-quarter turn should be made on the complete step Contrary body movement (CB.M ) is used on the lst, 4 th and $6 t h$ steps. The 2nd, 3rd and $4 t / 1$ steps (Q.Q.S. ) constitute a chassé ; this figure, however, may be taken straight, turning, or to the side in other variations of the Quickstep.
The reverse turn (Figs. 3 and 4) is counted S.S.S.S., Q.Q.S. The man steps forward with L. F., turning on it to L., to side with R F., still turning, back with L.F back with R F., turning on it to L., closes L.F., back to R.F., turning to L on R . heel ( Q Q.), and steps forward with L.F. C.B.M. is used on the list, 4th and 7 th steps. It should be noted that on the counts "Q.Q." the man actually makes one step only; but the girl makes two steps, therefore it is so counted
The girl's reverse is as follows: Step back with R.F , turning on it to L., close L.F. back to R.F., turning from R. heel on to L . hicel, step forward with R.F., forward with L F., turning on it to L . Take small step to side with R.F. and close L.F. up) to R.F. (Q.Q.), and step back with R.F. C.B.M. is used on lst, 4 th and 7th steps.

The most popular variations are the Quarter Turns and the Kig.\%ag, and an attractive movement can be made by joining them together, making the last step of the quarter turns the first step of the zig-zag
The Quarter Turns, Figs. 5 and 6, are counted S.Q.Q.S. SQ.Q.S. The man begins facing diagonally to R. He steps forward with R.F., turning on it to $R$, to side with LF., still turning, closes R.F. up to L.F. and steps diagonally back with L.F. Steps back with R.F., turning on it to the L., closes I_F. back to R.F., turning to $L$. on $R$ Leel ( $\mathrm{Q} Q$ ) and steps forward with L.F.

Both girl and man make a quarter turn to the $R$. on the first four steps and a quarter turn to the L. on the last four. C.B.M. is used on the 1st, 5 th and 8th steps. It will be noticed that the 1st, 2nd and 3rd steps are similar to the 1st, 2nd and 3rd of the natural turn and the 5 th, 6th, 7 th and 8 th similar to the 4 th, 5 th, 6 th and 7 th of the reverse turn
stepping back with L.F., turning on it to R..
to side with R.F., still turning. closing L.F. up to R.F., and stepping diagonally forward with R.F. She then steps forward with L F., turning on it to L., taikes a small step to the side with R.F., closes L.F. up 10 R.F., and steps back with R F. C.B.M is used on the 1st, 5th and 8th steps.

The Zig. Zag is composed of five slon steps, as follows : The man steps forward with I. F., tuming on it to L, to side with R.F., still turning, back (and across behind R.F) with L.F., bringins partner outside, closes R.F back to LF. and stejs forward with L.F. The girl steps back with R.F., tuming on it to L. closes L F. back to R.F , turning from R. lieel on to 1, heel, steps forward with R.F outside partner, to side with L.F., and brushes R.F. through (close to L.F.) as she steps back with it. In this figure a quarter turn is made to the L. on the first two steps, and a quarter turn to the R. on the last three. C.B M. is used on the 1st, 3rd and 5th steps. It should be noticed that the first two steps are similar to the reverse turn and the 4 th and 5 H h to the 5th and 6th of the natural turn

Another attractive variation that may be used with advantage after the quarter turns or the natural turn is the Cross Chasse. counted Q Q.S. Fol!uwing the last siep, of the quarter turns or natural turn, as the case may be, the man lakes a small step to side with R.F., closes L F up to it, and steps forward with R F. outside partner, going straight intu the 2nd, 3rd, 4th, etc, of the steps of the Quarter Turns or other suitable variation C.B.M. is used on the 3rd step. The girl takes a small step to side with L.F., closes R.F. up to it, and steps back with L.F. to go straight into next variation. C.B.M. is used on 3rd step

Other well known variations are the Quick step, Charleston step and the Drag.

In the accompanying diagrams the R.F. is shaded, the left in outline only. The dotted outline shows the position of font after a turn has been nade on it. Diagrams will be easier to follow if the dancer faces the direction in which the tocs are pointing and turns the diagran as he or she turns See Dancing; Fox Trot: Tango; Waltz.

QUILLAIA BARK. Panama or quillaia bark, because of its chief constituent, sa ponin, has the peculiar characteristic of forming a frothy solution in water. It is inodorous, but has an acrid taste, and is used as a febrifuge and diuretic. It is useful in forming emulsions, and in the form of tincture of quillaia is an ingredient of numerous shampooing preparations. It is an expectorant, but carc has to be taken in using it internally, as it may cause irritation of the digestive tract.

Cleaning Uses. One ounce of quillain bark, stewed for an hour in enough water to cover it, provides a simple means of freshening up suits that have become shiny. The liquid should be strained when ready for use, and then applied on a piece of material of the same colour as the suit itself. Fairly vigorous rubbing is required, and when this has been completed a clean. damp cloth should be placed over the suit and a hot iron used for pressing See Emulsion.

## Quilts and Quilting

## Modern Coverlets Worked in Simple and Traditional Designs

## This article includes instructions for making a down quilt, patchwork quilts and some details for hand quiltin; work. Readers should also consult the entries on Down: Embroidery: Nighe W'ear Case: Patchwork: Woolwork

A quilt is $n$ padded hed coverlet usually of the depth of the dorm padding will become silk, satin, or sateen, with an interlining of sheep's wool, flannel or cotton wool or packed with a down filling. The down obtained from the eider duck is the hest, and, inoidentally, the most expensive. Snme kinds of patchwork quilts are made without interlining and used over a separate lining, but the original idea was that the patchwork was the outer covering stitched through to a foundation lining. The stitching which holds a lining padding in place under another material is known as quilting.
Down Quilts. The down paddeal quilt is sometimes called an eiderdown, but only the most expensive are filled with the down from the breast and neck of the eider duck which is the softest filling known. Less expensive ones arc cygnet and goose down, separated from the feathers and purified before use Vegetable down is not suitable for this purpose as it so soon loses softnces and becomes lumpy Occasionally kapok is used mixed with biri down when a cheaper filling is required.

Down quilts are sold in double or single bed sizes and in many qualities. They can be made at home and covered with self-coloured material, or with panels, horders, or centre pieces of plain material, used in conjunction with a patterned fabric. When both plain and fancy materials are to be used, the panels and horders must be cut out and machined together. If the quilt is to he made entirely of one kind of fabric, the quilting design can be lirst marked out in chalk and then with a acking thread on to the silk. Artificial silk is quite suitable for this purpose and cotton backed satin is also used. Some people prefer sateen for the underside of the quilt as it is less likely to slip off the bed than the other fabrics. For a quilt to be used on a double hed the silk will need joining, but this will probably not be necessary for a single bed or cot quilt.
Sometimes an inner case of down proof sateen is made, but this adds to the weight of the quilt. The case is formed by joining together the two pieces of silk or other fabric cut or made up to the required size. The wrong side of the naterial should be soaped or waxed, as shown in Fig 1, before making up in order to retard the passage of the down. A piping of the same or contrasting material along the seam gives a professional appearance when the quilt is finished. One end must he left open fur filling.

In the home the down has to be carefully put into the case by hand, and the end which was left open must be sewn securely. It should then be placed quite flat on to a large table or bed, and the down arranged as evenly as possible by careful shaking and tapping with the outstretched hands. Without moving or disturhing the down, tack alnng the lines marked out for the quilting, ascertaining that all the tacking stitches go right through to the underside of the case. This process is most important, as otherwise, when quilting, uneven, and the wholc appearance of the quilt will be spoilt. It is best to use a tacking thread of a contrasting colour. Fig. 2 shows the quilt filled with down and tacked for quilting.
Quilting can be done by hand by stitching along the lines of the pattern and taking the needle through to the underside at each stitch but this would make the work rather laborious. It is therefore more ofien done by machining. Test the machinc on a piece of material similar to the cover: the stitch should be long, and neither top nur hottom tension

Quilt. Fig. 1. Showing the wrong side of the m rong side of the material being soaped
with down, and tacked ready for machining
should be tight. No trace of any puckers should be scen in the stitching.
When the machine is antisfactorily adjusted, raise the pressure foot to its greatest height, pass the quilt under it, commence stitching, and do not hurry the process. With the left hand carcfully smooth out any creases in both the top and underside of the eiderdown cover.

If a hand sewing-machine is heing used, a second person to guide and arrange the eiderdown is a great help. The quilting completed, the tacking cottons should he removed carefully so that no down is drawn through in doing so, and five or six eyelet holes should he buttonholed at convonient distances from the centre of the quilt to provide ventilation. In another form of quilted bedspreads, the designs of the patterned silk, satin, sateen or chintz used for the covers are outlined with running stitches taken through the interlining of wadding. These spreads are finished with brightly coloured plain shantung or cotton linings and are most effective.
Patchwork Quilts. For cottage bedrooms and for use with four poster beds patchwork quilts are always suitable. They may be made of cambrics, gingham, sateen and other similar materials, or of silks. Sometimes they are composed of blocks of linen 6 or 8 in. square embroidered in woolwork and joined by alternate plain squares of a contrasting colour. Edges may be linished with plain banding or with a binding. Transfers can be obtnined for such blocks. Another idea is to use alternate squares of a small patterned chintz and plain satcen. Designs for quilts which
more strictly deserve the name are made with patch work and hand quilting and are interlined and lined, the quilting being worked on the p!ain border and plain squares.
l'atchwork quilts can also be made by adapting the directions given in the first part of the article on patchwork (page 913). Sometimes the work forman panel in the middle of the quilt and a border of $18^{\circ} \mathrm{in}$. is added of plain material. Such patchwork requires a founclation. Haphazard, crazy patchworis is a way of using up odd scraps. but is conly suitable for a cottage quilt. Fancy stitches such as fenther-stitch, chain-stitch or blanketstitch are used to attach the patches to the foundation. Whatever the clesign decided upon. begin by tacking the first patch to the centre of the foundation and arrange the others round it.

A foundation for a quilt should be cut and made to allow $\frac{3}{2} \mathrm{yd}$. drop at either side of the bed and also at the end. When the top is conipleted turn in $\frac{1}{2 n}$. hem all round. If only the centro panel (large enough to cover the actual top of the hed) is of patchwork, a cotton foundation is cut just of the same aize as the panel and the lining may be chosen of a suitable colour and cut the full size required so that it also forms the border.
Otherwise cut the lining material carctly the same size as the quilt, tack it in position, turn in the raw edges, and fell to the patchwork. The most suitable material for lining

depends on the kind of fabric used for the patches. Sateen, woolback satin, jap, or Shantung silk is preferahle for backing more elaborate silk or brocade patchwork. For cotton quilts use only cotton or linen for lining, a small patterned old English print, cascment cloth, crash or coloured lawn are the materials which are generally employed.

A more formal type quilt is not made upon
a foundation, but the patches are cut out in geometrical shapes, such as triangles, squares, hexagons, and octugons, each piece being mounted on fairly stiff paper. I3lack and white triangles placed so as to form a boxshaped pattern is a familiar design that imitates tiling, but the best effect is gained with octagonal shapes. Cut out a template the exact size of patch required and cut the pieces of mounting paper from this so that all the patches correspond. Place a paper hevagon on the table and see how the edges may best be joined to the surrounding patches without overlapping.
Cut out all pieces of material allowing $\ddagger \mathrm{in}$. turnings, place them on to the paper shapes, turn the raw edges, and tack to the paper.

Prepare a nuinber of pieces in this way before commeucing to join them together. Place them edge to edge, right sides outside, and sew them with very small stitches, taking only a few threads of the material, or the patches will not lie flat.
When all the shapes have been joined together, a plain or quilted border can be stitched by hand or machined on to the patchwork, and the lining made in the way already described. It is particularly necessary when making such a patterned quilt to cut each
shape with accuracy, or the effect is spoilt, inaccuracies showing much more readily on a large surface than on small ones The paper used for mounting the patches must be torn away before the quilt is lined.
Rosette Quilt. Most attraotive for a coun. try bedroom is a form of quilt dating from the 18th century, or earlicr, made of rosettes. Some originals seen came from the West Indies, the materials used for the rosettes being soft, patterned cottons as worn by the plantation negroes. Any prints, patterned lawns or sateens may be used, provided that tho scheme is harmonious and the effect light and dainty
The method of making is simple Cut out a cardboard template the size of a small saucer (about 5 in . in diameter), the paper shapes to correspond, and the picces of material allowinc for turnings. Having tacked these to the paper, whip mund the edges of the material, and before drawing up tear anay the paper. Each patch or rosette is like a little flattened circular bag with the gathered top uppermost and is juined by a few stitches to the adjacent patches, but made up in auch a way that the quilt has an openwork effect through which the separate lining of some pretty plain coloured sateen shows.

lined with muslin and padded with cotton wool. The pillow foundations inay be made of sateen and stufied with down or kapok. Fig. 5 show's an example of a charming sachet in Italian quilting in which the design stands out with a raised effect. This work is equally suited to decorating a comtorter, to be laid over the foot of the bed, to match the sachet ur for a cot quilt, and such work would form a heautiful presont.
The cxample illustrated is made of white georgettc quilted over pink crêpe-de. Chine. The padding of the design consists of bright coloured wools. These are threaded between the two matorials in the lines of the design and show through the georgette with the most delicate effect when quilted.

QUINCE. This Persian tree (Cydonia vulgaris) is hardy in Great IBritain and is worth planting in small numbers in southern districts for the sake of its Howers and its !arge, hard, pear-shaped fruits, which make excellent marmalade. They need more than the usual quantity of water when used in this way. The quince is chiefly valued, however, as a stock on which to bud pear trees; it is known as a dwarfing stock, because it bas the effect of divarfing or restricting the growth of the pear trees and thus enconrages earlier fruiting. For gardens of rest ricted size pear trees of the quince stock should be planted. The chief varieties are the apple-shaped, pearshaped and Portugal. One named the Ser bian quince, introduced from the Balkan countries, is said to produce goorl crops even on young trees.

Quince Jam. The ingredients required for making quince

Fancy Quilting. Plain quilt. ing usually consists of lines of back-stitching arranged to cross diagonally alsout 1 or 2 in. apart. This is used sometimes with an interlining of wadding to make comforters, or small quilted spreads, and cot coverlets of silk or satin and may be done by machino or hand Fancy quilting in which the stitchery forms a pattern is also employed on materials for such coverlets. Fig. 3 shows a traditional design from Walea for a full-sized quilt. This style of work dates at least froin the Tudor period and is still corried on by women in the colliery villages. 'The quilts are interlined with sheep's wool or cotton wool,
 covered with sateen ur silk or other washable material and stitched all over by hand, as shown in the illustration.

An example of English quilting is shown in Fig. 4. This cot coverlet is of quilted satin, back-stitched by hand with embroidered motifs worked in padded satin-stitch, stemstitch and darning-stitch. Desigus for quilting may be obtained through embroidery pattern services. Traditional guilting patterns are adapted to transfer form. Designs are also obtainable for quilting babies' shoes and bonnets, and for hedroom slippers, dressinggowns and jackets.

Italian Quilting. Small decorative pillows and night wear sachets to match the bed auilt are dainty accessories. They may be madr of satin, taffeta or crêpe, the quilting,
jam consist of 6 lb . quinces. 3 pinte water, and 1 lb . lump sugar to cuery pint of pulp. Peel and quarter the quinces, and, after removing the cores, put them into a preserving pan with the water. Stew them slowly for several hours until the fruit is soft. then rub all through a wire sieve and measure the pulp. Put the whole back into the pan with the requisito amount of sugar, and boil it for $\frac{3}{3}$ hour, or until it sets

Quince Jelly. To make this jelly. necl and quarter a few quinces, and, after removing the cores, weigh the fruit. and to every it of this add $\frac{1}{2}$ pint water. Cook slowly until the fruit is soft. then strain the whole through a jelly bag, and measure the juice. Tn every pint of this add 1 lh . sugar; put both

Quince. Hardy fruit resembling the pear, and much used for jams and jellies
intu a preserving pan, and boil rapidly for a boul $\ddagger$ hour, or until they set. See Fruit Jelly

QUININE. Along with other alkaloids quinine is contained in cinchons bark. A large number of salts are formed with it, those nost in use being the sulphate, the hydrochloride and the acid hydrochloride. The drug has a marked power to reduce fever Its most atriking characteristic is its power to cure malarial fever by killing the parasite

The anmoniated tincture of quinine is common and efficient remedy at the start of a cold in the head, or influenzal attack. A teaspoonful in a wineglass of water, at hourly intervals until 4 doses have been taken, will often cut short such an attach, if begun carly.

QUINOL: In Photography. This is a photographic developer which is slow in action and tends to produce deusity in the high lights of a negative rather than to bring out details in the shadows or low lights. It thus gives negatives with great contrasts, which, while useful for special purposes, such as copying hack and white drawings, are excessive for ordinary negatives. When quinol is mixed in the right proportions with metol, a very valu: able developer, known as metol-hydroquinone, or M.Q., is obtained, in which the defects of both quinol and metol are overcome, the combined developer being quick acting, clean, and giving good gradation. See Hydroquinone: Metol-hydroquinone; Negative.

QUINSY. Acute inflanmation of the ton sils going on to the formation of pus is known as quinsy. It niost commonly attacks children and voung adults. An attack often follows exposure to wet and cold, and a person who has one attack is likely to have another.
Usually the patient first complains of sore throat, with dryness and some pain in

Quilting. Three examples showing different types of quilting. Fig. 3. Hand quilting in traditional $\mathbf{W e l s h}$ design. Fig. 4. Modern English band guilting. Fig. 5. Italian quilting
swallowing. Pain may be felt in the ear and on opening the mouth. The swelling of the tonsils increases rapidly, and the temperature rises, sometimes to $105^{\circ}$ while the pulse goes up to 120 or 130 beats per minute. The tonsils are very red and are coated with mucus. The patient's strength may rapidly decline. An abscess generally forms between the second and fourth day of the disease, and it bursts commonly into the mouth, but sometimes in the pharynz. This may ocour during sleep or in a fit of coughing. Inatant relief follows the bursting of the a bscess. Frequently in children the disease does not follow this severe course. Treatment should be supervised by a doctor.
Quinsy is infectious, the patient should therefore be kept isolated. To guard against further attacks the neck should be bathed with cold water every morning, and the mouth should be rinsed morning and evening with solution of potassium permanganate, 4 drops
in a half glass of watcr, diluted glycerin of borax, 1 in 20 , or a similar wash. See Tonsillitis.
QUINTAL. This measure of weight is really a hundredweight, being either 112 or 100 lb., according to the scale used See Hundred. weight.

Quire. This measure is used in selling writing-paper. A quire contains 24 sheets, and 20 quires make a ream. See Notepaper

QUIRK. This is the name given to a nariow channel or groove separating one portion of a moulding from another. The name is also applied to the bead or fillet of a beading plane, and a tool, similar to a metal spokeshave, known as a quirk router, is obtainable for use in forming quirks. See Moulding.

Quoin. This is the name given the external angle, or corner, of a building. See Brick: Concrete.

## RabBit Keeping for Pleasure or Profit

## With Some Attractive Recipes for Cooking Rabbit

The reader may consult the article Fur and those that will help him to make a simple rabbi butch, e.p. Amateur Carpentry: Chiscl: Hammer. See also Belgian Hare: Havana Rabbit
suoner or later Frosted greenstuffis or roots should also be avoided but, contrary to common belief, there is no harm in wet greenstuff so long as it is fed in reasunable quantities. Greenstuff of some kind or other, or roots, ahould be fed to all rabbits at least once a day.

As regards concentrated loods, an albuminoid ratio of about 1 to 5 is suitable for all rabbits, but this proportion may be varied according to nge The materials commonly employed for other farm atock are also useful for rablits and cover a wide range The following mixture has been tound to give gnod results in practice: bran 6 parts. barley meal 2 paits. hest white fish meal 1 part. all by weight, mixed well together and water added till it is crumbly and moist Separated milk: buttermilk, or whey, if availahie at a cheap rate, forms a valuable foodstuff and may he used to moiaten the ninah in the place ol water. Milk in any shape is particularly useful tor very young rabibits and breeding does and less fish meal is necessary where it is used.

Rules for Feeding. All rabbita should be fed twice daily at any convenient fixed times in the morning and evening The bulk of the ration is better given in the evening The following plan will be found most convenient. In the moming nll rabbits should be given as much concentrated food as they will clear up in ahout id hours In the evening they should receive a liheral ration of greenstuff or hay, or other bulky food All nuraing does and youngsters up to the age of about three months should he given the same amount of concentrated food at night as they had in the morning; and rabbits from nhout three months to six months old and pregnant does should be given about half this proportionate amount Other rabbita should ber Liven no concentraterd

Rabbits can be kept in $n$ comparatively amall space, and be maintained to a considerable extent on waste products from the ganden or allotment Green food for a few animals can usually be ohtained for the labour involved in collecting it. Rabbita are worth keeping both for their fleah and their fur while their manure is of value to the soil

The principles of rabbit keeping are outlined in Ieafleta 265 and 376 issucd by the Ministry of Agriculture The animala must be fed wisely, as unsuitable food quickly upsets them and prevents them from thriving. A properly balanced ration of sound and nourishing food should always be provided. Green food and roots judiciously given ensure good digestion. Generally speaking a rabbit thrives on a daily supply of food equal to 2 oz per 1 h . of its live weight. Water should always be supplied Clanges of diet must be effected very gradually and feeding should always be nt recular hours
lor breeding docs and for young and growing stock than for older rabbits

Bulk food, in the case of rabbits. covers a very wide range, almost all growing or dried plants, not directly poisonous. being useful A lew only need be inentioned : calbango. cauliflower and broccoli leaves, carrot and paranip tops, pea haulms. strawherry runners. the leaves and twigs of nearly all deciduous trees, e-g apple prunings, poplar twigs and leaves, clippings from hawthorn heages, etc Kohlrabi dried nettlea. hrambles swedpe

Rabbit. Pedigree varieties that are grown for their beautiful fur. 1. Silver. 2. Giant. 3. White. 4. Lop-eared Rabbit

A prospective purchaser of rabbits should visit a show and study the rabbits there. He should also read the papers devoted to them, note the names of succesaful breeders, and make inquiries about their reliability A breeder should not start operations with more than one breed. If the rabbita are to be kept for pleasure and for their flesh, one of the heavier breeds, auch as Belgian hare or Rhenish giant, should be selected

Suitable Foods. Feeding materiala are dividel into two classes, bulk food and concentrated fool. The hulk food represents the main part of the ration for ordinary cases Concentrated food is used to supplement the bulk food It is required in larger quantities
before Christmas, mangolds, nfter Christmas, oat, straw, etc, are all useful. Beet leaves and potato parings may be given, while such plants as dandelion, aow thistle, clover, chickweed and groundsel are good

With regard to greenstuff, special care should be taken to avoid sudden changes of any kind. Thus, if rabbita bave been fed during the winter on a bulk food composed mainly of roots and hay, it is dangerous to change suddenly to large quantities of cabbage or dandelion. Care should also be taken to avoid the use of grass or other plants which may have been contnminated by the excreta either of other rahbits or of dogs, or trouble from internal parasites will certainly ensue

lood at itll at night, only in the morning In the early spring and summer the feeding value of greenstuff is far higher than it is later on, and it is quite possible during that time to rear rablits on food of this kind alone Later on, however, concontrated food becomes increusingly necessary if the best results are to be ohtained, while if rabbits have heen fed on bulky food alone it is difficult to get them to lake to concentrates. It is leetter, therefore, to feed a small quantity of concentrated lood even in the spring and early summer. It is important alwnys to inquire as to the previous feeding of newly purchascd rabbits and to introduce any changes gradually.
Stock should be watched and individual requirements studied. Most rabbits will cat a good deal more than they really require, and some suffer in consequence. The rate of growth of youngeters of breeds which have an arlult weight of about 6 to 7 lb . should be 3 to 4 oz . per week. If large quantities of succulent greenstuffe or roots are being fed water is not very necessary, but it is prudent to kcep a supply of clean water in the hutches of brceding does and young stock.

Pedigree Rabbits. Perligree rabbits of the best known and most popular brecds are just
as hardy and as prolific as their humbler relations. They may be fed on anything which a pig would ordinarily eat, excepting salty things, with this proviso, that all food given to rabbits must be absolutely sweet and fresh Every imaginable type of table scraps, oddments of left-over pudding. crusts of bread, vegetable parings, apple peel, banana skins, orange peel, cooked potato peelings, oven tea leaves, if set aside during the day in a white enamelled pail or bowl, may be utilized These are chopped up roughly, scalded with boiling water, well drained, mixed to a dry crumbly mash with a fow handfuls of dry bran and given to the rabbits just before bedtime

Rabblts for Fur. The following are the best known and most popular breeds of pedigree fur rabbits: The Giant Blue Beveren is a very large-and beautiful rabbit, whose thick, soit fur is of a blue-grey colour. It makes up into all sorts of wraps intended for hard wear, fulllength fur coats capes, stoles, and muffs, besides being in much demand for trimmings of every description. There are certain cleverly dyed blue-grey furs on the market which may be at once detected by gently blowing the fur apart. The natural-coloured fur grows from a creamy white skin, but the dyed variety will be found to spring from n blue-grey one.

The Giant White Beveren is a snow-white rabbit with a rather long, soft coat and pale blue or pink eyes. Its fur makes evening wraps, children's coats and cape, and fur trimmings. For furs for home wear this rabbit is well worth breeding, but it would not be, as a rule, worth while to breed it for selling, on account of the strong competition in imported white rabbit furs.

The Black Beveren, or Sitka, as it is sometimes called, is a big rabbit with long, lustrous, soft, blaok fur, which makes excellent coats, stoles, muffe, and wide bands of trimming for frocks and suits The Chinchilla enjoys special popularity, on account of its very beautiful soft, grey-shaded coat, which should resemble real chinchilla as closely as possible in colour. It makes good wraps and coats and is much used for summer wear.

The Havana is a good-sized rabbit, not quite as big as the foregoing breeds. Its fur is an attractive and useful shade of brown. It makes good coat collars and cuffs, stoles, muffs and trimmings. The Argente de Champagne is a large rabbit whose rather long coat is of a very pale grey. When born the young ones are quite black, but they silver gradually through the black fur, so that at about 13 weeks they become silvery pewter colour. Their fur is useful for all ordinary purposes.
The Silver Grey is a rather smaller rabbit with a short, hard coat of closely mingled black and white hairs. Its fur makes good hardwearing collars, cuffs, muffs, and stoles to wear with tailored suits. Of uncommon and attractive appearance, it makes up well into useful short coats. The Black-and-Tan is quite a small rabbit, very prettily coloured. Its coat is a fine glossy black, with dull orange points and hairs, which makes narrow drese trimmings, and is much used for fur-backed gloves and fur-lined bedroom slippers. The White Polish rabbit, which has pink eyes, has a short white coat so closely resembling Russian ermine that it is in great request for trimmings as a substitute for that very expensive pelt.

In all breeds alike a furrier cares only about the thick winter coats of fully grown rabbits, and the quality of the fur makes more difference in the actual value than the choice of breed. It is best to start with only one or two varieties of pedigree rabbit, of which the Chinchilla and the Blue Beveren would be a very suitable choice. It is, of course, necessary
to keep the different breeds absolutely separate : to mix the strains would be to spoil the pedigree stock.

Pedigree fur rabbits should be bred from three times a year, after the age of 7 months, preferably from January to July. The youngsters should be in full adult fur at from 5 to 7 months old, and must then be watched very carefully and caught at the right moment for killing, i.e. when the fur is fully through, and before there is the slightest sign of the impend ing moult. Good pedigree stock can usually be obtained at prices ranging from 10s. for a promising youngster to as many guineas for a prize-winning adult, from reliable breeders. A start may be made with a buck and 2 to 6 does of the same breed, according to the accommodation available. Each must be housed in a separate hutch from the age of 11 or 12 weoks onward until old enough to breed from or for killing, as if run on together they fight or soil each other's fur, which spoils it for selling purposes.
Diseases of Rabblts. Canker of the ear is cansed by an itch mite burrowing in the skin. Its symptoms show the base of the ear hot and inflamed, and the orifice and interior crusted with scabs. To treat it, the scab should be softened with a warm 5 per cent solution of lysol, using a small brush or a stiff feather. When it is soft the scab should be carefully scooped out with a hairpin or a wooden skewer, and burned. The inside of the ear should and burned. The inside of the ear sho

Pig. 3

Rabbit Eatch. Fis. 1. 8mall and easily constructed batch with two
 showing out in partition. Fig. S. Corner joint of framed door
bo freely dust wis flowers of sulphur, this treatment being repeated after 4 or 5 days. If the animal continues to hold
its head on one side it means that the ear drum enough for its inhabitants, and it should be so has been pierced. In this case the disease will probably be fatal, so the rabbit had better be killed at once.
An itch mite in the skin is also responsible for the complaint known as scab. In this a scurfy scab is seen on the nose, eyelids, lips, forehead, or the base of the ears: later it spreads over the body. In the early stages the skin is inflamed and scaly, and small red pimples-form. The hair falls out and the animals scratch themselves a good deal. To cure it, the hair should be cut off. The scab should be thoroughly softened with soft soap, washed off with a warm 2 per cent solution of lysol, using a stiff brush, and anointed every day with one part of Peruvian balsam in one part of the spirit. Daily painting with tincture of iodine is recommended, but care must be taken to avoid the eyes.

Some rabbits suffer from inflammation of the eyes. In these cases the eyes are red, with a tendency to water. The eyelids stick together and diacharge matter. The trouble may arise from draughts, dirty or damp hutches or injuries and scratches. The eyes should be washed with camomile tea and 2 per cent boracic acid.

Other rabbits suffer from loss of hair, this taking the form of bald patches on the coat. It may be caused by a woakening of the hair follicles through poverty of blood or nervous trouble; or it may be due to hair mites which are seen as small white spots, especially on the flank, chest and tail. When it is due to a weakening of the hair follicles, the cure is to arranged as to admit of being cleaned quickly and easily. The hutch, moreover, should be ready before any stock is bought. With the exception of the hay rack, there need be no internal features of any kind in it. Partitions are not necessary, since movable nesting boxes can be used in their place. Outdoor hutches should stand on tarred bricks. They should always be arranged to face a wall or hedge, or some other object that will give shelter from the wind.

Two kinds of hutches may be used, one being at least 4 ft . and the other 3 ft . long. Both kinds should be about 3 ft . deep, from back to front, and about 18 or 20 in . high. The large hutches are used for breeding does and their progeny: the smaller ones for stud bucks, resting does, and growing youngsters. If rabbits are kept in any number there should be about three large hutches to every two small ones.
For the need of those who only keep rabbite on a small scale, a strong and easily constructed hutch is shown in Fig. 1. It has two compartments and is sufficiently roomy for breeding purposes. Figs. 2 and 3 show the front and side elevations, and other details are given in Figs. 4 and 5.

The sides should be made first; they are 24 in . high in front, 18 in . at the back, 19 in . wide, and formed from $\frac{4}{4}$-in. boards. Unless the wood is glued up to provide a piece of the required width, and this will mean very careful planing, tongued and grooved matchboarding should be fitted together to form the correct

restrict the amount of food to very little. The food given should be good and nourishing, with a high content of oil ; for example, carrots, cloves, linseed, hemp, lucerne, sunflower seed, and linseed oil in a mash. When it is due to mites, the complaint can be cured by anointing the bald patches with petroleum or linseed oil. The best cure, however, is to bathe the animal in a " or 3 per cent solution of lysol, afterwards rubbing it dry and placing it in a warm spot away from the draughts. Care should be taken to avoid getting any lysol in the animal's eyes, while the hutch must be thoroughly cleaned and disinfected.

Rickets, evidenced by crooked forelegs and an irregular gait, is usually inherited. It may, however, be accentuated by giving the animal an undue proportion of food that lacks lime salts, potatoes and roots, for instance To cure it is impossible, but it may be prevented by frequent changes of food and putting some salt in the mash. A small saltspoonful of calcium phosphate, two or three times a week. is also helpful.

Rabbit Hutches. The hutch should be located in a dry place under shelter : it should be large

width when the outer tongue and groove have been removed A l-in. square fillet should be nailed or screwed across the bottom and a 2 -in. by $\frac{3}{3}$. length secured in the same way across the top; the latter piece should be fastened on before the top is trimmed to the correct slope. The two ends are joined by the flooring at the bottom, suitable $3-\mathrm{in}$. boards to a width of 18 in being nailed to the bottom fillets to give a length of $42 \frac{1}{2}$ in between the sides. At the top (front) a $44 \cdot \mathrm{in}$. by $3 \frac{1}{2}-\mathrm{in}$. by $\mathrm{f}-\mathrm{in}$. length is let in as shown, and a similar length should he let into the sloping top so that the outer edge is in away from the back.
The middle partition is fitted in position, suitable slots being cut to allow for the top pieces, and an opening must be cut at the hottom back comer; this should be about 6 in . or aо square. A horizontal batten can be fartened to the partition on a level with the edge of the opening. The back is nailed on direct to the bottom boards and the top piece, and nails driven in from the ends as well as into the partition. The solid door is of tongued matching nailed to lengths of 3 in . by 1 in wond, and carefully fitted in the space; either cross garnet or ordinary back flap hinges, sa shown, can be used to hang the door The wire-covered framed door is made from 2 in. by 1 in. wood, either halved at the çorners, or preferably, joined with the mortise and tenon joint.

## Securing the Wire Nettink

The frame should be covered with stout wire netting on the inside, but the ends of the netting should be turned in neatly and secured with wire staples. The four legs or supports are out from 2 in. square material and notched out at the top half-way through, allowing a distance of 12 in . below and from 6 in. to 8 in. above the notch. These pieces are screwed on to the ends a short distance from the edges. The roof is composed of pieces of matchboarding 4 ft . long joined together to project about 2 in in front and at the back. groove to prevent the water running from the roof into the interior should be planed or cut with a gouge. Another method of forming it is to plane a V-shaped cut with a rebate plane.

A goorl way of housing a number of rabbits is to have $n$ stack of hutches one above the other. These oan be made on the lines suggested, but for protection against the weather it may he well to coat the whole of the woodwork with crcosote. The floors can be waterproofed by melting some pitch in an old saucepan, adding about a tableapoonful of tar to every lb of pitch, and basting all the cracks and crannies of the floor with the hot mixture. The whole should then be treated with a hot firt-iron to work the pitch well into the wood The floor should be strewn with sand, which may be thoroughly incorporated in the pitch by the nid of a blow lamp. Grent care should be exercised in melting the pitch, and the job is best done out of doors

How to Cook Rabbits. Boiling or stewing are the most usual methods of cooking a rabbit, but it may be roasted, baked, or made into soup or pies. When buying rabbita select those that are plump and free from discolora. tion, and pay attention to the eara, claws, and teeth. The ears should tear easily, the claws be smooth and sharp, and the teeth small
Unlike harcs, rabbits should be paunched immediately after they are killed, the atomach and intestincs being removed, and the inside thoroughly cleaned. If the rabbit is not to be cooked at once, hang it up until it is required, then remove the ears and cut off the legs at the first joint, skin it, and remove the eyes This is usually done by the poulterer if the rabbit is bought from a shop.

The kidneys and the fat that surrounds them should next be taken out, the diaphragns broken, and the heart and lungs drawn. The liver, heart. and kidneys only should be
reserved. Wash the rabbit well in two or threa bowls of oold salted water, then let it soak for about $\frac{t}{2}$ hour in some alted tepid water.

Only young rabbits should be roasted or baked, the older ones being better auited to stewing. Simmer the liver, heart, and kidneys in asilted water. When tender chop them finely and add them to some veal forcemeat (see page 481). Stuff the rabbit with the forcemeat, ow up the opening, and truss with the fore lega backward, the hindlega forward, and the head in an upright position. Tie a piece of fat bacon over the back, then put the rabbit into a tin with some dripping, and cook it in a moderate oven

Baste it frequently, and when it is almost done take off the bacon, dredge the rabbit with flour, baste it again, and let it brown.. Serve it on a hot dish after removing the atring and skewers, pour some thickened brown gravy round it, and serve more of the latter separately in a hot tureen; $\frac{?}{}$ hour to 1 hour is the time required for roasting. Red ourrant or rowanberry jelly, forcement halls, and rolls of bacon may be used as a garnish.

The dish called jugged rahbit is prepared in the same way as jugged bare. For boiling, first prepare the rabhit as directed. Truss it neatly, put it into a stewpan with enough white stock or water to cover it, and add 2 peeled and sliced onions, a bunch of parsley and herbs tied together, 4 cloves and the same number of peppercorns, and a little salt

Bring the whole to the boil, then akim it well and let it simmer gently for 1-2 hours, according to the age and size of the rabbit. When it is tender, lift it out of the pan, remove the string, and put the rabbit on to a hot dish, pruring over it some onion or parsley sance. Some neat rolls of toasted bacon should be used as a garnish.
Casserole of Rabbit. Draw and clean a rabbit, cut it into nent joints, and leave these to soak for about $\frac{1}{2}$ hour. Then dry them and put them into a pan containing 1 oz. hot melted dripping, adding also a chopped onion. When the rabbit is browned, take it out, and add 1 oz . flour to the fat in the pan. Brown that also, then pour in $1 \frac{1}{2}$ pints stock, and stir the sauce until it boils.

Into a casserole put alternate layers of rah. bit and thiok slices of peeled and par-boiled potato, using about $\frac{1}{2} \mathrm{lb}$. of the latter. Add a small bunch of herbs and seasoning to taste, then pour in the sauce. Put nnother $\frac{1}{2}$ lh thickly sliced potatoes on top, cover the casserole, and cook its contenta in a moderate oven for about lif hours, or until the ineat is tender Then take out the herbs and serve the whole in the ossserole, using a few molls of lightly fried bacon as a garnish.

Rabhits also make excellent curries, fricassécs and quenelles. Reripes for these three methods will be found under the general headings, Curry, Fricassée and Quenelle in this work Cold oooked rabbit can be used as a filling for patties by mixing 4 table spoonfuls chopped rabbit with 1 gill white sauce. Add chopped paraley and seasoning to trate.

Rabbit Stew. To stew a rabbit, cut it, after soaking, into neat pieces. Fry them lightly with an onion as for casecrole of rabbit, and put the pieces in a stew-jar. Add the flour and stock to the fat in the pan, and when smooth add two sliced carrots and a diced turnip. Boil up. add th belly pork cut in small picces, simmer for a fow minutes, then add to the rabbit in the stew-jar. Season well, and stew gently for $1 \frac{1}{2}$ to 2 hours.

Another excellent way of cooking rabbit is to stew it in milk. Put it in a pan with enough milk or milk and water to cover it, add an onion, a blade of mace, a bay lenf, and pepper and salt to taste, and stew it gently until it is tender 'T'hen take out the rabbit, place it on $n$ hot dish, and pour over it some thickened
gravy. Fried rolls of bacon should garnish this dish of stewed rabbit

Rabbit Pie. To make a rabbit pie cut a prepared rabbit into joints of a convenient size, and coat them with flour Then mix them in a pie-dish with $\& \mathrm{lb}$. bacon cut into small pieces, 2 teaspoonfuls chopped parsley, the grated rind of half a lemon, and seasoning to traste.

Pile the mixture fairly high in the centrc, pour in enough good brown stock to make the dish three parts full and garnish the sides with some small forcement balls. Cover the pie with rough puff pastry or short crust (see Pastry), leaving $n$ hole in the top, and bake it in a hot oven until the rabbit is cooked and the pastry lightly browned
Rabbit Soup. 'To prepure a noursshing soup, cut up the remains of a cooked rabbit, dipping the pieces in flour. Melt a lump of dripping in a saucepan and lightly fry the rabbit in it, together with a chopped onion. Pour in a pint of water and bring the whole to the boil, skimming it well. Slice a fairly large carrot, and add it with a bouquet gami to the soup. Simmer the latter for 2 hours, then strain and thicken it with 1 oz . flour mixed with any good brown sauce. Cook the soup for a further 5 min ., and season it well

## before serving

RABBIT WOOL. The soft, Huffy wool manulactured from the skin of the Angora rabbit is popularly known as rabbit wool. Because of its silky texture it is employed in white or a pale colour to make babies' knitted and crocheted caps, and it is used extensively as an edging for knitted coats and frocks
When the garment is finished, the rabbit wool should be brushed with a wire brush such as is used for cleaning suède.
RABIES : In Dogs. The disease known as hydrophobin when it affects human beings is called rabies in animals. The most commonly affected of these are dogs, wolves, and foxes, but almost every warm-blooded animal is susceptible to the poison of rabies. The dog is the chief propagator of the disease.

Rabies practically no longer exists in Great Britain, having been banished by the muzzling order and other sanitary measures. It exists abroad, however, and this renders necessary the enforcement of quarantine with regard to imported dogs
The first signs of rabies in a dog are as follow: He becomes sullen and fidgety, he has a suspicious look in his eyes, and continually licks the injured part through which he has been infected. If his ear has been bitten, he scratches it without cessation Occasionally he vomits, and very often eats such things as straw, grass, pieces of cloth, or carpet, etc.

The madness develops rapidly, and in the next stage the dog becomes exceodingly badtempered. It is not safe for even his master to go near him. He attacks other dogs, flies at strangers, destroys his bed, and if he is chained up, gnaws the wood of his kennel. About the second day of the disease a Targe quantity of saliva flows from the dog's mouth. This continues for only 8 or 10 hours, and then the animal suñers from insatiable thirst. Unlike a human being suffering from hydrophobia, a rabid dog has no difficulty in swallowing, and therefore he has mol dread of water. The rabid dog drinks constantly, but in many cases paralysis of the jaw muscles sets in. This may quickly extend to the body and limbs, and the animal then staggers or falls. If he barks the bark is hoarse and unnatural. About the fourth, fifth, or sixth day death comes, sometimes with convu!sions, but more often without a struggle
If anyone has been bitten by a dog, the animal should on no account be killed, but should be confined and observed. If he
appears to be rabid the bitten person should undergo the Pasteur preventive treatment of hydrophobia. The animal is killed, and its spinal cord, packed in glycerin, accompanies the patient to the Pasteur institute. See Dog ; Hydrophobia: Quarantine.
RACE GAME. Games of this type exist in great variety and new ones are constantly appearing. The principle of all is the same. A piece of cardhoard is marked for the course, and on it horses, counters, or other articles are placed, one for each of the players. The latter are provided with dice and each moves his horse or counter according to the number of his throw.

In some of these games obstacles are marked, and if a player, instead of passing over one of these, just reaches it, he is penalized by having to go back a certain distance or in some other way. Sometimes the course is the map of a country, across which the playets must go

RACQUET. This implement is used in several ball games, notably lawn tennis. while the hattledore is in origin the same. In sclecting a tennis raequet it is essential to choose one that feels thoroughly comfortable when swung in the band. This is the main consideration; others are weight, balance. the size of the handle and the nature of the gut. See Badminton; Lawn Tennis.

RADIATOR: In Heating. In the home the term radiator is used to denote a heating clement, such as a gas fire or an electric heater, but by far the most frequent use, though scientifically incorrect, is to denote the multitubular unit in a central heating system from which the heat is dissipated into the room, Actually the heat from such a unit is convected, and not directly radiated to any extent. However, radiator is the accepted trade term for this type of heating unit.

The most common form of radiator consists of a series of cast-iron loops, or pipes, through which the heated fluid passes. This fluid may be hot water, stcam, or hot air. In most domestic central heating systems the heating fluid is low-pressure hot water. With separate gas-heated radiator units steam or hot air is employed. See Boiler; Central Heating; Electricity; Gas; Heating; Hot Water Supply.

RADIATOR : On Motor Cars. A radia tor is an important part of the internal combustion engine. Considerable heat is generated in the cylinder walls by the firing of the compressed gases on the explosion stroke, these explosions occurring at from about 200 to 2,000 a minute
Rising in proportion to engine speed, a very high temperature is reached, and, unless a suitablo means is provided by which to cool the cylinders, the walls would be made red hot, and the pistons would scize or even melt, if of aluminium. With air-cooled engines the temperature is kept within reasonable limits by providing the outside of the cylinder with fins (cast integral with the cylinder block), by means of which the heat generated is the more quickly drawn off and dissipated to the air. In the water-cooled system the radiator is

Fig. 2 AirSpace
used to cool the water after it has flowed round the cylinders, and before it again passes to the cylinder jackets, where the water once more becomes heated up before Howing to the radiator. The cycle of operation continues either by the thermo-siphon or pump system, so long as the engine is running. Beyond occasionally replenishing the radiator with water, the systemı requires no attention Only soft water, such as rain water, should be used, otherwise the whole of the system will, sooner or later, become coated with a deposit similar to that on the inside of a kettle, which will serionsly interfere with its efficiency.
The radiator and water passages must he an designed that free circulation is obtained, and the water temperature docs not excced $212^{\circ} \mathrm{F}$., that is, boiling point at atmospheric pressure. Boiling may cause trouble in several ways. Steam locks may cause a burst, and at írequent intervals it will be necessary to fill up to replace the loss caused by evaporation and splashing over. In the latter case, thic loss may canse the water to fall to a level at which the circulation, if by thermo-siphon, will cease to function.
Should this happen, it inay be unsafe to fill up with stonecold water, because its sudden contact with the excessively hot cylinders may quite easily cause the metal to crack. Further, if all the water has boiled away the heat of the cylinders will be such as to cause the fresh water to boil the instant it is put in, with the risk that a serious explosion will result. The only safe course to adopt in this case is to allow the engine at least an hour in which to cool down.

The efliciency of the radiator is dependent upon the speed at which air passes through its interstices, which in turn is governed by the wind and road speed of the vehicle, i.e. as the engine speed rises, so will the road speed increase, presuming the car is in top gear, thereby increasing the air pressure on the mdiator. This conls the water more quickly, but since the engine speed will often be very high in relation to the road speed, as when climbing a hill in a low gear, it is common practice to fit a suction fan, driven off the engine, behind the radiator, to ensure as far as possible a draught of air that shall be proportionate to thic demands of the engine

Radiator efficiency dejends very considerably also upon climatic temperature, i.e. the radiator that is efficient in very hot weather will be too efficient in cold weather. In these circumstances, the fan, if fitted, should be disconnected, or a part of the radiator screened off. If this is not done the petrol consumption will be excessive, owing to the fact that the thermal efficiency of the engine will be too low. In other words, at a given road speed a wider throttle opening will be called for than would be needed during the summer months. From the foregoing it will be scen that over-cfficiency can be easily remedied, whereas over-heating of the engine, caused by too sinall a radiator, cannot be cured, cxcept by the fitting of a larger one, which will be found a costly business.

There are two main types of radiator-the
gilled tuhe pattern and the honeycomb The former is the least costly to construct, but each tube nust be of a fairly strong section of a bout $z_{4}^{3}$ in. inside diameter to be of sufficient strength to support itself. Consequently, the volume of water contained will ainount to a fair quantity, and, owing to the fact that the cooling power of the gilled tube is lass than the honeycomb pattern, a greater volume of water has to he carried by all radiators of the former class.

Fig. I shows in detail the method of con struction of the gilled tube radiator, from which it will be seen that there are only two points that are likely to leak, nancly, the top and bottom junction of the tubes with the body of the radiator, discounting the rest of the radiator that is common to both types. The tubes are arranged in vertical rows, those in the second row standing behind the gaps in the first, and so on.

The honeycomb radiator is constructed on entircly different lines. There are two forins, the original tubula one, as shown in Fig. 2, and another in which shaped plates are used ns the components (Fig. 3). In the original type the tubes are used in short lengths, arranged horizontally across the body of the radiator; the ends being left open so that the air can pass through the tubes instead of round thic outside, as is the case with the gilled-tuhe pattern just de scribed. The tubes are all shajed at each ond in the form of a hexagon, making them similar in appearance to the

Radiator. Fig. 3. Portion ol a
boneycomb type radiator, built p on the Gallas principle double ended box-spanner. 'The ends of the tuhes are slightly larger in diameter than the remaining portion: therefore, when the tuhes are packed closely so that the flats of the bexagons fit up together, a space is left between the round portion of the tubes, and it is between these spaces that the water flows

All the tubes are held together by soldering, one method being to immerse to a dopth o about ? in. the hexagon faces of the hlock of tubes.

With the thermo-siphon system the height of the radiator in relation to the engine is of considerable importance. On no account should the bottom of the radiator be morc than a little if any below the level of the cylinder water jacket. This is very important, because, as is well known, cold water will not risc. Owing to the lay-out of the chassis this feature cannot always be observed, and in such cases a water pump is installed to ensure a proper flow.

The repair of the gilled-tubc radiator is a simple soldering job, but the repair of the honeycomb type is far more difficult. A temporary repair can be mado by securing a plate coated with red lead over the leali, holding it in position by a long bolt passed through one of the tubes and screwed up tightly. See Motor Car.

Radio. See Broadcast Receiving Set: Wircless.
RADISH. This popular salad vegetable is grown for its red or white roots, which mav be long, round or oval. The quality depends largely on the rate of growth, thereforc seeds should be sown on rich, friable soil to ensure rapid development. Successive sowings may be made out of doors from February to August. The earliest sowings should be on a sheltered border, and during summer a slightly shady place is most suitable; seeds are sown in shallow drills 9 inches apart. Radishes should be pulled while the roots are young.

For spring sowing the long-rooterl varieties are preferred and the round or oval sorts for sowing in summer

By sowing secds on a bed of tine soil on a hotbed in a garden frame in January or carly

Radish. An attractivesalad veqetable. Those illusfrated are of the variety known as the turnig radish

Fehruary, excellent small roots will be availa lile long before those raised out of doors are ready. The large Black Spanish and Chinese Kose radishes are useful for winter salads; they are raised from seeds sown out of doors in July-August; as the plants are vigorous thoy must be thinned to 6 inches apart.
RADIUM: Medical Uses. The element radium, obtained from pitchblende, etnits rays of three sorts : a , or atoms of helium : $\beta$, or electrons; and $\gamma$, which resemble X.rays When these fall on living tissues they produce irritation. This may only be of such a degree as to stimulate the tissuc cells to increased activity, but it may reach a point where the cells are killed. The healthy cells of the body exhibit a greater resistance to irritation than do
those composing growths; hence it is possible, by regulating the amount of irritation produced, to kill the abnormal cells without scathe to the normal ones.

It requires judgement and experience to accomplish this, because it is clear that if the dosage is not sufficient for the purpose it may actually encourage tumour growth; while if it is excessive, damage may be done to the healthy tissues.

A large number of morbid conditions are treated with radium; some it cures and in others it acts as a palliative. Amongst these may be mentioncd birth marks, rodent ulcer, and other forms of cancer, sarcoma. lupus, myomata, cataract, lieloid scars, ringworm. leukaemin, pruritus, Giaves' disease. and no on. Radium emanation, a heavy gas, in glass or metal tubes, can be intenduced into the substance of tumours, and into the cavities of the hody, e.g the larynx. The latter is a great advantage, allowing, as it does, of a direct effect on diseaned tissues which camot well be treated with X-rays.

Drinking water containing radium emanations is said to have proverl markedly beneficial in rheumatoid arthritis, a disease which often shows little response to other forms of treat: ment. The waters at Bath, Droitwich and other spas are radio-active. Sea-water contains hotli radium and radium emanation. It is probable that the benefit derived from mud baths in rheumatism and allicd disorders is due to radio activity.

RAFFIA: For the Garden. A fibrous material greatly used in garden and greenhouse for tying plants, raffin is commonly confused with best. Actually raffia is a natural grass imported from Madagascar, whilat bast is usually obtained from the inner bark of the lime tree. They are similar in appearance and, horticulturally, serve the same purpose. Another substance known as raffia is made from strippings of the palin Raphia. See Apple: Bast: Grafting : Mistlctoe; Kose.

## Raffia Work: Embroidery and Weaving

## Methods of Decorating Useful Articles with this Fibre

Some ideas are here given of the wide possibilities of this work which mny ensily be varied or claborated. The reader should also consult the entries on Bread Basket; Embroidery: Hairpin Work: Rush Work: Wistepaper Basket: Work Basket

Strands of raffia are woven into mats, baskets, hats and other articles. They are surface, as in the tea cosy illustrated, also used for embroidery purposes and for shown in the Anierican cloth tea-trolly mat making motifs which may be applied as trimmings. In its natural colour, which is similar to that of atraw, raffia can be hought from the florist, and then dyed to the deaired shade; but it is sold ready dyed in a wide range of colours at liandicraft stores and in most art work departments in big shops, together with raflia varnish, sjecial canvas, needles and raffia cloth.

If dyeing is done at lome, the raffia should first he soaked in warm water for an hour. This process makes it more pliable and enables it to take the dye more ensily than would otherwise be possible. Almost any lind of dye used for household purposes is suitable, hat dye, applied with the brush with which it is usually sold, giving particularly good results. When a brush is used, the dye is best applied to the finished article, not to the nnwoven strands of raflia, for the latter would be a tedious process and an even effect difficult to obtain.
Rama Embroidery. The most suitable trimming for rush baskets. mats, hats or garden cushions is embroidery in raffia. It is equally useful for table mats in American cloth, raftin cloth or for tea cosies with canves foundations. Sometimes heads are employed and also wools in order to enhance the effect; sometimes the embroidery completely covers
the surface, as in the tea cosy illust rated,
(Fig. 1), or is only used to form a horder, as shown in the Ancrican eloth tea-trolly mat When embroidering with this fibre select designs that are suitable. Conventional or geometrical patterns are best. Nitural raltia ahould be soaked in warm water and allowed
to dry for a few houra before working. 1yed raftin having been already soakad does not require damping unless it feels brittle to the touch. Designs can be traced on canvas or raffia cloth over carbon paper. When the embroidery is meant to be flat, a warm iron may be preased over a damp cloth on the back of the work when finisherd Satin, blanket, lazy-daisy and stem stitch (see Embroidery) are the stitches most suitable for working the fibre, and special needles are sold for use with raffin, or crewel needles may be used for finer work. Raffia strands are split into narrower threads when the embroidery demands it.

A stiff canvas is preferable to a soft one and the mesh must be large enough to take the raffia strands. Rug canvas is suitable for large pieces of work Sperial raffia canvas has only a single thrcad mesh. Brond strands of raffia cover backgrounds best. Raffia cloth is a pleasant fabric for garden cushions and cosies and is also very useful fur covering such things as blotters and bookends to be embroidered with designs in raffia

It is always advisable to strengthen the back of this cloth with thin muslin or canvas before embroidering. The edges of a large picce of work such as a cushion cover should be tacked between strips of muslin to prevent fraying whilat embroidering. The raftia cloth is obtainable hoth natural and dyed and in three qualities, fine, medium and coarse.
Book-ends of white wood, raffia cloth to cover, raffin strands in various colours for embroidering the design for which a chart is provided, leather for the base of the bnok-ends to prevent it scraping a polished table and gold galon for finishing the edges of the work are ohtainable for a few shiliings from the FrancisLewis Studio, 18, Soho Square, London, W. 1. The hook-ends make a charming gift or add a decorative note to a table. A pretty hlotter or writing pad can easily be made to match, using raffia cloth over a cardhoard foundation lined with shot taffeta and finished with gold galon. Raffia cloth covers for bridge markers are also decorative, and pochettes can be made from this inaterial, or of canvas embroidered with designs in coloured raftia

For the tea cosy (Fig. 1) a picce of canvas 16 in . by 22 in is required. The width of the cosy at the lottom should be 13 in . across and the deptli shon!d be $9 \frac{1}{3}$ in. Malie the outline 1 in. larger than the finished article to allow for shrinkage in working
The simple design of apples and leaves inay be copied frec hand on to proper and transferred hy ineans of carbon paper. Alternately, any fruit border transfer of suitable size (about 3 inches wide) may be used. Begin ly working a straight edge of bright blue rallia over two holes and then a row of black. Fill in the background round the fruit with the blue. The apples are worked in yellow and two shades of orange. The leaves are filled in with green, working from centre to edge in satin stitch. Above the border a row of black is worked.
The rest of the design is filled in as follows: Work a vertical line in black exactly in the centre of the cosy. Work over 2 holes Then work a similar line on either side 2 in. from the centre, and another at a similar distance Fill in the spaces between, using a serics of vertical stitches over 4 holes, then over 6 hodes. Continue in this manner until the whole of the cosy is filled in Thent work the other side in the same way.

When finished place the two sides face to face and machine together, turn right side out, make $\Omega$ plait of black and white raffin and stitch this round the join, making a loop at the top for a handle. The cuds of the plait should be knotted, leaving the ratia loose to form a tassel. Split this up very finely to simulate silk.

Wrap some large wooden beads with orange ratiai by passing the needle through the hole and over the beiul. Thread a needle with a

Raffa. Fig. 1. Tea cosy embroidered in natural, black, yellow, blue and orange raffa on cọarse canvas and lined with deep blue sateen
strand ol green raffia pass it through the board through the centre opening, taking care wooden bead, thread a small black head on to it, pass back to make the stalk, lenving the black bead as a finish to the base of the large bead Make 6 berries in this way, tie them securely together with some green raffia. and stitch this at the base of the handle Pad the cosy with layers of cotton wool wadding and line it with blue sateen to match the blue raffin used for the border Raffin cloth may be used instead of covering the canvas with raffia embroidery The border and finishing would be worked in the same way and $\frac{1}{t}$ yd. of the raffia fabric would be required

Luncheon mats for garden or loggia table use and tray cloths for service trolleys are most practical when mude of almond green American cloth with an applied canvas border embroidered in raffia and with coloured beada at the ends The trolley mat illustrated in Fig. 2 should measure 18 in. by 12 in (without the beaded ends). Cut the American cloth to this size, place a piece of canvas under it and cut $\frac{1}{2}$ in. larger all round. Trace or draw the geometrical design on the canvas and embroider in brightly coloured raffias, using black for the The edge (see diagram $B$ ) is worked by outer edge Leave half inch of canvas for threading the needle with a contrasting shade turning. A large-eyed needle should be used.

When the bordcr has been worked, cut out the inside of the canvas and oatch down the embroidery to the American cloth with a fine needle and silk. Turn the edge of the canvay over that of the American cloth and buttonhole round both with black raffia. Buy or make a fringe of wooden beads to match the colours of the embroidery. Attach this to the raffia buttonholing at each end and finish off the two sides of fringe by using a large black head and a small coloured one.

Fig. 3. A, mat made of colonred raffia strands wound over a cardboard fonndation and woven in the centre. $B_{\text {, edge worked with running stitch. }}$ c, method of placing strands for central weaving. D, details of knotting

Weaving and Plaiting. Other effertive uses for raffin consist of weaving and plaiting the strands to make baskets, mats, hats, and other articles. Table mats are extremely simple to make in this manner. Oval and round cardboard foundations may be purchased or a set may be cut from a strong sheet of cardboard (imperial size). Six round mats 7 in. in diameter, 2 oval dish mate 9 in. by 6 in and one large oval 11 in. by 8 in make a set For $\Omega 7$ in. mnt (sce Fig. 3) a centre should be cut out in the cardboard of $2 \frac{1}{2} \mathrm{in}$. for the ovals cut out an opening in proportion. The raffia is simply bound over the card.
board through the centre opening, taking care to overlap the strands each time so that the cardboard does not show through. Near the end of each strand, thread it with a sharp pointed crewel necdle and take it through the cardboard and make firm by pushing the end beneath the already wound raffia strands. Continue winding till the cardboard shape is covered. Two or three strands may be used together to cover the cardboard more quickly

Rafla. Fig. 2. Mat for a tea trolley made of rreen American cloth with an applied reometrical design worked in colone reometrical desi
rafta on canvas of raffia and using a running stitch. Bring the needle up through the cardboard each time, then reverse the mat and bring the needle up through the same holes so that the stitches cross.
The centre werving is begun by taking a strand of the same coloured raffia as used for the edge straight across the opening; threading through the cardboard on the other side and bringing the strand back to the other side of the opening to give a double thickness. Fasten off and repeat round the opening; eight atrands should be sufficient for a smali mat (see Fig 3, C).
Now weave in and out of these strands from the centre for about 1 in. in diameter. Make a row of knots all round close up to this weaving, one on each strand, and then a second row of knots, leaving a small space between them and the weaving. Detail for the knots is shown in Fig. 3, D. More elaborate borders can be made to such mats introducing several colours with fanoy stitches. An example of weaving with raffia on a cane foundation is given in the article on Breal Basket, page 140

A plaited raffia basket is illustrated in Fig. 4. Rush may be used instead of raffia and instructions for making the plait, whioh can be equally well used for raffia, are given in the article on rushwork The five-way plait with five strands is particularly good for the purpose. Start at the bottom, making a small flat mat by sewing the plait together with raffia of the same colour. The base should be about 9 in . in diameter Make a circle of plait exactly the same size, and build this up to form the sides of the basket, which should measure 5 to 6 in. high. Fasten it off by stitching the end of the plait inside, arranging it so that the edge is even. Sew this part firmly to the base, then take two plaita, and twist them to form a handle. The two ends must be firmly stitched inside the basket, one being sewn where the side
was finished off The raffia flowers are embroidered on to the basket direct, using a long needle. Pink, mave and fuchsia shades are always pretty if the lining of the basket is chosen to match one of these colours Make a few rather short loop stitches for the centre of each flower, and round these make long loop stitches of a contrasting colour for the petals The less raffia is handled the better the result. For the stems twist a little green raffia round a piece of string or piping cord, stitching it here and there to hold it in place. One or two pockets should be made in the silk or satcen lining of the basket, and a cover can he made by cutting the lining sufficiently deep to meet over the top when drawn up by a slotted ribbon. A small bunch of Howers provides a pretty finish at cach end of the handle, or beads may be used as explained in Fig 1

Applied Raflia Trimming. Flowers or fruit may be worked separately like the spray shown in Fig. 5 These are effective for trimming beach or garden hats for ornn. menting fruit, bread or wastepaper basketa. A piece of canvas larger than the spray required is used to work on Sketch the design and fill in with the coloured raffia strands, using long buttonhole stitches from centre to edge. Use green for stalks and leaves The centres of the flowers are of beads. Cut awny the superfuous canvas from the spray when the embroidery is finished

RAFFLE. A raffle is a way of selling an article by chance or lottery. The price is subscribed by all the persons who take a share therein, and by drawing lots, or by some other chance method, one of them wins the article. At bazaars, and also privately, articles are disposed of in this way. A raffle, however, being a lottery, is illegal, even if held on behalf of charity, and persons who promote one are liable to prosecution. See Lottery.

RAFTER. A rafter is a support for the roof of a building, particularly those membera running upwards from the wall plate to the ridge board. Rafters are generally made of timber, although metal is occasionally employed. The size most commonly used for a house is 4 in . deep and 2 in . wide, placed not more than 14 in . apart. The dimensions of the rafters should be in accordance with the following table, in which the first column gives the distance between two points of support and the second column gives the respective depth and breadth of the rafters. The sizes given are those in commercial use and approximately the size of the material as it leaves the saw

Length of bearing
not exceeding
Dimensions

Rafters are practically always put in one continuous piece : they are generally notched

Fig. 4. Work basket in plaited raffla embroidered with raffa fowers. Fig. 5. Raffa flowers snitable for an applied trimming o a wastepaper basyet or garden hat
to fit on to the plate, which is the timber on the top of the wall. and are cut at an angle at the opposite end, so that they bear against the rilge board or other point of support. They are usually supported in the middle of their span by a long, horizontally disposed timber known as a purlin. Ther are prevented from sliding outward by means of collars, horizontal timbers fixed between opposite pairs of rafters. and have to resist heavy tensile strains.

A serviceable method of fixing small rafters is illustrated in Figs 1-2, which show how the rafter is fitted to a single or lean-to roof. At the upper end the rafter bears against the

single wall plate, and at the lower end it is bird-mouthed or notched to the wall plate (Fig. 2), both ends being secured to these two plates by means of stout nails. The same method is adopted in the case of a span roof, and the construction ansirers all requirements for any kind of roof that the amateur craftsman is likely to undertake. The correct angles are obtained by the use of a bevel sifuare and by accurate measurements. The best plan is to cut one of the rafters to fit perfectly and then usc it as a pattern. Ses Ceiling: Faves: Gutter : House: Roof, etc.

RAGGED ROBIN. This is the common name of a familiar wild plant (Lychnis floscuculi). Two varieties are worth growing in gardens, alba, white, and rubra plena, with double rose coloured blonms. They grow about 18 in high and thrive best in moist soil.

RAGOUT. This term is applied to certain rich meat stews, generally brown in colour and flavoured with vegetables and herbs

For beef ragoût, any of the cheajer cuts, such as steak for stewing, round, etc., may be used. Wipe $1 \frac{1}{2} \mathrm{l}$. beef, cut it into neat picces about 2 in. square. Heat 2 oz . good dripping in a saucepan, lay in the becf, a few pieces at a time, and fry them quickly till lightly browned on each side. Lift them out on to a plate and stir into the fat 1 oz . Hour. Fry this carefully until a rich brown, stir it frequently with a wooden spoon, as flour quickly burns Pour in 1 pint good stock or, failing that, "ater and a little of some variety of meat extract.

Stir this sance until it boils. Add the neat and 2 tablesponfuls each of carrot, turnip, and onion, cut in large cubcs, a small bunch of herbs, and 6 allspice. Simmer the ragoût for about an hour, or until the nicat is thoroughly tender.

Arrange the picces of beef in a circle, or some other neat style. Scason, skim and strain over the sauce, and put some of the best pieces of the vegetable in the centre, addling, if liked, a few stoned olives heated in the sauce. Other vegetables in season can be adderl, such as green peas, fincly cut French heans, etc Mutton can be made inton a ragoût in the same way, a few tomatoes being used in addition to the other vegetables.
RAGS: Their Uses. Household uses can be found for many kinds of rags. Thus kitchen rugs can be made from woollen rags by clipping the cloth into oblongs of uniform size, say 4 by 1 in ., and looping these through
a canvas back-cloth, pieiced for the purpose Coloured patterns of a simple sort can be formed, and if rug.maling is contemplated it is advisable to save scarlet and other brightly coloured woollen rags for the ornamentation of rugs predominantly of a darker colour. Mop-heads for polishing floors can be made by cutting old blanket into uniform strips and joining the pieces at the centre. Iron-holders and stair-pads are other uses for thick woollen cloth Linen and sill rags are valuable for polishing furniture and cotton ones for applying metal-cleaning liquids and pastes.
Too large an accumulation of rage is to be avoided. but by keeping an orderly system of rag-baga, one for nes sort and one for another, the household need never be short of kinds suitable for all purposes. See Rug.

RAILING: For House and Garden. A railing is essentially a fence composed of rails or poles, and is used to mark a boundary of one hind or other, or to serve as a protection

Rafter Method of fxing rafters for a simple leanMethod of fxing rafters hor a simple lean-
Fig. 1. Top end spiked to wall plate Fig. 2. Feet bled-mouthed to plate
(c.g. around a basement area, or the well of a staircase, guarded by balusters and handrail).
Borders and open spaces, such as lawns or flower beds, are often provided with light. low railings made of wrought iron, either
painted or galvanized. These are purchased in lengths, complete with standards, generally having an inverted U-shaped foot. and have merely to be driven into the ground The joints hetween the scetions are united by ineans of bolts passed through holes in thi standards.

When erecting railings on a low brickwork wall, one method is first to put up the standards, then the flat top rail, placing the railing bars through the holes in the top rail, plumbing them with the aid of a plumb line, and alining them with a cord stretched between standard and standard, and then making the feet secure with strong Portland cencont mortar worked up into the form of a cappin! on the wall.
Another method is to use the standaral aron coping, which is generally 9 in in width and more or less $V$-shape in cross-scction. This is bedried in cement mortar on top) of the wall, and provided where neccssary with holes for reception of the standards. In some designs of villa railings complete panels of an arnamental pattern are provided, and these are set on the upper and lower raila A common arrangement is to use cast or wrought iron standards and to hang the gate on them The standards are generally provided with braces to give them stability, and are set in concrete or stonework The horizontal mem bers are fixed to the standards, and the whole completed by the addition of the necessary ornamental pancla or railing bars. An alternative plan is to build two brick pillars. one on cach side of the gate. and hang the gate between them. In such cascs the horizontal rails are emhedded in the brickwork.

To preserve railings they should be painted at frequent intervals, certainly not less than ance every three years. The paint used should be of good durable outdoor quality. and before it is applied the railings should he thoroughly well brushed and all traces of rust and dirt removed. The paint should be well brushed into all cracks and crevices, is it is here that decay is most likely to occur:

## Railways: Model Engines \& Rolling Stock

Practical Advice on Installing and Equipping a Miniature Railroad
This contribution describes the construction and running of a Gage No. 0 Railay, with all its details Information is given on the selection and operation of clockwork. stam and electric locomotives The model engineer should refer also to the associated articles on Engine and Locomotite

A model railway built for the private plensure of its owner and friends may take one of many forms. It may comprise a tiny No. 00 (尽-in.) gauge system complete with all sorts of buildings and scenic effects in a space not much larger than an average dining room table. At the other extreme is the railway laid in a park perhaps several miles in extent. constructed to a gauge sufficiently large to serve some useful purpose. Passenger-carrying miniature railways form a popular feature of certain of our pleasure grounds.

For an indoor model railway-a type of line which comes within the scope of this article-the standard gauge of No. $0(11-\mathrm{in}$.) is recommended

The average tank engine model mensures 13 or $13 \frac{1}{2}$ in. long orer the buffers, and a six-coupled express engine from $15 \frac{1}{2}$ to $19 \frac{1}{2} \mathrm{in}$. overall length, according to type. A four wheeled goods wagon is $5!$ in. and an a verage model bogic carriage 13 in . in length This means that a goods train consisting of a tank engine and ten trucks measures just under if ft . in length, allowing for looseness of couplings, and a passenger train of an engine and three coaches will measure at least 5 ft . ong These dimensions will be useful to renember when it comes to planning a model railway to fit a given space.

An attic mom can be made to accommodate a system providing reasonably intereating
possibilities in both the construction and the linal operation of the line. The minimum curve recommended is 3 ft . radius, but, for the larger types of express engines so often modeller, curies with 4 ft radius may he used for points and ill station yards, with 4 ft . j in. to i ft . 0 in . radius curves on the main or other fast running lines. Super-elevation of the outer rail neal not exceed in on the aliarpest curve.
Lay-out Plans. The question of the lay out of the track must eventually be determined by the shape of the availaile site and its overall dimensions. The clockivork engine is more suited to the non-continuous typo of plan, but with the clectrically driven engine controlled from a point alongside the line it does not very much matter whether or not a circular lay out is adopted. For a steam inodel $n$ continuous portion of main line is essential, as most models will run for about fifteen to twenty minute non-stop, and the methods of outside control provided are somewhat primitive.

Where the plan is arranged on a terminus to terminus system a railway operated by clack. work engines should be designed with regatil to the length of run to be obtained, with a train load, at a single winding. This length varies from $1 ; 0$ to 100 feet. The distance between the starting and finishing points should therefore le $a$ definite fration
of-nr equal to-the average run of the weakest locomotive used on the system. In this way a model railway can be successfully operated by clockwork locomotives to a time table working without the labour of winding hecoming a noticeable factor, so long as several locomotives arc available.
Where a long room is available the two main stations may be at the adjacent ends of a non-continuous plan, such as that shown in Fig. I, the distance between the termini being equal to one half, one third or the total minimum length of run of the clockwork engine. In the case of an electric engine each station and half of the main line can be under the control of a separate operator.
Where the exigencies of the site demand it, the terminals may be placed quite closc tngether, as in Fig. 2, or may be combined as one unit. In the plan illustrated an additional (passing) station-a country roadside station with a simple equipment-is shoirn in about the middle of the main line. This railnay, if electrically controlled, could be morked by eithor one or two operators, the eections being arranged to suit.
Fig. 3 illustrates a plan much used for all types of lucomotives, but particularly suited to the steam engine. The main linc is con. tinuous, and at the same time a short-distance or local train may run from terminus A to terminus B, and an express train starting from A may make as many circuits of the continuous track as the signalman at the junction signal hox desires before being switched over into torminus B. The order of departure and arrival fast main line portions should emergo from is reversed on return journey. The terminal the straight or slightly curved scctions. stations are comparatively close together and are inside the circle, an advantage where a one-man control is necessary. For electrical control the rails may be divided into three sections. The junction signal box may contain slritches for the continuous main linc and the junction, and stations A and B can be controlled from their reapective signal boxes. The stations may be different in plan. In addition to the passenger platforms, terminus $A$ has a loconotive depôt, while terminus B may be provided with a goods yard.

Lines on Different Levels. In sorne cases, to get more features in a given space, the linea are arranged on difierent levels. For instance, it may be an advantage in the plan shown at Fig 3 to extend the stations over the top of the continuous main line, which is made to run in a tunncl under the station. This is possible only where a sufficient length is obtainable from the junction where the upper and lower levels meet. The head room required for an over and under crossing is about 5 in in No. 0 gauge, this dimension allowing for the depth of the track and ita supports. This means $2 \frac{1}{2} \mathrm{in}$ up and $2 \frac{1}{2}$ in down, and since the maximum gradient should be about 1 in 40 , a length of 100 in. is necessary to effect a crossing. It is possible to steepen the grading to 1 in 30 (the length between the level portion and the over and under crossing being 75 in .) where the trains can be rushed down and up tho necessary inclines.
Points to Note. Other points to be considered in planning aro the following :
(I) If prossiblo always provide a means for the engine to run round its train at an arriving platform or station. (2) Where a train has to shunt into a siding there must always be
 that it extends clear of all wheels and othe parts of the engine outside the running rails (Fig. 4, B). At the points the conductor rail is omitted from between the tracks and extended along the outside of the tracks. The shoe is thus always in contact with a conductor rail, either inside or outside, and cannot fall below ito proper level. The rails are arranged as shown on the plan (Fig. 4, A)

Third rail coniductor (omilled al points \& crossings)
Fir. 4. Electrically operated system. A, arrangement of conductor rail at crossings. B, extension of collector shoe to reach outside conductor
enough room beyond the points for the The made-up tinplatc track usually supplied longest train contemplated. (3) A turn. for toy electrical locomotives has an all-level table may be used to switch engines into system of rails, and the above remarks do various sidings, taking up much loes space not apply. The standard points and erossings than that occupied by points. (4) An oval are nade in such a manner as to cut out plan without any straight line is much hetter (i.e. render electrically dead) that portion of than a square plan with short straight lines the running track that is crossed and touched and curves at the corners. Straight portions by the collecting shoe on the locomotive, and are necessary, of course, to accommodate no short-circuiting can therefore occur. With stations. (5) Points to branches leaving the amateur-built tracks using points of orthodox design some such device as that shown in Fig. 4, B, is necessary.
Signal Systems. Signals are used in full-size railway engineering to indicate to the driver the state of the road ahead of him, and also to show the direction in which the points and crossings he may encounter are set for his train.
The semaphore signals are of various patterns and ralues, including home distant, and shunting or subsidiary signals. The absolute stop signal, termed a home signal, is shown in Fig. 5 . The permissive signal known as the distant signal indicates the state of the home signal which follows it. The distant when at danger (see Fig. 6) is a warning to the driver that the home signal ahead is against him, and that he must be prepared to stop at it. It may be "off" (i.e. at "line clear") when he nrrives within sight of it, but that does not matter, for he lias had the warning. On model railways distant signals are not absolutely necessary, ns in the casc of an electrically operated railway the signalman is also the driver. They are therefore useful as ornaments only. In a clockwork railway the distant signal can be on the site of the trip gear opcrating the brake on the engine, or the latter may be used instead of a visual "distant."

Dealing with shunting or subsidiary signals, the ringed semaphore arm shown in Fig. 8 is used for sidings or branch lines. For shunting purposes a small or "calling on" arm is often fitted lower down on the same post as a home signal to call on an engine for a limited distance past the main home signal at danger.

The home signal semaphore is coloured red on the front with a white stripe, and white on the back with a black stripe Tho lenses are red for danger and green for the lowered "all right" position. In the distant signal

yellow takes the place of rad both on the signal arm and in the "danger" lens. The chevron stripes on the arm are coloured black, back and front, and the end of the semaphore is always "fish" or "swallow" tailed, as shown in Fig. 6.

In many of the latest types of signuls the semaphore arm has an upward inclination from the horizontal for the line clear position as shown in Fig. 7. In this kind of signal, thercfore, the arin risce into the air instead of falling. The dutted outlines in Figs. 5. 6 and 7 show the lino clear position of the arms.

Railway. Fig. 11. Diagram showing the standard dimensions of rolling stock and permanent way for model railways, pauges No. 0 and No. 1 . A scale of measurements for cach rauge is given at foot. For references see accompanying table
Colour Light Signals. These are now coming numerous, as the final development is not yot into use, especially on urhan lines of railuay. complete. Light signals may he very casily In such signals a powerful electric lamp modelled by using the small light bulbs now is placed in a funnelshaped recess facing readily obtainable in the lower voltages the driver, and this light can bo seen quite clearly both day and night. The systems are

Fig. 9

Fig. 10
Railway. Model Signal Systems. Fig. 5. Home Rainway. Figodel Distant signal. Fig. 7. Howard inclining signal. Fig. 8. 8iding or branch line semaphore. Figs. 8 and 10 . Colour light signals

One system in which two lights arc employed (Fig. 9) is very suitable for model railway work. The danger position of the pair of signal lights is shown at $A$ in Fig. 10. The combination functions as a home signal, and a distont signal for the next section. One (the stop aignal) lamp shows red and the lower one yellow. A train must not pass this sigual. The next state (B), the upper light showing green, indicates that a train may pass up to the next signal. The third state (C), in which both lamps show green, means that two sections alicad are quite clear.

Model Buildings. Station buildings, bridges, tunnels, embankments and cuttings arc accessnrios essential to תuy permanent lay out. For a railway that must he dismantled after use these units may be made in separate components, laid alongside the line when in operation. For any railway that is permanently installed in $a$ room allotted to it, proper track material obtained in loose parts is recommended. A firm foundation about 2 ft .10 in . or 3 ft . from the ground level shonld be built up, and the sleepers nailed to this. Ballasting can he effected by glueing the surface of the base and sprinkling chickengrit on it while it is tacky. Where the track is purchased in lengths, with the wood sleepers made up on longitudinal battens, the hallast should be laid in loosely, as a considerable depth is necessary to reach to the top surface of the sleepers. Ready made tinplate track should only be employed when a permanent track is not possible.
Electric Locomotives. It is important, before purchasing an electrically diviven model locomotive or the component parts for making one, to know something of the various systems employed.

For use with dircet current of any voltage the ordinary electric motor with a scries wound field and armature is the best possible unit for traction purposes, whatever the size of the locomotive may be. The only disadvantage it has is that reversing inust be done either by

Kailway. Well arranged gauge No. 0 indoor railwas with tracks on two different levels Courlesn of JV. J. Hassett-Lowlie
a hand switch, or an antomatic polarised relay switch on the engine. It is necessary to reverse the relation between the direction of the currents in the armature and the wound field magnet. Simply reversing the supply of current to the rails will not make any difference to the direction of rotation of the motor.

All the larger and better qualities of model clectric locomotives have a mound field, and since roversing from a distance is desirable, a permanent magnet switch or reverser is usually fitted in the locomotive. This switch is sensitive to the direction of the current, and when the operator changes it over from positive to negative, or vice versa, the switch follows this movement and changes over the connexions in the motor, thereby effecting a reversal of the engine. Smaller models, in gauges Nos. 0 and 1 more particularly, a re fittell with motors having permanent magnet fields (like a car magneto). The field polarity is therefore constant, and the only path for the track current is through the armature of the motor. Changing this over reverses the motor.

Electric locomotives fitted with permanent magnet lields and also those with series motors and polarisel relny switches are usable only on railwass operated by direct current. Accumulators are the only really natisfactory sonrce of supply. However, it is possible to break down the house supply (dircet) current through a resistance or lamps, and this method can be used on model railuays where one or two engines only are employed.
The voltages used vary from 4 to 25 , the higher voltage, of course, decreasing the amperage consumed, and getting over many othor dilticulties. For a 4-volt loco. a 6 -volt accumulator should he installed to allow for drop in voltage and speed regulation. For a 25 -volt installation the sorrce of supply should be about 30 rolts maximum

In every section of the line governed by a separate opera tor a resistance switch to regulate spleed and a com. mutator switch to change over the current direction and effect reversal arc necensary. These may he combined and worked by one handle. The line may

## MODEL RAILWAY SYSTEMS IN GENERAL OSE

 Gauge No. 00 (合 in.)Scale, f mmi. to the foot: ithth full size

Clockwork Model Locomotives Clockwork is to be preferred as a mochanism for driving model locomotives where juveniles have to he catered for The youngstor can do no harm to himself or his surroundings in its use At the same time this form of motive powor is often employed by the more advanced molei railwryman. Where the latter's concern is chiefly railway operation, and he desires accuracy of visible cletail hoth in the track and rolling stock, then the spring motor has many advantages. The railway should the designed to suit the length of run at one winding

The modern merhanism can be supplied with reversing gear, brakes, and speed changes. Within recent years a variable speed governor on the lines of the gramoplione governor has been applied to the hetter quality motors A means of reversing from the trark is usua!ly litted, but it is rathet a clumsy device not recommended except for the small fourwheeled shunting enginc. a type of model for which the arrangenient was first introtuced. However, although the trip-genr is provided on the locomotive, the reverser need not be used, as special trigger rails are required to operate the mechanism. Clockwork locomotives should not be run with the wheels spinning in the ait. nor should the engine lie

Model London, Midland and Sco:tish express locomotive, Royal Scot Courlesh of Messrs Basxetl-Lowhe. Led
eft wound up for indelinite periods after usc I'he gears slould be kept quite clean, washed occasionally with paraffin, and lubricated frequently though not copiously with a light sewing machine or cycle oil

Spring motors were at one time fitted to morel engines nas largo as $\frac{21}{2} \mathrm{in}$. gauge. but the tendency now is to limit the use of this motive power to gange No. 0 ( $1 \ddagger \mathrm{in}$ ) and gauge No. ( 0 ( $\frac{5}{8} \mathrm{in}$.) locomotives

Steam Models. The steam loco. as a working morlel depends for its success on the provision of a setisfactory fire to turn the water in the boiler into steam at sufficient pressue Thero are practical reasons against making scale models of any type of locomotive in the gauge No. 0 size to work by steam power: 'The Inarger engines-those of American proportions more particularly-are quite easily modelled, and if the boilers are raised up, without regard to scale, to give more room for the flame of the lamn, it is possible to make a small type of locomotive steam well Of course, a small boiler means n short !ength of run.

Al! successful No 0 gange model steam locomotives are lired with methylated spirit lurned in a special form of vaporising lamp. The pilot wick vaporises the fuel and keeps the lamp alight As a rule plain cylindrical boilers with the flame undernenth are enployal in conjunction with these vaporising lamps. The same system is also used for No. I genge models, and as the boilcrs of these locomotives have a morc generous capacity, the length of run can be increased from eif minutes in a gauge No 0 scale model to 41 minutes in $\Omega$ similar gauge No. I engine.
'lhe stean pressures usod are somewhat low. varying from 15 to 25 J 1 b . per aq inch. This allows thin plates to le safely used in the construction of the boilers increasing
incidentally the value of the surfaces heated action, and the arca of the roof governs the by the lamp. The cylinders are usually of thic piston valve type, and work with very little frictional loss. There is no packing of any kind, and therefore pressures used nust the comparatively low. Care is required in lubricating the cylinders and valves, and the oil should be of the proper type and grade recommended by the makers, quite free from dirt and grit. Friction must be kept at the minimum, so that the low hoiler pressure can be used with effect.

Spirit reservoirs are usually poportioned so that the fuel is cxhausted binfore the water in the boiler seaches a dangerously low limit. The safety valve should be examined each time the engine is used to see that it has not stuck up during the period of disusc Rcversing is usually arranged by a change over valve, worlied from the cab, which commutates the directions of the "live" and cxhaust " steams
RAINPROOF CLOTH. Oilskin or mack. intosh cloth is neederl to resist really heavy wettings, but the treatment which makes it waterproof closes up the pores of the fabric. Rainproof cloth, while fairly resistant to ordinary showers, is just as well ventilated as unwaterpmofed fabrios Cottons, woollens, and silks can all be rainpmofed and, although principally employed to make raincoats, they can he used for ordinary suits and dresses.
'The processes used affect only in an imper. ceptible degree the appearance. touch, and colour of the article These processes cannot, however, be attempted at home without inviting disappointment and courting risks. The goods need first to be prepared and to have all grease removed, and the most efficacious results are obtained from a combination of chemical and mechanical methods. The cloth is best impregnated with a chemical (acctate of alumina), and this, unless properly donc, may spoil the colour.

The goods are then dried and given an in finitesimally fine film of was, and it is important to haye the right mixture of waxes. The "as may be rubbed on dry, when it is almost impossible to avoid the production of shiny streaks; or be applied in a melted state, for which purpose a trace of wax is laid on by means of a metal roller ; or the wax may lee dissolved, e.g. in petrol, into which the cloth is dipped.

A rainproof coat when wet is best dried near a firc. Mackintoshes are spoiled by heat ; rainproofs are bencfited, if not placed too close

RAINWATER: Domestic Uses. The co!lection and storage of rainvater is import. ant, especinlly in the came of any country house that depends upm a well for its water supply Care has oftell io be exercised in the consumption of the drinkiug supply, owing to the well or other sousce of supply being low during prolonged dry weather. In this case it is a gieat boon to hare a gool supply of fairly clean rainwater: Rainwater has the advantage of being soft, and is theiefore very effective for washing purposes

The uses to which the rainwater can be put depend upon the condition of the water, itself. If it is stored in a clean tank or cisteri, and properly filtered, it can bic used for almost any purpose in emergence. even for trinking, if iirst boiled. As so much dejicuds upon the state of tho water, it is worth while w see that it is caught and stored in clean tanks where it will not he greatly affectel by the surroundings. The rain will wash dirt off the roof, making the water in the collection tank dirty. To overcome this trosible, nil applaratus known as a "rainwater separator" may be used. The action is for the first foul washings of the roof to be turned anay to waste, only allowing the cleaner purtion of the rainfall to be stored. The apparatus is automatic in
action, and the arca of the roof governs the ize of the separator.
In inany cases it is almost essential to filter the water befure it is used for any domestic purposes, this being done by connecting the collection tanl: by means of a pipe to a modern filter. If the collection tank is in an expored position the fap should be covered by a wire gauze, of as finc a mesh as possible: this prevents small sticks and the like loom finding their way into the tank if the tank is placed near the roof an overllow should be made flowing to another tank or water butt, on the ground level or other convenient position. If this is not done, and the mof tank should overflow aftor . heavy rain, the interior of the house would probably suffer.

It is sometimes difficult to place a single tank so that it collects the whole of the rainwater, as the gutters cannot all slope in the same direction. For this reason water butts or tanks should be placed at the various out inderground tank and then pump it out by means of an urdinary hand pump, as required. The diagram shows how a large underground tank can be built of brick and rendered in cement. The rainwater passes first through a filter hed containing clean washed gravel and coke.

RAISIN: In Cookery. The dried fruit of the grape vine known as the raisin is extensively used in cooker!. Nuscatel raisins, which are dried on the vines, are considered to be the best, and, together with almonds, are often used as a dessert fruit Sultana raisins are prepared from a succial secdless grape.

Raisins should always be cleaned hefore use The simplest way of doing this is to rub them on top of a sicve with a tablespoonful of flour. but if they are very dirty they may be washed in the same way as currants.

Before raisins are mixed with other ingredients, the stalks should be carefully removed, and the stones taken out with a Iruit-stoning machine, if a vailable. Raisins are usually cut into small pieces. A little butter rubbed on hoth sides of a knife will prevent the fruit from sticking to it: if a food chopper is used, a few drops of lemon juice should be added instead. Ruisins can be bought ready stoned.
Raisin and Apple Pic. Raisins and app!cs together make the following excellent pie Niash and stone $f$ th raisins, leave them to soak in a basin of cold water for a fow hours, and then peel 1 I . apples, cut them into thick

Raisin Batter. A wholesome, steamed pudding appreciated in the nursery
ometimes to an possible to lead some of the water with milk, and bake the pie in a hot oven for
slices, and remove the cores. Strain off the water from the raisins, reserving it ; stand a funnel in the centre of a pie-dish, and fill the latter with the raisins and apple mixed together, a lew slices of thinly pared lemon rind, and 3 o7. Demerarn sugar
Adil ahout a gill of the water in which the raisins were sonked Make 6 oz . Haky pastry, roll it out to a thickners of din., and cut from it a picce large enough to cover the top of the pie and some narrow sirips for the cdges. Damp the erges of the dish. put on the strips. damp these also. and then lay on the top
 Rainwater. Sectional view of underkround tank and fler bed, showing how the
water is purifed in clean washed gravel and coke. before being delivered into e cement lined stornge tank
with milk, and bake tho pie in a hot oven for ahout $\&$ hour, or until the pastry is lightly brow ned and the fruit cooked. Serve it dusted with castor sugar

Raisin Batter. To make this steamed pucdding, arld $40 \%$. prepared raisins to an ordinary batter pudding mixture (see page 70). Decorate a greased mould with a few raisins, and pour in the mixture. Cover with greased paper and a lloured pudding.cloth, and stenm it for about 2 hours.

Rais.n Chutney. Chutney made from cqual quantities of apple and raisins can be prepared thus: Peel and cut 1 th apples and half that quantity of shallots into dice. mix them with l lb. stoned raisins, al lb. brown sugar, 2 oz salt, $\frac{1}{2}$ oz. mustard seed, pint vinegar, and cayenne to taste. Simmer them gently in a pan over the fire for about $1 \frac{1}{2}$ hours, then put the mixture into a dry jar or bottle and tie it down when cold.

Raisin Dumpling. Add (ioz. prepared raisins to ordinary suet dumpling mixture, divide it into small even-sized portions, and rall these into halls on a lloured pastry-board. Cook them rapidly in a saucepan of hoiling water for about $\frac{d}{}$ hour, or until they rise to the surface of the water, then take them out and serve them with sugnr, and, if liked, some custard anuce.

Raisin Wine. Boil together $\mathbf{f} \mathrm{lb}$. raisins and 6 gallons water, and when the fruit is soft rub it through a sieve so as to remove the stones. Then put the pulp back into the pan, pour it, with the water, over the sugar, and add $\frac{d}{d}$ pint dried yeast spread on toast. Leave the mixture to ferment, and when fermentation has almost ceased, put in 2 quarts of elder Howers tied in a muslin bag. taking them out again when the wine is sufficiently flavoured. Bottling may be done as noon as the wine is clear. See Batter; Dumpling: Pastry: Sultana.

RAISING PLATE. The name is given to a small heam which rests upon the tie heams in a mof for the purpose of supporting the lower ends of the conimon raiters. The expression is also applied in some districts to the pole plate, or wall plate.
The general purpose of this timber is to raise the rafters above the level of the brickwork composing the wall so that air can circulate
around it Another function is to tie the ends of the rafters together and also to distrihute the load by apreading it over a large area See Rafter: Roof.
RAKE. The garden twol named a rake is used for covering in newly sown seed, dragging nut surface weeds from beds and horders, for tidying top onil, and as an implement to separate crocks and stones from fine earth Rakes with steel-tonthed heads about 12 in long are hoth efficient for open-ground work but for llower-bed raking and dressing, tools of half that length are more suitable. If found preferable, a wooden - tonther rake may be used See Casting Gardening ; Nail

RAM : For Raising Water. The hydraulic rant utilizes the momenfum of a volume of moving water to force a portion of the water to a higher level than that of the original head The principle is illus. trated in Fig. 1. Water falls from the reservoir through pipe $A$ to a ram chamber having a valve $V^{1}$. The delivery valve $V^{2}$ is kept closed while $V^{\prime}$ is onen, owing to the greater pressure of water in the delivery pipe. When the velocity of the water escaping past $V^{\mathbf{1}}$ through the holes 00 reaches a certain figure this valve is suddenly forced up rgainst its seating, and the trapped water opens $V^{2}$ and enters the delivery pipe until its momentum is cxpenderl. Then $V^{2}$ closes, and $V^{2}$ opens again, the cycle of operations continuing as long as water is supplied with sufficient head to pipe A The grenter the lift, the smaller is the proportion of the water forced into the delivery pipe.

As a guide, it nay be taken that the quantity, D, delivered will be equal to half the quantity (F) that enters the ram chamber multiplied by $\frac{W}{Y}$ in leet, where $W=$ the working fall and $\mathbf{Y}=$ the total lift from the ram. Thus if the working fall be 10 ft . and the delivery head 100 ft ., and $F=200 \mathrm{gal}$. per minute, then I) $={ }^{2002} \times{ }^{10}$ giol gal. per minute.

The ram illustratad in Fig. 2 is suitable for working falls from 3 ft . to 10 ft ., with delivery up to a height of 100 ft . This latter figure does not take into account losses due to friction, which virtually increase the delivery head and diminish the practicable height to which water can be raised See Pump; Water Supply.

RAMBLER : The Rose. This term is applied to vigorous climbing roses chiefly of two types, those raised from Rosa multiflora and others raised from Rosa wichuraiana The multiflora ramblers are rather less rampant than those of the wichuraiana type; favourite varietics are Blush Rambler, Goldfinch, Pemberton's White Rambler, Tausendschon, Tea Rambler, and Violetta and Veilchenblau (the so-called blue roses). All these are suitable for covering poles pillars and arches. Some of the hest ramblers of the wichuraiana type are Alheric Barbier, American Pillar, Aviateur Blériot, Chatillon Rambler, Pink Climber, Dorothy Perkins, Dr. Van Fleet, Emily Gray Fraicheur, Hiawatha, Sander's White, Scarlct Climher and Thelma. These are suitable for covering arches, arbours and trellis. See Rose.

RAMMER. An earth rammer is used to consolidate the surface of the ground when making a path, or after erecting a post. A heavy wooden rammer is employed when setting paving stoncs or cobbles. It measures about 3 ft . in height and 8 or 9 in . in diameter, tapering towards the top, where it is furnished with a single hand grip. A
second grip is fitted at right angles nbout hall way down, and the lower end, or head, is shorl with hoope to prevent it splitting.

A rammer with an ion head is handy in thegarden and costs little The shaft is abont 5 ft . long, and the head may be from about 7 lb . to 10 lb . in weight and cither circular or rectangular in shape. A head which is should be selected. In use the shinft is grasped between both hands, raised about a foot off the ground, and driven downward with a throwing action For lighter work the rammer is hela firmly int the hands, and the ramming is effected rather more by pressing or pushing the earth downwards.

RAMONDIA. This is a charming rock garden plant with a rosette of large leaves; it bears pretty purplish flowers in early summer The hest are Heldreichii, lavender blue; pyrenaica, violet purple; and Nathalide, purple Ramondia must be planted llat against a shady rock with its roots in a crevice filled with a compost of loam, peat (or leaf-soil) and sand Propagation is by sowing sceds or by division in late summer

RAMPION. This is the common nanie of phyteuma, a genus of hardy plants helonging to the bellflower family. They thrive in well drained gritty soil in the mek garden Some of the best are canescens, lavender hlue: comosa, blue and white ; and orbiculare, purplish: they are increased by division in spring. Tho dense clusters of hoom on rather short stalks give these plants a bizarre appearance.
RANCIDITY. A chemical change which is termed rancidity takes place in fats or oils when exposed to unfavourable conditions of the atmosphere, or kept 100 long without proper preserpation. This change produces a most disagrecable taste and smell. and renders them unfit for food

Butter particularly has a tendency to become rancid, and this tendency is increased if it is made up without the addition, or the very scanty addition. of salt. Hut once butter has acquired a rancid taste it is not possible to restore it completely. though it can be much improved. Wash it well and melt it slowly over the fire, skimming it from time to time; then strain it and let it cool Sometimes butter which is actually fresh persesses a rancid Havour: this is due often to une ven churning or neglect to extract all the buttermilk.

Both olive and almond oil have $n$ tendency to hecome rancid Neither of these should be kept too long, and never in a very warm place; the bottles must be well corked Fish oil quickly acquires a rank, unpleasant taste. See Butter ; Fat : Food: Oil ; Suet, etc.
RANDIA. This is the name of the plant from which Indinn ink is made. It is a hothouse, cvergreen flowering shrub with white or ycllow fragrant blossoms, horne in spring. The soil required is a mixture of loam, peat, and charcoal, and the temperature should average not less than $60^{\circ}$. Propagation is by cuttings taken in the spring.

## Ranges for Large and Small Houses

Advice on Choosing and Firing this Adjunct to the Kitchen

Arlicles rela:ed to the one below include those on Anthracite Stove; Conl; Fuel. See also<br>Boiler: Central Heating: Cocker; Kl:chen; Oven

The older type of kitchen range earned for he tilled around with brickwork when the range itself an unenviable reputation, consuming as is being fitted into the house The design of a it did large quantities of fuel: often with flue is the work of a specialist just as much as poor and variable resulta. Thic causc was the design of the regulation of the air supply to generally to be found in badly designed or the firc. Too small a flue will give an incffective inefficiently built flues; open fires and badly draught, as will unnecessary projections, sharp constructed fire grates ; the absence of proper angles or oracks in the flue itself Too large a means of draught regulation; the absence of in sulation from the front and sides; the lack of a highly polished top, and in the de sign and placing of the loot-water hoiler. These defects are overcome in modern types of kitchen range. which are scien. tifically designed and provided with various fuel and abour-savink devices
Instead of supplying merely the working portion of the range and leaving the flue to bc built up in brick work by the builder, the stove manulacturers provide iron flues, which can

Range. Fig. 1. Small portable range, very economical and portable range

Huc will callse nusch of the heat given out by the fire to pass up the chimney A badly constructerl tlue may give rise to back diaughte, cnusing the smoke to be blown out into the kitchen.

Well dcsigned ranges are ly no means expensive, and the pur chaser should not be sntisfied with just what the builder cares to supply, but should take tho trouble to enquire of one or two manufac. turers, stating the duty required of the range and the approximato amount lie wishes to spend on it. If there is cnough cooking to

Range. Fig. 2. Larger type, with high pressure boiler, rack, and bot closet. Fig. 3. Single-oven range of conventiona patrern having ename Fig. 5. Oil-fred double-oven range with glass and steel canopy 2.3. Smith it liellstood, Lid., and 5, Irrior Oil Burners, Llal
keep tho range going during the cold weather, enclosing three sides of the fire box and thus the stove can be made to give a plentiful having a high degree of efficiency supply of hot water for baths and other domestic uses, but it must not be supposed that this will be obtained without an extra consumption of fucl, over and above that normally entailed in cooking.

In the warmer montha, when the range is only required at intervals for heavy duty, recourse can be had to the gas cooker which is gencrally installed in most houses as a matter of course. The problem of hot water supplies can bo overcome by the use of a gas circulator, this being brought into operation during the time that the range is out of use.

When a boiler and a gas cooker are fitted in the kitchen it is often a convenience to install a small portable range in the scullery Fig. 1 shows an efficient and inexpensive range obtainable in quite small sizes, ranging from 24 in . wide ( 28 in with a side hoiler) to 42 in . wide. This range can be obtained with enamel finish at an extra charge.

Fig. 2 illustrates a larger range of the same type, having a plate rack above, and fitted with a high pressure hot-water boiler A useful hot closet is provided in the skirting underneath. When the cooking requirements are greater there are two types of range which can be considered, the one (shown in Fig. 3) following conventional lines and the other (Fig. 4) being an approach to a pattern favoured on the continent, where the stove stands out in the kitchen, thus gotting sidelight and permitting accoss to the side of the range. In the latter an L -shaped boiler is fitted

The single oven range shown in Fig. 3 is made in sizes to suit a recess from 36 in . to 54 in . wide. The back and sides are tiled, and the base is enamelled. The type of boiler fitted depends on the quantity of water required to be heated, and the least powerful will deal with a 20 -gal. cylinder The bigger boilers arc somewhat expensive, and run into us much as a small independent boiler. It is generally better, when the hot water requirements are large, to install a separate coke-fired boiler for the purpose
An Oil-Fired Rangc. A larger range is illustrated in Fig 5, with two ovens and a glass and steel canopy. The range shown in the picture is arrangel for oil firing, a method quite practicable with stoves of this magnitude, though it involves some considerable outlay on the oil burner plant, storage tank, etc. The system illustrated is the "Prior," utilizing a trough shaped horizontal burner. The oil is fed hy gravity at the bottom of the trough. and the air necessary for combustion is supplied at low pressure from a blower. The sane pattern of range is available for coal firing.

A cooking stove of different design and principle has bcen evolved by a Swedish scientist and is now on the market. It depends upon the accumulation of heat for its efficiency. The fuel used is coke or anthracitc, and though the stove be kept alight day and night continuously, the total annual consumption is only about $1 \frac{1}{3}$ tons. The heat is accumulated by a heavy and massive iron
barrel surrounding the fire-the latter being quite small-and is conducted to other parts of the cooker in the proportions necessary The temperature of the Larrel is controlled by an automatic device which regulates the draught accordingly. The walls of the cooker are insulated so that very little heat escapes and the kitchen does not get ton warm A tank holds ahout 10 gallons of hot water, which is maintained at a temperature just below boiling point and is available for cooking or washing-up purposes. Features of the "Aga" cooker, as the stove is namied, are a boiling plate, over which toasting and frying are clone, a simmering plate and two ovens. The two hot plates arc covered when not in use by circular insulating lids which prevent heat being dissipated.
Combination Ranges. It is sometimos a convenience to be able to combinc in one stove the means of warming a room, heating water for the bath, ctc, and cooking. The range shown in Fig. 6 is typical of $a$ kind which allows a fair amount of cooking to be done at need, while preserving the comfort and cheery appearance of the open fire Beneath the oven is a griller, and above is a hot plate on which a saucepan, etc., can be kept warm after heating on the fire below. A hot-water boiler is located at the back of the fire. This kind of stove can be fitted into a recess in the kitchen in place of the ordinary range.
The Fuel to Use. Some of the combination appliances are specially designed for burning anthracite and coko, with which they give very good results, but in most ranges a good long. flame coal is the best fuel, as the Hames are extremely useful in heating the oven. The advice of the maker should be taken as to the most suitable fuel. Where kitchen coal, nuts or cobbles are recommended, care should be cxercised to find hot, frec-burning, clean coals which are well sized

When lighting the fire, woorl or paper or a firelighter should be employed in the ordinary way, care being taken to allow air to pass through freely from below. Coal and cinders from the previous day's fire should be built up lightly above the wood, and when oombustion is well eatablished further coal nay be added. The dampers should he arljusted according to whether heat is required first for hot water or cooking purposes. Much time will be saved if care is taken to use only paper and wood which are thoroughly dry, and it will assist matters greatly if the coal has heen kept in a dry place. Trouble is sometimes experienced in lighting a

Range. Fir. 6. Combination stove which cooks, heats bath water, and warms the sitting room Samiuel Smith.d. Sons, I.1d
lire, owing to the flues being cold, in which enso wood should he burned freely for a short tinio in order to warm up the range.

It is not adrisable to nllow a fire to become too low ; but it this has been done, only a very sinall quantity of fuel should be added to the dull fire. The fire should then be rakel, the draught opencd, and when the lire is burning more briskly fresh luel added, due care being taken not to put on too much at $n$ time.

In those ranges which depend to a great extent upon llame for heating the oven and boiler, the fire should he stoked at the time when oven or boiler heating is required, so that full advantage may be taken of the flame produced in the early stages of combustion.
RANUNCULUS. Some of the worst garden weeds -hs well as many beautiful hardy flowering plants are contnined in this genus The weeds are the various wild buttercupe of which the most troublcsome is the common buttercup (Ranunculus acris). Fair Maids of France (Aconitifolius flore pleno), which bears small double white fowers on stems 20 in

Ranunculus. Bright gold fowers of an attractive litt!e plant for a ahrubbery or rock Rarden
high inl May is a charning plant for moist soil it is happy by the waterside or in the bog garden. Amplexicaulis, 10 in , with grey leaves and white Howers, and lingua, 2 ft ., yellow llowers in summer, are also good plants for inuist soil

Several alpine buttercups are delightful flowering plants for the rock garden; the best of them are montanus, yellow; alpestris, glacialis and parmassifolius, ivith white flowers in carly summer: they need well drained gritty, loamy soil and slight shade.

There ane some brilliantly coloured flowers among the florists' varieties of tuherous rooted ranunculus of which there are various types-French, Turban and Persian: the double Turban varicties are very handsome. Jhe tubers should be planted, claws downwards, in enrly autumn or in February-March in well-drained soil with which sand has been mixed frcely, if nccessary: they should be set whout 2 in. deep. It is ivise to protect the bed with bracken or evergreen branches in screre weather and to lift and store the moots after the leaves have diel down. See Bachelor's Button

RAPE. Rape is the popular name of a salad vegetable, Rrassica napus which is usually grown ansl sold as mustard in the mixture of mustard and ciess. Cultivation is the same as for mustard. When used as mustard in mustard and cress the proportions of seed to be used should be as two of rape to one of cress in bulk. If sown thickly on
vacunt ground and dug in when a tew inches ligh. rape maker an excellent gicen manure. See Cress: Mustarl.
RASH. An cruption on the skin or the: mucous membrance is popularly called a rash. It may consist of redness, piinples, blisters, pustules, or mixtures of these. Alost of the infections diseames have characteristic rashes, which observe $n$ fnilly constant rule with regard to the time of their nppearance in the course of a particular diseasc. They may be summarised thus: The usual day of appear ance : First day: erraipelas, chicken-pox, rubella or German measies (may be on sccond or thirl day). Sceond day: scarlet fever Third or fourth day : small-pox: the fourth measles. Fifth day: typhus. Eighth or ninth day typhoid fever.

The distribution of the rash: Frysipelas unless there is a wound, on the bridge of the nose and the cheelss usually. Chicken-pox. over the body and in the inouth. German measles the fice and neck, then over the trink and limbs Scarlet fever, the neck and
chest. then wer the body. Small-pox the forchensl and wrists, then over the borly Mensles, the forehead, face, neck, fauces. and over the body. 'Typhus, the abrlomen. then over the body Typhoid. the abolomen back. chest and clsewhere.

A rash may alsn be c!ue to poisons, cither those formed within the body in digestive and other dizorders, or those which are intronluced into the boily: and a rash often follows the use of antitoxic sera.

RASP: Its Uses. A rasp is a kincl of rough file used for shaping wood and other comparatively soft inaterial. Amongst manv varieties the ordinary pattern is that known is the half-round, one side being llat and the other semicircular in cross section. Rasps are also obtainable llat, circular and square in cross section.

A cabinet rasp is a half-round rasp with bather finer teeth than the ordinary liud. The mugher types are employed for primary shaping and the rabinet rasps for further finishing the wood

## RASPBERRY AND RASPBERRY DISHES

## Success in Growing the Fruit and its Table Uses

The fol:owing article follows our usual plan. The grouing of the bush is $f$ rst desarited and infermation fiven ahout diseases and pests that attask it. Then come de:ails about preparing raspberries in various ways for the tahle

Rich soil is essential to the successful Queen Alexandra and November Abundance cultivation of the raspherry, an invaluable if required for jam or for cooking purposes. hardy bush fruit Before the canes are put raspberries should be gathered as soon as they in, the ground ought to be dug deeply and manured. A mulch or top dressing of manure in spring is also advised. Every 3 years basic slag, 4 oz . to the square yarl of ground. should he applied in autumin. The plants ought to he 2 ft apart in mivs $\overline{\mathrm{j}} \mathrm{ft}$. from each other.

In spring tho cancs of newly planted raspberties should be cnt down to within ubout $G$ in. of the ground to force the de. relopment of fiesh strong shoots which will hear fruits the following year. No further pruning is needed until nfter the fruits are gathered. The old canes ought then to be cut right out and a limited number of new ones, five or six on each plant, ought to be tied to the support. Similar pruning should be done every year when the fruits are over. Farly in the summer numernus fresh shoots or suckers will develop, but those in excess of the number required should be pulled up. They may if necessary be transplanted to form $n$ fresh plantation

Some of the best red varieties of summer fruiting raspberries arc The Devon, Superlative, Perfection, Park Lane, and Royal. Lloyd George is called a perpetual - fruiting variety because it locars fruit in autumn as well as in summer. It is pruned in the way described above. Yellow Antwerp) is one of the best yellow rasp). berries.

Autumn fruiting raspberrics, which bear crops in September and October, need quite different pruning from the summer fruiting raspluerries All the canes must be cut almost to the ground in spring, for the fruits will be proclucel by the fresh shoots Good varieties are Hailsham.

Rasphery Cultivation. 1. Soil preparation: $a$, well-dug bottom soil ; b, manure. 2. Plantina up to old soil mark: $n$, firm soil. 3. Maiden cut down (a) after planting. 4. The result. 5 and 6 . Theory of pruning: $a$. removal of tips encourages tip fruit only: $a, b$ and $c$ graded pruning.
the best method. 7. Planting too close. 8. How to train a clump. the best mathod. 7. Planting too close. 8. How to train a clump.
8. Training on wires : $a$, old canes cut out

Raspberry. Left. Large and luscious berries of the Perfection variety, a favourite kind with fruit growers. Riabt. Autumn fruiting variety known as Lloyd George
sticliy substance, the whole then being biwnt. In addition an autumn soil fumigant of 1 part naphthaline to 10 prarts finc coal ash should be forked in.

The raspberry weevil is difficult to deal with, because of its nocturnal habits. It must be sought at night time while engaged in feeding, when all affected shoots must be well shakien deer a board smeared with tar or with some similarly sticky substance.

Activity of the raspberry weevil is generally evident by badly eaten foliage, appearing without the presence of insects during daytime Soil fumigation with a recognized preparation dusing late autumn is a good remedy, also spraying with lead arsenate before any of the canes fruit. A more homely remedy consista of ashes soaked in paraffin and sprinkled round the plants. The weevil hides in the soil during the day.

Raspberry Moth. The raspberry moth is sometimes a serions pest. If an infected plantation be examined early in May it will be seen that many young shoots have withered owing to the attacks of the small red caterpillars of this moth, which bore their way into the shoots. The remedics are to keep the ground clean, frec from rubbish, weeds, old sticks, etc., and to spray the raspberry canes in winter with paraffin emmlsion. A further remedy that will be found effective in destroying the raspberry moth is to spray late in March with lime wash marle by using 12 lb . of quicklime in 10 gallons of water.

Raspberry Sawily. The larvac of the pest called the raspberty sawfly feed upon the pith and cause the canes to shrivel. Cater pillars are about $\frac{1}{2}$ in. long and may be identified hy their colouring of insipid green. The only remedies are burning of canes containinc grubs and spraying with lead arsenate paste during the late autumn. The paste should be purchased ready mixed, and used in the proportion of $4 \mathbf{0 7 .}$ to i) gallons of water. The mixture is very poisonous.

How to Cook. If required for jam or for cooking purposes, raspberries should be gathered as soon as they come readily off the cane, just in advance of perfect ripeness Choice raspberries intended for dessert should be picked with whites Pour the the stalks just before they are ripe enough and hake tha pudding in a moderate oven to drop off. Discard any damaged berries until it is set. and place the others in a glass or chinr Raspberry Trifle. Spread $\frac{1}{2} \mathrm{H}_{1}$. raspberries fruit dish. Castor sugar may be sprinkled on a large dish, sprinkle them with castor over them a little while hefore they are to sugar, and leave them for about $\frac{1}{2}$ hour, mixing be served, or it may he handed round at with them 3 mashed bananas. Split 6 small
the tablc. Like strawberries, raspberries may also be served with castor sugar and cream. Raspberries are mixed with red currants for stewing or for making into pies and tarts or for jam. With bananas, raspberries can be made into a good fruit pures.

Raspberry Jam. To every lb. of fruit used in making raspberry jam, I lb. sugar should be allowed Pick over the raspberries, and put them into a preserving pan with the sugar ; cook then very slowly, and keep them well stirred until the sugar has dissolved.

Raspberry Trifle. A very delicious fruit trife made with fresh fruit

Then bring the whole to the boil, and continue boiling for about one hour or until the jam sets when tested on a colld plate.

Raspberry Jelly. A very good raspberry and claret jelly can be made as follows: Boil up $\ddagger$ pint raspberries, $\$$ pint claret, $\{$ pint lemon juice, 407. sugar, the rind of a lemon, two cloves, and 23 oz. melted leaf gelatine. Strain the whole through muslin, and then pour a little of it into a wet mould.

When it sets, decorate it with some chopped pistachio nuts, cover these with a little more jelly, and let this set also. Then pour in what remains and put the mould in a cool place. When its contents are set, turn them into a glass dish and it will be ready to serve.

Raspberry Pudding. A raspberry pudding, in which red currants also are used, is made thus. Line the edges of a deep dish with a strip of short-crust pastry, and into the dish put I pint raspherries and half that quantity red currants. Sprinkle over them 2 oz. castor sugar; then heat up the yolks of 3 eggs, add to them another 2 oz. sugar, and lastly stir in lightly the stiffly whisked

Raspherry Moth an injarious insect pest which attacks the young shoots. Below is sean the larval form of the insect
Hn permission of the Miniserstry of Apri.

sponge cakes spread the cut sides with rasp berry jam, then arrange them tastefully in a glass dish and soak them, first with 1 gill hot milk and then with t gill sherry.

Make a pint of thick, vanilla Havoured custarl, and leave it to coosl, and when the sugar has well soaked the fruit, pile the lattel in small heaps on the sponge cahes. I'our the custard over them, stand the trifle in is cosel place, and then ilccorate the top irith 1 gill whisked cream, sweetened and llavoured with vanilla and garnished with chopped pistachic nuts and raspberries.

Raspberry Vinegar. This fruit vinegar is made loy putting 1! lb raspberries into a jar covering them with I pint white wine vinegar and letting them stand for 10 days. Stir then daily, then strain off and measure the liquid allowing I th. cane sugar to every pint Boil the vinegar and augar together for about 10 min., taking the scum from the top, and let the whole cool before bottling it. It should he kept in a cool place

Raspberry Wine. This wine is made by putting ${ }^{6}$ quarts ripe raspberries into an earthenware vessel, bruising them well with a heavy wooden spoon and then pouring over them if quarts cold water. Let them stand until the following day. stirring them fre quently, then strain the liquor through a fine hair sieve, draining the fruit thoroughly.

To each quart of liftuor add I lb. lump sugar stir the whole occasionally until the sugar is dissolved, and then turn it into a cask. Bung the latter looscly for several days until formentation ceases, thon tighten the bung and let it remain thus for 3 months The wine may then he bottled for use.

RASPBERRY BUN. For this bun take Iflb. llour, 8 oz margarine or butter, 2 eggs , n pinch of salt, \& lb sugar, 2 teaspoonfuls baking powder, some raspberry jam, and some milk. Rub the margarine into the flour, add the dry ingredients, the eggs (beaten) and sufticient milk to make a stiff paste. Make into about 24 buns, and place them on a wellgreased baking sheet. Make a liole in the top of each, and put in a little raspberry jam. pinching the dough together about it. Balie them in a hot oven for ahout 15 min See Bun; Cuconut Cake; Rock Bun.

RASPBERRY GATEAU. This rich sweet can be made by sieving together $\mathbf{6}$ o\%. flour. 2 o7. cornllour. half teasponnful haking:

Respberry Gateau. A rich sweet suitable for serving at parties
powder, and a pinch of salt. Rub into them ilb. butter, then stir in 1 oz. eastor augar, and mix the whole to a stiff but pliable paste, with the yolks of 2 eggs , adding milk as required. Roll the paste out to a round shape about an inch thick, line a deep, greased sandwich tin with it. hrush it over with milk, and hake for 20 min . in a briak oven

Jet it cool on a sieve, then split it into halves, and spread the inner sides with rasp)berry jam, filting the two picces together again. Whisk the whites of the 2 eggs to a stilf froth, fold into them $\& \mathrm{lb}$. castor augar and what remains from \& lb . raspberry jam, and add a few drops of cochineal. Shalic the mixture on top of the cake in small heaps,
put the cake back into the oven so that the ineringue may set, and sprinkle over it a few blanched and chopped pistachio nuts.
RASPBERRY SHORTCAKE. For this cakc take \& lb. Hour, 3\& oz butter, 2 oz lard, $\frac{1}{2}$ tensponful baking powder, a pinch of salt, teaspoonful lemon juice, and an egg Sift the llour, baking powder, and salt into a basin, then rub in the fat lightly with the tips of the fingers Beat the egg, poup it into the centre of the flour, add the lemon juice, and mix all into a firm duugh. Knead it thoroughly and divide it into two portions, and roll these portions into two rounds about $\$$ in thick and 8 in across
Thic paste must not be rolled out more than once, oo it must be shaped during the rolling. Lay one round in a cake ring, brush the top with oiled butter, and place the other round lightly over it. Bake these in a moderately quick oven from 15 to 20 min and let the cake cool. Strain the juice from a bottle of raspberries and make the fruit into a purée. Cream 2 oz. fresh butter, and add 4 oz . icing sugar and the raspberry puree. Split the shortcake in half, and arrange a layer of the filling between the two halves and garnish the top with the remainder of the mixturc and whipped cream. Put the shortcake into a dish, make a syrup with the raspbery juice and pour it round.

RAT : How to Destroy. There are no more unwelcome visitors to a house than rats, which not only raid the larder but do much damage to property and are notorious carriers of disense.

The two kinds of rats found in Great Britain are the black and the brown rat. The former has increased rapidly in numbers during recent years, and is well known as a earrier of the plague. It has a tail an inch longer than its body, which is about 7 or 8 in long. The brown rat, which more commonly infests houses, is licavier in build and longer in body, with a shorter tail and a coarser fur, grey-brown above and white below.
'The first intimation of the rat's arrival is very often the discovery of a biggish hole beside a garden path, generally near a dust bin or the back cloor. If a fox terrier or other dog is kept it will often be the first to give the alarn by scraping furiously at the hole. Very often the intruder has got inside the house undiscovered, and announces its presence by unmistakable gnawings and crunchings at the woodwork. It may have visited the lander during the night, and scraps of food dragged about the floor tell their own story. The rat is not usually to be detected by smell, although he is a confirmed scavenger and may have come straight out of drains that need overhauling. Where poultry are kept the presence of a rat is soon announced by fathers lying about; eggs begin to disappear and chickens, too, unless prompt measures are taken.
Preventive Measures. One of the first things to be donc is to cut off all possible sources of food supply, for rats acldom remain in any place wherc they cannot easily obtain food for their young ones. The practice of leaving grain or other food lying about in poultry runs encourages their visitations, and the same remark applies to refuse allowed to accumulate in gardens or back yards instead of being put away in dustbins. Where the foundations of a house are concreted and the brickwork laid in cement the building is rendered to some extent rat-proof, and preventive measures of this kind, together with the use of galvanized iron shecting, arc particularly adviobble for stables; granarics, and farm buildings
Brsement windows aro protected by a covering of heavy galvanized wire netting of $\frac{1}{2}$ in. mesh: Burrows under floors from which
rats have been dijuen should the tilled with concrete, broken glass, or orockery and cement. But the most inportant, as well as the least expensive. of all preventive measures is to cut off ford supplies, particularly in the form of garbage, and sec that the dust hin is properly covered. especially at night.

Usc of Poison. So far as private houses are concerned, the two principal methods of destroying rats are by the use of poison and by trapa. Various preparations containing phosphorus, strychnine or arsenic are sold evcrywhere by chemista, grocers, and oil merchants. Many of these are in the form of a paste, which is spread on some strong sme!ling food, such as a piece of kipper or bloater, a scrap of bacon or cheese.

The bait thue prepared is placed far enough down the hole to be beyond the reach of cats and doga na far as possible. A point to bo noted in purchasing theso rat poisons is that if they have been kept a long time in the tradesman's shop the virus may prove less effective, at least in its immediate results This explains why rats have been known to consume repented lloses of poisoned food without apparently experiencing any ill effects, and other measures have had to be resorted to.

The greatest care should he exercised in keeping these poisons where neither children nor domestic peta can get at them, or where they might be mistaken for something else, with disastrous results Children should be specially warned not to touch the tin or box containing the poison, which should either be put away on some high she!f, or preferably kept under lock and kev. It is always a difficult matter to safeguard hens unless the poison can be placed outside the run, and even then there is the risk of fowls getting out and being poisoned, while in addition birds have been known to pick up the prison and drop it inside the run

## Another Kind of Bait

A less dangerous varicty of bait is provided by the use of cither barium carhonate or red squill, as powder or liquid extract. An effective mixture of the first kind consists of onc part each by weight of barinm carbonate powder, grated cheese, dripping and line oatmenl. The fat is melted and mixed with the dry ingredients into a thick paste. Two parts of rolled oats may be substituted for the checse and oatmeal. A good red squill recipe is made up of 1 part of red squill, $2 \frac{1}{2}$ parts of fine oatmeal or rolled oats, and $1 \frac{1}{2}$ parts of dripping. Sugar is also used as an ingredient in rat poisons, another recipe consisting of 1 part of red squill and 2 parts each of fine ontmeal and castor sugar, which should be ruhbed through a finc sieve and thoroughly mixed.

Liquid extract of sed squill can be obtained from any chemist. The method of using it is to mix some of it with an equal quantity of cold milk that has been boiled, add sufficient bread to form a thick paste, and lay it in saucers or tin lids in places frequented by the rats. Should only the powdered form of red squill be available. it should be mixed with bread and milk in the proportion of 3 or 4 oz . to a pint of milk. Preparations containing red squill are probably the safest to use for poultry runs.

Another method of waging war on rats is by employing a acientifically prepared virus composed of cultures of microbes. Tho effect of such a poison is to infect the rat with intestinal discasc, which is contracted by others. This method, however, is attended by a considerable element of uncertainty, and it has the grave objection that the infocted rats become carriers of the diseasc, with serious risk to human beings Punsigation with sulphur dioxide gas is resorted to in warehouses, ctc., but is not alvisable for bouses.

Use of Traps. 'Ihe oldest contrivance for killing rats is by means of a trap. The chiel proint in its fnvour is that it involves no such risks as accompany the laying down of poison about a house, and when properly laited nnd set it very often achieves its purpose when other methods have failed The principal varictics include the wire trap in the form of a rectangular box, $1 \frac{1}{2}$ to 2 ft . in length, which opens with a powerlul spring. The door of the trap is held open by a catch so as to afford access to a brited hook, and the slightest displaccment of the hook, as when a rat enters and nibbles at the bait. releases the catch and closes the trap, leaving the rat a prisoner Stecl gins or toothed spring traps are in use, and nlso the ordinary spring trap which kills the rat when the spring is released. In the varnish or bindlime trap strang lithographic varnish is spread on a piece of card board about 15 in by 12 in

It sometimes happens that $n$ rat nfter eating the poisoned bait, goes to its nest nud dies there, with the result that an offensive smell invades the housc. In such esses a goorl deodorizer is found in chloride of zine, which should be applied in the following manner A hole is bored as near as possible to the spot hom which the evil odour is supposed to cmanate. It may be neccessary to use a brace and bit for this puiprose 'The chloride of zinc is dropperl into the bole, which is then elosed with a colk
Legal Points. The Icgal side of the subjoet has been dealt with in several Acts of Parliament in recent years, as the necessity for destroying rats became more generally recog. nized. Under the Protection of Animals Act, 1911, rentricting the use of poisons, it is a complete defence to a charge of contravening the Act that the poison was used to kill rats, provided all reasonable precautions were taken to safeguard domestic animals

A more important change was made by the Rats and Mice (Destruction) Act, 1919, by which the occupier of land or buildings is bound to take all reasonable and neccssary steps for the destruction of rats and mice, and in default is liable to a fine of $£ \bar{u}$, or $£ 20$ in a case where he was served with a notice under the Act.
RATAFIA : Its Uses. This name is given to a llavouring essence made from the kernels of certain fruits, as apricots and cherries It has an almond like flavour, and should be used only in small quantities, a few drops being sufficient for most purposes. It can be bought in small bott!es from most grocery stores, but can also be made at liome.
To prepare it, pound the stonce from 2 lb . morello cherries, with 1 oz . blanched bitter almonds and $\Omega$ little brandy, thon turn them into an earthenware jar, and pour over them four breakfastcupfuls good brandy. Cover the jar tightly, and let its contents stand for $1 \frac{1}{2}$ months, shaking them twice daily. Then strain the:n through a sieve lined with blot-ting-pajer. and add 8 oz. or more of whitc sugar candy previously dissolved in a gill of cold water. The liquor may then be bottled for use. The ingredients nay be reduced provided that the same proportions are maintained
Ratafia Biscuits. Tho ingredients for ratafia biscuits are $\ddagger \mathrm{ll}$. ground almonds, 7 oz. castur sugar, mixed well in a clean bowl into a paste with the whites of 3 large cegs, a few drops of ratafia cssence and a squecze of lemion juico These ingredients should be added graclually. The paste is transferred to a bag, made with stiff pajer or with canvas (co:nct shaje), and with the bottom aperture-made by cutting off the point with scissors-about $\frac{1}{2}$ in. in diameter.
The little biscuits are then forced out by e mple pressure on the bag, which is properly closed at the top. They are laid out, a little apart, on paper, then Hattened on toj with a
wet brush and sugar dusted over. They are ratey to be paid by the owner instead of by baked in a warm oven until nicely coloured The papier is afterwards wetted on the back, and the biscuits removed, after which they are dried for some time in ony wnem place

Ratana Pudding. Beat up 3 oggs and put them into a pie-dish, and in the incantime heat $1 \frac{1}{2}$ pints milli in a pan with 2 dessertsponnfuls sugar Pour the latter when hot over the egge, mix all well tngether, and then add a little ratafia llavouring Cover the surface of the custard with mtafia biseuits, and hake the pudding in a moderate oven for ahout to min., or until the custard is set.

Care must be taken in enoking that the pudding does not brown on top, and to prevent this it may be covered with a plate. The oven should be cool, otherwise the pudding will hoil and canse the cage to curdle. See Custard: Forcing.

RATCHET. The purpose of a ratohet is to permit movement in onc direction and not in another. The shape of the tecth and also that of the pawl may vary and may often be disguised in various forms, but exsentially the principle remains the same though. out. In general, when a ratehet forms part of a mechanism, the pawl is kept in engagement with the teeth of the ratchet hy means of a light spring.

The ratchet is employed in watches and clocks to prevent the spring flying backward after it has been wound up. In some lawn mowers a ratchet drive forms part of the gearing which rotates the knives Another application is in the frec wheel of a bicycle. while further cxamples arc found in the ratchet brace and ratehet screwdriver. Sec Paivl.

RATEABLE VALUE. The ratcable value of a dwelling house is the amnount at which it is assessed or valued for the purpose of paying the local rates Usually this value is the rent less an allowance for repairs, generally about one-sixth, although this allowance varics in different localities A house for which $£ 60$ a year is paid in rent wi!! have a ratenble value in the neighbourhood of $£ 50$. On this amount the rates and also the incornc tax are paid. At definite intervals houses are revalued for this purpose, and householders who think their rateable value too high can appeal against it to the local authority Sce Income Tnx; Rent.

RATES. Money needed to meet the expenses of local authoritien, such as town and urban councils, is raised by means of a rate levied on tho occupiers of all property within the district. Rates ano thus the complement of taxes, the one providing the national and the other the local resenues.

In raising rates the first thing is to make a valuation of all the property in the area covered by the council. Ench house and building is valued at a certain sum, known as the rateable value, this being something less than the annual rent. Thus a house for which the occupier pays a rent of $£ 60$ will be rated at $£ 50$, or thereahouts. The deduotion thus made represents an allowance for repairs, etc.

On this rateable value the rates are asacssed, being at the rate of so much in the $£$. For instance, if the ycarly rate is 7 s . Gd., a man whose house is rated at $£ 48$ will pay $£ 18$ a year in rates. The rates are assersed and collected by the local authority, being paid in some places half ycarly and in others cuery quarter. With the moncy the local nuthority meets, directly or indirectly, the exprenses of roads, sanitation, fice libraries, workhouses, etc. ; also part of the expenditure on cducation.

If a man owns the boise he lives in, he himsself pays the rates. The rating authority may in the case of houses whose rateable value does not exceed fl3 (or any higher value provinusly in force in the district) require the
the occupier. The owner is entitled tonn allowance of 10 per cent. if he phrs in advance It is also frequently arranged, even in the eave of large houses, that. the ouncr shall pay the rates The amount in these cases is charged to the tenant, who pays a sum, every werk or month, for rent which is really rent and rales together. For doing thin the landlord is usually allowed to deduct somet bing from the a mount lie pays in rates.
In Iondon and other large cities flats are usually let on the anme terms as small houses. The landlord pass the rates and charges an inclusive sum to the tenant. When coniparing rents this important consideration aloould not tre ovarlonked. A flat for which $£ 70$ a year is charged may be cheaper than a house let at £50. It all depends upon which party pavs the rates and upon their amount

Under the Rent Restriction Acts Inndlords who are respnnsible for rntes oan add to the rent any extra amount they are called upon to pay for ratcs; also they must reduce the rent if the rates are iedaced Rates are not charged on buildings that are unoceupied. The local authority can isauc summonsea and then distrain if rates are not paid, and in enses of hank. ruptey any amount owing lor rates is treated as a preferential debt.

Ratepnyers dis. satisfied with the nmount at which their houses arc valued can appeal, but such an appeal must be suppurted by very strong evidence to have any chance of success. To make an appenl, the rate payer should first cummunicate with the clerli of the local nuthority for the district in which he lives, who wil! inform him whal stepe are to be talien The only other remedy is in use whaterer influence he has to secure the clection to the local anthority oí men who will practise economy in spending the public inoney and so reduce the annual amount that is payable in the $£$ on the ratoable value

In Scotland the system differs. There the rates are divided between the owner and the nccupier, ench paying about one-half.

Societics instituted exclusively for the purposes of scienco, literature, or the fine arts, and supported wholly or in part by annual voluntary subscriptions, arc exempt from all rates, ns also are churches and voluntary achools.
By the important Act passed in 1028 hereditaments occupied as railrays, canals or docks, and those occupied as factories or workshops, unless primarily occupied and used for any of the following purposes: (a) dwelling house; (b) retaii shop; (c) distributive rholesale business; (d) storage; (e) publio supply undertaking (e.g. gas or water works), are rated at only onc-quarter of their not annual value. By the same Act agricultural land was entirely relieved by rates. In cases where premises are ued partly for the above purposes and pertly for other purposes, the annual value must be appertioned between them. See Income Tar; Ront; Repairs.

Rat Tail. A tapering formation as scen on these two spoons

RAT TAIL. This phrase is used tor the tapering formation found on the backs of many table sponns and table forks. It was introduced by English silecremiths about Ifif0 in arder to strengthen the handles af sponns. This rat lail formntion or shaping lasted for nearly a century, when it uas replaced by the tongue or shell, but it has been reproduced by morlern makers. See. Spmon; nlso illus helow.

## RATTAN: For Basket Work. For

 lonicstic purposea rattan cane forma a convenient matcrial for cleaning drains, but it is also extensively used in basket inaking. The whole cane is utilized to a inrge catent for making chairs and many linds of strong baskets; the outer akin is peeled off and used for caning chairs, one side of it being quite smonth and bright.The inner portion, known as pulp or pith, is treated by machinery and drawn through holes in a metal plate, the resulting material being available in lengtlis of several diameters, ranging from the finest, 00 , to the thickest, No. 15 The appearance of the prepared pith cane when made up in the form of a basket can be improved by singeing the minute fibres which are left on the outside Cenerally the matorial is used quite plain, but it can be dyed or stained.
The main advantage of rattan for baskct work is its length, and for this reason it is largely used, and forms a inost convenient material for boginners in haslict weaving. Owing to its lightness the rattan is particularly adapted for making light and fancy haskets. Used in conibination with raffin, it forms an excellent material for making table mats. See Basket Making: Osier.

RATTLESNAKE PLANT. Alan termed the rattlesnnke orchid, this plant belongs to $n$ genus of orchids botanically known as Gondyera. It is generally grown in stove or greenhouse. but there are two hardy species, pubescens and repens, which may be grown outdours where the position is inild and sheltered

Pubescens grows ahout 3 in . high, hears white Howers, sometimes called adder's violets, during summer, with dainty foliage of green veined with silver; it thould be planted in pockets of peat and leaf-mould during spring. See Orchid.

RAVIGOTE SAUCE. Cold ravigote sauce can be made by adding 3 teaspoonfuls chopped parsley, chives, chervil, tarragon, and shallot, mixed in equal quantitics, to $\frac{1}{1}$ pint mayonnaise sauce, and tinting the whole grecu with vegetable colouring

To make hot ravigote sauce, boil togethes $\frac{1}{d}$ gill each whito wine and tarragon vinegar and a choppel shallot. When the liquor is reduced to $\frac{1}{2}$ gill, pour in a breakfastcupful ol whitc sauce, and add also If dessertspoonfuls of chopped parsley, tarragon, and chervil, inixed in equal quantities. Boil up the whole, and then simmer it all a few minutes before scrving. See Mayonnaise.

RAVIOLI. This is a popular Ita!ian dish composed of noodle paste with a snvoury stuffing. Directions for making the paste will be found under the heading Nondlo.

For the stuffing use the following proportions of ingredients : 4 oz . cooked chicken, 2 oz. cooked ham, l oz. grated Parmesan oheesc, 1 yolk egg, 1 tablespoonful thick white sance or cream, 1 tablespoonful tomato sauce. 2 teasponnfuls finely chopped parsley, salt, cayenne, grated nutmeg to well scason, a few hrown breadcrumbs

Pound all the ingredients until smooth, and rub through a wire sicve. Season well. Roll out the noodle paste as thinly as possible, and stainp out rounds about 2 in . in diamcter. Place n amall spoonful of the stuffing in the centre of half the rounds and wet the edges.

Cuver cach with another round and press the edges well together. Put thom in a pan of rapidly boiling salted water and boil quickly for about 2 nin.: stirring gently, then hoil slowly for 10 min . Jift them out with a fish slice, drain well und place in layers in a well-buttered dish, conating each layer with toinato sauce and a good sprinkling of grated cheese. Cover the top with a good layer of sauce, sprinkle with bmwn brendcrumbs, and lot with pieces of butter. Re-heat in a hot oven for a few minutes. and serve at once. Anv kind of coolied poultry or game may he used for the stufling.

RAY: How to Cook. When smootlihacked this fish is usually called a skate, but if the surface of the back is studded with spines it is called a thornbacki It must be skinned and crimped, and may then bo hoiled or fried, and served with $n$ suitable garnish and shrimp or enper sauce.

As a rule the fish is purchased from the fishmonger ready skinned and crimped, but if this work has to be undertaken at home, proceed in the following manner: Cleanse the ray, reserving the liver, and remove the skin both sides, then lay it flat on the hoard, and with a sharp knifo cut off the tail and detach the ficsly parts from the spine bonc on either sides. Cut the pieces into long strips by cutting through thic cartilaginous or tinny parts. Place these strips in cold water, then turn the fish over and repent the process. adding the strips thus obtained to those already in water. Leave the pieces of fish in water, changing it frequently until the atrips nppear crimped.

To boil ray, put the crimped picces into a saucepan with sufficient water to cover them, and add 1 wineglassful vinegar, 2 oz salt. and a bunch of parsley Let thio water boil up, and then simmer for 15 min . Drain the fish and keep it hot. Put the liver of tho fish in a small saucepan, and cover it with some of the liquor in which the ray was hoiled: cook gently for 5 min . and then strain. Dish, the pieces o? ray, cut the liver in slices, and lay over them. Pour over Hollandaise or sonio piquant sauce.

Slices of the crimped ray can be curled round with a small pieco of liver in the centre; they can then be dried in sensoned flour. cgged and crumbed, and fried in boiling fat. The liver is very rich in oil, therefore only small portions must be served with each slice. Blanch the liver hefore dressing it. See Fish: Hollandaise Sauce; Skatc

RAYNAUD'S DISEASE The condition that is known a Raynaud's disease consists in a disordered action of the vaso-motor nerves to the bload vessels, principally those supplying the extremities. By firm contraction of sma!! nrteries a part is deprived of blood and is blanched, or by dilation of the small veins the part is engorged with vonous blood and is blue, or from interference with their nutrition certain tissues actuslly dic.

Men may be affected, but women are more liable. The disense is most like'y to occur betwren the ages of 15 and 30 . It may follow the acute infectious discases, and is often associated with Bright's discase; other diseases and heredity may also play a part. Cold is the chief exciting cause. The whitening of the fingers is popularly refeired to as dend lingers. See Gangrene.

RAZOR. The varieties of razor in general usc, which aro known as the hollow ground and the safety, are made and used on different principles. One of the main distinctions is in the matter of blades. A good hollow-ground razor consists essentinlly of n strong steel blade, which will lnst a lifetime. In the arfety, on the other hand, the blade is only one piast of the mechanism, and it requires to be renewed from time to time, for which purpose
a supply of suitable thades usually accompanies every razor

In use the hollow-ground has a more or less dingonal movement, nnd can be applied at any convenient angle. The safety must be held in a vertical position and moved straight doirn, never horizontally nor transversely. Each of the two varieties provides an effective means of shaving when properly used; the clioice of one or the other is a matter of individual preference

There are various patterns of safcty razor. In gencra! they comprise a head on which the blade is secured, and a stem or bandle. Some are provided with a means of stropping the blades. The blado is sometimes a solid stcel one, bollow ground like the older type of razor, but is more ofton a very thin steel plate of fine grain.

The chief characteristic of the hollow-ground tazor is the contour of the blade. It is thinnest in the centre, so that it has tho appearance of being holloworl out. The cutting edge is slightly wedgo shaped, the back thick and at-rong The width of the blade is from $\frac{1}{2}$ to ${ }_{6}$ in., the lengt $h$ about $\bar{t} \frac{1}{2}$ in., of which the actual blado measures 3 in., the remaining $\underline{2 f}$ in. being the tang.

The care of a hollow-ground razor consists main!y in lieeping the edge lien by the use of a good leather strop. At rare intervals it may require setting on the stone. After usc it should be laid nside for at lenst one dry, as the rest is good for the cdge, which otherwise will vorysoon become dull. The same razor should never be used every day, nor oven on two sucoessive days. The best plan to kecp them in good condi. tion is to linve 3 or 4 razors, and never

Reaction Example of a reaction less than tivo.

As it is not ensy to tell a good razor from a had one by inspection, it is hest when buying razors to lie guided by the name of the maker and the reputation of the retail shop.

Sharpening the Razor. The routine sharpening of $n$ razor consists of 20 or 30 double passes on the lenther side of the strop every time the razor is uscd, and is preferably done after slinving, so that the cdge has a few days' rest between stropping and use. The strop is hung up on a strong hook at the height of the chin from the tloor, the handle is grasped in the left hand and pulled hard to keep the strop quite flat. This tension is important, as a weak pull will result in the strop cur!ing minutely round the blade so that the ellge gets rounded instead of properly keen. With the other hand the razor is then sivept boldly up and down the strop with the blade lying flat, the back pressing only lightly, but the edgo firmly. The reversal at the end of the stroke is efficted by a turn of the tight wist, which lifts the edge and lays its other facc on the strop as the return stroke is commenced.

During stropping n faint drag should be felt and n swishing sound heard, not a scraping noise, and the blado may emit a ringing note, but this is almost inaudible. If a strop gets accidentally gashed, it is best clisearded and
replaced. The only dressing required on the leather is n mere touch of oil or grease, and the application should he postjonerl as long as the lenther retains its so!! p!iability and its velvety appeniance.
After a period of regular use and stropping n razor loses its kcenness of edge; it should then be given 10 or 12 light double passes on the canvals side, lieeping a very heavy tension on the strop, followed liy the ordinary work on the leather. A hlade that is not restored by this treatment, or that is found to require it nt frequent intervals, needs a touch of the oil stone; if the owner lins enough confidena to attempt this operation hiniself he shofild use a finc carborundum stone moistened with, paraffin, using light pressure and much care and patience. A magnifying glass may be employed to examine the progress of the work from time to time.

The blade must be held with the edge on the stone, hut the back overhanging so that the two planes ground on the stecl meet on the edge at a very fine angle. This is facilitated by the faces of the blade being ground hollow: Before resarting to such a drastic remedy as stoning it is well to try if a dull razor can be restored by $n$ month's rest out of use on tiv 10 min . in:mersion in irater kept builing all the while. I keen edge must le maintained on a ra\%or both fo: the sake of get ling a clean and com?o:table shave, and to avoid cutting the face, an accident generally due to a dull blado. See Slaving.

REACTION: In Wireless. Jhis is a mothod whereby tho high fiequency alternating currents in the anode circuit of a wireless receiving valve are tiansferrod back into the grid circuit of the valve, thereby reducing the losses in that circuit and thus increasing the efliciency of the receiver.

When the amount of energy transferied back is suflicient completely to overcome the losses in the grid circuit the valve will oscillate, and if the grin co:l is coupled to the aerial circuit interference will be causerl to nearby receivers.

There are several nays of ohtaining reaction, most of which utilize an inductance coil magnetically coupled to the grid coil. The transfer of energy may be controlled by adjusting the number of turns on the reaction coil, by varying the distanco between the reaction coil and the grid coil, or by using a fixed reaction coil in conjunotion with a variab!e capacity (reaction condensor).

A popular method is to employ n fixed reaction winding magnetically coupled to the grid coil, liaving a reaction condenser of 0001 to 0002 mifd . in series between one end of the reaction winding and the anode of the valve. It is necessary to insert a high frequency choke or a resistance of about 10,000 ohms lietween thie anode of the valve and high tension positive to confino the high frequency curnents to that part of the circuit containing the reaction condenser and coil.

A refinement is to employ a dilferential reaction condenser. This comprises two sets of fixed vanes and one ret of moving vanes, each half of the condenser having a cajacity of 0001 to 0002 mfl .

One scheme is tu connect the moving vaner to the anode of the valve and one set of fixed vanes to one end of the reaction winding. The other set of fixed vanes is joined to earth or low-tension negative.

The advantage of the differential method is that adljustments of the reaction condenser have a negligible effect upon the turing ol the grid circuit.

In all methods of obtaining reaction it is essential for the reaction coil winding to be in the same dircction as the grid coil "inding to which it is coupled. Lack of maction in receivers employing plug-in coils may frequently be remedied by reversing the

Ivo leads to the reaction coil holder. See against the edge of the job and planing Condenser; High Frequency: Inductance: until the rebate is completed

## Oscillations

Ream. A ream consists of 20 quires of paper. A quire contains 24 sheets, and therefore a rean contains 480 .
Rear Axle. See Differential Gear: Live Axle: Propeller Shaft.
REBATE : In Cabinet Making. This is a kind of groove that is made on the edge of a piece of wood in the form of a step. An example is that found on the back of almost all picture frames. The purpose of the rebate is to provide a space in whioh some object, such as a panel, can be used so that its surface or one of its surfaces may finish llush with the top surface of the framework

Genera!ly spenking, tho rebate should be used in places where one piece is to fit into, and be supported by, another. For example, boards may be rebated to a hall of their thiokness so that, when the two prepared boards are bronglit together, the rebates in each will enable both faces of the boards to finish flush and form a level surface. This is a rebated joint
Rebate Plane. This is a tool specially made for cutting rebates. The simplest form is a narrow, hardwood plane with an iron that is the full width of the body of the p!ane Useful sizes are those of $\downarrow \mathrm{in} ., 1 \mathrm{in}$. and I! in. wide

The plane may he made with either a skew or square mouth; the skew generally is pre forred, because the shavings escape more firely, so that there is lass liability of the plane choking. Such a tool, however, is not very satisfactory for the actual work of inaking the rehate : it is rencrally used for cleaning it out, after it has first been prepared with the cutting gauge or hy chiselling.

'To be effective, n rebate plane requires some means to prerent it from slipping sideways on the wood. The tool known as a fillister is a development of the simple rebate plane with the addiion of a lence or glard to prevent the plane wandering over the surface of $t$ he wood. The fence is a movable piece of liardwood clamped to the sole of the plane by setscrews. These may be adjusted so that the width of the rebate can be regulated. A small brass shoe-piece controls the depth of the rebate, and a separate cutter is provided for cutting the inner edge of the rebate. The sash fillister is somewhat similar to the inoving one, but the fence is supported on two rods which slide through the body of the plane. It is used by first adjusting the fence and the stop to the equisite width and depth of the rebate. The cutter is similarly adjusted, and the plane is worked along the edge of the timber, taking care to keep the face of the fence

Another type of rebate plane, as used for olcaning up the rebate. is that known as the bull. nosed plane, generally made in metal. This is only 3 or 4 in . long, and is extremely useful for all kinds of work. It is virtually a small metal plane in which the plane iron terminates on the front of the tool, so that it is possible to cican out rebates, or any other hollows, right up to the end of the slot See Plane
RECEIPT : In Law. A reccipt is a formal written ackowledgment that a debt or bill has teen paid. In Great Britain receipts must hear a twopenny stamp or the equiv. alent, which inust be cancelled by writing across it. Any person who gives an unstamped receipt for $£ 2$ or more is liable to a penalty of $£ 10$, and the unstamped receipt is worthless as evidence if the creditor again claims the money, although it may be afterstamped at any time and so become available as evidence if the penalty is paid.

A receipt serves as evidence that a debt has been paid, but the person who gave it is always at liberty to show, if he can, that although he gave a receipt he did not receive payment: or that there was a mistake of some kind. The receipt is not conclusive against him, although a court of law would require very strong evidence for it to decide against a receipt which had been properly worded

A receipt, however, is not necessary in English law: A debtor, for instance, cannot rcfuse to pay what he owes because his creditor refuses to give him a receipt. At the same time. if the creditor should refuse a receipt and the debtor declines to pay on that account, the judge will probably make the creditor pay the costs because his conduct has been unreasonable.

If the debt is paid in cash, a receipt should always be obtained, and kept for a time so that it can be produced in case a claim is made for payment. If the debt, however, is paid by cheque, a receipt is not so necessary, as it is always possible to prove that the cheque has been passed through the bank. A cheque, however, proves only that money has been paid; it does not prove that the money was paid in resprect of the debt which the creditor is claiming. It is not necessary to keep receipts for more than six jears, as after the lapse of that time a debt cannot be claimed They are, however, useful as evidence of the prices which have been paid for various articles.

Filcs for keeping receipts in order are sold by stationers and others. If they are placed on the file in the order they are received, as they should be, there will usually be little difficulty in turning quickly to a particular receipt when required. See Bill
RECEPTION: How to Arrange. The most usual form of reception is that which follows a wedding, and is given by the bride's parents or nearest relative. Invitations are issued about three weeks before the ceremony and are included in the invitation to the wedding.

Invitations for other receptions, which are mercly formal "At Homes," are issued on "At Home" cards. Such receptions are given either in the afternoon or cvening to introduce some suecially important newcomer or guest ; or by persons in an official position, such as the mayor of a town or the member for a constituenej, to enable
them to meet all householders or voters as their guests, the sole qualification being that the guest should be a member of the municipality or a voter.

Such receptions are naturally large, and are usually held in some public hall or rooms: where light refreshments are provided. The catering is generally given out to some competent firm, which will quote a price for thic numbers to be catered for and submit a statement of what that price will include It is usual to provide some form of amuse ment for the guests, music being the most popular. The musical items should not follow each other without a panse, but at rather long intervals, and people should have plenty of opportunity for meeting each other. See At Home: Evening Pnrty; Invitation: Wedding.

RECESS: Its Fitting. In a house n recess is a small semi-enclosed space formed by a depression contrived in $\Omega$ wall or near the juncture of two walls. Typical examples occur at either side of the break-forward breast of a fireplace, and are usually ter minated at their outer sides by the adjacent walls of the room. These recesses are partic ularly useful for the erection of fitments. as the two sides and the back are already formed by the walls. In a sitting room shelves can lie fitted for books, or glazed doors can be framed and shelves provided for china and glass. For a dining room with two recesses in a bungalow or cottage, the dresser illustrated, with instructions for making, in page 388 would be a most useful fit. ment, with shelves for books or chinn in the recess on the other side of the fircplace. Corner seats with shelres above for books are also space-saving furnishing ideas.

For bedrooms, cupboarda are usually the best fitments; one with shelves and the other with space for hanging clothes. Such cupboards are fully described with diagram for construction in page 32

RECIPE. A recipe is a formula for the preparation of a mixture or compound of any kind. It is chiefly used in cooking and medicine Directions for making cakes, puddings, sweetmeats, etc., are known as recijes, as are directions for making up medical prescriptions. Other classes of recipes are those for maling up various bouschold requisites, such as glue or starch, and for compounding the scents and mixtures used for toilet purposes.

RECTIFIER. In electricity this is an apparatus for converting an alternating current into unidirectinnal pulsations. Examples are the crystal or the thermionic valve rectifiers used in wireless receivers, and the metal or vaive rectitiers employed to charge L.T. batterics or provide H.T. current for receiving valves. In the latter case these pulsating currents are first passed through a filter circuit and smoothed into pure direct enrrent.

Volve rectiliers may he cither half-wave or full-wave. A half-wave rectitier comprises two clectrodes, viz. filament and anode. If tha filament is heated and an alternating current applied between the anode and filament, then current will flow through the valve during the positive half cycles of alternating current and will cease to flow during the negative half cycles. Thus the valve will deliver unidirectional pulsations which can he smoothed into ripple-frec direct current. By suitably arranging two half-wave rectifiers both the positive and negative half cycles of alternating current may be rectitied. This is the principle of the full-wave rectifier, in which two anodes are contained in one glass hulh Half-wave rectifiers are suitable for use in eliminators where only a comparatively smiall output is required

Dry rectifiers may comprise a number of metallic plates clamped together in alternatc layers, thic combination being arranged so that
a fric pasange is offered to alternations of one polarity and a path of extremely high resistance to alternations of opposite polarity One combination possessing this rectifying property is copper oxide and coppar

Dry rectifiers may be connected in circuit to give cither half-wave or full-wave rectification, and may a!sc be constructed to supply Iarge D.C. outputs. They require no uplicen. Other types include electrolytic rectifiem, in which two electrodes are immersed in an clectrolyte (e.g. Irad and aluminium in a solution of sodium plospliate), and gasculus restifiers, which may tako the form of a glass bulb containing an inert gns such as argon and the positive and negative clectrodes See Eliminator

RED CABBAGE. This is a reddish leaved variety of cubbage, grown principally for pick!ing. Tho finest plants are obfained
from secels suwn in August, but $n$ sowing in March will provide nesful pickling cabbages in late antumn Blood Red is one of the best varieties.
REDCAP FOWL. This hreed, which is essentially Britieh, takes its name from the large rose comb, which in a first-clars specimen measures about 5 in . by 4 in , and is covered with fine fed points which are known ns work Its eges weigh about 2 oz ench, and the cockerels when fatted are much appreciated as spring chickens. The weight of adult males runs from $0 \frac{1}{2} \mathrm{lb}$. to $7 \frac{1}{2} \mathrm{lb}$., and that of the females from 5 lh . 10 6it lb . Scc Chicken Fowl ; Poultry.
RED CAP PUDDING. This is identical with black crp pudding except that the currants which give the latter its name arc substituted by small pieces of glace cherries See Black Cap Pudding.

## Red Currants from Garden to Table <br> Hints on the Successful Cultivation of this Fruit

Atteation may be drawn here to the articics on other fruits that can be grown in English gardens, c.n. Black Currant; Gooseberry; Loganberry: Plum. See also Jam

The red and white currants are profitable be well rooted by the following autumn and
bush fruits and their management is simplo. They should be planted in autumn-at 4 ft apart-in well tilled and manured soil in a sunny place In the spring following planting the branches of young bushes should be shortened by about half In subecquent years the pruning consists of chortening the side shonts in July to within about six leaves of the main branches from which they grew and in winter pruning them agnin to within about $\frac{1}{2} \mathrm{in}$. of the base of the past sumener's growth. This treatment will reault in the devclopment of fruit spurs. Care must also be taken to thin out the bushes to present overcrowding. Red and white currants may he grown as single, double or tieble-stenimed cordons on a wall facing north: there the fruits will ripen later than those on bushes in the open garden. Cordons are pruned in the way already described.

Some of the best varicties of red currant are Fay's Prolific, New Mad Dutch. Perfec tion and Raby Castle. Of white currants Transparent and White Versaillaise should be clinsen.

Both red and white currant bushes are easily propagnted by cuttings, 10 in long, inserted out of duors in autumn in narrow trenches 6 in deep: a layer of annd must be placed in the bottom ol the trench and the cuttings made firm at the base They will

Red Curraat. 1. Soil preparation, showing bottom spit well manured. 2. Planting. 3. Good cutting. 4. The same suitably prepared. 5. Cutting planted; $a$, sandy soil. 8. First year pruning. 7. Secoud year praning. 8. Encouraining truit spars (a). 8. Mulching: $t$, manure under top soil
may then be transplanted to a reserve plot until large enough for planting permanently

Currant bushes benefit by a top-dressing of manure on the soil in epring, and once in three gears basic slag should be put on the ground in nutumn, at the rate of 4 oz . per square yard
Pests of the Bush. Among the many pests that are harmiful to red currants is the clearwing moth, which causes shrivelled foliage, the only remedy being remuval and burning of affected shoots and leaves. The shoot borer bores into buds and shoota, the remedy being a spraying with caustic wash in winter and burning of affected shoots during growth. The currant sawfly defoliates bushis, and itn larvac may be cleared by repented spraying witl, a good insecticide emulsified in soft sonp. Other pests inclucle the magpie moth, white woolly, brown scale, and winter moth.
Currant-leaf spot is $\Omega$ disease nppearing in the form of dirty black markings upon the foliage, shrivelling the leaves and weakening the remaining growth. Bushes thus affected should be sprayed during summer with a solution of sulphide of po'assium, all fallen lenves being promptly burned. Handy preventires of currant troubles are syringing with strong lime-water, or soot-dusting in early inorning while the leaves are damp with dew.

路

For protcction against birds there is notling better than old fish netting. When wasps are troublesome the bushes should be enshrouded in old curtains or butter. mualin.

How to Cook. When added to other fruits red currants serve to bring out the flavour, as, for example, when a tait is mado of raspberries and red currants. The juice is frequently added to red fruit "hile boil. ing, and improves both the flavour and the colour

Red currants should lie stewed in a strong syrup of sugar and water.

Pick and wash the fruit and put thein with the syrup in a stewpan Let them boil up and then remove them from lire till cool Replace on fire to boil up again before serving. Red currants are better when mixed with, raspherries for puddings, tarts, or flans
Red Currant Cream. This is made with $1 \frac{1}{2 l}$. picked ied curiants Put them into a stewpan, mash them with a wooden spoon, and then stew them gently in the oven or over the fire until all the juice runs out Strain the !ignor through a hair siere, measure it, and return to the stewpan To every pint of juice add 6 oz granulated sugar mind 2 oz gelatine dissolsed in 3 toblespoonfu!s warm vater.
Stir all togetlier until the sugar is nelted, then lwil them for $n$ few minutes, slimming the toj. Put into a hasin 1 pint cold milk or cream, and when the currant juice is nearly cold, strain it in by degrees Turn the whole into a mould to set If the cur. rants do not yield 1 pint juice $\Omega$ little water may be added.
Red Currant Ice. Use $\frac{1}{2} \mathrm{lb}$. red and 1 ll . whitecurrants and I gill rasp-berryorstrawberry purće to 1 pint rich custard, and proceed ac. cording to the gencralinstructions which arc given for making ices in pages 614-615. Red Currant Jam. To make well-flavoured and brightcoloured jam with red currants, pick the fruit, which must le vory dry, and put it into a pre. serving pan. letting it boil up, and continue boiling
 for 5 min Then add l lb. lump sugar for ench lb. fruit, and boil all together, stirring and pressing tho fruit with $n$ wooden spoon and skimming well; 35 min . should be sufficient to oltain a firm jam, but it may be tested by dropping a little on a cold plate
Red Currant Jelly. To make this, top and tail $8!\mathrm{b}$. red currants, and put them into a jar with 2 gills water and $\ddagger \mathrm{lb}$ granulated sugar Cover the jar with a salicer, put it into a large saucepan of water, and cook its contents gently at the side of the fire until the fruit is soft and all the juice extracted from it. Pour off the juice and drain it through a jelly bag. then put it into a preserving pan, nalding if lb. ump sugar to every quart of the fruit juice.
Boil the whole for about 40 min. or until it wil! set whon teated on a cold plate, and in the meantinc keep it well skimmed and stirred When cold, put the jelly into dry pota, tie it down, and store it in a cool, dry placa Red curmnt jelly is served with lare, roast or jugged rabbit, venison and sarldie of mutton: some people servo it with leg of mutton.

Red Currant Syrup. 'Lomake this, pick Iflls. red currants and ? lb . white curiants, and put them into $n$ bow! with II lb . strawherries or raspiberries. Press the fruit with a potato masher or wooten spoon in ordor to crush it, and strnin off the juice. Ifave this to ferment for about 6 days. then strain into a preserving pan, ald I 1h. lump sugar, and boil all toget her, taking off the scum as it riscs. When thoroughly boiled, cool it and bottle it for use.

RED HOT POKER. This is $n$ familiar hardy perennial with large tufts of narrow leaves and dense cylindrical clusters of small. brilliantly-coloured flowers on stems varging in height from 2 to 3 ft . Its botnnical name is Kniphofia or Tritomn, and it is known also as the torch lily, on accuunt of its torch-like inflorescences. The plants are hardy in well. drained soil, but they are apt to perish in ground that becomes water-logyed in winter. In cold districts the plants should be protected by placing bracken or other material round them. During the winter sume of the leaves will be disfigured by frost and wind; they should be cut off in spring when fresh growth begins.

The best time to plant is in March or early April; if the ground is heavy, sand and leaf. mould should be adrlcd An increased stock can be obtained by division in spring, but the planis dislike being disturbed.

The common red hot poker is Kniphofia aloides, which grows up to 5 ft . high and bears orange-red blooms, there are many varictics of this. A few other first-rate sorts are Macowanii, coral red, 2 ft ; Nelsoni, yellow, $2 \frac{1}{2} \mathrm{ft}$. Northiae, red and yellow. 4.5 ft . ; and Tuckii, vellow and red. Of the modern varieties Royal Standard, orange-red, 3.4 ft.; Goldelse, yellow, $2 \frac{1}{2} \mathrm{ft}$; and Mount Etna, reddish, 5 ft ., are very showy.

RED LEAD. Red lead is a crystalline powder known in chemistry as triplumbic tet roxide, or lead orthoplumbate, nccording to its purity. It has many cummercial usages, of which one is the manufacture of flint glass. Its use as a pigment is conmon, and it forms the base of the priming coats in painting.

The misture of red lend and gold size is n useful drier for painting; the same mixture is applied to the screwed joints of gas or hot water piping to ensure n leak-proof joint. A length of tuw or hemp is smeared with the paste and tiristed into the threads of the pipe, which is then screwed home. See Plumbing

RED MULLET. Superior in llavour to the gry mullet, the small, rose-coloured fish known as red mullet may be cooked in a tariety of ways. Baking and grilling are the best methods, but boiling is unsuitable.

For grilling, clean and dry 5 fish, score the skin across at frequent interva!s on hoth sides, and then let them soak for ahout $\frac{A}{d}$ hour in a mixture consisting of 1 gill melted butter, $1 \frac{1}{2}$ tablespoonfuls lemon juice, and scasoning to taste. Turn the fish occasionally so that both sides may be equally well sonked, then grill them before a clear fire for about 8 min . Scrve then garnished with a few puts of maitrc d'hôtel butter.
To bake red inullet, prepare two large fish acore them as directed for grilling, and then lay them in a greased baking dish previously sprinkled with a little chopperl parsley and fine breadcrumbs. Add seasoning to taste, squecze over a little lemon juier, finally adding some more parsley and breaderumbs Just before putting the fish into the oven to bake, lay a few small lumps of butter on top. The baling should take about $\ddagger$ hour. See Fish; Grey Mullet.

RED SPIDER. This minute pest attacks the leaves, chiefly of plants growing under glass and on sunny walls out of doors, sueks the sap from them and, if not restroyed, seriously weakens the plants. Thia pest is most troublcsorne in warra, dry conditions

Red Hot Poker. Torch-like red and yellow flower beads of the handsome Kniphofa
it can be destroyed by syringing the lower leat aurface with a solution of salt, 1 oz . in one gallon of water

REDUCER: In Photography. Nega tives which are too dense or too nearly opaque to print properly may be reduced by chemical solutions, just as negatives which are too thin may be intensified These processes are only to be used with caution by the amateur, awing to the risk of permanent damage by stnining.

Attempts should always be made to get satisfactory prints from a dense negative by chousing a soft printing paper before resorting to chemical reduction. Soft grade or portrait grade gaslight paper will frequently give pleasing prints from dense negatives, which on the ordinary grade paper show liarsh results.
There are three clazses of dense or semi upaque negatives, due to (1) over-dcvclopment of a correctly exposed negative; (2) overexposurc and over-development; (3) under exposure and over-derelopment; the last caso being probably the most common with amateur photographers.
The first variety of dence negative is some times due to not making sufficient allowance for temperature in hot weather when develop ing in a tank. The negative is dense all over though detail is clearly visible: but the shadows, which should be nearly clear glass, show a good deal of deposit, and the high lights are nearly opaque, all delicate toncs being lost.

The jرrint is harsh in contrast. Thus white dresses in portraits print dead white without detail. The best and safest reducer for such negatives is ammonium persulphate, made un as follows

Soldtion 1
Ammonium persulphate
40 gr .
Cold distilled water
402

## Sodlum sulphite <br> Soldtio: 2

Cold water
20 gr.
The negative having been soaked for alsout half hour in plain water or, more safely, in distilled water, to re-wet it uniformly and soften the gelatine, it is placed in a small, clean dish and about 2 oz of solution No. 1
oured over it, locking the dish gently. In a bout 2 min . the salution will turn cloudy, and reduction will have begun 'I'ten process should be ubservad carcfully, and the nagative examined at short intervals to see that ieduc tion is not procceding too far. In 5 min ., or less, reduction should be complete, and the engative should be taken out, quickly rinsed. and at once placed in solution No. 2 for 3 or 4 min., Which stops the reduction. Plain water is not effective. Afterwards wash well in the ordinary way.

On no nccount shou!d the negative be kept for more than 5 min . in the persulphnte solution. If one application is nut sufficient, a second hath of persulpliate solution may he used after the No. 2 bath and washing. It is equally important that No. 1 solution should not be used twice, nor should more than one negative be treated at a time. Fresh solutions must be used, or immovable stains will result.
This reducer acts proportionately to the density of the negative, i.c. it attacks the densest parts more than the thinner parts and so reduces harsh contrasts. Uscd as described, it is safe in oporation with properly lixed and washed negatives. Do not touch the surface with the fingers during the process or permanent narks will be produced.
Clearing Dense Over-exposed Nesatives
In the second variety of undue density, caused by over-cxposure and over-devclopment, the negative generally appears of almost uniform density, shadows as well as higlı lights, and may be even so dense that the subject can only be seen with difficulty when the negntive is held up to a strong light. Long printing gives flat or foggy prints with plenty' of detail. Enlargement is impossible. Here the best reducer is Farmer's solution, used fairly strong. This solution, when strong, attacks the shadows more than the high lights and so increases contrasts ; when weak it acts morc evenly. This property is taken advantage of by using it both strong and weak in reducing these opaque negatives.
Either take the negative straight from the fixing bath or after washing is completed, but not drying. If the negative has been dried it must be soaked for at least $\frac{1}{2}$ hour. Place it in a bath of (reshly made and unused plain hypo, 4 oz . hypo to 20 oz . water, without any acid alum or other chemical ns used in acid fixing salts. Make a solution of 1 oz . potassium ferricyanide in 10 oz . water. Pour the hypo off the negative; mix in a few drops of the ferricyanide solution until the solution has an orange tint.
Return the mixture to the dish containing the negative and watch the result carefully. Reduction proceeds quickly, and if details in the shadows disa ppear they cannot be restored. Remove the negative, therefore, while it is still somewhat too denso, and wash well in running water for $\frac{1}{2}$ hour Reduction continucs in the first portion of the washing period.

Next prepare fresh hypo and repeat the process, using less ferricyanide solution, making the mixture of hypo and ferricyanide a pale lemon tint. This second reduction will proceed nore slowly and will be much more even, but must be cnrefully watched. The first reduction increases contrasts, the sccond printing qualities. The negntive inust finally be well washed to remove all yellow stain.
The third case, under-exposure and overdevelopment, is most common with the annateur, and is the most difficult to remedy. In fact, it may be said that the best thing to do is to mal:e another, but corrcct, exposure. The negative is hard with opaque high lighls, Hhin, detailless shadows, and poor gradations. The print shows excessive contrast.

When under exposure is not too groat, improvement can be made by using the anmoniun persulphate reducer described
ahove, taling great care not to carry the reduction so far as to destroy what detail exists in the shadows. In this case reduction only makes the best of a bad job Local reduction is often useful, ns when the stiy portion or some high light in a negative is too llense. This can be effected with Farmer's reclucer, made as explained above, and applied with a camel-hair brush to the parts to be recluced after the negative has been bathed in the plain hypo solution. See Developing; Fxposure: Intensilier; Photography.

REED : The Grass. The giant reed of New Zealand (Arundo conspicua) is a vigomous ornamental grass, which bears pale Hower plumes in late summer and autumn, on stems 8 fcet or more high. The Provence reed (Arundo donax), which is equally tall, has leddish flowers. Arundo phragmites is a common waterside reed in this country; $\pi$ variety with variegated leaves (aureo variegata) is ornamental. The New Zealand nnd Provence reeds should be planted in asheltcred place in moist loamy soil, and it is wise to protect them with leavesor other covering in winter.
They should be planted in spring; that also is the season to propagate the peeds by division of the clumps.
REED: In Moulding. Is used in woodwork, a reed is a narrow convex moulding which can be worked by liand with a carving tool or a special plane, or by machinery. It is the opposite of the flute is moulding, and is used as a cabinet decoration, principally on table legs and also on picture frames See Beading: Moulding.

REED MACE. Reed mace is a hardy nquatic perennial herb bearing brown inflorescences. It is beat planted at the margins of shallow ponds, lakes, and strenms, during spring or autumn, and is propagated by division in February or March. The botanical name is Typha Two British species are angustifolia and latifolia: these are the plants commonly called bulrushes. They may be cut in autumn for indoor decoration.
REEL: The Dance. The Scottish reel for ballroom dancing is either a foursome or an eightsome. In the foursome two couples engage, but there inny be any number of sets on the floor. The two men take up prosition by standing back to back with their reapective partners facing them. In the opening inovement the dancers trace the figure 8 with $n$ skipping step and finish it setting to partners, when the dance is continued with variations of the two essential steps. These are the high cut, or beating movement of the free leg on the supporting leg, which remains stationary with perfectly straightened knce, and a travel. ling, kicking step known in the schottische.

Both steps require the turning out of the knces, and all work is done on toes and ball
ul the loot. in neither hop nor spring should the hecl touch the ground when coming down In the high cut the beating of the free leg should he on the ealf of the supporting leg hehind, and not on the ankle. In the travelling step a sjpring is inade on the first heat ; on the second and third beats there is no lorward movement, but a closing movement with the front foot and beat behind with the back fout

The Eightsome Reel. For the eightsome reel four couples take up position in a set as if for the Lancers The same steps as for the foursome are used in a modified form in the first part, but the special fenture of the dance is in the second jart, when cach woman dances in turn in the centre with each of the four men, while the others form a ring round the couple. Then each man goes into the centre and dances with each woinan in turn, and finally the tirst jart of the clance is repeated

The essence of Scottish dancing is the brilliance of the footwork; every step is performed witl angnlar precision and has a perfect place in the dance. When a reel is to be introduced into a programme it is quite usual for those who intend to engage in it to practise together, as, though there are only the limited number of correct steps, the arrangement admit of great rarintion The
arm work in Scottish reels should he below the lerel of the head, with a bend in the elbow emphasising the angularity which is char acteristic of the national dancing

In the Irish reel the body is held erect, and the arms passive at the sides almost throughout, so that nothing should distract the attention from the beauty of the footwork. The reel is a much quieter dance than the jig, the tapping movements being executed with great delicacy, and the whole effect should be of sparkiling lightness. The technique of Irish and Scottish reel dancing can only he acquired by most people, after lessous froin a good teacher, with a great deal of practice Reels should be danced with spirit, but without exuberance or exaggeration. See Highland Fling; Irish Jig; Schottische.

REFRIGERANT. Any drink which reliever thirst and allays feverishness is. called a refrigerant Examples include lemonade and all drinks made with fruit juice or with citric and tartaric acids. Thirst may often be best relieved by demulcent drinks, such as barley water. oatmeal water, or milk and water. A free use of iced drinks upsets digestion See In perial Drink: Lemonade.

## REFRIGERATORS FOR USE IN THE HOME <br> \section*{Modern Methods of Keeping Food Fresh}

Our articles on Kitchen and Larder may be consulted in association with the one below. Sec also Ice Safe : and the entries on th: various foods, e.g. Apple: Beef: Milk: Mutton Pork

Mechanical and other devices for reducing the temperature of the air in an enclosed space are known as refrigerators. Until recently the sole method of refrigeration or cold storage available for usc on a small scale was that of utilizing natural ice as the cooling agent. This system is exemplified in the ice safe described and illustrated on pinge 616. There are now several other systems available which are entircly automatic in action, needing simply a connexion to the elcctric mains, or the maintenance of a tiny jet of flame beneath the generator, according to the type of apparatus employed.

Refrigeration by the systems just mentioned depends upon the difference at a given pressure between the boiling point of certain volatile fluids (e.g. ammonia, boiling at $28^{\circ} \mathrm{F}$. below zero, or sulphur dioxide, boiling at $14^{\circ} \mathrm{F}$.) and that of water ( $212^{\circ} \mathrm{F}$.). The process is also dependent upon the law that when the pressure applied to a liquid is raised the boiling point is raised also. In order to freeze water it must be exposed to a temperature lower than $32^{\circ} \mathbf{F}$., and in order to obtain this lower temperature the water inust be brought in contact with a medium (the refrigerant) whieh has a lower boiling point than water. To make the process continuous and automatic the refrigerant must be caused to yield up the heat extracted, and then be made available for further use.
Heat abstracted from the substance in the cooling chamber is caused to evaporate a volatile fluid circulated in pipes around the chamber. The volatile fluid is then compressed, and its boiling point thus raised, so that it can be condensed and re-liquefied at available temperature, and the heat removed. The fluid now tlows back to the coil surrounding the cooling chainber, again to abstract heat from the food, ctc., therein contained
In the mechanical refrigerator the compressor is a pump olerated by the electric motor. In the non-mechanical type there are no such moving parts, the necessary pressure and movement of Huids being obtained by heating the generator cylinder with a gas or paraffin flame, or with an electric element.
The cycle of operations in a non-mechanical absorption system is illustrated in Fig. 1.

Heat applied to the aqueous solution of ammonia in the " boiler" liberates ammonia gas, which is then liquefied in the condenser. The liquid ammosia (as it is then) evaporates in a cylindrical vessel projecting into the refrigerator chamher, abstracting heat from the latter. The now gaseous nmmonin passea next to the absorber, there to be taken up by vater. The squeous ammonia falls liy gravity to the pumping coil, where the hent generates gas bubbles and so lifts the liquid through the punping pipe to the boiler. This pumping action slso causes the wenle liquid in the boiler, after liberation of the aininonia, to be returned to the absorber:

The function of the hydrogen is to assist hy its pressure the evaporation of the ammonia gas. The hydrogen, being freed from the ammonia gas by the dissolving of the latter in the absorber, returns to the evaporator via the gas heat exchanger It is cooled by passing through pipes on the outaide of which cir. culntcs the cold gas mixture exhausted from the evaporstor. The liquid heat exchanger lowers the temperature of the weak liquid as it passes from the hoiler to the absorler: The vessels and pipes forming the refrigerator unit are charged with the necessary hydugen. ammonia, and "ater at the factory, and are then bermetically senled A supply of cooling water fiows through the pipes surrounding the condenser and the absorber, and a heating llame or clectric elcment is kept in action while refrigeration goes on.

The compression refrigerator system illus trated in Fig. 3 works as follows: Liquid sulphur dioxile from the receiver D is ndmittell to the cooling coil by an expansion valice, 13, and cuaporates, extracting heat from brinc surrounding the coil, and thus cooling the refrigerating chamber. The gas goes on to the compressor, C, is compressed, and so made condensable at ordinary temperature. It is then passed through a radintor eoil, F, and clianges to a liquid, being stored in the liquid receiver 1), ready for further use. A thermos. stat, E, controls the electric motor for the compressor, statting up the latter when temperature rises above a predeterminci degrec, and stopping the motor when the desired low teinperature has been atinined.
 Courlesu of Electrolux. Lid

1 teaspoonful gela. tine, which has been placed in a cup and covered with cold water, left till soft, and then mixed with 3 tablespoonfuls of boiling water and stirred. Pour this amount of disaolved gelatine into every quart of milk and cream uscd The cream should be whipped and the tray containing the mixture should be removed every half hour until frozen and the ice cream stirred thoroughly. Salads, cold pies, melon and other fruit, milk, beer or soda water, are all greatly improved by refrigeration.

Now that firstclass refrigerators can be obtained on the hire purchase system extending over two years, and £4 or £5 down pays for installation, they bave hecome within the reach of many Choice of a Refrigerator. Whether an ap more people. The housewife should consider the paratus of the absorption type (Fig. 2) or one advisability of including one in her kitchen of the compression (mechanical) type (Fig. 4) equipment, not only from tho points of view is selected depends mainly on the operative of efficiency and labour saving, but also because agent available to the purchascr. The former fresh food is of more importance to the family can be obtained in rather smaller sizes, and has than anything else. Every year there are cases the advantage that no motor is needed. A of food poisoning which could be avoided connexion to the water supply is necessary if proper refrigeration of food was the rule and, unless oil is used for the heater flame, the apparatus must be connected also to the gas or electric service. In the mechanical refrigerator the condenser is generally air cooled, a fan sometimes forming part of the apparatus Both types are controlled by thermostats, and effective safety devices are incorporated. A gas, oil or electrically operated refrigerator will prevent waste of food in summer and in muggy winter weather. Lt will also enable the housewife to turn out dainty frozen dishes for the table with a minimum of trouble and expense.

With its assistance a cream or jelly can be mixed early in the day and will be set in time for lunch, or can he kept for the next day. Sundacs and ice cream can be mixed and left in the refrigerator until the mixture is frozen. When making, it is $n$ good plan to add

Larger refrigerating cabinet in which the cooling unit is operated by means of an electric motor

Sourleay of Kelvmator, Lt:

Careful attention should be given to from house to house with the duat casta refrigerator. Naturally it must be kept spot. lessly clean, or its end is defeated It should be looked at every day, washed out with a weak solution of soda and water whenever necessary, and each morning wiped over with a clean, damped cloth.

REFUSE: Its Removal. This term in cludes excretal refuse from house and stable, ashes, dust, waste from food, street sweepings, and trade waste. The removal by hand of dust bin refuse and street sweepings is known as scavenging. The removal from time to time by hand labour of excretal matters from privies or cesspools is known as the conservancy system. This method has to be resorted to in country districts, but in towns and cities excrement and waste water are removed in drains and sewers by what is called the water carriage system

All forms of refuse are likely to cause a nuisance or encourage discase if kept stored in or near the house for too long a time. For this reason the householder has a clear duty to see that the storage and disposal of refuse is carried out on hygienic lines. The quantity of refuse stored on the premises should be reduced as much as possilile by burning the easily destructible refuse every day. Vegetable and food scraps generally should be dealt with in this way, as they are particularly prone to give rise to trouble by decomposition.

The material that is not burnt should be stored in a hygienic type of metal ashbin with a well-fitting cover. The latter should always be kept in place to prevent the refuse from being blown away by the wind, and also to protect it from rain, as dampness favours decomposition The contents should be removed at least twice a week if possible. Horse manure should be removed frequently from stables. Nuisance from smell and flies is often caused by this form of refuse, but can be reduced by storing the manure in the cart in which it is to be removed

In country districts, where refuse is frequently dumped on the land, care should be taken to see that the refuse is well covered by at least 6 in . of soil until it has been well purificd by natural means, otherwise nuisance from sinell and flies will result. Excretal refuse must be treated with particular care, and where a cesspool system is in use it should be kept in good order, and care taken that any water supply in the near vicinity is not polluted thereby.

The practice of disposing of house refuse by dumping it on the surface of waste land and so making a shoot is not to be recommended, unless it is strictly controlled by the local authority. What is known as the Bradford System is the best form of controlled tipping. This is successfully carricd out in many large towns without causing any nuisance, and at a very great saving to the ratepayers. The inain feature of this system is that the refuse is tipped in layers about 6 ft. deep to proper levels. Care is taken that all tins and hollow receptacles are filled up solid. At the close of the day's work all refuse is covered up with soil or road sweepings about 6 to 9 in . deep. Special care is taken with any fish offial or other foul matter, which is buried deeply. Screens are provided to prevent light materials from blowing about.

There is no doubt that the most sanitary way of disposing of house refuse is by burning it in some form of destructor. Excretal refuse in most towns is carried away by the drains to the sewer, and so to special sewage works.

Duties of the Local Authority. The collection and removal of house refuse is a duty that devolves upon the local authority in every district. It is usually assigned to the sanitary department in towns and cities, and a staff of dustmen is employed for the purpose, who go
from house to house with the dust carts Ashpits are cleared by the dustman without assistance, but in some towns the houscholder is expected to get his dustbin taken out into
the strect and put back in its place affer it has been emptied. It is not an ideal or sanitary method, since people must pass rows of dustbins on the pavement, often standing in the hot sun Fortunately this practice is rapidly dying out.

Should there be any neglect or omission to clear a dustbin or ashpit, as may occur where a tenant has just come into a house that has been empty for some time, the sanitary au. thority should be at once informed in writing, as they are bound by law under a menalty to make the necessary arrangements . The tenant on his part should ascertain the time at which dust is collected in his neighbourhood, and make arrange. ments accordingly.

Open dust carts without protection of anykind are still employed, but the closed or partly closed type now used in many towns is more hygienic, as it involves little or no rish of dust being scattered a bout the roads in stormy weather The insanitary, high dust eart is rapidly giving way to thi motor dust van with a low loading line Many of these have automatic covers to secure dustless loading.

It should be noted that local authorities are only bound to remove house refusc; where a trade is car. ried on, and there is nothing in the nature of domestic work associated with it, responsibility for the removal of the refuse rests with the person who is carrying on business ont he premises. It is not always an easy inatter to decidc in which catcgory a given case may fall, and litigation has heen necessary to clear up doubtful points. Thus, clinkers from a steam laundry are trade refuse, but those from an hotcl are house refuse; but most authorities make arrangements to remove on payment of a sma! Ifee.

Garden rubbish should not be put in dust bins, although this is frequently done; if the quantity is not excessive the dust man may fake it if he chooses, and as a rule there is no difficulty, but with large quantitics the occupier must arrange for the removal as if it were trade refuse.

A better way of diaposing of garden and other similar refuse is to burn it in an incinerator. See Cessprool; Drains; Dustbin; Incinerator, Rubbish; Sanitation; Sewage.
REGENCY STYLE. In furniture decoration and architecture this is the term employed for designs created between (about) 1795 and 1830. Regency style was an offshoot of Empirc style and the designers were the modernists of the late Georgian period, though they were influenced by the work of Sheraton and Robert Aclain. Regency style at its hest was a wholesome revulsion from the trivial debased ideas borrowed from French
furniture of the worst school which had beconie fashionable at the end of the 18th century.

An archacological revival produced the Empirc style in France and its English derivative. An attempt was made by the leading designers to adapt Greek, Roman and Egyptian types of furniture and architectural features to contemporary use. Classica! influence had largely swayed the Adam designs. hut the Regency adaptations were on heavy, simple lines and some connoisscurs consider that beauty of form is rare in pieces of this period except in those which show direct development from the Sheraton school and in some of those designed by George Smith.
The originator of the Regency style in

England was Henry Holland, arclitect to the Prince Regent and designer of Carlton Housc. He applied detailed drawings of Roman fragmenta to designs for furniture, etc., and the work produced from these belongs to the more graceful examples of Regency style. The most characteristic work, however, wns the result of designs made by Thomas Hope, who, besides other sources of classical inspiration, drew on the cult for Egyptian designs which were the vogue in France. in 1804, after Napolcon's invasion of Egypit. In 1807 he published a book entitled "Household Furniture and Interior I lecoration," which contains illustrations of the picces most sought by collectors of Regency lurniture.
Kooms werc usually papered, marbled effects mado to resemble blocks being particularly liked and classical designs were popular on satin papers. Borders and mock pilasters were used. Marbled paper pillars, tinted to appear round were another feature, while doorways were sometimes grained to simulate rose and green marble. Pelmets and curtains were severe in form ; heavy satins, striped fabrics, and silk damasks were used for these and for upholstering furniture. Pictures were hung by tasscled cords instead of wire.
The association of strongly figured woods with inlay of brass and bronzed metal is characteristic of Regency furniture. Imboyna wood and zehra wooll were used as reneers for sccretaires and cabinets which were often enriched at the corners by Egyptian terminal tigures with heads and feet of ormolu. Mahogany and rosewood pieces were frequently decorated with gilded carving. English cabinet making of this period was of a high standard.

Chairs of this sty le commonly have a serollover back, and the legs splay out in a curve.

The settee illustrated is characteristic of the solid type of furniture made during this ןeriod, while the armchair shown in Fig. 2 is an example of the lighter style and is decorated with brass inlay The seats and backs are in some instances of cane mesh Circular tables, supported by a centre pillar and four splayed-out and curred supports, were made. and sofa tables with two end supports having yoke-shaped feet were introduced. Reeding was a favourite decoration. Towards the end of the period the short fluted straight sofa leg displaced the splayed support. Regency and Empire style franlily inspires certain modern designers and is particularly suited to the formal houses built at a bout this period A very simple adaptation for a small dining room is illustrated and described in pages 359-360. See Empire Style; Sheraton; Victorian Style.

REGISTRATION. In Great Britain certain facts must he registered, i.e. an official record of them must be made and kept in some public place. Such are births, marriages, and denths, which must all be registered with a registrar appointed for the purpose. Names used for husiness purposes, if they are not the exact names of the persons using them, must be registered. There is also a scheme in practice for registering the titlo to land. Letters and parcels can be registered for anfety. Motor cars and motor cycles must be registered. See Birth; 1)enth; Narriage ; Motor Car; Motor Cycle; Postage

REGISTRY OFFICE. This name is given to a shop or other place of business that serves as an agency for engaging domestic servants, governesses, ctc. Usually those requiring servants pay a fixed fee on entering their names and stating their requirements, and a further sum, which is a percentage on the wages given, when they are suited. Servants are not charged.

REHMANNIA. This is n herbaceous perennial, 2 or 3 ft . high. It is hardy in well-drained soil in the comparatively mild southern and western countics. and in summer bears rosy-purple flowers sonewhat resenbling those of the forglove but having $n$

Rehmannia. The rose-purple fowers of a plant
suitable for the greenhouse of for out of doors in mild districts
pronounced "lip." A variety named Pink Perfection is usually preferred to the typical kind because of its more attractive colouring. Rehmannia thrives in ordinary non-clavey garden soil with which sand and leaf-mould or peat have been mixed; it is an excellent pot plant for the cool greenhouse. Propagation is by seeds or division in spring. The secdlings must be raised under glass.

REINS. The reins are part of the harness of a horse, being used to hold it when it is ridden or driven They consist of two long straps of lenther ; one end is fastened to each side of the bit and the other is held in the hands of the rider or driver, who is able by this means to control and direct the movements of the horse. Reins are sold by saddlers and should he kept clean and bright by polishing. See Driving; Harness.
REJECTOR: In Wireless. This is a tuned oscillatory circuit comprising an inductance and capacity in parallel The device offers a high impedance to oscillations having a frequency to which the circuit is tuncd, and a low impedance to all other frequencies. Rejectors may be employed for the elimination of interfering broadcast transmissions.

A simple and effective rejector may he constructed as follows: Procure two (M) mifd. (maxinum) compression type semi-variable condensers, one bascboard-inounting coil holder, two terminals, a wooden baseboard, size 4 in $x 4$ in., and an ebonite terminal strip 4 in $x 2 \mathrm{in} . \times \frac{1}{4} \mathrm{in}$. 1)rill two holes in the ebonite strip for the terminals and also two holes for sccuring the strip to the kaseboard. Screw the terminal strip firmly to the baseboard and mount the two terminals in position. Next place the two semi-variable condensers and the coil holder on the baseboard and secure by means of wood screws.

Iooking at the rejector from the front (terminal strip end), join the left hand (aerial) terminal to one side of each compression condenser respectively Connect the reinaining side of the left hand compression condenser $\left(C_{1}\right)$ to one terminal (socket) on the coil holder. Join the other terminal (pin) on the coil holder to the remaining side of the right hand compression condenser ( $\mathrm{C}_{2}$ ) and thic remaining terminal on terminal strip.
Operating Details. Disconnect the aerial lead from the aerial terminal on the set and transfer to left hand terminal on rejector terininal strip. Join right hand terminal on strip to acrial telminal on set To oliminate a transmission working on a wave-length between 250 and 400 metres, insert a No. 50 coil in the rejector coil holiler (a No. 60 or 75 coil will be required for wave-lengt ha belween 400 and 550 metres). Set the right hand compression condenser to about one half its maximum value and adjust the left hand condenser until the interfering transmission disappears If neccssary a tinal adjustment may be carried out on the right hand compression condenser ( $\mathrm{C}_{2}$ ).
If the interfering transmission is particularly troublesonc try various settings of $C_{1}$, endeavouring cach time to find a corresponding adjustment for $\mathrm{C}_{2}$ for the minimum strength of the unwanted atation.

RELAPSING FEVER. An acute infectious fever, which is liable to a relapse or a series of relapses with intervening periods f́rec from fever, is, on this account, known as relapsing fever. The disease has occurred in epidemics in Great Britain and Ireland. Its incidence is favoured by overcrowding and want. and from the latter circumstance it was also known as famine fever.
RELAY, This is an electrical device usually comprising an electro-magnet having an armature which is arranged to close a switch in a local circuit when a relatively weak electric current flows through the inagnet windings. One household application is in the wiring of burglar alarms.

A relay station is a low power broadcast transmitter which radiates the prograinmes supplied by land line from a distant studio. Relay stations are intended to serve only a small area. See Bell; Burglar Alarm.

RELISH: In Cookery. A relish is any savoury ingredient calculated to give a piquancy to plain or tasteless dishes. The term is applicd also to special dishes which give a zest to the appetite. Pickles, sauces, chutney, and all table condiments arc considered relishes, and are added to meat and sauces to enhance the flavour. See Chutney ; Cocktail; Condiment; Hors d'Oeuvres; Picikle ; Sauce.

REMOTE CONTROL. This is a device for operating electrical apparatus at a dis tance. A locally controlled relay is usually emploved to make or break the nain circuit See Relay.

Rejector. Showing details of the rejector which is described in the text

REMOVAL. When a move to another house or flat has been decided on, it is advisable to obtain estinates from several firms of removal contractors. Representatives will call nt the house and make a calculation of the quantity of goods that have to be dealt with. and on their reports the estimates sent in by the lirms will be based.
It is always best to deal with a firm which has a staff large enough to cope with all omergoncies and experienced in the careful handling of all kinds of domestic furnishings. They will probably have a fixed scale of charges, and their estimate will include all the costs of packing, removing, unpreling, carrying furniture upstairs, fixing overmantels. ctc. They provide their own packing cases, and talie all responsibility for the goods while they are in their charge and which have been packed by their statf.
The sum charged dejrends largely on whether the goods ealı be packed into a single van or whether two or more may be required. It is advissble to sort out and dispose of all rubbish before moving, both on the score of less property to remove and of the opportunity afforded for getting rid of useless possessions.

Preliminary Arrangements. Before the removal there are various matters connected with the new house that should receive attention. Plumbing should be overhauled to see that all the taps and pipes are in working order. Roof gutters may need cleaning out, and the cisterns should be tested. Perhaps a new gas cooker is required; a goyser may have to be installed and new gas fires. Is this work may entail fresh pipes it should be finished before removal.

Where electricity is used the fittings should be decided on and all electrical work done before decorations, which also should be completed as far as possible before the furniture is brought into the house. Another labour saving point worth noting is to have
carpeta cleaned and delivered at the new home in time to be laid before the furniture is placed in the rooms. This does not apply to stair carpets, rugs or small carpets. The first would have too much traffic over them and the others are easy to lay and no heavy furniture need be placed on them. Linoleirm may also be fitted and laid wherever necessary. The house will, of course, have been thoroughly cleaned when the decorators have finished their work
Curtains and blinds may also be put up when the windows have been cleancd. Sometimes the incoming tenant arranges to take over such fixtures as pelmet boards, curtain poles and rods, blinds, lighting fittings and linoleum, and this also facilitates removal If these preparatory arrangements are all properly attended to and personal belongings are carefully packed in drawers of wardrobes and chests and well covered over, it is surprising how quickly a new home can le settled.

Packing Smaller Articles. Wherc there are many ornaments and much plate, china and Hlass, these things are usually packed the day before the removal under the supervision of the foreman. In any case packing cases are provided for smaller articles and pictures and for books. Large pictures should he protected by plenty of thick wrapping paper and moulded frames by. sacking. The firm will naturally only be responsible for goods packed by their own men, so that while it is always advisable to mention articles of particular value, it is best to leave the actual packing of them to the foreman.

Kitchen utensils and gardening implements are generally put in last. The former are packed in cases, with the exception of things which will be immediately required and which are best placed in a special box, so that they are easily got at on arrival. When the fumiture is being taken out, wardrobes and sideboards may be unscrewed and removed in sections if necessary, and this is the rafest plan where heavy furniture is concerned, as well as the most convenient. The leaves should always be taken out of a dining table and the table firmly screwed up to its smallest proportions, otherwise the screw underneath is
liable to become atrained or warped in transit Trouble with the piano depends mainly on its location in the house. If it has to be fetched down from an upstairs room careful handling is required not to damage walls and banisters; should there be sharp comers to negotiate, it may have to be taken out through a window, and an extra charge is made by the firm for the necessary apparatus

On arrival at the new premises the contractor's men look to the mistress of the house for instructions as to where all the things are to go, so it is always beat for her to be on the spot. Besides directing the disposal of the furniture, she will also see that any heavy picces which were removed in sections are properly screwed together again, and that mirrors. etc., over fireplaces are fixed in position

Where the removal involves a railway journey from one town to another the work of packing has to be very efficiently performed if breakages are to be avoided. Not only ornaments and amall articles, but every piece of furniture requires to be carcfully wrapped up and all edges and corners protected with straw or other material. Miriors and the more delicate pieces of drawing-room furniture need special attention, so that the packing-up takes longer to complete. The journey is made by goods train or motor vans, the contractors making all the necessary arrangements.

Legal Points. The important point for the householder to remember is that goods in transit are carried by the railway at the owner's risk, and, however carefully safeguarded, they are exposed to the risk of fire, whether in the goods yard or on the journey. It is therefore false economy not to take out an insurance policy covering the risk of fire while the furniture is in transit. Another point to note is that when more than one firm are engaged in the removal the householder should specially stipulate for an inclusive estimate, that is to say, an estimate which covers any charges made by the firm at the other end. Sce Electricity ; Fixtures; Lease Rent: Warehousing, etc.

REMOVE: The Course. A remove consists of the substantial dishes of the mest
course. Roast. boiled. or braised whole joints are removes, also beef à la mode, In rided fillets of beef or real, saddle of mutton, haunch of venison, or braised ham, etc. The remove follows the entrée.

RENANTHERA. This epiphytal orchid, shy blooming and suitable only for culture in a stove house, may be grown on bloctis of wood as described for other species in the article on orchids. It requires a minimum temperature of $60^{\circ}$ The growing period is from March to October. when roots reguire syringing twice daily. Plants rest during the winter period, and then require less moisture at their roots. Sec Orchid

RENDERING: With Mortar. Render ing consists in covering the surface of brick work or other structure with a coat of Poitland cement mortar. The rendering coat applied to the exterior of a house makes it more resistant to the weather. In a cement water tank the rendering keeps the water in the tank, or it may be used on the walls of a cellar to keep out damp. Rendering is often carried out for no other reason than to produce a smonth. impermeable, hard surface, an example of this being in the internal walls of a bitchen or of a scullery

The amateur will find that rendering with cement mortar is particularly beneficial to house property. The procedure to be followed must be guided largely by the nature of the work. In the case of small work, such as the briokwork immediately surrounding a trapped gulley at the outlet from the sink, it suffices to daub the wall with cement mortar, applying it with a trowel and smonthing it off. With a large aren, as, for instance, the whole of the exterior walls of a house, the rendering cont is kept uniform in thickness with the aid of screeds.

These are battens of wood about 2 in . wide and 1 in . thick, nailed to the wall to act as guides. They should be placed not more than 10 ft . apart, and set vertically with the aid of a plumb-line. Some horizontal screeds should also be put up. These can be kept straight by stretching a light line from one enil of the building to the other, and adjusting the
screeds until they are exactly parallel with it.

Rendering. Fig. 1. Preliminary spatter dash cont to rovide a key on brickwork. Fir. 2. Combings to furnish key
Courtesy of the sritish Porliand Cement Association, Lld

The screeds should he packed up so that the back of them is ahout $\frac{3}{3}$ in away from the normal wall surface, as this is necessary to provide for the first coat of mortar being worked underneath the screed The screeds are removed when the first coat has set Another plan that is sometimes adopted is to make the screeds in stmong cement mortar by working them up unt:l they are flat and true, and then allowing them to set hard. The wall surface at this atage has a series of ridgen upon it both vertically and horizontally, the upper surfaces or tips of the ridges heing on a level and true. In either case. the surface of the screed is used as a guide when finishing off the rendering coats

Rendering on Brickwork. With brickwork it is first necessary to rake out all the joints between the bricks and also to hack over the surface of them to roughen them so that they act as a key for the first rendering coat. In new brickwork which is intended afterwards to be rendered, facing bricks are often used which have a serrated surface. Another method of providing a key is to apply a spatter dash coat of cement and aand (l part sand. $1 \frac{1}{2}$ parts coarse graded sand, and 1 part water, all measured by volume) This is dashed on to the brickwork, leaving an uneven surface (Fig. 1). The spatter dash coat is left to dry for a couple of days.
Before applying the first coat, the face of the work is brushed down to remove the dust, and the hricks thoroughly wetted to assist the adhesion of the mortar. The latter may he prepared on a banker, or platform of wooden boards, in the proportion of one part of Portland cement and 4 parts of sand, for the first or rendering coat. The sand must be good clean, and sharp. and free from salt and earthy matter.

The proportions are obtained by measuring in bulk, using a pail or rough box for the purpose. The sand is measured up first, putting it on the hanker, and then measuring up the amount of Portland cement. This is put on top of the sand, and turned with the shovel two or three times. The remainder is stirred in with the shovel. Water is added and the whole mixed to a working consistency. It is applied to the brickwork with a large trowel, working as quickly as possible, filling the whole of one of the spaces between the screeds, working off the surface to an approximate fair surface, and trueing it up and straightening it by means of a floating rule

The work proceeds until the whole of the required surface is covered. The second or fining coat is applied usually ahout $\frac{1}{a}$ in thick, and should be composed of 1 part of Portland cement and 2 parts of sand, hoth measured by bulk. The same grade of sand should he used in the fining as for the rendering coat. The fining coat should be applied to the rendering coat as soon as the latter has set, hut before it is too dry, otherwise the fining will not adhere properly. A key is needed for the second coat and this is effected by combing the surface of the hacking coat when the latter has commenced to dry out and harden. The indentations should he about $\frac{\ddagger}{}$ in. apart and not more than $\frac{1}{k}$ in. deep (Fig. 2).
The surface is generally finished with a hand float, made of pine or other soft wood; in hetter-class work it is hrought first to a uniform face with a traversing rule, and then finished with a hand float. During the finishing process, the surface of the mortar must be kept wet with a brush, working up the face with the hand float in a kind of circular motion, as this tends to eliminate inequalities on the surface. This process is often known as scouring ; in addition to keeping the surface clear, it has the effect of hardening and consolidating the face

Finished in this way the mortar will dry out with a closely grained, compact, and smooth surface. If desired, it can be relieved by
jointing, that is, forming lines on the face junket and curds and whey. Rennet is about $\frac{1}{t}$ in wide and $\frac{1}{d}$ in deep, ruling them prepared from the stomach of a newly killed with a jointer. Other surface finishes are by calf. The stomach is thoroughly cleansed various methods of trowelling (Figs. 3-5). with salt and then drained for 3 or 4 hours. Alternatively, the work, if brought to a Afterwards it is stretched and well salted, smooth level surface, may be painted with and kept in the salt. one of the branded paints specially prepared for concrete and cement work. The ordinary paint is useless under these conditions. If it is desired that the aurface shall he waterproof the best plan is to use a recognized waterproofing material, which is generally obtained in powder form. and should be thoroughly mixed up at the time of preparing the mortar. See Cement: Damp: Mortar; Plaster.

RENNET. This is used in order to obtain a curdled condition of the milk. It is also employed for a similar purpose in making Curd; Junket.

## Rent and the Rent Acts

## The Leral Relations Between Landlord and Tenant

Agreements; Distraint; Landlord: Lease; Rates, are a few of the other articles that touch upon
Agreements; Distraint; Landlord: Lease; Rates, are a few of the other articles that touch upon
the aubject of rent. See also Furnished House; Ground Rent; House; Removal; Repairs
Rent is the money paid lor the use of houses or land. It is usually paid either weekly, or monthly, or quarterly, although landlord and tenant are at liberty to make any other arrangement about it For nearly all the smaller houres in the country rent is paid weekly, the collect or calling for it on Monday or Tuesday of each week. For the larger houses it is paid quarterly. Monthly payments are less common. but in London many persons pay rent for houses and flata by monthly instalments.

Furnished houses are usually let at a rent calculated by the week, but in this case it is not, as a rule, paid weekly. This division between weekly and monthly or quarterly corresponds roughly to the division between salaries and wages

The tenants of small houses usually pay rent and rates together, the weekly payment covering not rent only hut also rates. The landlord in such cases pays the rates from the money he receives. A number of flats are let on the same principle of an inclusive rent, as are most furnished houses. The landlord is obliged to show the amount he pays in rates, and under the Rent Restriction Acts he can increase the rent in order to cover any increase in the rates. Conversely, he must reduce the rent if the rates are reduced.

In some localities the plan of charging the rates on small houses direct to the tenants has been tricd, hut usually it is found that the other scheme is the more economical. The weckly rent paid by the tenant of a small house covers also any income tax which the landlord may have to pay on the property in question. In the case of larger houses, the Lenant pays this, but he can deduct the amount from the rent, and the landlord, if he is not liable to pay income tax, can recover it in the usual way.

Rent is not due until the midnight of the day upon which it is reserved to be paid, e.g. if rent is payable on Midsummer Day, it is not payable until midnight of June 24. Therefore it is not overdue until nfter midnight, and cannot be distrained for until it is overdue.
Rent Restriction. At common law land lord and tenant may agree on whatever rent they please, but with regard to certain dwelling houses this power is restricted by the Increase of Rent and Mortgage Interest (Restriction) Acta, 1920 and 1923, following certain earlier acte passed in 1915 and onward. These acts apply to dwelling houses huilt on or before April 2, 1919, where the annual amount of the atandard rent or rateable value does not exceed : in the metropolitan police district £105; in Scotland £90, and elaewhere $£ 78$. The meaning of "standard rent" and "rateable value" is given below. Dwelling house
includes a part.of a dwelling house which is let as a separate dwelling, e.g. one room in a house.
The acts do not cover furnished houses, ot rooms where attendance is provided at an inclusive rent, provided always that the furniture or attendance forms a substantial part of the letting. A house is none the less a dwelling house because part of the premises is used as a shop or office, or for any other husiness or professional purposes, but the acts do not apply to premises let for business purposes only.

Attendance always means attendance within the premises let; so that where the tenant of a flat which forms one of a large number in some London miansions pays for the services of someone to scrub the common staircase, and this payment is included in his rent, he is not apparently excluded from the act by reason of that circumstance.

For all dwelling houses within the acts there is a standard rent, and this standard rent is in the first place the rent at which the premises were let on Aug. 3, 1914. If they were not then let, the standard rent is the rent at which they were last let before that dise, or, if not let before, the rent at which they were first let after that date. Rateable value means the rateable value on Aug. 3, 1914.

Suppose the premises to have been let to tenants in the normal way continuously, no landlord can charge more than the standard rent until he has given a lawful and proper notice of increase. The notice must be one to expire at the end of 4 clear weeks, unless such notice is given on sccount of an increase in the rates, when it need only be one clear week Every notice must be true in substance, ie not false or misleading. No notice of increase of rent is valid unless the tenancy has been determined either by the lease running out or by notice to quit having expired.

In other words, the landlord can only give a notice of increase of rent where the tenant is holding over hy virtue of the act, and, but for the act, could be evicted. But if a tenancy may be terminated by notice, e.g. a weekly or yearly tenancy, if the landlond giver notice of incrase, it operstes as though it were a notice to terminate the tenancy from the earliest date at which it could be terminated by notice.

Rent Increases Allowed. The amount of the increases which may be charged is as follows
(a) On nay amount spent by the Inndlord on inprovement or structural alteration excluding decorations and repnirs, 6 per cent Interest on the capital sum if expenditure hefore July 2, 1820, and county court on the ground that the expenditure was unneressarv.
(b) The amunnt by which the ourrent rates exceed the rates payable on Aus 3, 1914.
(o) 15 per cent of the net rent. The net rent is, In casea where the tenant paya an inclusive rent (l.e. a rent which Inrludea ome payment in roapect of the ratas, which are then paid by the landlord), the standard rent leas the amount of the rates: in other caser (l.e. where the tenant pays his own rates to the ratandard rent
(d) Where the randlord is respohsible for the whole of the repairs, 25 ner cent of the net rent, and where he the reaponsible for part of the repairs mome amaller'amuunt fo lie elther agreed or declded by the county court.

When the tenancy is a sub-letting of part of a house, the sub-tensant may bave his rent increased by 10 per cent on the net rent of his part, and an amount equivalent to 5 per cent of the net rent of the dwelling house compris. ing the sub-tenancy may be charged to the tenant of the whole house. The tenant of $a$ house who sublets it in parts is bound to give his landlord, on temanc. a statement of particulars of the sub-tenancies The effect is that a tenant who aublets may increase the rent of his sub-tensnt by 10 per cent, but must band over hall of that increase to his own landlord

A tenant who has been served with notice ol increas under (c) or (d) above may, if the. bouse is not in a ressonsble state of repair, apply to the sanitary authority and obtain a certificate to that effect, and serve it upon his landlord; and thereupon he will have a good defence to any action brought for increase of rent and will not be bound to pay the inoreases till the place is put into proper repair. The certificate is not a defence if the state of the premises is due to the tenant's own fault. A landlord who transfers to a tenant any liability which he himself was under is to be deemed to have inoreased the tenant's rent to the eztent of that amount.

Decontrolling Houses. By an act of 1923, dwelling houser which have been protected by the Rent Reatriction Act may be " decontrolled," i.e. taken out of that protection in certain cases The restrictions will cease to spply in an $y$ of the following events :
(1) If the landlond was in possession of the whole of the dwelling house on the July 31, 1923, or came into possession of it at a later date. "Landlord" here means either a free. holder or $n$ tenant under a long lease at a small rent, and a dwelling bouse is not decontrolled if the tenant of a house who sub-lets rooms (and so is in a sense a landlord) comes into possession of one of the "dwelling houses" into which he bas divided the house, for be is not a " landlord" for the purposes of the act, liurther, where a Inndlord has let a house and his tenant has sublet part of it, that part will not become decontrolled if the landlord gets possession of the rest of the house on the tenant going out.
Posscsaion means actual possession, and the dwelling-house will not become decontrolled if there is merely a change in the tenancy with no interval between the end of the old tenancy and the beginning of the new tenancy. Thus, if a tenant whose tenancy runs from Saturday to Saturday, goes out on a Wednesday, having paid rant for the full week, and the new tenant enters on the following Monday, paying rent from the Saturday, the landlord will not at any time be entitled to possession, although he may actually enter, and the house will not be decontrolled. There must be an interval between the tenancies for which no rent is due by anyone The landlord should always enter the premises between the tenancies or send his agent there, in order to eatablish definitely that he is in possession. Acts such as having the dwelling-house cleaned or painted are very astiafactory evidence of being in possession.
(2) If the landlord grants to the tenant after the 31st July, 1923, a lease of the dwell.
ing-hnuae iot "term ol not reas than two yoars, ending not earlier than one gear after the date fixed at the time at which the lease is granted for the expiration of the Rent Restriction Acts. The Act wes due to expire on 25th Docember, 1931. in England, and on 28th Mav. 1932, in Scotland, huit, acoording to a statement made in Parlinment in Sept., 1931 it will be continuel for some time alter these dates. The granting of a lease will not operate to decontrol any dwelling-houses which are part of the principal dwelling-house and which are sublet to sub-tenants of the tenant to whom the lease is granted. Once a dwelling house is decontrolled. the landlord can charge any rent he nleases for it This means that there is a return to the usual house-letting syatem practised before the War, whereby the landlord in letting his house to a tenant obarged an economic rent, i.e. a sum to cover initial costa and show a fair margin of profit.

Arrears and the Rent Acts. A landlord can nut levy a distress for rent in the case of a dwelling-house within the Rent Restriction Acta without previously obtaining the leave of the county court.

Whether a house is within the Rent Kc atriotion Aots or not, an under-tenant or louger may obtain protection for his property against any diatress levied by the superior landlord for rent due by his tenant (i.e the immediate landlord of the auh-tenant). He should serve on the superior landlord or his agent a declaration in writing made and signed by him stating that the landlord's immediate tenant has no right of property or interest in the goods sought to be distrained, and that the same are the property of the under-tenant. An inventory of the goods referred to must be annexed to the declaration

## Tenants and Sub-Tenants

The declaration must also set forth the amount of rent (if any) due from the sub. tenant to the tenant, the times at which future instalments become due, and their amount, and must contain an undertaking to pay direct to the superior landlord instead of to the tenant any rent due or to become due until the arrears for which the distress has been levied have been paid off A landlord, when the rent due by his tenant is in arrear, may serve upon any aub-tenant of that tenant a notice requiring him to pay all future rent to the landlord, instead of to the tenant until the arreara have been paid off. When a sub-tenant receives such a notice he must pay bis rent to the landlord.

Deductions from Rent. Rent is invariably a net amount und not subject to any discount or other reduction, such ar $^{4}$ is customary in trade. It is only under exceptional circumstances that a tenant is entitled to make a deduction when paying his landlord An example of this is where the tenant has been called upon in an emergency to pay the ground rent and has done so in order to pro tect his own interests and to avoid trouble, or perhaps simply for the convenience of the landlord, or in his alsence. In such a case the tenant is entitled to deduct the amount from his next payment of rent. In the same way, when a lodger's goods are included in a distraint for rent duc by his landlord to the owner of the property, he can deduct their value, if they should be sold, from the amount of rent.

Quarter Days. For the larger housea rent is usually payable in England on one of the four statutory quarter days, namely Lady Day, March 25 ; Midaummer Day, June 24 : Michaelmas Day, Sept. 29; and Christmas Day, Dec. 25. In some tenancies, where no quarterly paymenta are expressly stipuleted for, the rent is payable at the end of each year, but in the great majority of leases and yenrly tenancics rent is payable on the quarter days.

When a house us vacant a tenant may be allowed to enter before the quarter day stated in his agreement. Refore the Great War, and the consequent shortrge of houmes, it was not unusual for a landlord to charge no rent 'or this extra period as an inducement to the tenant to take the house Now, however, the tenant will generally be expected to pay the lull rent from the date of entry. If he decides to leave the house before the tenancy has expired he is not entitled to make any deduction from the rent.

Recovery ol Possession. When premises are let for a fixed period the landlord cannot as a rule recover possession until the end of the period It is, however, in varin bly provided in a lease or agreement that the landlord ahall be entitled to recover possession if the tenant commita a breach of any of the terms of the letting -eg fails to pay the rent due, or to keep the premises in repair or uses the premises for some purpose for which he is forbidden by the ngreement to use them. In such a case, however. the landlord must firat serve a notice on the tenant and give him an opportunity of making good the breacher, and the court will not allow the tenant to be evicted if he does so and pays rensonable damages and costs.
When premises are let for an indelinite period, e.g. weckly, monthly, or yearly, the landlord cannot recover possession until be has served a notice to quit on the tenant, or the tenant has served one on the landlord, unless the tenant has committed some breach of the terms of his tenanoy which gives the landlord a right to recover possession.
Glving Notice. The length of the notice to quit may be atated in the tenancy agreement. If not, it will depend on the nature of the tenancy. In a weakly tenanoy. a week's notice is required, expiring on the day of the week on which the tenancy commenced. Thus, in a Monday to Monday tenancy, the notice must require the tenant to give up possension on some Monday at least one week after the notice is served. A month's notice must be given in a monthly tenancy, expiring on the date of the month on which the tenancy commenced. In a tenancy from year to year, six month's notice expiring on the day of the year on which the tenancy commenced. must be given. If the tenancy commenced on a quarter day, e.g June 24th, notice given on the previous quarter day but one, ie Christmas Day, will be sufficient, although there are not $18: 3$ days between Christmas and June 24th; but if the tenancy comnienced on a day not a quarter day, the full six montha' notice ( 183 days) must be given.

The notice should be in writing, addressed to the tenant and aigned by the landlord, and must atate clearly the promises to which it refers and the date on which it expires. A common printed form of notice much used by landlords requires the tenant to leave "on or before" a certain date. This form of words has been stated to be a bad notice and should not be used. A tensant is entitled to remain until midnight on the last day of his tenancy, so a notice expiring at noon would be bad. This branch of the law is very technical and all the reguirements must be strictly complied with. The notice may be served either personally or by post. A suitable form is as follows:
26. Plowden Road,
W. 20.

Octnber 1st, 1931.
I bereby give son notice to quit the premises now occupied by yoll as my tenant at 1/6, rountala Road, W.29, on Monday, October 12th, 1931
(Signed) Joun Dos
To:

## Elchard Roe, Esq. <br> 176, Fountain Řnad, <br> W. 29 .

No rent must be accepted for the period after the notice to quit hes expired (i e after

October $1: 2 t_{1}$ in the illustration) or the notice will be completely invalid Arrears may be accepted at any time. This does not apply to premises within the Rent Acts.

Notice and the Rent Acts. When a house is protected by the Rent Acts the landlord can only recover possession by applying to the court He must serve a notice to quit in the ordinary way, but his application for possession will be granted only if he can prove
(1) That the tenant has failed to pay his rent, or to perform some other obligation of the tenancy (see helow).
(2) That the tenant, or some sub-tenant of his, or some person living or lodging with him, Lhas been guilty of conduct which is a nuisance or annoyance to other occupiers, or that he has a!lowed the house to deteriorate by his neglect.
(3) That the tenant has given the landlord notice to quit and the landlord has in consequence taken some step, such as selling the house with vacant possession, which will scriously prejudice him if he cannot get possession. It follows, therefore, that a tenant in an ordinary case is not bound by any notice to quit he may give.
(4) That the landlord reasonably requires the house as a residence for himself, or for some child of his over 18, or for some person in his employment. In this case, however, the landlord must satisfy the court that some a!ternative accommodation suitable to the tenant is available. Altemative accommodation need not be provided in the following cases: (a) where the tenant was himself employed by the landlord and occupied the house in consequence of his enployment which has now ceased (e.g. was the manager of a shop who lived over the shop); ( $b$ ) where the landlord hecame landlord in some way other than by huying the house after May 5th. 1924, and requires the house ns a residence for himself or a child over 18, and the court is satislied that greater hardship would be caused by refusing to evict the tenant than by evicting him.
There are other grounds on which the landlord is entitled to recover possession, notably when the tenant has sublet the whole of the dwelling house, hut the above are the most important in practice It should be noted that even if the landiord suceceds in establishing one or other of the facts ahove, the court wi!l nevertheless not grant him possession unless it is satisfied that it is just and reasonable to do so. This is very important in practice, especially in a case where the landlord claims because the tenant is in arrear with his rent. In such a case the court will allow the tenant to remain in possession so long as ho pays his current rent and a small sum weekly of the arrears. If he fails to do this, the landord must again apply to the court, and if the court is satisfied thint there is no reasonable prospect of the tenant paying, it will grant an order for possession. When premises are within the Rent Acts, the Inndlord may accept rent after the expiration of the notice to quit.

These provisions restricting the right to recover possession will cease to apply to any house which is Gecontrolled, but the ohtaining of an order for possession on one of the grounds set out above will not of itself clecontrol a house.

It is a criminal olfence for a landlord to ask any prenium for letting a house to which the Rent Acts apply. A tenant, however, may agrec to accept a lump sum for giving up possession, hut landlords should exercise great care in entering into such an agreement, for it may be impossible to enforee it against the tenant. who may take and spend the money paid by the landlord and then refuse to perform his part of the bargain.

The Law in Scotland. In Scotland rent is paid hall-yearly as a rule on onc or ot her of the two term days, which are Whitsundav: May 15, and Martinmas, Nov. 11. These are called the legal ternis to distinguish them Irom the other dates in the Scottish legal calendar Candlemas. Feb 2, and Lamnias Aug 1, which are conventional terms Rent mav te paid on either of these latter terms if there is an agreement to that effect, but so far as the ordinary business of house letting is concrined tlie term days observan throinghout Scotland are Whilsunday and Martinmas.
A peculiarity of the northern system is that a tenant may enter on May 15 or Nov..11, hut in all the burghs he moves out at the end of his lenancy on diflerent dates. The moving-out dates are lixed a fortnight later than the term daps, namely May 28 and Nov 28.

The equivalent of the written or printed form of agrcement by which many English tenancies are governed is a document known as a missive, in which is set out the duration of the tenancy, the amount of the rent and when it is payable, the rates for which the tenant is responsible, and whatever conditions have been agreed upon as to repairs. No tenancy is effective until the missive has heen signed by the tenant

## House Letting in Scotland

The business connected with the letting of houses is carricd on as in England by house agents or factors, but a considerable portion of it is in the liands of lawyers. This applies especially to property let on weekly or monthly tenancies, hut it also includes larger houses and flats which are !et by the year or leased for longer periods The law agents undertake the advertising and letting of the property, collect the rents. and see that the conditions set out in the inissive are duly observed.

Notice to terminate a letting of a house must be given in writing forty days before Whitsun (May 15) or Martinmas (Nov. 11) if the letting is for over a year. If the letting is for four months or less the notice must be given some time not less than a third of the total let before the end, and if over four months then forty days before the end. All these periods may be altered by agreement between the parties concerned.

Special provisions apply to small houses entered in the valuation roll at a small amount. The maximum figure varies according to the size of the burgh in which the house is situated. No agreement for any letting of such a house is valid if made more than two mont hs before the let is to begin; lets for more than a month can only be ended on the 28th of a month at noon, and those for less than a month on a Monday at noon ; 40 days' notice must he given if the let is for 3 months or more. and a notice equal to a third of the let if the let is for less than three months. None of these conditions can be altered by agreement. If a tenant of such a house is seven days in arrear with his rent. the landlord may give him 48 hours' notice.

REPAIRS: To Houses. When $\pi$ house is let for a term of years the agrecment usually contains a clause stating whether the landlord undertakes all reasonable and necessary rejairs, or whether the liability rests on the tenant. In the $n$ bsence of such a clause there is no liability on either side so far as the agreement is concerned, hut there may be a statutory liahility. In Scotland, on the contrary, the landlord is liable for repairs, nud if he fails to carry them out the tenant may do so and deduct the cost from the rent.

Sometimes there is a covenant in a lease under which the premises are to be delivered up in a good state of repair on the expiry of the lease. The tenant should understand that in such a case he is liable to put the house in proper repair whatever may have been its
condition when he entered it. In this and all other cases everything depends on the terms of the agreement, and before he puts his signature to that document a tenant should always take the trouble to ascertain exactly what his pusition is in regard to repairs Thus the tenant is liable to the landlord for any disrepair if under an expiress agreement to yicld up the premises in gond repair
The usual oovenant in an ordinary tenancy other than by lease is that the tenant must keep the premises in a pmper state of repair. fair wear and tear excepted. and leave them in such a state at the end of the tenancy : and that the landlord shall have the right to enter the premises at any time or within reason to see that they arc in a proper state of repair. The landlord is under no liability to do repairs unless he has expressly agreed to do so, or there is a statutory duty imposed on him. Where liable, and he refuses, the tenant can do them and sue the landlord for the cost. The tenant cannot deduct such cost from the rent.
The tenant is bound to take ordinary care of the premises and to tnake good any damage done during his tenancy. He is not bound to replace windows or door panels that were hroken before he entered into possession, but if these or any other fittings should get broken afterwards he is liable for the repair.
A ronf which leaks after a tenant has taken over is often a matter of dispute. Apart from agreement or statute the landlord is not liable. It has been held in the courts that it is the tenant's duty to see to its repair': hut this is a doubtful proposition In most cases a landlord, in his own interest, will repair it so as to preserve his property : hut he would be quite within his rights in refusing to do so, and then the tenant in his own interest would prohably do it

## Repairs and the Rent Acts

Under the Rent Acts the subject of repairs acquired increased importnnce. Wherc the landlord is responsible, increase of rent is conditional upon a house being lept in proper repair, and he is dcemed to be responsible for all necessary repairs for which the tenant is not expressly liable. A certificate from the sanitary authority that a house is not in a reasonable state of repair is a good defence to any claim for increased rent.

A landlord is liable to his superior landlard or freeholder for repairs if the property is leaschold, and those who own their own house should carefully study the covenants of their lease. The ground landlord can compel him periodically to re-point the brickwork, etc. The landlord who is his own frecholder is liable to the local authority if his property becomes dilapidated.

Houses inhabited by the working elasses stand on a different fouting. The landlord here is deemed to warrant that the house is in a hahitable state when the tenancy begins and to contract that it shall be kept in reasonable repair during the tenancy. Such houses are those the rent of which docs not exceed $£ 40$ a year in London; $£ 26$ elsewhere. In no case does the implied warranty hold when the letting is for threc years and upwards, not determinable before that time by either party, and when the lessee has agreed to put the house into habitable condition.

A tenant who has agreed to repair and keep in repair his house is not hound to make a new house of it Unless he has expressly agreed to paint he need only paint so far as is necessary to preserve wood or imnwork, and not for decoration. Regard must be had to the kind of house, its age, situation, and the like. Thus a tenant of a house in Grosvenor Square, london, undertaking to keep it in repair, must conform to a much higher standard than a tenant in Mile End Road.

If the tenant fails to repair, when bound to do so, he will he liable in damages, but these
damages must not exceed the actual loss suffered by tho landlord. When a house is shortly to be pulled down or structurally altered, no damages can be recovered for failure to repair it.
A tenant should take care to see that the house is in good order before he enters it, for there is no implication of law, except as to working-class houses, that they are in such a state when let. unless they are let furnished. There is not even an implied condition that an unfurnished house is habitable: so if the new tenant finds tho drains aro unsound. he has no remedy unless the landlord waitanted them to be sound. See Dilapidatinns ; Drains: Rent.
REPOTTING. As plants raised from seeds or cuttings increase in size it becomes necessary to repot them, i.e. to placo them in larger pots of soil to provide the mots with the extra nourishment needed. The first repotting of the seedlings or rooted cuttings is in smail flower pots, $2 \frac{1}{2} \mathrm{in}$. wide: the next shift is to 5 in . pots, which are large enough for many kinds of flowering plants: 6,7 or even

8 in . flower pots are required to ensure the full development of certain kinds, e.g. chrysanthemum, cineraria, herbacenus calcenlaria.
Before disturbance for repotting, a plant must receive a thomugh soaking some few hours in advance. To turn a plant out of its pot grasp the stem between the fingers and invert the whole : then give the edge of the pot a sharp rap on the edge of a bench, and lift it clear of mots and soil. With a stick pick out the old drainage crocks and remove lonse soil.

The now pot must be scrupulously clcan, and it is worth while ensuring this condition by scrubbing it out with hot water. Clean crocks are desirable also. Suitable composts vary with different classes of plants. For palms and aspidistras, 2 jarts loam and half portions of leaf-mould, peat, and sand will be found excellent. The same materials in equal portions will satisfy ferns, whilst 2 parts good fibrous loam, 1 part well-decaved manure, and a littlo well-washed silver sand will suit such plants as fuchsias and geraniums. See Fern ; Potting.

## Repoussé Work in Brass and Copper

## Particulars of a Process that Gives Charming Results

This contribution should be read in conjur.ction with the article on Bowl. Where the elements of
simple repousséwork are explalned. See also Metal Work: Napkin Ring; Piercing: Silver Work

In its strict application, repoussé work mcans the formation in relief in thin metal of a pattern beaten up from the reverse side, but it now generally includes the shaping as well as the decoration of the article. It is a handicraft that can easily be done in the home, a workshop not being essential for its processes. Brass and copper are commonly employed, the most useful thicknesses of metal being from 26 to 22 imperial standard wire gauge.
In selecting the metal its ductility is of importance. Silver, although expensive, will bear considerable expansion and is pleasant to work on. Of the inexpensive metals copper is extremely ductile ; it can be finished with an agreeable surface and is not liable to crack. Brass is harder, and not so suitable for high relief, but for many small articles it is very useful. Pewter is extromely soft and easily worked, but it is liable to split, and only in the thinnest sheets can it be used for higli relief with any success. Iron and steel, particularly if thin, are capable of considerable expansion, but the repoussé ornament should be restrained.
Repoussé work may be begun with a few touls, the principal ones being shown in Fig. 1. The first is the hammer, the head of which should be steel, or at least steel faced; the handle of special form is about 10 in . long, quite slender for two-thirds of its length, and terminating in a knob of a flattened oval form. A boxwood mallet with a similar handle is also necessary.
A selection of small punches is required; these for a beginning should comprise a tracer, a number of raising tnols, pearls, punches, and matting tools. A steel scribing point is necessary, but it can be made from a knitting-needle ; a pair of shears, compasses, try-square, and steel rule complete the worker's equipment.
Although a number of small articles can be made without it, a pitch block is essential for good work. This is a block of wood covered with a thick layer of cement made by melting 4 lb . of best black pitch in an iron pot and stirring in $f \mathrm{lb}$. powdered resin and $\frac{1 \mathrm{l}}{\mathrm{b}}$. Russian tallow. When thoroughly mixed, add 4 to 5 lb . of plaster of Paris.

Fig. 1. Good outfit for the amateur, by means of which most of the work illustrated can be done courlesh of C. J. Ilucknett it Co., I.Id.
off the block. If the metal is warmed and wiped with an oily rag, any adhering pitch can be removed. The pattern should he plainly visible on the other side of the metal. and that side is now placed uppermost and fixed in the cement. A brass punch is placed between the raised marks and the hammer used to drive it into the metal.

It is better to work along gradually, making a slight hollow, and to repeat the proceas several times, rather than attempt to reach the required depth at one blow. It will be seen that much depends on the shape of the punch. If some hard brase rod and bar is obtained, it will be possible to form suitable shnpes with a a file. The sliaped end of tho punch must be quitc smooth and polished, as any uneven marks will show on the other side of the punched surface Having sufficiently deepenel the pattern, the metal is removed from the cement, warmed, cleaned, and then replaced with the raised surface uppermost

The shape of the pattern is now adjusted with the tracer, but this time it is placed on its side, so that hammer blows properly directed will work the raised pattern to its correct shape. This is a simplo operation, but care must be taken that only the lightest hammer blows are given, otherwise there is risk of driving the tool through the metal If the metal has liccome uneven during the previous work, it can bo levelled with the mallet, removing it from the cement and placing it on the sandbag, and when necessary on the flat iron, taling caro not to damage the raised surface.

Ornamentation of the Ground. If it is desired to punch or indent the surface of the ground, or give a matt effect, the metal must first be thomughly cleaned. Useful tools are the pearls, mado of round steel rod ground to a round point and polished; these are usually provided in 3 or 4 sizes. By obtaining n number of 5 in . lengths of $\frac{3}{16} \mathrm{in}$ steel rod, it will he possible to make suitable pearls, nnd also a tracer, which requires grinding to a blunt edge on both sides. Steel punches are made in the samo way, by using rod of suitable thickness and grinding the ends to the required shape. All steel punches must he hardencd and tempered, and the ends of them must be highly polished.

The methods described are suitable for all raised work, but with high relief it is necessary to removo the metal frequently for the purpose of annealing. Continusl hainmering, either direct or through n punch, has the sure effect of hardening the metal, and it is only when it is soft and ductile that the material can be thinned out. As a rule, the harder the metal is the more frequently must it be annealed.

More Elaborate Work. When the repousse worker has had experience in raising simple forms, nnd desires to attempt more elaborate work, it will be neccsarary to do some of the preliminary sinking on the sandbag. Owing to the skill required in the successful manipulation of the mallet and the prevention of undue straining of the material, it is not advisable to attempt this stage of the work until a fair knowledgo of the properties of thin metal has been gained.

When the sandbag is used, the surface of the flat iron, or a suitable hard surface, should be used in conjunction with it; after every few blows with the mallet, held as at Fig. 3, the work must be straightened on the flat surface: and frequent annealing must not be forgotten. The deeper the sinking is carried the thinner the metal becomes.

The surface finishing of repoussé work is an important matter, and consideration of the purpose of the finished work enters largely into it. If it is desired to tool the raised surfaces to any extent, it will lie necessary
to fill up the hollows before the motal is placed on the cement block. The surface modelling is done in the same way as ordinary raising, but using greater care. Punches suitable for working the particklar shapes are used. The tracer, omployed as descrilicel above, is a useful tool to define shapes.

Repousse decoration of bowl shapes is not so simple as in flat work, and diferent methods must be employed. Figs. 4 to $\overline{7}$ illustrate some of the progressivo stages in the process of decorating a small fruit dish. For a small bowl where it is impossible to use a punch. the method is to use a snarl held in the vico and a hammer. Sevoral shapes of snarl must be provided, and it is hardly possible for the amateur to attempt much of this work without a large equipment. The raising is carried ss far as pmssible with the snarl, and then tho bowl is filled with cement, so that the main portion of the work can be done from the front. Pinfessional workers rely almost entirely on surface modelling to obtain the effect, and are content to bulge tho decorated surface beforehand.
The sclection of suitablo designs is not difficult : many are to be found in the pages

of this Encyclopedia. It is important that the shaping should be done as far ns practicable before the ornament is worked. It is often possible to do the shaping and the decoration at the eamo time ; but it is only with a fow shapes that it is possible to shape the work after raising a portion of it Simple forms for trays and dishics can be done on the sandbag, and with the aid of one or two metal worker's stakes of varying sliape (see Silver Work) all but the most claboratc forms can be worked.

The method of procedure in advancerl work is very littlo different from ordinary raising, the main consideration being that of modelling. It is not always easy to gauge correctly the amount of sinking necessary to produce a pleasing surface effect ; only exporience en ables tho worker to obtnin tho approximate depth so that removal from the block can be reduced to a minimum.

With large bonls it is always advisable to completo the shapc as far as possible before the docoration is appliod, and also to use tho sandhag and mallet to heat out prominent portions of the design. This method assists the raising, because tho metal is spread more evenly than is possible on a large surface when only raising tools are cmployed.

Final surface linishing should not be nttempted unless the hollows have heen filled completely with pitch; if there is much work to do, it is advisablo to use $n$ harder pitch than is generally employed Matting tools should bo used always with discretion, and in lange work must be avoided for purprses of background effect. The main object in employing them sloould bo to give texture to leaves and drapery.

Cleaning and
 Finishing Themetal when worked is warmed and cleanerl and then dipped into an acid bath; it is washed and dried and then polished with a hard brush and powdered puinioe. If r highly polished surface is desired the prominent portions

Repoussé Work. Showing how the various toals are held and used for the successful execution of this decorative metal wark. Fig. 3. Inclination of the mallet when beating aut a hallaw in a flat piece of metal. Fig. 4. Method of holding the tracer. Fig. 5. Tracer held on its side to true-up shapes in the design. Fig. 6. How to hold the punch. Fig. 7. Method of holding the mallet for flattening metal
should be burnished and finally coated with cascade. The practical unit of resistance is lacquer. but it is usual for a plain surface to be left and then lacquered. A common finish for copper is oxidizstion: this is effected by dipping the metal in a solution of ammonium sulphide and thomughly washing when the desired colour is renched. Owing to the offensive odour of this liguid, the work should be done out of doors. To retain even the oxidized surface it should be lacquered.
REPP. The name rep or repp of this furnishing and dress fabric cones from the fact that the surface is ribbed.
The best furniture repps are made with threads of two different thicknesses running in both directions of the cloth. The structure is firm, and in good colours repp is a suitable material for covering chairs, settecs, etc. See Upholstery.

RESEDA. This is the botanical name of mignonette, a familiar plant with sweetsmelling flowers. It is sown out of doors in April for summer bloom, and in pots in August to produce winter blooms under glass. Resedn glauca, a hardy perennial with grey-green leaves and pale flowers in summer, is a useful border plant.

RESIN. The best-known resin, or rosin, is obtained by the distillation of crude turpentinc, which oxudes from pine-trees. It varies in colour from a pale amber to dark

Resiatance. Showing a complete resiatancecoupling unit as deacribed in the tezt
brown, according to its purity or method of preparation. It is a brittle solid with a glasslike fracture.
The solid resin is used for giving violin bows a grip on the strings, and in powder form is employed by golfers and tennis players to incresse the grip of the hands. Dissolved in turpentine or benzine a simple form of varnish is obtained, but the surface of the varnish is not sufficiently hard unlesm copal or mastic renins are also used with it.

Resin is used in soap making, and resin soap is supplied in the form of a coarse powder for household cleaning purposes, but owing to its colour it is not suitable for washing linen.

RESISTANCE. This is the opposition offered by an electric circuit to the How of clectric current. The resistance of a wire is directly proportional to ita length and in. verszly proportional to its cross sectional ares.
Copper and silver have a low resistance per unit length, whereas certain alloys, e.g., manganin, nichrome, etc., have a high resiatance per unit length.
Resistances are frequently employed in wireless receivers to prevent the passage of high frequency currents, to reduce voltages, and in certain methods of coupling valves in

Resistance Coupllng. In a wireless receiver this is a method of coupling the values of a low-frequency magnificr in cascade by means of resistances.

A resistance is connected in series with the anode of the valve and the signal voltages across the resistance are applied to the grid of the following valve by way of a coupling condenser The coupling condenser acts simply as a mcans of preventing the high tension voltage from reaching the grid of the valve. It offers a free path to the amplified signal voltages. A grid resistance or leak is joined between the grid of the valve and grid bias negative to allow the negativo charge on the grid to leak away and to maintain the grid at a steady negative potential.
The amplification per atage in a resistancecapacity coupled amplifier can never exceed that of the valve itself, and this figure is reached when the value of the anode resistance becomes infinity. In practice it is possible to obtain a magnification of about two-thirds the amplification factor of the valve. The use of $n$ high value anode resist ance in an endeavour to achieve the maximum amplification results in a loss of the upper musical frequencies and reduces the general brilliancy of tonc. become low pitched.

In general the value of the anode reaistance should not be greater than 250,000 ohms. When faultless reproduction is dosired the values of the anode resistances may be 100,000 ohms or even lower. The use of too high a value anode resiatance in the anode circuit of a detector valve may produce a complete lack of reaction. The coupling condenser should be sufficiently large to pass the lower musical frequencies, and 0.01 mfl . is a common value. It is essential for the condenser to possess high insulation, and for this reason the dielectric should be preferably of good quality mica. The grid resistances may have a value of 1-2 megohms.

A pmoperly designed resistance-capacity coupled low frequency magnifier will give very faithful reproduction, but the magnification per valve stage is considerably less than that obtainable with transformer coupling. See Annde; Capacity; Condenser; Dielectric: Grid; Resistance; [Rlenstat.
Respiration. See Breathing.
REST CURE. In the treatment of a large number of disorlers rest is an important. or it may be a necessary, element ; but the form of treatment for functional nerve diseases, such as neurasthenia, etc., associated with the name of W'cir Mitchell, is popularly known as the rest cure. The patient is kept in bed, but besides this is isolated, no that mental rest is secured as well as bodily.

The treatment includes more than reat, however, as an effort is made to improve nutrition by a genernus diet, including milk, and electricity and massage are used to improve muscular tone. The treatment is very suitable in some cases of neurasthenia.

REST HARROW. This is the common name of a gmup of hardy perennials or ahrubs (ononis) which bear pea-shaped Howers in summer. One of the best, suitable for the rock garden, is Ononis aragonensis, 18 in . high, with yellow flowers. Ononis fruticoss bears rosepink blooms. They should be planted in light or well-Irained s il, and in a sunny prosition. Seeds sown in summer or
cuttings taken at the samo time provide an increased stock. The commun rest harrow which grows wild in Britain is Ononis spinosa, a low-growing somewhat shrubby perennial with rose-pink blooms.

## RESTRANNER: Use in Photography.

 Chemicals used to prevent too vigomus a developing action on a negative or development paper are known as restrainers. Putassium or ammonium bromide is most commonly emplosed. They tend to delay density in negatives or bromide and gaslight papers while detail is formed. Potassium bromide is best kept as a 10 p.c. solution, i.e. containing 1 gr . of bromide in 10 min . of solution. Dissolve $\frac{1}{2} \mathrm{oz}$. ןpotassium bromide in $4 \frac{1}{2} \mathrm{oz}$. of distilled water and add about 5 min . of the solution to each ounco of developer.RESURRECTION PLANT. This is a most curious plant, known alao as the Ruse of Jericho: its botanical name is anastatica. If placed in water it has the extraordinary power of reviving even after it has been kept dry for many months, hence its popular name. Seedlings may be raised under glass in spring and planted out of doors in summer. After the leaves fall the plants become somewhat woody and remain dormant until put in water.
RETAINLNG WALL. Where the special function of a wall is to resist strain imposed upon a structure by adjacent earthwork it is known as a retaining wall. A common application of it is found in basement houses whero a low wall is provided to keep the carth in position around the area. See W'all.

RETCEING. An involuntary and unsuccessful effort to vomit is called retching; gas is sometimes expelled. When it exists it is often a useful thing to drink large draughts of warm water, or very hot water may be sipped. See Sickness; Vomiting.

RETINOSPORA. This is a group of handy evergreen conifers which is now merged in the genus cupressus or cypress. In gandens, however, the name retinospora still persists. One of the most beautiful is Retinospora pisifera, of which there are many varicties: argentea and squarrisa are handsone groyleaved kinds while plumosa aurea has yellow or golden leaves. Another species is Retinospora obtusa, of which attractive varicties are aurea and gracilis aurea. Planting should be done in September or carly Octuber or in April-May in loamy soil. Propagation is by cuttinga in a fraine in September. See Cypress.

Retouching. See Spotting.
RETRIEVER. Of the four varieties of retrievers the curly-costed are so few in number that they are seidom seen except at show

Retriever. Prize-winner of the aturdy short-coated Labrador variety
eyes which give him a kindly appearance, and he is as intelligent as he looks. The shoulders are so well placed as to give freedom of action. The body is shortish, of medium length in couplings, thus enabling him to gallop. The front lega are perfectly straight The Labrador is another variety Here the cont is peculiar, being short, very thick and somewhat like fur to the touch. There is scarcely any feathering on legs or thighs Altogether he is squarely, sturdily built. The eye, which should be a dark hazel, is sometimes still too light. The retriever is a first-olass dog for work, and very frequently proves the winner at field trials. The golden retriever is of Russian extraction.
Training. A retricver puppy may be broken in very early, the first step being to gain his confidence. Encouraged by the reward of a biscuit he should be taught to come at a gallop in response to a low whistle. To teach him to drop, take him into a quiet spot. secure his attention, and hold up ono hand, pressing him into $n$ recumbent position with the other. The command drop should be repeated every time He should remain in this position even when his master walks away; but if he refuses, he may be fastened to a peg untíl he does so. At six months old he may start learning to retrieve. He is first taught to fetoh some soft object, such ня a rolled-up bandkerchief, which his master throws a few yards in his sight, with the order "go fetch." The distance is extended gradually, until the object is dropped when he is not looking and he is ordered " hie seek" See Dog; Kennel; Mange, etc

REVERSI. This indoor gamo is played with (if counters on a bonrd resembling a chess board, but usually somewhat amaller.

Rheostat. Types of rheostat sultable for use as volume control in a wireless receiver

It can, however, be played on a chesy or draughts board. The 64 counters are red on onc side and green on the other. They are divided between the two players, one treating bis as red and the other treating his as green. The players in turn place onc on any vacar.t square on the board, each keeping his own colour uppermost.
The ohject of the game is to place the pieces so as to enclose one or more of the hostilo pieces between two of his own. This done, the enclosed pieces, which must be in a straight line, join the other side, i.e. they are turned over and so changed from red to green or vice versa. The game continues until all the pieces have been played out, and the player who has the most of his colour on the board is the winner.
REVOLVER. A revolver may be described as a pistol with a revolving cylinder, in which are a number of cartridge chambers. Several shats can therefore be fired withont re-loading the weapon. With revolvers may be classed the weapons known as automatic pistols, which have a magazine. The law about owning and carrying revolvers is the same as it is for pistols and other firearms.

In brief, these regulations decree that no person may possess any firearm or ammunition unless he holds a certificate to do so, such certificate being granted by the chief police officer of the district in which he resides. To secure a certificate of this kind the applicant must satisfy the police that he has good reanon for needing the revolver or other firearm, and that its possession is not likely to cause any danger to the public safety or any breach of the peace
lor these reasons a certificate will not be granted to anyone who is of intemperate habits, or is in any other way considered unfitted to possess a firenrm. The cost of a cortificate is bs. It should be renewed on Jan 3lat every year, and a fee of 2 a . odd paid for the renewal. The law provides also that any dealer who sells a revolver or nther fircarm must take the name and addiess of the porson to whom it is sold. These facts must be communicated to the police, and also put on record. It must be borne in mind that the possession of a certificate does not absolve the holder from procuring a gun licence.

Rovolvers are distinguished by the size or calibre of the bore, the unual sizes being 22 , $\cdot 32 \cdot 38$, and -455 . The smallest size, i.e. 22 , is of little value except as a target weapon. The 38 is the smallest calibre that can be relied upon to stop an assailant, but the defensive uses of the otliers are by no means negligible. Cartridges are sold according to the calibre See Gun.

RHAMNUS. Several hardy shribs of no great decorative value are included in this genus The British buckthorn (Rhamnus cathartica), a leaf losing shrub, 12-15 ft . high, bears black lierrics in autumn. The wood of Rhamnus frangula, another British shrub or small tree, makes excellent charcoal. Rhamnus alaternus, an evergreen, and its varicties with variegated leaves, are useful for shrubberies: they reach a height of 8 - 10 ft . The bark of one species of rha mnus supplies the medicinal preparation cascara sagrada. Propaga. tion is by cuttings in $n$ frame in late summer

RHEOSTAT. This is a variable rosistance userd in an electrical circuit for reducing voltage Rheostats having a value of 30-50 ohms are sometimes employed for contrulling volume in wireless reccivers, and are connected in series with the low-tension supply of a battery-operated screengrid valve. See Resistance.

RHEUMATIC FEVER. The chief danger in rheumatic fever or acute rheumatism is that the heart may become affected. There is fever, profuse sweating, inflammation and great pain in the joints, the attack lasting from 2 to 6 weeks, or longer, and the sufferer is liable to be attacked again. The younger the patient the greater is the liability to heart injury. In children the pains may be slight, and may be described as growing pains. There may be very little fever, but anacmia may develop, and a frequent accompaniment is choren, or St. Vitus's dance.

As soon as the disenso is recognized the patient should go to bed, and should wear a Hannel nightdress made to open all the way down; the sleeves should either be very loose or be slit from shoulder to wrist, and fasten with buttons. This is to facilitate the frequent bathing which is neccssary because of the sweating. Four or five nightdresses should be prepared. Remove the sheets and lot the patient lie betwcen soft.
ine blankets, or provide llamel sheets Absolute rest is essential, and thene must be $n o$ visitors. The general treatment is that of fever (q.v.), but a thomugh course of salicylates must be administered. When tho patient is convalescent, attention should be paid to the state of the throat and the question of removing diseased tonsils may have to be considered. The patient, especially if a child, should he seen by a doctor from time to time for some years after an attack of acute rheumatism.
RHEUMATISM. This term is applied verv loosely to a number of diseases differing from one another fundamentally. They are all. however, characterized by pain and inflammation in the joints or muscles or tendons. eto. See Fibmsitia : Lumbago

Rheumatlsm Root. A spring-flowering dwari plant suitable for a shady rockery

RHEUMATISM ROOT. This name has often been applied to a species of Jeffersonia, a hardy dwarf plant suitable for shady crevices in the rockery or as an edging for borders It beara white llowers during spring. and is best planted in October in ordinary sandy garden soil. Propagation of the plaht is by seed or by division of roots.

RHEUMATOID ARTHRITIS. The chronic joint disease known as rheumatoid arthritis is not a rheumatic affection, and must also be distinguished from osteo-arthritis, in which bony changes aro early and distinct. It is a chronic intlammation of the synovial membranes of joints and of the fibrous tissues which surround the joints
As in other chmnic arthritic diseases pain. swelling, and atiffess are likely to be increased by cold and dump, or by unaccustomed or undue strain on the joints. The joints of the fingers just below the knuckles aro generally those first affecterl, and usually in both hands, then the disease appears in the knces and feet : but it may involve nearly all the joints of the hody.

The prime cause of rhemmatoid arthritis is the activity of certain bacteria of low virulence. These form foci of infection, most commonly at the roots of the teeth or in the tonsils, but it may be at other situations in, or on, the body. The treatment of the disoase should therefore begin with a search for some such focus and an attempt to clean it up, with, possibly, a course of vaccine treatment in addition.

During the acute stage the patient should be kept at rest, and, as the deformity is caused in the first place by spasm of muscles the affected joints should be splinted in such $n$ position as to prevent deformity. When, however, the acute stage has passed off, the joints aro freely and fully moved by the doctor or someone under his direction.

Various methods, including fomentations, baths of various kinds, diathermy and electrical treatment, are used to diminish pain and swelling. Massage, whirlpool baths and electrical stimulation are also useful in preserving
the tone of the muscles The diet should be gener ous Cod liver oil is often a uselul addition Ultra violet rays aro often used in order to increase the general resistance to infection. and guniacol car honate of sulphur may be given to dismfect the bowel

RHODANTHE. This is a pretty half-hardy annual with pink or white ever lasting llowers which !ast a long time when cut. It is chielly suitable for culti. vation in pots in the green house although seedlings may be planted out of doors for the summer. Seeds are suwn under glass in March or out of doors in May. The chiel kind is Rhodanthe manglesii. The correct name of this plant is Helipterum manglesii. Other heliptermns supply the immortelle flowers which when dyed in various colours are used by florists in making wreaths and other lloral devices.

## RHODEISLAND

 RED. There are two varietics of this American breed of fowl, the single combed and the rose combed, and it is one are also decorated tiles, basell on the patterns of the hest winter layers. The rich brown of tapestry hangings. Very thick pigments. cggs in some strains average $\mathbf{2} \mathbf{\alpha} \mathbf{d}$ oz., the general red, blue, or turquoise, outlined in black, average being $\mathbf{7}$ or 8 to the lb . It carrics a lot and often on soft grounds, impart to the of lleah, which is of good colour and tine tiavour. clecorative scheme an opulent effect. TheThe hens are inost excellent mothers; the inscriptions are usually Persian
chicks are hardy and mature quickly Adult males weigh 6 lb to 8 ll ., and the females 5 lb . to 6 lb . They do well on frec range, also on the semi-sensitive system, but are not to be recommended for intensive or confined quarters, as they become very broody

The colour should be deep, rich red and even throughout; the tail should be black, and the wings should show black in both primaries and secondaries when opened out. The two colours must be clear and distinct; what is known as a peppered wing is a ball fault in an exhibition bird. The neck hackle of the male should mateh the body colour ; in the female it should be tipped with black. The comb, lobes, wattles and eyes should he red. the legs and feet rich yellow. See Fowl ; Poultry.

Rhodian Ware. sixieentlt century Turkish jng baving a blue back-
ground decorated with creamand red flower buds
$B_{u}$ permigsion of the Director, Viclopil
und Albert Museum. S Kensinuton

RHODIAN WARE. Some modern faience bowls and jugs which attempt to recapture the colont and design of medicval Rhodian pottery are brilliant and decorative, but it is hardly possible to mistake thom for the genuine old ware. 'This was produced from the 14th to the 18th century in the asland of Rbodes.

At first, owing to the fact that it was made by I'ersian exiles. it followed very clusely the inspiration of Persian ceramics. It was fabricated of a sandy, arti ticially fused, and highlv vitritied clay. covered with a hard, thick, glassy paste The forms include shallow dishes, ewers, flowerholders, lamps, and domestic ware generally. The decora tions comprise naturalistic Howers such as roses. tulips. and carnations, be sides birds. arahesques. and $\mathbf{a r i o u s}$ other types of oriental designs

Sornetimes the designs consisted of ships and conts of-arins, done for the conts-ol-arins, Jone fore

After the departure of the carly craftsmen they were replaced by Latin potters, who derived their ceramic motives from Eumpen tapestries, and continued at work until the middle of the 16 th century. After that Turkish workinen carried on the tradition, but the pottery: gradually deteriorated, until by the 18th century good work was no longer made See Pottery.

RHODODENDRON. This is the finest evergrcen flowering shrub suitable for cultivation out of cloors in the British Isles. In recent years numerous new species have been introduced from Western China and other far Eastern districts, and many hybrids have been raised in gardens at home A representative selection will provide hlossom from early

Rhododendron. 1. Tub planting: $a$, sand ; $b$, sandy peat; $c$, chopped turf : $d_{\text {. }}$ wood blocks. 2. Lawn planting: $a$, grass; b, sandy peat. 3. Cutting, with heel. 4. Pot prepared for cutting: a, silver sand. 5. Cutting plunged for rooting : $a$, moss ; $b$, fibre: $c$, steam pipes; $d$, glass; $b_{\text {, boz }}$ 6. Old plant plunged in open border on base of cinders spring until June. The leaf-losing azalen, which is regarded by gardeners as a distinct shiub, is now merged in the genus rhorlodendron hy botaniats. A few evergreen rhododendrons are beautiful shrubs for the heated greenhouse.

The rhododendrons of chief value to the ainateur garilener are those hardy evergreen kinds which provide such a brilliant display of blossom in May and June. Almost all of them are hybride or crossbreds which have been raised in gardens and nurseries, and new varieties are introluced every year. These are some of the most attractive: Bagshot Ruby.
S

Rhododendron. Flower clusters ol one of the
numerous beautiful varieties
Broughtonii, rusecrimson: Coma, pink: Cynthiu, rose crimson: Diphole Link; Doncaster, red: Everestianum, lilac-10se; fastuosum II pl., maluie: Gomer Watcrer hlush. Ioder's White: Nichacl Waterer: bright real: l'ink l'earl, ruse pink, and Sapplio, white will darli blotches. Nobleanum bears its red flowers in spring, sumetines in winter if the weather is nitd Other early llowering varictics are Ascot Rrilliant, red: Handsworth, white. and IRosa Munili, blush.

Thero are many beautiful rhododendrons ainong the npecies of wild typres of other lands. Some of them are low growing and suitable for ose-phe the rock garlich. e.g. : (auricum, hirsutum, rose-red: moupinense. blush: and racemusum, pale mse Angustinii, a taller shrub, bears benutiful lavender blue flowers in spring. The Swiss alpine rose is Rhododondron ferrugineum, a divarf with rose-red blooms

The Himalayan rhododendrons develop into immense bushes in sheltered gardens in mild purts of the country. but they are scarcely suitable for general planting-not because the shribs are not harily, but beeause they hloom early, and the Howers are liable to be spoilt by frost. Among them are: campylocarpum, yellow: urgenteum, cream-white ; Falconeri, with very large handsome leaves and pale flowers: and grande, whitc

Hardy azaleas inake a brilliant display in May and Jume. The colours of the llowers

Ruby-red clusters of bell-shaped fowers of the variety rhododendron, Bagshot Ruby
range through pink, salmon, apricot, rose. ahle Two of the most heautiful are javaniyellow and orange. No shrub surpasses then in splendour when they are in full beauty There are numerous named varieties.
The rhododendron is perfectly easy of culti vation if planted in lime-free loamy or peaty soil that does not dry out in hot weather. A slightly shaded situation is to be preferred to one in full sunshine, though the latter is suitable providing the soil is deep. The two most important details of cultivation are to remove the faded flowers to prevent the development of sced pods and to mulch the soil with leaf-mould in April When rhododendron bushes have hecome overgrown and need to be cut hard back this work should be done in April.
The cvergreen greenhouse rhododendrons should be potted in a compost of sandy peat : a minimum winter temperature of $60^{\circ}$ is suit-

## RHUBARB AND ITS HOUSEHOLD USES

## How to Grow Successfully and Cook Appetizingly

The entrics Forcing; Kitchen Garden contain further information bearing on this subject.
Sec also Flan; Frtier; Pastry and other cookery entries
The edihle rhubarb is Rheum rhaponticum, children, and it has a secondary astringent a hardy perennial which thrives in a deep rich soil. The roots are planted in February, about 3 in. beneath the surface, and in rows 2 to 3 ft . apart every way Before planting, sone well-mited manure should he worked into the soil. No stalks should be gathered from freshly planted rhuharh, and all flower stems shorild be reinoverl.
Forced rhu. barb is oh. tained by covering 2 -year-old plants with headless casks or harrela and surrounding the latterwith fresh manure or dry leaves. After large roots have been forced and cut, the old st nols may be divided in Narch, and replanted. For forcing in artificial heat under glass, 3 -year oli ronts are the best. They should be lifted and placed in darl corners in the heated greenhouse, or it frames with
 hottom heat. conditions which are and darkness are the forced rhubarb may thrive hest
Some of the hest varicties are Champagne, Albert, Victoria and The Sutton. All except Victoria (a late variety) are suitable for forcing. Of the ornamental kinds of rhubarb which are grown solely for the decorative value of the leaves and flowers the best are Alexandrac, Emodii and palmatum. They are vigorous plants which llourish in ordinary soil and may be propagated be division in autumn.

Use in Medicine. The thubarb used in medicine is obtained from the root of a plant grown in China and Tibet. It is one of the safest and most widely used purgatives for
children, and it has a secondary astringent
effect which makes it particularly useful in checking diarrhnea. Rhubarbincreases the llow of gastric juice into the stomach, stimulates the normal digestion, and also the liver. Consequently it is often prescribed in small doses as a stomachic.

Uses in Cookery. Rhuharb is widely used in cookery, being made into preserves, puddings, pies, compotes and many other swects. Stewed rhubarb with custard is a very popular dish in spring. It should be used when young and tender. The stalks only should be cooked, these being first wiped with a damp cloth and then cut into convenient lengths. lior stewing, pies, etc., a generous allowance of sugar is needed the quantity varying according to the age of the rlubarb. Add a little water and about 2 in of lemon rind. Young forced rhubarb and one or two var:ctics of young outdoor rhubarb stalks need not he peeled
Rhuharb makes excellent pies to be eaten hot or cold. Use short crust pastry. The rhubarb should be cut into short lengths and need not he stewed previously.

Rhubarb Charlotte. Stew \& lb. rhubarb cut into short lengths in a pint of water, the grated rind and juice of a lemon, and $\frac{1}{2} \mathrm{lh}$. sugar, and when the fruit -s soft, add the stiffly whisked whites of 2 eggs and $1 \frac{1}{2}$ oz gelatine previously dissolved in pint water and then atrained. Line the aides of a mould with sponge fingers, pour in the inixture and leave it to set. When cold, turn it out, and serve it with some vanillaHavoured custard.

Rhubarb Chutney. Stew 2 lb. rhubarb cut into short lengths with $\frac{1}{2}$. sugar. and in he meantime mix together 3 minced onions, 2 tahlespoonfuls fine salt, half that quantity curry powder, $\frac{1}{1}$ teaspoonfuí cayenne pepper, $\&$ lh stoned raisins, and ahout 3 pint inalt vinegar. When the rhubarb is tender, pour the mixlure over it, and stir the whole over the fire until it is well conked. Then turn it into jars and tie it down.

Rhubarb Flan. Wipe | |h rhuharb, cut it into thin slices, sprinkle it with 3 oz caster sugar, and leave it for an hour. In the meantime make 6 oz . flan pastry and hake it a light brown. When the rhubarb has stood for the required time, let it cook slowly in the oven until it is tender, then put it aside to cool. Add more sugar if required

When the pastry is cold, fill it with the rhuharl), reserving a few pieces for decorating the top, and over it heap the stiffly whisked whites of 2 cggs sweetencd with 2 dessertspoonfuls castor sugar. Put the flan hack into warm oven so that the meringue may set and place a few small pieces of rhuharh on top. It should be served cold

Rhubarb Fool. Rhubarb fool is made in the saine way as gooseberry fool, $\frac{1}{2}$ lb sugar being allowed to each pound of rhubarh.

Rhubarb Fritters. For these fritters, cut some voung. tender rhubarb into pieces a hout 3 in . long, dip them in batter and fry them in hoiling fat. When they are a golden-brown colour, lift them out and drain them, and serve them sprinkled with castor sugar

Rhubarb Jam. The ingredients are 1 lb each rhubarb and sugar, ! oz. lump ginger and the rind of half a lemon. Cut the rhuharb into pieces about ${ }^{3}$ in square and put these into a preserving pan with the sugar. Heat them slowly until the sugar has dissolved: then add the ginger, bruised and tied in a muslin bag, and the thinly peeled lemon rind tied in another bag. Bring the jam to the boil and continue boiling for about $1 \frac{1}{2}$ hours, removing the ginger and lemon before putting it into pots and finally tying it down.

Rhubarb Pudding. A baked pudding can he made from I lb rhubarb, $\$ \mathrm{lh}$. fine breadcrumbs, and sugar to taste. Peel and cut the rhubarb into short lengths, put a layer of it into the hottom of a deep buttered dish and sprinkle it with castor sugar. On the top put a laver of crumbs, and continue in this way until the dish is full, making the last layer of breaderumbs. On top place a few sinall lumps of butter and a little more castor sugar and bake the pudding in a hot oven until it is lightly browned. A boiled rhubarb, pudding can be made in a hasin lined and covered with suet crust. Cover with greased paper and a cloth and boil $1 \frac{1}{2}-2$ hours. See the directions for making Apple Pudding in page 29.

Rhubarb Wine. This fruit wine is made by cutting $5 \frac{1}{2} \mathrm{lb}$. rhuharb into short lengths, leaving them unpecled, and putting them into a wooden vessel. Mash them well to extract

Rhubarb. 1. Typical root. 2. Good planting: a, manured soil. 3. Division of clump. 4. Forcing in a box: a, covering boz: rests for same

the juice, pour over them 1 gallon cold water, and leave the whole for eight days, stirring occasionally:

Strain and measure it, and to every gallon of liquor add $3 \frac{1}{3} \mathrm{lb}$. white sugar and the juice of If lemons. Stir the mixture at intervals until the sugar has dissolved, then pour the wine into a cask and leave it in a warm place to ferment. When fermentation has ceased, cork up the bunghole and leave the wine in a cool place for about five months before bottling it.
REUS. These hardy shrubs are grown for the sake of their ornamental leaves or flowers. The sap is poisonous. One species, Rhus toxicodendron, or poison ivy, is a dangerous plant, for touching the leaves may lead to serious illness in people who are susceptible. There is, however, no need to cultivate this plant, for several others are more decurative. The most familiar is the Stag's horn sumach (Rhus typhina) which has very long, deeplycut leaves. The Venetian sumach (Rhus cotinus), known also as smoke bush, is very attractive when the cloud-like inflorescences are in full beauty in summer. Rhus cotinoides is valued for the sake of the brilliant autumnal colouring of its leaves. The sumachs, which
form large bushes, thrive in ordinary soil and are increased by seeds or root cuttings in spring.

RIB : Of the Body. There are 12 ribs on each side of the chest, of which the upper 7 are united by cartilages directly to the breastbone. These are called true ribs. The remain. ing 5 are known as false ribs. Of thesc latter the eighth is joined by cartilage to the seventh, the ninth to the eighth, and the tenth to the ninth. The ends of the eleventh and twelfth ribs are free, and for this reason these are called floating ribe.

Fracture of a rib is a common accident. Occasionally the fractured end may penetrate the lung. The symptoms of fracture are often very slight, but when such an accident is suspected, a doctor should be at once consulted. First, aid consists in applying the centre of a broad fold handage over the painful spot and tying on the uther side of the chest. According to the situation of the fracture another bandage is applied above or below the first. Their object is to limit the movement of the chest wall, but they should not be tight enough to cause pain. If any pressure at all is painful they should be left off. Later the doctor may continue with bandages.

## Ribbon Work and Trimming

## Effective Uses and Methods of Mahing Applied Decorations

Directions for making accessories which can be charminely trimmed with ribbon work may be
found under such headinge ss Bag; Curtain; Cuahion; Nighi Wear Case. See also Applique Work; Artificial Fiowers; Embroldery : Lald Work Rafia: Tranafer
l'he simplest form of ribbon work consists of making bows, rusettes and gathered ruchings: the most elaborate is combined with embroidery or appliqué work, and used to decorate furnishing accessories. Although frequently seen on cushions it is perhaps most suitable for pieces of needlework such as bedspreads, pelmet and curtain borders, handkerchief and nightwear sachets. The raised or looped formations of ribbon, often

Ribbon Work Fig. 1. Embroidered custuon, the chrysanthomum heads boing worked in narrow embroidery ribbon, while the stallys and leaves are in stom and satin etitoh
used in the work, make it less practical for hard wear than ordinary embroidery unless narrow ribbon is actually employed like a coarse thread, as in the example of the cushion illustrated in Fig. 1

Bows and Rosettes. Even a bow for trimming requires to be properly made, especially if the ribbon is wide. Leave an end and form a loop with small pleats, twist it round with cotton. Repeat the making of loops, measuring their length carefully until the required number is made. Arrange the loops to lie in even numbers each way and lcave an end to match the one at the beginning. Make a tie over with a separate piere of ribbon, sewing it tightly or loosely according to taste. Flat bows are made
by folding ends of ribbon over without pleating to form the desired size, and tacking them down A shorter piece of ribbon is then folded in the same way, so that the shorter bows lie Hatly above the longer ones, and stitched down. A flat tie-over strip is placed acroes the ribbon and finished off neatly at the back.
Ribbon rusettes are made in various ways. A small circle of stiff muslin or buckram is first cut out. To this are tacked the ribbon loops, any length desired, beginning at the edge and working towards the centre, longer loops being used towards the centre to make a rounded rosette. For another kind of rosette a wide ribbon can be used and folded over and the edges gathered strongly together. These are drawn up and sewn to the muslin or buckram foundation, beginning at the centre and work. ing round to the edge. If a narrow ribbon is used it is not folded, and if one with a picot edging is selected it gives an attractive finish.
Wheel-like ribbon decorations which form corner trimmings for cushions or sachets are easy to make on a muslin foundation. The centre is of puffed or ruched ribbon, and the edges are finished with loops and ends cut diagonally, the effect being like a big daisy. Garters can be quickly made of ruched ribbon. Two lengths are needed of $1 \&$ yd. each of 1 -in. wide ribbon. Contrasting colours may be used and stitching on buth sides connects the two lengths through which an clastic, wide, is run. The ribbron is gathered over this to the required size. The garters are inished with tiny rosettes or a ribbon Hower
Covering Small Articles. Ordinary wooden coat hangers can be made attractive when covered with satin or chiné ribbon. They need first to be padded with cotton-wool, sprinkled with sweet-smelling essence, or some perfumed powder, and then covered with ribbon gathered to fit the arms. One yard of 3 -in wide ribbon is enough to cover the wooden portion, and narrow ribbon to match is used to cover the metallic hook. At the base of this a buw, rosette or ribbon flower may be stitched if the hangers are being made for a gift or sale of work.
Ribbon-covered perfume sachets are easily made by sprinkling little pads of cotton wool with perfume or with sachet powder, covering them first with fine muslin, and then with
ribbon. An attractive effect is obtained when 2 narrow ribbons are interlaced to form a lattice work, the ends being mitred and left free. Long sachet pads to line the bottom of a clicst of drawers or wardrobe are made of perfumed wadding covered with coloured muslin, which is bound by ribbon in a contrast. ing colour.

Inexpensive shoe trees are made daintier il the wooden portion is painted or gilded and the metal bar is covered with about 1 yd. of 1 -in. wide ribbon. The ribbon is doubled and gathered over the metal, the gauging being drawn up entirely to cover it. A louped bow in the centre of the metal bar may be addcd if liked.

Plaited ribbon and jap silk to tone make a pretty sachet set. Two different-coloured double satin ribbons, $f$ in. wide, should be obtained, the quantity needed depending upon the size of the sachets. Having cut out the silk for the cuver and for the linings, the ribbon must be cut in lengths, each piece being in duplicate, one of each colour. The longest strip should go diagonally across the cover from corner to corner; the others follow in order of length.
The plaiting may now begin. Assuming the colours chosen are pink and deep rose, a pink strip is started from the left top corner and is carried across to the opposite one. This is stitched down to the edge of the cover. Across it lay a piece of rose ribbon, the shortest length used, and stitoh the two ends of this down, one un the left side and one on the right. For the next two rows, one on either side of the first row, two lengths of pink ribbon are* needed and over thein a piece of rose-coloured ribbon is placed, this passing under the first strip. Two more pieces are then laid across, and over and under these a piece of ribbon of the other colour is plaited.

The work proceeds in this way until the whole is covered. It will be easy to see whether the alternating colours are in the right order: but other points need watching. The edges of the ribbon lengths should just touch one another, and the ends should not be cut until they are stitched down. The stitches must be small and neat and the lengthe must be cut off slantwise. The corners need especial care, for here the ribhon is liable to bulge and refuse to lie flat. Care must be taken, too, that no uncovered spaces appear in the plaiting. When the plaiting is finished a cording of silk should be made to match the rose or pink, or the sachets may be finished off with a silk or tinsel bought cord or with a narrow gimp. For making up see Night Wcar Cases and Sachets.

Rlbbon Embroldery. For certain kinds of embroidcry ribbon makes an excellent medium, the flower-embroidered cushion illustrated in Fig. 1 providing a good example of the work. Choose a design that is not uvercrowded, transier it to the material, and then stretch the latter on a frame First embroider the stalks and leaves in thick silk, using stem stitch for the stalks and satin stitch for the

The large flowers should be rather paler than the small ones, and, if a chrysanthemum design such as that illustrated is chosen, make the undersides of the Howers a darker shade than the tops. Cut a piece of thin embroidery ribbon about 0 in . long, thread one end thmugh a needle with a very large eye, and pull up from the centre of the flower. Hold the ribbon flat with the left hand and put the needle down through the material at the tip of the petal. Use 2 or 3 shades of ribbon, making any petals that are underneatl darker than the rest. Do not pull the ribbon ton tight.

Embroidery ribbons can be succesafully used to work designs on tea-cosies. blotters and sachets. Beads may form centres to ribbon flower, or French knots in silk may be worked for this purpose. Many designs for raffia work

to twist for the desired length For a bud hid lidward VI
and lidward VII
Ribes speciosum, the on the oross if the pink rib thon used is wide enough) $2+\mathrm{in}$. by 2 in . Fold it in lialf lengthways and the cor ners to the centre (L). Pleat it twice each side so that the pleats meet in the centre (M). Cut a piece of ribbon the same shape, slightly larger and fold round the first piece ( $\mathbf{N}$ ) Make a cup from the green ribbon $I$ in. wide, cut as for the leal $(\mathrm{H})$, fold in turnings down the $V$ ahaped end, fasten one point to one side of the bud and the other point to the other side Wrap the cup over and twist ribhon below to make the stalk (O)
Ribbon Fern. This is the popular name of a greenhouse fern, Pteris serrulata.
RIBBON GRASS. This name is given to a vigorous
can be adapted for ribbon work. These narrow ribbons can also be uscd uccording to instructions given in the article on Laid Work, being cuuched down on to the maietia instead of being pulled through. More elaborate embroidery can he done in this manner, which is suitable for working designs on fine Cabricy

Ralsed Ribbon Work S'prays ol Howers which can be made separately and then npplied to trim cosies or sachiets are no diffioult to make with a little practice. Roses are effect:ve flowers for this type of ribbon work and details of making are illuatrated in Fig. 2 For the centre of a rose cut a strip of pink taffeta rib bon $1 \frac{1}{6}$ in. by 7 in. Fold it in half lengthways and gather twice as shown in ${ }^{3}$ Draw up the two threads tightly and finish off Rull up and stitch tirmly (C) Next talie an oblong ed in by 2 in. to make petal. Fold it in half lengthways and slope off the edges to the fold, as sliown in $D$, and gather round the raw edges, folding over each edge at the fold. Draw up the thread and fold this finished petal over the centre (E) The other petals should he each a little longer and wider and shaped as shown in Fig. 2, F. When all the petals are separately made, stitch them round the central ones und the rose is finished, as slown in $G$.
The leaves are from green riblon cut $1 \frac{1}{2}$ in wide by 2 in Fold it in half lengthways and slope off the top $(\mathrm{H})$. Gather down the point and the fold (J), then draw up, turn the ribbon right side out, and open up the leaf; Hatten out, pleat the base into proper shape and stitch it down firmly (K)

The various pieces of the spray can be tirst sewn to a piece of muslin if liked or applied directly on to the article to be decorated. No stalk is visible in the spray illustrated in Fig. ?, A, hut one is easily made by taking a short length of string, twisting a narrow green ribbon ruund it. inserting a leaf and continuing

Ribbon Work. Fig. 2. Applied ribbon trimming spray of garden roses made of pink and green tafleta ribbon, with diagrams for cutting out and sewing. See tert
perennial grass with pretty green and white caves (Plıalaris arundinacea variegata) Known also as gardeners' garters, it flourishes in ordinary soil, grows 2 ft. high and is increased by division in autumn. Phalaris canarienss provides the well-known seeds for cage hirds: it is an annual raised from sceds sown in spring.

RIBES. The family name of the currant and gooseberry is Ribes. In practice, however, the name is naually applied to the llowering currants, which are grown for decorntive purposes only. These shrubs thrive in ordinary soil, and may be planted at any time during the autumn, winter, or early sping. The only attention they need is pruning after Howering, and a top-dressing of well-decayed manure in autumn. Propagntion is best effected by means of seeds sown in the autumn, or by cuttings, layers, or suckers struck at the same period

The chiof kinds are aureum, fragrant yellow Howers ; aurantiacum, yellors, nnd sanguineum, red There are several varieties of the latter, of which the best are atrosanguineum uchsin-flowered currant, should be grown on a wall; it bears orimson, somewhat fuchaia. like Howers

RIBSTON PIPPIN. The dessert apple known as Rihaton Pippin is of medillm size, russet-brown in colour, and possersen a Havour second only to Cox's Orange Pippin It is a self-fertile variety, requiring a warm, welidrained soil, and is in season from November to January See Apple: Ieesert
RICE : The Food. Being very light and easily digosted, rice forms a valuable article of uliet, but ns it is almost entirely a starchy food and deficient in protein, meat or pulses should be taken with it Its good value is increasel by cooking or serving it with milk. On the average rice contains a bout 80 per cent of starch, 7 per cent of protein, tat less than d. wnter 12, and a trifle of mineral matter

When it is boiled rice absorbs abont five times its weight of water If not sufficiently boiled it is liable to cause indigestion To many prople one of the disadrantages of rice is that it has a slight binding effect This fanlt can be corrected by eating it with prunes, stewed Ínit, or jam But in cases of looseness of the howela this effect makes rice a valuable remedy.

The poliahed rice. which is commonly used, is deficient in the vitamin which prevents beri-beri This has been removed in the thin skin Where the dish consists almost wholly of polished rice beri-beri develops, but there is not this danger in a mixed dish, including milk, eggs, etc.

Two kinds of rice are employed, of which the pure white Carolina is usually preferced for purldings Rice llour and ground rice nie also inuch used for cakes, etc. The former is much more finely ground than the latter. Curry is served with Patna rice, which has long, pointed grains that separate easily after cooking. Rice should always he thoroughly washed before using, and to boil plainly should be scattered into fast boiling salted water: keep the lid off the pan and boil for $n$ bout 15 min .

An excellent rice and apple sweet can be made from 4 large apples. $\frac{1}{2} \mathrm{~b}$ rice, 4 teaspoon luls castor sugar, 4 cloves, and a little apricot jnm sauce. Boil the rice in solted water for about 10 min ., then strain it, and divide it into six equal portions. Grease four small hasins, and put a portion of rice in each, pressing it to the sides and hottom so that it acts as a lining. Peel and core the apples, place one in cach hasin, together with I teaspoonful sugar and a clove; then divide the two remaining portions of rice into halves, and cover the apples with them, pressing the rice well down. Put a piece of greased paper

Ribbon Grass. Close growing clumps of the decorative border plant. The variegated leaves are ver attractive in bouquets. of in vases of cut Howers
over each basin, and steam the contents for about an hour, or until the apples are soft and the rice tender. When the moulds are cooked, turn them out on to a hot dish, and serve them with a ssuce made by boiling two tablespoonfuls of apricot jam with a gill of water.

Rice Gâteau. Boil together 18 lumps of sugar and $\frac{1}{\text { gill of water until they become a }}$ golden brown colour, then use them to coat the inside of a hot pudding basin. Wash $\& \mathrm{lb}$. rice and cook it, until it is soft, in a saucepan of boiling water; then drain it and mix it in a basin with 2 oz butter.

Leave the mixture to cool before adding 3 o7. granulated sugar, \& lb. seedless raisins and a little vanilla flavouring, and when these are uall mixed stir in 2 beaten eggs mixed with 3 or 4 tablespoonfuls of milk. Turn the whole into the caramel-lined basin, cover it with a greased paper, and steam it for 1 hour in a saucepan of boiling water. The water should reach no higher than a third of the way up the basin. When the mixture is cooked, turn it on to a hot dish and decorate it with cream. The caramel will be found to coat the pudding

Rice Meringue. Cook $\ddagger \mathrm{lb}$. rice in a pint of milk until it is soft and has absorbed all the liquid, and let it cool a little before adding sugar to taste, and the beaten yolks of 3 eggs.

Pile the mixture up high on a flat dish, spread a thick layer of jam over it, and on top of this nut the whites of eggs, sweetened and whipped to a stiff froth. Dredge the whole with castor sugar, and then put it in a warm oven for a few minutes so that the meringue may set and become lightly browned.
Rice Pudding. The requisites for a rice pudding consist of 2 oz . rice, 1 pint milk, 1 oz . sugar, 1 oz . butter, and a little grated nutmeg. Wash the rice and mix it in a piedish with the sugar, pour over the milk, and on top grate the nutmeg, adding the butter with it. If time allows, stand the pudding aside for about an hour before cooking it, so that the rice may soften; then bake it in a moderately warm oven for $1 \frac{1}{\frac{1}{2}}$ to 2 hours, first bringing it to the boil and then letting it cook slowly. Another method is to put the rice with water to cover in the pudding dish, and cook in the oven until the rice swells and softens. Then add milk, etc., and proceed as above.
Rice Soup. A thick rice and tomato soup can be made from 2 oz . rice, a large tin of tomatoen, a carrot and an onion, a pint stock, a few celery seeds, and pepper and salt to taste. Put the rice, together with the peeled and sliced vegetables, into a saucepan, add the tomstoes with their liquor, the stock, the celery seeds tied in muslin, and the seasoning.
Bring all to the boil and then cook them slowly until the rice and vegetables are soft, stirring occasionally to prevent the rice from sticking to the pan. Then take out the celery seeds, rub the soup through a sieve and reheat it. If it is not of a good colour, add a few drops of cochineal
Rice Water. For sick persons and convalescents rice water is a cooling drink. To make it, wash 1 oz . Carolina rice, soak it for 3 hours in a pint of warm water, then boil it for an hour and strain it. 'Jo check diarrhoes rice water is thickened with isinglass, a teaspoonful to the pint. Cinnamon stick, clove, or lemon may be added to flavour the drink and a little sugar if desired.
A pleasant and also nourishing beverage for an invalid is made by boiling a tablespoonful ground rice with $\frac{1}{2}$ oz. candied peel cut small in $1 \frac{1}{2}$ pints of good milk. The rice is first mixed into a smooth paste with cold water and should be boiled for at least $\frac{1}{2}$ hour and then strasined.

Risotto. For a dish of risotto fry a chopped onion in 2 oz . butter in a stew-pan, then dilute it with $1 \frac{1}{2}$ pints stock. Stir in $\frac{\mathrm{lb}}{\mathrm{l}}$. prepared rice and cook for 20 min ., stirring Irequently. When swelled, sprinkle in 3 oz . grated cheeso, 1 gill tomato sauce. a grate of nutmeg and seasoning. Cover the pan for a few minutes and serve very hot.

Another savoury way of cooking rice, known as rice à la Milanaise, can be prepared by boiling some rice as directed for curry making, draining it thoroughly, and then frying it lightly in smoking hot fat. When it begins to brown, sprinkle in enough grated cheese to give it the desired flavour, and add also some cold, cooked and shredded fish, poultry, or game, and seasoning to taste. Mix and heat the whole thoroughly, and then serve it on a hot dish. See Curry; Ground Rice; Kedgeree.
RICE FLOWER. The Australian evergreen tlowering shrub Pimelea, or vice flower, grows about 3 ft . in height, and there are pink and white Howering varicties. It requires greenhouse treatment. The potting matcrial should be loam, peat, and silver sand, and the temperature that of a warnı, well-ventilated greenhouse. The points of shoots should be nipped off to induce bushy growth, and water must be given frecly cxcept in wintar-time. Propagation is by seeds sown in light sandy soil in springtime undér glass, or by cuttings taken at the same season of the ycar. Pimelca spectabilis posserwess white flowers in dense globular heada.

RICEARDIA. This is the botanical name of the white and yellow arum lilies which are so much valued for cultivation in pots under glass. The common white arum lily, Richardia (or Calla) aethiopica, is a South African herbaceous percnnial which bears large white flowered spathes in winter and spring under glass : in mild districts it may be planted by the waterside out of doors.

The usual method of cultivation is to pot the roots in Sept. in a compost of loam with a little decayed manure, keep them in a frame for 6 or 8 weeks and then force them into bloom in a heated greenhouse. Tho soil must be kept thoroughly moist when the plants are in full growth. When the flowers have faded arum lilies may be planted out of doors for the summer or gradually dried off in the flower pots. In September they are repotted.

The yellow arum lilies, Elliottiana and Pentlandii bloom in summer under glass During the winter the roots are at rest, the soil in the pots being kept dry. In Febiuary they are repotted and started into growth in a warm greenhouse.

RICHELIEU WORE. Although-this form of work comes under the class of linen emtroidery and has been mentioned in the general article on Embroidery it is so effective and wears so well that fuller details are here given. It may be used on house linen and also for dress and women's and children's underwear. It may be worked equally well on crêpe-de-Chinc, silk or linen. Floral, geometrical and figure designs are employed as motifs.

The materials required are the ground material such as those mentioned above, embroidery cotton of loose twist, linen lace thread, or embroidery silk, according to the ground material. Ali these working threads

Richelieu Work. Fig. 1. An effective form of linen embroidery consisting of motifs of conventional or original degign joined by worked bars. Fig. 2 .
Adaptation of ladder work for a border, showing the Adaptation of ladder work for a border, showing the
use of battonhole - Btitco
are made in many sizes, and that which is used should correspond with the texture of the ground material. A firm thread is used for the outlining, while a softer twist may be emploved for the bars and filling stitches. Ordinary long sewing needles are required and a pair of small embroidery scissors, very sharp, and with fine points, as the matcrial has to be cut away right under the pearl edge.
A transfer design is needed, suitable for this work. It should have bold patterns for the motifs, which are neld together with worked bars. Those who can do frechand drawings can make their own designs and trace them on the material with the aid of carbon paper. In the design illustrated four small motifa are placed together and an outline drawn to form a square; this can be varicd with a diamond, circle, or other shape to suit the purpose. Black has been used for the material so that the white stitchery should show up more clesrly. This in reality would be ugly and the needlework always matches the ground material in colour.

Richelieu work in its original form consisted only of buttonholed motifs and buttonhole bars with bullion-picots; but in its modern form it is mixed with Reticells work, hence the appearance of twisted bars and woven bars. Filling and veining stitches are introduced to make the motifs more interesting. Stem
stitch, back stitch and satin stitch are the nost used together with French knots for flower centres. After the design is transferred to the material, work over all the out lines of motifs and the outside edge of the design with small running stitches, then proceed to work the bars By the old mothod the outlines were buttonholed first and the hars laid as they were reached; but experienco has proved that stronger work is the result of working all the bars first and passing a button-hole-stitch through the end of each bar as the outline progresses.

Working the Picot Bars. The lower part of the illustration shows the outlined motifs and the connecting hars worked in various ways. To work a bar with bullion picot, secure the thread on the wrong side of the material and liring it up on the main outline of design; press the needle under onc of the stitches on a small motif, piching up a tiny piece of the material. Pass the needle back again under the stitch on outside of design, then hack ngain under the stitch on the motif; there should now be three threads laid. Now buttonhole from right to left half way across this bar, placing the stitches close together.

When the centre of the har is reached make a picot thus: Pass the needle up through the last huttonholestitch made, to about twothinds of its length, holding the needle in place with the right thumb, and with the left hand $t$ wist the thread ten times over and round the ncedle, from right to left, pushing the twists towards the eve of the needle, but still keeping tha right thumb on them. Draw the needle through with the left hand until the thread can be felt pulling under the thimb; then remove the Inticr and draw the needle through. Pass the needle up from below through the last hinttonhole stitch, draw through, and continue buttonholing to the end of the bar

A butlion picot often comes on the outside edge of a piece of work, when a Richelieu horder forms the edge of a teacloth, for instance, and in this case the picot is worked on the outline of the design. When the ncedle is inserted in the last stitch the thread is passed under and round the needle from right to left; push the needle through the twists, pull up the thread so that the spiral forms a semicircle, then continue to buttonhole the outline until the next picot occurs.

Where the space to be spuanned is wide, cross-bars are used as seen in the centre of the illustration between the two motifs on the upper half of the design, and where a space is long, branched hars are worked aa sces. nt the lower left-hand corner of the design. In order to work the cross-hars lay three threads obliquely across the space, fill one half with buttonhole-stitches and a picot in the centre: now lay threc threads from the last hittonhole stitch to the opposite corner of the space to make the third arm of the cross. Fill with buttonhole stitches and a picot, and bring the needle up through the last atitch at the centre. Lay three more threads right opposite to form the fourth arm of the cross. Bring up the needle again through the centre of the bars and fill the remaining fourth arm, which is half of the first long one laid.
A branched har has the first threads laid between one motif and another, half of which is buttcaholed with a picot halfway if the space permits. If it is a short space, the picot is omitted. Then the threads are lain for the branch bar either to the outline of the design or to another motif, as the cuse may be; work this har in the usual way then the needle is passed under the first bar and the remaining half is worked to match.

Twisted and Woven Bars. Twisted bars have only one thread laid, the second is twisted two or more times round it asco-ding to the
length of the bar. This should on!y be em. ployed where strong linen thread is used for working or where the space to be spanned is quite short, as lietween points of petals and the outside line in the illustration. Woven bars have three throads laid, and the needle talien under and over each thread as in darn. ing, always taking the working thread round the outside enge of the laid thremes.

To work the main outlines buttonhole from left to right as in scalloping, so that the pearl edge comes on the outside of the motif and on the inside of the square outline seen in the illustration. When all the huttonholing is done the nateria! has to be cut away under the pearl edge, taking care not to cut the bars. In the ilhastration the top helf of the material is cut away and shows how the bars connect the motifs.

Ladder Work Borders. On a linen of loose texture effective horders to Richelieu dewigns can be worked with buttonholed edges and bars under which the material is cut away.
Draw two threads about $\frac{1}{2} \mathrm{in}$. apart. These will form two lines for the buttonholing the pearl edge coming on the drawn thread line. Begin at the hottom left hand corner and work upivard, buttonholing the whole si:le, then turn the work so that the opposite edige or line will be at the left. and groceed to work upward as on the opposite side. When about $\frac{1}{d}$ in. is clone begin to lay a bar, the distence between the bars depending on the fineness of the material, and according to how much work it is desired to put into it. The illustra. tion given has been enlarged in order to show the detail more clarly. Pass the needle upward through the pearl edge of the buttonholestitch exactly opposite. now cross the ladeler and pass the needle up through the pearl edge of the last buttonhole stitch made on the second side of the ladder. Cross the ladder again and pass the needle up through the same stitch, on the opposite side. There arc now three threads laid, and these should he buttonholed as shown, working under the threads only, not through the material, as this will be cut away afterwards. Continue buttonholing on the second side of the ladder for $\frac{d}{}$ in., or according to the space to te left, then work another rung. When all the work is finished cut away the material right under the pearl edge, taking care not to cut the stitch, and buttonhole thic cut ends at the top and hottom of the ladider. See Embroidery: Ti ansfer.
RICKETS. A nutritional diseane of children, rickets, or rhachitis, usually hegins in the period between the sixth and the thirtieth month. In important factor in its production is the absence, or even shortage, of the supply to the tinsues of a sutstance described as vitamin D. This vitamin is present in sufficient quantities in the mother's milk when this is good. If, however, the mother's milk is thin, or if a child is fed on starchy foods, even with the addition of fat in the form of margarine, thete will be atarvation as regards this essential vitamin. This may apparently occur, also, if a child suffers from constant indigestion, especially if diarthoca is present.
$\lambda$ deficiency of the anti-rhachitic vitamin is made good if the body is sufficiently exposed to witra violet rays, either in natural sunlight or artificially produced. Fats deficient in the vitamin acquire it by being submitted to these ray's.

Rickets begin insidiously, hut sononer or later the child becomes restless and peevish, with a certain amount of fever and free sweating. from the head especially, when it sleeps. There is great tenderness over the body, the slightest touch heing resented. Tho appetite and digestion are impaired, and commonly there is constipation alternating with dia. rhoea The child tends to hecome pot-hellied. Another symptom is that teething is delayed,
the ends of the long bones beconce swollen, so that the wrists and other joints are unduly large, and there are rows of enlargemenis down each end of the chest in front. The child is slow in beginning to walk; the muscular weakness may be so great as to suggest paralysis.

As time goes on, the frontal eminences on the skull become enlarged, producing a hoad, square forehcad, and sometimes portions of the skiulf towards the back of the head becone thin and papery. The toones of the legs bend, causing how leg or knock knee, and there is commonly llat foot. The spine develops a hump and the walls of the chest are llattened; the bleast bone may be pushed forward, a condition described as pigeon breast. Sometimes, however, particularly if there is masal ohatruction, as from adenoids, the breast bone is depressed, forming the funnel-shaped chest. Children suffering from rickets are prone to certain nervous trouliles, such as convulsions, tetany, and a spasmodic type of choking, known as laryngismus stridulus.

It is nost important to prevent rickets. This can be done by giving a child the diel, the sunstine, the fresh air, and the excrcise which it requires.
A list of foods containing vitamin D is given under the heading liet. If natural sunlight is not available, a course of treatnent by artificial ultra-violet light'should be procured, if possible. Cod-liver oil is a very valuable addition to the diet, but should be given in an emulsion, or with malt, in view of the diffeulty of digesting the plain oil.
The child should not be allowed to get on its feet until the boncs are sufficiently strong, and to prevent its doing so it may he necessary to attach long splints to cither side of the hody and the corresponding limb. When tenderness has disappeared, gentle massage of the muscles should be employed, however. See Bow Legs ; Convulsions; liet; Light; Vitamin.
RIDDLE. More usually known as a sieve, this is an implement used for separating coarser material from that which is finer. See Sieve.

RIDGE BOARD. The topmost timber of a roof which is known as the ridge honrd is a horizontal board, and runs along the ridge or apex of the roof. The upper ends of the rafters hear upon it. See Corrugated Iron; Rafter : Roof.
RIDGING: In Gardening. This is a method of cultivation which exposes the largest possible area of ground to frost, snow, rain and wind, which help to disintegrate hard lumps and render the soil friable. It is carried out in autumn or carly winter, and is clone by throwing up the soil in the form of ridges.

RIDING. I good rider must have good hands and a good seat. Hands, by which is underatood a natural sensitiveness and responsiveness, together with a capacity for under standing animals ridden, cannot be nequired ; they are inborn The rules for good riding are summed up in the lines, "Your head and your heart keep up, your hands and your heels keep, down. Keep the knees close to your horse's side and elbows close to your own."
To mount a horse the rider should face its left side and, standing well forward, gather the reins up short in his left hand. He should take care not to hold the off rein tighter than the near one, as that may make the horse nove in a circle with the prospective rider on the outside of it.

Having with the left hand, which still holds the reins, taken a lirin grip of the horse's mane, he should steady the near stirrup with the right hand and then put his left foot into it. He should place the right hand on the furt her side of the cantle, or back of the saddle, and keeping the right leg atraight and high, so as to swing clear of the croup, should spring on to
the horse He then stendies the right stirrup, into which he places his right font, and is ready to start.

Both hands should hold the reins, the knuckles being upward, not downward as when driving. They should exert only the minimum amount of pressure nccessary to control the horse. The rider should learn, however, to grip with the thighs. knees, and sides of the legs. but should not grip hard unless :t is necessary The shins should be kept vertical and the feet parallel to the sides of the horse. When going slowly he should keep) the hall of the font on the tread of the stirrup, but when galloping he slonuld push it further through See Bit: Bridle: Horse : Pony; Saddle, etc.

RIFFLER FILE. A riffler filc is a doublo-ended file of peculiar formation, comprising a plain metal part, or bar. ourved at either end, these ends being cut to form the teeth of the file They are made in a wide variety of shapes and coarseness of cuts, and are invaluable when working hollow and rounded shapes in metal, fibre, or other material.
This type of file is used largely for cleaning up the corners and angles in chasings and engravings. It can be manipulated in odd corners in a manner that would be impossible with any other tool. See Casting; File.
RIGOR MORTIS. The stiffening of the muscles whioh occurs soon after denth is known ns rigor mortis. The commencement-and duration of the rigidity vary considerably. See Denth.
RIM LOCK. In this type of lock the case has a rim round it by which it is fixed with screws to the surface of the door. The bolt. or bolts, shoot into a box staple fixed in position on the dour jamb in the ordinary way. This type of lock is inore unsightly than the mortise lock, owing to the case lreing exposed, but it has the advantage of not weakening the door to the same exient. For this reason, it is very oxtensively used In better-class houses it is only fitted to the domestic rooms, such as thie kitchen and servanta' quarters, spare bedrooms and the like. See Jatch; Lock.

RIND. The peel or akin of fruits and vege tables is called the rind. The outer skin of pork, ham, or bacon also is sposen of as the rind. In reality this term meansan outer crust. To rind is a north country equivalent for to render. Preparing and olarifying fat and butter by melting is to rind or render. See Candied Peel ; Clarifying
RING: In Jewelry. Two ancient designs in rings are still often reproduced. One is the snake ring and the other is seen in the gemmel rings with clasped hands. of which some fine specimens liave been preserved Onc in the Londesborough collection is of silver with two hands clasperl, and on one side of each of the twin hoops there is an engraving, showing that this ring belonged to somo personage of high mink in the 16ith century. Thereare earlier examples in the Braybrooke collection, not on! y with twin hoops but also with three hoops, a fine one dating from the and of the loth century.

Signet rings were used for signing documents from a very carly date, while the Egyptian scarab was mounted on a ring and worn as a charm against evil. An intereating old ring is illustrated in Figs, 1-2. Dendly poison was contained under the ornamental top, which could unobtrusively be opened and the poison
dropped into wine or food. Rings were used in connexion with betrothals and weddings from the earliest times.

Rings connected with ecclesinstical usages hnve always been regarded as symbolical of dignity and authority by priesta, and on all state occasions there is a special ring that is invariably worn by the Pope. The stone in this ring contains a very fine cameo of the head of Christ. The stone from which this cameo is cut is a peculiarly beautiful specimen of a blood-stone. This ring is placed upon the Pope's finger immediately after his election, and it is handed down from one Pope to another.

Thumb rings were frequently worn, and many of these are in private collections or in muscums. Some are regarded as of great value, and are known as decade-rings, having ten projections at intervals round the shank, which were used as beads for repeating Aves. Many of thescerings are engraved with the ligures of saints. A favourite inscription on the signets or the inner lining of the slank on religious rings is that of St. Christopher, the patron saint of Roman Catholics, as regards protection in times of accident or danger.
Silver lings are not frequently found; but in all well-known collections there are many specimens that are made of iron, also of other base metala with enamel. Some beautiful specimens of glazed earthenware rings have been unearthed at various times, set with very fine mosaic ornaments or with cornelians or lapis lazuli.

## Care of Rings. The cleaning of gem rings

 should be regularly undertalien if the gems are set in open settings. Diamond rings can be placed in hot water, and then a softtoothbrush should be applied to the backs of the stonos, and any dirt or dust should he carefully brushed away from the setting. Rings can be dried best by covering them in a small recep. tacle containing very fine boxworid sawdust. Which has been heated They should then be brushed with a soft, dry brushA simple method of cleaning gems infinger rings, providing the stones are not foiled, is to

brush the backs of the stones through the open setting with a moderately stiff toothbrush which has been dipped in a small quantity of whisky or gin The spirit evapuratee, and thus saves the necessity of drying them.

In all cases where imitation or foiled coloured stones need cleaning, there should never be touched with anything moist, and inust not on nny account be immersed in water or brushed with a damp brush. Imitation stoncs are usually covered at the back with a foil, and it is necessary that this should never be allowed to become damp. The liest method for cleaning foiled stones is to brush the settings round them with a bristle brush, to which a small quantity of powdered chalk should be applied

Rings containing valuable gems should be left occasionally with a practical jeweller to examine the settings through a micrascope. and to remedy any defecta that may he discovered in the settings.

The simplest way of removing a tight ring from the finger is to wash the hand in cold water, rubbing the joint of the finger with plenty of soap. If this method fails, draw three or four lengths of thread across a piece of soap, put them through the finest needle that will take then, and then pass the latter between the ring and the finger, drawing the threada after it.

If the point of the needle is kept slanting upwards there will he no danger of pricking the finger. Hold the threads close to the finger, then alip the ring along them. It will usually be found to work off quite easily. If neither of these methods is successful, it will probably he necessary to have the ring filed. Tho hand should never be washed in hot water when a ring is to be removed, as beat causes the finger to swell. See Jewelry; Napkin Ring.

RINGING: In Gardening. A process sometimes adopted for the purpose of inducing vigorous barren fruit trees to bear fruits. It consists of cutting out narrow rings of bark all round or almost all round the branches; if the rings are only one-eighth of an inch wide they may encircle the branches: if wider than that the rings must not be completed. April is a suitable month for this work.

RINGWORM : How to Treat. The term ringworm is commonly applied to certain skin disenses caused by parasitio fungi It may be found on the scalp, the Leard, non-hairy parts of the borly, and the nails.

Ringworm of the scalp, which is highly contagious, is characterized by the appearance of one or more roundish, partially bald patches, the skin being red in colour and covered with fine greyish scales. The disease is more common in children than in grown people. One of the commonest menns of spreading it is by using the brush and comb or wearing the cap of a child suffering from the disease.

The disease is trented by the application of parasiticidal lotions or ointments. Every day the whole scalp should be thoroughly shampooed with soap and hot water. Then the more patently diseased hairs, which will come a way easily, should be plucked out with a fine pair of tweezers. Finnlly, a colourless indine should be applied once or tivice daily to the patches. This treatment must be continued for a long time. The treatment which gives the quickest results when obtainable is the exposure of the patches to the $\boldsymbol{X}$-rays

RIP SAW. This is a hand saw particularly adapted for cutting in the direction of the grain of wood The teeth are specially sliaped for that purpose, the front of them being vertical instead of sloping slightly backwards, as in the cross-cut saw It facilitates the cutting of long lengths of timber, cutting mather faster and more freely than the ordinary saw. See Saw.

Rising Front. See Swing-back

RISSOLE. To make cold meat rissoles, Almost any kind of fish, except very coarse pass 6 oz cold cooked meat, weighed after it has been trimmed. through the mincer twice,
adding 2 shallots and 3 sprigs parsley, then make a thick sauce with 1 oz . butter, 1 oz . flour, $1 \frac{1}{2}$ gills stock, 1 teaspoonful lemon juice and seasoning of salt and black pepper. Add also a pinch of ground mace. The flour should be fried with butter, and the stock must be well flavoured with vegetables. Add the minced meat to the sance, mix and spread the whole on a plate to cool Chicken and game can be used, with the addition of a little hacon.

Meanwhile prepare a small quantity of rough puff pastry, using about 6 oz . flour and 5 oz. butter, or butter and margarine mixed together. This pastry should be rolled about the thickness of a penny. If the pastry is too thick it is liable to become too deeply coloured beforc it is conked, or before the meat is heated right through.

Roll the pastry out into a square, thin sheet, then take portions of the inixture (about 1 dessertspoonful) and lay these in a row along the near edge of the pastry, leaving about 2 in . between each and keeping the heaps far enough from the edge to allow of the pastry being folded over a little beyond the mounds. Now wet the edge of the pastry. fold the flap over the heaps and press them with the thumbs in shape of a half circle. Cut out each with a 3 in. lluted cutter

The rissoles are now ready to be egged and crumbed, and should he fried in deep boiling fnt. Use a frving basket, and shake thens while frying gently to detach them from the sides of the baskiet and from each other. Dish on paper and garnish with fried paraley.
The rissole may be fried without any coating. When so treated, the half circle is laid on a Houred plate, turned over quickly and then fried as if egged and orumbed. It must not be dipped in flour, but only dusted with it.
Fish Rissoles. Lobster makes gond rissoles. Cut the meat of a very small lobster into dice, add to these $1 \underline{1}$ gills good white sauce, 1 teaspoonful leınon juice and seasoning, also a little anchovy butter. Mix all thoroughly together and heat up to boiling point in a small sauce. pan. Cool the mixture, make it up into rissoles, and fry in the manner previously directed. fish, is suitable for rissoles, but the llesh must be mixed with good white sauce and pounded. Cooked fish should be used, and 4 oz . will need $1 \frac{1}{2}$ gills sauce. With the more delicate varicties of fish add a little cream to the sance.

Cheese Rissoles. For these mix 1 dessertspoonful corntlour with 1 gill milk, then cook and stir them over a low fire for a ferv minutes. Move the pan to the side of the stove, and when its contents have cooled slightly add $1 \frac{1}{2}$ oz. grated cheese, the yolk of an egg, and a small lump of hutter. Add pepper and salt to taste, together with a little mustard: then turn the whole on to a plate and leave it to cool. When it has ret, form it into rissoles, using a little flour to make it adhere ; coat each with beaten egg and breadcrumbs, and fry in smoking hot fat. Drain, and serve at once, grating a little checse over each. or for the attachnient of objects with thin enrs, or lugs, to plate work. Rivets are uscd in many ways in other spheres than engineering anil metal work. For example, soft metal rivets are employed to fasten the parts of leather and textile work together, and also for attaching metal fittings to bage and straps.

For use on wood. as in the planking of small boats, copper rivets or nails are employed with wishers or burrs of the same material. The rivot is driven through the two planks, and the washer put on and closed up to the work. The superlluous projection is nipped off and the end riveted over the washer as in Fig. 2. The head of the rivet must be supported by a heavy hammer, or other suitahle mass of metal.

When leather or a like material is being joined, it is necessary to provide rivets with heads of a large area and washera of a corre-

## Rivets and Riveting Explained

## Practical Information for the Amateur Mechanic

The metal worker should consult the articles under the heading of Metel : also Bent Iron Work : Casting; Repousse. Reference is also suggested to Crockery: Pocket Knife: Perambulator, etc.
A rivet is a metal peg, resembling a short riveted on to leather, it almost always takes nail, which is clinched over at the ends aiter the place of a washer. Bifurcatcd rivets being driven in place, as shown at Fig. 1. used in leather work have large, fat heads It provides a permanent fixing for two plates and a shank divided into two prongs. When the rivet is used. The generic term for this sponding size. When a metal fitting is being style of rivet is tinman's rivet (Fig. 4).

Rivet. Fig. 1. Three types of rivet heads. Fig. 2. Rivet used with a washer for joining two planks. Fig. 3. Bifurcated rivet need in leather $\quad$. Fig. 4. Tinman's flat-head rivet. Fir. 5. Showing the tendency of metal plates to shear the rivet when the latter is not securely fastened. Fik. B. Result of an anusual strain on a rivet. Fig. 7. Single riveted lap joint. Fig. 8. Double riveted lap joint. Fig. 9. Possible space for leakage between two plates. Figs. 10 and 11. Caulking and fultering io prevent this leakage. Fig 12. Driving the plates together by means of a bollow punch. Fig 13. Three stages in ormiag a snap head. Fig. 14. Another type of punch used in riveting

Where tho rivet is of a metal dissimilar to, should be removerl. so that. the sharl) edges that of the plates being joined it should be of the holes are slightly chamfered, or the softer of the two. All rivets should be quite soft. If found to be too hard, so that the heards break off, the rivets should be annealed.

Joining Metal Plates. Riveted jointa in metal plates reyuiring to be secured to each other in the strongest possible manner aliould be made so that the rivets themrelves nre subjected only to a shearing stress. This means that the strain should be such that the two plates tend to cut the rivets in the same manner as the blades of a pair of acissors, as seen in Fig. 5. There should be little or no tendency to pull the head off the rivet, as is shown occurring in Fig. 6. For thin sheet metal work, rivets from $\frac{1}{\prime} \mathrm{in}$. to $\mathrm{I}^{\frac{3}{d}} \mathrm{in}$. are commonly employed The spacings may be from $\frac{1}{d}$ in. to 1 in. reapectively.

Rivets in tanks and toilers subjected to pressure, and those used in stee! structurcs, usually have a diameter equal to about twice the thickness of the plate. The spacing depends upon the kind of joint and the relative strengths. For a single riveted lap, joint, as illustrated in Fig. 7, the spacing would be about five times the single-plate thickness. Rivets under B in. in diameter are usually driven cold. A single riveted lap joint of good design has a tensional strength of only about 5:) per cent of the solid plate. In a double liveted joint, as at Fig. 8, the proportionate strength may rise to 70 per cent. In no case can a riveted joint be made as atrong as the original plate unless the plate is thickened up in itself at the rivets.

Caulking and Fullering. In larger work, that is to say, where plates of over ${ }^{3} 6 \mathrm{in}^{2}$ are employed, the joints are made pressure tight againat liquids and gases by caulking and fullering. Alt hough the plates may be drawn closely together around the rivets, they may not touch each other between them, as indicated in Fig. 0. There may be small open spaces under the heads and around the atalks of the rivets capable of creating a leak. The process of caulking and fullering hurrs the metal over at these places. It is done by blunt chisels of various shapes, and requires skill and experience to be a success. Fig. 11 shows at $A$ the cdges of a rivet being caulked over; at $B$, the plates of a single riveted lap joint are being similarly operated upon. The use of a fullering tool is shown at C in Fig. 10. In a thin sheet metal object such caulking is impossible, and the same result may be accomplished by wldering, brazing, or welding.
Forming the Snap Head. In order to pull together the plates of a riveted joint in shicet metal preparatury to hammering the rivet over, a hollow set punch may be used. Fig. 12 shows a combination set punch having in addition a recess or snap for forming cup or snap-headed rivets. 'The holding-up tool used beneath may also be provided with a sinking to suit the shape of the rivet being diven, and act as a anap in addition.
To form a snap head, the projection of the shank of the rivet before it is hammered over should be about $1 \ddagger$ times its diameter, as shown at 1). Fig. 13. The final neat rounded shape is ohtained by the use of the rivet snap, as at $F$, after the head has been forined roughly into a conical shape, as shown at F.. The blows, in the first part of the operation, should be clelivered at an angle, following around the rivet with a hammer of suitable weight. It should not be hit directly end on in the centre. The only exception to this method would be in the case of a countersunk rivet, as in Fig. 11, where the metal would for the most part be spread out by means of directly central hlows.

The holes in the plates may be drilled. or punched out in a machine for the purpose. In either case, the burr thus formed
rounded. A drilled hole is to be preferred to a punched one, as the metal around a punched one is weakened in the operation, and the strangth of the plates is thus locally impaired.

Rivets for cold driving should always be thoroughly annealed befure use. Iron rivets are to be preferred for this purpose, as the heads of stecl rivets are apt to crystallize when hammered over cold. Copper rivets used in a presaure-tight joint, to be soldered subsequently to riveting, should be tinned before use. This will ensure their taking to the solder. l'irst they sliould be cleaned by dipping in nitric acid The use of countersunk or Hush rivets should be avoided whereever it is possible, especially in cases where the rivets are subjected to the slightest tensional stress. A pan head, or snap (cup) headed rivet is much to be preferred. Rivets should be purchased with one head already formed. Plain wire should only be employed where both heads are of the countersunk form, and where the rivet is a long one.

ROACH: The Fish. The best season for this fresh-water fish is from early autum: until the end of Mareh, and it should not be eaten before the beginning of August To tell when roach is in good condition, examine the lins and the scales; the former should be red in appearance and the latter smonth to the touch; if rough, the fish is not gool. To prepare the fish, wash it, scale and gut it, and then wash agnin in clear water

Roach may be boiled or fried. Tu hoil, wipe the fish and score then cach side in 3 or 4 places. Put them into a stcwpan and just cover them with lukewarm water To each quart of water add 1 tableapoonful vinegar, 1 dessertspoonful salt, a bouquet garni, and 1 tablespoonful grated horseradish. Simmer from le min. to a quarter of an hour, and serve with parsley or anchovy sauce.

For frying, prepare the fish, washing them well in salted water, then wipe them quite dry. Dip in seasoned flour and fry them in a fryingpan in-butter, or in deep briling fat. When the fish are brown and crisp dish them on a disht paper, and hrush them with a little butter, which should be ready melted, and scatter over them dried and sifted sage, with seasoning of pepper and salt. The sage should be hented. and must be used sparingly. Garnish with fried parsley and cut lemon.

ROAD. Except on private roads, of which there are only, comparatively speaking, a few in existence, all persons have the right to travel on the roads at any time they like. As regards pedestrians, this right is unrestricted, save by the danger from moving vehicles; but drivers of motor cars, carts, carriages, and the like are legally bound to observe certain regulations, known as the rule of the road. They must also stop when directed to do so by a policeman on duty. Where a structure is crected on a road, the local highway authority may compel the person who crected it to remove it.

The extensive use of the raads by motorists has led to spiccial regulations for this form of traffic (for which see the article on Mntoring) and also, on the part of the associations of motorists, to special measures of assistance.

Warning Signs. To facilitate the safc and proper usage of the roads warning and direction signs of a distinctive character have been erected. At many road junctions and corners a white line is drawn in the middle of the road to compel velacles to keep to their proper side. Traffic signs inust now he of the size and type resctibed by the Ministiy of Transport
Roads and Property Owners. The owners of property have certain liabilities and duties with regard to the upkeep of roads. A householder who lives in a street which has nut been
taken over by the local authority is bound to bear his share of the cost of kecping the road in order, according to the length of his frontage to the road. Before a street is taken over the local authority will always require it to be properly made up at the expense of the owners of the property abutting on or served by it. In most towns and many rural districts the procedure is under the Public Health Acts or under the Private Streets Works Act Sitreet for this purpose includea a highway, road, lane, square, court, alley, or passage, whether a thoroughfare or not.

The first step is for the local council to pass a resolution to do such works as they deem necessary to any street or part of a strect which is not sewered, levelled, paved, metalled, Hagged, channclled, made good and lighted to their satisfaction. They must say whether they intend to proceed upon a mere frontage basis, or to take into account any works previously clone by the owners or occupiers of the premises; or to take into account the grenter or less degree of benefit to be derived by the respective premises. They may assess any premises which do not imınediately front. join or abut on the street, but access to which is reached from the street via a passage or otherwise. They may resolve to pay some or, indeed, all of the expenses out of the rates; but this is rarely done. They may include in the works the bringing of the street into level with other st reets.

Further Work of the Local Authority
The council's surveyor next makes plans and specifications, and prepares an eatimate of the cost, and submits to the council a provisional apportionment upon the several premises intended to be charged. In the absence of a special resolution, as above, the only premises which can be charged are those fronting, adjoining or abutting on the street, according to their frontage. I'laces of worship and burial grounds are not chargeable, but their sharc of any strect making must be borne by the rates.

Once a street has been taken over by the local authority, it is repairable by the inhabitants at large, and the householderowner has no more trouble with it. The most common objection to street works is that they are unreasonable, e.g. that the sewer proposed is too small, or unnecessarily large. A lucal authority may, however, lay an unnecessarily large sewer if they bear the surplus cost themselves. Again, an owner may object that the street has already been sewered once. After the scheme is finally approved by the justices, the authority proceed to do the work; and, when they have completed it, make a final apportionment on those liable, in the same proportions as the provisional apportionment.
Notice is served on the owners, any of whom may, within three months, object to pay. The only ground of objection is that the apportion. ment has not been validly made.
The cost of the work becomes a charge on the promises from the date of the completion of the work. Therefore, if A buys a house the owner of which has had the proper notice, and he sells it to A free from incumbrances, the owner must bear the cost of the paving, etc., if the work is completed before the day fixed for completion of the contract of rate. Otherwise A inust pay. As between the owner and a tenant of a house, the owner is liable to the local authority, but if the tenant holds on a lease wherein he has agreed to pry, in addition to rates, all imposition and charges imposed on the landlord in respect of the huuse, the landlord may claim reimbursement from the tenant. The local authority may make the amount payable by instalments spread over 30 years with 5 p.c. interest, and recover cach instal. ment from the tenant, the latter in turn boing able to deluct it from the rent. See Ratea.

ROASTING: Of Meat. Beforc nttompl. ing to roast or bake meat, preparations should lirst be made for heating the oven, either by building up a good fire and pulling out the damper over the oven or lighting the gas, or switching on the electric current. Gas or electric lient should be turned on nt least on min . before the nven is necded. The kind of meat to be cooked, its shape, proportion of lean, fat and bone must all be taken into consideration.
The time reguired for ronsting various kinds of meat and joints will be found under the different headings, Beef, Lamh, Pork, etc., and also in the Cook's Time-table in page 4 of wrappier. Part 13.
To prepare the joint quickly, scrape, wipe, trim. and tie it in shape. The usc of string is better than skewers, n.s the holes made by the latter allow the nutritive juices to escape Be careful that the lo ns and neck are jointed. Score the skin of pork with a sharp linife and rub it over with a little salad oil. Tie greaser prper over fatless meat, such ns veal, 10 prevent it from drying and scorching always removing the paper for the last 20 min to let the joint brown.

Put the joint on the trivet in a double baking tin if possible. The water in thic lower pan kecps the dripping from burning and causing an unpleasant amoke. Alternatively put a second in containing water on the shelf helow the joint. or add a gill of water to the tin in which the joint has been placed, adding more as it evnporates.

Place the joint in the hottest place in the oven for the first 10 min . This is most important. the object being to harden the meatalhumen on the surface. and thus seal up in the meat the juices that give liavour and nutriment. Then slacken the heat in ordel that the joint is cooked tiorough, not dark nor burnt on the outside and raw in the centre. After the preliminary sharp heat. the rule isthe larger the joint the slower the oven.
Basting the meat, that is, pouring a few apoonfuls of the hot dripping from the tin over the ineat. must be done frequently, to prevent it drying and shrivelling When cooked, place the joint on a hot dish and remove the string. Keep the meat hot whilst the gravy is made. Clear gravy is served with heef. mutton, lamb: thick with veal, pork, and stuffed joints.
Roasting Jack. The use of a roasting jack facilitates the turning of meat when ret to roast in front of the tire. The spit is occasionally called a jack, and the mechanical contris ance a bottle jack. The hottle jack is provided with an inside spring. When wound up it gives the spint, which is fastencd to it, a rotary movement bachward and forivard. so that the ineat is constantly changed in position and is oooked evenly on all sides.

The ronsting jack is a great convenience, ns it docs not require the constant attention of the cool: to prevent the mat from scorching on one side. By the aid of a roasting jack and a mest screen, meat can be roasted in front of the fire and cooked to perfection. It is thus actunlly roasted, whereas when placed in the oven it is balied. When roasted the air circulates freely round the joint, and all noxious fumes are entirely dissipaterl. See Baking: Beef: Dutoh Oven; Lamb: Mutton, etc.

## Robinia. See Acacia.

ROCAMBLE. A member of the onion family, rocamble is often called Spanish garlic, but is much milder than the true garlic. It is of perennial growth, and produces clusters of bulbs at root and stem, the former of the two bcing the mort suitable for propagation.

Cloves, or divisions, of bulbs are best planted in spring in light soil 2 in . dcep and ( 6 in njart. If preterred seed may be sown in drills at the rate of $\frac{1}{2} \mathrm{oz}$. per 25 ft ., crops taking about 8 monthe to reach full maturity. Bulhs should be

Rochea. Greennouse not plant with crimson flowers and succulent leaves
lifted when the foliage becomes yellow. and placed in the sin to dry, afterwards tying them in bunches and storing them in a dry place. See Garlic : Onion

ROCHEA. 'Thicse gicenhouse planta liear succulent leaves and llat bunchis of shows flowers in spring or summer. 'Ilhcy are casily grown in pots in a compost of ivell-drained sandy loam and need a minimum temperature of ahout 50 degrees. During the winter months they need comparatively litile water. Propagation is by cuttings inserted in pots of sandy soil in spring. liochea coccinea. with scarlet Howers in summer, is the favourite kind

ROCK BUN. Plain rock luns or rock eakes can be inade from $\frac{1}{4}$ ). butter. 1 Ih. flour 3 oz. castor sugar, 2 eggs, salt, and d teaspoonful baking-powder. Rub butter into llour, add sugar and eggs (benten), alsn flavouring of vanilla. Mix all well together and drop the misture, with two forks in small rocky heaps on to a tin lined with buttered paper. Cook the cakes in a moderatcly hot oven until they are lightly browned and firm 10 the touch.
To make fruit rock cakes. mix together $\$ \mathrm{Ib}$. flour, a pinch of salt, and 1 leaspoonful baking-poweler: then rub in 3 oz bulter and add 3 oz. sugar, $f$ lh. cleaned currants or sul. tanas and 1 oz. mixed beel, cut up finely. Stir a beaten egg into the mixture and then a little milk, kecping the whole to the desired stifiness. 13akc 1he cakes as directed in the previous recipe.

ROCKCRESS This name is popularly given to the white arahis. It is a low.growing, spreading plant much used in the rock garden and for spring flower heds; it thrives in ordinary well-drained soil and is increase by cuttings in June. The plants should he hard prunod after flowering. Aubrietia is the purple rock cress. See Aubr:etia.

ROCK CRYSTAL. A variety of colourless or nearly colourless and transparent quart\%, rock ervstal is found in different forms in many parts of the world In all forms it is an extremely hard mineral. being fusible only by the oxy-hydrogen llame and the electric furnace liock crystal is impervious to nost acids, hydrotluoric acid being practically the only exception.

A modern use of rock crystal is in the con siruction of lenses for photographic and optical work, the pelbbles for which are ob tained in Brazil. Large crystals, used in optical work, are found in the northern paris of Madagascar. The vellum stone of Madras is a form of rock crystal that is cut and polished and is then fashioned into ornaments Sep Lens.

ROCKER. The curved pieces added to the legs of a chair to uermit it to oscillate, or rock, to and fro are known as rockers. They are also used on criadles.
A projection or lever arm attached to a shaft that is capnble of motion in alternate directions is known as a rocker arm. This mechanism is found, for example, in the overhead valve gear of a motor car or motor cycle engine
ROCKERY. This term is commonly used in reference to a small rock garden or a mound of soil and stone so arranged as to provide a miniature representation of a rock or Alpine garden. Often a rockery is but a heap of soil and stones set in $n$ shady part of the garden and planted with ferns, London Pride, and a few other common plants But if it is in a sumny place and built correctly many choice Alpine or mountain llowers can be gown in a rockery. It slould be constructed in the way explained in the notes describing the rock garilen (q.v.)

ROCKET: The Plant. This is the popular name of an old fashioned hardy peren nial plant (Hesperis matronalis). Belonging to the wallilower family, it licars fragrant purple flowess in summer: the variety a ha has single white blooms. The double rockets, with white, lilac, or purple llowers, are very bcantiful, hut more diflicult of cultivation than the single linds: they should be incrensed by cuttings inserted in sandy soil in a frame or greenhouse in late summer. 'Ihere is no difficulte in raising the single rockets from scerls in early summer. looth single and doublo rockets llourish in ordinary well-tilled soil.

ROCKFOIL. This is the popular name of saxifrage, a large group or genus of charming llowering plants chielly suitalile for cultivation in the rock garden. adding greatly to its attraction. See Saxifrage.

Rackst. A delightful percnnial suitable for a sunny bed or border. This variety is well known for its delicate perfume

## Rock Gardens: Their Construction

## And the Plants that Give the Best Results

The reader of this article is referred to the entrics on the various plants and fowers suitable for the rock garden, e.g. Aubricria. Columbine; Edeluclss: Fern Gentian: Heron's Blll; Mass

The building of rock gardens, toth large with soil made firm Most alpine plants root and small. on which to oultivate alpine or deeply, and unleas thare is a fair depth of ani: mountain plants has made remarkable pro between the rocks they may deterorate or gress in late years, and this is not a matter even perish in dry weather It :s a mistake for surprise, for no plants are more fascinating to place one rock or stone directly on another than those which grow wild on the alpine there should be a good layer of soil between heights of Europe and other countries Most them, for many hlpines fourish best in crevicea of them bloom in axton'shing profusion and provide an enchanting display chiefly in spring and early summer. Most of them can be cultivated to perfection in this country $n$ a properly constructed rock garden.
The secreta of succeay are to choose a site in a sunny place and to provide thorough Oetw the rocks.
Ordinary non-clayey garden soil may torm the bulk of the material used in the rock garden; sand, leaf-mould and gritty material, such as broken stone or brick, must be mixed in frcely. Such a compost will suit numerous

Rock Garden : An eflective arrangement of plants. 1. Anemone bepatica caerulea 2. Androsace alpina. 3. Campanula rameri. 4. Primula denticulata cashmiriana. 6. Achillea argentea. 6. Adonis pyranaica. 7. Rock yarrow. 8 Alpine pink. 8. House leeks. 10. Aubrietla, Dr. Moles. 1i. Arabis alpina plena 12. Aethionema grandifors. 13. Gentiana acaulls. 14. Lychnig Lagascae. 15. Double gold dust. 16. Erikeron aurantiacus. 17. Iberla correaelolia 18. Aobrietia. Mrs. Lloyd Edwards. 19. Saxifraga apiculata. 20. Erodium macradenum. 21. Anemone pulsatilla. 22 Linum tenuifolium. 23. Saxitrara Ai200n. 24. Edelweiss 25. Phlox amoena. 26. Aubrietia, Firerior 30 Oeranit 32 Daphna 33 Remondia pyrenaica. 34. Gentiona acoulis. 35. Saxitraes $\begin{aligned} & \text { upestris } 33 \text { Ramondia pyrenaica. 34. Gentiana acaulis. 35. Saxitrara } \\ & \text { Camnosii. } 36 \text {. Lithospermum prostratum }\end{aligned}$ provided for at plant ing time by taking out holes nad tilling them with peat. or whatever is needed. If the avail able site is narrow. oare must be taken not to build too bigh ; other wisc the plants are almost certain to suffer from the effects of drought in summer.

The best time to put in rock plants is in September-October and early April As they are grown in small pots by nurserymen they can bowever be planted at any time, though it is unwise to set them in winter. In apring and early summer the rock garden must be watered very freely in dry weather. for it is then that the growth of the plants is most active They ought to be wutered thoroughly a lew hours before being planted it is an excellent plan to place a layer o drainage. Alpine plants are thoroughly hardy, stone ohips on the soil round about choice and do not succumb to frost, however severe; plants: this belps to kcep the roots moist. but they will not flourish in ill.drained soiL Perfect drainage is of the first inportance.

There are innumerable ways of building a rock garden : it is searcely possible or advisable to work to a set design. The aim should be to make it es natural in nppearance as possible, whether it be a miniature representation of a mountain chain. a boulder-atrewn slope, a rocky valley, or merely a grouping of rocks and soil arranged informally

If the soil is clayey it should be excavated to the depth of 10 or 12 in ., this epace then being filled with stones or broken bricks for drainage On naturally light land so such preparation is required. In setting the rocks care should be taken to place most of them on their broadest bases, and to ensure that they are firmly embedded in the soil: they should slope towards the mound of soil, not away from it Very few, if any, of the rocks should be placed on end; they have such an unnatural appearance. Here and there, however, to ensure a bold rock group or greater variety of outline it is permissible to set one on end A limited number of large rocks or stones is more effective than numerous small ones. it is diffioult to build a rock garden of distinction with the latter.

As the placing of the rocks proceeds, soil must be placed behind them, care being taken to sce that all spaces between thein are filled and that is essential to success. Vigorous spreading plants, such as pink. aubrietia alyssum, dwarf phlox, iberis or evergreen candytuft, nud arabis should not be set near oboice kinds, or the latter may be overrun and spmilt.
Stone for the Garden. The ohoice of a stone for building should be well considered In many parta of Great Britain igneous rocks, slates, shales, sand. stone, and limestonc are rendily obtainable, and of these the latter is unexcelled for rock work, cxcept in its orumbling form. Limestone in ita beat forms is beautiful alike in colour, outline, and texturc; it prossesses also the porosity that is exsential for the conveyance of moisture direct to the roots of alpine plante. In thuse

Rock Garden : how to arrange the stones. 1. Simple rock Rarden with base drainage. 2. Bad placing of stones. 3. Good placing. 4. Typical rock lopmation. 5. Good method of planting in pockets and fissures

Coustesy of Amatari Uarmenim
well-drained sol in a sunny place. The bellfowers are very beantiful, especially campanula pusilla, which bears a profusion of tiny blue bell-like flowers. Other good ones are garganica, G. if Wilson. pulloides and muralis, all of low growth, and carpatica. which grows a bout 12 in . high Most of them iike slight shade.

The silvery saxifrages are indispensable They flourish if planted in sunny pockets or crevices of gritty soil among the rocks; mortar rubble or a scattering of lime should be added A few beautiful sorts arc Aizoon, Engleri, lingulata, Cotyledon, and cochlearis The mossy saxifrages form moss-like evergreen cushions, and bloom very frecly in spring. They need well-drained soil in sun or whade Wallacei, hypnoides and muscoides are a tew of the best. The Cheddar pink (Dinnthus caesius) is easily managed in gritty soil, and edelwciss (leontopodium) flourishes in stony, loamy soil Veronica teucrium dubia hears masses of lovely blue flowers and thrives in ordinary rock garden compost.
Other indispensable sorts are the primulas irondosa und hirsuta, dwarf phlox, rock jasmine or androsace, vellow flax (Linum Havum), atonecrop or sedum, and houseleek Many of the gentians are somewhat difficult, they may grow, but often fail to bloom. One of the most reliable is Gentiana septemfida.

Miniature bulb flowers should be planted in autumn-c.g. hoop petticoat. angel's tears and cyclamen-Howered daffodil, squill, snowtlake, and glory of the snow' In spring sceds of low growing annuals may be sown to till spaces here and there; suitable kinds are toadflas. (linaria), portulaca, leptosiphon and violet cress (ionopsidium). Dirarf varieties of conifers, daphne. rhododendron, and other shrubs are often used in furnishing a rock garden.
ROCKING CHAIR. In a rocking chair the legs are mounted on curved rails, or rockers, so that the chair can be rocked backward and forward by a alight effort on the part of the occupant. Sec Chair.
ROCKINGHAM WARE. T'uo classes of pottery known by this name should be clearly distinguished. There is the ever-popular ware consisting of a cream-coloured earthenware hody, covered with a lead glaze heavily stained writh manganese oxide, which imparts to it a rich purplish-brown bloom, resembling a warm madder. This was introduced about 1788 by the Swinton worlis near Rotherham, and nained after the Marguess of Rockingham. on whose land the factory stood It was at its best down to 1806 , the carlier pieces having a plcasing variation in the glaze, which darkened as it slowly flowed down.
The modern Rockingham glaze, which is made at many factories at

Kockingnyw Ware. Plate of thia ware made about 1823 Brilish Museum home and abroad, tends to be flat and uriform, but in technical excellence modern Wedgwood and Ridgway Rockingham surpass anything ever done at Swinton. Pieces to collect include also the antique Cadogans-which werc lidless puzzle-pots filled from below, usually in the form of a peach, and a sprig of blosson for the handle-as well as the Toby snuff-taliers, often described as portraits of the great American Benjamin Franklin. The old mark was Brameld, with or without Rockingham Works. The Rockingham family crest of a griffin was adopted in 182:3.

Rock Garden. The blocks of stone have been laid out in rough terraces. On these terraces, between the
crevices of the rocks and even on the shallow steps, cluster such dainty rock plants as columbine, saxitrage. gentian, white rock cress, candytuft. aubrietia, and a host of others

Courtcsy ol Amateur Gardenima

There was also an output of cream-coloured and other ordinary wares, including dishes and plates enamelled with sprays of flowers, identified by the botanical name written on the back After 1806 much gnudy ware was turned out, and after 18.0 porcelain was also made. This continued down to 1842, when the factory was closed. A characteristic form of tea-sets liad the views painted inside the cups, with a simple gold design outside.
ROCKING HORSE. 'I'here are two main types of this toy, one somewhat simpler than the other, and each can be bought in several sizes and in various qualities of inaterial and fittings. The simpler type is mounted upon two curved rockers, the other on rockier bars. It is advisable, when buying, to choose a thoroughly strong horse, otherivise it will not stand the rough usage in the nursery to whioh it will probably be put. Most of these toys are portable, hut in some cases the horsc is fixed to the nursery floor

ROCK ROSE. This is the English name of cistus, a group of beautiful llowering shanbs, most of which are suitable only for planting in well-drained soil and n sumng place. The hardiest is Cistus laurifolius, 4 ft ., white. (Other beautiful sorts are crispus, 3 ft ., rose colour ; Horentinus, 2 ft., white; and ladaniferus, 3 ft., white and red They Hourish best in warm, southern gardens where the soil is dry Propagation is by cuttings in summer or by seeds in spring.

ROCOCO. This word is used in both architecture and furniture design for a style that is marked by an excessive use of curves and other forms of ornamentation, including shells, rockwork, scrolls, and foliage. It is usually introduced without regard to the constructional oharacter of the sork, and the figures are juinbled together.
This style prevailed in France and elsewhere in Europe in the 18th century, especially in its latter part. A few pieces of furniture by Chippendale and other English designers are in the rococo style, but these aro by no means their best work. See Louis Style.
ROD: The Measure. This measure of length, which is also called a pole or perch, and is much used in measuring land for allotments, etc., consists of $5 \frac{1}{2}$ yards, or $16 \frac{\mathrm{ft} \text {. Forty }}{\mathrm{f}} \mathrm{y}$ rods make a furlong. A square rod consists of

304 square yards, and 40 square rods make a rood In brickiwork a rod or rood consists of $16 \frac{1}{2} \mathrm{ft}$. by $16 \frac{1}{2}$ ft., i.e. $\because \overline{-} 2 t$ cubio ft . It conlains about 4,500 bricks and about 75 cubic ft . of inoitar.
RODGERSIA. These arc hardy ornamental plants which are grown in the bog garden, or in other deep, moist soil. One of the most striking is Rodgersia aesculifolia, which has large, handsome leaves and hears spikes of white llowers in summer. Pinnata, with bronze-coloured leaves and cream-white flowers, is another striking plant

RODINAL. This is a photographic developer with paramidophenol as the reducing agent and sodium sulphite as preservative. The original developm of the paramidophenol class was a German patent. Similar developers of British make are azol, certinal, kodol, and rytol. They are all concentrated solutions which licep exccedingly well and only require the addition of water for usc. See Jeveloper ; Paramidophenol

ROE. The milt or spawn of tish, which is known as roe, may be cooked in the fish or removed and made into savoury dishes The soft roe is used in the preparation of sarouries and hors d'oenvres, and the hard roe also han its culinary uses. See Coll's Ros; Herring; Hors d'Ocurres: Salinon.

ROGER DE COVERLEY. This is one of the old country dances and has its own individual tune. The dancers form up in two lines, men on one side, women on the other, parthers opposite to each other. The top, woman and the bottom mian then chassé between the lines with their right hands extended, take hands and turn round, after which thev return to their places. The tops man and bottom woman do the same

The manoeuvre is rejeated by the original couple, this time with the left hand, and is followed by the second couple as before. Next time they circle round each other back to back, and finally how and curtsy ; in each case the second couple follow
When all these figures have been done the leading woman and man face towards the top of the room and, whecling outward, lead the other cuuples down to the hottom Here they take hands and form an arch, beneath which the other couples pass. The couple which
originally began the dance is now at the bottom of the row, while a fresh couple is at the top. and the dance continues ns before It follows that each couple gors through the figures $t$ wice, once when at thic top of the row and once when at the hottom.

## Roll. See Bread

ROLLER BEARING. The essentia! difference het ween the roller and the ball bearing lies in the point of contact. With the ballbeasing the point of contact may he said to be a mathematical point, whereas iwith the roller heasing it is a lince equivalent to the length of the rollers The roller bearing provides a far greater hearing area, ands a much heavier load can he sustained than-by the ball type of equal size With the latter, light thrust loads are ho.ne by the point of contact of the balla with the groove in which they run; heavy thrusts are catcred for by the specially designed thrust berring that is usually cmployed in conjunction with a journal ball bearing
Oring to the abaence of a groove in the races of the roller bearing, a thrust load is not prossible, and to overcome this a roller bearing is produced ha ving taper rollers that run in taper races. This will take a heavy thrust in one direction: where opposed thrusts are present, two bearings are employed. Sce Ball Bearings ; Lubrication
ROLLER SKATE. Several kinds of roller skate are manufactured, the hest heing those fitted with hall-bearing whecls. They are made in several sizes, and generally each size is adjustable within certain limits The wheels are made in boxwood, aluminium and steel. Roller skates should be strongly made, and, as serious accidents may occur through the use of skates made of chcap materials, it is advisable to purchase only the hest quality.
The rollers shonld the kept well oiled, using a good quality lubricating oil. For rollers with plain hearings thin oil should be used. but for ball bearings it is advisable to use a thicker oil of the nineral kind which will not dry. Rust may be avoided by liceping all the mctal parts rubbed over with vaseline. It is not enough merely to wipe the parts over with a vaselined rag: the metal surfaces must be thoroughly well rubbed with a soft rag impregnated with vaseline. If the skates are to he placed on one side for any length of time. it is advisable to wipe them over with melted tallow
Small repairs, as new axles, wheels, screws, and rubber pads, can he done at home, but the necessary materials should be purchased. Parts can he obtained from the makers generally much cheaper than they can be made at home. See Skate.
ROLY-POLY PUDDING. There are scveral varictics of this pudding: the plain suet roll, currant roll, or pluin dulf. jam roll. treacle roll, and raisin roll. These arc ali boiled. The roll is sometimes haked insteal, and filled with jam, syrup, or a lind of Banbury cake mixture. When baked, the crust is often made with dripping or dripping and butter mixed. See Pastry; Suet Crust.
ROMAN HYACINTH. Bults of this favouritc early lower are less plentiful than formerly and are therefore expensive. Other hyacinths of which the bulhs have been specially prepared for forcing are grown in. stead. If Roman hyacinths are potted in August-Seplember in loany soil, placed in a shady frame for five or six weeks until weld rooted, and grown in a slightly heated green. house or room window, they will blonm towards the end of the year. They also do well in bowls of libre indoors. The bulbs are useless after llowering. See Bulb: Hyacinth.

ROMDNEYA. This striking perennial is commonly called the tree poppy: it reaches a theight of about's ft., has grcy-grcen leaves,

Rondeletia. The fragrant red flowers of $R$ adorata, an attractive rreenhouse dot plan
and hears large white poppy-like flowers in summer. There are two kinds, varying only slightly in appearance, Coulteri and trichocalyx. The most suitable position for these
plants is in a border at the font of n sunny wall in loamy soil In cold districts the stems are usually cut down by frost in winter, but if the roots are protected fresh shoots will develop in spring. These plants are increased by root cuttings placed in a box of sandy soil in a frame in spring.
ROMULEA. This is the name of a group of spring flowering bullos with flowers sone what resenbling those of the crocus They should be planted in autumin in sandy, loamy soil in a sunny sheltered position, or they may be grown in flower pots in the greenliouse Some of the best sorts are bulbocodium, blue and yellow, Clusii, lavender, and sjreciosn lavender-rose.
RONDELETIA. This evergreen flowering shrub, suitable for the greenhouse, grows to about 5 ft . in height. Its fragrant llowers are horne in compact heads in the summer. Rondelctins flourish in a compost of loain with a littlc peat and sand added
The temperature of the house should vary from 50 to 70 F ., according to the season Propagation is by cuttings struck in sand in the springtime. The favourite lind is speciosa or odorata. which has red llowers.

Rood. This measure of surface contains 40 square rods or 1,210 square yards. Four roods go to the acre. Sce Square Measure

## Roofs OF MANY Kinds

## Features of the Principal Types Used in Domestic Architecture

This artic!e. af.er describin? common methods of toofing and the materials used, denls in detail with the construction of a tupical ronf. See Corrugated ir-n; Cottage; Eaves: Gutter: House: Key; Mansord: Paranet: Purlin : Ratter: Slate; Thatshing; Tile cte.

Roofs are distinguished firstly by the ma. terials used for covering them, and sccondly by their form of construction. They may he covered with thatch, stone, tile, slate. lead, zinc, copper, iom. glass, bitumen, o. asphalte, etc., and according to the kind of material so will the form and method of construction vary

There arc flat, lean-to, couple or span, hip, mansard, and M roofs. 'These are further divided into low or high-pitched roots, as their sides make gieater or lesser angle with the horizon. In carpentry the ronf is the timber framing by which the covering materials arc supported: this in general consists of plates, principal rafters, common rafters, purlins, ridge boards, etc.

Filat roofs are covered with lead, zinc, or asphalte after heing formed with the neccssary wood construction, but roofs of ferro-concrete are conimon. Flat roofs are given a slight pitch or inclination, in order to throw off water that may fall on them in the form of rain or snow. The pitch may he anything between $4^{\circ}$ and $8^{\circ}$. The smalness of the pitch in the case of a lead covering is on account of the fact that lead will creep with the

Roof. Typical example of a span roof
varying influences of the temperature. For this reason the sizes of the pieces of lead are restricterl to a maximum of 7 ft . by 2 ft . 6 in It will he appreciated that the bigger the piece of lead used the more evident will be expansion and contraction. For similar reasons the sizes of zinc are restricted when used on a flat.
The formation of flat roofs varics according to their size. Ilates and joists form the main structure. the size of the joists varying with that of the roof To the joists are nailed T. and $G$. hoarding, which should he laid lengthways to the fall; the flat area is divided up into hays by the use of molls and drips. For an asphate covering the structure of the roof is similarly formed, or the base may he ferro-concrete.

Lean-to Roofs. Lean-to roofs have only one side or slope, the top part of which is generally fined to the main wall of anotlier building: they are commonly used for covering outhouses and sheds. The construction is very simple. A plate is fixed on to the main wall of the building that is to carry the top of the rafters. and another plate is fixed to the main wall of the shed or outhouse. Rafters are nailed to the two plates; an intervening purlin would be fixed if the common rafters were more than 10 ft . in length hetween the supports.
The pitch varies according to what kind of covering material is used. If the roof is tiled or thatched, $45^{\circ}$ would be a suitable pitch, $30^{\circ}$ for slate, and $10^{\circ}$ to $20^{\circ}$ for corrugated iron. If tiles, slates, or thatch are used the common afters should not exceed 12 in. apart, but with corrugated iron they may he placed 2 ft apart.
Span Roofs. Span or couple roofs have two wloping sides. They are composed of rafters that have their heads cut and fixed to a ridge hoard, and their feet to the wall plates at the base. The common rafters are arranged so as to project beyond the ualls of the building at least $(\mathrm{in}$. in order that any water falling from the roof will fall clear of walls. This kind of roof depends entirely upon the stability of the walls that carry it, because it has no tie l.cam to hold it in, hence if used for work of a permanent nature the span should not excecd 12 ft . If an addition to this kind of roof is made in the form of a tie heam it will take a
wider span. 巳t may be added to that given in the former case, but the roof then hecomes What is known as a closed span or couple roof The span on $n$ roof may bo increased by placing a piece of timber across the tien na a binder. Ties and binder are spikenl together and a long bolt known as a king bolt connects the binder with the ridge hoand at intervals of 7 ft to 8 ft . If the tie beams were not so supported they would san towards the centre These tie beams may be used ns ceiling joists, but the clear span for sucha roof should not exceed 20 ft
If it is desired to lake advantage of some of the space in a span roof the tic beams may be raised ahove the wall plates to a maximum height of half-way up the rafters; the ties in such a case are called collars, and the roof is termed a collar roof. This is not su strong a roof as the two preceding ones. In the ordinary couple rool much of the strain is placed unon the walls to which the plates are fixed. There is a tendency of the roof to spread, and the walls are thrust outward

Most buildings equire a roof with a span bigger than those mentioned, and additional timbers in the form of purlins and struts have to be introcluced. In houses of moderate size intermediate supports are found in the form of partition walls, upon which the ceiling joists or tie heams rest and from which struts are supporterl. While at the ends the purlin is built in tho wall. In onder to carry this type of purlin a collar is fixed to about every sixth pair of rafters. The collars are supprorted in turn by the struts that take their licaring from the supports benenth. This type of rool will take a span of 30 ft ., and may be formed at $30^{\circ}$ to $45^{\circ}$ pitch.

With a roof of the span mentionel it is hest to employ tivo purlins if it hes a pitch of $45^{\circ}$, thus dividing the length of the rafters into three. The top purlin is fixed on the collars The lower purlin is of a trussed design; that is, it has $n$ top and hottom memher, with intervening struts and tics in order to stiffen it up, and to prevent any sag.
Two span or couple ronfs may be built side by side to cover one span, such roofs being called II rools. A valley gutter, formed between the two roofs, is lined generally with lead, and arranged so as to fall towarla both ends ; that is, its highest bay is in the middle of the length of the roofs. A curl roof is one having the slope broken on two or all of its sides. In suchinstances the head of the rafters, wheic the slope changes, is cut and tixed to a heavy purlin or curb, these purlins being held together by tie beams or joists. In acldition to the top purlin another is fixed midway between the head and the feet of the rafters which are attached to the wall plate. The curb roof may be finished in the form of a Hat roof. As a means of lighting curh roofs, dormer windows are invariably introduced: when these roofs are nsed under suitable conditions they have a very pleasing effect, and they have the further important advantage of utilizing all the available space in the roof.

Roots tramed on 10 trusses form the best but the most expensive type of root 'Ille trusses inost gencrally used are the king prast and queen poat truse. These are lormed of faily large timbers and consist of a tie beam, principal rafter, struts, and a king prost. the queen truss nas two posts callexl qucon posts. These frames or trilsses are sup. ported by the walls, and

The joints used iri framing the two kinds of trusses are common to hoth. The head of the principal rafter is secured to the king post by stub tenon and shonlder, in addition to the 3 -waly strap. 'The struts and the baso of the king poast are joined with $n$ joint like that used at the head. I'lic head of the struts is joined to the principal rafter by the use of a stub tenon immed late! y under the purlin The hottom iron strap with the gib and cotter allow lor the tightening up of the joints on the tie beam and hase of the king post in the case of slight shrintage or ang of the inaterials
A mansard or a Frenc roof is formed by a combination of the ling post and queen post trusses: the former is placed rest on the wall plates; the trusses support over the latter, a combination which allows the purlins and tho pole plates, which in much of the space in a coof to be usefully turn carry the common rafters, th: feet of employed. Ihis type of roof is used in conthe lattor reating on the poleg plates. A truss mof is hetter able to withstand heavy loads than any of the roufa mentioned. All its meinbers are either in tension or compression. and with careful design it can be arranged so as to convey the loarl of the roof on tho angular points of the truss.
'Lhe head of the king post is prepared to receive the ridge board; at the hend of the truss there is a 3 -way iron strap, und at the hase there in also $n$ strapl of iron lititesl with a gil) and cotter. 'These straps hoth assist in producing a rigid structure 'the parlins are arranged so ns to rest on the pincipal rafter at the point of intersection of the strut: the pole plate is fixed on the erd of the tic beam

The queen post truss is intended for confs with a wider spun The 3-way strap, hotton straps, gibs and cotters will he used in duplicate, seeing there are two posts. Between the posts $n$ straining sill is placed at the base, and at the head as atraining beam.

'I'hoy are very heavy, end oftell prone to be damp. Concrete is much used for Hat rools, and when blended with a suitable waterproof composition and properly laid, it undoubtedly gives excelient results
'Ihatch, carried out in straw, recds, or beather, is held in disfavour by fire insurance authorities, and is generally considered to

harbour vermin and insects A thatcherd house is warm in win ter and cool in rum. mer, so that thatch has much to commend it when it can be properly used It is not practicable as a rooting material in any place where it is liable to be ignited by aparks, or from any other causc.
Corragated and other galv nized irons are not suitahle for divellings, despite the fact that they are fairly lasting, fire proof, vermin-proof, and impervious. Galvanized iron is hot in sumimer and cold in winter, and the nuise made by rain falling upon it is against its domestic use. Nevertheless it is probably the cheapest practicable roof covering. and for outbuildings, poultry houres and the like is a highly ratisfactory misterin, provided it is used in a reasonable manuer with due regard to its linsitations.

Construction of a Typical Roof. As an example of the construction of $n$ roof of a small houre, Figs 1 to 7 show progressive stages of the work. The walls having heen erected to plate height, that is, the height at which the brickwork terminates and the roof begins, a wooden tie, or piate, is laid horizon. tally upon the wall and bedded in mortar.
The next step is to prepare n number of rafters. These will generally measure about 4 in. deep and 2 in. broad, and will reach from approximately 12 in . heyond the face of the wall to the spex of the roof, that is, the junction with the ridge hoard One ond of the rafter is cut at an angle, so that it bears up against the ridge board, while the othor end is notched to fit on to the opposite portion of the plate. Having prenared a number of rafters. the work of erecting the ridge commences, for which purpose it is convenient to lay the ceiling joists in place on the top of the wall plate (Fig. 1).

The ioists are simpiy placed in position, being opnecd at approprinte distances apart, about 14 in . centres, and spiked to the plate to prevent them shifting. 'I'wo rafters are placed in position on the plate and against a ceiling joist, two or three rafters' longth from the end of the ridge. The upper enils of the raiters are pressed together so that they bear against the ridge bonrd, which is placed in position between them. The feet of the ratters are spiked to the plates, and their upper ends to the ridge board, the other end of which is
meanwhile supported in any confenient manner The sanic operation is gone through near the other end of the ricke, after having plumb dup the first pair of rafters hy comparing with n plumb-line auspended from the ridue to the ceiling joista. $\Lambda$ cros. strut is generally nniled tomporarily between the rafters and the plate to keep them from shi!ting.

Another pair of rafters is added near the centre of the ridge. after having tested the latter to ree that
it is no sagging or twistung. When the rest of the mfters are set in position in pairs One pair of rafters is set up ngainst the inside elge of the brickwork. and it the barge hoard is to overhang the walls more than a few inches, an outside rafter is nceded 'The ridge boarl projects a few inches beyond the line of the barge board. Where the rool terminates against a chimney stack, the ridge board is sup. portel on a brick corbel built out of the stack. or is carried on the end of $n$ pair ot rafters.
'lhe junction of two such roofs results in the neet! of fitting n number of short ralters to : dingonally placed meniber known as a hip ridge board, when it is at an ontside anglo, and a valley board when it is an inside angle. These are fitted in much the same way as the other rafters, except that it is nenessary to cut the ends to a different bevol. and to hevel the sides so that the board fits snugly into the angle between the two ridge boards This stage is illustraleal in Fig. 2 The triangular apace between the ridge and the valley or hip hoard is then filled up with short or jack rafters, the ends of which are cut to $n$ bevel in two planes, that is, the top and side of the rafter each shows a bevel. These are spiked in position similarly to the rest of the work.

## Supporting the Rafters

'To support the rafters, long horizontal heams of considerable strength aro provided, called purlins (Fig. 3). They are placed in position and provided with adeyuate menns of support at each end, and also at intermediate stages. At the ends they are generally built into the hrickwork of the gable. and at the hip are jointed to the hip or valley loards, and furtlier supported by collars or horizontal crosspieces of timher spiked to the rafters immediately beneath the purlins Struts are then ritted to intervening wall supports, unless the patition walls are carried out in brick, when they may lie huilt in position. Braces, or diagonal timbers running from the plate to the junction between the purlins and the gable ends are then spiked to the underside of the rafters, to take up the strain due to the pressure of the wind on the end of the house, and to prevent the roof from twisting.

An opening round the chimney stacks will have to be worked liy means of a trimmerthat is, a piece of wood jointed into the nearest continuous rafters-and to this trimmer the short rafters which have to terminate ngainst the stack are fixed (Fig. 4) A bracket piece is fitted to them and some roof boarding whereon to set the flashing for the chimney stack.
Valley boards (Fig. 5) are fitted to support the guttering material. 'These are simply

Roof: stages in construction. Fig. 1. Showing how ends of rafters and ceiling joists tht to tae plate. Fig. 2. Valley board and common raiters in place. Fig. 3. Parling in place, also dipand valley and tile Fig. 5. Dalley boards in place to support guttering. Fig. 6. Filling between the rafters to prevent ingress of wind. Fig. 7. Verke on gable end
rough boards nailed to the rafters and run from the eaves to the ridge in the angle bet ween the two roofs. The eaves are formed by cutting the overhanging ends of the rafters in two different directions one a vertical cut to provide $n$ bearing surface for the fascia board and the other liorizontally cut, to provide a support for the soffit board. Thesc boards are spiked to the ends of the rafteis and to each other. The near sidn of the soffit board. where it bears against the wall. may be supported by rough grounds to which it is nailed. The spasce between the rafters above the plate is filled in with brick, or any other material that will close up the aperture. to prevent the wind from driving underneath the ralters (Fig. 6).

At this stage the roof many be finished in scveral ways. The whole may be boarded with rough boards (or tongued and grooved boards in very good-class work), and thic tile or slate battens set upon them. Or weatherhoarding may be used set the wrong way up : that is, with the thick end uppermost, thus providing ledges whereon to lay the tiles Otherwise, tile battens may be simply nailed to the rafters, and the boarding omitted. On the score of economy this can be recominended, but it is generally considered that boarding before tiling the roof makes it perfectly weatheright, and gives a more equable temperature. In the case illustrated the rafters were simply battened for tiles. The battens terminate against the valley boards, or any other boards, such os those for the gutter. The next step is to lay the gutters, such as the valley and those around the ohininey stack, and also to put up the flashings. After this process has lieen completed the roof may be either tiled or slated.

The verges, or overhanging ends, are finished in various ways, hut the method in Fig. 7 reaults in a good appearance and is cconomical. A 9 in . hoard is cut to shape and set vertically against the ends of the purlins and plate, and the tile battens naided to the top edge. A moulding is then run along the upper erlge, the tiles laid flush with the edge of the mou!ding, and the joints pointed or filled in with cement mortar. The roof is completed by fixing the guttering. If stack pipes or iny other projections such as lightning conductors or flagstsfis are to be fixed to the roof, the fitting of the framework or brackets for them is best effected before undertaking the tiling.

Sheds and Outhouses. A simple nicthod of covering a boarded roof suitahle for a small shed is by using bituminous felting material The boards are generally set vertically-that is, they run from the plate to the ridge-and are supported by two or more purling, according to the size of the roof. The rooting material. if similar to tarred felt, should be laid in $n$ continuous strip from eaves to eaves, and should be nailed to the boards with regulation felt nails. The edges should overlap about 2 in . and he made watertight by the cenient generally obtainable from the makers of the rooting moterial. The edges are then covered on the outside with laths of wood ahout 2 in . wide and $\frac{t}{2} \mathrm{in}$. this:k; which should be bedded on the rooting cement and secured with stout wire nails.

A flat roof, as of an outhouse, can be laid in much the simne way. In this rase, it is of paramount importance that the joints between the strips of roofing material be rendered watertight with a liberal application of rooling cement. The seams should then be nailed with felt nails, spaced ahout 2 in. apart; but with this type of roof the difficulty is to render the side wall joints watertight. One wey to do this is to employ efficient Hachings, while another is to turn up the edges of the rooting material so that, when finished, the whole is very much like a large, shallow
tray. A fall must be provided in two directions down to the underlving slates with a joint ao that the rainwater can drain away to a of the same compound. Cracks, holes, ete, down gutter, and thence to a rainwater liead or other discharge pipe.
Repairing Leaky Roofs. The repair of leaky rools, and the way in which these difficultics are overcome, depends upon the nature of the roof covering. and is denlt with under such headings as Damp; Gutter ; Slate ; and 'l'ile

There is $a$ number of patent preparations sold for repairing roofs. An old slate roof can be made wnterproof by using a plastio bituminous compound. I'his is applied to the bottom edge of loose slates, which are bedded are filled up, and the surface of the roof is treaterl with a liquid preparation of bitumen. Sheet motal roofs can be reconditioned in a similar manner, using both the plnstio and liquid preparations.
In the case of a small roof covered with bituminous materinl, if this gets punctured through any cause. it can generally be dealt with by fixing a patch of similar material upon it and cementing down and nailing around the joint. Should it crack or split for any length, it would le best to cut out the affected section und provide a whole new piece.

## Roof Gardens: Planting and Treatment

How to Utilize Accessible Leads and House Tops
This article suggests idcos for transforming tlat roof spaces into welcome openair adititions
to the home. SSe also Arch: Garden Furniturc: Logzia: Trellis: Vcranda: Window Box,
and the entries on the various plants and shrubs mentioned
If a tiny garilen or balcony loggia, with growing flowers, creepers and shrubs to give a fresh, countrified nir. can be made on a drab lead, the recessed roof or the top of a town house, it will usually afford both interest and pleasure. Where twindow bores are not allowed a rmall flat piece of ronf can often be utilized for flowers without infringing regula tions. An awning can be fixed at no great cost which can be raised or lowered at will, and such garden furniture provided as can bc ensily movol, adjusted and folded awny when not in use. A grass mat is a pleasant addition when the surface of the roof is level, and adds to the gay appearance of the garden. Where there are children the clouble protection of a strung railing and a flower box showld be constructed on the open end wall of the lead or roof. The railing should also be fenced so that it affords no foothold.
Trel!is screens, as shown in Fig. l, make a delightful background and also alford privacy. When possible walls-unless of an attractive brick-should be washed with some good colour, such as dcep cream, palc !eaf green, ochre, or lemon yellow. Simple wind-screens can be contrived of Japanese matting.
In Fig. 1 fuchsias, geraniums, violas, petunias, etc., are planted in boxes painterl gicen, and hanging baskets are attached to the trellis.

Roof Garden. Fig. 1. Boxes of ivy-leaved geraniums and fuchsias, with wistaria, etc., on the trellises

In some of the newer houses architects have planned a terrace, balcony or roof garden, and such gardens are also to be found on the top of the more recently-built Iondon flats. The discovery of the value of light in the prevention of various diseases is now fully recugnized, and a terrace garden such as that shown in Fig. 2 is of immense value as a place where sun and air can be enjoyed. Such a roof space is formed by a sct back upper storey
The use of reinforced concrete for flat roofs makes thic planning of a mof garden easier, as it is possible to plant herlges in troughs and to lay out formal gardens with clipped box and other shruls. Rock gardens in miniature have nlso heen successfully made high ahove the traffic of city streets. Quick growing vines provide a green background; garden ormaments can he added, and in some cases a playing fountain.
Fig. 3 illustrates a kitchen roof garden. Tomatoes do particularly well grown in boxes and runner heans are hoth practical and decorative. On a large roof space the amateur may plan both flower and vegetable gardens, dividing them by means of a vinecovered trellis. Marrowr, cucumbers and mushrooms will grow together with minor crops of lettuce, radishes and mustard and cress. In addition paraley, mint and sage may be usefully cultivnted.
For this nore ambitious type of roof garden a tank for supplying water at air temperature with which the plants can he conveniently watererl during dry weather, and a good-sized can for the purpose, will he found useful.
Cultural Details. General cultural details essential to the success of roof gardens are careful and regular watering during spring and summer ; spraying of foliage in the evenings of hot days; forking-in of some good fertilizer once a fortnight during summer, and gentle pruning of trees and shrubs to keep their growths compact as they increase with age.
In the many cases where it is impracticable to lay down beds and borders, moof gardening is usually accomplieherl by means of pots, tubs, and hores. Common butter-tuhs are excellent for small plants, but larger specimens. such as trees nnd shrubs, are best accommodated in halved barrels or paraffin casks. The latter will require thorough cleansing, and a good method is to fill it with shavings and fire the interior until the oil is hurnt out. All receptacles brought into use will require holes drilled to nllow water to escape as well as thorough drainage crocking. Soil must be of gond heart and quality, owing to the difliculty of frequent change. Rich loam, leaf-mould, peat, decayed manure. coarse silver sand, and some good chemical fertilizer, will form excellent stock for compost. Each lox or tub should be nearly filled, with sulficient apace lt ft for watering. Arrangement

Roof Garden. Fig. 2. Roof garden on a country bouse. In the boxes antirrbinams and otber plants are krowing, while trellls work is provided for climbing shrubs Conrtesn of Our Homes and Gardens
is a matter of individual taste and structural convenience, a tuh in each corner, with boxes hetween, being a cominou base for most roofgarden schemes. All receptacles should he given a coating of preservative.

Trees, Shrubs and Flowers. The mof gardener has at disposal a pariety of trees, shrubs, climbing plants, perennials, annuals, hulbs, and alpine plants if the garden is suitably planned for the giowth of the last named.

Among other shrubs that will thrive with eare are the spindle tree, rhododendrons, spotted laurel, Jews nallow, liarberrics, akimmin, privet, mock orange, flowering currants, and amall standard hay trees. Single specimens of these need to be grown in tubs or boxes at least 18 in . wide and deep. There is scope for plants of olimbing or senii-climbing hahit, attached to chimney-stacks or poles, or trailed across trellis. Perennials that do well include Virginian creeper, Ainpelopsis Veitchii, white and yellow jasmine, mountain clematis, Clematis Jackmanni, and climbing roses. Amongst annual climbers which are of great use are canary creeper and nasturtium.

Annual flowers that are easily grown from seed sown in boxes are gudetias, clarkias. candytuft, nasturtium, sweet peas, alyssum, marigolds, eschscholtzias, annual chrysanthemuns, and Virginian stock. Tender anmuals and biennials, such as stocks, zinnias petınias, Phlox Drummondi, lobelins, geraniums, ageratums, fuchsias, and tobacco plants may be procured as seedlings.

Handy perennials are not always successful on roofs, but early flowering chrysanthemums, Solomon's seal, irises, creeping Jenny, carnations, polyanthus, London pride, perisinkles and sweet-tvilliams, will do fairly well. All the nbove must have plenty of water, preferably enrly in the morning and after sunfall. Bulbs, including lilies, may be grown, but the crocus has a special attraction for town sparrows, and is not reconimended.

ROOK PIE. Only young hirds should be used to make a rook pic. The following is an old country recipe : Take 6 to 8 young rooks, draw and skin them carcfully, and immerse them in cold water for 2 or 3 hours. Then split them and remove the linck bones. IVashis them carefully, changing the water twice, and dust each biril with a seasoning of salt and pepper, then pack them closely in a pie-dish.

Fig. 3. A kitchen garden on the house tops. Tomatoes are grown in bozes at the back, runner beans at the sides, and a marrow In the tub in the centre Courtes, of Our llomes and Gardens
crops develops many fibrous roots, which in turn prevent tho early running to seed of mature plants.
There are certain plants which are most easily propagated by cuttings actually taken from theroot. Such plants include the horscradish, bou. vardia, seakalc, oriental poppy, Japanese anemone, anchusa and burning bush.

Root Pruning. This practice is carried out by gardeners chiefly for the purpose of restricting the growth of vigorous unfruitful apple, pear, and plum trees and of encouraging the development of fruiting spurs The method is to dig a trench twisted together with the aid of a wheel used at 3 to 4 ft . from the trunk of the tree in by rope-makers. For domestic purposes rope autumn after the leaves have changed colour is used for lifts and lifting apparatus, such as and to fork awny the soil from beneath the blocks and tackle, and for various other purtrec until the thick roots are exposed; these poses. It is liable to deterioration through are then shortened by half or even two-thirds and fresh loamy soil is placed among them and pressed firmly.
Tho result of this trcatment is to check the growth of the trees scvercly for the next year or two. A better plan is to lift the young trees annually in autumn during two or threo ycars following planting, shorten long thick roots and replant immediately. This will probably prevent the need for severe root pruning in later ycars. If it bocomes necessary to root-prune old-established trees the roots on one side should be pruned one year and those on the other side the following year. See Division; Propagation; Pruning.

ROPE. Although this name is often given to cord over $t \mathrm{in}$. diameter, ropo is properly cordage over l in. diamcter. It is made with threads of hemp and other fibre, such as Ilax,

## Roses: Varieties Old and New

Bow to Obtain the Best Results in Garden Display and for Cutting
The amateur gardener may consult Flowe. Garden: Pergola: as well as such entries as Disbadding; Pruning. Attention is also drawn to the colour plate with this articie

The rose is the loveliest of all garden flowers ; it is now represented by hundreds of varieties, of which nany have been raised within recent years. The new ones are far superior to the old ones for garden display and for cutting for decorative purposes indoors; they bloom frcely not only in summer but, in autumn too, and a collection of the up-to-date varicties must be considered indispensable by every garden lover. It is often said that the new roses are less fragrant than the old ones, but that is not wholly true, for many of the latest novelties have sweet-scented blooms. A garden planted with a representative selection of the beat roses is almost as gay in September as in June and July; the plants continue. to make fresh growth during the summer and early autumn months and almost evory shoot is crowned with blossom.

Roses may conveniently be grouped into five main classes-ramblers, climbing roses, dwarf or bush roses, standards, and shrub roses. The modern types and varietics in cach of these classes are immensely superior to those seen in the gardens a generation ago and they ought chiefly to be planted.

Rambler Roses. There are two chief types of rambler rose-the wichuraiana and the multiflora. The varieties of the wichuraiana type are more popular, for they aro vigorous and easily managed, many of them have handsome lustrous leaves and all bear a profusion of blossom in high sumnicr. The following is a selection of the best : Alberic Barbier, pale yellow; Aviateur Blériot, yellow; American Pillar, rose and white; Chatillon Rambler, pale pink; Dr. Van Fleet, blush; Dorothy Perkins, rose pink; Emily Gray, yellow; Excclsa, crimson ; François Juranville, salmon yellow: Gardenia, cream; Hiawatha, crimson; Lady Gay. rose pink; Fraicheur, pale salmon; Minnehaha, deep rose; Sander's White, and Thelma, salmon pink.
Their management is simple. They ought to be planted in autumn or in early spring in deeply dug and well manured soil, and in March all the stems or branches should be cut down to within six inches of the ground. This treatment will force the development of fresh strong shoots from the baso which will bloom well in the following year. In subsequent years pruning should be done as soon as
the flowers have faded by cutting out the old stems which have flowered and tying the new shoots to tho support.

The multiflora type of rambler is less coinmonly known than formerly; it is being superseded by those of the wichuraiana type. Favourite varieties are Blush Rambler, with apple blossom-like clusters of bloom; Crimson Rambler, bright red; Tea Rambler, salmon and copper; Mrs. F. W. Flight, rose and white; Pemberton's Whito Rambler; Tausendschon, rose pink; and Violetta, lavender violet. Thesc need the same treatment rs given for wichuraiana rambler roses.

A few of the old rambler roses are still planted. Among them are Felicité Perpétuc and Aimće Vibert, white; Rêve d'Or, yellow, very rampant, and the yellow banksian rose which must be planted against a sunny wall and left unpruned until it is well established, and then needs to be thinned out.

Climbing Roses. The true climbing roses are less rampant than the rambler roses, though still vigorous enough to cover poles, pillars and arches; they are suitable also for walls. There are two types of these, those which are naturally of climbing growth and others called "sports," which have devcloped accidentally from dwarf roses and are distinguished by the prefix Climbing, c.g. "Climbing Ophclia."

Of the former, some of the best are Allen Chandler, red; Gloire de Dijon, salmon buff: Lady Waterlow, carminc-salmon; Lemon Pillar, pale yellow ; Madame Alfred Carrière, almost white; Scarlet Climber ; Souvenir do Claudius Denoyel, red; Wm. Allen Richardson, orange and yellow ; and Zephirine Drotthin, the thornless rose, rose pink.

Of the climbing "sports," the following are favourite roses-Climbing Carolinc Testout, pale rose; Climbing Independence Day, yellow: Climbing Lady Hillingdon, orange ycllow; Climbing Madame Herriot, orange salmon: Climbing Ophelia, blush: Climbing Sunburst, yellow:

The way to prune rosos in the first group, which are naturally climbers, is to cut out parts of the old branches in late summer or carly autumn to make room for new shonts. Special care is neerled in pruning the climbing "sports." They siould not be cut lown in the spring following planting as is advisable with the other climbing and rambling roses : mercly the tips of the branches are cut off.
Bush Roses. The dwarf or bush rose is perhaps the most important type of all: it reaches a height of from 18 in . to 2 or 3 ft ., according to the varicty, and if suitable sorts are chosen will supply blooms from June until November; but if tho weather is mild the trees may be planted between then and the middle, or even tho end, of March. Thoso planted early will be nost satisfactory the first year.
Success depends vary largely on correct preparation of the ground. This ought to be dug not less than two spits, about 20 in . deep; farmyard and stable manure or hop manure must be nuixed freely with the lower spit, and basic slag, 4 oz . per square yard, should be scattered on the soil when digging is finished, and forked beneath the surface. The rose bed or border ought to be prepared a week or two in advance of planting. Before the trees are put in the branches should be shortened by half. In exceptionally cold or exposed gardens it is wise to protect the bases of trees by heaps of old ashes or soil, but in most places they do not need this protection.
Pruning the Trees. This important task should be carried out early in April. All newly-planted trees, i.e. those put in between the previous October and March, must be pruned severely. Thin weakly shoots should be cut out and the three, four, or five remaining branches must be shortened to within five or six buds of the base of the previous year's
growth. This treatment will force the tres to send up fresh vigorous shoots which will hloom in summer.
In subsequent years the spring pruning must not be so severe unless it is wished to obtain bluoms for exhibition. Weakly shoots must be cut right out and the remaining branches shortened by about half or twothirds, according to whether they are vigorous or only moderately vigorous.

The summer pruning is just as important as the spring pruning If the hlooms are out for home decoration they should be removed with long stems; if the roses are left to fade on the trees the shooto which produced them should be cut to within three or four buda of the hase. As a result of this treatinent fresh strong shoots will grow that will bear blooms later on. It is an excellent plan to cut back nll shoots in this way as soon as the hlooms have faded: there will then be a succession of new shoots which in due course will hear flowers.
Best Garden Roses. The following is a list of the best bush or dwarf rose trees which will furnish a good display in the garden and provide llowers for cutting: A. M. Rouycr, reddish upricot: Betty Uprichard. carmine
growth, and after the tirst year they should be prunedlightly The hest varieticsare : A. Hill Gray, lemon ycllow: Anna Olivier, pale rose and buff ; G. Nahonnand, pale rose ; liady Hil. lingdon, yellow; Lady Roberts, apricot and
copper: Maman Cochet, rose; Marie Van Houtte, pale yellow and rose: Madame Antoine Marie, rose and white; Molly Sharman Cravford, white: Mrs. Foley Hobhs, whito tinged pink; Mra. Herbert Stevens, white: Muriel Wilson, palest len:on; White Maman Cochet and W K. Smith, blush white. For garden decoration the tea roses are less comnionly grown than formerly, as the hybrid teas have superseded them.

Pernetiana Roses. The Pernetiana roses, named after M. l'ernet, a French grower who originated this type, are remarkable for their intense and brilliant oolouring: the first yellow roses were pernetiana varieties. Very few of the true old pernetiana roses are now grown; they have been cross-bred with the hybrid teas and as a result a new race with the vigour of the latter and the rich colouring of the pernctianas has been raised. The best of this type are the following: Angele Perntt,

Madame E Herriot, deep salmon: Dazla, orange scarlet; Golden Emblem. yellow; Gwyneth Jones, orange carmine: Hortulanus Budde, red; Independence Day, yellow: I Zingari, orange and scarlct; Lady Roundway, copper yellow; Mrs. G. A Van Rossem, orange apricot; Ruth, carmine and ornngesalmon, and Souvenir de Claudius P'ernet, yellow. The flowers of many of these varieties are "thin," that is, they have few petals. The trees seem more susceptible than others to the attacks of hack spot, the worst disease of roses. They necd the same treatment as the hybrid teas; the shoots are rather linblo to die back in winter, therefore at the spring pruning the damaged parts must be cut off.
The liybrid perpetual roses form one of the oldest groups in cultivation. They are distinguished by vigorous growth, large well-formed double blooms chielly of one colour, but they do not Hower so freely in late summer and autumn as the hybrid tea roses

Favourite varieties are: Alfred Colomb, red : Captain Hayward, red; Cbarles I efebvre, crimson : Duke of Edinhurgh, red; Fisher Holmes, crimson; Hugh Dickson, red (vigorous, makes a large bush), Mrs. John Laing, pink. Ulrich Brun ner, rose ; a nd Victor Hugo, crimson. In spring, thin weakly shoots must be cut out, and the main hranches of the past summer's growth cut back by ahout two thirds
The divarf polyantha or haby rambler roses aro very popular for filling formal flower beds, for they bloon more or less all through the summer and early autumn. In spring they may he hard proned to keep them dwarf, or pruned lightly if it is wished to have hushes two feet or more high. A few of the hest are Alice Amos, rose and white; Chatillon Rose, rose pink; Eblouissant, crimson; Ellen Poulsen, rose; Katherine Zeimet, white; Kersbergen, crimson; Mrs. Cutbush, pink; Rufus, bright orimson.
Certain beautiful roses of vigorous growth soon develop into hushes from 2-4 feet or more high; they are not suitable for planting among
and salinon; Caroline Testout, pale rose; Clarice Goodacie, white: Emma Wright, salmon orange ; Ethel Somerset, pink; General McArthur, red; Golden Gleam, yellow; Julién Potin, vellow; Lady Alice Stanley, rose ; Lady lirrie, salmon and copper; Lieutenant Chauró, red; Lord Charlemont, crimson; Mabcl Morsc, yellow; Madame Abel Chatenay, carmine rose; Madame Buttertly, deep blush; Mre. A R Barraclough, carmine rose; Mrs. Henry Morsc, bright rose ; Mrs. Henry Bowles, rose; Mrs. Wemyss Quin, yellow: Ophelia, blush; Rapture, deep hlush; Rev. F. Pase-Roberts, ycllow; and Shot Nilk, cerise and salmon. All these belong to the class called hybrid teas They grow and flower freely and are strongly to be reconmended to amateur gardeners. The other types of rose which are grown as bushes or divalfs are the tea, bybrid perpetual, pernetiana and dwarf polyantha or baby rainbler.

The tea roscs thrive hest on well. drained soil: they are ideal for planting in a sunny border at the foot of a house wall. Most of them are of rather tuiggy spreading

Rose : four beautiful varieties. 1. Hugh Dickson, in colour midway between crimson and scarlet. 2. Mrs Bryce Allen, a rose of great fragrance, with rose-plak petals. 3. Clarice Goodacre, a vigorous, free-fowerinz rose which bears
ivory-white blooms. 4. Betty Uprichard, an excellent variety that bears blogsoms ranging in colour from delicate salmon-pink to glowing coppery carmine, suffused with orange

$$

the ordinary dwarf or bush roses, but look well in beds on the lawn, or they may be set in a sunny shrubbery. If planted in deeply dug and manured soil and pruned in late summer hy cutting out old branches or parts of them they will soon hecome eatablished. Some of the best are the modern hybrid musk roses, which hear hunches of hloom throughout the summer and early autumn months: Clytemnestra, salmon-rose; Felicia, rose-pink with yellow flush: Pax, white, and Penelope, salmon-pink

Others are Hugonis, single, yellow, early Howering: Moyesii, deep rose red flowers and handsome fruits, and rubrifolia, grown for the sake of its reddish shoots, which are most useful for cutting for decorative purposes. The Japanese Briars ( varieties of Rosa rugosa) form large bushes and bear single and double flowers: the fruits of the single-flowered varieties are handsome in autumn; the showiest variety is Conrad F. Meyer, a very vigorous shrub with thorny branches and bearing large double fragrant rose-pink blooms in May and June.

The old fashioned roses, e.g. the moss, Provence, York and Lancaster, are little grown nowadays, probably because they hloom only in summer. They should be planted in a sunny place in well tilled and manured soil ; pruning, which is done late in March, consists of cutting out all thin weakly shoots and shortening the main branches of the previous year's growth by ahout half

Standard Roses. Standard rose trees need similar treatment to the bush and dwarf roses of the same name. In planting care must be taken to keep the uppermost roots within 2 or 3 in . of the surface of the ground. The stems of standard roses are briars, and all shoots which grow on them should be cut off. They ought to be ataked securely at planting time to prevent damage in windy weather The stems of standards are $3-4 \mathrm{ft}$. high those of half standards 2-2! ft . high

Some of the best roses to grow as standards are Betty Uprichard, Caroline Testout, Clarice Goodacre, Emma Wright, Ethel Somerset, Fran Karl Druschki, Golden Gleam. Hugh Dickson, Indejendence Day, Iady Hillingdon, Lady Pirrie, M. D. Hamill, Madame Butter'Hy, Madame Melanic Soupert, Mrs. H. Bowles, Mrs. Wemyss Quin, Ophelia, Shot Silk, and W. A. Richardson.

The tea roses do well as half standards, but many other varieties can also be obtained in this type of tree. A few suitable sorts are Christine, Emma Wright, General McArthur Lady Pirrie, Los Angeles. Lond Charle mont. Nadame But terlly, Miss C. E. Van Rossem. Mrs. H. Morse, Rev. F. Page Roberts, and Shot Silk.

Fragrant Roses. The following varieties of roses, which may be grown as dwarfs or standards, have sweet-scented flowers: Angele Per net, orange yellow : Avoca, crimson; Bedford, crimson Cherry, yellow and rose: Clarice Goodacre, white ; Cornelia, rose: Dame Edith Helen, pink; Daily Mail scented rose. crimson: Ethel So merset, pink; Etoile de Hollande, crimson Felicia, pale rose and yellow: General

McArthur, red: George Dickson, crimson: Golden Gleam, yellow: Gustav Grunerwald, carmine rose; Hadley, crimson: Hoosier Beauty, crimson; Hugh Dickson, red: Ivy May, blush with deeper shading: Julien Potin, yellow ; Lady Alice Stanley, rose ; Lady Helen Maglona, dark red; Lady Pirrie, salmon; Lady Worthington Evans, crimson : Laurent Carle, carmine: Lieut. Chauré, red: Mabel Morse, yellow : Miss C. E. Van Rossem, crimson; Madame Abel Chatenay, salmon rose : Madame Butterfly, blush: Mrs Bryce Allen, rose pink; Mrs. G. A. Van Rossem. npricot: Mrs. John Laing, pink: Ophelia. hlush: Penelope, salmon rose: Shot Silk, cerise salmon: The General, red; Victor Hugo. crimson; Ulrich Brunner, rose red: Viscountess Folkestone, blush.

The best artificial manure tor rose heds is known as Tonks manure. It can be purchased from horticultural sundriesmen, and should be applied in March at the rate of 2 oz. per square yard of ground. Regular attention to such details as hoeing, "eeding and cutting out weak useless growths helps to cnsure success in rose growing. Suckers, i.e. shoots from the briar stock on which the named variety of rose was budded, must he uprooted as soon as they are seen; they can generally be distinguished by their prickly stems and light green leaves composed of seven leatlets.
Diseases of Rose Trees. 'The worst disease is black spot. This is a most serious trouble : the leaves are disligured by dark blotehes, and in a bad attack they fall. sometimes to such an extent that the trees hecome leafless in summer. All diseased leaves should be gathered and hurnt, and in winter sulphur should be scattered frecly on the soil and on the rose trees. Further precautions are to spray with Bordeaux mixture or with liver of sulphur (one oz. in two gallons of water) occasionally in spring and early summer. Alt shoots cut off in pruning ought to be burnt.
Mildew is another common discase of rose trees; it is recognized by the presence of greyish mould-like patches on leaves and stems, and is most. prevalent in late summer, especially in continued wet weather. Sulphur is the best antidote, and measures similar to those recommended for destroying hlack spot should be practised
Insect and Other Pests. Rose trees are ubject to the attacks of numerous pests. The commonest is aphis or greently, which can be destroyed hy spraying with one of the . advertised insecticides. or with paralfin

Roses : the best wags to plant them 1. Correct planting oi dwari bush. 2. Bad planting. 3. Standard, staked and planted : $a$, tarred end 4. Plantiug a climber: a tarred end. 5. Dwart, potted and prined 6. Pruning cuts
emulsion, which is made by dissolving a handful of soft soap in a little hot water adding two gallons of warm water and an eggcupful of paraffin. Various caterpillars attach the leaves, and the rose maggot often damages the Hower buds; these pests should be searched for and destroyed. Rolled leaves ought always to be cxamined
The attacks of the rose leaf hopper cause white blotches on the leaves, especially o rnse trees on walls; red spider and thrips, two minute pests, are chiefly troublesome on roses under glass and on walls-they attack the lower leaf surface: the frog-hopper or cuckoo spit infests the young shoots, the rose slugworm eats away the tissuc of the leaves. and the leaf-rolling sawtly rolls up the leaves until they become mere strips

A nicotine insecticide, sold by horticultural sundriesmen, is the hest wash to use against most of these pests. The leaf-cutting bee, which cuts semiciscular pieces from the leaves and uses them in its nest, is difficult to deal with: it should be watched, and if possible traced to its nest so that the latter can be deatroved
Roses in Pots. Pot roses grown under glass should be lifted from the ground in Octolier placed in (; in pots in a loamy compost, and placed in a cold greenhouse. No artificial heat whatever should be given the first scason After flowering. which will be scanty in result plunge the fots out of doors in ashes during the summer months, ic-pot in early autuinn. prunc in November, and then remove to a heatedgreenhouse All indoor roses should he stood out of doors. after flowering, in the summer. Climbing roses grown under glass should be planted in o well-drained border al loamy soil

ROSE BAY. The name of rose bay is applied to Nerium oleander and Epilobium angustifolium. The former, which is described under Oleander, is a greenhouse evergreen tlowering shrub. The latter, a hardy perennial herh of the evening primrose order, sometimes called the Fronch willow herb, produces willow-like folinge with crimson fowers. It grows to a height of 4 ft ., and flourishes by the waterside or in ordinary soil The illustration shows n dwarf splecies of Epilobium known as obcordatum. See Oleander

ROSE CAKE. Rose cakes are sinall vanilla llavoured cakes, so called hecause of their colour. They can be made by creaming together 3 oz . butter and 3 heaped tableapoon fuls sugar, then adding by degrees 2 or 3 eggs and 3 o\%. Ilour, beating the mixture well as each egg is added. Then mix in 3 heaped tablespoonfuls of cornflour, a little vanilla flavouring, and a few drops of pink colouring. Bake the mixture in small greased tins in a moder ately hot oven for ahout $\ddagger$ hour

ROSE CAMPION. Sometimes called rose of heaven, this is one of the showy border plants known as Lychnis, or campion. It grows a bout 18 in ., and produces rosy flowers in summer. See Campion; Lychnis
ROSE GARDEN. The ideal aspect for a rose garden is south or south-east, and all beds and borders will repay thorough trenching

Bose Garden. PLan of an offeotive rosery lad out in a small rarden. A-E, weeping of pillar roses: $\mathbf{F}-8$, etandard roses: $\mathbf{T}-\mathbf{W}$, hali-ntandards : numerals, bushes: double letters and $\mathbf{A}_{1}-I_{1}$, climbing roses
before planting. The design shown in the $1 t$ is hardy, grows 5 ft . or more high, and diagram is easily adaptable to larger or smaller bears single or double flowers of various colours spaces, and, if planted with good varieties, in late summer. See Hibiscus; Lavatera. will provide an attractive rosery. Its length and width respectively are 40 by 34 ft . The round centre bed has a diameter of 4 ft ., whilst those placed in the grass panels are 2 ft . wide. Paths uniformly have a breadth of 2 ft ., except under the entrance arch. where 2 ft . extra is allowed. South, east, and west borders are 3 ft . wide. and the north border 4 ft .

Pillar or weeping standards are planned $A, B, C$ D. and $E$. $F$ to $K$ are ordinary standards.
Beds T, U, V. and W aro devoted to halfstandards.
The outside panel bods, numbered 1 to 46 , and the side borders numbered 8 to 51 , are entirely planted with bush or dwarf roses.
The top borders, facing south, and numbered
1-7, 52-58, accommodate tca-scented roses.
Hybrid perpetuals are placed from 59 to 77 ; the first 12 being fragrant reds and the other 7 whites and pinks.

Behind these against the south fence. At to II, a delightful background consists of Penzance briars.
Suitable climbers for the trellis and remaining fences are arranged at $\mathrm{An}-\mathrm{Cc}$ and Tr-Vv. Varieties should be chosen from the selections given in the article on Rose on the previous page. See Pergola; Trellis, etc.

ROSE MALLOW. The shrub Hibiscus, or Syrian Mallow, is known as rose mallow.

ROSEMARY. This favourito shrub, which growe from 3 ft to 5 ft . high, has fragrant leaves, and bears pale mauve flowers in spring. It thrives best in well-drained soil, and must have a sunny place: a border at the foot of a house wall suits it well. Its botanical name is rosmarinus officinalis. Regular pruning is unnecessary, but straggling shoots shou!d be cut back as soon as the Howers are over. Propagation is by cuttings in boxes of sandy soil placed in a frame in August.

British grown rosemary yields cseential oil in the proportion of 24 oz . to 1 cwt . of leaves. This oil, which is distilled from rosemary leaves. is much used by manufacturers of scented soaps and perfumes like eau-deCologne.
Medicinal Uses. In medicine the essential oil of rosemary acts as a carminative and stimulant, and is a useful remedy for flatulence. The dose is $\frac{1}{2}$ to 3 minims on a piece of sugar. The oil or the spirit is of ten included in hair lotions. Insects do not like it, and it may be used to keep them away.
Rose of Jericho. This is another name for the resurrection plant (q.v).

ROSE OF SEARON. This is the popular name of a low-growing evergreen plant which bears large single yellow flowers in summer (Hypericum calycinum). It will thrive beneath trees, and if cut down each spring provides attractive greenery.

ROSETHE MULKEIN. This beautiful rock garden plant (ramondia) has large wrinkled leaves and bears bunches of purplish flowers in early summer. It must be planted in a crevice facing north or east, the rosette of leaves flat against the rock: a compost of loam; peat, and sand is suitable Ramondia pyrenaica, pale violet-purple, and Nataliac purple, are the two best kinds.
ROSEWATMR. As its name implies, this is a water manufactured from rose petals. It is made from what remains after the distillation of otto or attar of roses, and has to be diluted with twice its volume of water before use. It is used in toilet preparations and is also mixed with glycerin and applied to relieve chaps, etc. Occasionally, rosewater is employed as a Havouring agent in cookery. See Otto of Roses.

ROSEWOOD. This is a fancy hardwood of a rich dark colour, red or brown, with wavy streaks that are almost black. Formerly it was much used for pianos and cabinets, and as a veneer on plainer woods. To-day it is used to a slight extent for pianos and also for handles to carving tools and to the squares and levels used by woodworkers. It takes a good polish, but, as it is rather oily, glue is unable to get a good hold on it. One reason for its decline in popularity is that it has a tendency, even when well polished, to develop minute cracks in the pores of the wood.

The finest rosewood is the Brazilian variety. In character this is of a heavy, dense nature, rather coarse and open in the grain. Indian rosewood, known also as blackwood, has the same general characteristics as the Brazilian See Wood.

Rosin. This is an alternative name for resin. (q.v.).

ROSIN PLANT. Bearing two other names, Silphium and compass plant, this is a hardy herbaceous perennial belonging to the daisy order, bearing yellow flowers in sumnier. It is most suitable for a wild garden, and best grown in bold groups, requiring little or no attention, and ordinary soil.

ROTATION: Of Garden Crops. This may be termed a acientific method of cultiva-

Rosemary. Sprayz of the tragrant ofergrien shrub, from the oil is distilled for medion of which oil is dirtilled for medical and other uses
tion, based on
the principle that, although plants extract the same foods from the soil. there is a marked difference in the a mount used by any given kind.

As the requirements of all plants differ in regard to potash, nitrogen, and phosphates, any undue depletion of one or another has to be prevented by rotation in order to main. tain an equable fertility.

Under syste. matic rotation, crops of the same family should not succeed each other, whilst those with long perpendicular roots that feed at some depth
be followed by shallow feeders extracting nourishment only from the upper Inyer of soil

A simple method of rotative cultivation is to divide land for vegetables into 3 plots of equal size, recording them as 1,2 , and 3 , and cropping each on a three years turn-about system in the following manner.
Plot 1. First year: Beet; carrots: parsnipg potatoes. Second year Celery : beans: leeks letfluce: onions; pens: spinach; turnlps. Thirid year: Brussels sprouts:
ilowers ; kale s savoys.
procoli: cabbage : cauli lettuce onlons. year. ycar: Brussels sprouts: spinach; turnlps Second Howers; kale; savoys. Third ycar Beet. paranlps: potatoes.

Plot 3. Firat yca
cabbage: caulillowers: kale asels sprouts: broccoli lieet: carrots: parsnips; potatnes. Third year Celery; beans: lceks. Icttuce: onions. peas spinach: turnips.

ROUGE : The Make-up. No cosmet ic requires such careful and individual choice by its users as rouge. The exact sliade which enhances the particulart ype of face and colour ing of hair and eyes, the right amount for use by day or artilicial light, and the correct placing on the cheelis should all be considered by any one who wishes to improve her appearance by the application of rouge. Another important point which is frequently overluoked is the harmony of lipstick and rouge. It is not uncommon to see an orange shade of the latter and a cerise shade of the former applied at the same time, with unfortunate facial results.

Rouge is sold in three forms, liquid, compact, and as a crean. The first is rarely used, the second is convenient for application during the day, and the third is generally chosen by those who always employ rouge before powdering and after vanishing creain. It should be applied with the third finger in a little triangle com posed of three dabs on the cheek bone. For a thin face a fourth dab of rouge may be placed a little lower down. Then the dabs of colour are carefully blended with the second finger In the evening a touch of brighter compact rouge is sometimes given to gain added brilliancy.

Anyone who wishes to give a less full appear ance to her face by means of rouge should place it high on the clieek-hones, just beneath the eyes. Women with fluctuating colour should avoid the use of rouge. A heavy rouge also detracts from the eyes. It is easier to spoil the appearance by the abuse of rouge than to effect improvement by its use
The nearest shade to the natural colour is the right one in all cases Only very fair women with golden or red hair should use rouge with an orange tint. A raspberry red is the safest shade for most girls for both face and lip rouge.

Older women if they use a brilliant rouge may look hard and unnatural. If very pale a delicate shade of coral or rose should be faintly suggested. Dry rouge is the best for occasional evening use, as it is ensier to apply the exact amount required by this menns when rouging is not part of the daily facial make-up. See Beauty ; Make-up.

ROUGH CAST : For Walls. The surface treatment for walls known as rough cast consists in coating the face of the wall with mortar and, while it is still wet, throwing fine washed gravel or other hard material on to it. The surface becomes broken up and more or less filled with the small pieces. Rough casting is often used in lightly built houses for improving the weather-resisting qualities of the walls, and also for its decorative value.

In some buildings the whole of the work may be rough cast. but in others only the upper storeys or particular parts. In any case, the genera! treatment is the same. First the inortar, which should preferably be made with Portland cement, is prepared and the whole of the wall surface rendered with it. A supply of clean, washed gravel, finely broken stone, or similar hard material should be prepared. It is then picked up on a trowel,
thrown against the wall surface of the cement and allowed to set hard. The surface is often finished by washing it with cement wash Lime mortar can be used, but it has not the weather-resisting qualities of the Portland cement mortar. The propertics of the latter in this respect may be further increased by using one of the weatherproofing preparations
Rough cast as a structural material is easily and quickly applied to framed buildings, such as are built up of a timber framework and covered with expanded inetal lathing. In such cases the lathing is first covered with a sufficient thickness of the inortar This may consist of coarse stuff applied in one or two coats, according to the nature of the work. The rough cast may consist of stone and grit or washed gravel, mixed with hot lime and thrown on.with a trowel.
The rough cast may be made up in buckets. and should be applied to the walls in a semi-liquid state The surface should be finished by immediately washing it with lime inixed with a little ochire to act as a colouring material In many forms of timber and half-timber construction the rough cast is applied to a timber lathing, and the first coat is made of lime mortar well mixed with hair The second coat is also of lime mortar, and the rough cast is applied to this See Cement: Mortar Plaster: Rendering

ROUGH PUFF PASTRY. Although it is not quite equal to the real puff pastry, this is more economical, and can be made to serve many of the purposes for which puti pastry is necessary See Pastry.
ROULETTE: The Game. Although large sums are staked on roulette, the gaine can be played with counters. For this purpose a table fitted with a wheel, or a wheel alone can be bought, these being reproductions or modifications of the one used at Monte Carlo. The main principles are as follows although variations can be and are introduced.
The wheel is sunk into a cavity, either in the table or elsewhere. The base is on ball bearings, and it is marle to revolve very rapidly by turning. with the hand a small crosshar that rises from its axis. Round the whecl is a circular hoard divided into numbered compartinents, and on one or other of these the players stake. As the machine moves, a ball is thrown into it, and when it comes to rest the winning number is indicated by the resting ball.
The numbers on the board ane arranged as follows: $0,32,15,19,4,21,2,25,17,34,6$, $27,13,36,11,30,8,23,10,5,24,16,33,1$. $20,14,31,9,22,18,29,7,28,12,35,3,26$ Zero is coloured green; the others are white and red alternately. In the full game there is a lay-out at each end ol the table, and this is marked out into various divisions for the stakes. Down the centre of each are 12 rows of 3 squares cach; these contain the figures 1 to 36 , and at the top is a square for 0 On each side of these squares are spaces representing passe, manque. pair, impair. black, and red, and at the bottom are spaces marked oul I' 12, M 12, and D 12. The stakes may be laid on any of these squares.

Stakes can lie placed on any single number, or on two, three, four, or six numbers, and on yarious other combina.
tions Stakes are placed on P 1:2, M 12, and D 12, which refer to premicr, milieu, and dernier, and on the numbers 1 to 12,13 to 24 , and 25 to 36 respectively. On rouge, or red the stake is that the winning number will be red, and on noir, or black, that it will be black. Impair means that it will be an odd number, and pair that it will be an even one Manque means that the number will be from 1 to 18 , and passe that it will be from 19 to 36 . Players can stake on zero as a single number The odds against any single number are paid at the rate of 35 to 1

ROUP : A Poultry Disease. One of the most contagious diseases known to poultry breeders is roup. There are soveral forms of the disease

Diphtheric roup may be known from the swollen head and faces, and the yellowish and whitish patches or ulcers. In nasal roup there is a yellow discharge from the nostrils When the yellowish and whitish patches are seen in the mouth and throat, it is styled Avian roup Another form causes the eyes to swell and exude matter, and the numeroue membranes carry cheesy deposits. Roup in any form calls for complete isolation of al affected birds and of any that have been in contact with affected stock. If the birds are kept together, the disease will rapidly spread. with serious consequences to the poultry keeper

Remedies. In mild cases permanyanate ol potash will effect a cure. Crystals are mixed with the drinking water sufficient to make it a rosy pink, say as much as will cover a six. pence to 2 gallons of water.

Another remedy is sulphate of copper One ounce of the sulphate should be dissolved in 8 oz . of water, and given in the proportion of 1 oz . to cach gallon of water The face and head should be bathed with warm water, in which some disinfectant has been sprinkled and the mouth and throat painterl with carbolized glycerin. In bad cases the birds should he given warin food only

Carbolic powder should be well sprintiled about the houses, runs, and pens, and all houses and runs thoroughly cleansed and disinfected after the attack hias passed. They should not be used again for several months See Poultry

ROUT CAKE. The rich, sweet cake or biscuit mixture known as rout cate is made up into small fancy shapes and served with tea or light refreshments. To make it, sift 1 lb fine tlour and mix with $\frac{1}{2} \mathrm{lb}$. picked and clean currants. Put these in a warm place. Now beat to a cream $\frac{1}{2} \mathrm{lb}$. fresh butter, add the same quantity of castor sugar, and heat again till very light. Keep the basin just warm. and use a wooden spoon to beat with

Rowette wneel for nome players. It is sunk in a circular wooden surround, the latter being divided into compartments, each bearing a number from 0 to 36 on either a red or a black ground

Add alternately the llour and 3 eggs, which should liave been beaten
Mix these ingredients in by degrees and very lighty. pour in a little at a time 1 teaspoonfil rach rose and orange llower-water and 1 tablespoonful madeira or brandy. Dust $n$ baking-tin with sugar and llour and droj the mixture, which should be rather stiff in texture, on to it in little heaps. These must be even. Bake them in a hot oven. The cakes will cook in a few minutes, and should be about the size of a two-shilling piece.

Rout cakes are sometimes madc up as light spongy biscuits and baked in fancy tins, or they are moulcled on wooden blocks. The mixturc for thesc cakes is rather different from the first recife Rub 4 oz . butter into 1 |h. flour, add 1 dessertspoonful grated lemon rind, and $8 \frac{1}{2}$ oz. castor sugar ; make up the paste with 2 eggs well beaten and 1 very amall teaspoonfil carbonate of ammonia disalved in a little milk. Bake the cakes in greased and floured fancy tins in a sharp) oven.

ROUTER: The Plane. The router is used for inlay work or for finishing the bot toms of rccesses. A typical pattern is made of malleable iron, not unlike a spokeshave in apprearance. It comprises a working face through which a cutter projects, the amount of projection governing the depth of the recess. The carver's router has a hardwood block through which the iron, or cutter, projects, and is lixed in position by means of a hard. wood wedge. Various widths of cutter may be used. The tool is a combination of chisel and plane. It is worked forward and backward and in various directions until a Hat surface has bcen obtained on the bottom of the recess.
A modification of the router is used for cutting reeds and mouldings in positions remote fron the edge of the timber, or for similar purposes in curved wort Some routers are provided with adjustable grooves may be cut in the work parallel to the edge. See Plane.
ROWAN. Tlis familar ornamental tree, which is known also as the moun. tain ash, is, botanically, a crab (Pyrus aucuparia) and its red fruits, which are veryshowy in autumn, are useful formaking into jelly. It grows $20-30$ feet high and flourishes even in poor soil, is an excellent tree for town gardens and for planting in strects.
Rowan Jelly. This is served with game and venison. To malie it, the berries are first carefully wrshed, then placed in a preserving pan with enough water to cover them, and allowed to boil until soft. This takes $\ddagger$ hour or longer, according to the quantity. The berries are then tranaferred to a jelly bag, and crushed slightly before straining.

When all the juice has been extracted and has been thoroughly strained through the jelly bag into a basin or other dish, it is poured into the preserving pan. and sugar is added in the proportion of 1 lb . to each pint of juice. The liquid is then put on to boil and left until it jellies, which can be tested in the usual way by pouring a little into a saucer. The jelly is then poured into jars and sealed up. It should not be used for some time, is rowan jelly improves with keeping, and may be stored away for two years. See Jelly

Router Plane. Wood carver's router, with wooden stock. the cutting iron being secured by a wedge

Courlesil of 18. Mellujah. Lid covering, the outstanding is rubber lloo which is its durability. It aninntage of 10 to 30 years, accorling to its thicliness and the amount of wear it receives; being of self colour, or inlaid, it does not show wear. It can be liad in n variety of plain colours, also in marbled designs, so that colour schemes can be maintained, and by using borders of the same material in different shades various effects can be obtained. The marbled patterns are much more serviceable as they do not show footmarks so readily as the plain colours.
Laying the Rubber Floor. The material is made 3 ft . and 4 ft . wide by $\frac{1}{8} \mathrm{in}$. thick, but it can also be had in narrower widths for borders. and $\frac{3}{16}$ in. thick if desired. It can be laid direct on concrete, and in the case of a new building this is a great advantage as it saves the cost of Hoorboarding. The concrete must be thoroughly dry, ot herwise the rubber, being impervious to water, would hold any damp and cause knife dipping the latter in cold water occasionally
Cake: Icing.

## RUBBER

Uses Rubber has many practical applica. tions in the home in the form of mats and floor coverings, gloves, waterproofs, footwear and toys also countless uses for accessories it kitchen equipment. for games, the car and the garilen, etc. One of the most mportant furnish. gs is rubber lloor

ROYAL FERN. This is one of the most handsome of hardy ferns and is especially auitable for planting he the waterside. though

Rogal Fern. Osmunds palustrls, an evergreen necies of royal fern grown as a pot plant
it will thrive elsewhere in deep soil that docs not dry out in hot weather. It belongs to the group of so-called flowering ferns, for the spores are on separate shoots, not, is is usual, on the backs of tho fronds. The royal fern (Osmunda regalis) grows wild in some parts of Great Britain and in moist soil caches a height of 3-1 fect.
ROYAL ICING. To make this icing use 2 lb . icing sugar, 4 whites of eygs, and the juice of 2 lemons. Rub the icing sugar through a hatir sieve into a basin, make a well in the centre, and put in the slightly beaten white of egg. Mix in a little sugnr from the sides, add half the strained lemon juice, and mix the whole to n rather moist paste, adding more lemon juice as required If the lemons are large, all the juice may not be nceded. Use the icing at once, sinoothing it over with a large

Rubber Mats. For the bathroom there are marbled rubber mats, rubber tiling mats, sponge rubber mats, and diamond or corrugated patterns. It is advisable to have such mats with n roughened surface to prevent slipping, a smooth surface of rubber becoming very slipiery when wot. One rubher nat that
$f$ m They are generally made the cxact measurenosing to come over the edges. Risers can be fitted to give continuity of design, and verv pleasing effects can the obtained, particularly in marbled designs, if these are related to the larger clesigns used for hall and landings.

Stair treads can also b3 made with corim. gated or pyramid rubber matting, 直 in . or ${ }^{3}{ }^{3} \mathrm{in}$. thick, and separate nosing can be supplied to suit. The rubber mattings can be tacked on to wooden stairs or cemented on to stone stairs, although in the latter casc it is advisable to plug the stairs and screw the treads down.
the covering to sweat undernenth. eventually becoming loose and uneven. It is cxceedingly comfortable to walk on, quite silent, and, being a non-conduct or, does not allow cold to pass. If laid on a stone floor any unevenness will quickly show through, as the rubber, being pliable, fills the joints underneath and beds into every crevice; it is advisable, therefore. to see that the floor is levelled up hefore laying tho covering. Where large areas are covered and long lengths of the materinal used, the flooring need not be fastened down; it will lie llat by its own weight, providing it is not displaced hy moving heavy articles over it.
'lo stick the covering to a wooden floor certuin varieties of glue or cement can he used: this is advisable in doorways or where small picces are used to fill up comers. Special cements are used for sticking rubher floor covering to concrete.

The following is the method. Put a coating of the cement on both the underside of the lloor covering and on the concrete, using a brush about 3 in. wide ; allow both coats practically to dry before putting the covering down. It is hetier to cement the whole of the covering rather than the edges only, as in the latter case the material may bulge in the centre. Trim with a sharp knife, dipping the linife in water to make it cut easier.
There is no dilliculty in cleaning rubber floor covering. but it is necessary to scrub with cleaning powder, in addition to the use of ordinary soap and hot water, and wipe thoroughly dry. Petrol or ammonia must not he used, as these tend to soffen the tubber, and milk or oily subatances are also injurious

Rubber Tiled Flooring. Rubler inlaid tiling is a more expensive type of floor covering, but very good designs are made, and more elaborate patterns can be obtained than in the shect form of rubber covering. The inlaid tiling is made to suit the area to be covercd, and laid by men who specialize in this class of work; for this reason a plan or accurate measurements of the lloor is necesanry. For the house, ${ }^{3} \mathrm{if}$ in. thick will he quite serviceable, and this is the thinnest made. The design being made to suit the shape and size of the llomr allows for great scope in this direction, such as the use of panel designs, black and white tiling effects, or plain ait shades. It malies an excellent floor covering for the entrance hall, having the advantages of variety of design, durability and silence. It should he washed in the same way as ordinary rubber covering, but need not he polished, as the surface is good and readily cleaned.

Such Hoorings also have a beautiful effect for a dining room (see page 359). Nearly 100 colours and shades are available, enabling many designs and colour schemes to be elfiectril. These iloorings are non-a hoor bent and $1 /$ - gienic. They are therefore also most suitable for $t$.. nursery or hathroom.
Rubher stair treads can be of inlaid tiling hey are generally made the cxact measureosing to come over the edges. Risers can be

Stair treads can also bs made with corrmeads down.
can be placed in the bottom of the bath is fitted with suckers on the underside which keeps it in place ; this mat enables a person to recline confortably.

Rubber door mats can be made in practiv cally any size or shape to fit into a well or doorway. The general thickness is in., fnd they are perfornted in various patterns, and can be had lettered or witli monograms inlaid in a contrasting colour. The perforated rubber door mats are very seldom worn out; they are generally bmken by misuse and made unsightly. Care should therefore be taken not to fold or double the mat when it has been removed; it should be laid tlat or rolled. It can be scrubbed in the usual way.

There are rubber mats inade for use in the kitchen sink; these usually fit on the extension piece of porcelain sinks, and lave a grooved or roughened surface to prevent the dishes from slipping whilst draining. Other mats are the protective rubber table inats, usually made in coloured inarbled designs. Being thin and non-slipping they are useful under linen embroidered mats to prevent marks from hot plates and dishes on the polished surface of the table.

Rubber Gloves. Thin rubber gloves protect the hands when doing housework. They should be one or two sizes larger than ordinary gloves, and the hands must be dry when they are put on, or rubbed with French chalk to allow the gloves to slip on easily. If these gloves get torn or punctured they can be patched in the same way as a cycle tube, care being taken that the place to be patched is clean and dry before applying the solution. The amall cycle patches with tapercd edges are the most servicenble because they are not likely to turn up at the edge. The same method of mending may be applied to goloshes.
New Uses for Rubber. One of the uses to "hich rubber is now being put is for the upholstering of articles of furniture. For this either pneumatic or sponge rubber is employed. lubbler is also much used for brushes of all kinds, while buckets and other household utensils, egg cups for example, are made from it. In the kitchen and scullery the sink can be lined with rubber and the tables covered with it. Flowers made of rubber are sold for household decoration, while articles made from it include bulb howls, napkin rings and knife handles. Handbngs for ladies are also made from ruliber.
Rubber Solution. The name is given to a substance mainly consisting of rubber dissolved in benzol or naphtha. The composition varies with different makers. It is used for cementing rubber, and particularly in connexion with the repairing of cycle or motor car tires and tubes. See Flonr; Goloshes; Hose Pipe; Hot Water Bottle; Motor Car, etc.

RUBBER PLANT. The true rubber plant, Hevea braziliensis, is the one from which the rubber of commerce is collected. It may be grown under hothouse conditions, but has little attraction for foliage purposes.
The name is sometimes applied to the semi-hardy evergreen plant ficus elastica, which is usually grown as a specimen in ornamental pots for the puposes of room decoration. The plants flourish in ordinary potting mixture on tables and in windows ree from draughts. See India-rubber Plant.
RUBBER STAMP. Used for printing initials, dates, names and addresses, etc., with the aid of an inked pad, stainps made of rubber are obtainable in many shapes and sizes, mounted on a brass plate or metal frame and provided with a wooden handle.
RUBBISH: In the Garden. Accumulated rubbish in the garden is a conmon eyesore in plots of modest dimensions. Its disposal is not a difficult task, however, if dealt witl, in a systemntic nianner, and heaps

Rubbigh. Showing bow to dispose of garden retuse by means of burning 1. Ground base for furnace. 2. Method of building body. 3. Incinerator o operation. 4. Method of shelter : $a$, iron or zinc cover

RUCHING: In Needlework. The trimming, known a ruching, consists of a strip of material, with a gathering thread run down the middle, from end to end, and sewn along the gathering to the article it is to trim. Ruchings, or ruches as they are often termed, may also he pleated or boxpleated.

The atrips of mater ial for gathered ruch. ings are nearly always cut on the cross of the grain, so that their edges can be pulled out with the fingers into llutes, to emphasi\%e the frill Strips for pleated or box

There are two methods of disposal-burning pleated ruches are cut on the straight and deep burial. Every garden of modest size might be planned with facilities for the disposal of waste. In one corner a fair-sized hole should be dug, and therein may be thrown every bit of decayable vegetable matter from household and garden: indeed this may he augmented with sweepings from Hue and chimney and scrapings from the fowlhouse, all heing inade fairly firm and spinkled with lime.

Farly in the year the whole mass should be turned out and sprinkled with lime. In such manner rubbish is converted into a natural fertilizer of much value, particularly when trenched in for deep-rooting crops.

Everything that will not easily decay, such as liardwood, tree prunings, and cabliage stalks, together with weeds like dandelion and dock, should be burned, the ash being stored in a dry place for use in spring.

A Brick Destructor. The burning of this hard rubbish is best accomplished by means of a destructor built of bricks as shown, a simple structure with free circulation of air, which will burn steadily and quickly reduce its contents to a fine ash rich in fertilizing power. The lid is necessary to the contrivance, hecause it kecps refuse in a dry state, and allows accumulation until time is convenient for burning. Autumn leaves should be collected and placed in a large heap, covered with wire netting and left in the open until decayed.

All straight sticks from tree-prunings, with the exception of soft ones, should be kept for staking. See Incinerator; Manure.

RUBBLE: For Masonry. The term rubble refers to pieces of stone of irregular size and shape, and is applicable to practically any kind of stone. Simall and, irregular pieces of brick known as brick rubble are used in the formation of concrete for the foundations of buildings. Rubble walls are constructed of irregular-shapod stones. See Crazy Paving; Path; Stone.

RUBUS. This is the botanical name of an important group of shrubs which includes the raspberry, loganberry, and hlackberry, and others of purely ornamental value. Of those with handsome flowers the beat are Rubus deliciosus, with large white single Howers, and odoratus, with purple blooms.

RUBY. The value of the ruby is determined by its colouring, which varies in different specimens from a pale rose tint to dark red The latter, known as masculine rubies, are the more valuable, some of the finest being more costly than dianonds of the same size. In hardness, the ruby equals the sapphire. Garnets and red tourmalines, which are used as a substitute for rubies, sometimes resemble these gems closely in colour, hut they are softer, and can be detected with a tile.

Ruchings may be of any width, ranging from very narrow to very wide. The length the strips should be cut depends upon the nature of the ruche. For a gathered ruche a strip measuring half as long again as it is when finished should be allowed. That is, if a atrip of gathered ruching about 20 in . long is wanted a strip of 30 in . must be allowed For pleater or boxpleated designs, strips three times the length are required.

When joining crossway strips to gain the length required for gathered ruchings, malie the joins on the straight of the grain, which means they will run slantwise ncross from edge to edge

The edges of ruchings may be hemined, bound with narrow strips of material, picotstitched, or rolled. A finish for the edges of ruchings made of taffetas is a fringe, this heing achieved by fraying out the edges with a pin Another linish is pinking
To make a gathered ruche, cut and join the atrips wanted, and neaten the edges; then fold it up into halves, quarters, and further subdivisions, if possible, and mark each fold with a

pin or chalk line. Fold the article it is to trim into an exactly similar number of sections, and mark to match. Next run a gathering down the middle of the strip, draw it up slightly, and pin it to the article so that the marks correspond, thus making certain of the fullness being diatributed evenly; then run the ruche to the article along the middle. I desired, a line of fancy stitchery can be used to secure the ruche.

To make pleated or boxpleated ruchings, cut, join, and neaten the strips; then set thein in pleats, running a tacking along top and bottom edges as they are formed, and well press them afterwards. Run a cotton through the middle, to keep the pleats permanently in position, and sew them to the pelmet, cushion cover, garment, ctc. See Bag; Pleating
RUE : The Herb. This familiar herb is of some decorative value in the garden : it grows 3 or 4 ft . high, has greenish-blue leaves and yellow Howers in summer and flourishes in ordinary soil in a sunny border. Propagation is by seeds sown in spring.

## Rugs: Oriental and Other Makes <br> How to Make Wool and Rag Rugs at Home

In connexion with this article on tloor rugs see also Canvas Carpct: Colour: Hall: Kirman Rug: Mat: Nursery: Persian Carpet. Turkey Carpet Weaving: Wool. Information abnut Travelling Ruga is given under that heading
With the increase in number not only of in pattern, and of luxuriant pile. Bokhararuga smaller rooms. but also of parquet and wood include the styles called Turcoman, Afgian and block floors, and the employment of rubber and composition paved and tiled floorings, rugs are in greater demand than ever. There are also the hygienic and labour-saving merits of ruga to be considered, which make them suit. able for nursery and bedroom use in place of the all-over carpet, which cannot be daily removed from the floor for cleaning purposes
Rugs may be roughly divided into six classes. Samarkand The patterns are hased upon roses turned into octagons, with hooked diamonds and other geometrical motives woven all over. Similar borders are in soft, brownish-reds with blue and greens. The wide webbing at the sides should on no account be sacrificed. Modern pieces are exported coloured with aniline dyes and of inferior designs.

Chinese rugs are beautiful, and in many Oriental rugs: those made at Axminster, Persian rugs there is a prevalence of Chinese

Rug. Parsian prayer rug, crimson and green velvet. embroidered in silver thread. The fleld has a niche with scrolling stems and inscriptions. From the Mashbad Shrine
Wilton and other western carpet manufac- designs and motives. The two best known are turing centres; skin rugs; hand-woven rugs the cloud band and the dragon The former is in geometrical and other modern designs; rugs symbolical of heaven. Symbolism plays a worked with wool on canvas; rag rugs.
Oriental Rugs. Although European weavers hegan to employ their looms for rug and carpet making in the 15 th century, copying the knotted examples which were imported from Turkey, until the age of machinery Oriental rugs far excecded the supply of those made in the West.

Like other textile fabrics, Oriental ruga have interlacing warp and weft threads; in
to these fundamental threads they are composed of countless short pieces of coloured yarns, the cut ends of which form the pile. Each knot or tuft is tied by hand. Many or few dyes may be employed, but in most Oriental rugs an immensc number of shades are selected to make the design, thus giving the weaver great scope for original work. Knotting may be fine, which adds to labour but enhances beauty of forms employed; or it may be coarse, in which case bold patterns are generally worked.

With regard to Persian ruga, it should he noted that many rugs not strictly made in Persia are described under that title. IndoPersian rugs are well woven and of fine colour, but the detail of the designs is not usually so good as in the Persian carpets which influenced them. Some of the Caucasian rugs arenotably rich in colour, intereating

Garden carpets and rugs havc designs of gardens with walks, trees and flower-herls Such patterns were made as far back as the lith century in Persin.

Other rugs come from 'lurkey The demand for them is a large and growing one, and the industry that meets it has its headquarters at Istanbul and Smyrna. Imitation 'Turkish rugs are produced in British and conti nental factorics, but in thesc lighter shades predominate, and, though they are excellent reproductions of what are known as fancy Turkish rugs, they are not truly Oriental in character, as they lack the typical enstern colouring. They are designed chiefly for stair case and corridor use.

The best eastern ruga fetch high prices, and their colour and texture last through many lifetimes. Good modern examples can, however be bought at morlerate prices, which are woven by hand, the colouring of the better kinds being heautiful owing to the dyeing processes still in use for this class of work.

Among the most interesting Oriental rugs are those known as prayer ruga, made pri marily for the devotions of Mahomedans. 'They usually comprise $a$ niche, the point of which is directed towards Mecen, and beneath it is supposed to be placed a morsel of dried earth from Mecca, upon which the worshipper rests the forehead when he is at prayer Ritual objects may be portrayed near the niche, and from the point there sometimes hangs a lamp or a floral pendant. The ahape of the niche is a guide to the make of the rug

There are at least thirty ty pes of niches, those from Persia heing usually curved, and all others woven in straight lines. Caucasian and 'Turcoman лгe always, and Persian uaually, recog. nizable by having the field well filled with ornamental motives; while Turkish have plain fields, as the more conservative Mahomedans obey the Koran, which forbids them to cony figures. These rugs seldom exceed 6 ft . by 4 it
The Persian prayer rug illustrated has two horders filled with 18th-century conventional Horal patterns and inscriptions of the profes sion of the Islamic creed. The field has the curved and pointed niche with scrolling atems, flower motives and inscriptions. The rug is lined with silk and gold tissue dating from the same period.

English Rugs. Another class of rugy is manufactured in England by the Axminster Wilton and other carpet factories at home. These differ little except in size from carpet aquares, and are frequently made to match these, being useful for filling odd pieces of floor space in a carpeted room. Mohair rugs in black and self colours, though uninteresting, are very durable. Tufted wool

Rug with effective pine cone design worked in shades of tarra-cotta, biscuit, pale green, gold, tan, and deep blue
rugs are excellent for bedroom or nursery, and nost of them are reversible. Fibre rugs woven in good colours are suitable for bungalow and informal rooms Skin rugs of leopard, tiger, wolf, raccoon. bear and goat are handsome, but when laid on parquet floors have the great disadvantage of slipping easily. Skin hearth rugs are hest removed in summer weather, as they tend to give a room a hot appearance

Beautiful ruge are hand-woven in straight geometrical designs. The colourings are harmoniously graded and often in browns. natural wool colour, and a variety of beige shades. The interest is gained by subtle shading, and the patterns are usually of the simplest kind, such as cubes and broken stripes, and just sufficient to introduce pleasing light and shadow effects. Colours may appear to contrast violently, but this contrast is obtained in the same way as in old tapestryby the skilful use of several gradations of cach colour so that it never appears dead or crude

Handworked Wool Rugs. There are various methods of making wool rugs, but the general one is to hook the wool through the canvas or hessian to give a series of little tufta so closely worked together that they form a pile like that of a carpet. The canvas takes the place of the warp and weft threads of the Oriental rug. There is apecial canvas to be ohtained for the foundation marked in squares of 8 ridges. If the wool is of fine quality like the 6 ply Turkey rug wool, it is worked into every ridge, hut if of the coarser 2 ply cahle wool it is only knotted into every alternate one.

By means of a gauge, the wool is cut into little equal pieces, each ahout 2 in . long (Fig. 1), ready to be hooked into the canvas. To make the actual knot, a coarse crochet hook wi!l do. though there are several patent instruments on the market. One, Fig. 2, is like an ordinary crochet hook with a movable latch, which preventa the hook from catching when drawn back through the canvas. Another, Fig. 4, is like a pair of pliers which by a simple device knots the wool on the canvas in one opera. tion. Both make the same slip knot.

Chart designs are available from the various wool shops marked in squares to correspond exactly with the squares on the canvas This

makes the working out of an intricate de end of the rug is reached that should be sign very simple indeed. But simpler still for turned in in the same way. (See Fig. 10.) the plainer designs is the canvas which has been The selvedges at the side of the canvas are stencilled with a pattern. Line the rug when strong enough without turnings. The easiest finished with black hessian which will make it manner to work is to place the canvas on the softer to the feet and more durable in wear table and knot in rows from left to right, the When beginning a rug, turn in the end for finished part being nearest the worker.
If in and work through the two thicknesses. Patterns may be inspired by Oriental This will give a firm colge, and when the other motives auch na the pine cone design illus.

Rug : webuuu ui making. Yig. 1. The wool is cut in short uniform lengtos by means of a grooved gauge. Fig. 2. Regulation rug-making book resembling an ordinary crochet hook with movable latch. Fig. 3. Another method is by use of a bollow metal tube into which the wool is threaded. Fig. 4 . Knot-making tool in use. Fig. 5. Daing regulation hook: to knot the wool on the canvas it is frst doubled and drawn through under a ridge. Fig. 6. The book is pushed through the loop so that the wool lies behind the latch, and the two loose ends are booked. Fig. 7. These ends are pulled through the loop, the latter sliding over the latch. Fir. 8. The knot is then pulled tight and a similar tuft made in the nert ridge, and so on. Fig. 9. A row
an inch of canvas ghould be turned up on to the face of the work
trated, or they may be simply geometrical and worked in dark brown, havana brown, and three shades of beige, as in the other example shown Designs should always be conventional even where figures are introduced into nurvery rugs Squares, circles, triangles, and simple designs of llowers and leaves are all suitable for rug making, but the art of the designer lies in combining them successfully.

The particular kind of wool used is a matter for individual taste. What is known as cnble wool is a curly 2-ply yarn. It is more lustrous than Turkey rug wool, and produces a rug of a softer and longer pile. The pile of Turkey wool however, is wonderfully firm. It measures about $\frac{1}{2}$. in depth, and resembles more closely the pile scen in Eastern rugs.
A most ingenious way of making a pilc rug on hessian is by the Kwikumak method. The instrument, Fig 3 , which is fitted into a wooden handle, is a simple hollow metal tute pointed at the end and having a hole about I in. from the end. Through this hole the wool is threaded. As the instrument is pushed through and through the hessian following a stencilled pattern, it leaves loop on the other side of the material. These loops, when afterwards they are cut evenly with the scissors, form a close pile
Rag Rugs. There are two methods of making ray rugs In one the rag is pulled through the canvas with a large crochet hook while in the other the raga may be braided or twisted and sewn together. All kinds of rags are suitable for this purpose. For a hooked rug a piece of strong open-meshed hessian or sacking is required Having measured off the required size, hem or crochet it all round to give a firm edge. Stencil or draw in chalk a pattern upon it; an oldfashioned posy or wreath of Howers worked in bright colours in the centre suits these old world rugs. Various grotesque nnimals and birds were also worked in the brighter rags, leaving the more nondescript coloured ones for the bacliground.
For a hooked rug, the rags need to be about $t$ in in width more or less, according to the thickness of the various materials It is not essential to rew the strips together, though the longer they are the quicker they can be hooked through Use a coarse crochet hook for the work: the canvas is often stretched in a frame, but it is easy to work without. Place the pile of strips under the canvas either in the lap or under the table. Hook the strip of rag through the canvas to form a loop about $\frac{1}{2} \mathrm{in}$. in length. Then make another loop close by, and continue until the canvas is covered The loops are then clipped to give an even, mossy surface. A hooked rug should be lined with hessian to give it greater strength. To braid a rug like that shown in Fig. 11, it is necessary to cut the rage about 3 in witle If they arc made

Rug. Fig. 12. The strands are plaited ologely and evenly to make braid for the rug shown below hin be sewn together and pinned on to something firm. As soon as 1 ft . or more of the plaiting is finished, the sewing together is begun This is done with strong, waxed thread When making a circular rug, the braid is then wound round and round flatly, edge to edge, and the needle passed through and through in close, invisible stitches. A little practice is required to make the braid lie flat If too tightly wound it will buckle, but it must not be too loosely done, or the work will look rough
To make an oval rug, begin with a long. shaped centre, and wind round it. A dark centre usually looks well with outer rings of light and dark alter nately. A skilful braider can work in the colours while she is plaiting to a definite design. As the end of each strip of rag is reached, sew on another one. It is just as well if the strips are uneven in length, as then the joins will not come all in one place ; but this, of course, must happen when introducing a fresh colour, and then the join must be neat. Rag strips, in. wide, can be crocheted, using a large hook. Before beginning, join the strips together and wind into a ball. Begin by making 5 chain, join into a circle and then crochet round, increasing in order to make work lie flat.
narrower than this it is 'ather difficult to turn in the edges as ncatly as is necessary for tidy work. The edge should be turned in a bout $\frac{1}{2}$ in., and the strip folded over in half lengthways. so that the raw, fray ahle edges are insidc. This may be done while braiding, but if the material is stiff and wiry it is better to press it into its proper folds. Strips may be joined together to give lengths of about $1 \frac{1}{2}$ yards each, and are best folded and pressed beforehand, and wound on to pieces of cardboard to keep them in good shape.
Plait the rtrips closcly and evenly, just as hair is plaited, with 3 strands, as illustrated in Fig. 12. The ends

RULE : For Measuring. Of the many varieties of rule in ordinary use some are of wood and others are made of ateel and other materials Those made of wood range in sizc from the 6 in rule supplicd with small sets of drawing instruments to the 6 ft . lath used by the glazier. For amateur use the most convenient is the 4 -fold 2 ft . rule. This is marked on both sides in opposite directions, and although usually divicled into Athe and ${ }^{2}$ teths, it can be obtained in ${ }^{3}$ othe and $\frac{1}{1}$ the

In making accurate measuroments with a wooden rule, the edge should be used so that the marks can be transferred direct, and when several measurements are required on the surface of a board, they should be added together. For example, if distances of 2 in., then $f$ in. then 1 in and 6 in. are required, the method is to mark off 2 in lirat from the edge next 2 多 in., then 3 多 in., and finally $4!$ in

The 4 -fold rule can be employed na a square by folding it in the centio and the two halves together at the knuckle joint between 5 in. and 7 in., as at $A$, below. In dividing wide boarils into equal parts, the quickest method is to lay the rule diagonally across the wood so that opposite corners are touching. For example, supposing the board to be 103 in ., and it is required to divide it into 4 equal parts, the pencilshould be placed at 3 in., 6 in .

Rule. A, method of using folded us. of as suare divide a board into equal parts
a nd 9 in., and lines drawn through these points parallel with one edue, as at B , above. The rule is again useful in the latter operation, as it can be held between the fingers of the left hand, the pencil placed on the point, the brass tip of the ruler placed against it, and, with the fingera of the left hand acting as a guide, both ruler and pencil can be drawn down the wood. This is called lining with rule and pencil.

The engineer's steel rule is obtainable with. out a joint and engine divided into 12 in ., with the usual sub-divisions; the rule is also 2 -fold, and a 1 ft . 4 -fold The steel rule is essential for accurate metal working, the first-mentioned size being the most suitable.

Steel rules should be rubbed oc. casionally with an oily rag, as perspiration from the hands and dampness will soon make then rusty. See Measurement; Plumb Rule.

RULE JOINT. Used for tables and drop leaves, the rule joint is a method of hingeing two pieces of wood together so that a neat, closed joint is shown when the leaf is down. It is better than the square joint, which shows a space between the two hinged pieces. The joint is shown in Fig. I with the leaf up and in Fig. 2 with it down: A is the fized top, $B$ the leaf, $C$ the centre pin of hinge, and $D$ the commencing point of the curve of the joint. It will be seen
in Fig. 2 that a semicircle is formed when the leaf is down, the centre being at C , and that this neces. sitates the hinge being let into the wood. The hinge (Fig. 3) is specially made for rule joints, and is known as the table hinge: it is similar to a back flap, but as it is attached with the knuckle in the wood, the screw holes are countersunk on the opposite side. Hinges are made in sizes from 1 in . to $1 \frac{1}{1} \mathrm{in}$, 11 in . and 2 in.

The table hinge should not be confused with the rule joint hinge shown in Fig 4, which is used for another purpose. The method of marking out is shown in Fig. 5 ; the two pieces of wood should be the same thickness, and the gauge line at $C$ should be the depth of the hinge. The distance of the centre $\mathbf{C}$ from the end of the wood should be about $\frac{7}{7}$ of the thick. ness of the wood. Special planes are made to form the joints, but the latter can be easily out with ordinary rounds and hollows.
The first stage in working the round is shown in Fig. 6, a rebate being cleanly cut to the level of D. The second stage, in Fig. 7, consists of rounding the corner to a true quadrant, and then forming the hollow in the opposite piece so that the edge at the top equals that at $D$ and the curve is the exact opposite to the round. The two parts are placed together and the slots for the hinges marked out and cut. The short part of the hinge is on the side with the round and the pin of the knuckle is exactly under the top at $D$. The work can be polished in the ordinary way before the hinges are attached, but they should have been fitted previously. The rule joint hinge shown in Fig. 4 can be employed for narrow flaps, the edges of wood being shaped as above, but it is more suitable for hingeing flaps which are to fold over flat, and is used in some oard tables. See Hinge ; Joint; Rebate.

RULE OF TEE ROAD. By this phrase is understood the rules that should be observed by persons who drive vehicles of any kind on the roads. In Great Britain the main rule is to keep to the left. Another important rule is when overtaking another vehicle to pass it on the right. In crossing, the driver should bear to the lcft and pass behind a vehicle coming from the left. Drivers who infringe these rules are liable to legal penalties. See Driving; Motoring : Road.

RULER. The two words rule and ruler are often confused; the former relates to measuring and the latter to the drawing of lines. Although the rule can be used for the latter purpose, the jointed rules are not convenient. The ordinary boxwood 12 in . rule serves the double purpose; but the round ruler, generally made of ebony and about 1 in . in diameter, is useful for drawing parallel lines as well. See Rule.

RUM: The Liquor. Rum is a spirit distilled from fermented juice of the sugarcane or from molasses. It is coloured with caramel and improves with keeping. Sometimes pineapple and guavas are added in the making. Rum and milk is said to be one of the most powerful restoratives, and an oldfashioned remedy for a cold is a steaming

RUNNING: In Needlework. This is the simplest stitch, and the first to be taught in needlework. The needle is passed in and out of the material at regular intervals, taking up 3 or 4 threads at a time in a horizontal line. If the fabric is sufficiently soft and thin, several stitches are taken on the needle at once before the thread is drawn out. This stitch is used for plain seams and for making gathers. See Gathering; Seam.
RUPTURE: Its Treatment. In its widest application rupture or hernia is the abnormal protrusion of part or the whole of an organ of the body through the wall of the cavity that contains it. It occurs chiefly, however, in relation to the contents of the abdomen, and in the majority of cases the part which thus comes through is a portion of the intestinc. The cause is generally either weakened areas in the abdominal wall or increased pressure of the abdoninal contents due to some injury or sudden strain, as in lifting heavy weights, but thero are also other causes, as, for example, severe chronic cough in old people.
There are several kinds of abdominal rupture, the most common being inguinal hernia in the groin: femoral hernia is also in the groin, and umbilical hernia at the navel. A ventral hernia is a protrusion through a weak spot such as may be present in the scar of a wound, as, for instance, after the operation for appendicitis. A strangulated hernia is one in which the circulation of the blood is obstructed and is always dangerous.

A rupture appears as a rounded or pear. shaped swelling, the lower end usually being the broader. It increases in size when the patient stands, coughs, or makes a muscular effort. If it is a reducible hernia, it slips back into the abdomen when the patient lies down and presses on the swelling with his hand. (On his standing up it again comes out.
'The treatment of inguinal hernia consists of the wearing of a truss, or an operation for what is known as the radical cure. When a truss is used, great care should be taken never to let the inteatinc come down cven once, for whatever closing of the part has been effected will be at once undone. In adults a truss should fit perfectly, otherwise it may do harm by causing inflammation and favouring strangulation.

Femoral hernia is more common in women than in inen. A rounded swelling appears in

Rommer. Largo-sised rummer, the ongraved
decorative decign inoluding agrioaltural implements Courteay of Cech Davis
front of the thigh towards its inner side just below the junction with the abdomen. As in other forms, the treatment is either palliative by means of a truss or curative by operation.

There are three varieties of umbilical or navel hernia : the congenital, which is very rare : that in infants and children, which is common : and that which occurs in adults, most frequently in women who have had several children If properly treated this form of rupture in infants can be cured easily. The edges of the opening should be drawn together and held so by a strip of plaster. or a penny or a disk of lead may be wrapped in lint, placed over the navel, and held in place by strips of plaster In adults the palliative treatment consists in wearing a truss, or sometimes an abdominal belt which requires the addition of a truss pad. If obstruction occure, the lump becoming larger and firmer, the doctor should be summoned immediately.

In strangulated hernia severe pain extends through the abdomen, and there is vomiting, constipation and collapse. The doctor should be instantly summoned when a patient who has a bernia suddenly finds that it will not go back. When he has pain or discomfort in the lump: when he suffers from obstinate constipation, or from nausea or sickness. The
alarnı may prove to be groundless, but it is important that no risk should be run.
To prevent hernia, infants should be kept, if possible, from excessive crying and constipation should be prevented. Adults should avoid wearing belts, and excessive muscular straining after operations on the abdomen. Women should avoid tight lacing, and wear an abdominal bandage after childbirth.

RUSCUS. A group of low-growing, hardy evergreen shrubs of which the chief kind is the butcher's broom (Ruscus aculeatus) : this grows $2 \frac{1}{\mathrm{ft}}$. high, has apiny, so-called leaves (which are really modificd branches), and small greenish llowers.

Male and female llowers are on scparate plants and both kinds must be planted to ensure a crop of the red fruita in autumn. The butcher's broom will thrive in shady places.

RUSH: In the Garden. A few of the rushes are attractive waterside plants, but most of them are of little value in gardens. One of the most striking is the porcupinc rush (Juncus lacustris zebrinus): the leaves are marked with bands of green and white. In Juncus spiralis the leaves are spiral.

Rush Lily. Another name for the satin

## RUSH WORK: A USEFUL HANDICRAFT

With Directions for Making and Repairing Chairs, Stools and Baskets
For information on related sub, cets the reader is referred to the entries Basket Making; Cane; Osier: Raffia; Wicker Work, etc.

When dried the rush is used as a chair seat ing is in Figs. 1 and 2, and for making baskets and mats, and more rarely as a floor covering It provides a strong, soft, comfortable and inexpensive seat, and has the advantage of being easily worked.

Two varieties arc commonly used, ordinary rush, known as green, but more of a brownish green in colour, and salt rush, known as golden rush, and of a yellow colour; the latter is considered to be the better quality for general work. The rushes should be gathered in the late summer and carefully dried; they require no other preparation, as the drying leaves them in the form of libre. They are obtainable in large bundles in lengths up to 6 ft ., and after dipping them in water and leaving them for a fow hours they are ready for use.

Reseating a Chair. Although the framing of chairs is of special design when the seating is of rush, it is possible to re-seat almost any kind of frame provided that the corners, which will not be covered by the weaving, are built up to the same level as the rest of the seat. If a chair is to be re-seated with rush, all the old material must be removed and the framework thoroughly cleaned; but it will bc helpful to the beginner if he or she notes carefully the method of weaving when removing the old rush, to see where the rushes are twisted and where they are used singly, and also where and how extra lengthe are added.

The rails of the rush seat chair frame are mortised in about $\}$ in helow the top of the legs, and a corresponding amount is left on the outaides, but the inner sides of the rails are usually flush with the inner faces of the legs. Begin with one long, stout fibre and secure the thick end to the inside of the framework, as in A, Fig. 3, using a stout tack or a clout nail Bring it over to the front rail, quite close to the raised corner, and commence to twist from left to right. Carry the twisted portion down on

Rush Work. Fig. 1. Seat of rusi-seated chair. showing method of weaving the twisted rush in
sections. Fig. 2. Underside of seat with rush left

Rush Work. Fig. 3. How weaving is begun. Fig. 4. Reel knot lor joining lengths of rusb. Fig. 5. Professional knot. Fig. 6. Two lengtis twisted to form a strand. Figs. 7. and 8. Stages in weaving. Fik. 8. Small rushseated stool. Fir. 10. Two-colour twist
hand, using the thumb turned down and the one next to the latter and fingers to keep the on its right. The same movements of the plait even The right thumb and finger ahould be used in every hand is used to do the stroke for the building up of the twist. As plaiting, each length the thin portion of the rushes is reached, of rush being brought add a new length.
from the back over Rush and Cane Combined. The melon. towards the centre shaped hasket in Fig 11 is a very effective New lengthare placed way of using rush, the framework being made on the inside of a right- of split cane. The first stage is to make an hand length, and the oval band with a length of stout split cane, the 2 lengths plaited to- joint being made by making 2 tapering cuts gether, leaving the end so that the ends of the cane can he joined up of the old one minder- evenly and hound together. A useful size is neath when finished 12 in . by 9 in . A second hand is now made in with.
The plaited braid at Fig. 14 is particularly effective ; it is formed by first plaiting 3 rushes as at Fig. 3 for 6 in ., then one of the lengths is held firmly in the left hand while the right hand is used to push up the plait to reducc its length to about 2 in. Note the length which was held tight, so that when another 6 in of plait is done, the same are length an be held altern while the other two are pushed up close to the first.

The method is to dissolve $\frac{1}{} \mathrm{oz}$. green aniline dye in 1 pint hot water, then add $\ddagger$ gill strong vinegar Apply the stain with a brush, giving the work 2 or 3 coats, according to the depth of the colour required. When the stain is quite dry, make a size by dissolving $\frac{1}{2}$ oz. glue in 1 pint hot water and apply this while still hot to the whole of the stained surface.
Rush scats that have a few broken strands need not be re-seated if the rest of the work is in good condition. The method of repairing is to pull the broken strands through to the underneath, and to join on a new length to the corresponding straight length. The new piece should be twisted and pulled through to the top, carried over the frame, and then tied with a loop after passing it under a few strands. There is a limit to which repairs of this kind can be carried, but if the material is not very old and has not perished the work it can be lone with success.
It is usually the front edges of the seating which wear away quickest, and if many of the strands have given way it will be more satisfactory to re-seat the whole.
Rush for Baskets. Rush is used in making haskets, bags, and in other small ways. It is often combined with cane to produce such useful articles as the basket illustrated in Fig. 11. It is worked in its natural form and also twisted and plaited. Examples of plaiting are shown in Figs 12-16.

The simple twist at Fig. 12 is done with two rushes as follows: Tie the thick ends together and secure them to a hook in the wall or over a convenient nail. Hold one rush in each hand and twist outward, then take the right-hand rush over the left one, at the same time hringing the latter under the right one. The rushes are transferred to the opposite hands and the movements repented, inserting a new nush when required and keeping the twist of a uniform thickness.
A double twist is accomplished by first making 2 simple twists as above and tying them together and treating them as single rushes, but the twisting should be in the opposite direction, that is, from left to right ; this prevents the twist curling.
The 3-way plait at Fig. 13 is commenced with 3 rushes tied together and held in the left

The 5 -way plait at Fig. 15 is made with 5 rushes by interweaving each rush diagonally under one and over one, the outside rushes being so arranged that they start from the back and come forward over the next rush and towarda the centre. Wider plaits can be made in the same way by using 7,9 or 11 rushes.

The rattle twist at Fig. 16 is made with 5 rushes of even size tied together and held vertically by the tied portion in the left hand Take one of the rushes and bend it behind the two next to it on the right; do the same with the others in order, until they are laid down. Continue by laying each rush in its turn across the centre and over the last one

Rusb Work. Fig. 11. Combined with cane, rushes can be woven into a basket with twisted bandle. Fig. 12. Simple twist. Fig. 13. Three-way plait. Fig. 14. Plaited braid. Fig. 15. Five-way plait. Fig. 16. Rattle twist Fig. 11. courtesy of Druad Handicrafts
centre of the basket the work being kept as close as possible, because the damp material used in the first place will shrink when it dries

The handle can be given a decorative finish by twisting the rush spirally round it and carrying a wide length of coloured raffia with it, so that the raffia is covered in one turn and exposed in the next. and so on throughout the length. A stronger basket can be made by using tapered ash splints.

Plaited rush forms a mostconvenient and cheap method of filling up the sides of many kinds of basket woven either in cane or osier and suitahle for wastepaper or work baskets.

RUSK : The Biscuit. Rusks are made in small round shapes As soon as they are baked they are split open and reheated until they are so crisp and dry that they will keep fresh for some time when packed in airtight tins lined with grease-proof paper.

To make, sift I lb fine flour, with a pinch of ralt, into $n$ basin, then dissolve 2 oz butter in $f$ gill milk Cream $\frac{1}{2}$ oz ycast with 1 teaspoonful castor sugar and stir into it the warm milk and butter. Now beat in 3 cggs Pour these ingredients into the centro of the Hour and work them into a dough. Cover the bowl over and let it rise till very light. When risen, knead it till smooth, then make the dough into balls about the size of a large egg, only fatter Lay these in rows on a floured baking sheet and let them prove. Bake in a ljot oven for about $15 \mathrm{~m} / \mathrm{n}$. Talie up the rusks on to a sieve, split each in half and return to the tin with the broken side uppermost Crisp them in the oven, then cool and store them.

Rusk Pudding. A very good steamed pudding can be made witl rusks. Sonk 4 rusks in 1 pint milk for $\frac{1}{2}$ hour, then beat these up fine, add 0 oz cleaned and picked currants, 2 oz. choppred candied peel, the rind of a lemon (grated), $\frac{1}{1}$ tenspoonful nutmeg. and a pinch of salt. Cream 2 oz. butter with 3 oz castor sugar, add by degrees 2 wellbeaten eggs, and atir this to the rusk mixture. Steam in a buttered basin for about if hours. Serve it with sweet or brandy sauce.

RUSSET: The Apple. Apples of the russet family are distinguished by $n$ skin of rough texture and russet-brown colour. Generally these are of brisk flavour, and include the wetl-known Ard Cairn, Boston, Brownlee's, Egremont, Golden, Pincapple, and Royal russets.

Russian Cake, made in four separately prepared blocks and coated with almond fcing

RUSSIAN CAKE. Whisk 4 egge with 9 oz castor sugar for about 15 min ., or until the mixture is freo from dark otreaks, then fold into it $\frac{1}{2} \mathrm{lb}$ flour previously sieved with 1 teaspoonful baking-powder. At the same time add $\ddagger \mathrm{lb}$. melted butter and, if necessary, a small quantity of milk.
Mix the whole lightly, then turn half of it into a small greased baking-tin lined with greased paper that reaches just above the sides. Colour the remainder of the mixture with a fow drops of cochineal, put it into another prepared tin of the same size, and bake both in a hot oven for ahout 10 min . Then turn the cake carcfully on to a sieve to cool and take off the greased paper. When cold, cut ench arke into long strips.

Warm a little plum jam, thinning it down, if necessary, with a little water, rub it through a sieve, and then take two strips each of the white and pink cake. Brush one side of each with the jam and atick them together, arrang. ing the colours alternately. Wrap the block tightly in grease-proof paper, lay it on one side, and then proceed to make another block in the same way.

Prepare some almond paste, rolling it out to a long, thin sheet. Brush the outsides of tho blocks with warm jam, then cover them with the icing, smoothing the surface with a knife whioh has been dipped in hot water. Sce Almond Paste.

RUSSIAN POOL. This billiard game is soap, as it cannot resist the alkalis therein played on an ordinary billiard table by two Gas ands electric light fittings, grates and or more players. Five balls are necessary, radiatorf, are among the great number of white, yellow, groen, blue, and black The artioles t that can be protected from rust white is the ball struck by the cue. A gaine by a galvanizing process. consists of 200 points, or any other number that may bo agreed upon

To begin the game, the black ball is placed on the spot, the blue on the centre spot, the green on the left, and the yellow on the right corner of the $D$. The striker then plays the white ball from within the $D$, and his opening stroke must directly strike the black hall. He can then play at any of the others The play is very similar to that in ordinary billiards. Scores are sccured by making cannons, by sending the white ball into a pocket off one of the others-a losing hazard, as it is called-and by sending a coloured ball into a pucket, a winning hazard. In Russian pool, however, the black ball can only be used for the two top puckets; the blue for the two middle puckets, and yellow and greer, for the bottoll two pockets. For a simple cannon 2 points are scored If the black is used for a hazard 9 points are scored. The blue scores 7 , the green 5 , and the yellow 3 .

The rules of the game are drawn up by the Billiards Association and Control Coisncil. See Billiards; Pool; Snooker Pool

RUST : How to Avoid. In the home all fittings or articles that are made of steel or iron arc liable to rust. This a speara in the form of yellow spots, and is due to damp, exposure to the atmosphere, and sther causcs which set up chemioal action in che metal.
There are a nuinber of methods of protecting domestic utensils from rust Stainless steel and rustless iron have been perfected. The former is used not only for table knives, but for fireirons, stair-rods, and other articles of the kind. Rustless iron is employed for making garden tools, fire grates, kitchen utensils, name plates, and blind littings.

Galvanizing is a protection against rust in certain cases. It is suitable for bolts, chains, and other door and window fittings, as well as for bedstend and other springs, but not for anything that comes into contact with

Clean ilng Agents. There are various compositiol 18 for removing rust, but probably the most genorally useful cleansing agent is paraffing. Where the rust has been allowed to cat, into the metal some special hind of lubrifant inay be needed. For example, if the fireiryons have got badly rusted, a mixture of $t_{\text {wo }}$ parts of rottenstone and one part of sulo,hur is generally effective.
A useful method for cleaning up any iron $k$ fitchen utensil that has developed rust in the i/nterior is to put potato peelings in it with water and a lump of soda, and boil it up. For a tin kettle or pan that has rusted, a goud plan is to boil up borax and water in it and afterwards scour it thoroughly.

Articles that are not in regular usn or that have been put away for a time, during the holidays, for instance, should be safeguarded against rust. Many housewives are in the habit of using vaseline for this purpose, ot hers apply lard. An effective preservativo may be made with lard and camphor, in the proportion of $\frac{\downarrow}{2}$ oz. of the latter to 1 lb . of the former ; a little blacklead may be added as colouring. Grates, fireirons, etc., should be rubbed with this coniposition, loft for 24 hours, and then dried with a cloth. They will be rustproof for some time afterwards.
RUST FUNGI. Roscs, carnations, chrysanthemums, and other garden plants are liable to be attacked by rust, a fungoid diseaso appenring in the form of brownish or deep orangc patches. It is very common among wild roses, and its spores are carried to cultivated kinds by wind, insects, and birds.

Leaves and stems of roses are both liablo to infection, and infected leavea must be carefully collected and burnt, whilst other parts should be eprayed with a solution of potassium sulphide, 1 oz . to a gallon of water. Other plants may he treated in the same manner. See Rose.

## Rustic Work in Garden Furniture

The Making of Seats and Other Requisites for Outdoor Use
For thls form of crafismanshlp, the reader should consult, in oddtiton to the contribution below, the
entries on Archi : Pergola:
Under the heading of rustio work is grouped all that class of work, such as the construction of garden seate, small summer bouses, arches, and the like, which is built up by the most simple methods from unhewn timber. The material can be obtained at low cost in country districts, and is variously known as cordwood and poles. The best material is oak, but any of the hardwoods, such as chestnut or hornbeam, answer vcry well.

Opinions differ as to stripping off the bark where flowering plante are to be trained over the structure, there is far less risk of harbouring insects if the bark is peeled off The timber may bc varnished or treated with wood preservatives, but many prople prefer toretain the natural colour. Rustic work in cludes decoration with eleft timber, which offers considerable scope to the amateur wood. worker.

So far us jointe are conccried,

Rustic Work Fig. 1. Armchair, with details of the principal joints employed in its construction
these are almost always made with stout nails. either of the French or wire pattern, or of the wrought iron cut class. To ensure firm contact between the joints, both of the meeting surfaces should be slightly axed, to form a more or less flat surface where the parts fit together. as in Fig. 4. It is impossible to get any set design for this class of work, as the material. heing in its natural state, will be of quite dilferent shapes.

The timber used may be either the smaller branches of such trees as oak, the roots of fallen trees, or if straighter wood is required, having at the same time the natural appearance, the branches may bo trimined off the tops of such trees as larch, so as to leave the branch knots sticking out a few inches in a very rough state.
Rustic Armchair. Fig. I showsa rustic armehair that is simplo to make.

more pieces, us illus trated in Fig. 2. The exact construction will be governexl by the material at hand. In any case ineans should be provided to support the hack, so that it will be firm and rigid. The apace between the top rail and the rear seat rail should be filled in with ocld pieces of rustic material, arranging them so as to form rough dinmond-shaped openings, and nailing

Fir sapling or oak with the bark removed may be used. The front and book legs may he $2 \frac{1}{2}$ in or 3 in in dinmeter: the sent rails, arms, and top back rail about 2 in.; other rails If in. : and uprights on sides and back from ? in to If in. The general sizes for the chair are as follows Width over logs, 2 ft .3 in . depth over legs, 1 ft .10 in . height to seat, 1 ft 4 in . or Ift 5 in .; height to arm, $\geq \mathrm{ft} .4 \mathrm{in}$. height to top back rail, 2 ft .10 in . ; total height to top of back, 3 ft .2 in.

The principal joints are effected by means of dowels, preferably of oak. If we take the lixing of the seat rails to the legs as an example, the ends of the rails are slightly hollowed to fit them firmly to the top and seat rajl respecthe leg, as A, Fig. 1 The dowel is then prepared tively. The llat seat itself is of strong batiens and glued or painted in as indicated by the fixad to side rails on the legs at either end dotted lines. In the same way the top ends of of the seat.
the legs are bollowed to fit the arms and back rail respectively (see B) The arm is similarly fixed to the back leg.

The narrower rails and the uprights are fixed as at $C$. The end of the entering part is pared to a blunt point, and then driven tightly home into a hole bored to receive it. Fixing otherwise is clone with nails, these as a rule being driven in slantwise to provide a wedge. The seat is made from ten to twelve lengths of matcrial 2 in . to 3 in . wide, semicircular (or rather less) in scction. These are fised by nailing fillets to the inner faces of the seat rails. Across these fillets the seat laths, after being cut and trimmed to fit, are laid and nailed. Care should be taken to drive all nails well home. The back has a slight rake, so as to make the lean more comfortable.

Garden Seat. A strong rustic garden seat, such as that illustrated in Fig. 2, may be constructed in the following way. One end is lirst made up from three pieces of the wood, with the piece for the back, about 9 to 12 in . longer than the piece intended for the front, which should be about 2 ft . long These two pieces are joined together by the third or arm rest piece, using stout nails, and two cross members fixed in the shape of the letter $X$ between them as $n$ supprort. The other end is constructed in the same manner.

The two ends are joined together by longer pieccs, about 4 ft . in length, one to the front legs and onc to the back. These should be straight poles, or ordinary prepared wood of sufficient strength, as they represent the framework of the seat. Other lengths of rustic material are arranged as cross-braces hetween rails and front and rear legs, so as to hold them firmly together. The next step is to prepare the back, the top rail of which may be formed of a single piece of wood, or of two or

Fig. 3 shows how a seat can be built around the stem of a tree, so as to make a very pleasant garden sent for the summer time. The seat is supported by three legs, but where it surrounds the tree enlirely, more support will be necessary. The legs are cut to the required
length, set in position, and the arm-rest pieces fixed between the back uprights and the tops of the legs. The whole is rigidly braced with cross-pieces between the supporting legs, and the rails and supports for the seat The seat itself may be made in a similar manner to that described above

Joints in Rustic Work. In constructional work (e.g. the building of a summier house or the erection of a trellis) the important point is to see that the structure is rigid and stable. This is nccomplished by diagonal bracingthat is. arranging the timbers more or less in the form of the letter X The joints are mostly simple butt jointe, and are not inherently rigid. To remedy this defect the most practical plan is to cross-brace the uprights and horizontal members. The leading methods are described below, and other details will be found in the articles on Arch: Summer House : and Trellis.

Fig. 4 shows the method of axing the joints, that is, roughly flattening one side of each of the two pieces to the jointed, in order that they may fit together more conveniently for nailing.

Fig. 5 shows a good method of making a strong joint for; say, the seat rail to the legs of a ohair. It consista of sawing and ohiselling out a small piece of the leg in the manner shown, in the requisite position on the leg, and of such width that the rail will fit exactly into it. The joint is secured by ineans of a nail, or nails, driven through the leg into the top of the rail. The end of the rail should be sawn off as flat as possible.

The method of nailing the cross-pieces is illustrated in Fig 6, which shows a flat iron being held at the back. It is necessary that some means should be provided for the aupport of the material against the blows of the hammer. In some cases it might be better to use a large hanimer as a support, or the head of a small axe, but in general the means provided are governed by the position of the joint to be nailed. If some support is not given, the repeated blows of the hammer may not only cause the jointing pieces of wood to slip about, but might also break some other joint that has already been made. All nails should be driven well home, and if the points project, these should be clinched and Hattened

Rostic Work. Fig. 4. Axing the jolnt. Fig. E. Making a strong joint. Fir. 6. Nailing with flat iron at back for sapport. Fig. 7. Finishing of ends with spokeshave. Fig. 8. Another finish, with rouge and mallat
down, so that there is no possibility of their catching into and tearing garments.

Two methodr by which the ends of the rails and arm rests may be finished are shown in Figs. 7 and 8. In Fig. 7 the edges are being rounded off with a small spokeshave. This inas the advantage that the chance of getting splinters in the hands is greatly minimized, and avoids a good deal of damage to the cnds, as often, if the end is knocked, and the edge is still in the rough state, the outside grain is splintered, necessitating the splintered piece being torn right off. In the method shown at Fig. 8 a gouge and mallet aro employed and the end worked round as indicated.

RYE: Its Uses. Flour made from rye grain is suppused to contain more gluten than any other Hour except wheat. Because of the many diseases that attack rye, this flour is used only to a small extent, but when free from disease, it forms a palatable and nourish ing food for those with whom it agrees. With others, however, it sometimes causes stomach trouble and diarrhoea, and a great number of epidemics have been traced to its use. It niakes good, if rather coarse, bread, and can also be used instead of thour for making girdle cakes.

RYTOL : The Developer. This is a photo rraphic developer in tabloid form which is made by Burroughs, Wellcome \& Co., Ltd. It is an all-purpose developer of the paramidophenol class. It is clean-acting and nou-staining and aeeds only to be dissolved in water with a tabloid of rytol accelerator.

The tablet form makes it very convenient to store and to take about when developing has to be done on a journey or away from home. For normal dish development rytol is used as follows

The tabloids are broken up in the water with a glass rod, and, if atirred a little, dissolve quickly. Tables for development with rytol by time and temperature, for all brands of plates and films, are given in the Wellcome Photographic-Diary. The Watkins' development factor for normal contrast at normal strength is 12 See Developing.

SABLE: The Fur. The costly and highly prized fur known as sable is obtained from the animal of the same name, a species that is closely allied to the common marten.
There are several varieties of sable, that known as Russian sable being the most valuable. This is glossy and dark hrown in colour, and in the liest akins merges into a dim black towards the back. The darker the fur is the more valuable it becomes.

Cheaper kinds of sable are those exported from Canada. These also are thick and soft, but they are of a lighter shade, and are tinged with yellow. Experta are employed to hrush the tips of such sable with dye so that they more closely resemble the best Russian variety See Fur; Kolinski; Marten.

SACCHARIN. Glucidum, or saccharin, is an intensely sweet coal-tar product used instead of sugar by those suffering from diabetes, corpulence, and other affections in which sugar may be injurious. It ranges in aweetness from 300 to 600 times that of cane sugar, but has no nourishing qualities, and is excreted from the body unchanged. See Diet; Sugar.

SACCOLABIUM. The stove cpiphytal archid called saccolabium requires a temperature from $65^{\circ}$ to $75^{\circ}$. It may be grown in hanging baskets of teak, attached to blocks of wood, or in pots filled to the rim with crocks, charcoal, and splagnum moss. Its
growing period is March to November, and extent, everything depending upon the make resting time November to March. The plant and the care which has lioen bestowed "pon demands a moist atinosphere, and must then. The life of a saddle is increased many always be grown near the glass. It should be years by proper attention, whereas it is dewatered generously from March to September, and moderately afterwards. Propagation is by offeets. See Orchid.

SACHET. The small perfumed cases sold by chemists and used to impart a delicate fragrance to women's clothes are known as sachets. They are than liquid perfumes, but are often more lasting.

Larger sachets are made for holding handkerchiefs. gloves, stockings, etc. They are simply large squares or ohlong pieces of wadding. plentifully sprinliled with perfumed pow der, covered with fine muslin. and finally sewn into satin or sill: coverings and trimmed with embroidery, painting or ribbonwork. The edges In saddle-rooms airers
 ainting or ribbonwork. The edges In saddle-rooms airers and wooden liorses arc larger sachets are made in the same way and is dry, the lining should le brushed with a stiff used as nightdress cases. A long strip of wadding can be perfumed, covered with muslin and used as a lining to a drawer. On it resta the underwear, which absorbs the faint perfume, and can be protected with a similar covering sachet to keep out the dust. See Lavender; Night Wear Case ; Pot Pourri.
SACK: A Spanish Wine. The old name of a dry Spanish wine resembling sherry was sack. The following is Sir Walter Ruleigh's recipe for sack posset: Boil together $\frac{1}{2}$ pint of sherry and $\frac{1}{2}$ pint of ale and add gradually a quart of boiling cream or milk. Swecten the mixture well, and flavour with grated nutmeg. Put into a heated dish, cover and stand by the fire for two or three hours.

SADDLE : For a Horse. A good fitting saddle is just as important as a good fitting pair of boots. A badly fitting saddle is one of the most fruitful causes of injury to the back and withers of the horse and may either temporarily or permanently disable the animal. No matter what the shaple of a home may be the suddle has always a tendency to work forward, so that unless it fits properly, bruised withers and galls will result. Apart from this, comfort to the horse means conifort to the rider, loth of which features are inseparable from a properly fitting sarldle.

The rules for sidille fitting may lie summarized as follows: There inust be no pressure on the withers. There must be no pressure on the central line of the hack. Shoulder-blade movement must be ahsolutely free. There must be no pressure on the loins. The ribs must bear the weight in all evenly distributed manner, extending from the play of the shoulders to the last rith on either side.
In buying saddles many persons purchase second-hand ones, preferring one that has been used to a new one. The best saddlers have generally a number of these on sale, and are quite willing to fit them, or allow approval to approved clients. Good second-hand saddles are always in demand, and can be bought for about 75 per cent. of their original cost, in some cuses for less than half.

If it is a second-hand saddle that is desired, particular care should be taken to note the condition of the leather, the stuffing, the strength of the saddle-tree, the breadth and width of the arches, and the quality of the leather. Second-hand saddles vary to a large
in weight and ligh a francwork of stecl and wood, with hair st ultings. The sidesaddle, though still used by horsewomen, has been largely superseded by the seat astride

Directly a saddle is taken off the horse's back it should be exposed to the air in order to dry the lining, after removing the girths and stirrup leathery, and sponging the surface of the leather with warm water to re move mud stains. creased through careless treatment. It is a safe plan never to buy a saddle that has been either patched up, restitched, or repadded

A saddle suitable for $n$ hunter or hack ahould be made of the clioicest pigskin, light kept for this purpose. As soon as the saddle
is dry, the lining should lie brushed with a stiff brush, and the leather trented with a good saddle soal), polished with a brush and rubber.

The saddle should be kept covered up when not in use, and never left exposed to the emanations arising through decomposing organic matter from the stable, as nothing tends more towards rotting the leather. It is a great mistake to have saddle brackets placed in stables, and what applies to the saddle is equally applicable to harness. Another matter is to avoid the use of too much water. A sponge and chamois leather will Jo all that is necessary towards the renoval of mud and mud stains In suminer the saddle should always be aired in the open, as artificial heat destroys the vitality of leather. See Harness; Horse; Riding, etc.

SADDLE : Of Mutton. This is a largo joint consisting of the double loin from both sides of the sheep. The usual method of cooking is roasting as described under the general article on Mutton. See Carving.

SAFE: For the Home. A safe is a strongly built container, usually of steel or iron, it which money nnd other valuables can be ke"t secure. In its construction special devices have been introduced in onder to guard against the risk of fire and the attacks of burglar. There are various patterns, some of which aro suitable for the home, and a few of these are here described.

In one form the safe is very small, and equal in dimensions to an ordinary brick, being built into the wall in the place of $\Omega$ stretcher, that is, a brick which is laid lengthwise to the direction of the brick work of the wall. The brick is removed from the wall and the safe built into the cavity. Such a safe is located usually behind a picture or other article of furniture to concenl its whereabouts. A hiding place for a small safe or a strong box can be contrived beneath the lloor boards, locating it in $n$ situation where it is ordinarily concealed by a carpet.

The safo illustrated is $1 f$ in. thick at the thinneat part, has a drill-proof door, drillproof rivets, and two gunpowder-proof nonbreakable locks. The internal arrangement usually comprises shelf and drawers, the latter being provided with locks and keys.

Home Safes. To assist saving, a home safc can be obtained from all post offices where banking business is transacted. This safe is a locked box, the key of which is kept by the
post office authorities, who will open it when it is brought in and place its contents to the credit of the depositor's account. There is no oharge for a sale, but at least 2 s . must be deposited in it when it is taken out.
Home snfes are also supplied by the banks. From the Midland Bank, for example, a strong box of convenient size, with separate compartments for coins of various denomina tions and for notes, can be obtained on opening a home safe deposit account with an initia deposit of ls. or more. The key is kept by the bank and the contents are credited to the holder's account from time to time as the safe is bought to the bank and emptied.

SAFE IIGHT This is a0merther ber term uscd to indicate a light by whiol sensitive plates or papers may safely be developed. Actually no light is completely safe. If a plate be left near an ordinary dark rooms lamp with a coin upon it for 5 min ., and is then developed, an image of the coin will be seen on the plate.
The guiding rule in dark rocm illumination is to liave sufficient light to work in comfort without allowing any direot rays from the lamp to fall on the plate or film, and to avoid exposing the plate or film even to rellected diffused light longer than is absolutely necessary. Thus during development the developing dish can be kept covered with a card, lifting it only for a few seconds when examination of the plate is necessary.

A large light in the dark room is better than a small lamp. With the large lamp properly arrunged there is ample light to see all objects in the dark room, and to work in comfort, while the plates, if kept out of the direct rays of the light, are much less likely to be fogged than if they are held close up to a small so. called ruby lamp, which may be, actinically, extremely unsafe, and yet leaves the dark room in an unoomfortable, murky gloom.
The ideal arrangement is a ceiling reflector lamp, such as that shown in Fig. 1, by which the whole of the dark ronm is illuminated, hut with diffused light, so that no direct rays can reach plate or film. The screen should be about 10 in . by 8 in.
The Wratten darkroom lamp (Fig. 2) made by the Korlak Co. for gas, oil, or electric light, takes screens 7 in. hy 5 in . and 10 in . by 8 in These acreens are interchangeable according to the work in hand.

The screens for these lamps are sold separately as anfe lights, so that the amateur may aclapt an old lamp if sufficiently large, or may contrive one for himself out of wood if for electric light, or tin if for gas or oil, the whole of the interior being painted dead white.

Safe-light screens arc of different oolours according to the purpose for whioh they are required: pale yellow, for gaslight papers ; orange, for bromide papers; red, for ordinary plates and films: deep red, for fast ordinary and orthochromatic plates ; green, of various shades, for very fast orthochromatio and most panchromatio plates.

A fairly simple and satisfactory form of red light is made by placing a small electric light in a red liquid. Dissolve 100 gr of eosin dye and 1 oz . of potassium bichroniate in hot water, using just sufficient water to dissolve all but a small portion of the dyc. It is essen. tial fhat the solution bould be liltered before use
A small lamp, such as a pocket lashlight bulb or a motor headlight bulb, should be used, care being taken to protect the holder and the wire from conthot with the solution. Holder and wire may be covered with insulating tape coated over, after it is in place, with Chatterton's compound. A wide-necked bottle is filled just below the neck with the solution, and the bulb inserted, the wire being led through the cork. 'This will be a safe light for all ordinary plates, but not for panchromatic plates and filnis. See Dark Room; Developing

SAFFRON: In the Garden. In the garden this is Crocus sativus. In its cultivated forms it provides the saffron of commerce, a colouring matter obtained from its dried stigmas. It flowers in autumn, and should be planted in August, and will thrive in ordinary well-drained soil. See Crocus; Meadow Saffron.

SAFFRON: Uses in Cookery. The yellow colouring and flavouring agent known as anffron is manufactured into saffion water or essence, which can be lought in small
castor augar, mix them till a liquid is lormed, and then add $1 \frac{1}{2}$ gills hot milk mixed with the prepared aaffron water Strain the whole into a well made in the centre of the flour, etc., mix all to $n$ rather slack dough. then cover the basin and leave its contents to rise in a warm place for about $1 \frac{1}{2}$ hours.

Turn the dough on to a floured board, knead it for a few minutes and then divide it into small equal portions Mould each to a smonth bun shape, and place them on a greased baking-shect, leaving a space between each to allow for them to rise. Let them stand in a warm place for another 20 or 30 min . : use more flour to mould ; then bake them for about 15 min . in a hot oven.

When cooked, bruah them over with a glaze made of $\frac{1}{2}$ gill milk and 1 dessertspoonfu! castor sugar, and return them to the oven for a few seconds so that they miny dry

Saffron Cake. The use of the saffron not only Havours the cake, but gives it a bright yellow colour. Prepare the saffron water as for aafiron bun. Make the cake according to the recipe given for plain cake in page 174, saffiron water lseing used to moisten the dry ingredients mixed with an equal cuantity of mills to make rather leas than $\frac{1}{2}$ gill of liquid in all.

Saffron Tea. This is made by infusing a pinch of dried allron in a gill of hot water for a bout 10 min. , then straining it out and adding $\frac{1}{d}$ gill or more brandy and sugar to taste. The tea may be served either hot or cold.

SAGE. Chiefly used in cookery for flavouring and scasoning, sage is a hardy berh. The seed should be sown in a sunny, well.

Sage. Leaves of the fragrant tonjo berb
drained soil in carly spring, and the young plants shifted he sonn as thoy are large enough to handle. Stock is hest increased by slijes or cuttings, which may be taken annually. When the shoots are ready to out they should le tied up in bunches and hung, foliage downwards, in a dry loft or shed. The leaves may be rolled off when quite crisp and stored in dry, airtight hottles.

Sage Gargle. A good gargle can be miade by boiling $\frac{1}{2}$ pint sage leaves in, 1 pint water until the liquid is reduced by one-half. While boiling leep the pan covered, only removing the lid to observe the relluction of the liquor. Then atrain it and mix with the liquid an equal quantity of vincgar, port wine, and $1 \frac{1}{2} \mathrm{oz}$. honey. Bottle it for use, nnd warm it when required as a gargle.
Sage Tea. To make sage tell, put into a jug foz. freah sage leaves, jour upon them 1 pint
boiling water. Cover the vessel over and infuse it for 10 min ., then strain the tea and take as a tonic dose from $\frac{1}{2}$ to 1 wineglassful.

Sage WIne. To make 2 gallons of this modicinal wine ? peck sage lcaves will be needed, 2 gallons water, the whites of 2 eggs, 8 lb . raisins, 2 lemons, 1 orange $\frac{1}{2}$ pint brandy. $\frac{1}{2}$ oz isinglass, 3 oz sugar candy (brown) Piok the sage leaves, using either red or green Stone the raisins and cut them small. Loose dessert. raisins are best.

Boil 1 gallon water with the whites of the eggs, and pour it over the sagc leaves, which should be put into a wooden bowl. Put the rasins into another bowl with the rinds of the lemons and orange pared thin, also the strained juice, and pour over thess the remainder of the water, which should have been boiled up and allowed to become lukewarm. Cover over each vessel and leave till next day, stirring both occasionally

After leaving them the required time, mix both liquids together, and let them stand again, but this time for $\mathbf{6}$ days. Then strain into a cask or stone jar, previously putting into it the sugar candy. Let the wine work, and keep the vessel full while the fermentation takes place.

When the wine ceases to work add the isinglass and brandy and bung it up. Let it stand 10 weeks, then if not clear pour it off, strain, and return to the cask or jar with another $\frac{1}{2}$ oz. isinglass. Keep it twelve months before bottling.

SAGINA. This is a close-growing carpeting plant, known as pearlwort, which is sometimes used as a groundwork or an edging to Hower lorders: it bears tiny white flowers in summer. The yellow-leaved variety, aurea, is a favourite plant for use in carpet bedding designs. Ordinary soil suits it and propaga tion is by division

SAGITTARIA. The handsome water plant known as arrow-head or sagittaria is about 2 ft . in height, with spiky leaves and white flowers. The double-flowered variety is liner. It is in blossom in early summer, and should be planted in water about 10 in . deep. When first eatablished the roots may be sunk in a basket, after the manner of planting water lilies. Propagation is by seeds sown in spring-time, or by division of the roots of the plants at that period. See Water Lily.

SAGO. The best kinds of sago, which is prepared from the pith of a species of palm, are known as pearl sago, and are sold in amal and large grains. Sago is fairly nourishing, and its importance as a food may be compared with that of rice or potatoes. Its value for invalids consists mainly in its soothing effect on the stomach.

To thicken soup with sago, sprinkle it into the soup while boiling and cook it about 20 min ., stirring often to prevent it from be coming lumpy or sinking in the pan and browning. Use 2 oz . sago to each quart of soup, and cook tho grain thoroughly.

Sago Drink. Sago makes excellent invalid drinks and can be prepared in two ways. One method consists of putting 1 oz . rather large pearl sago into a saucepan with 1 pint cold water. Place the pan back from the fire, but in a warm position, and let the grain soak for 2 hours, then bring it to the boil and simmer for 20 min ., stirring frequently. Add 1 wineglassful port wine, a little grated nutmeg, and sugar to taste, and serve hot. For the second method, soak 1 oz. simall sago in cold water for 1 hour, strain off the water, and add $1 \frac{1}{2}$ pints new milk. Stir this over the fire until the food value of the sago is quite incorporated with the milk, add a little grated nutmeg, and sweeten to taste. Strain off the milk from the sago just before the latter has softened, sweeten and flavour it, and leave it to cool. It should be skimmed before serving.

Sago Mould. To make this, boil up I pint tail. Therc should be black shadings in face milk in a pan with a few pieces of thinly cut and ears. See Dog: Kennel. lemon rind, then sprinkle in 3 oz . washed sago, and simmer the whole gently until the mixture thickens and the sago is cooked

Keep it well stirred, take out the lemon rind, and let the mixture cool slightly at the side of the fire before adding 1 oz butter, if dessertspoonfuls sugar, and a beaten egg. Stir all these over gentle heat for a few minutes so that the egg may cook, then pour them into a wet mould and lea ve them to set. Serve the mould either with jam or stewed fruit
Sago Pudding To make a plain sago pudding. soak 3 oz . small sago in cold water for 1 hour. Meanwhile boil up slowly it pints milk, adding 1 oz sugar and a strip of lemon rind Pour of the water from the sago and stir it by degrees into the boiling milk; let all boil slowly for 15 min ., taking care to stir frequently. Remove the lemon peel, pour the mixture into a greased pie-dish, and bake it in a slow oven for about $\frac{1}{2}$ hour. Always boil the sago with the milk before baking the pudding; if this is not done the grain is liable to sink in a mass to the bottom of the pie-dish.
A richer pudding is made by beating 2 eggs with if oz. sugar and adding them to the sago and milk before turning it ifito the pie dish Omit the 1 oz . sugar given in the previous recipe. Butter the pie-dish for the richer pudding, and scatter 2 or 3 small pieces of butter on the top when the pudding is ready for the oven; also dust with castor sugar Bake about 20 min .

Sago and apples together make another good pudding Prepare it by soaking 2 to 3 oz . washed sago overnight in a pint of water, and the following day add $\frac{1}{4} \mathrm{lb}$. sugar and 5 or $(\mathrm{i}$ moderate-sized apples, peeled, cored, and finely chopped. Mix these well, then turn them into a greased pic-dish and bake them in a moderate oven for about 1 hour. The pudding may be served either hot or cold, and with cream or custard
SAILCLOTH. This fabric is a sort of duck made in cotton, linen or heinp, and in several degrees of coarseness and heaviness. Very stout cloths for outdoor structural uses or making hammocks and atretchers for deckchairs, can bo got from firms manufacturing window blinds for shop-fronts. The choice should be guided by the purpose in view. See Canvas.

ST. BERNARD. This dog may be either rough-coated or smooth, points otherwise being the same. They should have enormous bone, with absolutely atraight front legs, and no inclination to be cow-hocked behind. The latter, however, is not always achieved, as heavy dogs are very troublesome to rear straight. The richer the colour the better. It may bo red, orange, various shades of brindle, or white with patches of either. In portance is attached to the distribution of markings, which include white muzzle, white blaze up face, white collar round the neck, and white on chest, forelegs, feet, and end of

St. Beriard. Smooth-coated specimen of this bandsome breed of large dog

ST. BERNARD'S LILY. The popular name of a hardy herbaceous perennial (Anthericum liliago) in St. Bernard's lily. It grows 2 ft . high, has narrow leaves and bears white. Howers in summer.

St. Bruno's Lily (Anthericum liliastrum) is 3 ft . high and has large, white, funnel-shaped, ily-like flowers.

If the soil is clayey, leaf-mould and sand should be dug in frecly before planting. Propagation is by division in spring.

ST. CLOUD WARE. The soft-paste porcelain made at St. Cloud, ncar Paris, at the end of the 17th century represents the oldest chinaware produced in Europe, and it wis the

st. Cloud Ware. Pastille barner in modelled write porcelain: early $18 t \mathrm{~h}$ century. Heigat 5 in . Ull vernitasion of the Director. Victoria Alvert
forerunner of Sèvres. The fine regular paste can be recognized by its yellowish tinge, and the forms, which imitated those of China and Japan, were decorated with simple designs in a rich blue outlined in black, and heightened by a brilliant glaze. The factory was closed i 1773.
There is an ainple supply of whito pieces with modelled ornament, in the form of cups and saucers, jugs, flower-pots, statuettes and grotesque figures. A Chinese pattern especially favoured for reproduction was a white porcelain with prunus blossoms in relief In painted ware the underglaze-blue decoration prevails, but there are also pieces with red, purple, and yellow enamel. See Sèvres.

ST. DABEOC'S HEATH. A beautiful hardy heath (Daboecia polifolia) which grows wild in parts of Ireland and is often called Irish heather. It is about 12 in . high and bears urn-shaped reddish purple flowers in late summer; the white variety, alba, is very pretty. This heather should be planted in lime-free loamy soil ; peat may be added with advantage.

ST. JOHN'S WORT. A group of hardy flowering shrubs and plants (hypericum) of considerable value in the garden. One of the most useful of all is Hypericum calycinum (Rose of Sharon): it thrives in shady places and bears large yellow Howers in summer; it should be cut down each spring.

Androsaemum, 18 in., yellow flowers and black fruits, and inoserianium, 12 in ., are other good kinds. The best of all the shrubby species is Henryi, 2 ft . high. Coris is a charming little plant for light soil in the rock
garden. All have ycllow flowers and thrive girls than in boys. It may first be noticed in ordinery soil. The shrubly kinds are increased by cuttinge in a frame in summer, the others by division in spring.

St. Joseph's Lily. This is one of several names given to the Madonna lily (Lilium candidum). See Lily.

ST. JULIEN : The Wine. One of the best known brands of French claret is produced in the St. Julien district in the Nedoc. The name is often applied loosely to oheap clarets The higher-clnss St. Julien grouths nre of deeper colour and greater body and variety than the more delicate prorluots of Latour and Lafite. The bouquet closcly resombles the raspberry.

ST. VITUS'S DANCE. St. Vitus's dance, or chorea, is a nervous disease of young children which is much more common in
bout the unconsciously to jerk the hands or limbs about, twist the head, or pull faces. Instead of walking normally, the ohild's gait becones a series of jerky, irregular movements. An inherited nervous dispusition, debility. fright, or precociousness of mind are predisposing causes of the somplaint.
A child auffering from chorea shquld be placed at once under medical care, if for no other reason than that it is liable to or may be actunlly suffering from rheumatic discase of the heart. Rest in bed may be nocessary at the beginning, with a liberal diet of milk, eggs, and soups. Except in severe casps the symptoms pass of during slcep When the child is allowed up, and particularly when it goes out of dorre, care stoulld be taken to protect it from tho teasing of other ohildren.

## Salads and Accessories to Salad Making

## Many Dainty Ways of Serving these Health-giving Dishes

This aricie deals with a selection of appelizing salass, which in their various seasons fand place in the menu all the year round. Sec also Fruit Salad: Hors d'Ocuvres: Mayannaise: Ollve; Supper; Tarragon: Vinegar

Salads may be divided into plain aalads which accompany some dish and skilfully composed salads which form a course in themselves. The former kind are made of salad herbs and vegetablea, either raw or cooked and allow'cd to become cold, with the occasional inclusion of certain fruits. The latter kind contains among other salad ingrodients nuts, eggs, fish, cliceao, meat, game or poultry; or are composed entirely of mised fruits and served as the sweet coursc at luncheon or dinner. The secret of success lies in the proper blending of ingredients and the cool, inviting appearance of the finished salad. This may be served in a glass, china or pottery howl, or individual portions may be placed in salad saucers, or on glass plates. Fig. 1 illus. trates a plain salad appetizingly arranged in a out glass bowl, with glass servers, oil and vinegar bottles and salad plate. Fruit salade may be
served cither in a fruit set or in sundae glasses.
In making salads the first easential is to see that the ingredients are perfectly fresh. If tinned goods are used, they should be of first-class quality and removed from the tin immediately after opening it. In warm weather salad herbs, fruits, etc., gain added crispness by being kept for a few hours in a refrigerator When this is not possible a wire vagetable raok placed in an airy larder is the best receptacle to hold such items as endives, bunches of watercress, spiring onions, radishes and lettuces.

Salad vegetablos should be handled as little as possible, but must bo washed thoroughly in cold salted water. Watercress requires cleansing in several waters, mustard and cress should have the small black sceds removed. Endive and lettuce are prepared by cutting off the root and any outer leavea unft for use; the smallest leaves and henrt should be set aside for garnishing the top of the salad. Outer leaves of lettuces should be torn in pieces and not cut. The roots of spring onions should be cut off and the tops trimmed before washing, and afterwards the outer skins removed. Radishes may be sliced, but if small, round, and of bright colour, they form an effective garniah when left whole.

Alds to Preparation. Wire baskets are sold or straining the water out of lettuces, etc. after washing them. A clean cloth should be used where a basket is not available, held by the corners and the walad shaken gently in it until the ingredients are dry Moisture left on lettuce and other vegetables mins the salad and prevents the dresaing from properly adhering to them. The strainer illustrated in page 673 can be used as a salad basket; and another excellent device shown in the same page is the tomato slicer. A cutter with which cucumbers can be finely

Salad Dressings. The dreasing should not be added to the salad until it is ready to serve A good way with a green salad is to place the made dressing in the bottom of the bowl, reserving the portions of the salad to be used as garnishes, put the other ingredients into the drcssing and mix thoroughly. A simple French dressing is served with salads which accompany gamo, poultry, etc., but a mayon naise or thickencd dressing is usually best for those served an a separate course, with the exception of a salad composed entirely of fruit. Fruits such as bananns, apples, oranges, pincapple and chopped or ground nuts are now introduced into green salads and dresserl with mayonnaise. The best oil and vinegar should be used for dressings Rancid oil or malt vinegar completely ruin the flavour. Lemon juice may be subatituted for vinegar and oream or unswectened condensed milk is an excellent addition to a thick dreasing. Dircetions for making a mayonnaise dressing aro given in page 778.
A French dicesing for the lettuce and endive salad to accompany pqultry, eto., is made by mising 3 parts best salad oil with 1 part white winc vinegar. The lettuce leaves are dried, put into a basin, seasoned with salt and pepper, and equal parta of chopped tarragon leaves, chervil, parsley and chives (or onion) are scattered over them The salad is carefully lifted out when required, leaving any moisturc that may have drained from the leaves in the bottom of the hasin and placed in the mixed oil and vinegar in the salad bowl. The leaves arc turned about gently in the drcssing until thoroughly coated and served at once on side plates. The salad bowl may be rubbed round with a orust of bread containing a clove of garlic.

A dressing for a vegetable salad may be madc of 3 tablespoonfuls salad oil, 1 teaspoonful tarragon vinegar, 2 dessertapoonfuls white vinegar', salt, pepper, $\frac{3}{\text { teaspoonful madc }}$ mustard. The same quantity of lemon juice may be substituted for vinegar where the latter is not liked and ? teaspoonful castor sugar may be added. Put the mustard, salt and pepper into a basin and gradually stir in the oil; then add the vinegar, mixing throughly.

Salad Cream. A very good recipe for a salad cream whicl can be made in large quantities and stored in bottles is ns follows: The ingredients consist of the yolks of 6 hard-boiled cgga, 6 oz. butter, 2 oz . castor sugar, 룔 oz salt, 1 oz dry mustard, ca yenne pepper to taste, $\frac{1}{2}$ pint cream, $\&$ pint salad oil, $1 \frac{1}{2}$ gills white wine vinegar, 4 tablespoonfuls tarragon, chervil, and tonato vinegar mixed together, 2 tablespoonfula Worcester sauce, and 2 tea spoonfuls anohovy sauce.

Rub the eggs through a wire sieve, then pound them in a mortar till a perfectly amooth paste is obtained. Work the butter and sugar together until they are very light and creamy; in oold weather the butter inay be

Fig. 2. Cucumber slicer with which cucumberg can be thing and evenly cat. Fir. 3. Aluminiam erg cutter with which hard-boiled eggs may be sliced for garnishing salads
just melted, but it must not be allowed to oil or the mixture- will curdle. Add to the eggs the butter, sugar, salt, mustard, and pepper, and thoroughly incorporate them: then by degrees moisten the paste formed with the cream and, when that is mixed, work in the sauces. Last of all the ingredients. put in the oil and then the vinegars.
The oil must be mixed in first very carcfully and a few drops at a time. When thoroughly incorpornted add the vinegar. It is best to use the mortar entirely for mixing, as it prevents waste of ingredients If by any chance the salad cream curdles, it can be restored by placing the mortar in a pan of hot water and stirring till smooth again

A simple dressing may be made by passing the yolk of a hard boiled egg through a sieve, beating it line with a fork in a basin, then adding I saltapoonful dry mustard, saltspoonful salt, 1 teaspoonful castor sugar, I tablespoonful salad oil, I tablespoonful vinegar, and cayenne pepper to taste.

Brazilian Salad. This salad may be served either as hors d'oeuvres or as a separate luncheon course The ingredients are white grapes, apples, celery, brazil nuts and lettuce. Skin and pip the grapes, chop the apples, celery and nuts finely, mix with salad cream and place on crisp lettuce leaves either in a bowl or on small plates.

Butter Bean Salad. Soak and boil $\frac{1}{2} \mathrm{lb}$. butter beans until tender. Strain away the liquid. Add a little butter and seasoning to taste and leave the beans to get cold Mix with mayonnaise or thick salad dressing, and garnish with half slices of beetroot, strips of pimento and finely-chopped parsley.

Carrot Salad Raw carrot possesses dietetic value and a good luncheon salad may be made by grating enough carrot to fill a brealifastcup, sprinkling it with chopped parsley, a small piece of grated lemon rind, a dusting of pepper, salt and castor sugar. Add a little oil and lemon juice, just sufficient to moisten, and mix all togethe: Arrange small lettuce leaves lightly coated with the dressing round the salad, and garnish with freshly-grated carrot and pieces of olive.

## Cauliflower Salad. An excellent winter

 salad is made with cauliflower. Divide one large cold boiled cauliflower into sprigs. Sprinkle them with salt and pepper, and heap them up neatly in a salad bowl. Cut two tomatoes in slices and arrange them as a horder round, sprinkling them with a little chopped parsley. Pour about gill mayonnaise sauce or any other good salad-dressing over the cauliflower, and serve.Slices of beetroot which have been dipped in vinegar may be used with or instead of tomatoes.

Celery Salad. Equal quantities of raw apple and celery are cut into small pieces, placed in a bowl, and covered with mayonnaise sauce. A border of sliced tomato or bectroot may be added to this dish, which must not be prepared too long before it is eaten, in case the apple should become discoloured.
A nother celery salad which is excellent with cold pork, goose or chicken is inade of diced celery, beetroot and potatoes and chopped nuts. Cold cooked chestnuts may be used instead of the diced potato.

Cheese Salad. Cream checse is liked by most people as a luncheon salad ingredient, but any soft cheesc may be used or a cheess crab may be prepared. This is made from $2 \frac{1}{2}$ oz. dry cheese, $\frac{f_{2}}{}$ teaspoonful each made inustard and salad oil, salt and pepper to taste and enough vinegar to bind the whole into a paste. Grate the checse and mix with all the other ingredients until the paste is smooth. Serve small portions on a green salad previously prepared with French dressing.

When using a cream or soft cheesc cut it Continue these layers until the dish is full. into rounds, dip lettuce leaves in French arranging lettuce on top Garnish with the dressing and arrange round the bowl, place sieved yolk and chopped white of egg.

Lettuce and Fruit Salad. The ingredients are. I grape fruit, $\frac{1}{2}$ cupful chopped nuts. I cupful whitc grapes, 2 oranges, 2 tomatocs, 1 lettuce. Peel the grape fruit and orangea and divide into sections, skin and remove pips. Also skin and remove pips from grapes. Place fruit and nuts on top of lettuce, cover with mayonnaise and horder with tomato slices. Garnish with a tew grapes. shredded heads of 2 lettuces, add 1 ta blespoonful white tarragon vinegar, and season the mixture with pepper and salt. Then pile it high in the ccntre of a dish, cover it with mayonnaise sauce and garnish it with alternate groups of lettuce leaves, quarters of hard-boiled egg, shredded gherkin, and stoned olives. Endive may also be used as a garnish.

Crab Sa'aj. A good fish salad can be made by chopping up the flesh of a crab, moistening it with a little mayonnaise sauce, and then putting the mixture into 3 or 4 prepared tomatoes. The latter are scalded in boiling water for a couple of minutes, the skins removed, and an incision made in the top of each so that the inside can be scooped out with a small spoon. Sprinkle a little pepper and salt inside the empty tomato cases, and let them drain before filling them with crab. Garnish the salad with lettuce and cress.
Crayfish Salad. An equal quantity of crayfish flesh should be mixed with cold white fish which has been flaked and boned. Layers of lettuce, cress and endive, of lish and of hard-boiled eggs are placed in the bowl, cach layer being moistencd with salad cream. Sprigs of tarragon and chervil, cut gherkin, and strips of red chillies are used to garnish. Mayonnaise dressing may be used and a salad composed of turbot, halibut or hake without the crayfish can he prepared, and garnished with anchovies

Egg Salads. Hard boiled eggs may be cut in half and placed round a shallow glass bowl. In the centre is piled a mixture of diced potatocs and beetroot, seasoned and flavoured with chopped pickles, parsley and onion, and moistened with salad dressing. The eggs may be stuffed with pounded sardines and served on lettuce with a spoonful of mayonnaise sauce on each half of egg.
Another good egg salad is made of thick slices of hard-boiled eggs. An extra egg is boiled for garnishing and the yolk and white of this are separated; rub the yolk through a wire sieve. and chop up the white linely. Whip 3 tablespoonfula cream until it just hangs on the whisk, stir 3 tablespoonfuls mayonnaise sauce into it, and season the mixturc carefully.

Put a layer of crisp, clean lettuce in the hottom of the salad bowl, then one of egg, next of cold cooked macaroni cut into pieces about 1 in. long then a sprinkling of chopped celery and parsley, and a little dressing.

Lobster Salad.
To make a lobster salad. take the meat from a lobster, cut it into pieces of a convenient size, and season these slightly with salt, vinegar, and pepper. Shred some inner leaves of lettuce into the bottom of a salad bowl.cover itwjth a layer of lobster and нliced cucumber, and cover again with lettuce. Conlinue with these
plete, and decorate
 layers until the salad is complete, and decorate the top with slices of egg, tomato, or beetroot. Just hefore serving pour over some mayonnaise sauce and acld a sprinkling of powdered coral.

Orange Salad. A salad that goes well with roast meats, or accompanies wild duck. is made from a small cucumber, sweet oranges and chopped nuts. Most of the cucumber should be peeled and soaked for an hour in cold water hefore being cut into very thin slices. Prepare the oranges, removing all pips and pith. Arrange on cucumber slices and cover with salad cream, garnishing with the nuts and a horder of very thiuly cut unpeeled cucumber slices.

A good orange salad can be made by mixing the prepared orange quarters with chopped potatoes, apple and olives. The dressing for this salad is made of oil and orange juice, pepper and salt. and the salad is served on lettuce leaves, or in half orange skins placed in grape fruit glasses.

Prawn Salad. Take 1 pint shelled prawis, and sprinkle them with French dressing. Wash 2 moderate sized cabbage lettuces. and pull the leaves into small pieces. Put a layer of lettuce in the dish, cover it with prawns, then pour over it some mayonnaise sauce. Add another layer of lettuce and prawns, and continue until the bowl is full. Mayonnaise sance should cover the whole. The top should now be decorated with slices of tomato, cucumber, and hard-boiled egg, sprigs of cress, etc.

Salmon Salad. To prepare, take out the boncs, break the fish into flakes with a fork and pile it high in a salad bowl on a bed of green salad.

Pour over it some mayonnaise or salad dressing and leave it in a cool place for a little while before serving it; garnish with some sliced hard-boiled egg, a few crisp lettuce leaves, some cress, sliced gherkin and strips of pimento.

Sardine Salad. 'This salad is best served in individual portions. To prepare it, put a layer of thinly sliced celery in the bottom of each bowl, cover it with a little boiled and finely chopped onion, and then add a layer of sardines, skinned, boned, and cut into small pieces.

Cover this with some more celery, pour over it a little oil and vinegar dressing, and finally put on a layer of sieved hard-boiled
egg. Coralline pepper makes a good garnish for these salads.
Russian Salad. To make this salad, take 1 lb mixed cooked vegetables such as carrot. turnip. peas, French heans, potato and beetroot, and cut them into dice. Arrange them neatly in a glass salad bowl, adding a little cucumber and celery if liked: dress them with salad dressing made with crean or condensed milk instead of oil, and garnish with a border of sliced tomnto and chopped celery.

If preferred. a few sardines or anchovics boned, tailed and cut into halves may be placed on top of the vegetables. The chopped yolk and white of a hard-boiled egg may then be used as a suitable garnish
Another variety of Russian salad is made by arranging the flaked remains of any cooked white fish in a salad bowl, and covering the top with strips of anchovy and sardine, and some chopped gherkin, hard boiled egg, und capers. Slice some cold boiled potatoes thickly. place a border of these round the salad, and pour some mayonnaise over the centre.
Turkey Salad. An excellent supper salad is inade from pieces of cold turkey, which are cut uj and mixed with diced celery and sliredded endive and moistened with salad cream. Fresh, crisp lettuce leaves should be placed round the ealad and it should be garnished with chopped chestnuts, slices of hard-boiled eggs and gherkin.
Salad Bowl. Because salads are served in different ways, according to individual taste salad bowls may vary both in size and design. The larger ones, which are intended to hold walad for several persons, are deep bowls of cut or plain glass, pottery, china, or polished wood They are accompanied by salad servera, which consist of a two-pmnged fork and a spoon to match the bowl.
Smaller salad bowls, designed to hold just enough for one person, are also made of wood, glass, and china. They are sometimes preferred to the larger kinds, and are nlways useful on occasions when salad for une is required. Semi-porcelain, wood, glass, and pottery sets are obtainable for fruit salads comprising a bowl and six individual plates
SALAD BURNET. The hardy perennial herl, l'oterium, or salad burnet, bears leaves used for tlavouring salads and soups. It requires a sunny, dry position in ordinary light soil, and must be watered freely in time of drought. It is best planted during early spring in rows 6 in . apart and rows 8 in . asunder, removing Hower stems as soon as they appear. Roots should be lifted and replanted every year. Salad burnet is raised from seed sown in shallow drills during April or September.
SAL ALEMBROTH. The combination of perchloride of mercury and sal-ammoniac or sal alernbroth is a powerful antiseptio which has been used in surgery. Sal alembmth gauze and sal alembroth wool are useful antiseptic dressings for discharging wounds, ulcers, etc. The gauze and wool are usunlly tinted blue with un aniline dye, which becomes bleached when wet with the discharge.
SAL-AMMONIAC. Ammonium chloride is commonly known as sal-ammoniac. It is a common vapour inhalation in the treatment of chronic catarrhs and inflammations of the throat, larynx, and bronchial tubes.

Sal-ammoniac is used to make the electrolyte in batteries of the Leclanche type. See Ammonia; Battery; Bell.
SALE OF WORK. A sale of work is much the same ns a bazaar, though strictly speaking at the former nothing but needlework should be sold. In modern parlance the terms are practically interchangeable. Small sales of work may be held in the home with the aim of collecting money for charities. See Bazaar.

SALES : Advice About. The disposal of goods at reduced prices is known as a sale.

The time and manner of a sale vary according to the method and urgency of disposal, an auction sale being usual when the goods have to be sold without delay The sale of secondhand goods and many small articles is often effected through the advertisement columns of daily papers.

Special and after season sales are held for clothing and household furniture and requisites Bargains are often obtainable especially in slightly soiled house linen and blankets, in shoes, gloves, stockings and furs at the better class stores and shops.

SALICIN. A crystalline glucoside obtained from the bark of apecies of willow and poplar, salicin is used in the treatment of acute rheumatism. In the stomach and bowel it is converted into salicylic acid Pron. Sal-e-sin.

SALICYLATE. A salt of salicylic acid is called a salicylate. Those most often used in medicine are sodium salicylate, methyl salicylate or oil of wintergreen, salal or phenyl salicylate, and bismuth salicylate.

SALICYLIC ACID. A colourless, crystal line substance, salicylic acid is found in various plant products, including oil of wintergreen and oil of sweet birch, from which it can be prepared; but it is also prepared synthetically. It is used in treating ncute rheumatism, in doses of 5 to 20 grains but usually sodium salicylate, dose 10 to 30 grains, is preferred.

Excessive dosage with these substances causes symptoms of poisoning, referred to as salicylism, such as fullness in the head, noises in the ears, deafness. dimness of vision, sickness. delirium and cardiac depression. Such symptoms should at once be brought to the notice of the doctor.

Salicylic acid acts as an antiseptic, and is sometimes used as such in a lotion. It assists in dissolving off the horny cells of the skin and is used to remove corns and warts and in the treatment of skin disenses in which there is much scaling or thickening. See Aspirin:

## Wintergreen.

SALINE. Salts of the alkalis and of magnesium are used as purgatives under the name of saline. They include sodium sulphate, Rochelle salt or sodium, and potassium tartrate, sodinm phosphate, and Epsom salt or magnesium sulphate. The dose varies from $\frac{1}{2}$ to $\frac{1}{2} \mathrm{oz}$. Salts are best administered in warm water just after getting out of bed in the morning. Pcople who take salines habitually ought to take some other purgative, e.g. castor oil, at intervals. Sec Aperient ; Cathartic.
SALISBURIA. One of the most beantiful of all trees which are hardy in the British Isles. It is popularly called the maidenhair tree, because its leathets resemble the fronds of the maidenhair fern ; its hotanical name is Ginkgo biloba (Salisburia adiantifolia). The maidenhair tree is one of a limited number of leaf. losing conifers; it will eventually reach a beight of 60 ft . or more, though it is slow growing during its carly years. It is of graceful growth, and its fern-like leaves, which turn to pale gold in the autumn. are very beautiful. It thrives in ordinary soil and does well in town or country gardens.
SALIVA. The fluid poured out into the mouth consists of the mixed secretions of the salivary glands. These are the parotid, between the ear and the angle of the jaw; the submaxillary, under the horizontal part of the jawhone; and the sub-lingual, under the tongue. The saliva is an alkaline Huid; it lubricates the muuth and food, and digests starch by means of the ferment ptyalin which it contains. Among its various contents are the carbonate and phosphate of lime, which tend to adhere to the teeth and form tartar.
Muinps is an acute infectious disease in which there is inflammation of the parotid glands, and occasionally also of the other two
salivary glands Any of these glands may suffer from simple inflammation due to exposure to cold or injury, etc Hot applications to the skin over the gland may give some relief in early stages
A profuse llow of salivn, reteried to as salivation, may arise from dyspepsia, stomatitis, the excessive use of mercury and other drugs, such as arsenic indide of potassium, antimony, and tobacco and other causes The treatment depends on the cause.
SALLY LUNN. A kind of teacake baked in a round cake tin or cake ring is known as a Sally Lunn.

The following is a good recipe: Use 1 lb . flour, $\frac{1}{}$ teaspoonful salt, a scant $\frac{1}{2}$ oz. yeast, 1 teasponful castor sugar, 1 esg, $\frac{1}{2}$ pint sour milk or milk and water, and $1 \frac{1}{2}$ oz butter Save just sufficient of the egg as an egg wash for the cake when baked. Sift the Hour with the salt into a bowl and make a well in the centre, melt the butter in a pan, add the milk, and bring to the warmth of new milk.

Beat the egg, reserving a little ns directed, add to the milh, and varm it sufficiently to take the chill off it. Cream the yeast with the sugar, and gradually mix the milk and egg to it. Turn the liquid into the centre of the four and work all up into a dough, kneading it smooth.

Have ready four medium-sized tins, warm and grease them. Now divide the dough into four equal portions, work each portion into a smooth round, and lay them in the tins Place these on a baking shicet, cover them over, and set thein to prove in a warm place. When they have risen to double their size, hake them in n goud steady oven for 20 to 25 min. Turn the cakes out of the tins on to a cake-wire and brush the tops witli egg

Salmi. This term is used in cookery to deacribe a superior kind of ragoût made from game or poultry. See Game.
SALMON. Sometimes called the king of freshwater fish, salmon is, strictly speaking, also a salt fish, for it spends part of the year in the sea and the remainder in rivers. British salmon is considered the best, and is in season from early February to the end of August, but Canadian, Dutch, and other imported salmon can be obtained all the year round.

When buying salmon, select a fish with a small head and tail in proportion to its size, broad, thick shoulders, silvery bright scales, and tlesh of a pinky red sliade Salmon may be kept for several days after it is caught so long as it is stored in a cool place. but the fresher it is when cooked, the better
How to Cook. To boil salmon, remove the fins and gills, scrape the scales and cleanse the fish. Put it into a pan or fish-ketitle containing enough boiling salted water to cuver it, and let it cook slowly. The time required for cooking depends upon the weight of the fish, 10 min . being allowed for every lb . and 10 min extra

Salmon may also be grilled, but it should first be cut into slices about 1 in . thick, wiped with a cloth, and then brushed over with salad oil or melted hutter and seasoned to taste. Cook these before a clear fire or under a gas griller for about $\ddagger$ hour, and serve them with maitre d'hôtel butter, or any suitable sauce may be used.

To fry salmon, cut the tish into slices, wipe them with a oloth, brush them over with benten egg, and then coat them with breadcruinbs. Melt some fat in a frying-pan, and when it is smoking hot put in the slices, frying them on both sides until they are golden brown in colour Then drain them on paper and serve them hot with the addition of Hollandaise sauce.

When cooking chilled imported salmon, the flavour is improved if it is allowed to soak for an hour or longer in slightly salted water.
'I'hen dry the fish well, and cook by any o! the methods given for fresh salmon

Smoked salmon, cither cooked or in its raw state, is often served as hors d'oeurnes, while a special preparation of it, known ns lax, is preserved in oil. Both are cut into thin slices and garnished with herbs or pickles. Tinned salmon makes up into yood sandwiches, fish cakes, and various other delicncics

Salmon Cakes. Tinned salmon may be used to make tish cakes or fritters Break about half a tinful of salmon into flakes, mix it with \& lb boiled rice, and bind the two with the yolk of an egg. Add a little lemon juice and seasoning to taste, and heat the mixture in a pan over the fire. Then spread it on a plate to cool, shape it into round cakes, brush there over with white of egg, coat them with breadcrumbs, and then fry in smoking hot fat.
Salmon Chartreuse. Rinse a plain border mould in cold water and coat it thinly with melted aspic While it is setting remove the akin and bones from 1 lb . cooked salmon and pound the flesh in a mortar with 6 boncd anchovies and the yolks of 3 hard-hoiled eggs When the mixture is smooth, add $\frac{1}{2}$ glass sherry, the juice of $\frac{f}{\ddagger}$ lemon ; rub the whole through a hair sieve, scason it to taste with salt pepper, cayenne, and a little nutmeg, and then add to it a gill of lightly whisked cream and a little more than $\frac{1}{2}$ pint warmed aspic jelly. Pour the mixture into the prepared mould and leave it to set, serving it cold, with a little salad sprinkled witl। dressing heaped up in the centue.

Salmon Mayonnaise. Cold boiled salmon is needed to make a mayonnaise. Choose a middle cut of salmon, bo:l it according to the directions already given, and, when it is cold, take off the skin and cover the fish witl thick mnyonnaise sauce (sce paye 778)
Serve it garnished with thin, overlapping slices of cucumber If the fish is not specially cooked for the purpose, but the remains of cold ralmon are used instead, they may be flaked, piled up high on a dish, garnished with green salad, and the sauce poured over them.
Salmon Mousse. To make this, take the skin and hone from $\frac{1}{2} \mathrm{lb}$. cold boiled salmun, pound it well in a mortar, and then add to it a small teacupful of hot and seasoned fish stock in which a little gelatine has been dissolved.
Rub the whole through a sicve, then whip it up with 1 gill thick and slightly salted cream. Turn the mixture into a prepared souffé tin and place it in ice for a few hours before it is to be served. Chopped nspic makes a good garnish. See Fish; Lax; Maitne d'Hốtel; Potted Fish

SALMON TROUT. Salmon trout is a species of trout which migrate to the sea. In taste and colour their Hesh differs but slightly from young salmon. Salmon trout can be cooked according to any of the recipes given for salmon and trout. See Trout.

SALOL. By the interaction of salioylic acid and phenol (carbolic acid), salol may be obtained. It is insoluble in water, and is usually preseribed in cachets or suspended in mucilage. The dose is 5 to $\mathbf{1 5}$ grains.

Externally, it is sometimes diluted with powdered chalk or talcum as an antiseptic clusting powder. Internally, its chief uscs are as an intestinal disinfectant and in the treatment of rheumatic fever. In the intestine the drug is decomposed into carholio acid and salicylio acid. A solution in alcohol, with the addition of aromatics, is used as a mouth wash.

SALPIGLOSSIS. Amongat half-hardy annuals salpiglossis is valuable for cut bloom under glass, and showy for beds and borders outside. Propagation is by seeds sown in a frame or greenhouse in spring. Care must be

Salpiglossis. Brilliantly coloured flowers of an anoval plant much grown for ladoor decoration
taken not to sow too thickly, and to give the scedlings plenty of ventilation, or they may damp off. After they have leen hardened off the young plants may be safely planted out in June. Different varieties have such shades as blue and gold, golden yellow, gold-veined crimson, and purple. By sowing seeds under glass in September and growing the scedlings in alight warmth in ordinary potting compost a fine display in spring is assured
SALSIFY: The Plant. An excellent root vegetable for winter use which is casily grown in well tilled friable soil, free from fresh

Salsity, which somewhat resembles a parsnip in appearance and an oyster in flavour
emon juice. Put into a manure, from sceds sown out of doors in May ; the rows should be 15 in. from each other and the scedlings thinned to 8 or 9 in. apart.
During summer the only attention needed is to hoo frequently between the rows In autumn, when the tops have died down, the root may be lifted and stored in soil at the font of a wall or fence, or dug as required. If a fow ronts are left in the ground until spring, the fresh whoots, if out when a few inches high, furnish what are known as chards.

How to Cook. Salsify has heen popularly termed the oyster plant from its supposed resemblance to the oyster in flavour.
To prepare it as a vegetable, scrape the root gently, and lay it in cold vater to which has been added a tablespoonful of stewpan 98 much water as will a required to cover roots, add salt to it and let it boil up Drain the salsify, cut each stick into pieces 3 or 4 in long.

Plunge the pieces into the boiling milk or milk and water, add 107 . butter and a good squeeze of lemon juice, boil un and cook for from 30 to 40 min ., or until the pieces are
tender. Dish the salsify and keep it hot, then strain the liquor and keep it for making a thick white sauce with which to cover the roots Salsify may also be cooked according to any of the recipes given for celery. See Batter Fritter ; Sauce.
SALT: Household Uses. Salt is indis pensable in cookery and as a prescrvative of meat and other vegetables. One of the simplest and most effective of cleansing agents, salt removes stains and grease.
There are several grades of salt, and it is customary to keep the finest for the table and a coarser sort for cooking and other purposes. The latter is genemlly the pure rock salt, while the refined white table variety frequently has ground rice or some other ingredient added to prevent it from caking. All salt should be kept in a dry place, as it is highly susceptible to atmospheric changes and quickly loses its savour if allowed to become damp. Salt easily corrodes the silver or other metal of which many salt-cellars are made. and for this reason these should be lined with glass, kept clean and frequently replenished.

For culinary purposes salt is used for scasoning all dishes and is added to the water in which vegetables are cooked. Fresh fish or meat not required for immediate consumption should be spinkled with salt before being put away in the larder, and this precaution should never be omitted in hot weather, howevel secure the larder or meat safe may be against flies or bluebottles. In making ices the free\%ing mixture consists of ice well sprinkled with salt, which in dissolving keeps the temperature of the ice lower
Salt is an excellent cleanser for dishes of all kinds, especially for enamelled warc and for removing stains, for cleaning baths, bamboo furniture, ctc. Bcfore blackleading a kitchen range any grease spots should be got rid of, and this can be done effectively by rubbing with salt. When sweeping a carpet salt may be sprinkled over it to clean it and bring up the colour.

Amongst other uses for salt, a handful thrown in front of the fire makes it burn clear and hot for toasting. A bout a teaspoonful dropped into the bowl of a paraffin lamp will cause it to give a better light.
In medicine chloride of sodium, which is common anlt, has valuable therapeutic properties in the form of salt and brine baths. It is often employed as a gargle for the throat and is given as an emetic dissolved in hot wnter. See Emetic.

Garden Uses. There are various uses for salt in the garden; for instance, rock salt is an excellent stimulant for asparagus, bcetroot, and other vegetahles. This salt should be used at the rate of 7 lh . to the rod, but not more. Its valuc in this respect is due to the fact that it !iberates the potash already in the soil, so making it feed the plants that need it.
Salt is also used for killing weeds. It is useful for clearing them from gravel walks, especially in cases where, as domestic animals are kept, poisons cannot safely be employed. It should be applied in dry weather. See Fertilizer; Weed.

SALT BOX : How to Make. Owing to the corrosive effect of salt, the use of nails and metal fastenings is avoided as far as possible in making a salt box, which is usually of wood : because of the damp nature of the material the wood should be fairly thick and close grained. Beech is well suited for the work, but ash is often used, and American whitewood can be utilized. A convenient shape, illustrated in Fig. 1, incasures $10 \frac{1}{2} \mathrm{in}$. by 7 in . at the base, $4 \frac{1}{2} \mathrm{in}$. in front, and 7 in . at the back up to the lid. The wood is ${ }^{3} \mathrm{in}$. thick, the corners dovetailed.
Commence by planing up the front, $A$, to 49 in . by in ., and cut to 10 in . The sides, B ,
are the same thickness, and 7 in . wide, with a length of $7 \frac{1}{2} \mathrm{in}$. The back, C , is $10 \frac{1}{4} \mathrm{in}$. by $9 \frac{1}{2} \mathrm{in}$. by $\frac{3}{3} \mathrm{in}$. and the bottom, $D_{\text {, }}$, $9 \frac{1}{2} \mathrm{in}$. by 6 in. by ${ }_{4}^{3} \mathrm{in}$. The pieces are set out as in Figs. 2, 3, and 4 : the dovetail pins are cut on the ends of the front piece, A, the distance between the shoulders being $9 \mathrm{in} .$, and then placed on the sides in turn to mark out the exact shape of the sockets, as in Fig. 3.
Thesame is done with the back, C , as in Fig. 4 and then a $\frac{1}{\frac{1}{8}} \mathrm{in}$. wide and $\frac{\mathrm{in} \text {. deep grove is }}{}$ ploughed ? in. up from the bottom edge of each piece t, take the botton piece, $D$. On the latter plane a rebate to correspond with the grooves, $\frac{8}{}$ in. up the edge and $\frac{1}{1} \mathrm{in}$. deep, and complete the sides, B, by sawing off the front corner and planing smooth. Mark $1 \frac{1}{2}$ in down at the top of the back each side, saw off the waste, and plane down smooth, and then bore a $\ddagger$ in. hole 1 in. down in the centre. The parts are now ready to fit together, as in Fig. 5, and if the juints are true they can be glucd up and left to dry.
In the meantime the lid is prepared, one piece being $11 \frac{1}{4}$ in by $6 \frac{1}{2} \mathrm{in}$. by $\mathrm{s}_{3} \mathrm{in}$., and the other 111 in by 1 in . by $\frac{3}{3} \mathrm{in}$. The front edge of the large piece and both ends of hoth pieces should be rounded and filished smooth with glass paper. The glued box can now be trimined at the ends and cleaned up with a sharp smoothing plane, the top edge of the front being planed to the slope of the sides, and the narrow portion of the lid screwed on from the back Its lower edge in front must be planed down $\frac{1}{8}$ in., so that the sloping lid can be fitted. The top edge of the latter is now bevelled sufficiently to fit, and then attached with stout leather hinges, 2 in . long and $1 \frac{1}{\delta} \mathrm{in}$. wide. A neater job is made by cutting recesses $1 \frac{1}{2} \mathrm{in}$. from the ends to take the leather, which should be secured with $\frac{1}{2} \mathrm{in}$. mund-head screws.
The outside of the box should be sized and varnished; the inside is left plain, so that it can be washed out when necessary. On account of the action of salt on metal it is not advisable to use plain butt joints or to nail or screw the box together. The work can be
simplified by screwing on a plain base, whioh can be fitted on the outside and screwed from the bottom or fitted between the sides
SALT CELLAR. In England the first salt cellar was a large bowl placed in the centre of the table. This was ancceeded by a covered vessel known as the standing, or stecple saltes which was a fashionable piece in the 16 th and 17 th centuries, and was made of silver, rock crystal, and other valuable materials, some being, in add tion ornamented with gold or precious stones. Examples are highly prized
The modern salt cellar, which is a smaller vessel, came into vogue about 1700, and has been made in a great variety of styles. Round, oval, and octagonal examples exist both in silver and in Sheffield plate. Some stand on four feet and others on three, while some are without feet. Others have a square base. The claw and ball, the lion's paw and the stepped cone are among the types of feet found.

Decoration takes the form of embossing, piercing and chasing. Some have beaded and others gadroon edges. Designs such as those illust rated are much copied for modern silver salt cellars; others are made of glass, china, pottery and clectro-plate. Thesc metal containers should have glass linings, otherwise the salt is liable to corrode the silver or plate. Usually made in pairs or sets of four, salt cellars should match in style the pepper and mustard pots in use on the table. With most salt cellars a small spoon is provided. See Silver: Table Laying

SALTING: Of Food. By adopting this method of preservation many foods are kept in good condition which otherwise would rapidly decay. Also many articles of diet which only last for a season can be preserved and become Fig. 3 and spice. all kernels should be removed. The meat must be rubbed all over in every part, and any hollows left by skewers or kernels being cut out should be filled up with salt. A round of beef weighing 20 lb . will take 1 l lb . salt. Meat should be salted ss soon as possible after being killed if the weather is warm, but if the atmosphere is chilly or frosty it ahould be kept for a few days, and if the frost is in it, it must be thawed hefore being salted. In very cold weather the chill must be taken ofi the salt before it is used. To make

Fig 5
Salt Bor. Fig. 1. Salt bor made from close-gralned wood. Figs. 2-4. Showing how front, back, and sides are dovetailed into each other to svold use of nails. Fig. 5. The parts ready for gluelog together meat red, a little saltpetre should first be rubbed over it.

To salt fish, clean and wash it, then dry it thoroughly and cut it open down the back. Wipe it with a clean cloth, score it, and place
valuable adjuncts to dishes or may form dishes in themselves and help to vary the menu.

To salt food, the dry salt may be rubbed over the surface, or it may be made into liquid brine with water. Salt pork is treated with brine. Fig. 4 also heef and occasionally mutton. The brine often has an admixture of saltpetre, sugar

When meat is plainly salted
a layer of salt on it each side. Keep the salt on it three days, then liang it up to dry or smokeit. Lometimes thespine bone is removed from the fish before salting
Some varieties of green vegetables may be salted and will keep all the winter. The best

Salt Cellar. Two beautitul examples of old silver sale cellars, belonging to the period of George III
vegetables to treat in this fashion are French beans or scarlet runners. The beans must be cut on a dry morning, wiped, and laid in earthenware jars in lnyers with a good sprink. ling of salt between each layer. Let salt cuver the top of them. Secure them from the air and kecp in a cool, dry cellar. See Beef; Pickle; Pork

SALTPETRE. Communly known as nitre or potassium nitrate, faltpetre is a natural product obtained by the lixiviation of earth, where the occurrence is in the form of an efflorescence; purification is effected by crystallization. It is used merlicinally for the treatment of asthma and culds; it is a constituent of some explosives and fireworks, and in chemical fertilizers. Wall or limesaltpetre made by fixation of nitrogen from the air is used as a manure. As a brine, saltpetre is employed in the salting of meat.

## Salts. See Epsom Salts; Saline.

SALTS OF LEMON. This preparation, which is known also as oxalic acid, consists of equal parts of cream of lartar and potassium oxalate. It is ured for cleaning white straw hats, remuving iron stains from linen, and fruit stains and other marks from woollen and silk materials. It is exceedingly poisonous, and should therefore be kept well nut of the reach of children Directions for treatment in cases of poisoning are given under the heading oxalic acid (q.v.).

SALUKI. Of this dog there are two varieties, the rough and the smooth, the former being the more popular. Tbe rough coated hnve feathers on the ears, on the limbs and on the tail, but the smouth dogs are free from this. In height the saluki varies from 24 in . to 28 in . according to the locality of its origin The females are smaller than the males. In general conformation the bread resembles the greyliound. In colour the saluki is either fawn, cream, white, red, grizzle, black and tan or tri-colour. As a breed thev

Saluki. Specimen of this breed of dos which somewhat resembles the greyhound
are very nice dogs, usually aweet tempered, obedient and intelligent

The bead should be long and narrow, the eyes dark or hazel, ears well feathered and also the limbs, whilst the tail should bave a superabundance of feather on it and he carried in the so-called ring-tail fashion.

SALVER. There is no hard or last rulc as to the distinction between a salver and a tray, but in general a salver is regarded as " smaller edition of the tray proper. It is used for carrying a single cup of tea or other drink, and also by a servant for presenting a letter or card. A sniall salver is generally kept for this purpose on the hall table. larger aalver makes a charming addition to the broakfast table when used as a stand for the coffee pot and hot milk jug

Salvers are made of silver and Sheffield plate, as well as of

which is emphasized by the moulded designs and scenic reliefs pressed upon them This ware was supposed to originate in Samos

During the Greco-Roman period the manufacture was taken up by a number of provincial potteries, especially in Gau! and the Rhincland Almost all the so-called Samian ware found in conjunction with RomanoBritish remains was imported from these centres and its production did not survive that period
This eart henware which is more precisely called terra sigillata, is distinguished by its close grained body, sometimes showing traces of having boen turned in the lathe. and displaying, when broken, a light-red fracture all through It is coateduniformly with a thin, tranaparent sealing-wax glaze, which was produced by means of a solution of green vitriol. It is usually specimens date from the 17 th century, but and dishes are gencrally small, and are seldom ones made in the 18th, and having ball and claw feet A great variet $y$ of decoration was used thereon by the $18 t h$ century silversmiths and their successors, these including the gadroon and ornament in the shape of dolphins, masks. shells, scrolls, vine leaves, etc Old salvers of Sheffield plate are usually tinned on the underside See Silver: Trav.

SALVIA. The botanical name of sage, of which there are some splendid ornamental kinds suitable for the greenhouse and for planting out of doors. The purple sage (Salria virgata nemorosa) is the best of the hardy kinds; it is a showy herbaceous perennial, 2-3 ft. high. with violet-purple flowers in July-August. Propagation is by cuttings in a frame in apring. Salvia azurca Pitcherii, 4 ft . high, is a lovoly blue-Howered plant for a warm sheltered border, at its best in late summer.

The scarlet sage (Salvia splendens) is one of the most brilliant of summer bedding Howers, and is invaluable for the greenhouse also. Seedlings raised in a heated greenhouse in January-February will provide plants for putting out of doors early in June, or cuttings can he taken from the old plants in Auguat. and kept safe from frost in winter. Exceptionally fine varieties are Pride of Zurich, Fireball and Harbinger, which should be chosen in preference to the type.

The blue sage (Salvia patens) is a half-bardy tuberous rooted pcrennial easily raised from seeds sown in warmth under glass in February ; the scedlings may be planted out of doors early in June, or grown in pots for greenhouse decoration. In autumn the tubers should be lifted, stored in sand for the winter and started into growth again under glass in spring.

The hardy annual sage called the Clary (Salvia horminum) is raised from secds sown out of doors in September or in April; its heauty lies in the coloured bracts which surround the small Howers. The purple-blue variety named Blue Beard is the hest.

SAL VOLATILE. Aromatic spirit of ammonia, commonly called sal volatile, is a reliable heart stimulant in fainting, shock, etc. It is also sometimes prescribed before meals as a gastric stimulant in chronio indigestion.

SAMIAN WARE. Modern reproductions of the lustrous red terra-cotta fabrics which go by the name of Samian ware are attractive in form, suggesting a classical atmosphere,
found unbroken. See Pottery.
SAMOYEDE. The samoyede dog belongs to the Arctic breeds, sharing in common with the others a foxv head, small, erect ears. a tail

Sampler dating from 1800, with small flgures, birds and trees. ambroidered in coloured silks upon fine canvas. In the centre is the following moral verse: "Virtue the chiefest beauty of the mind, the nobleat ornament of human kind. Virtue our saferuard and our guiding star, that atirs up reason when our senses err"

Samoyede. Breed of white Arctic dog which has
curled over the back, and a close, soft undercoat, through which long harsh hair grows, forming the outer coat. This is usually of a very brilliant white, and is of a texture that does not soil readily. They are smaller than one would expect in dogs that are capable of drawing heavy weights, the males weighing about 50 lb , and bitches about 10 lb less Those who own them find that they are very sociable and well mannered. See Dog; Kennel.
SAMPLER. In its earliest form a sample was a picce of work that exhibita in a smal apace all the stitches and processes of the work which it represents. Calico samplers were provided for tho young in carly Victorian days in order that plain stitchery should be practised.

A sampler of that kind would exhibit plain liemming, hensstitching, back. stitching, gathering and setting into a hand, pleating, tuckrunning, running and felling, buttonholea and sewing on buttons, whipping and setting on a frill, the insertion of a gusset, piping, how to put on a crossway false hem, an ordinary calico patch, how to sew ou a tape, how to make a loop and eyelet hole Featherstitch and French knots as simple forms of decora tion would also be shown.

Docorative sainplers, such as the one illustrated, were worked by old and young from Elizabethan times down to about 1840, aftes which they went out of fashion. Now that such great store is set on period needlework again, old samplers aro being copied and originals are sought in antique shops. Samplers can be turned to charm ing account by being mounted on pole
fire screens, blotters, work bags, etc. On page 177 an excellent idea for a calendar, utilizing a modern sampler in cross-stitch, is illustrated and described. Designs can be obtained in good needlework departments, and those interested in the subject will do well if able to study the examples in the Textiles Department at South Kensington.

Although modern samplers are often worked quickly in cross-stitch, this does not do justice to the beauty possible in these pieces. In a sampler such as the one illustrated a great number of stitches are employed. The proper stitch should be used to form particular objects. Satin-stitch and stemstitch are used for animals and figures, petit point fills in vases and cross-stitch is reserved for trees and the dark portions of the border. All objects illustrated on a sampler are much conventionalized. Some interesting modern samplers have central motifs of motor cars, speedboats, airships and borders introducing modern musical instruments. In one case these subjects were copied from magazine advcrtisements on to fine canvas and con ventionalized in the stitchery. If preserved, such samplers will have a historic interest in years to come, and to-day make amusing needlework pictures when glazed and mounted in narrow black frames.

SANATORIUM. An establishment for the treatment of the sick may be called a sanstorium, though the name is more especially used for places where convalescents or consumptives are treated. Sanatorium treatment of consumption is valuable, not only because patients are under direct supervision in conditions as favourable as possible, but because the patients receive a proper training in looking after themselves. See Consumption

SAND: In Gardening. Sand is an important ingredient of garden soil. Clay land is greatly improved by an occasional application of builder's sand. Silver sand is used in the preparation of potting composts : plant cuttings often form roots better in sand than in soil.

SAND: In Brilding. The three main sources from which sand is obtained for building purposes are pit, river, and seashore. The fine sand is used for plasterer's mortar, the more coarso varietics for ordinary mortar. Its function when mixed with mortar is to produce regular shrinkage of the materials, and also channels for crystallization in setting

Pit sand is the first in quality, and has sharp angular grains. It may contain impurities such as clay, earth, or organic matter. River sand is practically free of impurities, but owing to the action of the water its grains arc not sharp and angular. Sea sand is not to be recommended for building work, especially plastering, because the saline matter it holds attracts any moisture that is in the air. This will result in damp walls, and prove injurious to decorating on them. Sea sand is, however, used for bricklayer's mortar, and is very useful in constructing playing pits for the children. See Brick: Cement ; Mortar.
SANDALWOOD. This is a hard, close grained, yellowish-brown wood. It has a fragrant smell, which increases with age, and when it is burning there is an aromatic odour. Ground into powder, it is used in cosmetics, and an aromatic oil is distilled from it, and used in medicine as an internal disinfectant. As a wood it is used chiefly for small fancy ware, carved articles, finger plates for doors, etc. See Wood.
SANDARAC. Among resins of the lao kind, sandarac is an important substanoe. It is a hard resin of yellowish tinge which melts at a heat of $300^{\circ} \mathrm{F}$. and breaks with a lustrous fracture, exuding from pine trees in North Africa. It is known variously as pine
gum, white pine resin, and gum juniper. It is completely soluble in spirits of wine, and photographic negative varnish, and is also used by book binders and for school blackboards. Being hard, it requires making more elastic by mixing with a West Indian resin known as elemi. This material is much used to soften or toughen varnishes. See Resin ; Shellac.

SANDBAG. Used in repoussé and art metal work, the sandbag is a leather or linen receptacle filled with well-washed silver sand. The linen or canvas covered bag is useful for supporting the pitch block and deadening the noise made by the hammering. The leather bag of 3 in . to 9 in . diameter is made in two shapes, one with a hollow centre, known as a ring, to hold the pitch or cement bowl used in repoussé work and metal chasing. The other, in the form of a round pad, is used for beating out metal to a hollow form. To preserve leather sandbags, the cover should be wiped over with an oily rag. See Repoussé.
Sand Box. See Pounce Pot.
SAND CAKE. A variety of cornflour cake, this is made by sieving ? lb . cornflour, then measuring out 1 oz . of it and mixing it with $1 \frac{1}{2}$ teaspoonfuls baking-powder. Separate the yolks from the whites of 3 eggs, beat up the yolks, and stir half of them into $\frac{1}{\frac{1}{2}} \mathrm{lb}$. castor sugar, previously creamed with 7 oz . margarine. Beat the mixture for 5 min . before adding the remainder of the yolks, continue beating for a fow minutes, and then fold in the larger portion of the cornflour.

Add the whites of egg, whisked to a stiff froth, and also a little lemon or vanilla Havouring; mix the whole thoroughly, and lastly stir in the baking-powder and the remainder of the cornHour. A little milk may be used if necessary. Turn the mixture into a greased cake-tin, lined with greased paper that reaches just above the top of the tin, and bake it in a moderately hot oven for about $\frac{3}{8}$ hour. Then takc it from the tin, carcfully remove the paper from round it, and let the cake cool on a sieve.

SAND GLASS. Sand glasses, which are also known as hour glasses, are used to measure time; for instance, the time needed to boil an egg. See Egg Boiler ; Hour Glass.

SAND MYRTWJ. This dwarf evergreen flowering shrub belongs to the family of heaths, and botanically is known as Ledum. The chief kind is buxifolium, about 6 in. high, with small, glossy leaves and white flowers, being particularly suitable for the rock garden.

Sand myrtle thrives in equal parts of leafmould, peat, and sand, with plenty of moisture at all times. It is planted in spring or autumn, and propagated by layering of shoots in October.

## Sandpaper. See Glass Paper.

SANDSTONE. Consisting of a compactod mass of sand bound together by lime carbonate, iron oxide and silicas, sandstone as a building material is comparatively soft, lending itself easily to delicate architectural decoration. For this reason it is often carved and embellished, frequently in a very elaborate manner. See Stone.

SANDWICE. It is always advisable at a picnic bridge, or informal evening party to have some less well-known but really good sandwiches to introduce to the guests. When estimating quantities it is well to allow two sandwiches per head (where other refreshments are also provided). Three quartern sandwich loaves to 3 lb . butter will make sandwiches for 100 people if the bread is properly cut.

Almost any kind of cold meat or fish can be used for sandwiches, while other savoury fillings include cheese, sliced hard-boiled egge, potted meats, olives and cream cheese, nuts
and salad vegetables. S'weet sandwiches may be filled with jam, honey and banana, lemoncurd, walnuts and stoned raisins. grated chocolate, or honey mixed with chopped nuts.

The bread should be thinly cut and fresb, though not too new, or it will break in the making. A very sharp, long-bladed knife should be used. The filling should be laid on one slice, seasoning added if required, the remaining piece of bread prossed firmly on the top and the edges trimmed. For picnic purposes the crust is often allowed to remain as the sandwiches keep a better shape. For afternoon tea or buffet service the crumb only is left and is cut into square, diamond, or triangular shapes. For bridge parties it is sometimes stamped out with cutters into spade, heart, diamond and club shapes. Plain biscuits, rye biscuits, toast, bridge rolls and brioches are all used for making sandwiches in place of ordinary bread. The first two are good for savoury pastes and crean cheese fillings; thin, hot, toasted brown or white bread is liked for Canadian loaf cheese and for hot bacon sandwiches, while small finger rolls are suitable for any kinds of fillings and brioches for sweet sandwiches. Potted meat or fish paste sandwiches are dainty for tea when the bread used is sufficiently thin and fresh to be rolled.

The bread, biscuit, toast or roll should always be buttered. Butter adds to the food value and prevents juices from the fillings soaking through the sandwich. The butter should be creamed with a wooden spoon before spreading on the uncut loaf. Fillings must not be scanty or the sandwich will be dry and tasteless, but they must not be so lavish that they ooze out. Pack sandwiches for a picnic in waxed paper and wrap wet butter-muslin, or a napkin wrung out in cold water, round the whole until they are required.

Meat Fillings. Meat used for sandwich making should be free from gristle and cut into very thin slices or pieces of convenient size. Ham often improves beef, chicken and tongue. If savoury sandwiches are wanted. either tomato sauce, finely chopped pickle or chutney may be spread over the layers of meat. Seasoning must not be forgotten. All kind of sausages, cut into thin slices and the skins removed, make good fillings. Pate de foie gras is a favourite filling. Doubledecker sandwiches are liked with a layer of chicken and another of finely-chopped salad moistened slightly with mayonnaise and separated by an extra piece of buttered bread. Grated ham may be used with or instead of the chicken, and both will make an excellent filling for a hot, toasted sandwich. The meat is first warmed in a saucepan with a little butter and chopped parsley and then spread on a piece of buttered toast and covered with another piece.

Fish Sandwiches. Cold fish should be Haked and freed from bones. It requires sauce, or cucumber, tomato or lettuce salad to make it tasty. Bloaters, smoked haddocks and kippers make excellent fillings for brown bread sandwiches. Remove the skin and bones and mix with a little anchovy sauce and cayenne. Lobster or crab is good when pounded and mixed with a little thick mayonnaise sauce. Cod's roe with cream and seasoning makes popular sandwiches. l3reak up 3 tablespoonfuls cooked roe, season it with anchovy essence, pepper and a squeeze of lemon-juice and moisten the whole with a tablespoonful of cream. Spread the mixture on thin brown bread-and-butter and form into sand wiches.
Sardine sandwiches can be made in several ways. The fish should be drained from the oil, skin and bone removed and pounded, adding seasoning and a squeeze of lemon-juice. An excellent filling is made by adding the yolk
of a hard-boiled egg. I teaspoonful enchory essence, I dessertspoonful anchovy paste and 1 oz. butter to the sardines, pounding them to n smooth mixture and spreading on brown or white bread-and-hutter.

Egg Sandwiches. The yolks of two hardboiled eggs make a good filling when mixed with anchovy essence, chopped olives, and sufficient cream or creamed butter to bind the ingredients. Another egg sandwich is made of slices of hard-boiled eggs and tomatoes, or the slices of hard-boiled egg may be noistencl with asalal cream and placed between two layers of finely chopped ralad.

Cheese Sandwiches. Cheese may be grated. mixerl with butter and seasoning and spread on a layer of chopped watercress betwoen thin bread-and-butter. Alternatively it may he cut into thin slices, spread with mustard, sprinkled with seasoning and made into andwichcs, with rye crisp breal well buttered and Havoured with ehopperl gherkin.

Crean chese is good mixed with walnuts or other nuts, or with chopped olives. Chopped lettuce or watercress, or finely diced apple and celery with cream checar, may also be used as a filling for thin brown bread-and. butter.

Sweet Sandwiches. Mixed nurs and sweetened whipped ercam make a good filling spread over a thin laver of apricot jain on split, swectened brioches, white or brown buttered finger rolls, or alices of plain cake. Chopjed and stoned dates with pounded almonds and lemon-curd make an unusual sandwich with buttered currant bread. Honey may be substituted for the curd if a sweeter mixture is liked. French plums are excellent with walnuts and creain. Chocolate grated and mixed with whipped cream Havoured with a few drops of vanilla essence may be used hetween thinly s!iced bananas and hread-andbutter, or the grated chocolate with pounded almonds and enough swectened cream to form the mixture into a paste makes an excellent filling for a sandwich of wafer biscuits. Sponge tingers are equally good when put together in pairs with whipped cream and strawberry or apricot jam between.
Sandwich Sets. Practical and decorative sets for sandwich service are obtainable in china, pottery, glass and in a variety of shapes and sizes. The dish for the sandwiches is usually oblong, and plates to match are often square in shape. Small tiered and plated stands to hold several plates of sandwiches are uscful for tea and bridge parties, as they take up less apace on the table.

SANDWICE CAKE. The phrase sandwich cake is usually applied to a light, spongy cake baked in two shallow tins or cut into two after haking, and then spread with jain. Directions for making such a cate will be found under the heading jam sandwich. Cream, chocolate icing and other mixtures are sometimes uscd as a filling instead of jam, the cake being then named accordingly. See Janı Sandwich.

SANDWORT. The prpular name of a group of beautiful low-growing rock-garden plants (Arenaria) which bloom in spring and carly summer. The finest of all are montana and grandiflora, which soon apread if planted in gritty soil in a sunny place and bear a profusion of white flowers.
The Balearic sandwort (Arenaria halcarica) should be planted in light soil at the foot of a shady rock, which it will cover with a veil of delicate leaves and tiny white flowers. Propagation is by secds sown in spring in a frame.
SANITATION: Of the House. The important points about any system of sanita. tion are to see that the refusc of whatever kind is removed completely, rapidly, and continuously, and that it is protected as much as
possible from the outside nir. Methods used in the country where sewers do not exist are called conservancy metlooda, and in towns where sewers and a plentiful water-supply exist, the water carriage system is used. In both of these systenis waste waters and excretal refuse have to be removed.
Conservancy Methods. Dealing first with conservancy methods, the old types known as privy middens and privics are thoroughly insanitary and should be abolished as the material is never completely or rapilly removed, and is not protected from flies, etc. Earth closets and pail closets are less objectionable and can be made reasonably sanitary if emptied frequently, at least twice a week, and kept scrupulously clean. The material should be dug into trenches well awny from the house or any sounce of water supply, and should be covered with at least four inches of earth.
lath and washing water should not be allowed to run into the nearest ditch, where it may gire rise to a nuisance, but should be run through a serics of porous drains at a depth of about 6 in. helow the ground. This is better than running it on the surface of the soil. At the house end of the pipes a grid should be fixed to strain off large particlea, which might clog the pipes if left undisturbed.
Cesspools should be connected with the housc in the same way as a sewer. They should be placed at a safe distance from the house or water supply, and must be ventilated, and constructed so as to be watertight. Perindic removal of the contents of the cesspool is neccasary if the water supply of the house is small. If taking the waste water of the house also, the overflow pipe may lead the sewage either under apecially prepared land or on to a proper filter-bed, but care must always he taken that the water supply is safeguarded.
Water Carriage System. Coming next to the water carriage system, this is the ideal method, as refuse is carried away completely, and rapidly by a flow of water. The main drain is partly below and partly above ground. The latter part is called the soil-pipe and is carried well ahove the roof of the house and coverod by a wire cage to prevent binls from building nests and blocking it; the open top allows air to circulate through the drainage system. Into the soil pipe open the discharge pipes for water closcts, slop sinks and urinals, all of which have a proper trap, with an adequate seal of water to prevent drain gases getting back into the house.

Baths, washing and kitchen sinks must also have a trap, but they discharge into a pipe on the side of the house, distinct from the soil pipe, and then into a gully. This gully is again trapped before discharging into the main drain. Rain water sometimes has a pipe to itself discharging into a gully. The different discharges finally reach the drain and then pass through a final trap before entering the sewer, so preventing sewer-gas from entering the house drain.
The householder can always obtain the help of a sanitary inspector from the health office of the local authority, and would be well advised always to have a thorough inspection undertaken bcfore entering a house. In particular is it necessary to have the drains tested by a competent inspector.
The matters that the householder himself can decide are to sce that all sanitary appliances are made of smooth, impermeable material : that the water closet is of good type: that the flush is adequate; that the traps are sound, actually contain water and are not blocked; that outside and inside pipes and taps do not leak and are of sound material, and that lavatories are well-ventilated and in the right position. The sanitation of a house requires considerable supervision. All appliances, and water-closets in particular, must be
kept clean. The pan of the latter can be cleansed at intervals with a rag moistened with spirits of salt. or by using one of the powiler preparations advertised. If an accessible trap geta blocked it may be cleared by unscrewing the stopper which is at the hottom of the trap: but this is only possible with the traps of sinks, basins, and baths.
The kitchen sink and its trap can usually be lept clean by pouring down it every week a pailful of boiling water containing $\frac{\mathrm{lb}}{\mathrm{l}}$. of soda. A smell in a sink can lie removed by pouring in a pailful of hot water containing a tablespoonful of permanganate of potash and allowing it to stand for a coulple of hours. Grids over gullies and pipe heads must be kept clear of leares and dehris. Gullies in the open must be cleansed regularly, and in summer when the water in the acal may evaporate, they should be llushed with water.
The Chemical Closet. This closet uses exactly the opposite principle to the dry carth closet ; reliance is placed upon liquid chemicals for the inmediato sterilization and the disintegration of sewago and paper, an as to produce an inoffensive liquid.

There are two kinds generally in use the portable and the permanent. The former consista of a ventilation chamber through which an air draught carrics any chemical fumes to the outlet pipe at the back of the seat. The inner containor is provided for the reception of urine and excreta. For operation in this case, a charge of 1 pint of chemical is added to I gallon of water and placed in the container. The matter entering the container becones deodorized and sterilized. When full the contents may be disposed of in a similar way to that employed in the earth closet. The sewnge may, however, be used as a manure after it has been mixed with alacked lime, decaycd vegetation, and earth. This type of chemical closet is largely used in motor coaches, acroplanes, small cottages, etc.

The second tupe is for buildings of a more permanent character where no sewers exist. An underground tank is provided into which the closets empty direct. When the tank is full, the contenta are disposel of by opening an outlet valve which lets the contents discharge into a sonkiaway, where it percolates into the earth. Should the soil not be suitable (e.g. clay), then an ordinary cesspool is used from which the contents are discharged over the eartli. or it may be carried awny to any convenient place for disposal. See (iesspool; Drains: Earth Closet: Pipe: Septic Tank: Water Closet, cte.

SANTOLINA. The botanical name of $n$ group of hand $y$ shrubs with fragrant leaves and daisy-like llowers in summer: they grow 18-i4 in. high, thrive in ordinary well-drained soil, and make attractive low hedgos, or may

Santolina. Soft downy foliage of the species
be planted in the rock garden. The chief kinds are the grey-leaved. yellow-flowered Santolina clamaccyparissus and the greenieaved, white-llowered viridis. Propagation is by cuttings in a frame in late summer.

Saponaria. See Soapwort.
SAPPHIRE. Sapphires are found in almost every shate of blue. In some specimens a blueviolet tint is seen, in others cornflower blue. The lnst named are the most highly prized. Large sapphires are generally cheaper than rubies of the same size, but a Hawless sapphire of a deep shade always commands a high price. The value of the gem is best judged at night, hecause the cheaper stones lose their blueness, and some of them appear almost black in nrtificial light: but good stones retain their colour.
Rings, brooches, pendants, and bracelets are all set with sapphires. Diamonds are almost invariably used with them, for the intense blucness of the sapphire accentuates the whiteness of diamonds by contrast.
Stones that are sometimes confused with sapphires include the blue tourmaline and the bluc topnz. These, of course, are inferior gems, and usually may be detected by their light. ness. They are also softer than the genuine stone, and are therefore more easily seratched. Sce Diainonds: Jewelry.

SAPWOOD. The wood of very young trees, known as anpwoonl, is gencrally light in colour and porous. In some trecs the colour changes very little indeed as the tree grows older and such are called sapwood trees. They are found in Great Britain among the sycamores, breches, and hollies.
Although sapwood may be regarded as imperfect timher, there are onc or two cases in which its value is considerable, exceeding that of heartwood or wood that is completely mature. For instance, the sapwood of the hickory has a greater value for handles and the like than the henrtwood. Many of the American woods are noted for their abundant sapwood, notably the satin walnut, the lohlolly pine and the basswood. See Wood.

SARDINE. Among the cheap varictics of the so-called preserved sardincs, sprats, very small herrings, brisling or pilchards are substituted for the real fish. Nonc of these, however, possesses the delicate Havour of the true sardine, which is caught off the cossts of Brittany and Sardinia from June to the middle of October, and is, ns a genernl rule, preserved in oil or tomato mauce and exported.
Sardincs are useful as a savoury. also for serving as hors d'ocuvres and in salads. Sardine nustard, which is employed to give a zest to fish dishes and also for spreading on savoury biscuits, is made by pounding the sardines and mixing with hard-hoiled egga, chopped shallot, dry mustard, oil and scasoning.

A good way of preparing sardines consists of cutting the tails from a small tinful of these lish, removing the hones and then Haking the Hesh into small pieces. Melt 3 oz . butter in a saucepan, add la oz. llour, mixing it well in, and then pour in gradually $1 \ddagger$ pints white stock, stirring all the time until the mixture boils
Then cook it slowly for a few minutes, add to it the flaked fish, a teacupful of breadcrumbs, a little of the oil from the tin, 3 teaspoonfuls tomato sauce, a squceze of lemon juice, and salt and cayenne to taste. Mix all thesc ingredients together, then turn them into a small pie-dish, sprinkle the top with browned crumbs and reheat in the oven.

Fried and devilled sardines make another good dish. The fish should be split open, honed, and folded together again, then sprinkled with dry mustard, cayenne, salt and lemon juice and allowed to stand for about 15 min . They should then be fried in a sauté pan in their own oil and served on crouttons of
fried bread. Another method of frving sardincs
is to skin them, dip them in batter, and then cook them in a pan of smoking hot fat. Serve garnished with parsley.

To grill sardines. drain them from their oil, cont them with sicped llour, and then cooks them hefore a clear tire or beneath a gas griller for 4 or 5 min . Serve them inmediately with a plate of brown bread and butter, garnishing them with lemon. Sardinc egg.s can be made in the same way ns anchovy eggs, substituting sardines for anchovies.
To make n sardine omelette add 3 or 4 chopped sardines and a teaspoonful anchovy essence to a plain omelctte mixture and cook as deseribed under omelette.

A nother savoury can be made by removing the hones and skins from eight sardines. Then take some thin slices of brow"l bread, butter them, and cut them into lingors, each rather larger thun a sardine. Place cach sardinc between iwo of theso fingers, press thein together, and fry a golden brown in hot fat.
To prepare rardine toast, remove the heads and tails from 4 sardines, split the lish open, and take out the backhonc. Then lny the halves together rgain, hent them in the oven, and place on tinger-shaped picces of hot huttered toast.

Keep them hot, and in the meantime melt $\frac{1}{2}$ oz. butter in a small sauccpan, add to it 3 yolks and 1 white of egg whisked together, 3 teaspoonfuls vinegar, and a little salt and cayenne. Whisk this mixture over a slow fire unt! 1 it becomes thick and creamy ; take care that it does not hoil, or the eggs will curdle.

## Sash Windows: Renewing the Cords

## Practical Instructions for Carrying out Repairs

With the sid of the illustrations and directions tere given, the amatcur mecianic will be
ab!c to keep his sashes and cords in order. See also Burglary; Casement: Glass; Window

A sash window is a type of opening and closing window in which the upper and lower windows are weighted to facilitate their movement in an upward or downward direction. The window is halanced by means of heavy iron or lead weights, arranged to move up or down in a well in the framework. Two such weights are usel to cach moving window, being arranged onc on cither side of it. The weights are connected to the window with sash cords, which passover grooved pulleys sunk llush with the framework. The pulleys are placed at the extreme top of the framework.

In modern work both upper and lower sashes are movable, hut in some of the o!d designs only the loottom sish is arranged to move. consequently the ventilation of the room sulfers.

The sashes are arranged in the frame so that they pass cach other as they are raised or lowered. They alide in grooves formed by the casings of the frame, and are suspended on sash cord. Although betwern the sashes there is a parting slip, the centre rails of the sashes are arranged so that they meet, and they are splayed so as to form a good fit in order to prevent then rattling. and to make them wind and water tight. It is on the centre rail that the fastening is fixed in order to keep the window closed.

The sash cord is attached to the window by means of 1 in . wire nails hammered through the cord. An alternative method to this employs a screw and washer which is turned home at the end of the cord. A circular recess is usually made in the side of the winclow in which this screw is placed. Two common methods are used for the attachment of the cord to the weight. One has a loop threaded through an eye in the top of the weight, the frec end of which is hound to the length of the cord with fine string. The other method simply has a knot tied at the end of the cord after it has lieen passed through the cye in the weight.

Pour it over the sardines, sprinkle with chopped parsley and red pepper, and serve. Sardincs and tomntoes on toast may be prepared in the same way, cxcept that a little mashed tomato is sprend over the toast hefore the sardine and the egg mixture are added. See Hors d'Ocurres; Omelette; Sindwich.

SARDONYX. This is a particularly heautifu! variety of onys, composed of alternate layers of white or light-coloured chalecdony and rich. orange-brown cornclian. See Onyx.

SARSAPARILLA. The dried root of a tree imported from Central Imerica, and known as .Iamaicn sarsaparilla, has been used medicinally, but it is not now included as a remedy in the British l'harmacoporia. In the dried form it would appear to have no medicinal properties.

Sarsaparilla is a common ingredient of manv tonics and blood purifying mixtures, in which other drugs arn included. Common preparations are: The liquid extract of sarsnparilla. dose, 2 to 4 lluid drams: the concentraterd compound solution of sarsaparilla, dose, 2 to $s$ tluid drams. The drug is in no ciremmstances prescribed by itself. Pron. Sir"sa-pa-ril'a.
SARSENET. The name has to a large extent droppied out of usc, locanse oldfashioned sarsenet has been superseded by Jap silk, white, black. or coloured. The material is a plain, thin, and rather shiny silk. Sarsenct ribbon is suitable for making soft binding for the edges of dress seams, perambulator rugs, cot blanticts, and so on.

Where this sccond inethod of construction is cmployed care must be taken to prevent any free eird of cord from fouling the movement of the weight. The weights used for window sashes are extremely long and thin, in order that they may slile in the small space in the frame allotted to them.

Repairing the Sash Cord. It sometimes happens that a sash cord breaks nfter the windows have been in use for some time; consequently the balance weight will fall, and the sashes will he hard to move. It is not a difficult matter, however, to replace a hroken sash cord, and the process is clearly shown in the photographs on the next page.
ligs. 2 to 10 illustrate the renewal of the cords in top and bottom sashes of the double window frame, shown at Fig. 1. Procectling with the lower window first, it should he raised some distance, and if it shows any tendency to drop down, it should be kept up with a atick of wood. In the majority of cases this precaution is not necessary, as the defective sash usually jams readily.
The head at the bottom of the window frame is removed with a chiscl. The tool should he placed as nearly as possible under the nails holding the bead down. To prevent damage to the paintwork the point of a knife should be used to hreak the joint hetween bead and sill before prizing up the bead.

Onc of the side beads is next removed, when the lower sash may be swung clear, and the broken cord removed from the frame. The fitting of the new sash cord is carried out as detailed below for the top sash.

In enses where it is only necessary to repair the top sash. the bottom sash must also be removed, this being done lirst (Fig. 2). When detaching the cord, take care that it does not conce away suddenly. as if that should happen the weight would drop, pull the cord right through the pulley, and be lost inside. When

or a " mouse " is used with u length of atring. to one exact length to cut the new cord repuires mouse end which the cord is attaohed. The careful consideration. If it is not long enough, is a long. thin leaslen weight, small the weight will be drawn to the top beiore the enough to pass over the groove in the pulley. window is closed. in the case of the bottom snsh. and having a loop at one end for the attach. If the cord is too long a top sash will not close, ment of the string. The other end of the string owing to the weight baving already reached is securely fratened to the new cond. The the bottom. The best plan is to make a rough mouse is pushed over the pulley and drops measurement of the length of the cord tacked down into the weight box, carrying with it the to the sash, and to mark this length downward string. Fig. 7 illustrates the use of a picce of chain for the purpose.

Having pulled the cord through to the hole from which the weight was withdrawn, this end of the cord is joined to the weight. In Fig. 8 the inethod adopted is to bind over the frec end of the cord with strong string. The the sash desig free end of the new cord is left hanging while on with 1 in . wire nails. During this operation the old cord is removed from the sash. This it is important to sec that the end of the cord latter operation is performed with a small cold is carefully tucked out of the way, na it may chisel and a hammer, as shown in Fig. 9 below. sulisequently cause trouble by jamming if left. loose. A nail or two at the very end of the cord will obviate any possibility of trouble in this direction. Wherc new ansh cords are fitted oll both sides of the sash they must lie of the samo length.

The replacement of the sashes will not present any difficultiea, as the operations are the reverse to the dismantling processes. In $\Omega$ double window, as shown in lig. I, one sash should be finished hefore tackling a similar window on the other side in order to avoid confusing the beads or even the sashes. The depressions mado by the nails in the fillets may be filled in with putty, which is brought up lorel with the woodwork. If the work is carcfully done a coat of paint will hide any trace of removal or replacement. While the new cord is out it is a good jlan to rub it over with linsced oil.

SASH CRAMP. This is a tool used by woodworkers for cramping up a frainework of consiclerable size All patterns comprise a stiff inetal bar having one adjustable jaw, which can be moved along the length of the bar and secured by a tapered peg or wedge. The fixed head comprises a clamp serew, which forces a movable head along the har.

The work to the oramped is placed between the jawsand tho movable jaw secured by the pin on the side of the framework. The screw is rotated and pressure brought to bear upon the fraine by means of the wliding head Generally, two of these cramps are needed for a frame, so that equal pressure may be excrted on each end.
the cord is nearly off it should be finally removed by hand, and a knot tied in it to prevent any riak of losing the end.

Removing the Top Sash. The top sash may now be removed, as in Fig. 3, by prizing away the parting slip. Fig. 4 shows the sash taken out. with the broken cord. An opening at the bottom of the frame is normally covered by a fillet. which has to the removed, but is frequently difficult to find owing to its being covered with paint. A few taps with the hammer will crack the joints, when it may be removed, as in Fig. 5. The weight is disclosed behind this partition, and is then removed, as indicated in Fig. 6.

In order to fit the new cord n length of a more flexible material is first run over the pulley and down the space inside. A piece of chain

Sash. Fig. 1. Set of double windows of which the sashes are to te repaired. Fig. 2. Removing lower sash from framework. Fig. 3. Removing parting slip, after which top sash may be swung out of frame. Fig. 4. Showing broken sash cord. Fig. 5. Removing fllet in frame to give access to weight pocket. Fig. W. Weight being removed from pocket. Fig. 7. Chain being used to run new cord over pulley. Fig. 8. Method of attaching new cord to weight. Fig. 9. Removing old cord with bammer and cold chisel. Fig. 10. Fizing new cord to sash with nails

Sash Tood. A alyecial type of hrush known 9s a sosh tool is ndapted for puinting the eashes of windows. See Print.

SASSAFRAS. Tlie dried root of the sRasnffras tree contains a volatile oil which gives it an astringent aromatic tnate. Sksmafras is practically never used internally oxcept as an ingredient of the concentrated compound solution of sarsaparilla. Tise oil is used to destroy lice and nits. which it does very effectively. It is also used in the treatment of ringworm.
A few chips of massafras or woud added to ordinary tea are said to have a beneficial result if taken by persons suffering from rheumatism. Sassafras lcaves abound in mucilugc. and can be used for thickening soups.

SATEEN. Cheap satin that is balf silk and half cotton is often called sateen to listinguish it from the more expensive al!-silk satin. Cottons made with a satiny face and used principally for linings are called sateens. They show a more or less finc, round twill. They are dyed in a variety of colours, and are also obtainable patterned. Close-woven cotton sateens are suitable for covering down quilta, and the best are exceptionally close-textured, and sold as down proof. implying that the feathers will not work their way through.

SATIN. This fahric has a shiny aurface, with a short nap which hicles the thread structure more or less completely. Pure silk satin drapes better and is softer to the touch than either cotton backed or artiticial silk satin. The last kind is most useful us a furnishing fabric.

Wool back satin is chietly used for dressing gowns and for frocks and coats for small children.

SATIN FLOWER. The satin llower is a hardy perennial plant, excellent for small herbaccous borders, hernuse of its neat habit,

Satin Flower. Delicate blue flowers and spiky leaves of Sisyrinchlom Bermudianum
graceful growth, and briglit flowers. It has narrow leaves and thickened rootatocks
The best known species is Sisyrinchinm grandiforum, with purple or mauve flowers in spring : height about 1 ft .
The white form, album, makes charming clumps in the herbaceous border, and is also suitable for the rockery. S. angustifolium, with narrow leaves, and pale blue flowers in summer, and Bermudianum, blue, is also worth growing.
Satin fower does well in loam with a liberal admixture of leaf-mould and sand. Propagation is by seed and by division in spring.

SATIN WALNUT. This is the name given to thio wood of the sweet gum, a common tree in the swampy purts of the lower Mississippi rallcy, where it grows to n large size ; it is also found in most parts of the United States. The tree is similar in appearance to the maple, but it exules a liquid known as red gam or liquid. ambur. When cut the timber is of a brown shade, varied at times and occasion. nlly markedwith black ätripes.

On account of its even straight texture and the widths in which it can bo obtained (up to 18 in . with an average of 14 in .), it is a useful wood for the amateur. It is used for furniture making, fretwork, and wood-turning; it is easy to work, takes a goon polish, stains well and forms strong glued joints. The wood is liable to warp and twist. but with proper scasoning this can be reduced to a minimum. In working satin walnut, it is advisable to cut up the material some time before it is planed. but the wood should be kept in a warm room and not allowed to get damp. Satin walnut can be used for carving on account of and even grain. It is also made up in the form of plywood. See Plywood; Walnut; Wood.

SATINWOOD. The varieties of satinwood are named after the part of the world from which they come. Satinwood is used as a veneer, for small cahinets, in fretwork and inlaying, and for the backs of hair brushes and other fancy articles. In colour it is light orange, and has a close, smooth grain with a lustrous, mottled and sntiny surface, and $n$ transparrnt appearance.

Satinwood works well, but takes glue rather badly, owing to the dense nature of the wood : it polishes well, and a fine finish can be obtained on it. Adam, Hepplewhite and Sheraton used the wood freely, but. owing probably to its acarcity, in small quantities. It was employed in conjunction with mahog. any and fancy woods of all kinds, such as amhoyna, tulip wood, and purplewnod. Designs were often painted on satinwood pieces. When

Satsuma Ware. Vase in modern white Satsuma ware with crackled uriace and slightly raised design
the satinwood is carefully selected its beautiful marking or grain requires little or mo decoration beyond a handing or hinrder of mahogany. See Inlaying: Marquetry; Pier Table; Shera ton; Veneer; Wood.
SATSUMA WARE This is the highest class of Japanese pottery, and as the name is freely applied to the productions of other factories, as well as to modern counterfeits, the utmost caution is needed in the purchase of pieces o named.
Some Satsuma warc has an ivory gleam with lowtoned pigments, and minute jencillings in gold. Another type was produced in pure white, with a net work of lines in the glazo surpassing the intricacy of Chinese crackle. Some redclay bodies were decorated with yellow or black monochromes, especially for incense boxes and tea jars. Others were coated with metallic llambé glazes, dis. playing reds and violets, and other combinations resembling shot silk. A class of faience producer during the 19 th century is decoratcd with opulent enamelled colours and gold. s often vellumlike. or has coloured glazes. The genuine warc, which is never porcelain, s sometimes claimed to go back to the 16 th century. It may be recognized often by thic string mark on the base, showing where the picce was detached from the wheel, and also hy the fact that the spirals in the paste turn from left to right, because the wheel was rotated by the Satsuma potters with the left foot

The pieces were always small. Some of the hetter examples of modern Sutsuma are producerl in the studios at Kobe and Tokyo, and are highly prized by connoisseurs. These picees are not to be confused with the regular industry which has existed for many years in Yokoliama, Kyoto, Awata, and other pottery centres in Japan, engaged in fabricating for export modern pieces of so caller Satauma. They can be readily detected by their poor workmanship, their coarse decoration. gilding, large size, and their yellowish tinge. See Pottery.
SaUCE MAKING

## Recipes for Piquant, Savoury, Sweet and Store Sauces

Fpom these foundations most sauces can be made by adding different Havourings and seasonings. Sec also Apple ; Brandy; Bread; Cranberry; Espapnole; Hollandoise; Horseradish; Ma,tre d'H8iel ; and Mint Sauces. In connexion with the Store Sauces, the entries Apple; Chutney ; Ketchup; Pickle; Soy; Vinegar, should be consulted

Sauces, savoury and sweet, are the liquid should never he used in place of butter, as it is accompaniments to meat, fish, poultry, too oily and does not mix smoothly with thic vegetables: sweet puddings and dessert. flour. The flour must be a good white, The savoury sances differ from gravy in that especially for a white sauce, otherwise it wil gravy is the juice extracted from the food be a dirty, unappetizing colour. It must br cooked, sonietimes thickened with a little quite dry and free from lumps. flour, whilat sance is a mixture of thickened Care must be taken not to overcook the fat, stock or milk and fat, with scasonings adderl.

There are numerons sauces to serve with all cooked foods, but with the exception of the few which have for their bascs oil, wine or vinegar, or fruit (viz. mayonnaise, Hollandaisc or mint sauces; npple, cranberry, gooseberry, etc.), they are all variations of two standard foundation sauces-brown and white sauces.

For successful sauce maling it is necessary to use the very best ingredients. Margarine
as this will spoil the Havour and cause globules of oil to rest on the sauce; it will also he indigestible. The flour must always be hlended smoothly with the fat before any liquid is arded. Flour must be thoroughly cooked. otherwise the sauce will have a rough, raw taste. All sauces containing flour should lie cooked at least five minutes after adding the liquid. For savoury sauces at lenst half the liquid added must consist of brown or white
atock. Care and judgement must be used in scasonings. Too much will destroy the distinctive llavour of the sauce; too little will make it insipid. The best rule is to taste it during the making.

White and Brown Roux. A white or brown roux is the thiokening for white or brown sauces. The roux consista of the first mixing of the flour with the fat. In white roux care must be taken not to cook the flour until it browns; in brown roux the fat and llour are cooked until they turn brown. There are other liaisons, or thickenings, for sauces, such as eggs, arrowroot or cornilour mixed with water, or a blend of raw butter and flour, but for standard foundation sauces white or brown roux is generally used.

When sauce is frequently required it is a great saving of time to kecp a quantity of white and brown roux ready made. It will keep for weeks if tightly covercd. A heaped-up tableapoonful of roux will thicken a pint of liquid. The roux when wanted should be alightly heated by the side of the fire, and the heated liquid added slowly, stirring until boiling.

To make white rous to thicken half a pint of liquid weigh 1 oz. Hour and 1 oz. butter. Melt the butter in a thick saucepan, and then stir in the llour very gradually. Let it cook for several minutes, stirring all the time, until it becomos a smooth crcanny paste, but be careful it does not change colour.

Brown roux is made in exactly the same way except that it is cooked longer to brow" the flour, and to hasten this the lieat may he increased, though it will need constant watching and stirring. When time is short the Hour can be browned first in the oven, but as it hurns very quickly it nust be carefully watched and turned over to brown evenly. If the roux is for immediate use, the liquid (milk, or milk and water: atock, or atock and water) is added at this stango. Then it is only necessary to ald the seasonings and llavourings to achieve the particular sance you wish to make. All nalles are amnother if strained through a tine pointed strainer, or tammy cloth, unless they contain paraley. capery, or other aolid ingiedients that must he kept in

Unless sances are served immediately they arc apt to go lumpy, atiff, or form a skin on top. To prevent this, and nlso to keep the auce hot, the sauceprall containing it should he atood in a larger pan containing hot water to come half-way up the saucepan. The snuce should be covered with a lid, and if it is a thick sauce a little piece of butter, or a spoonful of the liquid from which it is made, placed on top of it. This prevents a skin forming, and can he stirred into the sauce before serving. If a bain-maric is available, it is the best means of keeping the sance hot
Foundation White Sauce. After making the white roux as already Ilescribed, add slowly $\frac{1}{2}$ pint liquid (milk or mixture of milk and water: white stock or fish stock and water). Stir until hoiling and cook for live minutes, add salt and pepper to taste, and use.

From this foundation saluce can be made Anchory, Parsley, and Caper sauces. (Sce entrics under separate headings in this work.) Also, Onion sauce ( 2 large onions, hoiled, drained and chopped, added to $\frac{1}{\frac{1}{2}}$ pint white sauce) ; Egg sauce ( 1 hard-boiled egg. chopped, adderl to $\underset{\perp}{\underline{1}}$ pint white sauce); Mustard sauce (2 teaspoonfuls dry mustard added with flour when making sauce); Checse sauce (2 oz. grated checse added to $\frac{1}{2}$ pint sance); Celery sance (add 1 small cooked and chopped head of celery to pint sauce). When white sauce is to he used for fish it should be made from fish stock, or half fish stock and milk.
Béchamel Sauce. This is $n$ rich white foundation anuce. To make it, take $\frac{1}{2}$ pint milk or equal parts milk and white atock, or fish stock, 1 oz . butter, 1 oz . flour 1 table-
spoonful cream, a small carrot and same quantity of turnip, 1 small onion stuck with cloves, $a$ few spriga of parsley and a bay leaf, salt and pepper.

Make the roux with butter and lour. Put milk in a saucepan with prepared vegetables, paraley and bay leaf, and simmer 15 minutes. Then strain, and add liquid gradually to the roux, stirring all the time until boiling. Cook for five minutes more, scason well and strain. Re-heat and add creain, and use as required. Use fish stock if for fish.

Melted Butter Sauce. This must not lie confused with white sauce. It is a sauce in which butter is the chief ingreslient, and is served with salmon or ot her choice fish, and with some vegetables. To make it, put into a small saucepan 1 oz . butter, melt it and add 1 oz . Hour slowly, then add a teacupful water and the juice of a lemon. Season with salt and pepper and cook for nnother five minutes. stirring all the time, then culd a little grated nutnieg and 3 oz . more butter. Stir until the butter is melted, but do not boil sgain. Milk should never be added to melted butter.

Allemande or Yellow Sauce. Half pint Béchamel sauce, yolks of two iggs, 1 tablesponnful crenm, I teaspoonful lemon juice. pinch nutmeg. Mix the egg yolks and cream together and mix into the Bechanel sance. away from the hent. Re-heat without boiling, then add the lemon juice and nutmeg Stir well and serve.

Bearnaise Sauce. Hall pint Béchnmel suluce, 2 tablespoonfuls vinegar, 2 finelvchopped shallots, $1 \frac{1}{2}$ oz. butter. 2 egg yolks, 1! tablespoonfuls stock.

Put vinegar in a small saucopan, add shallota and hoil until vinegar is reduced to half Stir in the hot Béchamel sauce. Beat up the egg yolks with the stock, and strain into the sauce. Whisk over gentle hent until well blended, but do not boil. Reinove from heat and mix in the butter a small piece at a time. Season and pour through a strainer Do not re-lient after adding the hutter as it will curdle.

Soubise Sauce. Half pint Réchamel sauce, 4 onions. boiled, well-drained and chopped, 2 tableapoonfula cream. Mix all well together and re-heat slowly.

Tomato Sauce. Half pound tomatoes. $\frac{1}{2}$ pint Bechamel sauce, pinch sugar. Bake the tomntoes in a gentle oven until soft, rub through a sieve and add the pulp to the hot Béchamel sauce. Add about half a teaspoonful sugar, stir well and re-heat.

Velouté Sauce. Half pint Béchamel sauce, I teaspoonful lemon juice, hay leaf, 4 peppercomis, I tablespoonful crean. Simmer the Béchamel sance with the hiny lenf and peppercorns for 10 minutes, strain and return to the pan to re-heat. Add the lemon juice and atir in the cream, re-hent, but do not boil.

Shrimp, Oyster. Lohster and Crab sance are made from veloutce sauce miade with fish stock. Add 6 chopped oysters, or 2 oz. chopped lobster or crah, or a gill of pioked and chopped shrimps to $\frac{1}{2}$ pint velouté sauce, as required A little lobster hutter added to lobster sauce is an improvement. (See Lolister.)

Foundation Brown Sauce. This is the groundwork for many savoury sauces. Take 1 oz . butter, $1 \frac{1}{2} \mathrm{oz}$. flour. $\frac{1}{2}$ pint hrown atock, I small onion, piece of oarrot and turnip scasoning.

Make the brown roux as described. Fry onion lightly and add to roux. Add stock away from heat, then add the chopped vegetables and seasoning. simmer for half an hour, then strain and make thoroughly hot to serve.

Chasseur Sauce. This rich brown sauce. served with venison, is made by boiling together $\frac{1}{2}$ pint brown sauce with I gill port wine, 2 oz . red currant jelly, I oz glaze, a squeeze of lemon juiceand a dash of cayenne. When liquid is reduced to $\frac{1}{2}$ pint, strain and serve.

Chestnut Sauce. This is made by adding $\frac{1}{\text { pint blanched, boiled and mashed cheatnuta }}$ to $\frac{1}{2}$ pint hrown sauce. Mix smoothly and make thoroughly hot before serving.

Piquant Sauce. Eapagnole (q v.) or brown nauce forms the foundation of this sauce. Sinmer together 1 gill vinegar, I dessertspoonful chopped onion or sliallot, 2 tablespoonfuls each chopped capers and gherkins. When the onion is tender, and the vinegar reduced to about half its original quantity, pour in 1 pint Espagnole sauce, boil up, and If necessary add noore seasoning. Just before serving stir in 1 tablespoonful chopped pursley.

Genevoise Sauce. This is a rich lorown fish sauce Idd 1 glass Madeira or sherry, and a few drops ench of garlic vinegar, lemon juice. and anchovy easence to I pint Espagnole sance Re-heat the sance, season it, and at the last moment whisk in $\frac{1}{2}$ oz. fresh butter, adding it in small fragments. Do not let the sauce re-boil.

Mushroom Sauce. Add $\& \mathrm{lb}$. Button mush. rooms tossed in hot hutter to $\underset{d}{d}$ pint Espagnole or brown sauce.

Reform Sauce. To make it, take 1 pint Espagnole sauce, $\frac{1}{2}$ gill vinegar, 12 peppercorns, I teasponnful red currant jelly, $1 \frac{1}{2}$ gills port wine or claret, cayenne pepper. Add peppercorns to vinegar, and boil until reduced to half quantity. Stir in jelly, wine and a few grains cryenne. Cook slowly for 10 minutes, add Espagnole sauce strain. re-heat and use

Sweet Sauces. There is a great variety of sweet sauces to he rerved with hoiled, steanied oi haked puddings, etc. Those most in everyday usc are custard saluce (aee Custard) and sweet white sauce, which is an ordinary white foundation smuce sweetened with 2 teasponnfuls sugar to the pint.

Jlam sauce is made by hoiling together 2 tablespoonfuls jam, it pint water, and a few drops lemon juice until reduced to twothirds. Strain and serve. Marmalade aauce is made in the same way, omitting the lemon juice. Fruit sauces though classed as sweet are often served with nieat and fish: e.g. spple sance. cranherry sauce with pork and turkej, and green gooseberry sauce with boiled mackerel. Treacle sauce is made by hoiling togetlier 2 tablespoonfuls syrup or treacle I gill water, 1 teas noonful lemon juice. until reduced to two-thirds. Thicken with I teaspoonful cornflour. For lemon asuce ald a tableapoonful loaf sugar to a breakfastcupful boiling water, having first rubbed two lumps over the rind of a lemon. Mix a desscrtapoonful cornflour with a little cold water, and atir into the sugar and water Bring to the boil, stirring all the time. Add the juice of a lemon, stir well, and serve. Orange sance is made in the same way, using half the quantity of sugar

Gooseberry Sauce. Top, tail, and wash a pint green gooseberries, and put them in a pan with a gill of water. Simmer until fruit is soft, rub through a sieve and put into a clean pan Add I oz. butter, 2 oz. sugar, a pinch grated nutmeg, and re-heat. A few drope of green colouring may be added.

Chocolate Sauce. 'I'wo ounces grated ehocolate, 1 oz . castor sugar, teaspuonful vanilla essence, $\frac{1}{d}$ pint water, 2 teas poonfuls cornflour. Boil sugnr, water and chocolate together for a few minutes. Blend cornflour with a little water and add to chocolate mixture. Stir until hoiling, add vanilla, and use.

Hard Sauce. A quarter pound fresh butter, 6 sweet almonds, 2 bitter almonds, 2 oz . castor sugar, 1 tablespoonful sherry, $\frac{1}{2}$ ta bles poonful brandy. Blanch, chop and pound the alinonds to a smooth paste. Cream the butter and sugar, add the almonds. Add the sherry and brandy, mix well and serve hot.

Store Sauces. Hesides the savoury and sweet sauces that are made for immediato use there are a number of piquant sauces or relishes
that can be stored to use for cold meat, fish poultry, etc. All these take a long time to make, and great care and patience are needed. The best ingredients must always be used

Harvey Sauce. One quart best vinegar, 3 or 4 anchovies, 1 tablespoonful soy (Indian or Japanese soy can be bought ready prepared for use), 1 tahlespoonful walnut ketchup, a grated sliallot, a grated clove or garlic, $\frac{1}{4}$ oz. cayenne, few drops cochineal Place all the ingredients in a wide-necked, unglazed jar. and cover closely. Let it stand for 14 days, stirring it once a day. Then strain off into hottles, cork well, and store in a cool place.

Tomato Sauce for Bottling. Bake as many tomatoes as are available in a slow oven until soft. Then rub through a sieve and measure the pulp, and to every quart allow 1 pint chilli vinegar, $\frac{1}{2}$ pint soy, 1 tablespoonful anchovy essence, 2 grated shallots, 1 grated clove of garlic, salt to taste. Put all ingredients in a stew pan and simmer until slallots and garlic are tender. Then pass through a fine hair sieve, and store in airtight bottles

Worcester Sauce. One quart best malt vinegar, 6 tahlespoonfuls walnut ketchup, 4 tablespoonfuls essence of anchovy, 4 tablespoonfuls soy, 4 grated shallots, salt to taste. Put all ingredients in a wide-nceked unglazed jar, cover closely. Stir the contents 3 or 4 times daily for three wecks, then strain ofl into small bottles, cork, and store in a cool, dry place.

Thick Piquant Sauce, or Chutney Sauce. One pint vinegar, 2 tablespoonfuls mushroom ketchup, 2 tablespoonfuls soy, 4 dessertspoonfuls chopped pickled walnuts, 2 dessertspoon fuls chopped chutney, $\frac{1}{4}$ oz. bruised garlic, 7 or 8 finely chopped anchovies. Mix all ingredients together in a wide-necked jar, let it remain in a warm place for a month Give the contents a good stirring daily. Pour off into small bottles, cover securely. and store in a cool, dry place.

SAUCE BOAT. There are two main types, and one of each kind is usually included in a dinner service. One is fitted with a lid and ladle and a stand to match, making it in effect a small tureen. The other is the sauce boat proper, with lip and handle made so that the liquid can be poured out as from a jug; of this kind there are some beautiful examples in silver and Shefficld plate.

Silver and Sheffield plate sauce boats made in the 18th century are valued by collectors. They are usually of the conventional shape, but with a variety of decoration on the handles and the feet, and sometimes round the rim The supports are in several styles, some having a plinth and others having claw feet. Less frequently seen are oval boats with two lips.

SAUCEPAN. Enamel saucepans are very casily kept clean, but should always be of good quality, or the enamel is liable to crack

Sauceran. Fig. 1. Saucepan made up of two semicircular pans which can be used separately or together over one burner. Fig. 2. Four square aluminium saucepans of different sizes, but made to $\hat{A}$ together so that they can be used over one light
and small chips find their way into the food. Iron saucepans are chiefly need ed where there is a range and are used for boiling vegetables, for certain stews and boiled puddings. They are too heavy for ordinary usc. Stainless steel saucepans afforl excellent wear, but are expensive to buy.

Copper saucepans are good conductors of heat but require to be lined with tin or nickel, as these metals arc not chemically acted upon by acids. Alumin. ium pans arc inost generally used, as they are light and easily cleaned. Most of the newer types of fuel and space saving saucepans are made in this metal. Figs. 1 and 2 illustrate examples of these pans, which are helpful on a small cooker.

Double saucepans for heating porridge milk, etc., are made in both enamel and aluminium ware. A modern development has a lip through which water can be poured to keep the milk, custard or sauce in the upper part from burning. Another saucepan which is uscful for milk has a patent lid, through the sides of which the milk can bubble and return through the centre without boiling over.

Vegctable saucepans comprise one with a wire cage, which when lifted up strains

Fig. 3. Wooden rack for h. Wooden rack
the peas, beans, etc., so that the water runs back into the pan. Another device has a special lock lid and a serics of holes on one side so that vegetables can be strained without a colander after they arc cooked. A dual purpose saucepan possesses a movable handle and a lid which can be converted into a frying pan by transferring the handle to it.

Cleaning Saucepans. Saucepan lids should be thoroughly cleaned and dried to keep them free from rust. As the cover should always be removed when not in use, a saucepan lid rack is illustrated in Fig. 3,
which has proved a convenient little accessory when placed near the cooker. Tiered metal saucepan racks which admit a free passage of air to the saucepans take up little room in a corner.
Saucepan brushes are sold in sets to hang up over the draining board. These can be used with cleaning and scouring solutions for removing hard deposits of grease and food from saucepans. Wire brushes should not be used for aluminium ware, which should be scoured with silver sand, rinsed and dried thoroughly. No soda should be used in cleansing aluminium pans or added to food cooked in them, as it turns them black. Food should not be allowed to stand all night in any saucepan. New pans should be filled with cold water, brought to the boil, emptied, rinsed out in clear water and thoroughly dried. Iron and cnamel saucepans may be washed with soapy water to which soda has been added. See Aluminium; Copper; Kitchen
SAUERKRAUT. Cabbage which bas undergonc fermentation can be purchased ready for cooking under the name of sauerkraut. This is served usually with sausages, ham or boiled bacon.
The French way of preparing this dish is without pickling and fermenting the cabbage. Wash and shred the white hearts of two cabbages very finc, removing the hard parts. Now wash the shreds thoroughly, using several waters, and drain them quite dry. Put the shreds into an carthenware pan with about 4 tablespoonfuls salt; add 8 peppercorns and a breakfastcupful white wine vinegar. Stir the cabluage well in the vinegar and let it remain for some hours. It might, if more convenient, be soused overnight and used next day. Wash it well before cooking, then put it into a casserole with 1 pint stock, $\frac{3}{4} \mathrm{lb}$. sliced fat bacon. Bring gently to the boil and simmer till the cabbage is tender. Add to the stock when cooking it a tablespoonful of vinegar.
SAUMUR. The delicate French sparkling white wine known as Saumur is an excellent substitute for champagne. It is sound, wholesome and light.
SAUSAGE : To Make and Cook. Sausages should always be purchased from a reliable dealer, and as many sorts contain more or less bread as well as beef or pork they should be cooked as soon as possible. To prevent the skins from bursting through the swelling of the bread, they should be pricked with a fork or a trussing necdle; there is less danger of the skins bursting if the sausages are blanched or scalded before being fried. Cook them slowly, turning them frequently until nicely browned. Serve them alone or with bacon, or on fingers of fried bread or toast. Sausages may also be toasted or grilled before a clear fire or under a gas griller.
The usual method of naking sausages consists in passing the meat through a mincer and forcing it into the skin or container. The meat may be passed through the machine twice. Have ready a well cleansed sausage skin, fix it on to the machine or hold it open and force the meat into it, then separate the sausages by twisting the skin at intervals of 4 in . Only fresh meat should be used, all skin and gristle being removed and a proportion of fat added. The meat is then cut into dice, breadcrumbs mixed in if desired, together with seasoning accorling to taste.
Pork sausages should be flavoured with sage; beef, onion and swect herbs; veal and ham, lemon and sweet herbs; for mutton a stronger flavouring will be necessary, and a small proportion of suct and breadcrumbs must be added. The flavouring may consist of shallots, anchovies, pepper, salt, and mace.
Sausage Forcemeat. The forcemeat known as sausage meat is used for stuffing fowls and turkeys. To prepare it, skin l lb. sausages,
put the meat into a basin, and mix it with 5 oz breadcrumbs, a pinch of powdered mace, and salt and pepper to taste, binding the whole with the beaten yolk of an egg. The finely chopped liver of a turkey can be added if desired. This forcemeat can also be made into balls, rolled in flour, and fried or baked.

Sausage Roll. To make sausage rolls, skin 1 lb . pork sausages, divide each into three portions, and put them on one side. Make $\frac{1}{2} \mathrm{lb}$. flaky pastry and roll it out $\frac{1}{8} \mathrm{in}$. thick, and cut it into pieces about 4 in . square. Turn these over to the other side, and roll the pieces of sausage into thinner rolls, not quite so long as the pieces of pastry. Place one on each piece, damp round the edges of the pastry and fold it over in half. Press the edges together, trim off any rough pieces, and with the back of a knife make two slits in the top.

Brush the rolls over with beaten egg or a little milk, put them on a baking sheet in a hot oven and cook them for about 30-40 min. When the pastry is cooked and of a golden brown colour, the heat of the oven can be reduced, and, if necessary, the browning shelf may be removed. When cooked, let the rolls cool on a sieve. See Hors d'Oeuvres : Pastry; Stuffing.

SAUTE. This French word means tossed. It is a method of cooking food that resembles frying, and is sometimes known as French frying. It differs from real frying in that less fat is used. Consequently the food so cooked should be turned or tossed frequently to prevent it from burning or sticking to the bottom of the pan. See Potato.
SAUTERNE. The white wine produced at Sauterne in the Gironde, France, is made from white grapes which are picked over-ripe, and is considered the finest of all naturally sweet wines. The best and most widely known sauterne is Château Yquem, the most delicately aromatic of wines in France, and probably in the world. It has a colour resembling liquid gold, with exquisite bouquet and flavour. Barsar is not so sweet and has a flavour of its own. Sauternes are usually served with fish and poultry, but may be drunk throughout a meal. See Dinner; Wine.
SAVELOY. A savoury kind of sausage often served as hors d'oeuvres, the saveloy differs from the ordinary pork sausage mainly because the pork used in its preparation is salted. When bought ready made, it is thoroughly cooked, and served cold. It is covered in a bright red skin, which must be pulled off the slices before they are eaten.

SAVINGS BANK. In Great Britain savings banks, which differ from ordinary banks in receiving money on deposit only, not on current account, are of two main kinds. These are the savings banks conducted by the state through the post office; and the trustce savings banks over which the state exercises supervision. In addition the joint-stock banks have departments for receiving savings, and in one or two places, notably Birmingham municipal banks have been opened. There are also savings banks in connexion with railway companies, while the army, the nary, and a number of schools have them. Some of these are worked in connexion with the post office Canada, Australia, and other parts of the British Empire have also savings banks under state control.

All these banks receive money on which they pay interest. This can be withdrawn at any time, usually after a very short notice. The rate of interest paid is usually low; in the post office savings bank it is only 6 d . in the $£$ for the year, or $2 \frac{1}{2}$ p.c.; but where security of capital is essential, banks that offer a high rate of interest should be avoided.
To open an account in a savings bank it is only necessary to fill up certain forms and de posit a sum of money. The post office will not
take sums of less than 1s. or odd amounts in pence, but penny banks and certain others take from a penny upward. Each depositor is provided with a book, which must be presented when money is withdrawn, and should be sent to the bank oncc a year in order that the interest may be added.

As regards the post office savings banks, the following conditions are laid down. An account can be opened for, or by, a person of any age, but if it is for a child under seven the money deposited cannot be withdrawn until the child is seven years old. Deposits in thesc banks cannot be attached in casc of debt. The annount which may be deposited in a single year is limited to $£ 500$. It is illegal for a person to have more than one account, or to have one account in the post office savings bank and another in a trustee savings bank. He may, however, act as trustee in accounts for the benefit of others
Money can be deposited at any post office which is a savings bank, and if it is for more than $£ 50$ a receipt will be sent from the head office. Otherwise the stamp and signature in the depositor's book is the only receipt. On presenting his deposit book at any P.O. savings bank a depositor can withdraw on demand any sum up to $£ 3$. If more than $£ 3$ is required a form of notice of withdrawal must be filled up and posted to London. These forms can be obtained from any post office.

The depositor receives a warrant for the amount, and he can get the money by taking this with his book to the post office named in his form of withdrawal. Sums up to $£ 10$ may be withdrawn by telegraph if the depositor pays for the telegram and a service charge of ls. in addition.

If a depositor wishes to authorize another person to receive payments from the bank on his behalf, he can sign a form for that purpose. Forms of application for claiming the deposits of deceased persons are obtainable at a post office. A depositor not under the age of 16 may nominate a person or persons to receive any sums from the amount due to him at the time of death.

SAVINGS CERTIFICATE. National Savings Certificates, formerly known as War Savings Certificates, offer a means of investing small sums in a government security bearing a high rate of interest free of income tax. The present issue, which is known as the third, was begun on October 1, 1923. The purchase price for a single certificate is 16 s . and the certificates are repayable at any time on application, together with any interest which has accrued. A single certificate of the third issue becomes worth $£ 1$ at the end of six years, and $£ 14 \mathrm{~s}$. Od. at the end of 10 years. National savings stamps of the value of 6 d . and cards to which such stamps may be affixed can be obtained.
Special facilities for the accumulation of small sums for investment in national savings certificates are also provided by savings associations established under the auspices of the National Savings Committee, Sanctuary Buildings, Westminster, S.W.1, and the Scottish Savings Committee, 122, George Street, Edinburgh, who will give information and advice on this subject.
No person or body of persons or institution authorized to purchase national savings certificates may either individually or jointly hold or have any interest in more than 500 single certificates, or other equivalent in multiple certificates. A person becoming entitled on the death of another person to certificates which bring his holding above that number may, however, retain the excess, but may not purchase more.

Interest. On the first anniversary of the date of purchase a certificate of the third
issue becomes worth 16s. 3d. Thereafter its value increases by the addition of 3d. at the end of each complete period of four months with a bonus of 1s. at the end of ten years. The following table shows how the value of a certificate increases up to the end of the tenth year :

Any certificate retained after the tenth year will increase in value by the addition of ld. at the end of each complete month.

Repayment. Repayment with accumulated interest may be obtained at any time on written application by the registered holder to the Controller, Money Order Department, General Post Office, London, except in the case of a child under seven, years of age. Forms of application for repayment can be obtained at inost post offices.

SAVORY: The Plant. Both summer and winter savories are used for flavouring soups and sauces. The annual is the summer savory, Satureia hortensis. It is raised from seed sown in April in drills, 6 in. apart, in rich soil in a sunny position. As soon as the plants are 2 in . high they should be thinned out to 6 in . apart every way. When the plants flower they should be pulled up and stored for winter use.

The winter savory, S. montana, which is an evergreen, thrives in any ordinary garden soil in a sunny position, and may be planted in spring or autumn, about 1 ft . apart every way. Propagation is by seeds or cuttings, and the shoots may be gathered as recommended above.

SAVOURY: The Dish. A highly flavoured side dish, known as a savoury, is served after the sweet, or may take its place when the dinner is informal. Savouries may be of fish, game, white meats, dressed vegetables, or some preparation of cheese or eggs. They are frequently served in china pipkins, ramekin cases, or may be dished altogether in silver or fireproof dishes.

Sometimes the savoury is of a very simple nature, such as Scotch woodcock or mushroom toast; at other times it may be more substantial, a cheese soufflé or dressed tomatoes; but it is always chosen to contrast with the entrée. It is really a substitute for cheese after a meal. In summer it is often served cold. See Anchovy; Aspic; Cheese; Tomato, etc.

SAVOY BISCUIT. Savoy biscuits are used in the making of many fancy sweets. These biscuits can be laid out on a sheet of cartridge paper by the aid of a savoy bag and baked in a fairly hot oven. Or bake them in sponge finger tins which have been floured and sugared

The ingredients and proportions to be used would be 3 eggs to 6 oz . castor sugar and 8 oz . flour. The eggs must be whisked stiffly for about $\ddagger$ hour with the sugar, then folded in quickly with the Hour and a little delicate flavouring, such as vanilla, added last; then place the mixture in a savoy bag to shape for baking.

SAVOY CABBAGE. A valuable hardy autumn and winter vegetable which is raised from seeds sown out of doors in April and May; it produces a large firm head of deep green, crinkled leaves. The seedlings should be planted out in summer, the large varieties at about 20 in . apart, the small ones at 12 in . apart. Of the large Savoys suitable sorts are Drumhead and New Year, and of the small ones, Dwarf Green Curled and Little Gem. For methods of cooking see Cabbage.

## Saws: The Various Types

## Their Different Uses and How to Sharpen Them

Other information on this subject will be found in the articles on the various kinds of saw, e.g Bow Saw : Cross Cut Saw ; Frame Saw; Hack Saw : Keyhole Saw: Pruning Saw. See also Amateur Carpentry: Tools; and the entries on the wondworking processes in which the use of the saw is essential, e.g. Dovetail Joint Mitre: Picture Frame

The cross-cut saw is used for cutting across the grain of wood, while a rip saw works along the grain. The average length of the crosscut hand-saw is about 26 in ., and the number of teeth to the inch depends on the work for which it is intended. The tenon or back saw, Fig. 1, is 12 in. to 18 in . in length, and the number of teeth to the inch about 10 . The top edge has a strip or back of grooved steel or brass, fitting the blade, and giving strength and rigidity.
The panel saw is a small hand-saw with line teeth that may be used for the same purposes as the cross-cut and ripping saws, and also as a tenon saw and for many woodsawing jobs. The amateur who wants a general-purpose tool is advised to buy this type. The dovetail is similar to the tenon, but smaller and with tiner tecth; its usual length is 10 in . It is used in making dovetail and other joints that entail very accurate work. For cutting beading and similar small work a light brass-backed saw is often used with a straight handle. like that of a bradawl.
For cutting shaped outlines in wood a bow saw is usually employed. The frame is generally of beech and the handles and blades can be

obtained sepmately, so that the latter may easily be cenewed. The saw blade is tightened for use with a tourniquet arrangement. This tightening is absolutely necessary, otherwise the blacle will snap, but when the saw is out of use the blade should be slacked off. In addition to the bow saw, compass and keyhole saws are used for shaped work, and for starting a cut to be completed by the bow saw.

The first difficulty which the amateur finds in using a saw, especially a cross-cut saw, is to start the cut. There is a tendency for the saw to jump about and inake a series of small jagged cuts on the edge of the wood. Figs. 2 and 4 show how the preliminary saw cut should be made and how the handle of the saw should be held. The left-hand thumb should be placed on the wood against the hlade of the saw to guide it. Then take two or three gentle up-strokes before making the first down or forward stroke. The pressure should be as light as possible. $\boldsymbol{7}$ The preliminary cut made, the sawing can proceed.

The two chicf rulcs for accurate sawing are to use long strolies, and not press too heavily. Any attempt to force the saw too quickly through the wood will make it more difficult to guide for one thing, and for another it will make the blade jam, the teeth not being able to clear theniselves properly. Draw the saw slowly backward nnil forwarl. and the work will be done more quickly and with less labour. About sixty strokes a minute with a 26 in. saw is right.

When sawing off a piece from $\Omega$ long board, both ends of the latter should be supported, and the board so kept horizontal. To use only one support and hold the hoard horizontal by the pressure of one linee is bad, because the board is bound to vibrate, and the sawing will probably be uneven, because the nttention of the worker is divided between it and the support of the board. When a long hoard has to be sawn acrose the midide, it is best to liave an assistant holding it to prevent the board sagging, and so binding the saw blade. During the last few strokes. when cutting a short or long picce, it should be supported, or it will break away and split the end of the hoard. The last few strokes of the saw should be as lightly made as the first, to prevent the breaking a way of the fibres of the wood at the corner. Short pieces of board may he held in the bench vice, תs in Fig. 3.

With a tenon or similar saw nearly all the work is done on the bench. The sawing should be clone against the bench stop, or by using a bench hook. as shown in Fig. I. The bench hook is hooked against the front of the bench, and the wood to be sawn is pressed firmly against the top of the hook with the left hand.

Considerable practice is required to saw a straiglit line and to saw squarely, particularly when using the cross-cut saw on thick stuff. A saw may be following the line marked on the top of the material, and yet be considerably to one sille of it underneath. The tendency generally is to incline the handle end of the saw towards the side on which the worker is standing. By giving what appears to be a contrary slope it will generally be found that the wood is being cut squarely, and a little practice will enable the amateur to keep his saw cuts squarc.

A saw may persistently saw to one side of a line when all the rules of sawing have been observed. This will be duc to a defect in the saw itself. Either the blade has twisted or the teeth of the saw have been set more on one side than the other.

A point the amateur often overlooks is the waste which occurs when $\Omega$ saw cut is made. A board l ft . in length when sawn exactly through the middle does not produce two picces each 6 in . long. Wach piece is 6 in . less half the width of the saw cut or kerf. When careful work is being done this width becomes important, and must be allowed for when cutting. Saw on the outside of the line, so that the saiv kerf is in the waste piece of wood. This will save much planing and fitting.
Setting and Sharpening. Saws should be set and sharpened at regular intervals, and they should be set before they are sharpened. The set is the amount to which the tecth are bent sidewavs. This is to make them cut a kerf wider than the thickness of the blade to allow the latter to run freely. Saws should be set to $\Omega$ maximum for cutting wet wood, or cross-cutting soft wood, and to a minimum for ripping hard, dry wood.

The simplest way of setting a saw is by means of a hand-set, Fig. 6, with the saw held in a vice. The hand-set contains a number of slots or notches of various sizes to suit different thickness of saws. A slot is fitted over a tooth, and the latter then bent over to the required angle. Alternate teeth are bent over on one side of the blade, and the remainder on the other. The accuracy of this method depends largely upon the eye of the worker, and a hand set with a gauge attachment is best for the beginner. When the tooth is bent over sufficiently the gauge just touches the blade of the saw, and this ensures that the teeth are set uniformly. There are other types of saw-set on the market. Professional saw sharpeners place the saw on a metal block with hevelled edges, and strike the tecth with a sawsetting hnmmer.

Saws are sharpened by filing the teeth with a three-cornered file. A proper and suitable sawfile has the same section as the tooth space,

Saw. Fig. 1. Tenon saw in use on work supported by a bench hook. Fig. 2. Making the preliminary cut with a cross-cut saw. Fig. 3. Short board held in bench vice. Fig. 4. Correct position to adopt when cutting a thick plank. Fig. 5. Ripping a long board through the centre

apples, cherries, larch pears, pincs, pluins, raspberries roses, turnips. and other trees and plants. The larvae of leaf-fecrling kiads should be picked off by hand, or, as an alternative, should be destroyed with sprinklings of the poisonous hellebore powder.

Pith-boring grubs can only be cradicated by removing and burning shoots that wither suddeniy. Cator-
and thus files the front of one tooth and the back of the preceding one simultaneously. Such files arc made in various sizes. a $4 \frac{1}{2}$ in. file being suitable for hand saws and a $3 \frac{3}{2}$ in for tenon saws. The saw should be held, teeth upward, in a long-jawed vice the teeth projecting only slightly above the jaws. A simple
wooden vice can easily be made by the amatcur. The jaws should be faced with a thickness of leather. The appliance has legs to stand on the Hoor against a hench or table and thus bring the tool to a convenient height for the work. Another way is to clamp the saw between two pieees of wood the length of the saw.

Before beginning, look along the top of the tecth and see that they are in a straight line. With a blunt saw it will be found that they are uncven, and the first thing to do is to straighten them. This is done with a flat file run over the points of the teeth. T'o ensure accuracy, fit the file in a groove in a picec of wood. The latter held against the saw blade acts as a guide and enables all the ends of the teeth to be filed with a perfect regularity.
The saw should be sharpened from the handle end. The file is held on a slight slope to the horizontal, as in Fig. 7, not more than a few degrees, and its direction should bc at an angle across the tecth, not at right angles. Two or three strokes of the file will suffice to sharpen each tooth. and the file should only be used on the forward strokes. The back of the tooth is filed to bring it to a sharp point again, though the front of the next tooth to the right gets filed away to some extent. When one set of tceth has been filed the saw should be turned over and the other set similarly treated. The file should still slope towards the handle when the saw has been turned.

The angle at which the file is pointed across the teeth varies with each type of saw. In the case of a rip saw the file is only just off the square ; with a cross cut, tenon or panel saw it is off about $20^{\circ}$ to $30^{\circ}$. The more the filing is done out of the square the finer the point and the keener the cutting. Naturally, the teeth are weaker, and saws thus will want more frequent sharpening. Generally speaking, sharpen finely for soft woods and squarely for hard woods.

Saw's when not in use should be thoroughly greased to protect them from rust. A grooved piece of wood the length of the saw should be prepared, and kept over the teeth when the saw is not in usc. To make such a cover, the grooved edge of a piece of stout matching can be ripped off to a width of about $1 \frac{1}{2} \mathrm{in}$. A couple of holes are bored to take a cord for tying it to the saw.

SAWFLY. Various kinds of sawflics are very troublesome in the garden, attacking
pillars injurious to young fruit must be combated by spraying with the poisonous arsenate of learl, whilst all fallen fruit should be immediately collected and hurnt. Kainit should be applied in autumn. See Apple Sawfly; Currant Sawty : Goose berry Sawfly; Spraying. SAXIFRAGE. This is one of the most important groups of rock garden plants, popu larly called rockfoil. There are several types, two of the most notable being the mossy and silvery saxifrages.
The mossy saxifrages form wide-sprcading masses of moss-like grecnery and bear white or reddish Howers in spring: they like well drained, sandy or gritty loamy soil and slight sharle, though they will flourish in the sunshine. Some of the best are ohypnoides (1)ovedale moss), white; muscoides, red; decipiens, red and Wallacci, whitc. Many showy crossbred forms have been raised and these are largely grown. e.g. Guildford Scedling, Crimson King, and sanguinca superba. Two, hypnoides densa and muscoides densa, are of dense growth.

There are some charming flowers among the silvery saxifrages, which should be planted

Saxifrage. One of the large-leaved aaxifrages, ligulata, which beara rose-purple fowera
in gritty soil containing linie, in sunny rock crevices. Most of them have grey-green leaves, and in May and June the dainty panicles of bloom are delightful. A few of the best are aizoon and its varietics, cochlcaris, white; Kolenatiana, pink: lantoscana superba white; Macnabiana, white with red spots; Hostii, cream with pink spots : and Tumbling Waters, whitc. Longifolia bears immense panicles of white flowers, but the plant dies after fowering.
A few of the most attractive saxifrages in the remaining groups are apiculata, ycllow; burscriana gloria, white; Gricshachii, crimson; Irvingii, pink, and oppositifolia, rose-purple. These, which flower early in spring, should be planted in very gritty soil or in the moraine. London pride, so useful as an edging to shady borders. is Saxifraga umbrosa; it bears pinkish flowers profusely in May. Saxifraga ligulata and cordifolia are vigorous plants with large leaves and spikes of rose coloured Howers in spring.
The usual way of propagating saxifrages is by detaching offsets, potting them in small pots of gritty soil and keeping them in a frame until they are well rooted. They may also be raised from sceds sown in pans of fincly sifted sandy soil placed in a frame in spring, but the scedlings grow slowly.
SCABIES: The Disease. The skin discasc popularly known as the itch is duc to the presence of the female itch mite, which forms winding burrows in which she lays her eggs, her position being indicated on the surface by a small vesicle or blister. There is intense itching, increased when the sufferer is warm in bed at night, and from scratching and other irritation cezema results.

Treatment consists in anointing the body from the neek downwards with sulphur ointment on three consccutive nights. The fourth night a hot bath is taken, and the patient gets fresh underclothing. What he has been wearing may be sent to a steam disinfector, be boiled at home, or things which would damage may be soaked in a solution of lysol.
The Disease in Poultry. A form of scabies, called depluming scabies, attacks fowls. It takes the form of feather cating, and is usually due to the small mite at the roots, but sometimes to lice. There are two kinds of feather plucking, the eating of the bird's own feathers, and the plucking of those of other birds. The discase appears usually about April, and is most prevalent in the spring and summer. Besides the loss of feathers the birds become thin and lay fewer eggs or none at all.

To cure the disease it is first necessary to isolate the affected bird or birds. The mites yield readily to treatment if oil of cloves is rubbed into the infected area, but a mixture of one part of creosote to 20 parts of lard is perhaps a better remedy. Another remedy is to wet the base of the feathers with soapy water, and then dust the birds with fresh pyrethrum. See Gapes; Poultry.
SCABIOUS. The pincushion flower or scabious is a delightful plant for the garden; there are perennial and annual kinds. The flowers of the latter are of various colourscrimson, maroon, lavender and pink. Seeds should be sown under glass in March, and the seedlings planted out of doors in May; these plants may be treated as biennials, secds being sown in summer and the seedlings set finally in autumn, when they will bloom the following year. The ordinary varietics reach a height of $2-3$ feet, the Tom Thumb varietics 12 inches.

The finest perennial lind is the Caucasian scabious (Scabiosa caucasica), which bears long-stemmed lavender-blue flowers of great value for cutting. It thrives best in welldrained soil. On heavy land it is liable to perish in winter, and there should be grown as

Sicabious. Flowers of the annual scabious varyin from a deep wine colour to pale blue
a biennial from sceds sown every year in May. Propagation may also be effected by division in September.
SCAFFOLDING: In Building. By scaffolding as applied to building works is meant the temporary plaiforms raised to varying heights to enable those employed on the job to work in comfort, and to support the materials which are being used for the structure.
The bricklayer's scaffold is the type used generally to assist in the erection of sinall houses, and it is made up with a number of members that are given different names, according to the position into which they are placed. The poles that are fixed in the ground are called stanclards. These are fir poles stripped of their bark, 4 or 5 in . in diameter and 25 to 30 ft . long. If longer poles are required two are lashed together. The hole dug for the standard is about 2 ft . in diameter and 2 to 3 ft . deep. Where it is not desirable to break the surface of the ground, the standards may be placed in tubs or boxes containing sufficient earth. The firm planting of the standards gives lateral strength to the scaffold.

The ledgers are horizontal poles fixed to the standards by means of scaffold cords or lashes; they are placed at the height required for comfortable working, from 4 ft . to 5 ft .6 in . apart. Scaffold cords are made of hemp or steel wire, about 20 ft . in length. It is essential that they should be in good condition, as it is upon the proper tying and strength of these cords that the security of the scaffold depends.
The standards are planted, as a rule, about 4 to 5 ft . from the building, with the ledgers firmly attached to them. A support is formed to receive the putlogs, one end of these resting on the ledger and the other bearing on the wall of the structure, for which purpose, on a new building, holes are left to receive them. The putlogs are lashed to the ledgers and securely wedged into the wall.

Putlogs are made from birch, 5 to 6 ft . in length and 3 to 4 in . square on section. They are spaced 4 to 5 ft . apart on the ledgers and form a base on to which the scaffold boards are placed. These latter are usually 12 ft . long, 9 in . wide and $1 \frac{1}{2} \mathrm{in}$. thick, and are often bound at the ends with hoop iron to make them durable. In erecting a scaffold, and particularly in laying the boards, great care must be taken. Traps must be avoided, that is, the overlapping of the boards on the putlogs, otherwise a scrious accident might occur. The boards are butted, but where the joints occur, two putlogs should be placed about 3 in. apart, in order to give ample
bearing for the boards at the ends. If the :caffold adjoins a roadway it is desirable to have guard boards at the sides to prevent any materials falling on to persons below. A safety rail may be provicled as an additional safeguard to the workers. A scaffolding may require bracing to give addlitional stability. Braces are formed with similar poles to those used for standards; they are lashed diagonally across the framework to the standards and ledgers.

Within the area of some local authoritics scaffoldings have to be approved by an offleer of that authority before they may be used ; this applies particularly to the London districts, where there are by-laws affecting the erection of any scaffolding used for building purposes. Scaffolding must be properly put together in spite of its temporary nature, because it invariably has to carry very heavy weights, and the lives of the men using it will be imperilled if strong and adequate framing is not provided for it. It is highly important that the services of an experienced workman should be utilized in raising anything but the most simple erection. See Trestle.

SCAGLIO'LA. Scaglio'la is a conıposition of coloured materials to imitate marble, which is sometimes known as mischia. It is composed of gypsum, or sulphate of lime, calcined to evolve the surplus moisture and to reduce it to a fine powder.

When it is required for use, sufficient water is added to the mixture to form a paste, and this causes the diffusion of the colours required. Experience alone can supply the knowledge as to which gypsums to mix in order to produce colourings. This material is laid on to brick walls in the form of a plaster, and may be trowelled to a smooth surface. See Marble.

SCALD: How to Treat. A burn produced by a hot liquid or vapour is spoken of as a scald.

The top of the foot is a common site for a scald, and when this happens the greatest care must be taken in exposing the injury. If the boot is on it may be better to cut the lace than loosen it in the usual way, and a sock or stocking should always be cut off. It will further help in the removal of a stocking if the foot is placed in warm water. As in burns from other causes, the first symptom to be treated is the shock-like condition. Warmth and stimulants are necessary.

In dressing the burn, if the skin is broken, greasy applications should not be used, as they interfere with the cleansing of the wound by the doctor. Cloths wrung out of warm boracic lotion are the best immediate application and they should be kept continuously moist with the lotion. See Burn.

SCALE: The Insect. An insect known as scale affects many shrubs and flowers, both indoors and out. The males are small black flies, and the females have the appearance of small scales, or plates, which affix themselves to the leaves or bark of plants in small brown or grey spots. Apples and pears, stonc fruit, roses and palms are those which are chiefly affected.

One remedy is to spray with paraffin emulsion; whilc, in the case of stem infection. methylated spirit brushed into the bark is effective. Paraffin emulsion is made by dissolving a handful of soft soap in hot water, adding an eggcupful of paraffin and two gallons of water. See Beeswax; Spraying.

SCALES : For Weighing. A pair of scales is a necessary adjunct to every household. In addition to those used in the kitchen for weighing food, scales are useful on the writing-table. For this purpose small pairs are made of brass and other metals, or of wood with brass fittings, with weights suited to the
weighing of letters and smail parcels. Scales are also used by photographers.

Kitchen seales are of two main types. One requires certain weights and works by means of a balance the articles weighed being put into a shallow pan on one side and the weights on the other. An ordinary pair will weigh anything up to $7 \mathrm{lb} .$, but larger ones can be bought. The other type works by means of a spring. weights heing unneccssary. The articles to be weighed are placed in a pan at the top, and their pressure moves a pointer on a dial to mark the correct weight. Modern examples are made of porcelain and are washable and hygienic. They usually weigh up to 14 lb .

SCALLOP : How t Prepare. Small portions of meat or fish cooked in a savoury manner in scaliop shells or dishes of that shape are called scallops. The name is that of a shellfish, and the shell itself is so hard that it is not injured by being placed in a hot oven. When the fish has been disposed of, these shells are often kept for cooking tish.
Scallops are usually obtained trom the fish. monger ready for cooking, but if they must be prepared at home open them with an oyster knife in the same way that an oyster shell is opened, then trim away the beards and black parts and wash them well in two or three waters. They are somewhat indigestible and it is essential that they be well cooked. The name is sometimes found spelt escalop on menus.
To cook scallops. parboil the fish in their own liquor for 5 min., then drain and keep them hot in their shells. Put the liquor into a small stewpan with 1 tablespoonful creany white sauce for each fish. Add a little extra seasoning and a squeeze of lemon juice, then make all hot over the firc. Pour over each scallop in its shell a spoonful of sauce, then coat with fried breadcrumbs. The shells should be well washed
Scallops may also be stewed. After preparing the fish well wash them, then put them into a stewpan, cover them with warm water, and simmer for from 15 to 20 min . Dish them in a china baking-dish covered with white sauce, which should be made partly with the liquor in which the fish have been stewed.

To fry scallops, prepare, wash, drain, and blanch them, then dip each in a rich light batter and fry in deep fat. Pile them up on a dish paper and garnish with fried parsley. Serve with them shrimp or oyster sauce. Add to the batter a little butter and season the scallops well.

SCALLOPING: How to Work. This is used to form a fancy edge on babies' clothes, underwear, frocks and house-linen. It is worked on white flannel with Hoss silk, on silk and cotton wear with embroidery cotton or silk, on linen with linen embroidery thread.
In the case of flannel, long-cloth and nainsook it can be worked on the single material, but when working on thin silk or crêpe-deChine it is advisable to sew a narrow strip of tissue paper or fine book muslin. under the edge of the material on which the scalloping will be worked. This prevents puckering, and gives a firm, even edge.

The design is put on the material by means of a transfer which is ironed off in the usual way. These transfers are sold by the yard in various shapes. The ordinary scallop pattern is in a semicircle; there are fancy vandykes made up of 3 or 4 semicircles on each side of it. The design illustrated is a wide one, each scallop measuring $2 \frac{1}{2} \mathrm{in}$. It is not necessary to buy a scallop transfer, as a coin and a soft lead pencil will provide various designs. For the average scallop, which.is about 1 in . wide when worked, a halfpenny will act as the tracing medium.

To mark the design draw a line across the diameter of the coin, so that the exact half
can be used. Pin the material taut on a drawing hoard. so that the cut edge is away from the worker, then place the coin on the material about of from the edge and draw

sicalloping. The aesign is padued and then worked on buttonnole stitch 'he materia being subsequently cut away from the outer edge

SCAR. The tissue which tilkes the place of norinal tissue in a healed breach of tissue from disease or a wound is called a scar or cicatrix. At lirst a scar is red and soft, but becomos gradually harder and whiter. It never contains hairs and sweat glands. like ordinary skin. When large as after an extensive burn. in contracting it produces puckering of the skin which may interfere scriously with movement. Scars, if irritated, rather readily developeancemusgrowth
round the coin from one point of the centre line to the other when a half circle will result on the material which forms the outside line of the scallop. To make the inside line, draw the coin inward until there is a space of $\frac{3}{16} \mathrm{in}$. from the pencil line to the edge of the coin, at the centre of the scallop). Again draw round half the coin, but beginning this tine on a level with the points of the first semicircle drawn. instcad of in a line with the centre of the coin.

For successive scallops the coin must be placed against the previous one, taking care that the guiding line is quite straight. As a further guide the starting point for the first semicircle could be marked on the coin. By the same method a permanent scallop rule can be cut out in stiff cardboard maling about ten scallops, and this can be moverl along for any tongth of material. Tiny scallops for babies clothes can be made with a sixpence. and the larger ones with a halfpenny and a penny, marking the shapes on the cardhoard.

Somotimes the work is padiled as shown at the right side of the illustration. The buttonhole work is done from left to right, holding the material with the cut edge towards the palm of the hand. After joining the thread on the wrong side, bring it through to the right side on the lower line. Then, holding the thread down in a loop under the left thumb, put the needle down through the material on the top line, and bring it up again on the lower linc, next to the spot where it came up before, as the work must be close and even. Draw the needle through, still keeping the loop down under the left thumb, and only release it as the last bit of thread is drawn through. This will make the pearl edge, and after the whole work is completed the material is cul away under this pearl edgo.
For the latter purpose a very sharp pair of embroidery scissors must be employed, so that the material can be cut clean away without cutting the embroidery stitches. See Embroidery : Night Wear Case : Transfer

SCALY LEG. This diseasc of poultry is due to a ting mite. The scales of the legs and feet become raised and separated, and a chalk-like excretion accumulates between and ovor them. The disease is slightly contagious. Infecterd birds are lame, have a difliculty in perehing, and get out of condition.
To cure the disease the isolation of the discased birds is essential. The legs should he bathed in hot water in order to soften the crusts. These are then romoved and a mixture of one part of creosote to 20 parts of lard is alplied. The limb, some days after treatment, should be well cleaned with hot water and soft soap. Sce Poultry.
SCANTLING. This is a term used in build. ing and carp ntry work for the dimensions of a piers of timber, i.e. its length, breadth, and thickness. The name is often applied to an actual piece of timher, which differs from other timber in not acrording with some series of standard sizes, in the same way as battens and planks. See Batten: Board; Plank.

SCARAB. Egyptian gems that are moulded or cut in the form of the sacred scarabaeus, or bcetlc, were originally used as amulets, and afterwards for personal ornament. They were made in all available materials, including green hasalt, lapis lazuli, serpentine, emerald cornelian, jasper, amethyst and onyx, besides wood, ivory and gold. The most numerous were in pottery or faience, covered with a bluiah -green glaze.

On the flat, oval base scarabs were usually incised with the names or representations of divine, royal and official personages, or with goorl luck mottoes and magical devices. Scarabs were also used as scals, being either strung round the neck or mounted in metal signet rings. Many imitations of old scarabs are made and used in modern fancy jewelry when fashion dictates. See Ring.

SCARBOROUGH LILY. The common name of Vallota purpurea, a half hardy bulb suitable for cultivation in pots in grecnhouse or room window: it bears showy lily-like scarlet flowers in August. The leaves are evergreen. During winter the soil must not be watered until moderately dry but in summer it must be kept moist.

The bults should be potted in carly summer. one in each 5 -in flower pot, in a compost of loam two-thirds, and leaf-mould one-third, with a scattering of sand. The Scarborough lily flowers most freely when the pots arc full of roots : repotting should be done only when absolutely necessary. In spring some of the old surface soil should be removed and

Scarborough Lily. Scarlet flowers of an evergreen plant for the greenhouse or room window
replaced with fresh compost. This plant, when well rooted, benefits by occasional applications of guano or liquid manure.

SCARECROW. Originally this was a dead crow strung up to a stake to scare other birds from the crops. Now the word is generally given to many types of bird scarer, including the familiar old man of the fields. made of a rough wooden cross upon which hangs an old coat topped with an ancient hat.

Modern scarccrows, which are known usually an bird scarers, are more effective than these examples that quiclily lose their terror in the eyes of feathered raiders. They include laths strung with bunches of tin, or pieces of glass attached to swaying hoops, and so slung that when the wind blows the tin or glass tinkles, alarming the birds and causing them to Hy away. Whatever type is adopted, the scarecrow must repeatedly be altered, hecause familiarity with the same patteril breeds contempt and ceases to puzzle the raiders. See Bird Nearer: Netting.

SCARF. The primary use of a scarf is to protect the throat and shoulders from cold, but frequently it is worn by women merely for its decorative qualitios.

A silk scarl $1 \frac{1}{2}$ yd. long and 1 ft . wide can be quickly crocheted in three shades of one colour. Two hanks of crochet silk are required of the palest shadcs, one of the medium and one of the darkest: also a No. 11 crochet hook. Make 8: chain and work 5 in. in the darkest shade; brealk off, join medium shade and work another 5 in. Breals off and join palest shade. Work this 34 in. and then linish off with 5 in . of the medium and 5 in of darkest shade.

Knitted Scarves Scarves are simple to knit. Any number of stitches may be cast on the needle, according to the width required. and plain or plain and purl knitting or some other pattern, used. The knitting should bo continued until the scarf is of the necessary length, then the stitches shonld be cast off and fringe added to the two ends. To obtain an even edge, slip the first stitch of each line.

A fringed scarf call be made in Shetland floss; 4 oz. tloss, a pair of No. 7 needles, and a medium size bone crochet hook are nceded to make it. The scarf measures 48 in . long and $11 \frac{1}{2} \mathrm{in}$. wide, and the linitting is worked at a tension that will prolluse about 18 stitches to 3 in . in width, and 30 rows to 3 in in depth.

Commence by easting on 60 stitches, and for the first row * knit li- wool forward knit 2 together 6 times, and repeat from ${ }^{*}$ to the end of the row, finishing with knit 12. Repeat this row 11 times, making 12 rows in all. The 13th row consists of * wool forward, knit 2 together 6 times; knit 12, repeat from * to the end of the row, finishing with wool forward, linit 2 together 6 times. Repeat this row 11 times, making 12 rows in all.

Then repeat from the first row until the work measures 48 in ., and cast off. For the fringe, take 6 lengths of the wool, each about 10 in . long, and with the crochet-hook pull through the first stitch at one end of the scarf, and knot.

Repeat this all along the row in about every third stitch of the knitting, and then fringe the other end to correspond.

A scarf made from brushed wool might be composed of two different colours arranged in bancls. For a scarf 2 yards long and 20 in . wide, 9 oz . of rose-coloured wool and 3 oz . of white wool are needed; but if thicker wool is used, these quantities must be increased accordingly. The white wool is used for the bands and part of the fringe, and the whole is done in plain knitting. Work at a tension of 5 stitches to the inch in width.

Begin by casting on 100 stitches, and knit 54 rows or 6 in. With the rose-coloured wool;
then 18 rows or -1 in. with the white, twisting the rose wool over the white before linitting the first stitch, so as to bring it in line. Work another ? in. with the rose wool, and then make another band of white. This also should he 2 in. wirle. Knit $1 \frac{1}{2}$ yd. with the rose wool, allowing for a second set of white stripes, and making the latter correspond with those at the other end. The searf will then be complete.

For the fringe, wind the wools over a card or thin book measuring 5 in. across, and cut them through at one end. Take two sirands together, double them, and with a bone crochet hook draw the loop of the threads through one of the wasting-on or casting-off stitches. This will depend upon to whish end of the scarf the fringe is first applied. Pass the ends of the cut wools through the loop and draw them up closely. Repeat this all along both curls of the scarf, clipping the hottom of the fringe to make it even. Lastly, brush the searf on one or both sides with the special wire brush that can be bought for the purpose.

Any other colours may be chosen instead of rose and white, and the scarf can be made a narrower width by casting on 60 instead of 100 stitches. See Crochet; Knitting.

SCARFED JOINT. In carpentry various kinds of scarfed joints are used when it is necessary to join the ends of timbers to increase their length. An ordinary scaried joint is made by cutting the two ends of the timber to a long ang!e, and glueing, dowelling, bolting, or otherwise securing the two parts together. It is essential to have both angles alike and both faces square to each other.
III the case of a lapped scarfed joint, instcad of making the joint at an angle, half of each end is cut away so that each picce of material can lap on to the other, as shown in Fig 1. This is a useful all-round joint, easy to malic, and is practically an ordinary lapped halving joint. When used in timber the joint should be square, and secured with nuts and bolts. Such a joint would not be suitable for an upright post which has to support a moving load. For the best proportions the longth should be twice the hreadth of the pieces that are to be joined.
The splayed scarling joint used for lengthening tie beams is shown in Fig. 2. Proper proportions for the length of the joint are alout $3 \frac{1}{2}$ times the greatest brearlth. The tabled scarling in Fig. 3 has the advantage that it naturally resists tension as well as compression strains, and shrinkage of the timber docs not seriously affect its security ; but it requires careful fitting. The sides of the timber have to be very earefully marked out and the lines accuratcly worked to them, all the joint faces heing kept perfectly square and true. see Joint.
SCARLET FEVER. A common infections discase, scarlet fever, or scarlatinn, owes its name to the vividness of its rash. The specitic cause secms to be a variety of streptococcus which gencrally enters the borly through the

Scarfed Joint : three varieties. Fir. 1. Lapped joint. Fig. 2. Splayed scarfed joint: Fig. 3. Tabled scarfed joint, a lype that resists both tension and compression strains from those parts. and throat have also a scarlet colour. called the red strawberry-tongue. Possibly the infection may pass backwards lisease A third com plication is acute rheumatism.

The general treat ment of scarlet fever is that of an infectious discase (q.v.) and of the state of fever (q.v.) The mouth and throat should be kept very clean by the use of
nose and throat; moreover, the infection is most often communicated by the secretions

The incubation period is usually about three or four days. Then the patient becomes fevered and suffers from sore throat and prolsably vomiting, especially if it is a child. On the second day the rash appears, first on the neek and chest but in the course of a day or two usually covering the whole body. with the exception of the skin around the mouth. The rash consists of tiny red spots, each being surrounded by an areola of pink. The mouth

The tonguc is furred at the beginning of the fever and may have the appearance described as the white strawberry-tongue. In this the surface is covered with white fur but is dotted over with red spots due to swollen papillae projecting through the fur. Later on the fur is thrown off, leaving a clean red surface, but the redness of the papillae is of a different shade and they are.still conspicuous; this is

With the appearance of the rash the temperature rises further, reaching $102^{\circ}$ to $103^{\circ} \mathrm{F}$. or more. The rash lasts for three or four days and then fades, the temperature also gradually declining. About seven days after the appearance of the rash peeling begins, and this usually goes on for two or three weeks at least.

Several very important complications may occur in scarlet fever. There may be inflammation of the kidneys. The urine becomes scanty and contains albumin and often blood, while there is swelling of the feet, ankles and face, or even more generally. Another complication is inflammation of the iniddle car. Infection passes up the Eustachian tubes from the nose and throat and commonly causes a suppurative disclarge from the car.

stored in any glazed vessel, such as one of the old-fashioned red breadpans, if placed layer for layer between rock-salt. It is quite possibie to have perfectly fresh beans at Christmas time by em. ploying this method. Scarle: runner beans are cooked in the same way as lirench an antiseptic month beans. See Beans; lirench Beans. wash (q.v.) several SCENT : The Various Kinds. The scent times daily, and it sold in shops consists of simple Hower cxtracts, will oftou be necessary rose, violet, etc., and of blended bourpucts. to use a nasal douche as well.

By inoculation with a vaccine a skin reaction is obtained in persons susceptible to scarlet fever, and these can then be given a prophylactic serum or vaccine. Sera are also used in treatment. See Quarantine; Rasl.

SCARLET RUNNER. This lavouritc climbing bean yiclds very profitable crops if well grown. It needs decply dug and manured soil to ensure that the plants do not suffer from lack of moisture in dry weather. It is not a success on poor land. Seeds should be sown during the second week in May at about 9 in apart in a double row, the lines of the row 18 in . apart: it is wisc first to put in tall sticks at 9 in . from each other on both sides of the prepared soil and to set one seed near each stick. A few seeds should be sown in a box of soil to provide seedlings which may be needed in case some of the seeds sown in the open fail to germinate. Another plan is to sow all the sceds in boxes of soil in a frame in April and to plant the seedlings in May. Stout sticlss 7 or 8 ft . high are needed to support the beans adequatcly.

Although the finest crops are obtained from plants in the open garden, runner beans do fairly well in partial shade and may be sown to cover a fence or trellis in suburban gardens.
The dwarling system is adopted by many market and some private gardeners. In this the rows are drawn about a yard apart, and the twiners pinched out regularly as soon as the plants have got well into bloom. Such a row makes a good border in a cottage or suburban garden. Under this mode of culture it is a good plan to sow a double row, the lines a foot apart, and to set the sceds in angles with each other at 9 in. apart. A pint of average runners contains about 180 beans.
The modern varieties bear large clusters of big, fleshy porls. Some of the best are l'rizewinner, Best of All, and Scarlet Emperor. The old varicty, Painted Lady has pink and white flowers.

Surplus beans should be stripped from the haulm at the first sign of frost. They may be
 Each season new perfumes of the second class appear from the great perfunery houses, where subtle ingredients are mixed to obtain something a little different from the scents already on the market, something exclusive, whic cannot be successfully imitated. The artistry which evolves a new, fashionable bouquet commands a high price : but, apart from this, the cost of materials and production renders it impossible for any good scent to be cheap.

To the make-up of these expensive seents go one or more of the natural perfames
dissolved in alcohol. Some of these natural perfumes are vahable in themselves, most are costly to extract. They include the essential o:ls or attars of flowers; the animal scents; ambergris from the sperm of whales; musk from glands in the musk deer, musk ox, and musk rat; civet from the civet cat ; balsams such as santal and opopanax from the wood of trees and shrubs : oils like bergamot from the skin of citron fruits: oils from lenves such as verbena and geranium: from roots such as orris; and from the vanilla and tonka beans, the last developing the principle for the perfume known as New Mown Hay

To obtain the essential oils from flowers in their absolute purity three processes are used. The first of these is distillation, in which the llowers, roses for instance, are heaped into boilers, through which steam passes, and gradually the essence oozes into a glass tube at the base of the still, to be collected in precious drops. The second process is effleurage, in which cold, purified grease is spread on glass trays and the flowers, jonquil luberose, or jasmine, are sprinkled over the surface to yield their scent to the grease, and the next day aro removed, when fresh blossonis take their place until the grease is thoroughly impregnater
Maceration is the third process. Nome grease is placed in a vessel and melted by a water bath at as low a temperature as possible. Into the liquid grease the flowers-this process is chiofly used for violets-are stirred, left immersed for a day, and strained off, fresh llowers being added until the liquid can absorb no more of the perfume.
In these last two processes the scent is extracted from the grease by alcohol being stirred into it for hours and then left quiescent, when the fat separates, relinquishing the perfume to the alcohol, which is drawn off, evaporated, and condensed, until only the pure essential oil remains. Orris root is used to imitate the essential oil of violet, and oil of geranium that of the rose. Even in the almost priceless Turkish attar of roses the petals are often sprinkled with geraniuin oil before being placed in the still.
Some of the cbeap scents depend largely for their composition on chemical combinations imitating the natural perfumes. Their chief defect is that often their imitative values do not last, and this accounts for the unpleasant odour of much cheap perfumery when stale, the chemicals used having been affected by exposure. Some of the cheaper flower perlumes are quite pleasant in use, but their chen pness is duc either to extreme dilution of the natural scent, in which case they have no lasting quality, or to a less expensive natural oil being substituted for that of the name of the flower on the bottle. Shortly after use they possess only a vague, meaningless sweetness.
Scent should be regarded as a luxury of refinement and worthy of a good price. The best qualitics are economical in use, as a few drops suffice to give the delicate fragrance. See Eau-de-Cologne : Glass; Lavender Water; l'ot-Pourri ; Sachet, etc.
SCHIPPERKE. The littlo skipper, to give an English rendering of its Flemish name, is an affectionate and lively small dog with an inguiring mind; a vigilant watch-dog, keen ratter and intelligent companion.

Wholly black in colour, he has a sharp foxy appearance, with a short straight back, well rounded at the hindquarters, and a dense, larsh coat which is developed into a bristling fril! around the neck. Tho legs are straight and small boned, the feet small and cat-like. There is no tail ; that is to say, some are born without one, the others have it docked in infancy. The small eyes are brown and bright; the cars small, sharp-pointed and carricd stiffly erect. The weight should be about twelve pounds. riec Dog; Kennel. Pron. Ship per-ki.

Schizanthus. The botanical name of the beautiful half-hardy annual called the butterfly flower (q.v.).
Schnapps. Hollands gin is also frequently known as Nchnapps. See Gin.

SCHNAUZER. This is a German varicty of terrier. It is a rough coated terrier, stoutly built, docked and weighing about 24 lb . In colour they arc grizzle or greyish and very active, sagacious, game and companionable. The schnauzer is a haudy dog and puppies are not difficult to rear.
SCHOOL: How to Choose. For those who require a day school the difficulty is not unduly great, because the choice is distinctly limited. A school in the neighbourhood of the home must be selected, and for many persons this will be a schoo! supported by the local education authority. The majority of these arc the elementary schools; but for the more advanced pupils there are secondary schools, where the teaching reaches a very high standard of excellence.
For those who desire to send their children 10 day schools of a different kind there is also ample provision. As regards boys, most towns have a public school in the shape of a grammar school, which is mainly attended by day pupils. These, with which the great day schools in London, St. Paul's, Westminster, Dulwich, and others, may be classed for our purpose, give a very good education at moderate fees. Travelling facilitics make it possible for many boys living in country and suburban districts to attend them. These schools, however, do not take boys until they have reached a certain age, 12 or thereabouts, and have attained a certain proficiency.

Younger boys may be sent to the kinder. garten department of a girls' school, or to some other school which provides training for juveniles, and from thence, when about seven or cight, pass to a preparatory school for boys, of which there arc many excelleut ones under private control. Siome of the large schools, St. Paul's, for instance, run preparatory schools quite apart from the main school.

The education of girls belonging to the same social class as the boys mentioned is provided for by a chain of public schools, controlled by companies not working for profit, and by a large number of private schools. The former invariably provide an excellent education, and most of them have a junior department, where both boys and girls are taken as soon as they need a school.

The latter class vary very inucb, and no general statement can be made about them. Those who think of sending daughters to a school of this class should make careful inquiries, especially from persons who have themselves sent girls there. Private schools

Schipparke. Champion of a breed ol small alert
dog which makes a trustworthy guard
are preferred by many on socia! grounds, and they are certainly better suited for children who, for reasons of health. are unequal to the strain of a public school.

Boarding Schools. For the limited class of parents who send their children to a boarding school there is a wide varicty of choice. Concerning the age at which they should be sent there is a certain difference of opinion. Some send boys as carly as 8 , and it is generally agreed that they should go not much later than 12 or 13 if they are to benefit properly from the public school training. Girls are usually sent to boarding school at a later age, not before 14, and this may be regarded as a sound principle.

For boys these schools may be divided into two classes. These are preparatory schools, nearly all private ventures, and the great public schools, as they are called. The curriculum and arrangements of the one are deliberately planned to lead to the other.

As, therefore, the private schools prepare for the public schools, parents should, if possible, choose a preparatory school that has a special interest in the public school for which the boy is intended. Monetary considerations are important here, as the fees of many preparatory schools reach a very high figure. Parents should, however, be warned against choosing a school merely because the fees are low. People only get what they pay for, or less in education, as they do in other things, and the cheapness may be made possible by economy in food or some other essential of health. Persons who cannot pay for a good boarding school will do much better to send a boy to a day school.

## Entering Boys at Public Schools

Parents who wish to eend their boys to one of the large public schools should enter the name as carly as possible. The age at which names are received varies from school to school, but the necessary information can always be obtained from the headmaster or the bursar.

As between ono public school and another, there is little to be said. The fees do not vary enormously, but it must be rememberecl that, though the schools at the top socially may not charge much more in fees than do the others, they cost more in other ways, as certain expensive standards of dress and living are maintained by the boys. Moreover, generally speak. ing, it is inadvisable to throw a boy into the society of those who in after life will possess far more moncy than he is likely to have, at least as a young man.
Of the boarding schools for girls, a few are public schools, run on lines not unlike those of the boys' schools, but the great majority arc private schools. For those with adequate means the public schools can be unreservedly recommended, but the private schools vary, both as regards charges and as regards efficiency, more perhaps than any other class, either for boys or girls. For one of these the choice should only lo made after very careful inquiry, whiclr should be in addition to personal inspection. Some of them make a great point of deportment, and training for the life of London society but this is useless, except for a few girls.
Many of these schools, and also many of the preparatory schools, are situated by the sea, and this makes an appeal to a great number of parents. It is quite certain that the sea air is. excellent for children, and regular sea bathing is a distinct advantage, but parents should not let these considerations outweigh all others.

Scholarships. Many boys are enabled to pass through a public school by the aid of scholarships, and in the same way boys from the elementary schools pass to the secondary ones. In both cases the compctition is fairly severe, and in the case of the best public schools it is very severe indeed. Those only
can hope to succeed who, in addition to marked abilities, are sent quite early to a good preparatory school and are specially conched.

Boys with good voices can obtain an excellent cducation in one or other of the choir schools, where also financial assistance is given tnwards the cost of educntion. For girls there ale not so many scholarships.

Other methods of educating children are practised on a smaller scale. There are one or two schools devoted to co-education, in which some persons belicve. Others send children abroad to be educated, Switzerland being popular for this purpose. In this way they obtain $a$ knowledge of modern langunges: but unless the school is a very good one it is probable that the loss is as great as the gain.

SCHOTTISCHE. In the ordinary schot. tische the first, second and third movements are the same as in the polka, the woman beginning with the right foot and her partuer with the left. The fourth movement is a slight spring on the toc of the commencing foot and then, as in the polka, the step is made, beginning with the other foot.

Having performed the full step from side to side, the half step is made by a little spring on the toc of the first foot ; left, man, right, his partner. The other foot is passed behind, rested on the toe, and a spring is made on the lirst foot again. Then the movement is repented with the other foot. The half step is used for turning.

In the Highland schottische the couple face each other, hop twice on the right foot, give a beat in the fifth position in front and one behind with the left foot. Then each passes to the left with the first 4 morements of the ordinary schottische and repeats the whole step to the right. They then join arms, turn round with 8 hops and repcat. See leel.

SCIATICA. Neuralgic pain in the great sciatic nerve running down the back of the thigh is known as sciatica. It is more common in men than in women, chiefly amongst those who are constantly exposed to the weather.
Throughout the course of an acute attack the patient is best in bed. At the start poultices along the course of the nerve often relicve the pain. At the same time they ensure the limb being kept at rest. After a day or two the poultices may be discontinued, large pads of dry cotton wool being wrapped about. the limb in their place.

At the onset of the attack some aperient, such as 2 or 3 gr . of cascara, to be followed next morning by a teaspoonful of Epsom salt, is usually advisable. To control the pain, aspirin in 7 to 10 gr . doses orery 4 hours masy be taken under medical advice.

Stimulating applications, such as liniments of belladonna, aconite or chloroform, the galvanic electric current, hot water douches, or alternating douches of hot and cold water may be tried. See Gout; Poultice; Rheumatism. Pron. Si-ĭt'i-ca.

SCILLA. This group of spring and early summer flowering bulbs is popularly linown as squills and blucbells. They are planted in carly autumn in ordinary soil and flourish in sumny or partially shaded places: blucbells are happy in deep shade. The bulls of the small carly kinds should be set 2 in . decp, the larger ones 3 in . deep. The best of the dow growing early spring squills are sibirica and bifolia with bluc flowers; they look well in the rock garden, tlower border and shrubbery and on the lawn.

The common bluebell is Scilla mutans, of which there are varieties with rose-pink palc blue, dark blue and white Howers. One named Scilla autumnalis, 6 in., has pur-plish-bluc Howers in early autumn. The Spanish blue bell (hispanica) 15 in., bears showy spikes of bloom in various colours in

May. The italian squill (ltalica) and the Good tca-scones can be made by sifting l lb. Peruvian squill (peruviana), 6 in., have finc flour with $\frac{1}{4} \mathrm{oz}$. carbonate of sonda, $\frac{1}{2}$ oz. pale blue flowers in early summer and are cream of tartar and a good pinch of sait intc suitable for the rock garlen. Scillas may be set in pots in carly autumn and grown in an unheated or slightly heated greenhouse to

Scilla. Three of these blue spring foowering bulbs grown in a pot for bouse decoration Courtesy of Amateur Gardening
provide bloom in early spring. They are suitable also for planting in bowls of fibre in the home. See Bulb; Hyacinth. Pron. Síl'a.

SCISSORS. In a pair of scissors the flats of the blades slide over each other so that a shearing action is obtained; the blades are ground to a wide angle, not a finc angle, as for a knife. Scissor blades should be bent slightly so that their natural spring makes the cutting edges scrape each other as the scissors are closed, and the pivot should be a screw locked by riveting the point over. Many houschold scissors lack these features, and the scraping action has to be got by a twisting action of the thumb and finger. It is thus difficult to use a pair of right-hand scissors with the left hand. To test the shearing action of scissors, when buying them the rings should be held one in each hand and the scissors opened and shut; under this test the blades should not llap freely, but a steady grind should be felt. though a pair that is stiff to work should be rejected.

Repairs. If scissors get loose after long service the pivot should be tightened a little by laying the scissors on a heavy piece of iron with the head of the screw down and drawing the rivet tighter by light hammer Hows on the screw point, the screw having heen first tightened with a screwdriver if possible.

When scissors get blunt the edges must be ground with an oilstone or on a grindstone, cutting at right angles to the plane of the flat of the blade, the scissors being held wide open for the purpose. On no account must any attempt be made to grind the flats of the blades. See Cutting-out; Grindstonc ; Pruning; Secateur; Shears.
Scolopendrium. This is the botanical name of the popular hart's tongue fern. See Fern ; Hart's Tongue Fern; Rock Garden.

SCONE : How to Bake. Scones may be cooked in the oven or on a girdle. The mixture for these cakes is usually of a plain character, and the raising agent employed consists of hicarbonate of soda and cream of tartar or baking-powder.

If a little extra time and trouble is taken by sifting the carbonate of onda and cream of tartar with the flour two or three times, the scones will be greatly improved. Buttermilk, or sour milk, is considered to be superior to fresh milk for moistening the dough, in which case a smaller proportion of cream of tartar is required for mixing with the carbonate of soda.
a basin. Work together 4 oz . butter and $2 \frac{1}{2} \mathrm{oz}$. castor sugar, adding, when properly creamed, 2 well-bcaten eggs and $1 \frac{1}{2}$ gills milic. Mix up the flour into a stiff dough with the liquid, roll it out about $\frac{3}{4} \mathrm{in}$. thick, and cut it into small round pieces.

Cut out as many as possible, then fold up the dough, roll it out again and cut another batch, proceeding in this manner until all the mixture is used up. The shaping must be done expeditiously, and as each round is cut out it must be turned over and placed on the bakingsheet. No fruit is added to these scones, and they should be scrved hot, split and thickly buttered. Brown scones can be made by using half wholemeal flour and half white Hour. A little more milk may be necessary to get the right consistency. For sultana scones add 2 oz. cleancd sultanas.

Excellent baking-powder scones can be made by increasing the quantity of milk for lea-scones by 1 gill, and adding to the Hour 2 heaped tcaspoonfuls of baking-powder in place of the carbonate of soda and cream of tartar. These scones should be shaped with a tablespoon dipped in flour, as they are toc moist to handle casily. They must be baked in a very hot oven, and caten hot from the oven. See Girdlc Cakc.
SCOOP. A scoop is a shovel-like implement used for moving food or other material. The shovel attached to a coal box is sometimes called a coal scoop, while the spoon cinployed for soft sugar is occasionally known as a sugar scoop. Other examples are the crumb and the marrow scoops. See Coal Box : Shovel ; Sugar Basin.

SCORCHING. For scorch marks on linen mix together $\frac{1}{2}$ pint vinegar, 2 oz . fuller's earth, $\frac{1}{2}$ oz. shredded white soap, and the juice of ${ }_{2}^{2}$ onions, and boil them up until they form a thin paste. Spread this over the marks, allow it to dry on the material, and then wash it out. The process may te repeated if necessary. The onion juice is obtained by peeling and slicing the onions and then pounding or squeczing them. Silk or wool that has been badly scorched will rarcly yield to treatment. See Ironing.
SCORZONERA : The Plant. A vegetable with long thin roots which is useful in winter though not very commonly grown in this country. It is easily managed in deep well tilled soil free from fresh manure. Sceds are sown in April in drills 12 to 15 in . apart, and the scedlings are thinned out to 9 in . apart. In autumn or winter the roots are dug as they arc needed.
SCOTCH BROTH: How to Make. The basis of Scotch broth is mutton, and it is Havoured with vegetables and thickened with pearl barley. To make it, take 3 lb . middle and scrag end of a neck of mutton joint it and cut all into neat pieces. Put these into a large sauccpan with 3 quarts cold water and $\frac{1}{4}$ oz. salt and boil up, skimming off all impurities.

Now prepare and cut in large pieces 2 goodsized turnips, 2 leeks, 2 onions and 1 head of celery; add these with a large bouquet garni to the mutton, boil up again and then simmer gently for four hours. Strain through a sieve into a basin, rinse out the saucepan and return the liquor to it, adding $3 \frac{1}{2}$ oz. pearl barley which has been washed and parboiled.

When the broth boils up again, add to it a mixture of fresh vegetables cut into dice. These should consist of 2 small carrots, 2 large turnips, 1 small head cclery with 2 onions and 2 lceks shrelded fincly. Season with salt and pepper and boil gently for I hour, skimming the broth free from fat. Sometimes carrots are omitted Whether the portions of mutton are served in the broth is a matter of taste.

SCOTCH BUN. This bun requires two days for making. To prepare the dough, sieve together 1 lb . flour and 3 oz . sugar. Then rub in a little less than $\frac{1}{4} \mathrm{lb}$. butter. When the mixture is quite smooth cream together $\frac{1}{2} \mathrm{oz}$. yeast and a pinch of salt; pour in $\frac{1}{4}$ pint cold milk, and strain the whole into the flour, etc. Well knead the mixture, and then leave it overnight in a warm room, covering the bowl in which it is placed with a thick cloth.
The centre of the bun must be prepared the following day with $\frac{1}{4} \mathrm{lb}$. of the above mixture, $\frac{1}{2} \mathrm{oz}$. spicc, $\frac{1}{4}$ teacupful treacle, a wellbeaten egg, $1 \frac{1}{2} \mathrm{lb}$. mixed raisins, currants, and sultanas, a few sweet almonds, and $\frac{1}{4} \mathrm{lb}$. shredded candied peel. Mix all these ingredients in a basin, afterwards kneading well and moulding the mixture with a little flour.
To make the cover of the bun, take the rest of the dough, rolling ${ }_{3}^{2}$ of it into a round, and lift the inside part of the bun into this. Then draw up the dough at the sides to reach the top, brushing beaten egg over the edges, and roll out the remaining dough for the top portion. Put on the top round as neatly as possible, and prick the bun all over with a fork, making deep holes all over the surface. Brush the bun over with a little milk, and bake in a moderate oven till brown. This should make a 3 lb . bun.
Scotch Fir. The common name of Pinus sylvestris, a conifer which is invaluable for planting in exposed places. See Pine.

SCOTCH KALE. This is a very hardy varicty of borecole or kale and includes dwarf and tall curled kinds. No type of winter green excels it for free yielding crops during autumn, winter, and spring.

The kale reaches a height of from 2 ft . to 3 ft ., with heads of deeply curled leaves, which are at their best after exposure to frost. Seeds are sown on a reserve border in April, and the seedlings are planted out in summer at $2 \frac{1}{2} \mathrm{ft}$. apart. See Kitchen Garden.
Scotch Pancake. This is another name for the tea-calkes known as girdle cakes (q.v.).
Scotch Terrier. See Aberdeen Terrier.
SCOTCH WOODCOCK. The savoury that is called by this name is prepared by mixing $1 \frac{1}{2}$ teaspoonfuls flour to a smooth pastc with 1 tablespoonful milk and putting what remains from a gill of the latter into a pan with 1 oz. butter. When these are hot, stir them on to the flour, mix all together, and boil them up.
Simmer them for a fow minutes, kecping them well stirred, draw the pan to the side of the fire and let its contents cool slightly before stirring in one by one the yolks of 2 eggs. Continue stirring the whole over gentle heat so that the eggs may cook, then add salt and cayenne to taste, and a teaspoonful of chopped parsley. Have ready some small rounds or squares of hot, buttered toast, spread them first with some anchovy paste, and then with the hot mixture. Send them to table at once, garnished with narrow strips of anchovy laid across the egg.
SCRAP BOOK. Brown paper makes an effective book. Sheets cut to the required size and stitched together with strong thread, or fastened at the corner with a piece of ribbon run through, make an excellent background for all kinds of pictures. Books for hospitals, especially for sick children, can be made out of coloured and glazed calico, pink or blue, with the edges pinked and a piece of silk cord or ribbon threaded through to kcep the sheets in place. If the calico will not take paste satisfactorily, a little seccotine or fish glue will serve the purpose equally well. The great advantage of such books is their lightness.

For the pictures themselves there is no need to seek far. Coloured advertisements cut out and pasted up neatly without the printed matter, and illustrations from bulb catalogues,
or those distributed by seed merchants are useful. Such pictures should be cut out in silhouette if the best effect is to be obtained. Old Christmas and birthday cards, scraps from crackers, and the covers of magazines all help to provide colour and variety. Flour paste is usually sufficient for this work, though for thick cards something stronger may be nceded.

SCRAPER: For Boots. In one sense this word refers to an article used for removing dirt from boots and shoes. Such are usually placed just outside the door of a house. Sce Boot Scraper.

SCRAPER: The Tool. The scraper is a tool for giving a better finish to an article already machined or worked. The type for woodworking, illustrated, consists of an oblong strip of sheet steel about 6 in . by 3 in . and in

Scraper. Oblong strip of steal beinz used as a finishes in woodwork
thickness about $\frac{1}{18} \mathrm{in}$. This tool is largely employed in cabinet making. The method of using is to hold it in both hands a few degrees out of the perpendicular away from the operator. The two thumbs are placed in the middle of the scraper on the side nearest the uscr, while the fingers grip the other side. Pressure now applicd by the thumbs will give the scraper a bend in the middle and away from the operator. The lower edge is put upon the work and a strong forward motion im. parted by the upper arm.

In the majority of cases the scraper is used in the same direction as the grain of the wood; but experience is the only guide in this
woolly after scraping; this can be cured by scraping with the grain but from the opposite direction. It is sometimes useful to approach the scraper to the wood in an oblique direction, this having a decided tendency to kcep the grain in place, but it has the disadvantage of making a slower cut.
The method of sharpening represents a radical departure from the standard practice of tool sharpening. The scraper is set firmly in a vice between two pieces of wood, the top projecting a little. A fine file is then run over the top, and the burr thus created removed with a fine oil stone rubbed on the top and sides. When both edges are sharp a round rod of hard cast steel or similar material is pressed on the edge of the scraper at an angle of about $45^{\circ}$ with it. The sharpened edge is thus destroyed and another burr created. This burr is the scraping edge of the tool.

Scrapers are extensively employed in metal fitting. Such a tool can be made from an old file, the teeth of which have been ground away on the grindstone and the edges ground sharp and smooth. Such scrapers are durable and efficient. See Cabinet Making; Metal Fitting.

SCREED. A projecting strip known as a screed is employed in plastering and rendering as a guide in the preparation of a flat surface. It may be of wood or metal or of the same material as the surfacing of the wall.
Wooden screeds are fixed to the face of the wall or other surface with the aid of rough grounds or thin packing picces. The face of the screed is levelled, or brought into line with the desired face for the work. Two screeds are set vertically and two horizontally, then all four are adjusted until their faces truly represent the outer surface of the wall covering. Lincs are stretched from one screed to another and any additional screeds added wherever they are requisite.

The wall surface is thus divided into a series of cells, the screeds being usually about 2 to 3 ft . apart. When this preliminary work has been clone the covering material is then applied, and afterwards levelled with a long batten. When the plaster has set sufficiently the screeds can be removed and the spaces filled in with plaster, etc., or more generally are embedded in the second and finishing coats when these will be of sufficient thickness.

In other cases screcds are made in the form of little walls of cement or plaster and their faces levelled, the spaccs between being -subsequently filled in with the same material. See Lath; Plaster; Rendering.

## SCREENS: USEFUL AND DECORATIVE

## Their Choice, Construction and Renovation

For further informa:ion on the work suggested below consult Marquetry; such entries as Embroidery; Fire Scrien; Inlaying; Lacquer; Lead Art Craft; Leather Work; Moulding; Mitre Joint; Painting on Texite Fabrics ; Patchwork; Plywood; Tapestry; Veneer.

To be decorative and practical is the twofold object of the screen. Styles which, by reason of spindle-like legs or of openwork carvings on their pancls, let through draughts, are only useful where they hide something unattractive ; if not required for this purpose they should be admitted to rooms only on the same principle as pictures-by right of intrinsic beauty.

When choosing a screen it is worth while taking thought and trouble to secure the right type, as it presents such a large surface to annoy or please the cye, and however beautiful in itself it can mar a room by being out of key.
Reproductions of rare and artistic screens can be obtained at a variety of prices, and for durability those in leather have cverything to reconmend them. In brown, antique finished hide with no trimming but brass nail heads, they look their best in an oak-furnished dining room or hall, while the embossed or lightly modelled heraldic device style of
ornamentation supplies variety to the same type of screen. The quaintly patterned and coloured leather screen, with its conventional fruit and floral motifs is; when placed against a plain wall, a joy in mellow richness of tint and the same may be said of those panelled with grouped figures after the style of various schools of painting.

The most beautiful type of leather screens are painted and lacquered. The illustration with a Chinese design might have graced a Queen Anne room (though screens were then often six-fold), or have been seen during the middle 18 th century period when Chippendalc and other great designers were influenced by Chinese styles. Copies of such screens look beautiful in rooms which suggest 18 th century furnishing. With certain severe types of modern interior decoration, plain gold lacquered screens may look more effective.
For the living-room tapestry screens are often suitable, and panelled with necdlework

Screen. Wooden screen with mountain landscape design inlaid with coloured marquetry and with inlaid line at the edges of the panels coloured marquetry and with inlaid line at the e
Courtes"/ of Rowle" Galleries
panels of this sercen will also be found in the arlicle on Lacyuer Work, and that on Enamel should also be consulted Floral designs can be selected a prett.y idea being to copy flowers from a cretonne used in the furnishing of the room. A beantiful effect can be achieved by treating the upper panels with pokerwork in colours (see 1. 977), staining the lower pancls and framework with marquetry stains. Wood carving can a!so b? effectively introduced in low relief and incised designs

Another form of decora tion is by means of glass and lead art craft (see page 706). A screen for a hall looks well with glazed upper panels trealed in this manner, the rest of the screen being stained or lacquered a bright colour. If canvals is used to cover the pancls, a conventional design may first be stencilled on the fabric (see Stencilling), or lesigns may be embroidered in coloured wools.

Making a Screen. The three and four fold screen can be made by the a mateur in many different patterns. The plain form illustrated in Fig. I will
serve as a guide to their construction. The plain screen can lee given a lecorative effect by means of the panels, which can be of omamental wood, and many linds of plywood are of valuc. Canvas in artistic sliades can be stretched on plywood and used as panels.
The construction of the framework of a screen is straightforward, but the material must be well scasoned to prevent warping, and planed quite straight and true For a ful!-size screen the wood should be at least 2 in . by ${ }_{4}^{3} \mathrm{in}$., but $2 \frac{1}{2}$ by 1 in . is advised. The extra thickness will make the screen heavie!, but this is not a disadvantage. Before the joints are marked out, the method of sccuring the panels should be determined. Two methods are suitable: in one the panel is let into a ploughed groove, as in Fig. 2, and in the other the panel is held in position by slups of beading, as in ligg 3 .
The haunched mortise and tenon joint for the corners of the grooved frame is shown in Fig. 4: the grooves should be ploughed to fit the pancling and carried to a depth of $\frac{3}{8} \mathrm{in}$. The same joint should be made at the corners in the case of a plain frame, but the tenon will be flush with the inner edges of the frainc. The choice of material depends on the panelling. If a canvas-covered pinel is litted, the frame can be of deal, pine, or whitewood stained to match the inaterial; if a decorative wood is used the framework should match the panels. The uprights and rails should be placed together in marking out, so that the position of the mortises, tenons, and shoulders can be quite accurately indicated.
In the present design the uprights are 5 ft .6 in. , and the rails 2 ft , with a $2 \frac{1}{2} \mathrm{in}$. by lin. framework, and the top panel should be lft .5 in . high. The frames should be cramped

1apestry are highly decorative. Drawing room screens may have Chippendale style mahogany frames, glass-topped and with lower panels of brocade. Sometimes beautiful old needlework is utilized under glass for this type of screen, or in combination with a gilt scrolldesigned frame in the French style. Cheap Oriental screens are not to be recommended. as the paper backing under the embroidered gauze is so easily split and torn.

All-glass panelled screcns are decorative in suitable rooms. and are useful where it is desired that draughts but not light should be excluded. Mirror glass is used in sectional designs, and such screens tend to make a room look larger. As a general rule, glass of any lind is more suitable when confined to the upper panels of a solidly constructed wooden screen.

For a bedroom plain-coloured canvas, silk or cotton material repeating an established tone in the room is restful and pleasant. A different patterned cretonne or thintz to that already draping the room should be aroided. Some people like a gathered washing material merely tied with tapes on to one of the wooden frames sold for the purpose, so that the whole thing can be washed. The objection to this type of screen is that it is not a draught preventer.

Decoration of Screens. For the nursery or living-room a wooden screen can be most decoralive, light and yet durable. The white enamelled example illustrated is most practical, as it is washable; the other wooden screen shown has a mountain landscaje design inlaid with marquetry of coloured woods. Less ambitious designs in marquetry could be confincd to the upper panels of a screen constructed after the style of Fig. 1. This screen could also be enamelled and decorated like the nursery screen illustrated. The animal pictures can be drawn frechand, traced, or stencilled and painted in oil colours. Ideas for the suitable decoration of the opper

Screen. Four-fold hide screen with antique gold lacquer design on a cream-coloured ground Courtes// of Waring \& Gillow. Ltd.
 melled wooden screen for a nursery, with
stencilled and painted in bright colours
up and carefully tested for squareness, and it should be noted that any carelessness in cutting the joints may cause the frame to warp. As much of the surface finishing as possible should be done before the frame is glucd up if the panels are let in the framing, the final cleaning up and subsequent polishing being done in the usual way, either wax or oil being preferable. The canvas-covercd panels are very effective; the material should be pasted on, or if it has been embroidered or stencilled in a coloured pattern it can be stretched and tacked carefully to the edges of the panels.

If beading is used it should have a rounded edge, and be secured to the frame with panel pins, the corners being mitred. An alternative design can be made to the same proportions with plywood panels of Oregon pine, a centre upright being fitted, and the panels secured with $\frac{1}{4}$ round beading. Made with deal framing and stained either brown or green, the screen is both-effective and inexpensive. The divisions can be hinged with the simple hinge shown in Fig. 5; or the usual form of screen hinge in Fig. 6. The latter enables the divisions to be folded in either direction, and keeps them close together. They are both easy to fit, slots being made to take the thickness of the material.
Renovating a Screen. A canvas or other plainly covered screen that has become shabby need not be discarded as useless, for it can be casily renovated. If the framework is stout, glazed calico can be used to cover it, being fastened round the edges by brassheaded nails, and in the folds by tacks.

By means of fish glue, scissors, and some bright-coloured pictures, the screen can be transformed into a gay and attractive piece of furniture for the nursery. Suitable pictures can be obtained from book wrappers, magazines, and old children's books. The pictures should be cut out neatly, brushed over with a thin coating of glue, special attention being paid to the corners, and stuck on to the screen.

One fold should be finished before another is begun, and the top row should be done first. It is generally best to start at a corner, not in
lainting on satin provides one of the most effective ways of renovating panelled screens. The frames themselves must be in good condition, and the satin of a colour that will harmonize with the wood. Embroidery and painting may be happily combined. IDesigns may also be outlined in coloured beads. If white or some pale shade of artificial silk

or satin is used, a glass covering that will protect it from dust and yet show the work to the best advantage is essential. Worked and painted panels can be made up into screens, the cost depending on the size and style of mounting.

SCREENING: In Wireless. This is a method of preventing interaction between two adjacent circuits by interposing a metal shield. The screening should be arranged so as to minimize both magnetic and capacity couplings, otherwise instability is liable to occur.

In simple sets a single metal sheet (usually of copper or aluminium ) may suffice, but

Fig 1

Fig. 4
the centre. It does not in sensitive multi-valve receivers it is sometime matter whether the pictures necessary to enclose the adjacent amplifying are the same size or not, but stages in metal boxes. In sets employing up as they must fit exactly into to five valves the screening is normally conthe width of the screen and they should not be overlapped, it will probably be necessary to have a very wide one, or one, or two narrow ones at the end of the row. Thin white varnish, as used for lamp-shades, should be brushed over the pictures to complete the work.

A screell frame can be covered with furnishing satin and decorated with shaped pieces of embroidery at the top of each panel framed by $a$ gimp trimming, which in a wider form edges cach fold of the screen. This method has been used successfully for covering an old screen, and dcpends on careful measurement, the neat strctching of the material over the frame and the skilful manipulation of the edging gimp. Hand cmbroidery or appliqué work can be used instead of bought pieces if more time can bc devoted to the manufacture of the screen, or the scheme lends itself to all sorts of combinations of materials and colours in forming pancls fined to the high-frequency stages. Inductance coils should be carcfully placed in relation to the screening, since if the coils are mounted too close to the metal shiclds a marked loss of efficiency may occur. The metal work comprising the screening is normally joined to earth, and thercfore to low-tension negative. It is essential to insulate from the screens all wiring not at carth potential.
SCREW : For Wood and Metal. The screw is a cylindrical piece of metal or wood having a spiral groore cut along the whole or a considerable portion of its length. At onc end provision is made for imparting a turning motion to it.

The wood screw has a tapered shank, which taper varies according to the nature and the application of the wood with which the screw is used. The thread resulting from the spiral groove cut along the shank is decper, thinner, and spaced farther apart in the wood screw than in the metal screw. The former terminates at its lower end in a sharp point. The metal screw, on the other hand, has a fine thread of little depth and in many patterns the thread is formed along the whole length of the shank. The shank is parallel and docs not terminate in a point.

In principle the screw represents an inclined plane moved by a force up or along another inclined plane. These are represented by the screw thread and, in the case of the metal screw, the thread of the screwed hole. The wood screw makes its own thread as it advances. Metal has such solid properties that only a hole of the correct diameter and shape, tapped out with a cutting tool having an identical pitch, allows the screw to be turned into it. The angle of the inclined plane is known as the pitch angle of the screw, and the spacing of the threads as the pitch. The difference of type between the two classes of screw is necessary owing to the entircly different natures of wood and metal.

The countersunk wood screw is designed to sink flush with the wood, and is used where an unbroken surface is required, as in a table top. The round-head screw is useful where the material is too thin to permit countersinking, and this type is also used for its inore decorative appearance. It is often japanned and used with rim locks, barrel bolts, and thumb latches.

Where a good appearance is desired iron screws may be blued, tinned, or finished to match any particular work with which they will be afterwards associated. Screws for outside work can be had with a galvanized finisl. Raised-head screws are a combination of the

Fig. 2

Fig 3

Fig. 5

Fig. 6

Screen. Fig. 1. Easily made wood and canvas three-fold screen. Fig. 2. Method of securing panels by a plougbed grovve. Fig. 3. Panel held by strips of beading. Fig. 4. Haunched mortise and tenon joint for framework. Figs. 5 and 6 . Types of screen hinges
countersunk and round-head pattern. These are often employed with a small brass cup, or socket, for use in hardwood, where they may be renoved from time to time without the risk of clamaging the surrounding wood.

To enable a screw to be introduced into wood, it is necessary to bore a hole somewhat smaller in diameter than the screw. This is most conveniently accomplished with a ginulet. After the loole has been made, the screw can bc driven with the aid of a screwdriver, or with a screwdriver bit in a carpenter's brace. If two pieces have to be screwed together, the screw can only bite properly into one of them, which should preferably be the thicker if there is any differencc. What is known as a clearing hole is drilled in the first piece, and the termination of the hole on the face of the work should be properly countersunk. The head should draw

Screw. Diagram illustratin3
process of screming in wood
shank can just turn is provided
Driving screws into plaster is a difficult operation; either it will be necessary to fix a wooden plug or to employ one of the patent fibre plugs. The method is described and illustrated in the article Plug (q.v.).

Screws for Metal. The thread and pitch of metal screws vary with particular requirements, two standard threads much in use being the Whitworth and British Association sizes. The former is the thread nost commonly used in machinery, and the latter for model work and small screws generally. Except for special purposes, the thread of a metal screw is taken to the head of the screw
Metal screws can only be driven into material after a hole has been drilled and tapped to receive them. The tapping process consists in making a screw thread of the same size and shape as that on the screw which is to be screwed into it. See Hand Screw; Sitocks and Dies.
SCREW CUTTING. So far as the amateur is concerned, there arc two ways of cutting a screw thread, namely, by the use of stocks, dies, and taps, or in a lathe. The first of these methods is described in the article on Stocks and Dies.

In using the lathe there is far more to be considered than a mere operating of the tool rest and the lead screw control nut of the lathe saddle. Some makes of small lathes are provided with a dog clutch on the lead screw instcad of a split nut on the saddle. The first thing to do is to set the change wheels in accordance with the table of changes provided, selecting, if possible, a pitch that has an even multiple of the pitch of the lead screw. In other words, if there are 8 threads to the inch on the lead screw, then 16, 24, 32, and so on are even numbers, and the dog clutch or split nut that governs the travel of the saddle may be engaged at any point without fear of the tool failing to come up in register with the partly cut thread.

If an unequal number of threads per inch must be cut, it will be necessary to stop the
lathe at the end of each cut and line up at the chalk marks previously made at two points, the first on the mandrel and the second on the lead screw. corresponding marks being made on the body of the lathe. As soon as all four marks line up the saddle may engage with the lead screw on no account before. This is illustrated in

## Fig. 1.

The work to be screwed is first turned to the required diameter, and a small extension, left on the end, turned to the root diameter of the thread, so as to avoid the possibility of cutting the thread too deep (Fig. 2). The work should then be placed in the lathe, either between centres or in a chuck, according to its shape. Next set the tool, ground level with the centre of the work, and at an angle of $90^{\circ}$ to the lathe bed.

Now approach the tool close up to the outside diameter of the work, so as to get the first position and reading of the handfeed index. If one is not fitted, chalk a mark on the hand wheel, then withdraw the tool a little way and place it, by means of the tool rest, about $f$ in. from the work towards the tail stock. Then return the tool about one-sixth of a revolution of the hand wheel nearer the work, as indicated by the position of the chalk mark just made.

Start the lathe, having first engaged the back gear and the lead screw clutch, and make the first cut, withdrawing the tool smartly when the end of the cut is reached, at the same time throwing out the lead screw clutch. Then return the tool towards the tail stock to its original position and set about $5^{\circ}$ deeper than the one-sixth just given : throw in the clutch and make the next cut.
This process is repeated until the thread is of the correct depth. In the case of work that is held in a chuck, it is an casy matter to test the progress of the thread with the part into which it is to be screwed. The chuck may even be unscrewed of the mandrel without fear of upsetting the register of the tool with the thread. Where the work is placed between centres great care must be

taken. if the work is removed, to see that the arm of the carricr that is in contact with the driving stud on the face plate is again the driving arm when the work is replaced; otherwise the work will be half a revolution out by the time the driving stud makes contact with the other arm, and this will bring the tool out of register with the thread. and break off. or soap and water should be used square thread section.

Great care must be taken in depthing the tool at each cut, and it must be borne in mind that the nearer the thread gets to completion, the greater will be the edge contact of the tool: therefore the depth of cut must be reduced gradually as the thread nears completion.

Screw Thread. Fig. 1. Standarj Whitworth. Fig, 2 Internation atandard (metric asstem). Fig. 3. Acme standard. Fig. 4 Buttreas
thread. Fig. 5. Common type of square thread. Fig. 8. Double thread hread. Fig. S. Common type of square thread. Fig. B. Double thread that the point of the tool will wedge up

If the above points are noted little trouble will be experienced when cutting fine threads, but for coarse threads, after the first 3 or 4 cuts, the tool should be very slightly moved by means of the tool rest across the thread. so as to cause it to cut on one face only, reversing the process so that the next cut is on the opposite facc (Fig. 3). The depthing of the tool is carried out as previously explained. When cutting a square thread this procedure is absolutely necessary for both fine and coarse threads. Plenty of thin oil

Screw Threads. There are two classes of screw thread, the triangular and the square. The former is used where grip and maximum security are required, and the latter where progressive movement is necessary with as little binding or frictional effort as possible. The lead screw that operates the saddle of a lathe is a notable example; in fact, the screws of all forms of high-class machinery that are a part of the various controls are of

The most common type of $V$ thread is the Whitworth, which varies in pitch, i.e. in the number of threads to the inch, in relation to the diameter of the bolt. The shape of the thread is shown in Fig. 1. One-sixth of the full depth of the thread is counded off at the top and bottom to facilitate the cutting of the thread, and to render the exposed thread of the male member, the bolt. less liable to injury. Where threads are formed by the use of stocks and dies, the shape of the thread will obviously be correct, but when the thread is cut in a lathe, such would not be the case unless great care is taken to see that the screw. cutting tool is ground to the angle of $55^{\circ}$ on the cutting faces.
Other standard screw threads are B.S.F., British Standard fine; B.A.S.T., British Association screw threads, the various sizes of which are stated in millimetres; B.S.P., British Standard pipe, used for all barrel work, such as gas fitting, etc.; and the I.S.T., International Standard thread (Fig. 2), better known as the metric thread. With
this type the angle of the thread is $60^{\circ}$, the top of the thread being flat and the bottom rounded. The American Standard sthe Sellers thead) is practic ally identical with the International in regard to shape of thread, but the pitch corresponds very nearly to the Whitworth table.

Two other types are the Acme and Buttress thread. The former, Fig. 3, is a modification of the square thread, used chiefly in machine tool work where a disengaging nut is required. Owing to the fact that the thread is wider at the botton for a given pitch than the equare thread, it is much strongcr
The Buttress thread (Fig. 4) is sometimes used where a screw has to resist a force acting always in one direction. It has one surface normal to the axis of the screw, like the square thread; the other,
as shown, is at an angle of about $45^{\circ}$. drill, and revolves automatically when the
The square thread in Fig. 5 cannot be handle is pressed down. A spring in the produced satisfactorily by dies, and has to be cut in a lathe. More than one thread may be cut on the same bar, if clesired, i.e. 2,3 , or more separate threads, termed leads, may go to make the complete screw, the pitch remaining the same in each case, as seen in Fig. 6. See Metal Turning ; Screw : Stocks and Dies.

## SCREWDRIVER: How to Use. A

 good screwdriver for general use is that known as the London pattern, which has a flat blade (Fig. 1, A). The cabinet screwdriver (B) with a cylindrical shank and oval or spherical handle is also a favourite. A long driver as used by electricians (C) is handy for many awkward jobs where the screw is difficult of access. In D) the blade and handle are forged from one picce of steel, the handle being made up to a comfortable grip with wooden scales riveted on.Ratchet screwdrivers (E, F) permit the blade to be kept in engagement with the slot of the screw during the whole operation of driving or withdrawal. Right or left-hand motion is secured by moving up or down a slide on the ferrule, and a centre position gives a neutral position, with the ratchet out of action. In another type the shank is spirally grooved like the shaft of an Archimedean

Screwdriver. Fig. 1. A, London pattern, which has a flat blade. B, cabinet screwdriver. C, long-shanked driver for electricians. $D$, screwdriver with blade and handle forged from one piece of steel. E and $F$, ratchet screwdrivers

Screwdriver. Fig. 2. Showing double-handed grip necessary for a large rewdriver. Fig. 3. Using screwdriver bit in brace hen driving a sc ward, it is started in the hole by taking it in the right hand and screwing it into the hole as far as it will go casily, without risk of cutting the fingers on the sharp celge of the head. The point of the screwdriver is then put in place in the slot in the head of the screw, the screwdriver being vertical, the palm of the right hand resting on the
end of the handle, and the thumb and end of the handle, and the thumb and

The process of driving the screw consists in turning the screwdriver to the right, while keeping a considerable pressure on it to prevent it from jumping off the head of the screw (Fig. 2). This pressure is liable to make the screw fall over to one side if it is excessive or directed out of the truc line before the screw is half-way home. 'The fingers of the left hand are, therefore, placed loosely round the blade of the screwdriver a little above the point, so that they can act as a check on obliquity.

When the screw is right home it must not be overtightened, since this may cause the screw threads to break the timber round them, which destroys the hold of the screw,
liable to happen with short or thin screws in soft woods. If it is found quite impossible to drive a screw it must be removed and the hole deepened or eularged before the screw is re-driven. With small. screws in hard timber, the screw should be withdrawn and the hole enlarged if the effort of driving becomes too great, or the screw may break.

A screwdriver scldoin requires any attention if it has been correctly hardened and tempered in the first place. After a lot of hard service, however, the point may get rather bruised and rounded, when it can be restored in a few minutes by filing with a smootl file on the two long flats and right across the point, being carcful to keep the actual Hat point square with the length of the ool and as thick as will enter comfortably into the size screw for which the tool is meant. See Plumbing.

SCREW PINE. The screw pine, also known as Pandanus, can be successfully reared in Britain in a hothousc, if grown in a moist and sunny position in ordinary potting soil in the intermediate house. It is lest propagated by means of shoots or offscts. It will attain a height of 3 ft . or more. Pandanus Veitchii is most frequently seen.

SCREW PLATE. Used for cutting small sizes in screw threads, a screw plate is obtain. able in two forms. One to hold dies consists of a flat frame of steel with an adjusting thumb screw at one end; the other is a Hat plate of stec containing a number of graduated holes forming dies. The latter tool is only serviceable for the smaller sizes, since no proper clearance is possible for the chips. See Stocks and Dies.

SCRIBER: The Tool. The scriber is used for marking purposes in every kind of metal work. It is made of steel hardened and sharpened to a fine point. The double end and is particularly gauge, being drawn along with one leg in
contact with skirting and the other, in line, fit, so that they may be made to stand up or Infantile scurvy, sometimes called Barlow's touching the dresser leg, so scratching a line to project below the base and overhang the on the latter showing the amount of material edge of the table or work being operated on, to be removed. When scribing the pilasters of a cupboard over the skirting, or to the wall, or when scribing a skirting board to the floor, the dividers are set to the greatest distance between the edge of the board and the wall or floor, as the case may be. See Cupboard: Dresser; Skirting Board.

## SCRIBING GAUGE. This instrument

 is used to obtain measurements from any Hat surface of predetermined accuracy. In as illustrated. The scriber is held in a in horizontal and vertical planes.
SCRUBBING BRUSH. The scrubbing brush used in the ordinary household consists of a plain solid stock, usually of birch, set with knots of bass, bassine, white fibre, or mixture.

In a machine-made scrub, a short piece of steel wire is punched crossways into each hole in the stock, pulling down with it a portion of the material used, and doubling it up to form the knot, the ands of the wire being forced into the wond at the bottom of the hole. It should be noted that the knots tightly fill the hole, otherwise there is little to prevent them soon falling out in use. Although a brush made by this process is not to be comparcd with a hand-drawn brush, it answers very well, providing the holes are well filled. A scrubbing brush with a long swivel operated handle, which obviates knecling, is illustrated in page $15 \%$.
SCRUPLE. This weight, used by chemists, consists of 20 grains , troy weight. Three scruples make a
the testing and marking off of engincering drachm and 24 scruples go to the ounce. See components of all kinds, the surface plate or Apothecaries' Weight. table is the basis of all morsurements.

The surface is a specially prepared casting, rilbed up at the back so that it forms a rigid base for any work laid on it, and with a top surface finished ofl to a high degree of accuracy. The smaller plates used on the fitter's bench are surfaced to $1-10000 \mathrm{in}$. by hand scraping in comparison with another plate, or by a patented grinding process. Work of all linds can be mounted on the surface table and with the scribing gange surfaces may ve marked out and tested, or machining and centre lines drawn on the job according to the requirements. A sheet of plate glass is sufficiently true for amateur usc.
The diagram, Fig. 1, indicates bow the bench surface plate and scribing gauge may be employed to mark out the levels of various lugs forming part of a casting. Theso lugs have to be planed off to the level shown by lines $A, B$, and $C$, which are all exactly the same height from the underneath side of the casting resting on the surface plate. The drawing at the same time shows the simplest form of surface gauge that can be made. This comprises a block of metal, the under surface of which is machincd Eat, and $\Omega$ steel arm pivoted to the block with a screw which will inake it work so stiffly that it will remain in any position to which it is set. This is hest acconiplished by fitting a double spring washer under the head of the screw. The end of the arm should be bent over, pointed, and be made of a steel that can be hardened and tempered
Metal work requires to be locally chalked where the scriber is to make a mark. 'To preserve the marks, should the chalk be rubbed oll, centre-punch dots are lightly hammered along the narked lines.
Figs. 2 and 3 illustrate a scribing block of a more claborate kincl. A V-slot in one of the vertical faces of the basc block is uscful for working against shafts and other round objects, while for obtaining scribed lines parallel to the edge of the surface table, or from any other straight edge, two pegs may be fitted in holes in the base. The steel pegs should be a push

SCULLERY. In small houses and flats the scullery is often combined with the kitchen. Sometimes where the kitchen is also used for meals, a scullery adjoins, which is provided with a sink and a useful cupboard fitted for brushes, brooms, cte., and also with shelves for cleaning requisites, and pots and pans, so that washing up, the preparation of vegetablcs, and rough work may not have to be done in the kitchen. A ncat little scullery of this type is shown in our illustration.

In larger houses the scullery equipment is necessarily more comprehensive. There arc usually two or even three sinks, and various labour-saving rlevices may be included, such as an clectric clothes washer, mangle and dishwasher. Furnishing and fittinge for sculleries are on the same lines as for kitchens. See Cuphoard; Kitchen; Pantry; Sink.
Scurf. See Dandruff: Hair.

SCURVY. It has long been known that scurvy, or scorbutus, can be prevented by including fresh food, especially vegetables and fruit, in the diet, and the disease is now rare, apart from war conditions. It has been found that the differencc between fresh and preserved or dried ood, as regards the liability to cause scurvy, consists in the absence from the latier of a complex substance called water-soluble vitamin $C$.

Scullery provided with sink and cuphoard. The walls are painted and there is a tiled surround to the glazed stoneware sink

Humphre! \& Vera Joel
kecping the blade resting lightly on the ground, and alightly pulling the tip of the hlade inward (Fig. 2). The scythe is then swung back to the right and the operation re prated, moving the fect forward slightly, and taling another cut of about 6 to ! in . of grass, according to the length of the grass to lic cut It is convenient to begin on the left of the work, and work down the grass in $n$ straight line. then returning to the starting point and again cutting to the right, as the tip of the scytho will be found always to come out into the space already cleared by the original cut.
Owing to the moisture in the grass the edge of a scythe rapidly loses its sharpmess, which is rwewed by tho application of a stone, specially prepared for the purpose, shaped like the round of $a$ ladder
SEA HOLLY. The name of a group of harily flowering plants (eryngium) which are qencrally of thistle-lilie appearance: the Howers, when cut, are useful for indoor decoration and last a long time. The beauty of the plants lies in the bluc or grey-blue colouring of the stems and thistle-like llower heads. 'lho sea hollics are casily grown in ordinary well drained soil in a sunny place. Some of the best kinds are alpinum, 2-3 ft ., blue; oliverianum superhum, 3 ft., blue; planum, : ft., small blue Howerhcads; and the new varicty named Violetta, 3 ft., violet-blue. Giganteum has pale grey-blue stems and Howers. The plants may be propagated by division in autumn or raised from seeds sown in a box of soil placed in a frame in spring.

SEAKALE. A vegetable valued for the young blanched succulent shonts in winter alld spring. It may be raised from seeds sown in spring in shallow drills drawn at 2 ft . apart.

Scakgle. Hlanched heads of this popular winter and spring vegetable

scylue: 1 wo movements in using thas tool. Fig. 1. Berinning of the stroke. Fig. 2. The end
removed, and the soil between the rows should be hoed frequently. In the autumin when the leaves have died down, the roots may be lifted and forced into growth imiler cover. Later supplies are obtained by covering the soi! over the roots out of doors, with heaps of sifted ashes or sifter soil and culting the new shoots as soon as they begin to pierce the covering. Scalale may be forced by lifting erowns from the beds out of loors, and placing them in a frame or house from which all light is excluded, in an average temperature of $60^{\circ}$. The young plants should receive liberal soakings of tepid water, and in about six weeks the seakale will be ready for cutting. If the bouse is not quite lark the lale will biennial from seels sown in boxes of soil in yellow or purple in colour and coarse in duly, the secdings heing potted subsequently illavour.

How to Cook. Sea kale is in scason from February to June. It may be boiled and dished on toast with sauce poured orer it, stcwed or made into sarourics.
To cook it, wash and trim it, then tie the heads into small bundles and plunge into fast boiling water. Boil the seakale quickly from 20 to $25 \mathrm{~min} .$, then drain it, untie the buncles and arrange them on a slice of toast. The sauce may be poured over or lianded round. Good melted butter sauce, Hollandaise or béchamel sauce, is most suitable.

Seakale may be boiled in stock and served with brown sauce. but the brown

## Sealing Wax: Its Decorative Uses

Brilliant Effects that Can be Obtained by this Medium
This article belongs to the group of those describing art crafts, which includes, a mong many others Enamelling: Cesso : Italian Renaissance Work; Lacquer Work; Repousse Work; Stencilling

Scaling wax may be used to decorate candlesticks, boves, vases, etc., and to make smaller articles, such as beads and pendants. It call be obtained in every colour, from delicate shades of rose, mauve and blue to black, and also in bronze colours, silver and gold.
Surfaces coated with scaling wax are of pure colour, smooth and brilliant. The composition is a fine coloured lacquer, and for this reason oriental designs are particularly good carried out in gold or silver wax on a ground of vermilion or black wax. The draw back to the craft is that the wax, being brittle, is easily chipped. The advantage is that such chip3 can be repaired by holding the broken surface over a spirit llame and allowing the edges of the crack to run together. When working, if not satisfiel with the result the wax can be re-melted and the process started again.

The materials needed for scaling wax craft arc inexpensive, and requisites for the work are stocked by most stationcrs and at handicraft studios where materials for art crafts are sold. All that is required is a spiritlamp, a broad-bladerl knife, a wax spatula and a moulder, stcel linitting-needles of various sizes, methylated spirit, and scaling wax of various colours. In addition to thesc, a piece of soft rag should be handy for wiping the melted wax off the tools and drying the cooled bcads and pendants; a tumbler of cold water is needed, in which to cool the beads, etc., and the table-top should be protected by a narble slab or small shect of plate glass.

Making Beads. Beads can be made with sealing wax in the following manner. Heat a knitting-ncedle in the flame of the spiritlamp, and press it into a small piece of the wax. After deciding on the colour of the beads, or on the foundation colour if they are to be multicoloured, the wax of this colour should be broken into picces of an appropriate size.

Having got the bead on the needle, allow it to cool; then return it to the flame and rotate slowly. The bead will gradually hecoinc oval in shape, and the shaping may be assisted by the knife. A little nicety of judgement is required at this point to tell exactly the moment at which to take the bead out of the llame. If it becomes too hot the wax will Irop off, and, on the other hand, unless it is sulficiently heated the bead will suffer in shape. Very little experience, however, is necded to judge this point correctly, and the bead may be cooled by dipping it into a tumbler of cold water, if the heating goes too far before cxactly the right shape is obtained.
To blend other colours, two methods may be employed. The sticks may be heated one at a time and a little placed on the shaped bead. This is heated carefully and rotated slowly until the colours mingle with the foundation colour. After that it is cooled in water, dried, and passed quickly through the Hame again to restore the lustrc. As an alternative mcthod sealing wax of the desired colour is dissolved in methylated spirit to the consistency of cream, and the solution is painted on the shaped bead. This method is used when designs are painted on beads to obtain something of the effect of Venetian glass.
The bead must now be removed from the necdle. Heat the ncedle just above and below the bead, slide the bead backward and forward a few times to ensure a good hole for threading, and finally let it drop off the needle into a glass of cold water, which will set the shape. The special silk prepared for stringing heavy beads is suitable for threading, and any shape, round, Aat, oblong, oval, cte., will do for the beads. Pendants or a central plaque for the
necklace arc made on a picce of stout cardhoard cut to shape, a hole bored at cach side, and supported on a strong hairpin, the whole of the plaque covered with wax of any colour. Let the wax spread evenly over one side first hy holding the plaque over the flame once or twice. When this side is dry coat the other in the same way. When the plaque is quite dry, paint or stencil a design in colours, using wax dissolved in spirit.

Decorating Small Articles. One method of ornamenting candlesticlis and wooden cases for match hoxes. comh cases, bridge pencils and other small articles
 suitable for a bazaar stall is to warm whatever has been chosento be decorated, and atthc same time heat the tip of the stick of scaling wax Then, beginning at the top, dab the wax on in spots leaving a space between each spot, and every now and again hold the article over the flaine, rotating slowly and always in the same direction, until the spots of wax have melted and run smoothly over the surface. Repeat these operations until the entire surface is covered.

It must be remeinbered that this methol of decoration must not be apllied to any celluloid arlicle.
Colours may be blended by melting a sccond or a third colour over the first and blending all together over the Hame. Silveror gold wax may thus be used to fleck the background in an attractive manner over blue, green or black.

When a raised motif is required to decorate the corners or centre of a small article, or to make a border, the spatula and moulder may be used. Wreaths, baskets of flowers and tiny designs found on flowered china are specially suitable for this work. It is best to make a few trials with the hot sealing wax on a piece of cardboard and experiment on one or two flower shapes. Roses are easily modelled.

Mark a place with a pencil on the article where the raised work is to come. Heat the wax in the llame of the spirit lamp and let a tiny drop fall for each flower. Use two shades of pink for a cluster of roses and put several drops one over the other. Then, while the wax is still plastic, press with the spatula round the centre and make little separste dents to form petals and a dent in the middle of thesc for the rose centrc. Heat the tool a little if the wax becomes hard. The tiny leaves may be made of green, silver or gold wax and consist of a drop of wax, the spatula being drawn quickly through to make a central vein and shape the leaf.

Enamelling with Sealing Wax. The most artistic effects in sealing wax decoration are obtainable by using solutions of the different coloured waxes in methylated spirit. This
inexpensive craft has the appearance of line enamel work and can be used on a ground of sealing was to decoratc beads, or on wooden articles covered with the wax, or on pottery and glass.

The first step is to choose the article to bc so enamelled, and to decide upon the colouring. Then break up a stick of sealing wax and place it in a small bottle, covering it with methylated spirit. Cork tightly and leave overnight to dissolve. Shake it up well. Usc in the same way as liquid enamel ; a small sable brush is the best tool to employ.
Colour the design, attempting no shading, and working quickly and evenly. Practice is required to prevent the work from being patchy. The pressure on the brush must be even, and the sealing wax must be kept stirred. If it is too thick dilute it with methylated spirit. Kecp the bottles well corked, and clean the brushes in methylated spirit. The shading is added when the first coat is dry.

One section must be done at once and allowed to dry, as the work is ugly if the enamel is thicker on one side than another. As the work is dry in a very sliort time, it should appeal to those who have nowhere to put things during the drying process.

The illustrations give a good idea of the possibilities of this form of handicraft. Fig. ] is a useful flower vase. Its colour is dark brown, and it is decorated in white sealing wax sharled with fawn, the design being a ring of conventional applc blossom. Fig. 2 is a vase of white crackle ware, its decoration being done in sealing wax enamel representing multicoloured anemoncs. Fig. 3 is an alabaster powder box. The design on the lid, which was outlined entirely in black, shows brightly coloured flowers and leaves painted in sealing wax enamel. Gcometrical desigus and the Greck key pattern are also suitable.

SEALSKIN. The beauty and the dur ability of scalskin make it one of the most valuable furs in existence. It is usually

Sealing Wux. Fig. 2. Vase of crackle ware ornamented with a design of anemones. Fig. 3. Powder box in a!abaster, with decorated lid
made up into coats, but is also used for coat collars and cuffs.

Musquash is often treated to resemble scalskin, but may usually be recognized by its size. A large number of musquash skins are nceded to make a coat, so that the seams are numerous compared with those on a genuine seal. Coney and clectric seal, made from rabbit skins, are other skins, are other dog, an intelligent and entertaining companion Those who find it difficult to than it is owing to the long moustaches. distinguish between genuine and imitation The colour is uniformly white, or there may skins should examine the leather. In real scalskin this is never dyed, while in musquash and other imitations it is invariably of the same shade as the fur itself.
Sealskin is also imitated in a special kind of silk plush. This seal plush is generally dark brown or black, and is used for making winter coats, for trimmings and for travelling rugs. See Fur.

SEALYHAM. This type of terrier is a breed of small dog that has, during the 20th century, become very popular and fashionable. Founded upon a hybrid between the Jack Russell and Welsh terriers by later crossings

## SEAMS FOR PLAIN SEWING

## Some Helpful Directions for the Needlewoman

This article suggests reference to such entries as Dressmaking; Mending; Pattern; Sewing Machine, and also to various stitching operations, e.
The plain seam is the one most commonly used in needlework. To make it, lay together the two pieces of material to be joined, with the right sides facing and the two edges exactly level, and tack along the two thicknesses where the permanent stitching is to be put in. It is a good plan, when a garment is being cut out with the aid of a paper pattern, to mark the material round the pattern edges with chalk, so that, after the pattern is removed, there is a guide to the amount of material that should be taken up in seams, etc. After tacking, carcfully stitch the seam by machine; or, if small light articles are being made up, run the seam by hand if preferred, as in Fig. 1.

The stitching of all scams of garments should be commenced at the top, i.c. the waist of a skirt, shoulder of a sleeve, and so on If one of the two edges is on the cross or bias of the fabric, it should be laid uppermost, as it is apt to stretch out of shape. When stitching a shoulder seam, always ease in the back shoulder-edge and stretch the front, in order to get a better fit over the shoulder blades.

It is the custom, when stitching seams of dresses or coats that take a concave curve at the waist, to stretch this part of each seam, so that it will still more follow the curve of the figure. Seams that take a convex curve are held in, so that they will not stretch, otherwise the shape would be spoiled. In stitching the seams of a 2 -picce coat sleeve, commence by stitching the shorter or inner seam, and do the longer or back scam afterwards, easing in the clbow part of the wider or upper portion to the elbow part of the narrower portion, so as to give it more play at the bend of the arm. After any plain seams are stitched, remove tackings, and iron the scam edges open flat. If the seams are curved, however, be carcful to snip the tirnings here and there, evenly and regularly,
as in Fig. 2, otherwise it will not be possible to iron them flat; the material under the scam edges will become dented or cockled up. Many seams have their edges notched or snipped out in this way, even if they are not curved, merely to give a better effect and to prevent the edges fraying out too rapidly.

Unless the raw cdges of these plain seams are to be covered with a lining, they have to be finished off. In dresses it is usual to overcast the cdges, as in Fig. 2. In unlined coats or wraps, the edges are bound with lute ribbon or Prussian binding, the binding being folded double, so that the seam edge can be stitched between. In some silken materials that have little tendency to fray, such as taffetas, the edges are merely pinked out; in heavier materials of this nature, such as velours, they are often pinked out or herringboned down.

Overlapped Seam. This seam is applied in the making of outer garments, and also on underclothes, pyjamas, etc. It may be used to make skirt seams, to set in yokes, and to attach strappings. It is easily made. Turn in the edge that is to be uppermost, to the amount of turning allowed, and tack along; then lap it on to the remaining edge, and again tack down, as in Fig. 3. Machine as far within the fold as desired, taking care not to go beyond the edge of the turning. The raw edges can be neatened in any of the ways previously mentioned.

French Seam. A seam often employed on delicate materials, such as lawn, muslin, crêpe-de-Chine, net, lace and georgette is the French seam. To make, set the two layers of material together, with the wrong sides facing and raw edges level, and run or machine as close to the raw edges as possible. If it is not easy to stitch as near to these as is desired, cut the turnings a way quite narrow afterwards. Now turn the material to bring the wrong side outside, and the seam lying along the
with the Dandie top of the fold; then stitch the two layers Dinmont and the together again, close up to the raw edges, as in Cheshire terrier, its Fig. 4, so that these are enclosed in a little characteristics have tube. become fixed and type. it pc
it has short legs. a long body, strong neck, deep chest, and the short tail is carried vertically. The coat is short and hard, with crinkly, broken upper coat on the back. The drop cars lic close to the face the powerful muzzle appears broader be patches of biack or liver colour.
ally it is brown marked with black.
The smaller specimens are the more desirable. The Sealyham is affectionate and faithful, playful, and of quick intelligence; intruders are grected with continuous barking. A first-class dog for the home, it is withal a splendid ratter. As a sporting dog, he is estcemed for badger-hunting, for which his short legs and pluck fit him, whilst his steady baying enables the hunters to locate him and his quarry. The name is derived from the Edwardes estate, in Pembrokeshire, from the Edwardes estate, in Pembro
where the breed originated. Sce Dog.

Flat Seam. The stitch and fell seam is employed for flat seams. Lay together the two pieces to be joined, with right sides facing and one edge nearly $\frac{1}{4} \mathrm{in}$. bclow the other ; then tack along an $\frac{1}{8} \mathrm{in}$. below the narrower edge, and afterwards machine, run, or backstitch along this line. Fold the whole seam flat over on to the material, so that the narrower edge lies underneath, fold the edge of the wider turning under, and neatly hem down, as in Fig. ${ }^{6}$.
Oversewn Seam. The iop-sewn or oversewn seam is used when it is desired 10 join the selvedges of longcloth, calico, cambric, and similar cotton materials. Tack together the two selvedges and neatly oversew, working from right to left, as in Fig. 6, and making the stitches of an even slant. No knotted ends of cotton should show. Leave a generous end of the cotton, and push it down on to the edges towards the left, so that the stitches can be made over it, at the same time not letting it drop below the position at which the needle passes through the edges. When the seam is completely oversewn, open out the two thicknesses and lay them flat on the table, and press the stitches down with the thimble to make the seam flat.

Counter Hem Seam. A counter hem figures largely in the making of men's and boys' shirts, in which a specially strong, flat seam is wanted. Turn under one edge to the wrong side about $\frac{1}{8} \mathrm{in}$. and turn the other edge over to the right side to match. Lap one edge over the other so that the raw edges face, and run a line of tacking down the middle; then machine both edges down as close up to the folds as possible. If desired, hemming may be resorted to, instead of machining, as in Fig. 7.

Flannel Seam. On flannel materials, it is usual to use a stitch-and-herringbone seam. The edges are first stitched by hand or machine in a plain seanm, which is then pressed open flat with the fingers, and has the raw edges herringboned down, as in Fig. 8, the material being too bulky to permit of turning the edges under, as for hems.
Whipped Seam. When the edges of fine underwear or baby clothes are to be joined to lace, insertion, or beading, a whipped seam is generally employed. Take the material in the left hand, with the wrong side towards you and raw edge upwards, and roll this raw edge over towards you as a very tiny roll, with the thumb and first finger of the left hand, doing about 1 in . Let the roll rest over the first finger, with the beading or lace above, and whip them together as shown in Fig. 9, drawing the two edges together.
If the material is to have fullness, as in the case of a skirt part that is to be joined to a bodice by a band of insertion, the skirt edge must be rolled and whipped separately from the trimming, pulling up the cotton as the work proceeds in order to get the requisite fullness. After the edge is completely rolled and whipped, it is oversewn to the trimming exactly over the first stitches, so retaining the neat effect of the seam. This rolling and whipping can be used to apply a frill to an edge, the frill, if full, being rolled and whipped and drawn up, while the garment edge is afterwards rolled, and whipped to the frill as explained for beading.

Openwork Seams. Many blouses, summer dresses, baby clothes, etc., show open-work seams, which often have the effect of real hem-stitching. It is usually necessary first to hem or roll and whip the two edges that are to be joined, though in some cases a mere
turning in of the edges will sulfice. After the regulated if necessary. At the same time, a 1 wo edges are neatened, tack them down on to a strip of stiff paper, with the desired space between, and niake the openwork stitchery, with embroidery silk or embroidery cotton, according to the nature of the fabric.

One type of hand-worked seam is shown in Fig. J.0; but there are many others, simple herringboning being one that is much favoured, while another popular method is faggoting (see page 444) In all cases the needle should be slipled along one of the hems to bring it out to the right side in the position needed for making each stitch or group of stitches. After the stitchery is worked, the tackings are snipped and the paper removed. Openwork can also be used to attach lace to the neatened edges of underwear, etc.

SEA PIE. For this popular dish the following ingredients are required: l lb. buttock steak, $\frac{3}{3}$ lb flour, 5 oz. suet, a carrot, an onion, a small turnip, and pepper and salt to taste. Cut the meat and the vegetables into thin slices and place these in layers in a saucepan, seasoning them with salt and pepper and covering them with. cold water.

Let the whole simmer for $\frac{1}{2}$ hour, and then remove the meat from the pan. With the suct, Hour, and some water make a light crust and roll it out on a Houred board. Roll the meat in this crust return it to the saucepan with the vegetables and the liquor, and let it simmer for all hour.
Sea Pink. This is an alternative name for the plant more usually known as thrift (q.v.).

SEA SICKNESS. The effect of the up and down motion of a ship in the water is comparable to that prorluced by swinging, and in nıany people it produces a fecling of nausea and sickness, which culminates in vomiting and complete prostration. The scientific explanation of this troublesome malady is that it is due to a disturbance of the circulation in the brain and in the labyrinth of the ear.
While scrious results arc very rare, there is always some danger to those who are of apoplectic tendency, to sufferers from heart discase or rupture, and to pregnant women.
For three or four days before starting a voyage care should be taken that the food is readily digestible. The bowels should be
dose of 20 gr . of the bromide of ammonium may be talien three times a day, in a wineglassful of water after meals. This treatment may be continued during the first few days of the voyage. If the voyage is a short one, a single dose of this drug ( 30 gr .) should be taken about two hours before starting. Chloretone is often a preventive. A light ineal should be taken $\frac{1}{2}$ to 2 hours before the voyage. A firm bandage worn round the abdomen often acts to some extent as a preventive of sickness.
A person who is apprehensive of being sick should sit in a low deck-chair, either facing or with the back to the bow of the ship. The chair should preferably be on deck, but in a shelterel part. A safer position still is to lie down, preferably on the right side, and bring the knees well up towards the body. Above all it is essential to keep comfortably warm. If sickness threatens, it is best to abstain from solid food, to suck chips of ice, or to take a glass of iced champagne in sips. When there is much nausea, but no vomiting, the stomach will be relieved by taking a pint of warm water to which a pinch of bicarhonate of soda has been arded. This will empty the stomach and make the traveller more comfortable. When vomiting has continued until the stomach is empty, and distressing retching ensues, a little light food should be taken, if possible, such as gruel, arrowroot, warm nilk and water, or mill and sodawater. If the sickness continucs for some days other treatment will be required from the ship's doctor.

SEASONING. Every varicty of spice or herb which imparts a relish, or brings out more distinctly the flavour of ingredients used for culinary purposes, is a seasoning. The term does not always imply mere salt and pepper, although salt may be reckoned to be scasoning of the first importance. Next in order would come the various descriptions of pepper and herbs, such as are used in forcemeats.

Srasoning is largely a matter of individual taste, therefore quantitics given in recipes should not be too strictly adbered to. The safest way is to taste while cooking until the correct amount of seasoning has been added. See Flavouring; Ginger; Nutmeg; Pepper; Salt: Sauce; Soup; Spice; Stuffing, ctc.

SEAWEED : Its Uses. There are several kinds of edible seaweed, but few of them are caten except in the ncighbourhoods in which they are found, and even then only in limited quantitics. The most valuable of them is known as Irish or carrageen moss. It contains certain medical properties and is recommended for invalid dict. Another kind of seaweed, found along the Welsh coast, is sometimes used as food, and in Sicotland some varictics of seaweed are also cdible. See Irish Moss.
SEBORRHOEA. Certain conditions of the fat-producing glands of the skin cause an abnormal amount of secretion. This is known as seborrhoca or pityriasis, and is of an oily or a dry character. the latter taking the form of greyish or yellowish scales. The condition always begins on the scalp, from which it may spread llownward to the face. neck, and other parts of the body.

The local treatment for dry seborrhoca of the scalp is given under the heading dandruff. Where the scurf attacks the non-hairy portions as well as the scalp, a mild sulphur ointment such as the following may be lightly rubbed in once or twice a day
Precipitated sulphur
24 gr.
Benzoated lard
$1 \%$.
Local treatment of oily seborrhoca consists in washing the surface several times a day with soap and warm soft water, and then dabbing on the following lotion :
Tannic acid
20 mr
Methylated spirit
$20 \%$
SECATEUR. The pruning instrument known as a secatcur has two cutting blades fastened together by a rivet, and actuated by a spring after the manner of clippers. It is invaluable for pruning purposes in the garden. See Pruning; Scissors.

SECRETAIRE. For all practical purposes the secretaire is identical with the bureau or the desk, but the name is retained by certain pieces of furniture, mainly those of French make.
Secretaires in which the influence of French models is seen were made by Sheraton. Some of these were shaped somewhat in the style of a cabinet. See Ijurcau; Marquetry; Sheraton: Writing Tablc.
SEDATIVE. Any drug used to ca!m an excited nervous system, to relieve restlessness, to quiet an overstrung heart, or an irritable stomach or bronchial tubes, ctc., may be termed a sedative. As most of the so-called nerve sedatives have a greater or less depressing action on the heart, they should be used with caution, and never taken except under a doctor's supervision.
SEDGE. Under this name are included hardy perennial grasses, one or two of which are useful for the purpose of decorating moist spots in gardens, or by the sides of marshes in the wild garden. They are propagated by division of the plants in spring. Pendu!a, 5 ft ., is one of the best. Those with variegated leaves, i.e. Acuta variegata and Gallica variegala, are attractive. See Japanese Garden : Wild Garden.
Sedum. This is the botanical name of stonecrop (q.v.).
SEED : For the Garden. Every seed is really a plant in miniature, containing the embryo, together with the food required to assist carly development. To stimulate its growth, warmth, moisture, and air are necessary. Given these conditions the plant sends forth its radicle, or young root, into the earth, whilst the young stem bursts through the seed covering, gradually lifting the soil and making way for the seed leaves. After this has occurred, truc leaves form and hair ronts develop.
Sced should not be sown during very cold or frosty weather, hut from February onward, when there is gentle warmth from the sum and while the soil is in a friable condition without
excess of moisture. Sceds always germinatc best in darkness, and consequently sowings made in pans, pots, or boxes should be covered with glass, over which is spread a shect of paper to exclude both sunshine and light, as well as to conserve moisture and maintain some degree of warmth. As a gencral rule seeds should not be more than a year old, as their vitality becomes weaker with age, and slower germination results; some even become quite sterile.
Plants may be raised from seed in various ways e.g. sown broxdcast, in drills, in prepared beds, in cold frames, on hotbeds, and under cover of a greenhouse. Some seeds possess a hard covering and, consequently, are morc difficult to germinate speedily ; this may be facilitated by slightly notching the hard coat, taking great care not to cut deeper than the outer covering, or testa as it is termed botanically. Another method is to soak the seed for a few hours previous to sowing.

Depth of secd sowing depends upon size, and to some extent upon weather conditions. Some tiny seeds need hardly be covered at all, whilst large seeds like beans and peas must be sown deep to ensure the greater degrec of moisture requisite for their germination. Our diagrams show sowing methods in detail.

Seed Bed. A properly made-up seed bed is of great service in the garden for raising scedlings of flowering plants and vegetables to be afterwards planted out. The soil must be dug and the surface pulverized: the addition of sand and sifted leaf-mould is beneficial on heavy land.

Draw drills to the required depth with a stick or hoe, setting the line carcfully to ensure straight drills. After sowing seed and before removing the linc, label each row according to its contents, including date and weather conditions. Labels are made of plance wood painted with white flatting.

Seed Testing. In Great Britain an Act of larliament passed in 1920 made it obligatory for a seller of seeds to give to the buyer a written statement of the varicty, purity, and germination of the seeds in question. Seeds must not contain more than a certain minimum parcentage of injurious wecds. There is an official seed testing station at Cambridge. See Scedling; Sowing.

Seed. How to prepare a seed bed. 1. Antumn preparation : $a$, ridged top soil; $b$, manure; $c$, well dug bottom soil ; $d$, sand or exhansted manure. 2. Bed prepared: $a$, ridges and sand incorporated. S. Sowing: $a$, seed covered in ; $b$, rain channels. 4. Hardy and tender seedlings in one bed: $a$, top soil prepared as in Fig. 1 ; $b$, pockets of extra manure under tender seeds : $c$, manure; $d$, bottom soil; $e$, glass-covered shelters propped up and facing south

SEED CAKE. This cake derives its name discriminate between desired and undesired
from the caraway sceds that are added to a plain cake mixture.
Secd rock cakes are made by adding 2 or more teaspoonfuls caraway seeds to every $\frac{1}{2} \mathrm{lb}$. flour used, as in making ordinary rock cakes. See Cake: Rock Bun.

SEEDLINGS : Their Care, After seedlings have formed their first true leaves they require special attention. In the open ground

Seedling. 1. Sturdy seedling. 2. Attenuated specimen: $a$, where damping off begins. 3. Seedlings pricked off into pan. 4. Notched stick for lifting ting seedlings. 5. Efective protection against birds: $a$, nails in wood triangles ; $b$ black cotton. 6. Seedlings nnder frame on hotbed : a, plunged pots; $b$, box of seedlings; c, light. 7 . Soot protection against slugs. 8. Sun protection. 9. Planting for protection against frost. 10. Planting in depression to conserve moisture. 11. Same earthed-up during bad weather. 12. Seedling
lifted with a ball of soil
transplanting should be performed as soon as seedlings can conveniently be handled, whilst those raised in the greenhouse must bc placed close to the glass.
Great care is essential at this stage to avoid over-watering, giving the tiny plants just sufficient water to keep them moist: overwatcring is one cause of damping-off (q.v.).
Showery weather should be chosen for thinning and transplanting, as disturbed plants quickly recover if lifted and replanted without delay.
Seedlings should be carcfully thinned out, and in due course transplanted to form sturdy plants for garden and grcenhouse. Very tiny secdlings, like those of the gloxinia, should be handled by means of a small stick, notched Vshape at one end, as shown in our diagrams, which also indicate other ways of clealing with young and fragile plants. The smaller seedlings often produce the finest mature plants.

## SEIDLITZ POWDER. The effervescing

 powder of sodium tartrate is commonly called a seidlitz powder. It is a valuable saline purgative.SELAGINELLA. This family of greenhouse fern-like plants thrives in a mixture of loam, leaf-mould and sand. They require a shady position, and may be propagated by means of cuttings at any time of the year.

The plants are evergreen, of erect, dwarf, or trailing habit, and are differently known as tree, club or crecping moss. They succeed best in a tem perature varying from 50 deg. to 55 deg . from September to March, and from 55 deg. to 65 deg . for the rest of the year. Erect growers are involvens, martensii, and caulescens. Dwarf species include the excellent densa, whilst trailing kinds are cacsia and kraussiana. All these are desirable plants for a greenhouse.

SELECTIVITY. In wireless reception this is the ability of a receiving set to
broadcast transmissions. In considering the question of selectivity attention must be given also to sensitivity and quality of reproduction (or fidelity), because all threc factors arc interrelated.

The selectivity of a recciver is directly proportional to the number of tuned circuits, and may be increased by adding an extra tuned circuit between the acrial and the input to the set. This procedure may have an adverse effect upon the sensitivity, and in practice one or more high. frequency amplifying stages are usually employed in order to provide at one and the same time a gain in selectivity and sensitivity. The highfrequency amplifier more than compensates for any loss in sensitivity occasioned by the use of selective circuits.

The degrec of sclectivity is largely affected by the efficiency of the tuning inductances. A coil having high losses due to the use of too thin wire, an unsuitable ratio of diameter to length, large self capacity, etc., will cause damping, a factor which flattens the tuning and so reduces the ability of the receiver to separate stations. Circuits containing coils with relatively large inductance and condensers of small capacity are desirable from the point of view of selectivity, because weaker couplings between the stages can then bc employed without any appreciable loss in signal voltage.

A long aerial-earth system is detrimental to selectivity. A short single wire outdoor aerial or a small indoor acrial or frame is, therefore, indicated. The earth lead should be taken to its earthed point by the most direct routc. A good earth and an acrial which is free from high resistance joints are absolutely essential.

The aerial should be loosely coupled to the grid circuit of the first valve, either by way of a tapping point along the grid coil or by using a separate small acrial coil inductively coupled to the grid coil. An equivalent effect may bc obtained by inserting a small fixed or variable condenser in series with the aerial lead, a

Selaginella, or Resurrection Plant, an evergreen po! plant needing greenhouse cultivation
suitable value for the medium broadcast waveband being 0001 mfd .

Reaction, when intelligently employed, greatly improves the selective propertics of a sct. One of the difficulties in designing a recciver to give high selectivity is the possibility of high note loss. If the tuned circuits have very low losses, so that the tuning at resonance causes cutting of the side bands, there will bo a decrease in the high note response, the magnitude of which will depend upon the extent of the side band cutting.

This can be remedied by employing a bandpass filter, comprising ganged tuning circuits prior to the first high-frequency amplifying valve, the high-frequency stage or stages being either choke coupled or coupled by Hatly tuned circuits.

The band-pass filter can be designed to pass a predetermined band of frequencies, such as a band of ninc kilocycles in width. An alternative is to use a number of tuned high. frequency stages having cach tuning circuit comparatively flatly tuned; the required degree of selectivity thus being achieved gradually. This entails a multi-valve receiver. It will therefore be seen that in the case of small wircless receivers the clegree of sclectivity is a compromise involving sensitivity and quality of reproduction. Thus in a two or three valve set operated in the vicinity of a powerful broadcast transmitter, if the selectivity is sufficiently high to ensure the elimination of the nearby transmission within a few degrees on the tuning dial or dials, the sensitivity on distant transmissions may be decreased.

In general, a well-designed recciver provided with high-frequency amplification will be both selective and sensitive, whereas the degree of selcetivity obtainable in a small set without high-frequency amplification is mainly limited by sensitivity and fidelity. The use of the superheterodync principle is a method by which high selectivity may be obtained with the retention of simplicity in operation. Sce Superheterodyne; Wireless.
SELF HEAL. The cominon name of prunella, a low-growing hardy plant suitable for poor soil in odd corners. Prunella vulgaris is a troublesome lawn weed. The best of the cultivated kinds are grandiflora, purplish, and Webbiana, rose purple.
SELF-STARTER : On Motor Cars. Cnlike the steam enginc and the electric motor, which can be started by the opening of a valve or the use of a switch, the internal combustion engine must be rotated first before it will commence to operate. The name self-starter has been applied to the clectric starter, now a standard fitment on practically all classes of motor vehicles. See Starter.
SELF-TONING PAPER. Self-toning paper is a photographic printing-out paper, the film of which contains the chemicals necessary for producing a pleasing tone. All that is required with most brands of selftoning paper is to wash it for about 5 min ., and fix and wash again in the ordinary way. Gelatino-chloride self-toning papers, such as Ilford Intona, do not require the preliminary washing. Collodio-chloride, or collodion, papers require the initial washing. All self-toning papers have to be printed much darker than ordinary P.O.P., as a good deal of depth is lost in tho tixing bath, which is really a combined toning and fixing bath. This applies particularly to the collodion papers.
For all self-toning papirs a plain hypo bath of 2 oz . to 3 oz . of hypo to 1 pint of water will give good brown asd warm sepia to purple tones, according to the brand of paper used. See that the prints are properly fixed, and the instructions as to time for fixing which are given with each paper carefully followed. The hypo bath should not be too strong
for collodion papers, 2 oz . to 3 oz . to the pint, while variations in the strength of the bath do not affect the colour of the print. The normal bath preceded by washing gives a pleasing brown tone, but cold purple tones can be obtained by washing before fixing in a 10 per cent solution of common salt ( 1 oz . salt in 9 oz . water) and rinsing the prints in fresh water.

All baths, whether salt or hypo, must only be used once with self-toning papers. Not more fixing solution than is necessary to cover the print properly should be used, since the gold toning chemicals are on the face of the print itself. If too big a bath is used they will be diluted too much. Fixing baths for self-toning prints must not be acid; to make ccrtain of this a few drops of ammonia, or 10 gr . of sodium carbonate, may be added to each pint of the solution. Sclf-toning prints, as P.O.1'., must be well washed after fixing. One hour in rumning water or 5 min . in cach of 12 changes of water is necessary. See Toning.

SELTZER. Originally this was the name of a mineral water obtained from Selters in Germany, but to-day the word is used for certain artificial preparations that resemble, more or less, the natural water. Seltzer is a highly aerated alkaline water that contains bicarbonate of sodium, calcium, magnesium, sulphate of potassium, and similar salts. It is valuable in cases of chronic indigestion and disorders of the respiratory organs. See Mineral Water.

SEMOLINA : As a Food. Being a product of wheat, semolina contains considerable nutritive qualities and makes excellent milk puddings, but unless Havoured is rather insipid. The flavouring, such as lemon, nutmeg, or cinnamon, should be added when boiling the semolina with the milk so that it may be equally distributed.
To make a semolina pudding put 1 pint milk into a stewpan with a strip of lemon rind and a pinch of salt, and bring to the boil, then sprinkle in $2 \frac{1}{2}$ oz. semolina, and stir over the firc for about 10 min . to cook the grain. Beat together the yolks of 2 eggs with $\frac{3}{4}$ oz. castor sugar. Remove the pan from the fire and take out the lemon rind when slightly cooled add the yolks of the eggs and sugar, and lastly fold in the whipped whites of the eggs. Turn into a greased pic-dish and bake for 15 to 20 min . in a moderate oven. For quite a plain pudding omit the eggs, and add the sugar just before putting the pudding into the oven.

Semolina Blanemange. Boil up a quar't of milk, then sprinkle in $\frac{1}{4}$ lb. semolina, and stir well until the latter is cooked and the mixture thick and creamy. Add the grated rind of a lemon and 3 dessertspoonfuls castor sugar, and when the latter is thoroughly dissolved pour the mixture into a wet mould.
When the blancmange is set, turn it on to a dish, heap a small tinful of cherries round it and pour the syrup round. Cream should be served separately.
Semolina Cheese. For this savoury take 3 tablespoonfuls semolina, 2 oz . each butter and grated checse, a little milk, and pepper and salt to taste. Boil the semolina with the butter and half the cheese in a very little milk, and scason it with pepper and salt. When cooked, turn out the mixture into a pie-dish to cool, and then cut it into small,

Semolina Blancmange, a delicious and decorative party sweet
round cakes. Arrange these on a well. greased dish, sprinkle them with the rest of the checse, and bake them for about ten minutes in a hot oven.
Semolina Soup. Strain I quart white stock into a salucepan and bring it to the hoil, adding a few peppercorns ticd in a piece of muslin. When it reaches boiling point, sprinkle in $1 \frac{1}{2}$ dessertspoonfuls semolina. Continue cooking until the latter is soft and then draw the pan to the side of the fire, allowing the soup to cool a little.

Beat up the yolk of an egg, mix it with $\frac{1}{4}$ pint cream, and then strain it into the soup, stirring the whole until the egg is cooked. The peppercorns may then be taken out, a little salt added, and the soup served, accompanied by diced crontons. See Blancmange; Croûton.

## Sempervivum. See Houseleek.

SENECIO. This is the name of a group of annual and perennial plants, some of which are valuable in the garden, while others arc weeds. The most familiar of the latter is the familiar groundscl. Senecio (Jacobaea) elcgans is a very pretty annual which may be sown under glass in March, the scedlings being planted out in May or potted for summer decoration in the greenhouse. Or seeds can be sown out of doors in April where the plants are to bloon in summer.
The daisy-like flowers are of many bright colours, carminc, crimson, purple, etc., and the plants, which grow about 18 in . high, last long in beauty. Scnecio multibracteatus is a showy greenhouse perennial, 18-24 in. high, with rose-coloured blooms. Of the hardy perennial senecios the best are pulcher, 2 ft ., redrlish purple, which is suitable for the herbaccous border, and clivorum, Wilsonianus and tangutica, vigorous, rather coarse-looking plants, 4 ft . high, with large bunches of yellow flowers in summer, suitable for the wild garden or waterside.
SENEGA. Preparations of the dried root of Polygala senega are used in medicine for their stimulating effect on the lining membrane of the bronchial tubos. Senega is usually prescribed in chronic bronchitis where the expectoration is profuse and sticky, but is contra-indicated in acute bronchitis.

SENNA. The dried leaves of the senna plant are largely used in medicine on account. of their mild purgative action. Common preparations and the close of each are :
Confection of senua, 60 to 120 gr .
Compound mixture of senna, or black draught, to 2 fluid oz.
(6) to 120 gr .

Senna is commonly used for habitual slight constipation. The compound liquorice powder, which owes most of its purgative effect to its contained senna, is a common houschold remedy. See Apericnt; Constipation.

SENSITIVE PLANT. This name is given to Mimosa pudica, the leaves of which close together when they are touched by hand. This is a hothouse perennial plant and flourishes
in sandy soil in a sunny part of the house. It is often treated as an annual. and grown from seeds sown in spring.

SENSITIVITY: In Wireless. This is the ability of a receiver to respond to weak transmissions. A set which gives loud signals when tuned to a very weak distant transmission is said to possess good sensitivity, whereas a receiver which gives weak signals when tuned to a very powerful nearby transmission possesses bad sensitivity.

A set designed for high sensitivity normally incorporates one or more high-frequency amplify ing stages. See Amplifier.

SEPARATION : Of Husband and Wite. A husband is bound to support his wife in his home and a wife is bound to live with her husband. If the parties wish to put an end to these marriage obligations without putting an end to the marriage itself by a divorce, or if one of them has behaved in such a way that the other is entitled to refuse ro live with him or her, they may either (1) enter into a separation agreement, (2) obtain a decree of judicial separation; or (3) obtain a separation order from a court of summary jurisdiction.

Separation Agreement. By this the parties agree to live apart and not to interfere with one another, and the husband provides for the support of the wife and any children. The wife agrees not to make her husband liable for her future debts. The agreement must be made in contemplation of an immediate separation, and if a husband and wife who are still cohabiting enter into a deed whereby the husband promises that if at any future time the wife shall separate from him he will make her such and such an allowance, the agreement is bad. Immediately after the agreement the parties must cease to reside together, and merely ceasing to cohabit is not enough. If after a separation spouses decide to live together again they enter into a deed of reconciliation, and in this they may make provision for the possibility of their again being separated. A separation agreement is put an end to by the resuming of cohabitation between the parties. In cases where spouses have agreed to separate, neither can complain of desertion.

Judicial Separation. Whereas a separation agrecment may be entered into at the will of the parties and without any special cause, a judicial separation is a decree of the High Court and can be obtained only on proof of (1) cruelty ; (2) adultery, (3) desertion for two years or more ; or (4) failure to obey a decree for restitution of conjugal rights.
Cruelty may bo mental as well as physical. Jesertion occurs when one spouse refuses to live with the other without some reasonable cause, such as the exigencies of business. If one spouse deserts the other, a decree for restitution of conjugal rights may be obtained at once, and, if not obeyed, the other spouse may obtain a judicial separation without waiting two years. The court may also make orders for the custody of any children and for the payment of alimony to the wife. This is usually such sum as will make the wife's income equal to one-third of the joint incomes of husband and wife. Thus, where the husband's income is $£ 1,000$ and the wife's $£ 200$, alimony from the husband would be $£ 200$, making the wife's income $£ 400$ in all.

Separation Order. A married woman may apply to a magistrate's court for a separation order (1) if her husband has been convicted of an aggravated assault upon her or has been convicted upon indictment of any assault upon her and sentenced to a fine of more than $£ 5$ or imprisonment exceeding two months; (2) if her husband has deserted her or has been guilty of persistent cruelty or wilful neglect to provide for her or her children ; (3) if her husband is an habitual drunkard. The like
power is given to a husband whose wife is an habitual drunkard.
The separation order may make all or any of the following provisions: that the husband (or wife) shall no longer be bound to cohabit: some provision for the legal custody of any children (this does not include illegitimate children): that the husband shall pay a weekly sum not exceeding $£ 2$ for the maintenance of the wife and a sum not exceeding 10 s . a week for each child. Before the husband can be ordered to pay anything, there must be evidence that he has means, or is able to earn more than sufficient money for his own maintenance. The wife's means are also taken into account. If any change takes place in the means of either of the parties after the order, the husband may apply to have the amount reduced or the wife to have it increased, as the case may be.

A husband deserts his wife either if he leaves her or if he shuts her out of his house. A woman who has been guilty of adultery cannot obtain a separation order, and if a woman commits adultery after an order has been obtained, the order for the allowance cannot be enforced. The separation order is not enforceable while husband and wife are residing together, and the order comes to an end if they continue to reside together for three months after it is made, or if they resume cohabitation. Neither a separation agreement, a judicial separation, nor a separation order puts an end to the marriage.

Separation Allowance. This term is used in two distinct senses. In one it is the allowance that a husband makes to a wife on their separation. It may be quite voluntary, but it is often the result of legal proceedings and is linked with a separation order. When an order of this kind is made the husband is usually ordered by the court to pay a certain sum towards maintaining his wife.

This amount varies according to circumstances, the main, but not the only consideration, being the means of the husband. A weekly wage earner will be ordered to make a weekly payment, while a richer man is ordered to allow his wife a larger sum of so much a year. The court, in fixing the sum, will take into account the wife's habitual standard of living and also any income which she may possess in her own right.
The maintenance of the children, in cases where there are children, is a very important matter in fixing a separation allowance. If the wife is to bring up and educate young children she will obviously be granted a larger allowance than if she is not. The court may fix a distinct amount for a child or for the children which the husband must pay, this being in addition to the separation allowance made to the wife.

Allowances in the Fighting Services. In the other sense a separation allowance is the money paid by the state to the wives and dependents of soldiers, sailors, and airmen on active service. These allowances are very numerous and prominent in time of war, but there are comparatively few of them in time of peace. The amounts are altered from time to time according to variations in the cost of living and other matters.

Such a separation payment takes the form of an allowance of so much a week for a wife and so much for each child. A certain amount of the allowance is deducted from the man's pay, out of which he can, if he wishes, add to the allowance. Allowances to father mother, and other relatives are only made if they are dependent, either wholly or partially upon the soldier or sailor See Allowance.

SEPARATOR : For Milk. This is a dairy appliance used for separating the cream from new milk. The principle upon which most of these instruments work is that of centrifugal force. The milk is led into a chamber where disks of tin or similar metal are caused to rotate at high speed. This churns up the milk and causes watery ingredients to be thrown out to the outside of the bowl, while the cream rotates near the central axis of the disks. By various forms of mechanism the cream and what is known as the skim milk are separated and led off through different channels to separate collecting vessels. A small type is inanufactured as a hand-power machine, but other kinds are a vailable which are driven by electricity, thus giving a more regular rotation of the disks, consequent better separating effect.

## Notes for the Month

SEPT. 1.-Partridge shooting begins
SEITr. 29.-Quarter Day

Septicaemia. See Blood Poisoning.
SEPTIC TANK. A septic tank is employed in a particular process of sewage purification. It is used in certain towns, also in institutions and large houses in the country as a considerable amount of land is needed for the treatment of the liquid passing out of the tank. The tank makes use of certain germs which split up aud tirfuefy the solids that are suspended in sewage.

The tank is merely a chamber dug out of the ground and lined with brickwork, several feet in depth and roofed in, and of such a size that it takes the sewage 12 to 24 hours to pass through it. In some of these tanks there is no roof. but in either case the inlet and outlet pipes open below the surface of the sewage. A thiek scum forms on the surface of the scwage and this helps the germs by keeping them warm and protecting them from the air. Gases are produced which are highly intlammable, and these gases are sometimes collected and used as fuel.
After passing through the tank, a considerable amount of the solids in the sewage have been digested. The sewage is purer but, nevertheless, so black and offensive that further treatment is necessary by filtering through clinker or coke. or, in some cases, by distributing the sewage over a tract of land and allowing it to percolate through the soil. Some solid matter settles on the bottom of the tank, and has to be cleaned away every twelve months or so. Disinfectants, in any amount, added to the sewage prevent the septic tank from working properly.

Owing to the nuisance from small, these tanks should be placed at an ader,uate distance from a house. They are satisfactory in their results but require careful and skilled supervision, and are of no value for small domestic establishments.
The Semi-septic Tank. This is a variation of the scptic tank, for in this type the work of purification is not completed in the tank itself, and only the primary process of dis integration goes on there. The breaking down

## Servants and Their Duties

## Hints Towards Comfort and Contentment for Employer and Employed

Shorter entries, e.g. Butler; Chauffeur: Cook; Mousemaid : Nurse; Parlourmaid, deal with
the various duties of various classes of servants. See also Character: Employers' Liability: Housekecping; Insurance: Kitchen
When servants are engaged through the chauffeurs. They live in their own houses, medium of advertisements or a registry office, or in any other way, a personal interview should be arranged if possible. The smaller the household the more the mistress and servant or servants come in contact and personality must count if the best results are to he ohtained. It is also important for servants to se the style of the house or flat. Should a servant have come from a larger establishment, he or she may show at once that the new place will not suit; if from a smaller one, the mistress may feol that too much training will be requirel before the servant is up to the standard of the home and of the other servants kept.
After a satisfactory interview it is well to arrange for a personal reference. If the employer who is parting with the servant will give this, a better idea of the work and character is obtained both by the answers of the employer to the questions, which should be clearly thought out beforchand, so that nothing essential is missed, and by the aspect of the house. If a personal reference is unobtainable, it is never wise to accept from the servant a written reference. The late em ployer should be asked for a direct character, and this will be a better guide as to the servant's suitability for the new place.

Outdoor servants are almost entirely men, the two largest classes being gardeners and
of the solids is only partly carried out, and so the semi-septic tank is made on the smal size, so that the partially treated sewagc passes out to another stage for treatment. In this class of tank, therefore, the sewage is settled and partial liquefaction of the suspended matter takes place, besides the equalization in the strength of the sewage by its bricf stay in the tank.

The second stage is to pass this effluent out for oxidation. 'This is accomplished in scveral ways If there is plenty of suitable land available, it can be fed on the land, but the commonest way is treatment in one of the many forms of contact or filter beds now in use. These consist of a variety of materials of an indestructible nature. The essential fenture is plenty of surface area to ensure the growth of bacteria Probably the commonest material is a hard clinker, gauge one to three inches. For small systens one contact bed may be found sufficient, but in the large several beds. are used See Cesspool; Sanitation.
SERGE: The Dress Material. Most scrges are inclined to become shiny after long wear, and, on the whole, those which feel hardest to the tonch take on a polish first. Serges such as cheviots, with a short nap of fibre on the surface usually do not shine unti the nap has worn away, but the wearing-off of the Huif lends a thrcadbare appearance.

Botany serge is finc, soft, and warm, and the best. cloths of the sort show a neat and even twill. Serge shrinks less than flannel. and if white serge is washed and dried with care and bleached occasionally, it will be prevented from turning a dingy yellow. It is a useful material for sports wear and for children's coats. etc.
SERPENTINE LINE. In furniture this is a line used in design. The front of the piece is convex in the centre, whence it sweeps in wave-like form towards the wings, which hecome concave. It was much used by Hepplewhite for sideboards, dressing tables, etc. See Fender: Sideboard or sometimes in houses on the cstate of their employer, and, like other workers, receive a weekly wage. With domestic servants may he classed charwomen, jobbing gardeners, and others who work for more than one employer, doing a day's work here and there. They are paid so much a day.
Men servants classed as incloor servants are not very numerous. In larger houses a butler and perhaps one or two footmen are kept, and in some cases a ralet. Men servants, like the women, receive board and lodging as part of their pay. A manservant requires a licence.
Where only one maid is kept she is known as a general servant. Two maids usually divide the duties of cook and house-parlourmaid. Bigger houscholds may have in addition, a parlourmaid, between-maid, kitchen-maid and scullery-maid. A housckeeper may superintend the other women servants and there may be a lady's maid.

Nurses and under-nurses are kept in houses where there are children. In the larger houses their duties are strictly confined to looking after the children, but in the smaller ones a nurse-housenaid may be kept to do the work of a housemaid as well.

While it is impossible to keep to a hard and fast set of rules, a certain number are
essential to order and comfort. If more than
one scrvant is kept it is important to assign duties at the outset with even more decision than in the case of one experienced maid, who may be allowed to have some views of her owra

If a servant is to be put on board wages when the family go on holiday, this should be explained to her. The term board wages means the servant's ordinary rate of pay plus an allowance for food, and also for lodging if the house is shut up, the amount varying according to circumstances. When the maid accompanics the family, the question of board wages does not arise, but there may be friction if servants find themselves treated in this way without having been informed of it when they came.

Another matter to be decided when en gaging a servant is whether her friends shall be allowed to visit her This is a question that must be settled in every case in accordance with individual wishes

## Comfort Essential to Good Work

Goorl or bad servants can make or mar the home. They should be well treated and, if good, their work should be respected and appreciated, and a real interest taken in them. Perhaps the most frequent causes of complaint are uncomfortable bedrooms, badly furnished, more than one maid in a small room or more than two in any room, insufficient or poor quality of food, and the matter of outings. In newer houses a small sitting-room or recess off the kitchen makes for comfort.
It is impossible to expect good work from anyone who cannot sleep in comfort. If the house is too small to accommodate the desired number of servants, it is best to have daily help.

Good food, without waste, is essential. The mistress should retain complete control of the larder and, unless she has an experienced cook, herself solve the problem of left-overs so that they shall not be wasted or eaten under protest in the kitchen. Where a servant asks for some special inexpensive article of diet, it should be provided for her.
Outings In this matter hard and fast rules cannot be laid down. One afternoon and evening a week and every second Sunday afternoon and evening are the usual minimum. The hour of return in some places is fixed at 10 p.m. With a young servant this hour should be late enough, but if permission be occasionally asked to go to a theatre or other entertainment, it should not be withheld without good reason. Where there are several maids it may be difficult to arrange extra outings for all, and favouritism should be a voided.

In the case of the general servant, if she gets through her work, she should be encouraged to have as much time as possible to herself. In a small family an only servant is often lonely, and the kind and sensible thing to do is to allow her to invite a friend or rclative to the house. A special sitting-room is not possible in the small house, but if the kitchen cannot be comfortable, owing to its size, it can sometimes be arranged for her to use the dining room after the evening meal. A good servant commands, and is worth, high wages. When a maid is young and inexperienced a mistress must expect tactfully to train her if the home is to be well run.

Where three servants or more can be kept their work is so clearly defined in the kitchen, sitting-rooms, and bedrooms that a well. organized household becomes a simpler matter than where all the duties have to be performed by a cook-general and house-parlourmaid, or a general alone. Where only two maids are kept, it is essential that they should get on well together, and that any housework which the cook is expected to do should be clearly understood on engagement. It is usual for her to be responsible for cleaning the
dining room, breakfast room, should there be one, hall and steps. Sometimes she takes in the breakfast. and usually clears it away and washes up while the house-parlourmaid is busy in the bedrooms.
The cook assists in making the beds, and after that her duties are confined to the kitchen. except on the occasions when the other maid is out. The house-parlourmaid combines the duties of parlourmaid with that of housemaid, and should be dressed for luncheon. A simple dinner is usually arranged, with which she can cope, on the days when the cook is out. Where there are children a nurse-housemaid is sometimes kept as the second servant and the parlourmaid side of her duties require to be simplified.

Some people solve the two-servant question by engaging a husband and wife. They may both be trained servants. in which case the woman acts as cook-housekeeper and the man undertakes the duties of butler. When engaging a husband and wife the highest personal references are advisable, as it is a more serious matter if they have to be dismissed than is the case when a single servant provee a failure.
Maid's Uniform. The question of uniform sometimes presents difficulties, especially in the case of the general servant. Should she object to uniform she can usually be persuaded to wear an overall in the morning with a coarse apron for rougher work, and a dark dress in the afternoon with muslin apron, collar and cuffs. Very often if the mistress helps with the purchase of a smart uniform any difficulty in getting it worn is o vercome.
Where a parlourmaid and housemaid are kept some mistresses like to provide the afternoon uniform so that both maids, if required to wait at table, or to assist in pouring out the tea at an "at home," present an attractive appearance. Black dresses need not necessarily be worn; brown, blue, claret colour or bottle green are sometimes preferred, with a pretty style of cap, apron, cuffs, and collar. In the morning parlourmaids and housemaids wear cotton dresses. Small patterns are more useful than plain colours. The house parlourmaid should wear a clean apron under her coarser one, so that the latter can be quickly taken off should she have to answer the door or a sitting-room bell in the morning. A rubber apron is a convenience to protect the maid's afternoon uniform when washing up. Neat shoes are important.

Cooks wear dresses with short skirts and either large linen aprons or overalls in the kitchen. Caps are optional. Where there are stone floors to kitchen and scullery boots are more comfortable than shoes.
Where one manservant is kept he does not wear livery. Black coat and dark trousers is the customary uniform. In many houses where no regular servant is kept, the housewife is relieved, of the more laborious domestic duties by hiring the services of a daily girl. She may be engaged for the whole day, in which case she will probably wear uniform in the afternoon, or for the forenoon only, or for a couple of hours, according to requirements. Her wages are paid weekly and she may get her meals or not, as agreed upon.

Insurance. One of the duties of an employer is to see that his or her servants are insured under the national health insurance scheme and that the cards are regularly stamped. Any failure in this respect renders the employer liable to a fine. Servants are not insured against unemplowent, but it is desirable to insure them against any accident that may happen to them in the course of their employment. The best way of doing this is to take out a combined insurance policy which covers risk from fire and burglary and also insures the servants against accident.

SERVICE HATCH. As a general rule a service hatch is an opening about 2 ft . squarc provided with a door or doors, forming a means of direct communication from the dining room to the adjoining kitchen or pantry. It is particularly helpful in a house or fla! where only one maid is emploved. as the

meas can be handed through the service hatch from time to time as requisite, whilc the plates and dishes after use may be returned by the same means, thus obviating the neccssity of the maid entering the dining room.

In most cases the service hatch consist. merely of a door, which may be hinged or arranged to slide sideways or upward in grooves. The sides of the hatch are generally lined with wood, in the same manner as a door or window opening, and are also provided with a wide window board or shelf.

To prevent odours from coming through from the kitchen two doors or two sets of double doors can be provided, and the hatch made a couple of feet deeper. One set of doors will be hung on the dining room side of the wall, and the other on the kitchen side. The articles as they are prepared for table are placed in the hatch, and the doors closed on the kitchen side. Those on the dining room side are then opened whenever the articles are necded, and the dirty plates replaced, the doors being closed afterwards on the dining room side. In the case of the hatch illustrated, one the other is opened and kitchen or dining room is obtainable. No noise, sounds of talking, or sinell of cooking can penctrate. Hatches are sometimes arranged to open above built-in dressers, or form portions of the backs of sideboards. See Dining Room; Kitchen ; Pantry.
SERVICE LIFT. In houses with a basement kitchen the installation of a service lift saves the labour of carrying trays up and downstairs and also prevents food from getting cold during the transit from kitchen to dining room table. Before proceeding with plans for installation inquiries should be made to ascertain if there are any landlord's restrictions that preclude it. In some cases the local authority has requirements which must be met.
When the dining room is immediately over the kitchen the lift can be planned to rise in a corner of the room. Sometimes such a lift is of the disappearing type and is operated from

In the room side. kitchen, wheeled into the dining room and there converted into a rigid table
below ascending through a hole in the floor. When the cage descends the floor boards on top return to their usual position. In other cases a built-in cabinct conceals the lift.
A service lift can be operated by electricity or by hand power. In the former case it can be worked from either the upper or lower floor. In the latter case the hauling rope must be adjusted so that it is not loose enough to rattle against the casing, or too tight so that it grates. If a self-sustaining gear is used, the cage is locked into position as soon as either the winding handle or the hauling rope is released. The lift may be fitted with a brake worked by l foot pedal: in this case the lift is moved when the foot presses the pedal and the brake comes into operation when the foot is removed See Dining Room
SERVICE PIPE. This name is given to a pipe conducting the principal supply of water or gas to a building, made of lead or galvanized iron, respectively. Generally there is a stop cock in the run of the water service pipe in any convenient position $n$ or just cutside the building, so that the water can be entirely cut off if necessary. A draw-off cock should be placed on the house side of the stop cock so that the entire system can be drained.

In the case of the gas service pipc, this is usually the property of the gas supply company, and runs from the gas main to the ga: meter. See Gas; Pipe; Water Supply.
SERVICE WAGON. Known also as dinner wagons, service trolleys, tea wagons and table wagons, service wagons may bc obtained in oak, walnut or mahogany, and also in enamelled or plain white wood for nursery use. They are made with two or threc tiers or trays, and in some cases are so con structed as to be readily convertible into tables.

The small two-tiered kind is

Service Wagon. Two views of a two-tiered wagon which can be laid in the
kitcben, wheeled into the dining room and there converted into a rigid table and obviates the carrying of heavy trays. As such a wagon is table height it can be arranged and laid as an afternoon tea table, cakes, ctc. being placed on the lower tier.

The wagon illustrated can be converted inte a rigid table at which four pcople can be seated for luncheon or dinner. Slight pull on a small button enables anyone instantly to change the wagon while loaded into a table or vice-versa. When laid in the kitchen, the table is converted into the wagon shown on the left, wheeled into the garden or dining room, and converted into the table shown on the right. The cellulose finish resists damage to heat ; if hot liquids are spilt and removed at once they will not stain the surface. Wagons with three tiers are obtainable, which swing into position and form a table at which six people can sit.
Making a Trolley. The simplicity of this dinner or service wagon, made throughout in oak, commends it immediately. The overall height is $31 \mathrm{in} .$, length 26 in., and width 16 in ., 2 in. of the total height being accounted for
by the rubber-covered castors serewed to the four uprights. The uprights are of $1 \frac{1}{4}-\mathrm{in}$. square woorl, the fronts, backs, and sides of the trays or shelves being $1, \frac{1}{3}$ in by $\frac{3}{1} \mathrm{in}$. thick. The shelves or tray-bottoms are of 5 -ply oak, each $24 \frac{7}{8} \mathrm{in}$. long by $14 \frac{7}{2}$ in. wide.

Dowel joints are used throughout. The thee tray-fronts are first dowelled and ghed to the front uprights, the bottom trayfront being 4 in . up from the loottom, the middle one $1: 2$ in. higher, and the top one 12 in . above that. Proced in exactly the same manner with the back. When the glue has set perfeclly, join front and back together as shown at Fig. 1, the jointing heing shown in detail at l"ig. 2.
The 5-ply shelves or tray-bottoms (Fig. 4) rest and are glued upon $\frac{1}{4}$-in. square strips of oak glued to the inside lower edge of each tray-front and side and back (Fig. 3), the trayhottoms being notched out at each corner to

Service Wagon. Fig. 1. Wagon made in oak. Fig. 2. Detail of jointing. Figs. 3 and 4. Tray bottom and method of attachment
ensure : 2 neat fit. Fitting the rubber-covered castors completes the wagon, which may be polished or left in its natural colour. See Dining Room; Dowel.

## Serviette. See Napkin.

SETSCREW. This name is given to a small, usually headless screw used to aflix one part to another. Setscrews are employed for fixing a small pulley or gearwheel to a shaft, a knob to a spindle, and for like purposes. As the name suggests, the screw is used to set or fix the position of a movable part on another part.
SET SQUARE. This name is applicd to an instrument used for testing or marking out rectangles. Carpenters and engineers use squares when working in wood and metal, but the term set square is more correctly limited to the squares used by draughtsmen. In a simple form it may consist of a thin, flat picce of pear wood triangular in shape. Two of the sides form a right angle, and the third is at an angle of $45^{\circ}$ or $60^{\circ}$ to one of the other sides.

In almost all cases it is necessary that one of the edges of the instrument should rest upon a T-square or hatten, which is set in position parallel with the hase line or principal horizontal line. By sliding the set square along the batten or T to the desired spot and drawing a line against the edge of the square, the angle formed between this line and the horizontal or base line will be $90^{\circ}$.

As a test for accuracy of the square portion of the instrument, turn the square over without moving the batten. If the square is correct, a second line drawn from the same point as the first will exactly coincide ; but if the square is incorrect, the lines will be
tapered, and the amount of taper at the extremity of the squarc will be the amount of error in the instrument.
Squares should always be kept clean and in a dry place, preferably hung up on the wall. Celluloid or ivorine set squares are liest cleaned by washing them in soap and water. Wooden squares may be cleaned with a linen rag moistened with petrol, and then polished. See Drawing ; Mcasure nent; Rule; T-Square.

SETTEE. The settee is a long seat, usually upholstered, and having arms at either end. It thus differs from the sofa, being rather a development of the sectile. It

appeared in England about the end of the Hepplewhite becams famous owing to his 17 th eentury, and some splendid pieces, notable wheel-back settecs, made of satinwood and for their upholstery, were made at that time. painted. In general his settees have the The example illustrated is in walnut, with six crest rail in the form of a wave that flows cabriole legs, and high-backed seat covered in benutiful brocaderl silk. Later the uphol. stery was left out from the back and sides, and the settee hecame in ellect two or three chairs with a single back.

Chippendale designed settees with open backs, earved with riblion work and C serolls. Chinese frets occasionally form the backs, and the square legs are connected by rails.

## The Settee Bed and its Construction

## A Convenient Piece of Furniture for the Flat or Small House

Th's con ribution d scribes the making of an article that will serve as a seat by day and as a hed by night. To make it, the amateur needs a knnwiledge of the vari. us proccsses that are described under such entries as Dovetail; Joint; Mortisc. See also Chair; Chair Bed ; Divan; Üpholstery

A settee bed, as it is called, is a picee of making an allowance of $1 \frac{1}{2} \mathrm{in}$. in height when furniture that will serve as a settee during the setting out the working drawing.
day and as a bed during the night. Such beds have to a great extent been replaced by divans, but are suitable for bungalows and bed-sitting rooms. There is only one main type ol settec bed, but they are made in various sizes and patterns. and in various materials and qualities of material.
The setiez bed shown in Fig. I will be found comfortable and inviting, and the extrat cushion shown at the back can lie transferred to the seat for those who prefer it. As a bed the appearance of the settee will be as in Fig. 2, the opening out heing of the simplest descrip. tion and specdily effected. The main dimensions, excluding cushions, are : height of seat over framings, 9 in. ; height of arms, 1 it. $11 \frac{1}{2} \mathrm{in}$. height of back fraining from ground, when vertical, 3 ft ; length of seat over upright, 4 ft .2 in ; length orev arms, 4 ft .4 in. ; width of sides over uprights, 2 ft .4 in . ; length of armis, 2 ft .111 in . ; length of back, seat and foot frames, 3 ft 10 in ; width of back and seat frames, 2 ft .3 in ; wilth of foot frame, 1 ft .11 in net; and with stop extensions as required.

Probably the best wood to select for general purposes is oak, stained to a rich mut-brown colour and bright polished. The legs or uprights (A, Fig. 4) require 4 pieces of 2 in . by 2 in., the length given in the cutting list allowing a sharde for paring in tinishing to include it stub tenon at the lop end to enter the arm Mortises should be cut for the seat and lower rails, and the legs may be mounted on castors,

The arms (B) linish $3 \frac{1}{4} \mathrm{in}$. loy $\frac{7}{8} \mathrm{in}$., and have the edges slightly rounded away for comfort. When litted in position they project

This should result in a firm but light rectangular framing, when lowered to seat level it will be supported by strut feet which fold between the inner edges of the stiles in the manner indicated at Fig. 7. These strut supports (M, Figs. 5 and 7) take 2 pieces of hardwood $12 \frac{1}{2} \mathrm{in}$. by $1 \frac{1}{4} \mathrm{in}$. by $\frac{7}{8} \mathrm{in}$. and are bolted right through J and M with $\frac{3}{8}$ in. roundheaded bolts. The heads are sunk and the bolts are nutted on the inside so that they

1 in. on the outer side and $\frac{1}{4}$ in on the inner, and 1 in . in front. which would allow $6 \frac{1}{2}$ in net for adjustment projection off the arm at the back when finished. Just behind the back upright the arm is reduced to $2 \frac{1}{4}$ in. as in Fig. 6.
The seat rail (C) takes two pieces to finish $2 \frac{1}{2} \mathrm{in}$. by $\frac{7}{8} \mathrm{in}$., tenoned or dowelled to the legs, and similar rails (G, Fig. 3) are fitted to the legs at the same level front and back. A stretcher rail running between the front and back rails may be dovetailed in if desired. The underlraming pivot freely without play. A section at 0 rails (D) and corresponding rails (H, Fig. 3) (Fig. 5) shows how the bolt is entered. fitted to the sides and front respectively may finish $1 \frac{1}{4} \mathrm{in}$. by $\frac{7}{6}$ in. net.
The panels (E, Fig. 4) between the arms and seat rails have a visible height of $13 \frac{1}{2}$ in., and are fitted into position with $\frac{1}{2}$ in. stub tenons top and bottom, the net finished width being $4 \frac{1}{2}$ in., using $\frac{8}{8} \mathrm{in}$ or $\frac{3}{8} \mathrm{in}$. thickness as preferred. The panelled effect can be of applied mould glued and pinned on. If this main framing is carefully put together a substantial and lasting result will be obtained. The separate framings for the back. seat and foot ends forming the cushion rests may next be dealt with, and a nicely smoothed finish with the edges slightly rounded away will give the best effect.

Reference to Fig. 5 shows that the whole back frame is hinged to the back edge of the seat frame, and supported at a convenient angle by an adjustment rod behind in the slotted arm, as in Fig. 6 Two outer stiles (J) and one centre stile will be required to finish $1 \frac{7}{8}$ in. by $\frac{7}{8}$ in. and also 2 rails (K) to finish 3 ft .10 in . by $1 \frac{7}{8} \mathrm{in}$. by $\frac{7}{8} \mathrm{in}$. This allows for jointing and clearance between the arms so that the framing may fold down between for portability. The stiles and rails should be mortised and tenoned together and pinned. The slats or laths ( L ) may be anything between

The stretcher rail between may be of the same substance as the legs, tenoned and pinned in. When the strut support is lowered and bearing the frame it is held in position by means of a clutch (N, Figs. 5 and 7) which is of $\frac{7}{8} \mathrm{in}$. by $\frac{7}{8} \mathrm{in}$., or $1 \frac{1}{4} \mathrm{in}$. by $1 \frac{1}{4} \mathrm{in}$. thickness in the length and with a $1 \frac{1}{4} \mathrm{in}$. projection at the extremity to pass over the stretcher rail of the strut and grip it. This clutch is hinged to the lower rail of the framing and is of a length to butt closely between the rails. The position, approximately, for bolting the strut to the framing will leave a space between the framing and the top of the strut leg of $2 \frac{1}{2} \mathrm{in}$., or $4 \frac{3}{8}$ in from the outer edge of the framing; this indicates a position which should be suitable for allowing the clutch to overlap and grip the strut rail

The seat frame is of the eame dimensions as the back. It may be made with 3 in . by $\frac{3}{\frac{3}{6}} \mathrm{in}$. laths, which will be sufficiently thick to give a bearing, whilst wide enough to be comfortable. Seven laths are indicated in the illustration, and the centre and thicker stile is omitted, but the finished effect of the whole will be better if the frame is fitted with an equal number of laths to the back frame, with an extra one to replace the centre stile.

The foot-end frame itself is 1 ft .11 in wide only, but otherwise it is put together with stiles rails and laths in a similar manner to the back. This footend frame lies loosely under the seat frame, and when home is flush with the front of the seat frame
When extended it rlrops into position level with the seat rame. The latter rests upon two stonfillets 2 ft .3 in . by $l_{\frac{7}{8}}$ in. by $1 \frac{1}{4}$ in., screwed to the underside of the stiles (Fig. 5) and with a similar projection to that indicated for the
clutch, which will stop against the seat rail (G, Fig 3) and prevent the foot frame from dropping out of position. The frame is supported by a strut and locked with a clutch similarly to the back frame. The total length of the frames when let down horizontally will thus be 6 ft .5 in . In Fig. 7 the strut support is shown in action with the clutch indicated.

In lig 1 the foot-end frame is omitted to show more clearly the position of its entry. When being drawn out or pushed home it travels on fillets screwed to each of the side rails (C) in a similar manner to a drawer runner. A cutting list is given on the previous page, with the lengths slightly on the full side, in most instances, $t_{0}$ ) allow for finishing : widths and thicknesses are net.
The Cushions. Much of the comfort of a settee bed depends on the cushions, especially when they are used as mattresses. Unless they are well upholstered they will wear thin and provide little, if any, protection from the hard laths. The ordinary flock filling employed for mattresses can be used if it is properly packed in the inner casing, but as it is liable to wear limp and so become uncomfortable, the better plan is to use well curled horsehair
The most satisfactory method of making the cushions is to use springs, and in this case they should be about 6 in . thick and fitted with 4 in. springs set at close intervals. For the amateur the best method of making them is to cut out oblong pieces of stout canvas, and sew the springs to two pieces, each spring touching the other. The sides should be fitted in with narrow material, and then each in turn covered with flock or hair to a thickness of 2 in . or so, and then with tapestry or repp. The two sides should be buttoned together so as to give rigidity and also to keep the two surfaces parallel.

SETTER: The Dog. The English setter is one of the handsomest of dogs, but, unlike the retriever, he is not greatly kept for show

Setter. Young Engligh setter, a beautiful ailkycoated aporting dog
purposes. Several beautiful colours are recognized, such as black and white, lemon and white, liver and white, etc. The long silky coat is slightly wary.
The shoulders should be well sloped, the loins wide, slightly arched and muscular, the brisket deep, and the ribs widely sprung. The legs should be strong and muscular ; the feet close and compact. The head should be long and lean ; the skull oval from ear to ear, allowing plenty of room for the brain. The muzzle should be moderately deep and fairly square; the nostrils wide. The neck should be rather long, muscular and lean. The tail should be carried almost on a line with the back.
The colour of the Irish setter is a rich golden chestnut, entirely devoid of black. The Gordon, or black-and-tan, is the rarest of the three. He is somewhat more strongly built than his English cousin, and his head is much heavier. See Dog; Kennel.

## Settle: Antique and Reproduction Pieces

How to Construct a Useful and Decorative Hall Seat

The reader may also consult the articles on Ingle Nook: Jacobean Style; Tudor Style; while references for the constructive side of this contribution include Cabinet Making; Chest: Corner Seat; Halved Joint; Wood Carving

This word is used for a kind of wooden bench be nearer $\frac{7}{k}$ in. Two pieces are glued together or seat. Most settles have arms and a high for each upright. and the top curve is drawn back and will hold three or four persons. Marle of oak and heavy in style, settles appeared in England perliaps as early as the twelfth century. The high back was a protection against draughts, and some had in addition a canopy. Gradually they became more elahorate, and some examples of the Tudor and Stuart periods are beautifully carved. In some the fronts are divided into panels around which is finely

Beautifully carved old oak settle with box seat ; 17th century Courtesil of 'r. Eidwards. Ilarrogate to a radius of $7 \frac{1}{2}$ in., 2 in from the end. The curve should be reversed on one side to line is sawn with a bow-saw, and finished with a spokeshave, and the small piece cut olf, as shown at B, should be placed on one side for use on the under side of the top board.

The back may be in one piece, glued up with 3 or 4 lengths and finished to $2 \mathrm{ft} .11 \frac{1}{2} \mathrm{in}$. by 2) ft. 5 in., or formed with one $2 \mathrm{ft} .11 \frac{1}{2} \mathrm{in}$. by 1 ft .1 in., with a lower length, 1 ft . 5 in., of plywood. The back is fitted in r rebate cut in the upright sides, as shown. Two frames, $D$ and $E$, are prepared from 2 in by 1 in wood (deal will do for this) to 2 ft . 10 in . by 1 ft .1 in The ends may be screwed or halved together, and then screwed to the sides and back. The frame, D, is Hush with the bottom, and the top of E is 1 ft .5 in. up. The top of D frame shoold be covered with a piece of plywood measurexecuted carving. A number of settles were ing the samc outside-size as the frame. made in the 16th and 17 th centuries, but early in the 18th the piece went out of fashion. In the 19th, reproductions of the old settles made their appearance.

Strap work ornamentation is found on many British settles. They had inlaid chequer board decoration on the stiles and rails, and occasionally the arms were inlaid. In some, as shown in our illustration of a beautifully carved 17th century settle, the bottom of the piece was constructed as a chest.

Settles are made to-day in reproductions of the old styles, and are suitable in halls or living. rooms furnished in oak period styles. Loose velvet cushions, fringed or tassellerl, are permissible, but a settle is never upholstered.

Making a Monk's Bench. A type of settle with a movable back and box seat was made in Tudor and Jucobean times. The back was adjustable to form a table and the picce is often known as a monk's bench. Copied to-day for hall furnishing, this is and picturesque style of seat, whes not only a table, but also a rug chest.

The monk's bench provides suitable surfaces for incised carving. The suggestions given in Figs. 1 and 2 are taken from old English carvings, and they may he exccuted with a few simple tools without any previous experience of wood-carving. By the method of construction shown in Fig. 3 there are no mortise and tenon joints, the lapped halving joint only being used. Oak is the correct wood, but the carving will be easier if seasoned yellow pine is used, and finished by wax polishing only or by staining.

The upright sides, A , are 2 ft .5 in . by 1 ft .3 in by 1 in . But if machineplaned wood is used, the thickness will
the back on top of $E$, as indicated at $F$, but two end pieces, $G$, the same width and thickness, should be joined to it with the halving joint and project 1 in . in front, the ends being rounded as shown A 2 ft .10 in . by 1 ft . 5 in frame, shown at $H$, is made from 2 in . by $l \mathrm{in}$. wood, halved at the corners, and a rebate cut at the back to take a panel $K$, measuring 2 ft . $6 \frac{3}{3} \mathrm{in}$. ly $\mathrm{l} \mathrm{ft} .1 \frac{3}{4} \mathrm{in}$. by $\frac{1}{2}$ in. This framed panel should be fitted under the projections at $G$ and screwed up from the front

The binged seat Hap giving access to the locker at the bottom of the bench is 2 ft .6 in . by 1 ft .1 in . by 1 in . ; the front colge is rounded and two battens of 2 in . by 1 in . wood screwed under at the ends, so as to fit inside the rail $E$ and prevent the wood from warping. The top board, which forms a table whell resting on the arms is 3 ft .6 in . by 1 ft .6 in. by 1 in ., and is hinged $1 \frac{1}{2} \mathrm{in}$. away to the back $C$. In order to allow the hoard to tilt back slightly when upright, a chamfer should be plancd $1 \frac{1}{2}$ in. wide and $\frac{1}{k}$ down at the hinge side. The pieces $B$, neatly cleancd with a spokeshave. are screwed to the top board, as shown.

Carving the Panels. The carved decoration may be drawn direct, or on paper and transferred. The border lines, as well as the curves, are cut with a veiner and enlarged with a quick gouge as indicated at M. Slight recesses are worked with a flat gouge as shown at N , and finished as indicated at 0 . The tool cuts at $P$ are done in a similar manner. The effect gained by the simple incising of all lincs with a veiner is quite effective; but, if thought too difficult, the gouge work may be omitted.

SEVRES. The richly decorated porcelain characteristic of the famous French factory at Sèvres is rightly admired for its unique qualities of form and colour. Only the longest of purses could hope to acquire examples worth having, and the lover of antique china must usually be content to study old Sèvres in public galleries.

Started in 1756, Sèvres has always enjoyed royal or state patronage. For the first 13 ycar's it produced soft-paste porcelain of the St. Cloud type. In 1769 a now era opened with the introduction of hard-paste, similar to that of China and Dresden. Since then practically all French porcelain has been made with china-clay and felspar, and hard-paste Sevres is thercfore distinguishable from the English reproductions made in bonc porcelain at Coalport and elsewhere. It now became possible to turn out enormous vases, as well as plaques for painted scenes. During the Louis Seize period many of these plaques were set in ormolu mounts on rich marquetry, and a delightful corn-flower-bluc was introduced. The important class of biscuit figures, by great sculptors, is quite distinct from the homelier groups emanating

Sevres. Left, trembleuse cup, cover and saucer, painted with medallions of children and a wreath of flowers on cover. Centre,
fat-shaped gros-bleu vase and cover with white and gold scroll bandles. Right, large gros-bleu cup and saucer painted flat-shaped gros-bleu vase and cover with white and gold scroll handles. Right, large gros-bleu cup and saucer painted
with pastoral landscape and figures and with gilt scrolls and wreaths of fowers

Peat, which removes offensive odours effectually, may by its antiscptic effect interfere with the desired bacterial action. The excreta disappear as such in about a month, and with proper care the process can be carried out without being in the least degrec , ffensive. An arrangement of pails has been devised whereby the liquid excreta are strained into a lower pail and disposed of separately.

It has been pointed out by experts that urine diluted to $l$ in -20 with water, and carefully applicd to certain vegetables, promotes very vigorous growth, and that in the case of carrots it destroys one of their nost common trom Dresclen and Che!sea. Since the new consumed without causing diarrhoea, typhoid, pests. Slop water on such a system would have factory was erceted in 1876 there has been a or any other lilth disease. The earth which is to be disposed of separately, but could be revival of soft-paste porcelain, but it has not the delicacy and charm of the old Sevres.
The mark of the double L , established in 1753 at Chantilly, with A to represent the year, was continued at Sèvres from 1756 to 1777. That year was indicated by Z, W having been omitted. The sccond cycle began with AA, and reached 1795 with RP, when the dating was varicd for a time. Since 1818 the year has been expressed by its last two figures. From 1810 to 1848 imperfect pieces bore no mark, whereas since that date they have had a wheel-cut through the main mark. From 1854 to 1870 a crowned N stood for the emperor, and a $T$ meant that the piece was soft-pastc. After 1888 the mark became a potter at the wheel, with the word Sèvres and the two-figure date.

The fact that during the 19 th century white biscuit pieces were freely sold has been a fruitful source of mystification. Large quantities were bought for decoration either in Paris or in England, so that the only part of them which was of genuine Sevres origin was the body. It is estimated that of all the socalled soft-paste Sevres in collections ninetenths were decorated elsewhere. See China: St. Cloud Ware
SEWAGE. This describes the refuse from a house. In towns it is carried away through the drain pipes, in connexion with which an elahorate sewage system provides for its removal and disposal. In country districts residents have often to makt their own arrangements for its disposal, and one way of doing this is by means of a cesspool.
Some of the contents of sewage have a high manurial value. The processes carried out at sewage works in connexion with the water carriage systems of towns remove the grealer part of this value, as neither the solid part of the treated sewagn, the sludge, nor the watery affluent is of much use. Where a cesspool is used for a country house, the action of bacteria reduces the solid constituents of the sewage to a soluble condition and the liquid can be drawn out for distribution in a garden.

A cesspool should be lined with cement, otherwise the contents soak out into the surrounding soil at a depth where nitrification processes do not go on, and the sewage may make its way in the ground water and so into shallow or surface wells. In this way typhoid fever, diarrhoea, and other diseases may be propagated. Even if it has a cement lining, a cesspool should be at a lower level than a well used for drinking water, and at least 100 ft . from any woll, spring, or stream.
There is much to be said for the disposal of excreta by using an earth closet and burying the contents of the pails in the upper layers of the garden soil, where nitrification will go on and thereby promote plant growth. Where such a systen has been tried plentiful crops of vegetables have been obtained, and have been
used in the closets should preferably he garden soil, and it is important that it sloould be collected on a dry day and stored in a dry place. utilized for watering, either by irrigation or by spraying. See Cesspool; Drains; Earth Closet; Sanitation; Septic Tank; Water Closet.

## Sewing Machines and Their Care

## How the Busy Housewife can Save Time and Money

In connexion with this article that on Oiling should be read. See also entries on various neediework processes, e.g. Dressmaking; Scam

The earliest type of sewing machine, still used for children's machines, is that known as the chain-stitch, which uses only one thread. The machine in generial use is the lock-atitch. In this there are two threads, one attached to the needle and the other to a spool enclosed in a shuttle. The needle sarries the thread through the material, and, in rising, causes the thread to form a loop. The shuttle passes through the loop, which, in its passage to the top of the material, carries with it the thread from the shuttle. The tension caused by the thread attached to the needle forming the next stitch pulls up the lower thread tight (lig. I, A).

There are two methods of moving the shuttle in general use, one being known as the reciprocating and the other as the oscillating shuttle. The former will be found on some of the older machines, and it is therefore briefly described here. In the reciprocating shutile machine there are two shafts to convert the rotary motion from the wheel. One runs horizontally into the interior of the arm at the top of the machine, carrying at one end the heavy balance whecl, and at the other end the disk and roller for imparting the upward and downward motion to the needle-bar, together with a bevel gear wheel. The other spindle is vertical, with a similar bevel gear wheel at the top and the cam at the bottom for operating the feed lever and a balanced crank, this giving the reciprocating movement to the shuttle carrier, by means of a straight connecting rod.

The shuttle movement is at right angles to the direction of the sewing, and the shuttle slides in a shallow recess. The whole of the

Sewing Machine. Fig. 1. A, stitch correctly made. B and C, stitches which result from faulty tension
movement is directed towards obtaining an exactly corresponding movement of the needle and the shuttle, and the operation of adjusting these two disconnected parts is called timing. The timing is effected by adjusting the two bevel gear whecls, so that when the needlebar is at the bottom of its stroke the shuttle must be in such a position that it can pass through the loop formed by the thread directly the needle commences its upward stroke.

The action of the lock-stitch is assured by this adjustment, but there are other points to be considered in order to obtain a good stitch. It is necessary to have the thread in the shuttle correctly threaded and at a suitable tension, and the thread in the needle adjusted in connexion with the take-up lever, so that when the ncedle-bar descends it carries the lever with its attached thread and then allows it to spring upward with the ascending stroke to gather the surplus thread used to form the loop and not required for the stitch.

Leading Types. A vibrating shuttle machine is illustrated in Figs. 2, 3 and 4 . In this the top spindle is formed with a crank which produces a swerving movement in the vertical lever $A$. This lever is connected at $B$ to an arm $C$ attached to the crank $D$ of the shuttle carrier E . The feed movement is obtained through the cam at $F$ (lig. 2), which is attached to a crank at G (Fig. 4), operating the bar H , and imparting a backward and forward movement.

The needle-bar movement is shown at Fig. 3. The presser foot, indicated at $P$, presses the work down on the feed and also prevents the work being pulled up with the ascent of the needlc. The pressure produced by the spring can be regulated by a screw at the top of the bar. It is lifted up by a lever at 0 working on the principle of an eccentric.

The internal mechanism is the same for both hand and stand machines. the only dilference being in the method of turning the balance wheel. In the hand machinc a gear case is attached to the framework of the machine, and contains a large-toothed wheel provided with a handle which engages with a small-toothed whecl. The latter is connected with a movable arm, which can be attached to the balance wheel and easily removed to place the handle out of action. The stand machine has a driving wheel of large diameter, turned by a connecting rod attached to a treadle. A
belt from the driving wheel transmits the thread trom the shuttle loosely. If the tension power to the pulley, which forms part of the top balance wheel.
There is a type of machine in extensive use in which an oscillating hook-shaped shuttle carrics the lower thread in a circular bobhin. This shuttle may work in a horizontal planc, or in a vertical one. Therc are several other kinds of sewing mnchine in use, as, for example, those having a circular container for the lower thread in the form of a rotary hook. Instead of moving backward and forward, the hook continues to revolve and it is so arranged that when the needle is at the bottom of its stroke the point of the hook is a little behind it and carrips the thread with it to form the lock of the stitch.

Onc of the best methods of operating a sewing machine is by neans of an electric motor. This is attached to the back of the table. In some cases the motor is startcd and the specd regulated by means of a treadle or foot controller; in others a switch-lever is fitted on the tatle by the side of the drivingwheel and acts as a starter, regulator, brake and stop.

Care of the Machine. The machinc which is regularly used and frequently oiled will not, as a rule, go wrong; it is irregular use and improper oiling that usually cause trouble. There are certain oiling points in every machine in which the spout of the oilcan should ba placed, but from time to time the underneath mechanism and that portion covered hy the frame should be attended to. The main causes of stiffness in running, are clogged or gummed up oil and dust, small particles of fibre and grit. A machinc that is in regular usc is subject to trouble caused by dust and fibre, and it is necessary to examine the unexposed parts and clean them up occasionally. Only the finest mineral oil should be purchased and a very small quantity used at a time, all the oil holes being noted so that the oiling is thorough.

It is in the shuttle race that dust is likely to congregatc, and this portion of the mechanism must be kept quite clean; it can be wiped over with a soft rag soaked in paraffin, the connecting bars and other parts being wiped over at the same time. If the machine has been noglected and the oil has gummed up, it will be necessary to use a stiff brush with plenty of paraffin, which should be wiped off before the new oil is applied.

The regulation of the tension shonld be carefully attended to, for the success of the stitching mainly depends on it. Referring again to Fig 1, the correct stitch is shown at A; but if the tension is not enough, the thread from the needle will not do more than hold the is too tight, the shuttle may find a difficulty in passing through the loop, which is also liable to break, and, in addition, the shuttle thread, when it is pulled up, will be drawn through the material. The tension plates are fitted with a spring and an adjusting screw, so that different tensions can be given to the thrend when sewing different materials. When the machine makes a good stitch with both the upper and lower tensions fairly slack, there is nothing wrong with the other adjustments.

Using the Machine. Faults in sewing are morc generally the result of carelcss use than of defective mechanism. A bent or imperfect needlo, which is a frequent cause of missed stitches, may be due to the needle not being set straight in the needle-bar, or the needlebar being bent. Other reasons may be that the needle is incorrectly set or unsuitable for the size of the cotton. The take-up spring may be set ton long, or the hole in the needle-plate too large. All these faults can be adjusted, with the exception of the latter, when a new plate should be fitted. Special care should be given to the choice of the ncedle; makers usually give a table showing the size rcquired for various thicknesses of cotton. The correct position is generally marked by a fine cut on the needlebar, and when the eyc of the needle is centred on the needle. plate the mark on the bar should coincide with one on the frame. The casies run the point of it into the cyc of the machinc needle, and let it remain until the screw is tightened up on the bar. The alinement of the needle should be frequently noted, as the uareless handling of the material before the needle is entirely raised will often cause a bend, and if this is allowed to remain it may not only cause missed stitches, but also damage the needle hole or the shuttle.

As a rule, the hand machine is easily worked, but the treadle machine is found difficult at first. In order to become well accustomed to the movement of the treadle, the balance or hand wheel should be loosened by raising the small catch so that it will

Fig. 4. Underneath view of vibrating shuttle machine, showing the positions of the various parts and oiling points way of centring the needle is to place an The action of the stitch regulator should be ordinary necdle fiat on the needle-plate and tested, and in those machines fitted with a
turn without moving the other parts of the machinc. The presser-foot should be raised both feet placed on the treadle, and the balance or handwheel revolved towards the machinist, never in the opposite direction The fect are so placed that the tocs and heels can be used with equal power, and have so much control over the treadle that the tiy wheel can be used slowly or quickly.

Practice should next be gained in guiding. the material For this the needle is raised some material placed under it, and the presser-bar let down. The shuttle should not be used, and there should be no thread in the needle. The handwheel should bc turned forward and the material guided as the fecd carries it along. The presser-bat should be lifted to turn the material, which on no account must be pulled, as this action will bend and perhaps break the necdle : and on no account should the machine be worked unless there is some material between the foot of the presser-bar and the feed. tested, and in those machines fitted with a reversible feed this should be noted and its action practised.

The method of winding the cotton on the bobbin is more or less automatic, but if the winding is not perfectly even the adjustments should be noted and, if out of order, put right. The shuttlc should be fitted with a bobbin, and correctly threaded so that the cotton runs out freely. The necdle is threaded and the tension tested, and then the actua! sewing commences.

In all modern machines there are a number of attachments for use in various kinds of work. These include, a mongst others, a straight guide which serves to dircet the material in a straight line, and which can be adjusted in various distances from the stitch-holc. The quilter guide is used for quilting padded materials in straight lines and squares. It is attached to the presscr-bar and is casily adjusted. An automatic method of hemming can be arranged by the use of the hemmer. an attachment fitted to the presser-bar in place of the ordinary foot. The corder is a similar attachment, having a groove underneath to allow the cord to pass directly under the ncedle. The gatherer is a useful attachment adjusted by the length of stitch It allows the lower of two pieces of material to be pleated or frilled, while the upper is straight and firmly stitched.

SHAD: The Fish. The several salt water fish of the-herring tribe known as shad may be cooked in various ways, but perhaps the best methods arc to broil it, or else to stew it in white wine, as in lirance.

To broil shad, scale, clcan, and wash the tish, which should weigh from 2 lb . to $2 \frac{1}{2} \mathrm{lb}$., then cut off the head and score each side. Put it into a dish and sprinkle with salt and pepper, then pour over it enough oil to
steep it and let it soak all night. The next day broil the fish very gently for about $\frac{3}{4}$ hour, turning it over during the operation. It is important to score it before putting it to soak, so that the seasoning may work into the Hesh. Cook it each side about 20 to 35 min . Dish it very hot, and serve it with maitre d'hôtel sauce.

To stew shad, scale and cleanse the fish and dry thoroughly, then bind it together with tape to prevent it opening where it has been gutted. Put it into an oval stewpan with 3 shallots, a clove of garlic, 1 blade of mace, 15 black peppercorns, a bouquet garni and salt to taste. Cover the fish with $\frac{1}{2}$ pint white stock and $\frac{1}{2}$ pint white wine. Stew gently for 35 min., basting the fish occasionally, then dish it up and remove the tape. Strain off the liquor and add $\frac{1}{2}$ pint of it to the same quantity of béchamel sauce. Mix well over the fire and pour over the fish.

It is better to fillet the shad if it is to be fried. Dip each fillet into well-seasoned Hour and fry gently in boiling fat. Garnish with fried parsley. The roe of the fish may be separated from it, floured and fried at the same time as the fillets. and served with the fish. See Sauce.

Shaddock. This is an alternative name for grape fruit (q.v.).

SHADE: For the Eye. These shades may be classified under two headings. One type, generally for one eye only, is for holding in place boracic wool or other dressing which may be necessary. These shades are usually made of celluloid, being flesh colour on the outside and green on the inside, and are held in place by an clastic band which slips around the head.

A reading shade for both eyes is made from stiffened cloth or card with a brass wire, which fits around the outer edge of shade and above the ears. It is used for keeping oblique light off the eyes, and in cases of inflammation to protect them from bright light. See Eye.

SHAGREEN. The fine grained parchment made from the skin of the shark is termed shagreen. It was formerly used for the cases made to hold tea caddies and similar articles. The word is also used for untanned leather with an artificially grained surface, usually dyed pale green, with which various fancy leather goods are covered.

SHALLOT. The shallot is a very useful and easily grown vegetable of the onion family. The hulbs may be set during winter or early spring at about 6 in . apart in rows 10-12 in. from each other. Deeply dug and manured soil is necessary to ensure good results. Late in July, when the leaves have turned ycllow, the bulbs should be lifted, cleaned and stored for use. Old professional gardeners advise planting the bulbs on the

Shallot, an easily grown vegetable of the onion family which is
shortest day and lifting them on the longest day. If large bulbs are wanted the giant or Russian shallot should be grown. Shallots are cxcellent for pickling.

Use in Cookery. Shallots are used in cook ery for Havouring purposes, and also for pickling. They resemble garlic, but are milder, and are often used as a substitute for the latter when a strong llavour of onion is objected to. To store shallots, hang them up in strings, but do not keep them in the pantry. See Garlic Onion; Pickle.

SHAMPOO: For the Hair. Children's hair needs washing oftener than that of adults. Soap containing a little formalin makes a good cleansing shampoo. Very fair or white hair is best shampooed with shredded white Castile soap. A simple shampoo wash is made up from 1 oz . shredded soap, $\frac{1}{4}$ oz. carbonate of soda, 1 teaspoonful borax. Dissolve the soap in a pint of boiling water, then add the other ingredients. Use as much as is required, preferably warm. Ordinary washing soda should not be added to the rinsing water as it renders the hair brittle.

Several preparations are used for brightening the hair when it is shampooed. Camomile is the oldest and simplest. Put the flowers in a muslin bag and pour on boiling water. Rinse the hair with this infusion when the lather has been removed. Henna is often incorporated with shampoo powders, in order to tint the hair slightly. Medicated and brightening shampoo preparations should be allowed to remain on the hair in lather long enough for the chemical ingredients to operate, 5 to 10 min . being usually the time necessary. Coconut oil is the basis of various oil shampoos which produce a good lather.

Dry shampoos, though injurious to the hair if used too frequently, have advantages that give them a ready sale. They can be safely used by people suffering from colds, and their action is so rapid that they make excellent emergency shampoos. The powder should be applied to the hair with a pad of cotton wool, and removed later with a stiff brush. If the subsequent brushing is sufficiently thorough to remove all traces of powder ill effects rarely follow. See Egg Shampoo; Hair; Henna.

Shawl. Baby's head shawl knitted in Shetland wool a powder or a paste.

Plain shantungs in natural or dyed shades wash and wear well. They are therefore suitable for children's clothes. Shantung should be ironed while it is dry or it will lose its gloss
SHAVING. The requisites for shaving are a razor, a brush, some soap, and some water Most men use a razor of the safety type and a special brush. Ordinary soap can be used, but shaving soap is much better, as it makes lathering easier. It may be in stick form, in

Hot water is best for lathering the face, as it expands the skin and helps the lathering properties of the soap. Thoroughly moisten the brush and rub lightly on the soap, then commence to work up the lather by a circular movement. If a soap powder is used, sprinkle a little on the wet brush. If a paste is used, it is best to smear a little on the chin before applying the hot lather brush. A very stiff and stubborn beard requires longer lathering than when the growth to be removed is only moderate. Stiff beards shave more easily witl/ a moist rather than with a thick lather.
Shaving Soap. Soap employed for shaving generally coutains an emollient such as lano lin or spermaceti, which has a softening effect on the skin. The chief object of a shaving soap is to provide a good lather, and also to soften the skin and so facilitate the work of the razor See Chest of Drawers; Razor.

SHAWL. Shawls may bo divided into four classes : the knitted or crocheted, the woven woollen, the woven silk, and the lace variety. Those in the first class are mainly utilitarian. Good patterns for knitted or crocheted shawls with full instructions can be obtained from wool shops and fancywork departments in stores.
Three oz. of white Shet land wool, $\frac{1}{2}$ oz. of pinis or blue wool of a similar thickness, and a medium-sized bone crochet-hook ar needed to make the baby's head shawl shown in our illustration. Commence with the white wool in the centre of the shawl by making 8 chain and joining to form a ring. For the first round work 3 chain to form the first treble, 23 treble into the ring, and join with

SHAMROCK. The name is vaguely applied to all sorts of trefoils and clovers. The true shamrock is either the whiteflowered clover, Trifolium repens, or the yellow.flowered suckling clover, Trifolium minus.
SHANDYGAFF. This con sists of a mixture of bitter ale and ginger beer, half and half; "rich man's shandygaff" is a mixture of champagne and ale, served usually in a pewter tankard and regarded as a great restorative.
SHANTUNG: The Silk. The crisp, hard-wearing, pale fawn coloured silk stulfs known as shantung are made by hand from the cocoons of the uncultivated silkworm. The threads are somewhat irregular, thick threads here and there not being regarded as blemishes. This material dyes well and is much employed in printed designs fordressing wraps.
a slipstitch to the 3 chain at the beginning of
the round. The second round consists the round. The second round consists of
3 chain to stand for a treble, 1 more treble into the same place, 2 chain, 2 more treble into the same place, * miss 2 treble of the previous row, 2 treble into the next, 2 chain, 2 more treble into the same place, miss 2 treble of the previous row, 2 treble into the next, 2 chain, 2 more treble into the same place, 2 chain, 2 more treble into the same place; repeat from * all round and join with a slipstitch.

The third round is worked thus : Slipstitch into the space between the treble of the pre vious row, ${ }^{*} 3$ chain to stand for treble, 1 more treble into the same place, 2 chain, 2 more treble, 2 chain, 2 more treble, and into the next space between the treble of the previous row work 2 treble, 2 chain, 2 treble all into the same place. Into the next space between the treble work 2 treble, 2 chain, 2 treble all into the same space, and repeat from ${ }^{*}$ all round, joining with a slipstitch. Continuc in this manner, always making one extra pattern between each corner pattern, until the shawl is the right size.

Begin the edging by working 7 treble into each slace between the treble of the previous row. Then between each pattern work one
double chain; then another 7 treble into the next space between the treble of the previous row. With the coloured wool work all round the cdge of the treble in double chain and the shawl is done.

Woven Shawls. Many of the woven woollen shawls are also merely useful, being made in quict colours with horder of deeper tonc and plain fringe, or in checks and tartans; but there are, in addition, hand-woven shawls which arc carried out in brightly contrasted stripes or with Horal borders, while gaily embroidered woollen varicties are often picked up as souvenirs when abroad, and can be utilized in a number of way's.

The linest woven all-over patterned or embroidered shawls come from Kashmir, and are made of the soft under wool of the special shawl goat. These shawls are highly valuable possessions when made at the best period. Sinilar shawls of inferior quality were made in India and have been imitated in France, and the Paisley shawl was modelled on them.

Shawls of several different patterns, chiclly oriental, are made in Paisley. The best known design is the pine or cone, woven generally on a red ground, with yellow, blue, green and other threads. A black centre is a characteristic of some of thesc shawls.

The richness, harmony and brilliance of the colours are as remarkable as the permanence which leaves shawls 100 years old as beautiful as ever. Their soft wool is attractive to moths, and they should be protected by wrapping in newspaper in storage. They can be washed and cleaned, but it is advisable to keep them out of the way of dirt.

To the woven silk class belong the most beautiful of all shawls: Chinese varieties, hand embroillercd on heavy crêpe, some in sclf colour, others with Howers and birds in many brilliant hues on a black or coloured ground, fringed with knotted silk. Less expensive are plain silk and erêpe-de-Chine shawls, relying on beauty of colour and fringe for their decorative value. Such shawls can be made with four squares of crêpe-de-Chine, each a yard square, joined together with faggot-stitching, a hand-made tasselled fringe in stilf-coloured sill trimming the edge. Other evening shawls are of iinselled brocades with woven coloured borders.

Lace shawls are usually Spanish lace, black or white silk blonde, or Limerick needle-run or appliqué, and though more often square, are occasionally triangular in shape. There are also the Lggyptian shawls of tinselled net and the silk embroidered net Rumanian shawls.

SHEARER: The Style. The work of Thomas Shearer as a designer is largely associated with that of Hepplewhite. In general it was in the direction of simplicity, and a reaction from the more ornate designs of Chippendale. The two assisted in bringing about a revival in the use of turning, and are considered to have done more than any other designers to develop bedroom furniture.

Some of Shearer's pieces, notably his tables, of which new types were introduced under his influence, possess considerable distinction. Mention may also be made of his tea caddies. Square, oblong, or round in plan, these were delicately inlaid or painted with fans, ovals, or circles upon their tops.

SHEARS : For the Garden. An ordinary pattern of garden sliears is illust rated in Fig. 1, which is typical of a variety of similar imple ments ranging in size of blade from $4 \frac{1}{2}$ to 10 in . long. A convenient size for ordinary use has blades 7 to 8 in. long. The handles, which are usually longer than the blades, are made of hardivood and very securely fixed to the tangs or ends of the blades.
As a good cutting action depends upon the correct manner in which the two cutting edges close over one another, it is imperative that
the joint shall be a close one, and kecp the the whole length of the blade. Either type of faces of the blades in contact with each other shears may be uscd for grass cutting or for during the cut. In the better patterns contact trimming privet, yow, and similar hedges. is effected by tightening up the pivot pin,
 which takes the form of a bolt with a fly nut and spring washer. This may be correctly adjusted by tightening the nut as occasion requires. The joints should be lubricated with ordinary light machine oil.
'To clean the blades, the nut is unscrewed, also for trimming the edges of lawns, and to the spring washer removed, and the two keep the grass edge straight ; it is as well to parts of the shears scparated any dirt which stretch a garden line along the edge of the ber prevents the blades working frcely being cleaned away with a greasy rag or with one saturated in paraffin. This cleaning process should be followed by a liberal application of lubricating oil, and, if nccessary, the cutting cdges should be sharponed on an oilstone and the shears reassembled. The cutting edge forms an angle with the flat or under side. This angle must be maintaincd, and on no account should the flat side be touched with the stone.

Different types of shears are made with straight handles or with a cranked handle. The object of the latter is to enable the shears to be operated over a flat grass lawn without the necessity of knocking the knuckles on the ground, the crank enabling the blades to be kept parallel with the ground and to cut over

Shed. Fig. 1. Diagram showing a substantial lean-to workshop, built in the angle formed by two walls. Full particulars of construction, together with the quantities and material required, are given in the next page

For cutting round curved borders and in awkward corncrs, the grass shears illustrated in lig. 2 are useful. These are formed of a single picce of metal, the two ends forming the blades, with a U, or bend, more or less circular in shape, acting as a spring. This implement is operated with one hand by squeezing the blades together and then releasing them.

When any considerable length of grass ellging or border is to be trimmed, it is desirable to use a regulation pair of border shears. So far as the blades are concerned, these are shaped like and operate upon the same principle as ordinary garden shears, but the shanks of the blades are turned up nearly at right angles and in the same plane as the blades. They are provided with hardwood handles, about 3 ft . in length or more; they should be of such a height that they can casily be operated by the hands while the gardener carries on his work in an upright position.

There is a certain knack in handling thesc shears which can only be acquired by cxperience, but, in general, the left hand should grasp the handle that is attached to the bottom one of the pair of blades. Consequently, this handle should be kept more or less stationary, so that the bottom blade glides along the ground, while the right hand manipu lates the other handle.
Shears of all kinds should be smeared with petroleum jelly when putting them away, as this will prevent rusting and keep the edge in good condition. See Osicr.
SHED. A light struc ture, generally made of wood, the shed is seen in many shapes and sizes. Its main use is for the storage of materials and tools, but it is also used for potting plants or for a smaller amateur work shop. Diagrams and

Shed. Fig. 2. Principal joints used in building the lean-to shown in the previous paze. A, mortise and tenon. B, balved ioint and how it fis torether. C, mortise and tenon for top and bottom of uprights
instructions for building a bicycle shed are 5 in . by $\gamma^{5}$ in. conch holts and nuts. Secure given on page 95 of this work. Particulars of a larger and more substantial structure to house a motor cycle combination will be found in the article on Garage (q.v.). A light garden shed is described and illustrated on page 517. An excellent shed may be constructed along the lines indicated for a garage, varying the doors and lighting to suit individual needs.

Lean-to Building. A shed or outhouse intended as a permanent crection may quite conveniently take the form of a lean-to built into the angle formed by two walls, as shown in Fig. 1. The slied is $\mathbf{1 0} \mathrm{ft}$. long by 8 ft . wide, and the height to the eaves is 7 ft . The following material is required :

150 it. run 2 in. sq. deal
56 ft . run, 3 in Ly 2 in . deal, for framework.
1 ledged and braced door, 6 ft .6 in . by 3 it. 6 in wide.
1 pair 18 -in. cross garnets, lock and key.
80 sq . ft. 1 in. tongued and grooved llooring.
$98-\mathrm{ft}$. lengthe of 3 in . by 2 in for floor joists.
5 windows (casements) glazed, with butts, haudles and cascment stays.
110 -it. length batten, 2 in . by in . for the llashing. 5 shecta of corrugated galvanized iron, 9 ft . by 2 ft 2 in.
1 roll of roofling felt
15 yd of 2 -in. galvanized wire netting, 2 ft . wide or alternatively 1 square ( 100 sq . ft .) -in . 1 . G . and B. match lining.

86 sq. ft. 1 -in rebated weathertoard for the walls.
70 ft ., 1 in . by $\downarrow \mathrm{in}$. architrave for door and windows.
7 IL . paint
1 gall. creosote.
No allowance has been made for a foundation, as it is presumed the yard has already been cemented over or paved. If not, this will have to he done, either with cement, concrete or asphalte. In cither case the framework and joists should rest upon bricks, placed about 1 ft . apart, so as to allow free circulation of air and prevent damp rising. The ground being prepared, proceed by making up the front of the building in one section. Then make the end section. Fig. I shows the general idea of the work, while details of the different joints are given in a separate diagram (Fig. 2).
Having made the two frames, erect them on their site. and bolt the corners together with

5 in. by ${ }^{5} \sigma$ in. coach holts and nuts. Secure
the frainework to the wall of the house with staples and screws. The woatherhoarding can then be added, nailing it to each upright with 2 in . wire nails. The windows can either be made or purchased ready for use. Horticultural or "greenhouse" glass will be quite good enough for the glazing. 'The roof is most conveniently covered with corrugated iron, but it should be lined inside with tarred felt supported on galvanized wire netting or, alternatively, may be boarded with matchlining.

When walls and roof are complete, lay the floor joists, and securely nail the flooring with 2 in . floor brads. The joists and the underside of the flooring should be coated with creosote as a preservative. A strong and rigid floor is very necessary, especially beneath the legs of the work bench and any other heavy tools. A gutter and drain-pipe may be added if clesired. Make a good watcrtight connexion between the corrugated iron and the walls, by means of proper llashings litted as indicated in Fig. 1. A lean-to built in this way inight become a landlord's fixture, but if a framework is made for the end and back of the structure where they abut on the existing brick wall, and the roof is supported at its juncture with the walls by battens screwed to blocks let into the brickwork, the fixture will be a tenant's fixture, and therefore will be removable.

Sectional Building. We illustrate representative types of shed which are sold made $\mathrm{u} p$ in sections ready for erecting. The ends and sides are bolted together and the roof frames are tixed on top. There is a great deal of competition in this class of product, and some very cheap stuff is to bc met with. It is least cxpensive in the long rim to buy a good substantial building, since the first cost is

shed.
Fig. उ. Exterior view of a sectional span rool workanop or tool shed ed. Fig 4. The same partly erected, showing local authority. Courtesy of Alfred Turrell \& Sons method of asaembling the sections. Fig. 6. Useful lean-to shed made up on the same principle
then the only one, for some years at least. If the covering material is weatherboard, then the purchaser should specify that it be either the rehated or the tongued, grooved and moulded variety ( $\frac{3}{4} \mathrm{in}$. to 1 in .), which presents $n$ flat surface to the interior. If vertical boarding is employed the material should be T. G. and B. matchboard, not less than fin. and preferably thicker. Unless a bricked or concreted site has been prepared, a Hooring will he needed, laid on 3 in . by 2 in . joists, which in turn rest on sleeper plates supported preferably by low brick piers. The floor boards should be $\frac{3}{4} \mathrm{in}$. to 1 in . thick, and should be tongued and grooved.

Legal Points. If a tenant erects a shed on his premises for temporary use during his nccupation he will ordinarily he able to remove it at the end of his tenancy. If, however, the shed is in the nature of a permanent structure and cannot be removed without material injury to the property, the tenant must leave it as the landlord's property. Thus a conservatory entirely detached from the house could probably be renoved, but one fixed to and communicating with the rooms would belong to the landlord and be irremovable.

The ercetion of some sheds is controlled by regulations as to the position of the structure and the materials of which it may be built, and inquiry as to these should be nade of the

Where premises are insured against fire, a shed added later will not be covered by the policy unless on arrangement to that effect

Tri-
is made and an additional premium paid if required The presence of a wooden shed near to a house may increase the premium on the house itself. If the shed is of any particular value, or if it adds to the value of the house (as would probably be the case if $s$ garage were erected), the rates on the house will probably be increased

SHEEP. The main article of food that is obtained from the sheep is known as mutton, but other parts of the animal make nourishing and cconomical dishes.
Sheep's Head. To make a good broth procure a sheep's head ready dressed from the butcher. It must be soaked in warm water for an hour to finish the cleansing. The head should be split open and the tongue and hrains removed. Place the two halves of the head in a large saucepan with 3 qt. cold water, bring
to the boil and carefully remove all scum. Add $\frac{1}{2}$ oz. salt, 2 onions, 2 carrots, 2 turnips, $\frac{1}{2}$ a head of celery, and a bouquet garni. Simmer gently for 3 hours, then take up the head, cut off the flesh and shape in neat pieces. Strain the broth, return it to the saucepan with the pieces of meat, add a few freshly boiled vegetablce cut in shreds, and 3 oz. well-washed rice. Simmer it for half an hour and pour into a tureen in which two tablespoonfuls of chopped parsley have been scattcred.
The tongue and brains may be used for some other dish as a garnish, or they may be cooked and served covered with tomato or piquant sauce. Two ounces of pearl barley make a very good thickening for this broth in place of rice. Blanch the barley for 10 min ., then tie it loosely in a muslin bag and add it to the soup with the vegetables. When the soup is strained, untie the bag, and stir the barley into it. Sometimes the vegetables first added to Havour the soup are cut small and served with it ; if this is done the soup need not be strained, and the barley, after being blanched, may be added loose when the soup is half cooked. The meat from a boiled sheep's head niay be pressed into a inould and lilled up with jellied stock. Cover and press with a weight and turn out when cold.
Sheep's Heart. A shecp's heart is first washed in two or three successive lots of warm water, freed from pipes, etc., and then soaked for $\frac{1}{2}$ hour in cold, salted water. Dry it in a clean cloth, stuff it with sage and onion stuffing, and sew up the hole. Roast it in an iron pan in which a lump of dripping about twice the sizc of a hen's egg has been melted. Let the pan stand at the side of the fire, and baste the heart frequently with the fat. The cooking should take about $\frac{3}{3}$ hour. Serve the heart with red currant jelly and some sauce made by thickening some of the fat with a little flour, mixing them smoothly, and adding some stock.
Sheep's Tongue. This dish may be prepared in several ways. Frying is perhaps the simplest, and may be done in the following way: Soak 2 tongues in cold salted water for 3 hours, then wash then in clean water and put them into a pan containing enough stock to cover thein. Cook them very slowly until they are tender ; then skin and trim them and slice each lengthways into halves. Season the pieces to taste, coat them with flour, then brush them over with egg and roll them in fine breadcrumbs.
Fry them in a pan of smoking hot fat, and when they are golden brown on both sides lift them out and serve on a bed of mashed potatoes. A little gravy may be poured round them.

Sheep's Trotter. To fry, prepare 4 trotters by washing and scraping them, boil them up in a pan containing just enough cold water to cover them, and then strain off the water and rinse the pan. Wash the trotters for the second time, and put them back in the pan with enough white stock to cover them.

Cook them gently at the side of the fire until they are tender, then take them out and bone them, finally pressing them between two plates with a weight on top. When they are quite cold cut them into pieces of a convenient size, season to Laste, brush them over with egg, and coat with breadcrumbs. Fry them in a pan of smoking hot fat, and serve garnislıed with parsley and cut lemon. Any suitable sauce may be served separately.

For baking prepare the trotters as directed in the previous recipe, cooking them in stock until they are tender, and then cutting the meat into neat pieces. Put some of the latter into the bottom of a greased dish, cover them with some sliced tomato and scasoning to taste, and on the top put a layer of fine breadcrumbs. Continue in this way until the dish is full.
and on top of the last layer, which should be of breaderumbs, place a few small pieces of butter. Pour in about $\frac{1}{2}$ gill stock, and bake the whole in a warm oven until it is of a golden brown colour. See Brains; Brawn; Mutton.

SHEEPDOG. The old English sheepdog is a most attractive animal. His shaggy coat, in which there is no curl, coupled with a closely docked tail, gives him a quaint appearance, and at the rame time affords ample protection against the worst of weathers.

Sheepdor. Thoroughbred specimen of the attractive
breed known as the old English sheepdog
breed known as the old English sheepdog
If he is groomed every day there is no reason why the coat should become matted or untidy. The colour may be any shade of grey, grizzle, bluc or blue merled, with or without white miarkings. What is termed a pigeon-blue is much esteemed. The forclegs should be heavily boned and dead straight, and, as they are clothed with hair to the fcet, they look enormous. See Dog: Kennel : Lurcher.
Sheep Laurel. See Kalmia.
SHEEPSKIN. Sheepskin is used a great deal for bookbinding, but its wearing qualities are not of the hest, and its use is confined to the cheaper class of work. It is more suitable for ladies' handbags or hats, or such goods as are not glued or pasted on to a hard substance.

In covering books or other articies with sheepskin, care must be taken to preserve the artificial grain. Glue is generally used in preference to paste for this purpose. This applies more to split skins than to those of full thickness. To prepare the leather for gold tooling or lettering, it should be washed with paste water, which is thin paste about the consistency of milk, and afterwards with two coats of glair (white of egg), or, better still, with glue water and one coat of glair. See Bookbinding; Leather.

SHEET. There are two standard sizes of shcets, namely, for double beds and single beds. In cheaper makes single sheets are sometimes too small for comfortable use on a bed $3-\mathrm{ft}$. wide and of full leugth. All sheets are usually bought in pairs, and the length should be judged by the length of the bed, allowing for a good turn over at each end.

Materials vary according to the taste and means of the purchaser. A heavy linen sheet wears better than any other, and is preferred by most people, especially in the summer. As linen is colder than cotton because of its smooth surface, some people prefer not to use it in the winter. The cotton materials range from coarse twill to a smooth and strong union. A good union, while not as expensive as real linen, is satisfactory in wear, and fecls pleasant to the skin. Shects may be quite plain, embroidered at the tops, ornamented with hemstitching, or with wide crochet edging.
An embroidered initial in the right-hand top corner is almost essential to the housewife who prides herself on her house-linen. If the name is marked in ink, it should be at the extreme end of the top hem, and so arranged that when the sheet is turned down the name is hidden underneath. The initial, on the contrary should be arranged so that it is plainly visible. Some people like an claborately embroidered monogram in the very centre of the top, this serving instead of other embroidery.
Sheets should be aired when they come back from the laundry. If the house has a good hot cupboard, it will be enough to put them away in their places, and when they are used again they will be sufficiently aired. See Initial Linen ; Marking; Mending; Pillow Case.

## Sheffield Plate for the Collector

## With Particulars About its Marks and Decorations

Various articles in this Encyclopedia deal with the collection of articles for beautifying the home,
the aim of each being to indicate whal is possible to the average householder. Such include
Brass; Pewter; Silver See also Candelabrum; Gadroon; Jug; Taperholder; Wina Cooler, etc.

Much of the plated Sheffield ware of to-day is really B.M., i.e. Britannia metal, an alloy which was instrumental in killing the pewter trade, as the various articles made in it could be covered over with a deposit of silver. Much, too, is E.P.N.S., i.c. electro-platerl on nickel silver, a useful combination of decorative silver with a hard-wearing metal, the silver being deposited by the aid of electricity.
The credit for discovering a method of thinly coating a base metal with silver is due to Thoinas Bolsover, or Boulsover, presumably but not certainly a native of Sheffield; but the practical developing and perfecting of the new process is due to another Sheffield man, Joseph Hancock, a cutler, who died in 1791. Sheffield plate of value to collectors was made during the latter half of the 18th and the early half of the 19th century.

The manufacture of this plate consisted in the overlaying of an ingot of copper alloy with a thin sheet of silver, both absolutely, i.e. chemically, clean and level. By means of a borax flux, applied to the edges of the silver, adhesion at the edge was secured when the fusion of the silver began in the furnace. The ingot, when removed from the furnace and cleaned, was rolled out to the thickness required, or to that suggested by experience.

Later the process was extended to silverplating on both sides of the copper alloy. This necessitated much care in preparation of the ingot, as the sandwich of copper and two silver sheets required two outer protecting shents of silver, mochanically treated to prevent adhesion to the under sheets.
The branched candlestick illustrated in Fig. 1, which dates from about 1780, shows the popular gadroon ornament. This type of added elging was cither in fine silver, or clse copper alloy much more thickly cased with silver than the rest of the article; and in many cases the copper shows through the thinner plating while the ornamental borders remain unimpaired with repeated cleanings.

The ornament on Sheffield plate will be found to be chasing of the kind known as flat surface chasing, or clse what is now called repoussé work, and in some pieces both methods are combined. In flat surface chasing the design is carried out with a blunt punch, which is held vertically in one hand and hit by blows from a special hammer, Nothing is removed from the surface of the metal, as would be the case in engraving it with a burin or a scorper. In repoussé the raised portion is worked from the back. In the case of circular and oval articles, the border is

Sheffield Plate. Fig. 1. Branched candlestick, C. 1780, an example showing fluted decoration and gadroon edging. A holder for a third light is Gilled by a stopper
made separately and securcd by means of solder. An example of such a border is illustrated on the winc cooler shown in Fig. 2. Many articles are ornamented with a geometrical or strapwork pattern with the field or background punethed out in a press. It was found that better results were obtained in this way than by piercing, i.e. cutting with a saw and finishing with a file, as was done by silversmiths. The sugar basket illustrated in Fig. 3 is a beautiful example of such work.

The marks on Sheffield plate are many in number considering the short period, just over n century, during which the ware was being made. They generally consist of the maker's name and sometimes a device before and after it. The Sheffield plate makers do not seem to have followed the example of the pewterers and deliberately to have used marks which were colourable imitations of the silver hall-marks. Some ware has the name of the firm only, some has a device or devices only.

As the best styles in decoration of Shefficld plate coincide with the Robert Aclam period, the most desirable pieces to collect show classical influence and ornament. In addition such pieces are to be preferred because they

Sheffleld Plate. Fig. 2. Wine cooler, c. 1780, with decorated handles and border
All photographs l!! courtes!! of C'happle \& Mantell
are practical and more casily kept clean than the heavily chased and ambossed style of ornament which came into fashion later in the 19th century. Utility is the best guide as to which pieces to collect. The classical vase shape with very little? decuration beyond bead ing, is beautiful for a hot-water jug (Fig. 4), for coffec pot and milk jug. With such pieces and two pairs of candlesticks, a plain tea cadily. a cake basket, which is equally useful for fruit; and an oval teatray with a pisreed work rim, would inake a represcntative and useful collection. Sheffield plate is occasimally picked up at auction sales for comparatively small prices, but is worth obtaining in good shapes with restrained ornament.

Inkstands are useful of the simple type with decorated edge and look particularly well Hanked by candlesticks of Adam design, or in the company of $\Omega$ wax-jack taper holder such as that illustrated in Fig. 5, with ornamented border.

The best way to display Shcffield plate is to use it in the home. It must be carefully cleaned and handled, and if it should the cleaning of Sheld does not show through in places, good plate- and in cases where they are fitted against the powler is quitc safe. Wherc the copper is wall or in a recess they may be supported on exposed none of the polishes that contain the inner side by a long batten or fillet secured oxalic acid is to be used, as the acid cats to the wall. Shelves are preferably securcd slowly into the base metal. Pieces in this to the bearers with screws, as they can then state are unsuitable to hold food unless they are relined.

SHELF: How to Fix. In fitting up shelves it is gencrally preferable to use shelving board, which is simply good quality white or ycllow deal in a
prepared form.
One surface is machine planed to a good linish, the cdges and sides are clean and square, and the material is uniform in thickness and width.
Shelving board is obtainable in various si\%es; those chirfly used by the amateur are known as 6, 7, 9 . and 11 in. boards, and range from $\frac{1}{2}$ in thick up to about 1 in. These sizes are nominal, and the actual diametcr will measure somewhat less than those mentioned Wher to bear this in nin width of the proposed shelves appropriate to the stock widths of the shelving board, as this obviates the necessity of ripping scveral lengths of timber and planing the edges up to obtain the requisite width. Generally it is possible to provide most ordinary shelves by using a single-width
tongued and grooved
board, and the most handy width for an ordinary shelf is 9 in .

When it is desired to use a width of, say. 12 to 14 in . or thereabouts, 2 ordinary, straightedged boards can be used and the edges held together with cross battens screwed to the underside of the shelves, or the edges may be properly planed up and gluad together. Alternatives are to use tongued and grooved floorboard. When 2 or more pieces of board are placed edge to edge, the tonguc of one board fits into the groove of the next and so on. Consequently as one surface of the floorboard is prepared nicely finished up, it can conveniently be used for the wider varieties of shelves.

All that is necessary is to remove the tongue from one side by chiselling it off and, if necessary, cleaning up the edge with a small plane. If the boards are arranged so that the tongue is on the face or visible side of the shelf, there will he no need to remove the grooved portion of the board which adjoins the wall. For spans up to 3 ft . or 4 ft .,

Sheffleld Plate. Fig. 4. Hot-water jug of classical Adam design, c. 1784
 cithernoved When desired without dama cither to the hoards or to the wall. It is necessary that they should be fixed, otherwise the joints will scparate. Alternatively, the boards may be united with battens of wood screwed to the undersides of the shelves, as above described.

With regard to the thickness of material, it can be taken as a hasis that the ordinary 9 in . shelving, 1 in . thick, will be satisfactory for spans up to 3 ft . or 4 ft . From 3 ft . to 2 ft . $\AA \frac{3}{4}$ in shelf should be used, and for less than 2 ft ., $\frac{1}{2} \mathrm{in}$. shelving is generally satisfactory.
The method of supporting the shelves is determined by their location. If it is practicable to fit battens or bearers to the walls, this planis to bere commended. The battens may conveniently be securedwith fibre plugs and screws. When the shelves are not near a return wall on which the ends may be carried by

Fig. 5. Wax-jack, c. 1800, with ornamental border and handles
bearers, the best method is to fix vertical battens to the supporting wall at suitable intervals, and to carry the shelving on brackets screwed to these uprights. The shelves should be notched round the verticals to fit close to the wall.
When movable or adjustable shelving is wanted, the home worker can utilize slotted iron strips of the kind described in the article on Bookcase (q.v.). See Dresser.
SHELL : Collecting Specimens. Without going out of the British Isles, about 350 different kinds of shells may be found, the colour and pattern of each varying within wide limits. Every country walk or seaside ramble may therefore yield a new specimen for the collection.
The land shell which will be met with most frequently is the snail, since there are about 40 different types. They may be found all the year round, although the months from April to December yicld the largest harvest. The evening, and especially the evening of a damp day, is the best hour during which to search for snails, since this is their usual feeding time. At other times search may be made under rubbish beaps, among tree roots, under fallen logs, stones, and leaves.
The snails most frequently found are the following: the common snail, with dark brown bands on an olive shell; the shrub and garden snails, which are similar, but both classes vary in colour; the girdled snail, with a yellowish-green shell not unlike the prettier and more rare green snail. In addition to these there are the pale green heath snail and the greyish bristly snail, the gored snail, found where chalk and lime ahound, and the hlack-tipped snail, frequently mistaken for it.
As regards salt-water shells, any stretch of beach will prove a veritable treasure trove. Many of the shells will be broken, and therefore of no value, but any bunch of seaweed or small rock pool may be searched with profit. A pocket lens should be included in the shell hunter's outfit, since many shells, especially those found in sea-water, are extremely small, and only a lens can decide the difference between two shells which may look alike to the naked eye. If the shell is boiled in order to clean it, the inmate will be killed in the process. It may then be removed by means of a wire or pin. The boiling removes dirt, salt, etc., from the shell. Each shell should then be dried and painted over with white of egg, or a thin solution of gum arabic, before bring added to the museum.

The small white cardboard boxes used by jewellers make excellent cabinets in which to store the shells, although larger boxes will be required for larger shells, such as oysters, mussels, scallops and the like. First put in a layer of cotton wool and then arrange the shell on this, using white cotton wool in the case of dark-coloured shells, and vice versa. This done, label each box with the name of the specimen and the date and place of finding. If any of the specimens cannot be identificd, a visit to the nearest reference library, where the coloured plates of books on shells can be consulted, will soon solve the difficulty.
SHELLAC. Shellac is a fine resin, found in Indian trees, and is due to the action of the lac insect. The larva punctures the bark of the tree twigs, feeds on the gummy or resinous sap, and cxudes a secretion which embeds the insect. The female secretes a red fluid known as lac dye.
The lac includes the twigs 2 or 3 in . long, on which it is formed in nodules, and is known as stick lac. For export to England it may take the following forms: seed lac, shellac, button lac, or garnet lac. Sced lac consists of the small lumps of natural lac broken off the twigs and washed.
Shellac is melted out of sced lac in rough bags held near a charcoal fire, the bngs being
wrung to squeeze out the molten resin. It is spread on cylinders, allowed to cool, and scraped off in Hakes. The best quality of shellac is of a bright pale orange colour, quite transparent, and free from dirt and grit. Button lac only differs in that it is melted into larger pieces. Garnet lac is moulded into thick, flat pieces.
Shellac is soluble in methylated spirit and spirits of wine, and in this form is used as a french polish. It is also employed to make lacquers, or spirit varnishes, in various degrees of clearness. Although lacquers may be made up from the raw material, it is better to obtain prepared solutions from a reputable firm, specifying the colour or absence of tint required. See French Polishing; Lacquer; Polish; Resin; Varnish.
SHELLFISH. People with delicate diges tions can more often cat oysters than any other kind of shellfish. If tinned shellfish are used, the contents of the tin when opened should at once be turned out into an carthenware bowl and carefully examined.

Many people suffer from a peculiar idiosyncrasy which causes the development of a digestive upset of greater or less severity after eating shellfish of any kind. With others these symptoms only develop if the shellfish have not been perfectly fresh. The symptoms in these cases rescmble those of ptomaine poisoning. and the same treatment is to be carricd out. See Crab; Fish; Lobster; Mussel; out. See Crab; Fish; Lobster ; Mussel
Oyster ; Prawn: Ptomaine Poisoning Shrimp: Winkle.
SHELL STITCH: In Crochet. The shell stitch forms a solid or all-over pattern in crochet work. The original stitch is a cockleshell shape, as scen in the sample illustrated, hut there are many modern variations of it with spaces between the shells, and alternate rows of open stitches and solid shells. It is used where a close pattern is required.
The number of chain stitches on the foundation row should be divisible by 3 with 2 stitches over. To work the first row, put 1 treble in the fifth chain from the hook, then 3 more trebles in the same place; ${ }^{*}$ miss 2 stitches, 1 double crochet in the next stitch, miss 2 stitches, 5 trebles in the next stitch, and repeat from * to the end of the row, finishing with a shell of 5 trebles.
For the second row slip-stitch over the first 2 trebles of first shell, and work 1 double crochet into the centre treble of the same shell, putting the hook into the back loop of the stitch throughout the pattern. * 5 trebles in the next double crochet, 1 double crochet in the centre treble of the next shell and repeat from * to the end of the row, finishing with 1 double crochet in the centre of the last shell, turn with 4 chains.
For the third row put 4 trebles in the first double crochet over which the turning chains stand, then 1 double crochet in the centre of the next shell and repeat shells and double crochet alternately all along. Take noto that a shell is always worked over a double crochet, and a double crochet in the middle of a shell of the previous row. Repeat the last 2 rows for the amount of pattern required if a straight piece of the same width all the way up is wanted.

Where a sloped edge to narrow the piece is desired, the decreasing
is made on the shell by working 3 trebles only in the end shell, and also where the shell begins the row at the opposite sidc. Then, on the return row, this decreased shell is not worked into. By this method of working a gradual slope is given to the piece. See Crochet.
SHEPHERDS' PIE. Mash 2 lb . cooked potatocs, add to them 1 oz. melted butter, seasoning to taste, and a little milk if the mixture is too dry. Put a layer of these potatocs at the bottom of a greased pie-dish and a little round the sides, fill the dish to within an inch of the top with $1 \frac{1}{2} \mathrm{lb}$. diced cooked meat and one or two rashers of bacon also diced.

Pour over some gravy made by melting 1 oz butter in a pan, stirring in ? oz. flour, and cooking the latter, together with 3 tablespoonfuls finely chopped onion, until it is lightly browned. Add $\frac{3}{3}$ pint stock, stir the gravy until it boils, then scason it to taste. After pouring it over the meat, cover the pie with the remainder of the mashed potatoes, smoothing the top with a knife, brushing it over with beaten egg, and then sprinkling it with browned breadcrumbs. Bake the pie in a moderate oven until it is heated through and lightly browned on top. See Mince.
SHERATON : The Style. Thomas Shera. ton, one of the great cabinet makers of the 18th century, made a few remarkably beautiful pieces which are to day highly valucd. He is chielly, however, famous for his designs. His book, The Cabinet Maker's and Upholsterer's Drawing Book, published in 1791 contains several hundred designs for furniture. His style reflects the sedate influence of Robert Adam, and was a reaction from the scroll and rococo work associated with exaggerated French styles in vogue before the Empirc style and with some of the more ornate and less successful Chippendale designs. Sheraton was influenced to some extent by the new French style which developicd from the Directoire into the Empire with its olfshoot the English Regency style.
The Drawing Book, which gives a great number of his designs, reveals many instances of his skill, not only in fashioning beautiful pieces of furniture, but in introducing into them features that, without in any way mar ring their grace, add grently to their accommodation and allow them to be used for more than one purpose. It gives also designs for such articles as work tables, shaving tables, fire screens, and clock cases. The library received a good deal of attention from him Tables, suited to its special nceds, and steps are shown therein as well as bookcascs in considerable variety of design.
Satinwood, which came into use about this time, was greatly favoured by Sheraton. He had a special liking for the E. India varicty, with its delightful figure and fine straw colour.

Shell Stitch. The appearance of this crochet stitch when finished

Harewood and amboyna were also adopted designed by him gencrally had serpentinc or from Frenoh styles, and applied in vencers over bow fronts. That illustrated in Fig. 1 is typical cheaper and more casily worked woorls. of the plainer type of sideboard, and is a good
 example of the combination of that grace and utility for which his work is noted. Scere taires venecred with satinwood are cliarac teristic pieces.

He designed many tables after this style, including pier, card and sofa tahles. The latter had sometimes only two legs spreading out into yoked feet. Other tables were in satin wood with painted tops.
Sheraton's designs for chairs were particularly graccful. The high-water mark of English chair making was reached at the close of the 18th century and his Drawing Book excreised a powerful influence on contemporary chairs. The canc backed bergère chair, illustrated in Fig. 2, is an example of the beauty of line and

According to one authority, the chief characteristics of Sheraton furniture are the use of the straight line in design and a porfect com binntion of proportion and constructional bulk.

Dual Purpose Pieces. Sheraton's designs hare a very wide range, wider than that of any other of the great English cabinct makers. Many of his idcas find expression in space saving furniture of to-day. He was without a rival in the invention and construction of dual purpose picces. such as a table which could be opened out to serve as a writing table and a dressing table with concealed mirrors and other features. In his day the bedroom was used to some extent for entertaining, so his folding furniture was extremely uscful, an example being a dressing table which could serve also as a card table. Beds suitable for alcoves and sofa beds were also designed by him, and tho latter he developed into the sofa of the drawing room of his period with its white und gold effect. He also designed many graceful four poster and state beds.

His cabinets, which resembled bookeases, were very popular. In them the upper part formed the bookease proper, while the lower, which projected, contained drawers. Between the upper and the lower divisions he fixed a writing table. This was covered by a sloping lid that fitted down to enlarge the surface of the table. The lid also covered sets of small drawers, between which were the divisions known as secret drawers, which are frequently scen in the bureaux of to-day.

Use of Marquetry. Sheraton made cxcellent, because restrained, use of marquetry as a decoration. His designs for this were often scrolis of satinwood and festoons of drapery, or husks and shell ornaments with a fan pattern in the spandrils of his arches. This was usually upon a groundwork of mahogany, but if the piece itself was of satinwood the inlay would be in different coloured vencers to give a pleasing contrast. Sometimes he introduced trophies of musical instruments, wreaths of flowers. and figures with foliated scroll extremities. Another feature was inlaid lines of vencer.

Sheraton did not himself make a grent number of pieces, but many cabinct maliers carricd out his designs, and these laid the foundations of Sheraton furniture. In general its lines are very graceful. He favoured square, tapering legs for his pieces. The sidehoards
proportional value of his designs for this type.
One point worthy of notice is that the ornamental backs of his chairs do not rise direct from the seat as they do in Chippendale's designs, but rest on a narrow plinth or rail 1 or 2 in. above the back of the seat. See Antique Furniture : Chair: Marquetry.
SHERBET : The Drink. This cooling refreshing drink had its origin in the East. There are many different methods of preparing sherbet, but the most approved is a mixture of fruit juice, sugar, and water, cooled on ice A varicty of this drink is made from a bought powder, but prepared at home with fresh fruit as the main ingredient it is a far more whole some and refreshing summer beverage.
To make this drink with strawberries, red currants, etc., allow 1 lb . fruit, 10 oz . loaf sugar, 1 tablespoonful orange-llower water, the strained juice of a lemon, and 3 pints cold water. Let the fruit soak in the water for 6 hours, then strain it through muslin into a jug or basin in which has been placed the sugar, strained juice of lemon, and the orange-flower water. Cover the vessel over and let all stand one hour, stirring occasionally till the sugar is dissolved. Ice before serving.

Sherbet may bc made entirely with lemon juice. To each quart of water allow the thinly pared rinds of 4 and the strained juice of 9 lemons, also $1 \frac{1}{2} \mathrm{lb}$. loaf sugar. Put the lenion rind and sugar with 1 quart cold water into a stewpan, and bring it slowly to the boil. Thein strain it into a basin

Sheraton. Fig. 2. Cane-backed bergere chair with fine inlaid lines of veneer on the square tapering legs
and cool. Add the juice of the lemons and a little fruit essence and set it on ice before scrving.

SHERRY: The Wine. Sherry is mate from white grapes grown in the Jerce district in the province of Cadiz and other vincyards in the south of Spain. There are sereral types, ranging from the Fino, a light-coloured delicate wine of the Amoroso type, to the Oloroso, a rich, full-bodied winc. Very Old Solera and Fine Solera are conimonly used as descriptive terms. These if blended wines, have no right to the title. Soleras consist entirely of natural wines and are always paic. The word Solera means foundation, and applied to the winc it means an old wine kept in casks which are never moved so long as it cxists as a foundation on which younger wines are reared.
There are old golds, old browns such as the Old East India Brown, and pale straw-coloured Vino de Pasto. The name of the last, like that of Amontillado. is often takan in vain. Vino de pasto (wine for repast) is often applied in England to a superior dry sherry - in Spain it may mean a very cheap winc.
Good sherry has a well-developed bouquet and pale amber colour, and a fine delicate taste. It is not only the purest but also the most wholesome of wines, and can be taken by the gouty without ill effects. It has value as a restorative, and is prescribed by Spanish physicians instead of brandy. The alcoholic qualitics develop considerably by kecping. Sherry will improve in the decanter, and will keep its excellence unimpaired for several days.

Dry sherry alone or with vermouth is a good appetizer, and mixed with soda water or Perrier is a refreshing summer drink. The wine is served with soup and fish, and at the end of dinner with dessert, either instead of or as weli as port. See Wine.

SHETLAND WOOL. The strong but fincly spun natural-coloured wool obtained from the sheep of the Shetland Isles is made into shawls and underwear of a lace-like texture.
A substitute for Shetland wool, sold under the same name and obtainable in a varicty of colours, is now extensively used. It is considerably cheaper than real Shetland wool, and can be bought by the ounce from most

## wool shops.

SHIELD FERN.
This is the popular name of a group of hardy evergrecn ferns known botanically as aspidiunı or polystichum. They flourish in shady places in soil with which leaf - mould and thoroughly decayed inanure are mixed. Planting may be done in autumn or spring. Propagal ion is bv spores sown in boxes of soil ill a frame in spring or by division at that scason. There are numerons beautiful varicties of the hard shield fern(aculeatum) and the soft shicld fern (angulare).

SHIN : Of Beef. The lower portion of the forcleg of the bullock is known as the shin.

It makes excellent soup, but is not so satis. factory as steak or some portions of gravy beef for beef tea. See Beef; Stew.

SHINGLE : For Roofing. As a roofing matcrial shingles are thin strips of oak and other wood, about 12 in . by $4 \mathrm{in} .$, which are used in the same way as tiles on roofs of a fairly high pitch. Although quite common in America, their use in Great Britain has been practically confined to the S.E. counties, and then for church spires and such structures as lych gates.

Oak shingles are split or rent from the block, and are thus uneven in surface. In rooling they are laid to an ordinary tile gange, and generally fixed with copper nails to thin boarding covering the rafters. Hips and valleys are close cut and fitted with soakers, a varicty of lead tlashing. Hips may be close cut and mitred, or oak hip pieces may be cut out of the solid and used to course with the rest.

Shingles may be laid on laths where the roof is not open, but they should not be used to corer a roof laid with a pitch of less than $30^{\circ}$, as the rain is sure to work up between the courses and cause leaks. As shingles arc apt to curl up under the heat of the sun they should be laid with not more than 4 in . of their 12 in . length exposed, and in this connexion it is important to lay the shingles on the right side. This is cssentially a matter of direction of grain, the tendency of the wood being to curl towards the centre.

A shingled roof should be coated with a wood preservative if the separate picces are not first dipped in creosote or some other suitable preservative: where the supply of water is dependent on that from the roof, it is advisable to leave them plain. Shingles arc imitated in asbestos and cement, and although more expensive they are fireproof and easily laid, and form an excellent roofing for bungalows. Sce Bungalow; House; Roof.

SHINGLES: A Skin Disease. Shingles, or herpes zoster, is an affection in which small blebs or blisters, like those of herpes, form along the course of one of-the skin nerves; but while in simple herpes there is rarely more than slight tingling or burning, herpes zoster is often an extremely painful complaint Exposure to damp and chill, and injury to a nerve or nerves, as after an accident or operation, are the chicf causes.

Bcyond protccting the blisters by covering with some simple dusting powder and a pad of cotton wool, little local treatment is required. The following powder may be mixed and dusted lightly on the blisters :
Zine oxide
Boracic acid
Starch
2 parts will presorib pain is very severe, the doctor will prescribe other general sedatives ove the blisters.
Ship. Model vessels are described and illustrated in this Encyclopedia under the headings boat (́q.v.) and yacht (q.v.).
SHIRLEYPOPPY. This favourite hardy annual blooms in summer from sceds sown out of doors in autumn or spring. It was raised from the wild tield poppy by the Rev. W. Wilks, formerly vicar of Shirlcy. See Poppy.
SHOCK. After a severe injury or an operation, a condition of extreme prostration may result in which there is pallor, a suh-normal temperature, a rapid, fceble pulse, blunted mentality, and great muscular wealiness. This condition is spoken of as surgical shock.
The treatment of shock consists of warmth, quiet in a darkened

Shooting Board. Fig. 1. Shooting board ready ior use. Fig. 2. Planing the way of the grain
light brown. This will take about 35 min . It may be decorated with comfits, and with a thistle and leaves cut out of candied peel.
SHORT CIRCUIT. The term short circuit is employed to describe a direct path of very low resistance between the poles of a supply of clectromotive force. Short circuits are seldom met with in modern homes, the preventives being adequate insulation of the conductors and proper proportioning and disposition of any exposed metallic conductors of electricity.

When a short circuit occurs in an electric lighting circuit, the sudden rush of current Hows through the wircs or conductors of any apparatus in the circuit affected, and continues to do so either until some part of the conducting wire is fused or melted or the supply of clectricity is cut off. To obviate the danger of fire, a fuse of soft metal wire, or its cquivalent, is introduced into some part of the wiring. Its function is to melt at a low tcm peraturc and thus interrupt the circuit before the latter becomes dangerously overheated. In any well-designed house-lighting system sufficient fuses (q.v.) of proper value are incorporated for this purpose. See Electricity

## Short Sight. See Myopia.

SHORT WAVE : In Wireless. This is the name given to a band of wave-lengths below about 100 metres. Signals on this wave band can be received over great distances owing to reflection and refraction by the Heaviside layer, nn ionised layer which is thought to exist many miles above the earth's surface.

Broadcasting stations transmitting on such short wave-lengths can be received with simple apparatus (e.g. a detector valve with reaction followed by one or more stages of low-frequency magnification). It is desirable to employ a tuning condenser having a capacity not greater than 00025 mfd . and incorporat ing slow-motion gearing, otherwise the tuning in of stations becomes a matter of difficulty The detector grid condenser may have a value of $\cdot 0001 \mathrm{mfd}$., and the grid leak 4-5 megohms.
A short single wire aerial is an advantage, and the inscrtion of a very small condenser, e.g. a neutralizing condenser, in series with the aerial frequently assists in obtaining efficient reaction control. There is sometimes a tendency for sets employing a transformercoupled low-frequency stage, or stages, to "grunt" when the reaction control is adjusted near the point of oscillation One remedy is to connect a resistance (value -5-1 nicgohm) across the secondary winding of the first transformer.

Short-wave receivers are particularly susccptible to " hand-capacity" effects, i.e. a change in the tuning or reaction adjustments when the hand is placed near to or removed away from the vicinity of the panel. To obviate this trouble the moving vanes of the tuning condenser and, if possible, the reaction condenser should be joined to earth. An earthed shield of copper or aluminium may also be placed behind the pancl or, alternatively, the panel may be of netal.

When telephones are worn, these can be isolated from any stray high-frequency currents by connecting a 002 mfd . fixed condenser across the telephone terminals on the set and inserting a high-frequency cholic in series with one of the leads.

SHOULDER: Its Dislocation. The great renge and frcedom of movement at the shoulder joint necessary for the proper functooning of the upper limb is such that dislocation here is of great frequency as compared with other joints.
Dislocation of the shoulder joint commonly results from a fall on the hand or elbow, or a
violent twisting of the arm. First-aid treatment is to support the limb in a sling and apply cold applications. See Bandage ; Dislocation.
SHOVEL. A type of shovel that can be adapted to many uses in the home has a D-shaped end handle, but patterns may be obtained with a T-sbaped end. The blades in some patterns are placed at different angles to the handles, and have a greater depth with the sides formed higher above the level of the blade, to permit of a greater carrying capacity. As a general rule, however, for mov ing earth and the like, the sides are not raised to any great extent, and the tool has to cut into the earth to get the material. Too large a shovel should not be employed, as its con tinual use will soon tire anyone not accustomed to such work.

SHREWSBURY BISCUIT. This is a rich biscuit without aerating powder. The ingredients are 8 oz . soft flour, 4 oz . butter, and 4 oz . castor sugar. Dough is made firm with ons small egg and a little orange juice. Work the egg and sugar into a soft paste, then gradually incorporate the flour into which the butter has been already rubbed. It is rolled out to a sheet about $\frac{1}{1}$ in. thick, and baked in a hot oven. A few currants may be worked into the dough or the pieces mny be washed over with milk and variously dipped on to finely chopped almonds or grated chocolate.

SHRIMP. There are two kinds of shrimp the brown and the red, the latter being the best and most expensive. Shrimps are usually ready boiled when bought, but if boiled at home, they should be put into a pan of boiling salted water and cooled rapidly until they change colour. Freshly boiled shrimps are firm: of a bright colour, and have their tails turned stiffly inwards.

The dish known as creamed shrimps can be prepared in the following way: Stir together in a chafing dish $1 \frac{1}{2}$ gills milk, the yolk of an cgg, and a teaspoonful of anchovy sauce, then add $\frac{1}{2}$ pint shelled shrimps, and salt, pepper and cayenne to taste. Heat the mixture well, but do not let it boil, or the egg will curdle. Kcep stirring all the time, and serve the whole on buttered toast.
Shrimps in aspic make a good cold dish. To prepare it, line some small moulds with aspic jelly, putting a fairly thick layer at the bottom. When the jelly has set, put 2 or 3 shrimps in each mould, and fill it up with more jelly. If onc large mould is used, the shrimps and aspic may be used in layers. When set, turn out the jelly and garnish it with cress, chervil, slices of hard-boiled egg or beetroot.
A very good stuffing for baked sole is prepared by mixing $\frac{1}{4} \mathrm{lb}$ shirimps with 5 or 6 tablespoonfuls of breadcrumbs, a dessert spoonful of finely chopped parsley, and a little anchovy essence, binding the whole with some beaten egg, and then adding salt and pepper to taste.
SHRUB: The Drink. This drink can be made from the juice of lemons, currants, or rasplerries with the addition of spirits such as rum or brandy.

SHRUB: The Tree. So many beautifu Howering shrubs have bcen introduced that the shrubbery can now be made most attrac tive, and if a careful selection is made one or another will be in bloom throughout the year. These are some of the best now available Hamamelis mollis (Chinese witch hazel), yellow, fragrant, winter; laurustinus, pink buds and whitc flowers, winter ; crica darleyensis (Mediterrancan heather), 12 to 24 inches, reddish, winter; the almond, blush, early spring; forsythia spectabilis (golden bell), April; berberis Darwinii, orange yellow, and berberis stenophylla, vellow, April-May; ornamental cherries, plumis and crabs, April-May; rhododendron and azalea, May-June; Viburnum
plicatum (guclder rosc), .June-July; phila delphus or mock orange. June-July ; hardy fuchsia, August-September ; ceanothus Gloire de Versailles, blue, August-September.

Of the newer kinds special mention should be made of the barberries, which bear a profusion of brilliantly coloured fruits in autumn e.g. Wilsonae, aggregata, polyantha and subcaulialata; buddleia variabilis, mauve flowers in summer, a vigorous slurub; cytisus Dorothy Walpole, crimson, a showy broom, phil adelphus (mock orange) Virginale, double white; prunus cerasus Kanzan double pink cherry; pyracantha rogersiana with yellow fruits; pyrus Eleyi, crimson-flowered crab ; ribes King Edward VII, a crimson flowering currant; symphoricarpus laevigatus (snow berry), with unusually large white fruits and viburnum fragrans. white fragrant flowers in early spring.

Shrubs suitable for shady places are mahonia (berberis aquifolium), butcher's broom (ruscus), St. John's Wort (hypericum calycinum); laurustinus; laurel, box and aucuba.

Beautiful shrubs for house walls are wistaria, summer and winter jasmine, ceanothus Veitchianus, ccanothus Gloire de Versailles, pyrus japonica, pyracantha, cotoneaster horizontalis, chinonanthus fragrans, clematis in varicty, escallonin macrantha, forsythia suspensa, hydrangea scandens (climbing hydrangea), kerria japonica fl. pl., magnolia stellata and honeysuckle.

SHUTTER: For the House. Shutters for windows may be classed under three heads: louvered, lifting or sliding. and box shutters. Louvered shutters open outward on to the external walls. a half of the shutter folding on cither side of the window; if the window is a wicle one cach half shutter may again fold in halves by arranging rebates and butts. This type of shutter permits air to enter frcely although the shutters are closed.

Lifting or sliding shutters are arranged so as to slide vertically in front of the window on the inside. Their working is similar to a double hung sliding eash.

Box shutters are arranged to close across the winclow. They arc usually hung at right angles to the window, and sometimes the walle at the sides are splayed so as to provide for better light when the shutters are out of use Box shutters are so named because they fold and hinge back into a box or recess on either side of the window. See Blinds; Louvre.

SHUTTER: Of a Camera. A shutter is a device whereby the time of exposure of a photographic plate is controlled, from 1 sec . or more down to $\frac{1}{10}$ sec. or less. With the earlier cameras cxposure was regulated by removing a velvet lined cap from the lens by hand, time being estimated, the shortest being about $\frac{1}{4}$ scc.
The focal plane shutter (q.v.) consists of a blind with a number of openings of different width (Fig. 1), the width of the opening governing the length of the exposure. The blind in this case is placed close to the plate itself instead of in front of the lens. Except in the case of a few pinholes, no repairs should be attempted by the amatcur:
In magazine-plate cameras the shutter consists of a metal plate which is drawn across the lens by a spiral spring. Only one speed and time are usually available. If the shutter does not work properly remove the front of the camera by unscrewing it. The shutter will be found on the reverse side, and any defect will be at once visible. Do not stretch the spiral spring, or the shutter will not work properly or at the right speed. Any rust may be removed with a few drops of paraffiu on a mall brush
In other simple types of shutter, additional speeds are provided by means of a piston with an air leak. In these cases no oil of any kind
may be applied or the working of the shutter will be completely spoiled. In the simpler and cheaper types of variable speed shutters stiff working may perhaps be remedied by washing out with benzine, but it is generally best with all shutters working at more than onc speed to send them to a firm which specializes in shutter repairs. On no account attempt to force a shutter if it does not work properly.
The shutters described so far are of the before-lens or behind-lens type. Most modern hand and folding cameras of better quality are fitted with between-lens shutters. placed between the two components of the lens along with the iris diaphragm They arc constructed of metal alone, are complicated and delicate mechanisms, and repair should on no account be attempted by the amateur.

One of the simpler but thoroughly reliable types of this diaphragm shutter is shown, Fig. 2, as fitted to the Kodak Autographic Brownie. It provides three speeds, bulb, and time. When the shutter is set to bulb it remains open as long as the release is pressed. At time one pressure of the relcase uncovers the lens, and a second pressure is required to close the shutter. The speeds are $\frac{-1}{2 \xi}, 3^{2} \sigma$, and ${ }^{1} \frac{1}{6} \mathrm{f} \mathrm{sec}$.

The shutter will be seen in the photograph (the lens having been removed) to consist essentially of five thin metal plates or blades, which swing back together, as nearly' as possible instantaneously, when the rclease is pressed. The plates are shaped so that the full opening is obtained as quickly as possible. On this rests the efficiency of any shutter of this type. If in an exposure of, say, $\frac{1}{1} \frac{1}{2 e c}$., $\frac{1}{5}$ of the time is taken for the shutter to open to its full aperture and another $\frac{1}{5}$ for it to close, $\frac{2}{8}$ or 40 per cent of exposure time is not effective, and the shut ter's efficieucy is said to be 60 per cent.
In the more elaborate and more cxpensive types of between-lens shutter, greater efficiency and number of speeds are available.

Perhaps the finest type of shutter is the Multispeed, made by Ross, Ltd. It is highly efficient, and gives a great range of speeds from 2 sec . down

Shutter. Fig. 1. Focal plane shutter of great effeciency. Fig. 2. Simple type ot
diaphragm shutter which provides three apeed,
Courtes! of Kodak, Ltd.
to ฐ ${ }^{2} 0^{2}$ se sec., so that it is not inferior in speed o the best focal-plane shutter, while it is superior in that it gives several speeds slower than the focal plane, a matter of great importance in landscape and other branches of photography.

When a camera with a between-lens or any other type of shutter worked by springs is to be put away for a time, always see that it is released, i.e. closed.
The accuracy of a shutter is a matter of some importance to the photo. grapher. A simple way of testing any shutter is to fasten a piece of white paper on the edge of the baize-covered table of a gramophone which carries the record. The gramophone is wound up until it revolves at a regular rate of 1 revolution per sec., counted as 30 revolutions in $\frac{1}{2} \mathrm{~min}$. The gramophone is placed in a good light, and when the record table is revolving it is photographed. On the resulting photograph the paper strip will show movement according to the actual time of exposure. On either side of the image of the paper strip a line is drawn to the centre of the gramophone disk, making an angle.

Measure this angle with a protractor, and divide it by 360. The result is the exposure in a fraction of a sec. Thus, if the angle is $40^{\circ}$. $40 \div 360$ gives $\frac{2}{4}$, that is, the shutter gave an exposure, say, of $\frac{1}{6}$ of a sec. when set to r $^{1} \delta$ sec., not a serious error, but indicating that the shutter is a little slow.

With cameras whose shutters are not provided with the slow speeds so useful for short-time exposures, various pneumatic appliances are available which can be attached to work the ordinary release. One variety givea extra speeds from $\frac{1}{2}$ to 4 sec . by means of an adjustable air-valve. Others, such as the Kodak Self-Timer and the Ensign AutoTimer, give automatic exposures from $\frac{1}{2} \mathrm{sec}$. to 10 sec. The Kodak form of this release acts from $\frac{1}{2} \mathrm{sec}$. to 3 min . after it is set, so that the photographer may include himself in the picture or the group that is being photographed. See Camera; Exposure.
SHUTTLECOCK. A shuttlecock or shuttle is used in the child's game of shuttlecock and battledore, and also in badminton. It is very light in weight, being essentially a rounded cork, around the flat top of which a number of small quill feathers have been stuck. While a child's shuttlecock could easily be improvised in the home, the weight and
balance are of such importance to it in badminton that a home-made one would be of little use. For outdoor badminton, hcuvier shuttlecocks are provided, the bases being made of rubber instcad of cork. See Badminton : Battledore.

SIBERIAN CRAB. This is the popular name of a handsome hardy tree (Pyrus baccata). It is beautiful when in blossom in spring and again when in fruit in autumn. It Hourishes in ordinary soil. The fruits make excellent jelly.

## Sibthorpia. See Moneywort.

SICILIAN BUTTERCUP. This fowl is one of the light or non-sitting breeds, lays white eggs, which average 8 to the lb. but its record does not entitle it to be recommended on its laying properties only. The cockerel is red in colour, wing bows orange red. primaries black with the outer web bay; secondaries, outer web. reddish bay, innerblack and bay, tail a mixture of black and reddish bay; comb, face, wattles and lobes red, legs olive green. The pullet is buff on breast, free from inarking; back golden buff finely marked with black; tail black except two uppermost feathers, which are mottled with buff. In these birds the comb is the most distinctive feature in both sexes. It is like a buttercup, the two leaves of which it is formed meet, and the spikes stand up all round the comb, the centre forming a hollow or cup. See Fowl ; Poultry.

Sick Headache. See Migraine.
SICKLE. For cutting grass in odd corners of the garden or trimming hedges, a sickle is often useful where it is impossible to employ the scythe. It consists of a curved blade of steel, with either a sharp or serrated edge, and a round, wooden handle, the cutting edge being on the inside.

The cutting edge should be kept very keen by sharpening on a coarse stone, or carborundum scythe or hook stone, known in some districts as a rubber. The tip of the tool is sharpened first, then the rest of the blade is sharpened by placing the tip of the tool on the ground, holding the hook firmly with the left hand and manipulating the rubber with the right, rubbing on either side of the cutting edge alternately. See Grindstone; Scythe; Shears.

SICKNESS. In a particular sense the term sickness means nausea, with or without vomiting. It may indicate gastritis or some other stomach complaint, or may be due to other definite causes. The fact that an infant returns some of its milk after a feed is not necessarily vomiting, but usually means that it has taken too much Vomiting in a child may often be benefited by $\frac{1}{2}$ to 1 teaspoonful of castor oil, which is retained more often than might be expected. See Biliousness; Gastritis; Morning Sickness; Nausea; Sea Sickness ; Vomiting.

SIDALCEA. These beautiful hardy herbaceous plants are 3 or 4 feet high and bear mallow - like flowers in summer. They flourish in ordinary garden soil and are increased by division in autumn or by sowing seeds in spring in a frame. Of the older sorts Listeri, carmine rose, and candida, white, are the best; many new varieties with flowers of various shades of rose and crimson have been raiscd.

## Sideboards: Antique and Modern

## How to Choose Them and How to Make a Light Modern Type

A great number of articles in this Encyclopedia are connected with this subject. Suci, include those on allied pieces of furniture: e.g. Cupboard; Dresser; on the various furniture styles, e.g. Hepplewhite; Sheraton; and on the woods employed, c.g. Mahogany; Oak. See also
Dining Room: French Polishing: Furniture; Inlaying; Polishing. The maker of a sijcboard rench Polishing Furniture,

Sideboards may be broadly divided into two classes : those showing the original table construction of this piece of dining-room furniture, consisting of a board placed on trestles at the side of the room and used for service at meals, and those of threefold construction which incorporated the two pedestals often found as separate adjuncts to the sideboard proper early in the 18th century.
Cupboards were fitted into some of these pedestals, and others might perlaps have accommodation for bottles. In others drawers were fitted. and the tops were used as stands for knife urns or candelabra. When some furniture designer made these three pieces into one the second class of sideboards was evolved.

Our first illustration shows an example of the older pattern dating from Tudor times This style of sideloard, reproduced for periol furnishing in oak to-day, was the immediate successor of the board on trestles. Many beantifully carved examples of Jacobsan side. boards are still extant, some having backs and fitted with drawers under the table surface.
Some of the Quecn Anne period sideboards, made in oak or walnut, stoorl on turned legs connected by gracefully curved strctchers, while others (in walnut) had cabriole legs and were usually without backs, but fitted with drawers
The Threefold Pattern. Sheraton describes the sidebourd of his period as often made without drawers of any sort, having simply a rail a little ornamented, and pedestala, on which were rases, at each end Soine sideboards had loollowed fronts, and under them it was customary to place the wine cooler. Sheraton, however, soon improved on these existing pieces. His sideboards are in the main straight. but with curved or serpentine fronts, and most ol them designed without backs They were made in mahogany, and some were inlaid. One beautiful example typical of his work is illustrated in the article on Sheraton style.
Sheraton's Drawing Book shows designs for several sideboards. Three comparatively simple ones are each provided with $n$ rail at the back. One of the three is furnished with holdere for candles. A secret drawer, which opens by mans of a spring, is fitted into one of them, while another is flanked by pedestal cuphoards on which knife urns or other articles may stand

In another he introduced a rail at the back in which was framed a small round mirror, thus starting a style which developed into the huge niirror backing of the sideboards of the mid-Victorian period Sheraton's pedestals

Sideboard. Tudor example, dating from early in the 18 th century, and illustrating the first development of this piece from the board placed on trestles at the side of the dining hall Bu Dermission of the Director, Victoria \& Alvert Museum. South Kensington
were rounded in shape, and the knife urns were placed within them, while on the topls, where the urns stand in most sideboards, he placed something resembling a round, two-tiered stand, surmounted by a candelabrum. In another piece he replaced the rail at the back by a wooden strip.

In pieces designed by Hepplewhite the right hand drawer was fitted with partitions for bottles, and belind it was a place for cloths
the beautiful sideboards that bear their name Chippendale's Cabinet-Makers' Director, however, contains several designs for the pieces of furniture known as sideboard tables, one or two of which anticipate the modern sideboard.
Adam sideboards have usually two cup boards and a drawer between them, the space beneath leeing open. The front shows the graceful lines associated with this name, and the cupbeard doors are often beautifully ornamented with oval panels. The board proper is below the level of the cupboard tops, thus continuing the idea that they werc once separate pieces of furniture, and the lack is formed by a rail. Regency sideboards showed the same features associated with mounts of bronzed metal or brass. A development of these was the chiffonier.

Our second illustration is an cxample of a beautiful sideboard which shows the Adam influence and clearly displays the threefold construction. It is of mahogany veneered with Spanish mahogany and the pedestal cupboards have side doors at either end of the piece.
As the sideboard became morc popular, it was made in a greater variety of styles, but the threefold arrangement was retained in Victorian pieces. Some were made without legs, the space beneath the drawers being fitted with cupboards In many the centre cupboard was marle to hold a cellarette. Another change was the introduction of the large mirror into the back, flanked by bracket shelves and heavy carved and scrolled side pieces. The Victorian sideboard assumed vast dimensions in kecping with the great display of silver plate which was considered necessary in the dining room of the period.

Modern sideboards arc of light construction and usually of small size. Mahoginy, walnut and oak remain the fivourite woods, and some are beautifully inlaid (see page 626)
or napkins. In the left-hand drawer were two divisions; the back one was lined with green cloth to hold platc, and the front one lined with lead to hold water for washing purposes. His standard sidehoard was from $5 \mathrm{~J}_{3} \mathrm{ft}$ to 7 ft . long, about 3 ft . high, and from 28 to 32 in wide. Hepplewhite made good use of the serpentine line to give grace to his pieces.

Chippendale did not make sideboards, although he designed pedestals for the Adam brothers, and these were incorporated into

Beautiful mahogany sidenoard, vencered with Spanish mahogany, showing the influence of the Adamatyle and the threefold development of this piece accomplished by incorporating two pedestal cupboards Humplirely \& Vera Joel

They show the developurent of the thireefold idea by having cuploards at either side and a drawer or drawers in the middle, but many of the smaller pieces go back to the original type as far as the table top is concerned, adding merely a back rail. The piece for which constructional details are given also shows the modern use of the stretcher, a correct and pleasing feature in an oak sideboard of ot herwisc simple design.

Making an Oak Sideboard. In most modern houses a length of 4 ft . is ample for a sideboard. It gives reasonable accommodation without occupying too much space. A sideboard of this size in modern style is shown in. Fig. 1. It has two handy cutlery drawers and capacious cupboard space. In addition the doors have a useful sholf arrangement. The latter need not be followed exactly, but can be adapted to suit individual reguirements.

Although a somewhat massive item the construction is comparatively simple because use is made wherever practicable of readymade furniture parts, thus avoiding nost of the difficult worls. For instance, legs rearlyturned and grooved can be obtalined. The various rails. too, are grooved, and the same applies to the mouldings. Again, the doors. instead of being framed up, are formed of pieces of thicls venecred plywood. The virtue of this is that, apart from the climina-
tion of a good deal of work, the plywood will stand without danger of shrinkage.

The leading dimensions are indicated in Fig. 2, and Fig. 3 shows how the main carcass is put together. Deal first with the legs. These are usually sold in sets of four, two legs having a single groove, and two having two grooves each. The double-grooved ones are put at the back. Another leg with no grooves at all is needed for the centre.

To ensure the joints being all marlied out alike, the legs should be fixed together temporarily and the marks squared across the whole. All the rails are tenoned into the legs, with the exception of the top front rail, which is dovetailed. They all stand upright, except the first and sccond front rails, which lie flat (Fig. 3). If we except for the minute the stretcher rails, which are plain, all the back and side rails are grooved. A special grooved moulding can be obtained which requires simply to be cut to length and the tenons formed at the ends. The sccond back and side rails must be grooved at both edges. All the front rails are plain.

Those to whom simplicity is all-inuportant can omit many of the mortises in the legs. This is done by cutting short tenons on the rails to fit into the grooves in the legs. For a stronger job deep nortises must be cut, and corresponding tenons formed on the rails. In any case mortises aro necessary where the front rails and stretchers are fixed. When all the joints have been marked out the legs can be separated and the joints cut.

The same plan of fixing together the parts can be adopted in the case of the rails. The shoulders of all frout and back rails are the same length, so that it is an advantage to cramp thesc together and square the marks across. The same thing applies to the side rails. If it is decided to cut short tenons, the length of these is fixed automatically by the depth of the grooves. In any case

sideboard. Fig. 1. Uselul 4-it. sideboard in oak which can be constructed by following the directions given in the text and the working diagrams below
rule the grooves are $t$ in. deep. This means that $\frac{1}{2}$ in. must be added to the sight size in both length and breadth.

When assembling the main carcass the two sides shou'd be put together independently and the glue allowed to sct before the remaining rails are a!ded. This saves the necessity of dealing with many joints in onc operation. Lay one leg on the bench, glue in all the rails, and slide in the panels. When the other leg has been put on the whole can be cramped up. Test for squareness before pulting the unit aside to sct.
I.t is advisable to have assistance when
remember to allow for the tenons when cutting the rails to length.

A close-up view of the front joints is given in Fig. 4. Note specially the dovetnil joint at the top. The shoulder length of this is the same as that of the other rails. Notes on the actual culting of the various joints used are given under their respective headings in this work, and the article on Joint may uscfully be consulted. The centre leg joints are similar to those of the others except that there is no dovetail at the top. Instead, the rail here runs right through and a joint like that shown in Fig. 5 is formed.

The various panels are of $\frac{3}{16}$ in. plywood.
 Those at the sides are oak veneered. For the back a cheaper birch plywood is good enough. Allowance for the part projecting into the grooves must be made when cutting out. As a adding the front and back rails. The lack should be put together as far as possible first; that is, the centre uprights and the panels should be assembled. When this has been done the whole back should be fixed to the sides and the job stood upon its feet. If only one cramp is available nails can be driven into the joints to prevent their springing apart.

Next add one set of front rails to one leg. glue in the centre leg, and put in the remaining set of rails. This necessitates slightly st raining the sides outwards. The top front rail is glued in last. Test for squareness in both plan and elevation.

Drawer runners and guides are fixed as shown in Fig. 4. The groove in the runner is necessary when a dustboard is desired. Screws are used to fix the rumers. The guides, which prevent the drawers from rocking from side to side, are gluerl and nailed aborc. An extra wide runner is necded in the centre to support both drawers. Plain squares of wood are fixed to the rails to hold the cupboard bottom, which can be made of

Fig 2. Front and side elevations of the oak sideboard shown above. Fig 3. How the main carcass is put logether. Fig. 4. Close-up view of leg joints. Fig. 5 , Detail of top of centre leg. Fig. G. Useful shelf arrangement at back of doors; it is put together first and added to the door as a complete structure
plywood in. or $\frac{t}{2}$ in. thick. The sectional riew in Fig. 2 shows how the top is made. A special rebated top moulding is mitred together and a piece of veneered plywood glued in the rebate. This saves having to joint op several pieces to make the width.

It has already been mentioned that thick plywood is used for the doors. Fig. 6 shows how the hanging shelves are made up. The complete shelf structure is put together first, and this added as a whole to the back of the door. The middle shelf rests in grooves, and the bottom tits in rehates in the uprights. The small inset sketch shows how the whole is fixed to the door by pocket screwing. Onc important point is that the uprights of the shelves must stand in trom the door edges, otherwise the door will bind when opened. The decorative mouldings on the doors and drawers are simply glued and nailed. The corners are mitred. Use the usual dovetail or lap joints for making the drawers.

SIDECAR. It is possible, though not advisable, to fit a sidecar to any motor cycle of 175 cc . or over. The main objection to using a sidecas with small engines is that the average pace of such a combination is well below the speed of traffic streams on the open road. The presence of a comparatively slow vehicle in a fast traffic stream creates dangerous eddies, necessitating frequent overtaking, and is therefore to be discouraged on the ground of public safety.

Moreover, the occupants are uncomfortable. because they are forced on to the camber, and much larger vehicles constantly rush by them at higher speeds. An engine of 500 cc . should be regarded as the minimum from this point of view a larger engine being preferable, though a 350 cc . sidecar combination is ratisfactory on other grounds. Morcover, when a sidecar is drawn by an engine of 750 cc . or $1,000 \mathrm{cc}$. the running costs approach very closely to those of a small car, sio that the 500 cc . sidecar thus represents the best compromise. The maximuin regular load for a sidecar combination consists of two people and a quite small child. It is not economical to carry a woman and one or two children in the chair and a pillion passenger on the carricr behind the driver, as is often attempted at holiday times. The heavy load makes the machine slow, with the disadvantages described above, and imposes stresses on the mechanism which are reflected in the cost of upliecp.

The novice should not take a sidecar on the road without receiving instruction from a practised driver. When the peculiar steering is once mastered the machine is entirely controllable, and can be turned in a smaller space than any other vehicle, but the novice is extremely likely to upset it on left-hand corners until he has bcen instructed how to corner. He will also experience difliculty on cambered roads until he realizes that the front wheel is used solely to steer the machine and not to balance it, for he is probably accus. tomed to a bicycle, with which the front wheel is used to balance as well as to stecr.

Where storage space is limited, a folding sidecar chassis is recommended. The entire outfit when folded then occupies little more width than a motor cycle; when extended, the frame is as safe as a rigid pattern. It

Measurements at A.A.\&
B.B. must be ıdentical C. Forward position of sidecar wheel

Sidecar. Diagrams in plan and elevation, showing the correct method of lining up sidecar to motor cycle
is usually best to buy the sidecar chassis from the malier of the motor cycle, as it will then be designed to fit special lugs brazed into the frame; the sidecar can easily be set in proper alinement and the connexions will not shift, as might occur with bolted joints.

It is not possible to provide weather protection for the driver, though wind screens and leg shields are obtainable to keep off wind and rain in some degree: the sidecar. however, should always have a hood and screen. If ample engine power is available, a boot for luggage should be formed in the tail of the chair. It is clenner and more convenient than a grid. Sidecars are sold having brakes on the side wheel, but these are not recommended except to the expert driver. The standard motor cycle brakes are adequate for ordinary purposes, and on precipitous hills further retardation can be obtained by descending on bottom gear. The diagram indicates the proper method of adjusting the sidecar on the frame of the motor cycle.

Owing to the extra load punctures are more common with a sidecar than with a motor cycle. It is easy to store a spare wheel on the tail of the sidecar and it is unwise to buy such an outfit without detachable and interchangeable wheels. See Motor Cycle.
SIEVE: Its Uses. A sieve or sifter is really an appliance for separating the finer from the coarser particles of any loose material. It consists generally of a framework with a number of strands stretched across it; the diameter and distance apart of the strands determine the size of the particles which can pass through the sifter

The ordinary household sieve has a hardwood rim with a very fine gauze or mesh stretched over the lower part of it and sccured by a second or outer rim and is useful for sifting sugar and many other ingredients used in the kitchen. Fine sieves for culinary purposes have meahes of hair, muslin, and wire gauze.
Sieves for grain and chaff have wooden rims and cane bottoms and vary from 15 in . to 28 in diameter.

The potato sieve, with a diameter of about 24 in ., has an oak rim about $3 \frac{1}{2} \mathrm{in}$. decp and a very wide mesh, varying from $\frac{3}{4}$ in. to 2 in . It is employed to sort out the small potatoes from those of sufficient size to be suitable for seed purposes or for ordinary consumption. See Cinder Sifter.

Sifter. Wood uscd for a kind of sieve for sugar, etc. See Flour Sifter.

SIGHT. This word means, in one sense, the faculty of seeing. As a general rule persons whose sight is not normal suffer either from myopia or short sight, or from presbyopia or long sight, the latter being usually due to increasing age.

Sight Testing. It is quite impossible for anyone who is not an oculist or a qualified optician to test vision with any degree of accuracy, and to obtain spectacles except on an expert's prescription is fraught with danger

For example, hypermetropia, or long sight, and astig. matism may both be present, but may be concealed by muscular action; either of these conditions may be responsible for a large degrce of eye strain, and may be produstive of severo headache. An crror
of vision may always be suspected if headaches are frequent when the eyes are subjected to any strain, as in reading or writing, or especially when visiting a theatre or cinema

Persons over 40 ycars of age are very linble to suffer from presbyopia. In this condition, the distant vision may be normal, but glasses are required for all near work, and will need to be strengthened at inter vals of about five years. See Astigınatism: Eye; Myopia; Spectacles. Signal. The recognized traffic signals are illustrated in the article on Motoring (q.v.).

SIGNATURE : In Law. When the law requires a signature to bc affixed to any document, as a rule it is sufficient to sign with the ordinary signature, not necessarily with the full name, but anything which is intended for a signature is enough in law. It has even been held that a printed name at the top of a billhead, invoice, etc., is a sufficient signature. Except in the case of a will, where the signature must be placed at the foot or end of the will, the signature may be placed anywherc. It may also the made by initials or even by onc initial or by a typed or stamped signature. See Cheque; Will.

SILENE. This group of hardy perennials and annuals is known as the catchfly or campion The favourite annual kind is Sileno pendula, which is largely grown as a groundwork for flower beds; it becomes a mass of rose-pink blooms in late spring. It is raised from seeds sown out of doors in June, the seedlings being planted in the flower beds in October. The perennials are chietly rock garden plants. Silene schafta, 6 in., rose coloured Howers in July-August; alpestris, white, July; and maritima, 6 in., with clouble white flowers in summer, are some of the best Sileno acaulis is of moss-like growth, and needs very gritty soil. Propagation is by seeds sown in spring in a frame or by division.

SILICA. Many materials contain this substance; rock crystal quartz, and flint are practically pure silica. Chemically silica is an oxide of silicium with silicon as its base. Silica is the chief substance of which glass is made; in a pulverized state such as sand, it is an essential ingredient in strong mortar. Plate glass and window glass or, as it is sometimes called, crown glass, are silicntes of soda, and tlint glass is a similar compound with a considerable addition of lead silicate.

A proprietary brand of paints with a zinc oxide base is known as silicate paint. A preparation known as silicate petrifying liquid is sold for treating damp or porous brick or stone walls, cement and plaster surfaces, etc See Damp

SILK. The quality, texture and sheen of silk vary considerably, according to the kind of silkworm that produces it. The strong, natural coloured silks called tussore or shantong are obtained from a so-called wild silkworm. Finer silks, bright yellow and white in colour, are produced by the mulberry silkworm.

Chiffon, crépe-de-Chine, ninon, velvet, satin, taffeta, georgette, stockinette, and brocade are but a few of the fabrics that are composed chiefly of silk. It is very suitable for clothing, as it is a bad conductor of heat thus kecping in the heat of the body. Being light, and not bulky or clumsy, it is particularly useful for under-garments, as the surface is smooth and soft, and does not irritate delicate skins. Silk is very durable, and absorbs moisture, although not so readily as wool.

Plain silk, poplin, and velvet are still sometimes made into curtains, whilst silk damask and tapestry are employed for upholstery. Hand-woven materials in silli are particularly beautiful and give good wear. Fine silks are suitable for cushion covers, as feathers do not easily work through. The use of pure sill: for
furnishing fabrics has been largely superseded by artificial silk mixtures.

As silk is not a cheap fabric it is more adulterated than any other material, the object being to give weight and generally to improve the appearance of silks of poor quality and uneven texture. Coloured glace silks are frequently loaded with mineral salts. These weighted silks wear badly, splitting after being in use a short time. Other common fillings are clay, starch, ultramarine and size. Although it is beyond the power of the housewife to determine the actual quantity of such adulteration, some idea of it can be obtained by rubbing and shaking a small piece of silk over a sheet of paper, using black paper for bright-coloured silk, and white paper for dark silks. If the iabric is heavily loaded, a little of the filling will come out as dust, and the silk will 'ree thin and look poor after the treatment.

Another simple test is to soak a pattern of the silk in warm water for $\frac{2}{2}$ hour, and then wash it carefully, using ordinary soap If the character of the fabric is hardly changed, this proves that the silk has not been adulterated to any extent. A thread of pure silk when heated in a flame shrivels and forms a little bump or knob at the end; silk containing tin salts does not do this, but forms ash similar in length to the thread burnt.

Mending and Washing. As a rule it is not advisable to spend much time on monding silk garments that have commenced to wear. Unlike cotton materials, silk threads, when once they show serious signs of wear, rapidly break down and the fabric is of little use Should a perfectly sound garment become torn or burnt it can be mended by inserting a neat patch or by placing a piece of silk under the rent and darning it to the garment. Woven silk underwear and stockings can be darned in the ordinary way, but to avoid straining the fabric it is advisable to use silk thread similar in texture to that employed in manu facture. It is worth taking good articles to be mended invisibly by an expert.

The appearance of some of the more elaborate varieties, especially ribbons, corded and glace silk, is spoilt by washing with soap and water These can be dry cleaned at home (see Dry Cleaning), or sent to the cleaners.

Washing silks are strong, and require little skill in getting up, but the more delicate silks, such as crêpe-de-Chine, ninon, and foulards, need careful treatment. Alkalis, such as washing soda, strong soaps and soap powders, are actually harmful to any silk fabric, and aminonia should be used judiciously for dark-coloured silks only Silk, being an animal product, must not be boiled, nor must it be washed in very hot water.

## How to Wash Silk Articles

Before commencing to wash, sort all silk articles into three distinct lots, white silks coloured, and black. The white silks should be washed first, commencing with the least soiled and finest fabrics Prepare sufficient warm soapy water for the amount of washing to be done; the lather can be obtained by using soap jelly or soap flakes. Soap flakes are made by shredding yellow soap, and drying and storing it ready for use. When required, put about two tablespoonfuls of Hakes into the bath, and pour on a little boiling water, adding warn water or more soap as may be found necessary.

It must be remembered that no cleansing whatever takes place unless there is a lather on the water. The amount of soap that is necessary to do this entirely depends on the nature of the water, whether hard or soft. When dissolved soap is required quickly, place a cake of yellow soap in a wire cage soap-saver and pour boiling water over it.

Wash silk garments by kneading and squeezing. A little hard yellow soap can be
rubbed on to any specially soiled parts such as collars, cuffs or bands When the garments are quite clean on the right side turn them and wash them on the other side; it is gencrally advisable to have a second washing water. Hard rubbing should be avoided, especially lor loose!y woven sillis. When clean, rinse lirst in warm water, then in cold this removes the soap and clears the fabrics. The appearance of white silk is cuhanced by careful blueing which counteracts the yellow tinge that white silks invariably acquire after having been laundered several times.

Stiffening and Ironing. Silks that require stiffening should be immersed in gum water To make gum water, dissolve 2 oz. best white gum arabic crystals in $\frac{1}{2}$ pint of water: strain the solution through muslin and bottle. When required, 1 to 4 teaspoonfuls of this solution should be added to $\frac{1}{2}$ pint of cold water For large articles, such as dresses and curtains, the quantities must be increased proportionately. Thick silks, such as corded shantung and tussore, are better not stiffened. The appearance of glossy silks is improved by adding a dessertspoonful of methylated spirit to the stiffening water Small silk articles, after being wrung out, can be rolled down tightly in a clean cloth. On no account should silk be completely dried and damped down but should be ironed when half dried out.
The finished appearance of washed silk depends on the ironing. The object should be to iron it in such a way that the finished appearance resembles as closely as possible the material when new. Therefore, some silks should be ironed on the right side and some on the wrong. The following look better if ironed on the right side : Jap, glace, foulard, tussore and shantung.
Any patterned silks, embroidered or corded, should be ironed on the wrong side, also silk lace, crêpe-de-Chine, ninon, georgette and stockinette. Coloured silks can be success fully got up by following the same directions, but the colours are improved by adding 1 tablespoonful of both salt and vinegar to the last rinsing water. Salt sets, ind vinegar brightens, the colours that have been faded by the soap The colour of black silk is improved by steeping for a short time after rinsing in deep blue water.
Removing Stains. Stains are not so casily removed from silk as from cotton and linen, and some stain removers, such as chloride of lime or eau-de-javelle, must not be employed. When using a bought stain remover, notice carefully if it is suitable for silk fabrics. Use oxalic acid with care to remove rust and ink stains from silk. Turpentine should not be employed to remove paint from silken fabrics, but instead a mixture of one part benzine to two parts of methylated spirit should be used.
Silk for Needlework. Spun silk is used in knitting, crochet, and embroidery of all kinds It is divided into two main classes, real silk and artificial. Real silk washes and wears well, and can be re-dyed at home For knitting and crochet and all ncedlework purposes it is the more satisfactory to handle, as it is soft and the stitches stay in position, while artificial silk is springy, and requires careful handling, particularly in knitting when there are a lot of stitches on the needle. For'some decorative purposes the brilliant gloss of artilicial silk thread is valuable.

Knitting silks consist of very fine strands very loosely twisted, while crochet silks have a decided twist, to prevent the crochet hook from piercing the silk and dividing the strands. A tine artificial silk is also macle for crochet, which is about half the thickness of the standnrd twist. Crêpe twists are also made in both classes. These silks are usua!ly sold in hanks and balls of 2 oz . and 4 oz ., while embroirlery silks are made up in small skeins.

Tests for Silk. Though in dyeing propertics spun silk differs considerably from the artificial products, the housewife may find it difficult to differentiate between the fabrics in their bleached statc. The burning test may be helpful, though not always conclusive. Real silk fibre is practically non-inflammable. When ignited the flame does not run, and the ash forms a knob or globule, a smell as of burnt feathers or hair being given off. Some kinds of artificial silk do not flare, but the substance melts back into globules, and the characteristic smell of burnel animal feathers is absent. Another type of artilicial silk flares up and burns away, with an odour like that of burning paper. The tests are made more difficult by the practice of combining the different materials in the yarn See Bag; Candleshade; Curtain; Embroidery; Painting on Tertile Fabrics; Patchwork: Ribbon Work: Stockings: Weaving

Silkie Fowl. A curious and distinctive breed notable for its sense of maternal responsibility

SILKIE FOWL. Quite distinctive in the shape and colour of its comb, the colour of its lobes, facc, wattles, and legs, and in the texture of its plumage, the Silkie fowl is unique amongst poultry. It is not a great layer, nor is it a table bird, owing to the fact that it is so small; its bones are dark purple, the skin also is dark. The plumage is very soft, fine and without web, so that the bird appears to be clothed in a coat of down.
Silkies are bred in four colours-white, black, buff, and partridge. The only utility claim that can be put forward on their behalf is that they arc most trustworthy mothers, and no fowl can beat them as a broody. Some exhibitors use half-bred Silkie-Wyandottes for incubation purposes with good results. See Fowl; Poultry.

SILL: In Building Construction. A sill is the horizontal piece of stone, brickwork, concrete, or timber at the base of a framed opening, such as a door or window. Ground sills are the lowest pieces of timber which support the posts and superstructure of a timber building, while the term also refers to he lowest member of a studded partition
Sills for door frames should be formed of oak; they may be 4 in . by 3 in . or 6 in . by 3 in ., and weather on the external side. The sills of window frames may be of oak, but in many instances similar material to that with which the frame is made is uscd. External door sills arc formed with York stone, cement, bricks, ctc., the former being the most expensive. The first essential for any cxternal door sill is a good foundation of Portland cement concretc. External window sills arc
formed of stone, brick, cement, concrete or tiles bedded in cement.
Provision should always lee made to den with the water that is liable to be reccived during rainfall. With an ordinary window sill this is accomplished by cutting a throat or groove on the underncath side about $\frac{3}{3} \mathrm{in}$. from the front cige. In the casc of a door a picce of iron usually 1 in . by $\frac{1}{2} \mathrm{in}$., is placed on edge into a prepared groove between the wood sill and the brick or stone sill on which the formor rests. It is called a water-bar and should be bedded into place with red and white lead. A door sill is liable to wear hollow. especially if made of wood. To remedy this
a slot is cut to include the worn portion and a new piece of wood let in. See Door: Window

SILVER: Medical Uses. In the form of the nitrate or lunar caustic silver is often used in medicine as a caustic where a limited and superticial action is required. Lotions of silver are sometimes used on account of their astringent and styptic action.

A very weak solution 1 to 2 gr . of silver nitrate to the oz., dropped in the new-born infant's eycs, after they have been first thorougbly cleansed with weal warm boracic solution, is an efficient protection against ophthalmia neonatorum.

## SIlver Ware: British "Period" Styles

## Pieces that Lend Grace and Beauty to Domestic Life

The reader shou'd further consult the entries on the various silver articles, e.g. Cream Jug; Muflinecr; Porringer : Punch Bowl; Spoon; Tankard; Teapot. See also Cutlery; Glass Ware; Pcwter: P.erc:ng; Repousse ; Sheffie!d Plate and ihe subsequent article on Silver Work

Fino cramples survive of English silver work done during early Tudor times, especially piecer for church use in the form of stancling mazers or communion cups. In a prosperous household a large salt container of hour glass shape, and beautifully proportioned, might bc found in daily use with eilver cups and silver-mounted rrinking hoons, some odd spoons, a basin and ewer, onc or two dishes and candlesticks in silver. In the 16 th and 17 th centuries tankards, dishes, and other articles were often made in silver gilt or parcel (partly) gilt.
The discoveries of silver in Anserica and its importation in the 16 th century placed it well within reach of the affluent. The result was a great increase of domestic plate and the distinction between rich and poor at one time was marked by their uses of silver or pewter for eating and drinking vessels.
Much of interest can be learned about silver ware from the copics that were made by the pewterers. All through the history of the two crafts it is found that when the shape of a spoon was morlified by the silversmith, the hrass or latten spoon makers copied it and so did the pewterers. When the silversmiths cvolved a new candlestick for table use, the pewterers, ever on the watch for something new, copied it, making it a little thicker and sonetincs a little more clumy to tompensate for the greater softness of their alloy.

Later the silversmilhs were copied by the Sheflield plate workers, but the silversmiths themselies were affected artistically by any art inspiration that came to them from without. The influence of the work of such great designers as the brothers Adam, Chippendale, and . Iosiah Werlgwood upon the craft of the silversmith can be scen in countless little details which, not in use before their time, must therefo:c be attributed directly to these inthences. Much beautiful silver vare was made during the 17th and 18 th centurics in Scotland and Ircland, and bears the Edinburgh, Glasgow and Dublin marks, while some early pieces were marked at Cork.
Drinking Vessels. From church plate to evervday domestic ware, the silversmith's craft has been largely concerned with articles for the service of drink and food. Silver drinking vessels are known by various names, and the line of demarcation between one and another is not always precisely drawn. Prominent among them are the cups used for winc, which are represented to day by the wine glass, and the challenge cup, given to successful athletes. A main feature of these eups, except in the case of the loving cup type, with two handles, is the absence of that accessory.
Goblets are usually, but not always, bellied, and are supported on a straight sicm whith may be square, but is more commonly rounded. The vessel linown as a steeple cup, made in the reign of James I, is not unlike the goblet It has a cover which either tits like a cap or
does not rest directly on the brim, but is raised thercfrom by three or four slender balusters The cover terminates in a spilse which suggests a church stetple.

The beaker is another type of drinking vessel Like the cup and the goblet, it is without spout and a handle, but unlike them it has no foot, resembling in this rospect the modern tumbler. As a rule, beakers are severely plain, with straight sides and surfaces decorated with a chased design or a raised pattern. The sides taper and the diameter is nearly always larger at the top than at the bottom. The beaker dates from 'ludor times. Tho hanap was a large standing cup also of early date, and richly orna mented.

The silver mug was made in a varicty of styles, al. though in cssentials one differs very little from another. They may bequite plain or they may have a bulbous body. A scroll or a bow handle is seen on some examples, and the decoration includes reeding

Early tankards have straight sides, and are decorated elaborately with chasing and repousse work. In the middle of the lith century they were designed in plainer styles with flat lids, but in the 38th they were made with domed lids. Fig. 1 shows a typically shaped tankard of the time of Gcorge II. Nore ornamental picces of later date showed cliascd designs and raised patterns on the hellied bodies and decorative knohs on the licls. 'The flagon is very similar to the tanliard except that it is of even earlier date. Porringers, posset cups, and caudle cupa, all popular vessels from the collec. tor's point of view, may be linked with drinling vessels.
The porringer of the time of Charles II
possessed a cover and usually was of the shape illustrated on the left of Fig. 2, about $\dot{G}$ to 8 in. high being the size of these pieces. Later porringers were made without lids and with straighter sides, as seen in the example on the right of Fig. 2, dating from 1764. Caudle cups in the l8th century were made after the style of thic earlier covercd porringers.

Liquor Service Vessels. The silver jug has developed along more than one line, according to the use for which it was intended. The cream jug is one form of it, while the hot-water jug of to day is not unlite the wine jug of two centuries ago. The jug may also be regarded as the ancestor of the chocolate pot and the coffice pot, two pieces of some interest to the lover of old silver. Of these the chocolate pot, in use in high society in the time of Queen Anne, has its spout fixed almost at right angles to the handle. The latter is sometimes quite straight like the handle of a saucepan, not bored and fixed at top and bottom to the body, as is the handle of a teapot

The earlicst silver coffee pots resembled truncated cones with a straight spout and a wooden handle. Fig. 3 shows one of these dating from Charlcs II. They were next made with an octagonal body, and later with a bellied one and a curved spout, the decoration becoming gradually more elaborate. A vessel very like the coffee pot, and used for the same purpose, is the biggin The difference is that the latter had a very small spout, this being little more than a lip. Both chocolate pots and biggins are rare, but coffec pots of the carly 18 th century are more frequently seen The teapot came a little later than the vessels just mentioned. There exist a few in the Qucen Anne style, which has been much copied, but antique examples are mainly of Gcorgian date. The early onez were without feet, and for them stands to match were often made. Some George 1 teapots are of octagonal plan with domed covers and faceted tapering spouts.
The tea urn and the kettle may suitably be mentioned together. The kettle in silver with a lamp, under it was made early in the 18th eentury, the urn coming a little later The early kettles were usually spherical in shape, and a few of them were in a gimbal on a tripod frame, thus enabling the contents to be poured out by tilting the vessel. Others had a pair of snuffers attached to the stand and the spout of the kettle was fitted with a hinged lid. Shell work and scroll work are found on 18th century kettles. The most beautiful urns are those that show the Adam influence aud follow the classical model by having the body shaped like a Greek vase and add to this chasing and other graceful decoration
Of the other silver vessels that were used for holding liquor, two of the most coveted are the punch bowl and its near relative, the montcith. An example of a punch howl dating from the time of Ceorge II is illustrated in Fig. 4. The ladles which were made for these

Silver. Fig. 2. Left. beautiful example of large, covered norr.nger, dating design. Right, smaller porringer without cover, dating from the reign of George III

Silver. Fig. s. Contee rot, or conical shape, dating from Charles 11 ; London mark, date 1681-2
$B_{y}$ pernission ot the Director, Victoria \& Albert
bowls with handles often of whalebone or a hardwood, are also prized by collectors.

The best-known kind of sauceboat has a long lip, a scroll handle, and is supported on threc feet; but perhaps more prized is the oval one with both ends pinched to form lips. The feet, rims and handles lend themselves to graceful treatment which they received from the craftsmen of the $18 t h$ century Tureens are roind or oval, a gadroon border and scro.l feet being seen ol some fincexamples

Two ressels al lied to those men lioned are the pipkin and the argyle. The former s a kind of saucepan which was used for warming food in a living-room or bedroom when

Fig. 4. Punch Bowl with hollow flutes and straight gadroon edge ; Irish mark, maker Robert Calderwood, 1732 Courtesu of the Goldsmiths' and Silversmiths' Co., Ltd
so that the cover can, if necessary, be used as an extra dish.

Silver baskets, which were and are used for holding bread, cake and fruit, form a popular class of silverware. Bread baskets date from the 17 th century, the earliest being without fect or handles. In the 18th century occasionally handles were on either side. The example illustrated in Fig. 5 is on feet formed of satyr masks and terminating in scrolls. The handle luas caryatid supports, the sides of the basket are pierced and engraved with fruit and conrentional scrolls. It was made in London and dates from 1739. Later these baskets took the form of an oval tray on a short stem, and a shaped foot. For these piercing was a usual lind of decoration, and chasing was occasion ally combined with it.

Sugar basins, known at one time as sugar baskets, fall into the same category. The earliest were quite plain, but later they were embossed and fluted, and later still piercing and other decorative effects were introduced. A glass lining was essential for the pierced pieces, which have often a foot and a bale handle. Others have feet of the ball, lion's paw, or ball and claw pattern.

Castors and Condiment Sets. Sugar was also placed for use in castors or dredgers, of which there exist some charming examples of 18th century work. These castors were made in a variety of shapes. The body, for instance, may be straight or cylindrical, oval or octagonal. Others are shaped like a vase with a bulge just above a short stem. The top or dome was at irst quite small, butin time it became larger and was ornamented in a varicty of ways, some pieces very elaborately indced. This ornamentation took the form, in addition to grace ful and reg ular patterns for the holes, of chasing engraving and em . bossing.

Castors of this kind were not used for sugar only They are very often seen in sets of three, the largest being for sligar and the two smaller, which a formal meal was not required. They are are equal in size, for pepper, white and black. usually bellied at the base and diminish in diameter from the waist to the brim, where there is a small lip at right angles to the handle. The argyle was used for holding gravy at the table. It has a jacket, wall, or other contrivance for holding hot water, the idea being to keep the gravy warm. With a handle and a short spout, the argyle is not unlike a tea pot.
Silver Dishes and Baskets. A fruit or cake dish known as a tazza was originally used and described as a drinking vessel. The rimmed dish is supported on a short stem having a round or square foot.

Silver dishes and plates were frequently seen on the tables of the rich in the 17th and 18th centurics, and the former have popular representatives in the entréc and other dishes of to-day. Occasionally they were part of a silver dinner servise.

Dishes used for meat are generally oval, and some are provided with a cover. Those used for vegetables have sometimes three or four divisions, while others have a wooden handle straight out from the side. Of all dishes, the entrée or brealifast dish lencls itself most readily to graccful treatment, and good examples fetch high prices. Some are provided with a second tray for holding hot water, and many have detachable handles,

Vessels in which pepper was contained werc known not only as castors or dredgers, but as mullineers. Salt cellars succeeded the big trencher or bell-shaped salts which usually stood in the mitdle of the dining table. The bell salts which were made from 1590 to 1613 were made in 3 tiers, the 2 lower having the receptacle for salt and the top one being pierced for pepper. Early examples of salt cellars date from Willian III, when they were circular in shape and supported on feet, and also in the same shape from Queen Anne's day: Afterwards they became fashionable in oval, ostagonal, and, at the end of the 18 th century, in boat shapes.

Mustard pots in silver date from about the middle of the l8th cen tury. The majority of examples are glass lined and agrec in styles with

Fig. 5. Cake Basket with feet formed of satgr masks and terminating in scrolls, the sides of the basket being pierced and engraved; London mark, dating from 1739

But besides these there are many books dealing with the silversmith's craft and particularly with hall marks

Hall Marks. In the early days of the guilds, when pride in the work done was the rule and good work was insisted upon by the master, it became necessary to have a mark which was a ready means for the identification of the worker. To this was added a place mark to show the town of origin, a date mark to show the year of manufacture and a quality mark ns n guarantee of the quality of metal used.
Of all the old English silver still in existence nine-tenths at least bear the mark of the Goldsmiths' Hall in London. The symbols

London ball marks from
1300 to present day used in London for gold are : the carat mark, which is $22,18,15 \cdot 625$, 12.5 , or 9.375 . the standard marli, a crown. which is placed on the 22 or 18 carat standard only : the town mark, a leopard's head, crowned until 1823 , butun. crowned since: the date letter; and the makers' mark, usually their initials, and always impressed by themselves.
On silver the sterling standard of 925 parts, or 11 oz .2 dwt . out of 12 oz ., is denoted by a lion pessunt instead of the crown The higher standard of 958 parts, or $11 \frac{1}{2}$ oz out of 12 oz ., which was the compulsory minimum for plate from 1697 to 1720, and is still permissible, is distinguished by a figure of Britannia and a lion's head erased instead of the lion passant and the leopard's head This so-called new standard is not, hospever, marked in Ireland.
The standard marks at Birmingham and Chester, as well as for Sheffield silver, are the same as above. Edinburgh and Glasgow replace the crown and the silver marks by a thistle and a lion rampant reapectively. although since 1914 Glasgow also uses the thistle alternatively. The lower gold standards in Scotland arc 15, 12, and 9 . In Dublin the 22 -carat gold and the silver standard have a crowned harp, the 18-carat a unicorn's head. and there is an inter. mediate 20 carat Irish standard. with a plume of feathers
The present pro rincial town marks, and their carliest dates, are : Birming ham, anchor, 1773 Chester, sword and three sheaves, 1701 Sheffield, crown 1773 ; Edinburgh, castle, 1457: Glas gow, tree, fish, and bell, 1819; Dublin, Hibernia, 1638. The London date mark is indicated by the letters A to U, omitting J, each cycle of 20 years being distinguished by the style of the letter and the shape of the shield. l'rom 1438 to 1558 there were 7 cycles, during

Silver. Standard hall marks of the provincial offlces, both closed and active, are given, in addition to the London hall marks shown above

T

Courlesy of Herbert Jenlins. LId.
which the shields followed the outline of the letter. From 1558 to 1738 the shields resembled a rectangle on a triangular base. After 1738 the shieid's base was usually curved to a cusped point at the middle In the 1876-1895 cycle the shield's chief was a double concave line, and since 1896 the shields have had three lobes to the base. The cycle now in operation runs to the year 1935

The date-letters of the provincial offices are in different styles, shiclds, and cycles. They arc 25 -year cycles at Birmingham, Edinburgh, and Dublin, and 25-ycar alternating with 20 -year cycles at Chester and Sheflield, J being ing ball marks is at Glasgow.

Care of Silver. The best kinds of modern silver are simple in design and rely for beauty on graceful shape and fine workmanship. Most of the plain classical types of table silver are copied. but very highly decorated designs are considered unsuitable for two reasons : they are not strictly hygienic owing to the difficulty of removing particles of food from the interstices, and they take too long to clean The price of modern silver articles varics in a way out of all proportion to the intrinsic valuc of the metal used and is almost entirely dependent on quality of design and workmanship.

For cleaning purposes some housewives prefer rouge, which is used by jewcllers, and mixed with water containing ammonia it is a good cleanser. Others may prefer jeweller's soap, which gives most excellent results. Some, again, put their faith in plate powders, while others always use polishing fluids.

A good cleansing agent is precipitated chalk, and the finer the better, applicd with ammonia and water, or with sal volatile if expense is not to be considered. Do not use whiting as it is sold in the rough, but cither precipitate the chalk or buy it ready-made. After cleaning renove all traces of the rouge, paste, chalk, or other cleaning and polishing dium by means of a brush.
It is a popular fallacy that washing has an injurious eflect upon silver, causing it to become discoloured and destroying its polish. The truth is, however, that if silver is to be lept in good condition, it should be washed immediately after use, and then cleaned in the
nsual way. Warm soapy water, to which a little ammonia has been added, should be used. If rubbing is necessary, choose a soft sponge small enough to be passed inside the neckiz of jugs, etc

Filig'ec silver is sometimes difficult to clean because dust collects in the crevices and seldom yieldes to sponging. For this an old tooth brush will be found effective. The bristles should be fairly stiff, but not hard enough to produce scratches. Silver ware should be dried thoroughly after it is washed, and if it does not require cleaning rub it well with a chamois leather. This will restore its polish

Silver inkstands that are distigured by ink splashes of long standing are sometimes difficult to clean, though stains that receive early attention can always be washed away with hot soapy water. A paste made from water and chloride of lime is often effective in obstinate cases. It should be applied with a soft rag, and allowed to dry on the stains before being rubbed off.

The storing of food in silver utensils is never attended with risks, because silver, unlike copper and brass, is n metal that is not acted upon by food acids.

When not in use, silver cutlery is best stored in a large piece of baize. Each knife, fork, and spoon should be rolled up separately, and the baize then tied securely with string or tape. This method of storage keeps out the air and thus obviates the need for constant polishing.

If silver has to be repaired it must go to a working silversmith, not to an ironmonger Silver will stand a vast amount of hard usage, and in repairs it will stand the fire necessary for hard soldering. If silver has oncc been soft soldered and later on requires repair with hard solder, all traces of the previous soft solder repair must be removed Repair can be donc quite easily by a qualified silversmith, and good silver should on no account be entrusted to anyone else.

SILVER BEET. Also called seakale beet, this is a vegetable of striking appearance, grown for the sake of its edible stems and midribs, which are cooked in the same way as seakale, and for the leaves which are treated as spinach. It is raised from sceds sown out of doors in April and May. Sce Seakale: Spinach.

SILVER BELL TREE. The snowdrop or silver bell tree, of the family Halesin, is one of the most beautiful of summer-leafing trees when in bloom, its white Howers bearing a marked resemblance to snowdrops. It does not often attain a greater height than 15 ft . It is therefore suitable for a small shrubbery, or for a lawn. The best kind of this tree is Halcsia tetraptera.

SILVER FOX. Perbaps the nost expensive of all fox furs, silver fox derives its name from the long silvery white hairs that provide such an attractive contrast to its rich, glossy black coat. In firmness it is unequalled, yet it has a remarkable softness that gives it a foremost place among good furs. See Fur.

SILVERING: Of Mirrors. In the pro duction of mirrors one surface of the glass is coated with a mixture of silver, and this process is known as silvering.

A method that should give satislactory results is as follows: Prepare a solution of nitrate of silver in the proportions of 90 gr . of the silver to 4 oz . of distilled water. Prepare a solution of pure caustic potash in the proportions of 1 oz . of potash to 25 oz . of distilled water, and a third solution consisting of 1 oz of millis sugar in powder form to 11 oz . of distilled water.
The half of the first solution is placed in a clean tumbler or other glass vessel, and pure ammonia (sp.g. $0 \cdot 880$ ) added to it very slowly, drop by drop, until the precipitate is just dissolved. Twice the quantity of the second
solution is added, and ammonia again added to the solution until it just becomes clear. It is then further diluted with distilled water, the proportions being $1 \frac{1}{2}$ times that of the combined solution. The next step is to add gradually some of the first solution until a slight grey precipitate is formed which does not redissolve. It is then allowed to settle and after that some of the third solution is added and well stirred.

The plate glass to be silvered has now to be properly cleaned. This can be done by washing in a solution of ammonia water, following this by washing in a solution of hydrochloric acid, in the proportions of 1 part of the acid to 100 parts of distilled water. The glass is then rinsed, dried, and polished with a perfectly clean cloth. The plate must now be placed on a dish and carcfully levelled until the surface of the glass is perfectly flat and horizontal: when the solution is poured very gently on to the glass so that it will cover the whole plate.

The operation must be carried out in a warm room, which must be quite free from dust, and the glass allowed to remain for several hours. At the end of that time the solution is poured off the plate, the latter again set level, and a fresh supply of solution poured upon it, and left there until the silver has deposited. The plate is well rinsed in distilled water and set aside to dry. It is then given a coat of varnish, following this by $n$ coat of good paint made up from finely ground red lead and a little turpentine.
Every vessel used for the solutions for the separate steps in the various processes must be chemically clean, and the processes carried out in a cleanly manner.

SILVER LEAF: The Disease. This malady attacks plum trees chiefly, but several other fruit trees, as well as laurel and some other shrubs, are liable to it. There is no cure, and diseased branchcs should be cut off and burnt. Silver leaf is easily recognized by the silver-grey colour of the leaves. The Victoria plum is particularly liable to this discasc. The law requires all branches attacked by silver leaf discase to be cut off and burnt. The disease is believed to make more rapid head. way on heavy soils and in damp situations. Any improvement, therefore, in the drainage of an orchard will help the trees.

SIIVERSIDE : Of Beef. That portion of the round of beef which is known as the silverside is considered, when salted, to be a prime boiling joint; it is also economical, as there is little bone and practically no fat attached to it. The round is divided into two, cut downward, one part being called the topside and the other part the silverside; but the latter is most usually salted or pickled. Silverside also may be boiled, braized or stewed without salting, and sometimes it is roasted. It is usual to obtain it ready pickled from the butcher, but it may be prepared at home by directions given for salting, and will take about 10 days to pickle properly.

When about to cook, wash the meat frce from brinc, wipe and weigh it, but if it appenrs very salt when sent home it is better to soak it for an hour in cold or tepid water, changing the water several times. If too much salt is left in the meat it will be hard when cooked and the liquor from it will be unfit for culinary purposes. This lifuor, if strained off, makes very good stock for pea or lentil soup. The butcher should skewer the silverside together neatly, adding a small lump of fat. The slewers must be removed when dishing the meat. It must be carved in very thin slices, a small piece of fat being served with the lean. See Beef; Salting.

SILVER WEDDING. This term is used for the 25th anniversary of a wedding day. It has become a custon that the presents given on such occasions shall be of silver.

## Silver Work for the Amateur

Ornaments for the Home and for Personal Adornment
The metal worker who is interested in this subject should turn to the articles in this work under the general heading of Metal; also to Drilling: Riveting; Soldering; Wire. Those on Bowl; Spoon and other articles made may also he consulted, while kindred operations are described under Enamelling; Repousse, etc.

The working of silver, as dealt with in this The parts are cut apart with a pair of shears article, falls into three main divisions. The and the edges trued up with a file. The next first is confincd to the manipulation of the step is to bend up the sides on a hardwood flat metal and includes riveting, silver soldering, block, as in Fig. 2, A, fitted in the vice or repoussé, and chasing. The scond deals firmly attached to a table, using a mallet with beaten work, such as the shaping of and working very lightly so as not to bruise bowls and other round shapes worked from the the metal. The back is turned over on a piece Hat metal. Another form of silver work of stecl measuring $\frac{1}{8}$ in. thick, as at B, the comprises the use of the metal when it has top edge being rounded and made perfectly been drawn out in the form of wire in any section. It can also be cast and used with enamel, but these operations are beyond the scope of the present article.

Silver is generally sold by the oz. and measured by the metal gauge, but the thicknesses men. tioned will be in S.W.G., and itshould be obtained rolled ready for nse from a silversmith. or a
 smooth with emery cloth.

Having folded the metal on to the face of the stake, place a length of $\frac{1}{8} \mathrm{in}$. steel rod in the hollow and carry the metal around it to close it in, as in C. The corner pieces arc bent in the centre at right angles, as at D , and the holes for the rivets drilled. These pieces arc placed in position one at a time, the holes marked through and corresponding holes drilled in the sides. The lid is cut to the shape shown at $E$ and the edges first turned over at right angles and then folded over quite flat, as at F. The back projection is turned over on the narrow stake and the round completed as at $G$, in the same way as the bottom. The two rounded portions are placed together to mark out the cuts to form the hinge ; thesc are then made with a piercing saw, as at H and J , and trued up with a file. A length of brass or copper wire is then cut to the length of the side and fitted in.
If the hinge work has been neatly done there is no need to solder the round in a small piece of work, but in muking a larger casket on similar lines it is safer to solder the joint, especially with a heavy lid. Considerable variety is possible in the design of small boxes, and a pleasing effect is to use hinges (cither pierced or in repoussé) soldered or riveted to the lid and back. Hairpin boxes jewel caskets, and stamp boxes are suggestions for this type of work.
Hollow Work. The second division in silver working is that of forming bowl shapes from the Hat metal, and this can be done by three distinct methods. The commonest is that of forming the shape by beating it into a depression on a block of wood, or over the edge of a block. The simplest article to commence with is a pin bowl, as in Fig. 3, made from a piece of $18 \mathrm{~S} . W . G$. silver from 3 in. to 4 in. in diameter. With a compass draw the size of the base inside a 4 in circle; it should be about 2 in . in diameter.
A Cigarette Box. A simple piece of wor for the beginner might consist of a cigarettebox, with corner angleplates forming feet and a linged lid. Suitable gauge is 20 S.W.G., and a piece measuring $9 \frac{1}{2} \mathrm{in}$. by 7 in. will be sufficient for the whole of the box. Mark out the piece of metal as in Fig. 1. A forms the basc and sides, $B$ the top, and $C$ the angle-pieces. The small squares surrounding $A$ are waste, but they will be found useful for making various small articles.

Fig. 3. Two silver pin bowls which can be made by following the instructions given here. A shaping block is also shown

Fig. 4. Hiocking uammer deing used on a bollow block
aving 1 in. all round to form the sides. Next provide a stake of the necessary shape (Fig. 3). This is made from a piece of hard. wood about 3 in . square and 0 in . long. Place the block upright in the vice, mark a 2 in. diameter circle in the centre, and then with a gouge cut out a concave lepression to a depth of $\frac{1}{2}$ in., finishing the hollow as smoothly as possible.

Place the metal over the depression on the block, and, as shown in Fig. 4, beat down the metal into the hollow with the bail end of the hammor, or with a bossing mallet (A, Fig. 6). These tools are shown in Jig. 5. A series of blows should be struck all ronnd
plete the sides should be nearly upright, as at F, and it will be somewhat difficult to procced further with the hammer

The final stage calls for the use of a stake but as this is rather expensive, the beginner will find the round end of a poker quite as good for small work Before the final shaping is done the silver must he annealed by placing it on top of a shallow bowl filled witl, charcoal or small coke, and playing a blow pipe flame over it until it is red hot. The alternative is to place the bowl over a gas flame, but the greatest care must be taken not to overheat the metal. A good earthenware bowl should be provided to hold the picklc of equal parts of sulphuric acid and water, and the annealed metal is then dipped in it and left until it becomes frosty white, when it is washed and dried in sawdust.
The howl is now placed on an appropriatcly shaped stake and the edge beaten over. or the same process followed with the poker head, as

Silvet work. Fig. o. duats necessary tor makiag the gllver pla dowis shown in the previous dage, and for other hollow work at G, Pig. 6. and this will result in the shape as at H .

Planishing The bowl at this stage should be quite even in shape, but to rive it 1 he desired finish, the surface must be planished after being again annealed. A stakc is alinost a necessity if the planishing is to be done in a workmanlike manner, but if a conical shaped poker head can the metal, and the result will be as shown at be obtained and the end filed off, it will be J3, Fig. 6. The Lowl is tilted up a little as possible to get close to the inside corner. at C. and another round of blows is given; The rcgular and cven hammer marks on this will bring the sides up higher, as at D. handmade silver wotk give it a beauty and The next stage is similar with the bowl still charm that is impossible to produce in any higher, us at $E$, and when this round is com- other way: but the real effect of the

Silver Work. Fig. 6. Various necesges in making bowls : A, beating hollow in metal with bossing mallet ; $B$, result of striking a series of blows round the metal; C, bowl tilted for another round of blows; $D$, result of second round : E, third round of blows; F. Its result, sides nearly upright ; $G$, beating edge round a poker head; $H$, resulting shape; J, shape with out-turned edge; $K$, method ot turning edge; $L$, out-turned edge flattened; $M$ and $N$, methods of forming a fluted edge; 0 , notched block for fluted edge; $P$, panelled shape achieved by flattening rounded sides

Fig. 7. Ding the rassing hammer io coursing
planishing is to true up the surface and stiffen the shape. It is possible to spoil the work with careless planishing, the hammer blows must be evenly spaced and weighted, and if the hammering is heavier in one part than another the bowl will be uneven and difficult to true up.

Another method of forming a bowl requires no other tools than a hammer or mallet and an anvil, or very hard wooden block. It is done by placing the metal on the anvil and. commencing in the centre, hammering in concentric circles to the outside. The

Fig. 8. Shape 10 a vase, shown in section, waicn can be made from a circular piece of silver
suceess of this metlod depends on accurate hammer work. Full directions are given in the article on Bowl (q.v.), where the shaping of a copper one is illustrated.

Once having worked out a simple bowl shape by either of the above methods, it will not be difficult to form this into other shapes. It is just as casy to turn the edges out as in. For example, the shape at J, Fig. 6, can be worked on a stalke as at $K$, and the edge flattened out as at $L$ bv hammering the edge on a bick iron. Fluted forms can be formed by using a raising hammer as at $M$ and $N$, on a notched block as at $O$ and panelled shapes can be worked by flattening the round sides as at $P$.

Coursing. This process consists of hainmering the metal against a stake, as shown in lig. 7. The metal is held in contact with the stake about 1 in . below where the hammer is struck in order that the metal is hammered on to the stake. To make the shape shown in the section at Fig. 8, a piece of $16 \mathrm{~S} . \mathrm{IV} . \mathrm{G}$. silver should be cut in a circle a little larger than the contour of the section, as shown liy the dotted lines. Next draw a number of concentric circles commencing 1 in . from the centre, cach one increasing in radius to the outside, in order to guide the hammer blows. The metal is now beaten into a rough bowl shape with a mallet, by driving it into a hollow stake. The stake shown in Fig. 7 is then fixed in the rice, and the hammering commenced, the blows being carried completely round; a second course follows $\frac{1}{2}$ in. higher up, and each succeeding course is followed out in the same way as locfore.
The metal has a tendency to work into wrinkles. These must not be allowed to increase in size, but must be flattened out at
once; if these wrinkles are allowed to form it is probable that the work will split at that point. The advantage of this form of shaping is that all kinds of shapes can be beaten out, but owing to the initial difficulties and the expense of silver contpared with copper, the beginner will be well advised to undertake some preliminary rais ing with the latter metal. A selection of suitable tools is shown in Fig. 9. The necessity of frequent rehearsal, since the effect would be largely annealing must not bo forgotten.

Soldering. The worker cannot advance very far without silver soldering. This requires the use of a blow pipe and a spirit lamp. A small piece of work suitable for a first attempt is a naplin ring which has been made up from the fiat and has to be joined.

The method of using the mouth blow pipe is as follows. The portions surrounding the joins are freshly scraped or filed, fixed in place with binding wire, and touched with borax, which is rubbed down with a little water, and applied in the form of a thick cream. Small snippets of silver solder are placed close up to the joint, which is now ready for the application of the flame.

The lamp flame is directed around the work first to warm it, and presently the borax will boil up and then run into a fluid state, carrying with it the solder. The parts to be united must be kept in close contact till the work has cooled. S'ce Soldering.
SIMMERING. The cookery term sim mering consists in keeping any liquid in a heated condition just below and never actually reaching boiling point.

SIMNEL CAKE. 'This cake, eaten in Lent, is made by creaming 6 oz . each butter and sugar and then beating in four eggs, adding each one separately. Mix in 9 oz . Hour, 1 lb . cleaned currants, 5 oz. mixed chopped peel, 2 oz . shredded almonds, and $\frac{1}{2}$ teaspoonful mixed spice. Lastly, add 1 tablespoonful milk.

Turn the mixture into a tin lined with buttered paper, and bake it in a moderate oven for about 2 honrs. Leave it to tool on a sieve, and when it is cold cut it into two rounds. Divide ${ }_{1} . \mathrm{lb}$. of almond paste into two, roll it into two rounils of the sance size as the calic, put one round betwern the pieces of eake and lay the other on top. Mark a trellis pattern on the latter, brush it over with beaten egg, and put it into the oven so that it may become lightly browned. See Almond l'aste.

SINGEING: In Cookerý. Poultry and game are singed, after being plucked, in order to remove long hairs and down without risk of tearing the skin. Singeing is best done with a long, loose spill of white kitchen paper. The bird is held in the left hand by the scaly part of the legs, and the lighted paper is applied quickly and just long enough to burn off the hairs. The bird is then wiped free from any particles of paper. Pigs are singed after scalding to remove long lairs or bristles.

SINGING GAMES. The traditional sing. ing games are still popular among small children, and are hard to heat for charm and variety. They have also a distinct colucational value, combining singing, dancing, and rhythmic movement.
A pretty entertainment may be given by children of from four to ten years of age simply by the joyous performance of a dozen or so of these games. They involve littlo

Silver Work. Fig, y. Tools used in the process known as raising Courtesy of C. I. Pluclinctt is Co., LIA
spoiled by a lack of spontancity, but the organizer of the entertainment should be careful that the children know the correct tunes and that the games are played with the proper actions. If all the small plavers are dressed in similar costumes, such as the Kate Greenaway stylo, the effect will be doubly cliarming. Books can be obtained which offer a large choice of these games, giving the music and describing the actions. Some of these singing games will be found under their own headings in this work, e.g. Nuts in May.

SINK. In every house the sink is a necessary sanitary fitting, whether in the scullery or the kitchen, for the cleansing of and on a level with the garden. Such a room usually possessers a window with charming possibilities, and this can often be takell as a
domestic utensils and other purposes. One of the best and most serviceable sinks to use in the small housc is made of glazed stoneware. The deep pattern has many advantages over the shallow one, and is usually fitted with a washer and plug, so that the sink itself can be filled with water for washing up purposes. Should a stoppage occur in the drain pipe, directions for rectifying are given on page 381 .

Sink Brush. The brush used for cleaning a sink is usually flat with rounded end set with stiff hass linots and a short handle. The knots should be drawn in with wire as hot water would melt the pitch if they ware stuck in. Bass does not depreciate by use in water, and the open spread of this material in a sink brush enables it to be kept free from the waste which is prevented from going down the sink drain. See Brush; Draining Board; Drains; Gas; Kitchen; Scullery; Washing Up.
SIRLOIN : Of Beef. The sirloin is that portion of tho ribs which lies between the rump and the wing, or fore-ribs. It corresponds in position to the loin in a carcass of mutton. Sirloin is a prime roasting joint and should be cooked with the bone left in it If it is boned the flavour will be spoilt.

Attached to the rib bone underneath is a very delicate portion of tlesh called the under cut or fillet. This part is better eaten hot, and should always be carved off first. It should be cut down to the bone in slices; about $\frac{x}{4}$ in. thick, but the slices carved from the top portion of the joint must be as thin as possible. See Baling ; Beef ; Carving.

Sisyrinchium. See Satin Flower.

## Sititing-rooms and Their Furnishing

## Distinctive Ideas for the Odd Reception Room

Suggestions for the arrangement of family reception rooms are given in the articles on Dining Room: Drawing Room; Living-Room; Lounge. Readers are also referred to the entrics on Attic ; Colour ; Cottage ; Decoration ; Flat ; Fireplace ; Furniture; House ; Panelling; Rugs

In many houses there is a room which is pensive if carricd out with a sense of colour and furnished as an odd sitting-room with a jumble good taste. In other cases the room is upstairs of pieces which have seen better days and no and perhaps is chiefly used by one individual particular colour scheme to bring them into or by the younger members of the houschold. harmony. Sometimes this room is called a To begin with, take the basement or ground-morning- or breakfast-room, and is in the base- floor back room as an example. Even if there ment or semi-basement nest to tho kitchen is a pleasant view into the garden, such a and this can often he takell as a liecp walls and ceiling a pale colour and have starting-point for the housewife's plans for briglit accessorics such as a mirror over the redecoration. These plans call bequite inex- bireplace or opposite the window, one or two

Sitting-room. Fig. 1. Comiortably turnished sitting-room with charming tiled fireptace and built-in bookcases. The floral design of the loose covers unites the colour scheme of the room

Humphren \& Vera Joel
pieces of lacquered brass or copper, and some pale tinted or white glazed pottery to reflect or catch the light. In $n$ small room the plainer the wall surface the better, but distempered walls will not have the same durability of surfacc as a faintly marbled or patterned paper.

An incxpensive oriental carpet is a good choice for such a room, as it can be obtained in bright, light colourings which at the same time do not show marks. In a smill room a dark fawn shade of hair carpet and wool handworked rugs, designed in colours to match those in the cretonne selected for the window curtains, will prove a delightfu' scheme with beige or old ivory ground to the wallpaper and faint pink or ivory washed ceiling.

A window seat upholstered in the same cretonne as the curtains is attractive where there is a bow window. A boxpleatcd or gathered valance for both seat and curtains is the appropriate finish. Glass curtains are not always necessary, especially when the ground of the practical curtains is light in colour. If required, inner curtsins may be marle of a plain cream net with a border of stripes necdle-run with wools to match the colours of the patterned rugs and hangings. Such a border gives a distinctice note, which can be also picked up in the stencilled patterns on imitation vellum lampshades and on handpainted washable door plates of a cellulose composition. These latter items are obtainable for a few shillings cach. A still better idea is to paint designs copicd from those on the cretonne curtains, on the back of plain glass door plates. It is these small things which count so much in interior decoration.

With regard to the style of the furniture, having surrounded it with such an agreeable setting, it really does not matter vitally in a room of this type. Naturally it is nicer if of good simple design and excellent workmanship, but with the absence of drab accessories and in particular of nll ornaments which do not give or reflect light or enrich colour, and the resolute banning of rubbish, the room will be both homely and charming. Wicker or cane chairs should be enamelled the same colour that is chosen for the woodwork of the room, or, if this is stained brown then to match the ground of the carpet. Upholstered

Fig. 3. Sitting-room for a man, with thoraugnly comiortable chairs, charming brick freplace and attractive built-in cupboards flanked with bookshelves Humphrey \& Vera Jocl

Victorian chairs are best given loose covers. If new small chairs have to be bought, those with larlder backs and rush seats have much to commend them as they are neither old nor modern in style and harmonize with other furniture of odd periods and with cretonne, linen or chintz hangings.

In a typical upstairs town sitting-room of medium height and about 12 ft . square, perhaps a fenture which has to be reckoned with might be the sitting-room tiles. These may be, for example, leaf-green, the woodwork and mantelpiece being already enamelled the usual ivory sliade. In order to achieve brightness, height and warmth in a room with a cold aspect, the walls could be painted a pinky beige and the ceiling distempered the same colour.

The floorboards are best stained oak-brown and wax polished. The carpet might have a darker brown ground and be unobtrusively patterned in beige. Brown furnishing satin or velvet would be used for the curtains, lined green on a grey ground.

Sitting-room. Fig. 2. Restful country sitting-room blending the old world with the new by the use of a few unobtrusively modern pieces of furniture

Humpliren \& Vera Joel
with fadeless grcen poplin while the glass curtains would be of string-coloured net. A printed linen or glazed chintz chosen for the loose covers should have a leaf-grcen ground and be patterned with dull pinks, lavender and soft yellow. Plain cushions should repeat the darker notes of colour.

Acharmingsittingroom of this type is shown in Fig. 1. Good use has been made of the recesscs on cither side of the chimney breast by litting them with bookshelves. The modern weathcred oak writing-table and chair have nothing eccentric about their style. They would accord perfectly with any other plain pieces suitable in such a room. An alternative to the settee would be a well-upholstered divan, covered in plain brown velvet or furnishing rep, measuring 6 ft . by 3 ft ., raised from the Hoor on $n$ strong frame and piled with cushions against the wall. The cushious would repcat the colours of the patterned material used for the loose covers of the chairs. Thrce-piece suites are not to be had cheaply; they are not wise investments unless the frames are strong and well upholstered. Single armchairs can sometimes be piclicd up in reliable qualities for a comparatively low price at an auction salo.

For the same kind of room, but with a sunny aspoct, the scheme could be worked out with pale green walls ivory-washed ceiling, and furnishing fabrics of different shades of grey with a printed linen having a brightly coloured conventional pattern in clear tones of lemon-yellow, coral, black light blue and

Individual Tastes. In some cases a sitting. room can be decorated and arranged according to individual requirements. A pleasant room for one musically inclined is illustrated in Fig. 2. This is in a country house, and the walls and ceiling are of parchment colour which enhances the overhead oak heams. There are two rounded niches which have been titted with bookshelves, a delightful window with sinuple curtains which could be of velvet to tone with the plain carpet. There is a thoroughly comfortable chair for a privileged listencr, an old oali chest and a modern oak writing-table, but otherwise the room is restfully empty of unnecessary furniture, and there are no pictures Colour is supplied by the books, flowers and the garden view. In such a room the mantelshelf should not be overcrowderl. A bit of coloured glass, an old spode or lustre dish or jug, or a pottery figure piece, to break the line against the wall, are a good choice; there should be no small ornaments or fussy details to the furnishing accessories.

Our third illustration is of a delightful sitting-room particularly suitable for a man. The walls havo a panelled effect obtained by applying moulded strips of wood on panel boards. The plain frieze and ceiling are cream washed. A specially good feature is the use made of a recess for a built-in bookcase and cupboard with mirror glass door, a smallev cupboard and spaces for gramophone, etc., being firted below. The brick fireplace with its pattern of mellow colour against the woodwork is enhanced by the white pottery book ends and jar. The fire is a gas one mado to
simulate glowing logs The low hook table suits the height of the chairs, which are most sensibly and attractivelv covered, one in velvet and the other in a furnishing oil baize. At the opposite end of the room (not seen in the photograph) is a beautifully made leathertopped writing-table designed on square, modern lines and an equally suitable modern cabinet with a drawer under the cupboard.

Such a room suggests a colour scheme completing the harmony of tones in the woodwork and brick fireplace. To carpet it all over in brown velvet pile would look most comfortable and suitable at dirst, but would not be good in wear owing to marks from cigaretto ash and footmarks. The oriental carpet, or wriven geometrically patterned rugs, would be again the best choice in subdued shades with a gond deal of rust, dull reds and browns in their colouring. A fine shade of red that is between rust and crimson. which is particularly good in velvet, might be used for the curtains, and one of the armehairs might be covered in this fabric, while brown would be used for the other chairs. Instead of velvet, quite an excellent furnishing material is a fairly closewoven tweed. A llecked brown, beiga and red mixture, piped with plain brown, would be most practical, comfortable and effective for covering the armchairs and for the window curtains. The last should bc lined with fadeless brown casement cloth.

If linen or cretonne curtains are preferred they should have conventional patterns; either a checked or geometrical design of reds, browns, greens and wine colour on a beige ground would be suitahle. Another good fabric for covering the chairs would he plain and checked mohair. An effective style with this material would be to use a plaid mixture of brown and tan for the seats of the chairs and a plain brown for the back and cushion. Alternatively a plaid mohair could be used entirely to cover one chair and a plain mohair to cover the other. The ground of the plaid must match the plain fabric in colour.

SIZE. Size is a glutinous substance commonly made from the parings of leather, hoofs, parchment, etc., after prolonged boiling in water, and purification by straining. It may also be made from common glue and potatoes. Painters use size in connexion with various kinds of work. Before a wood lloor is varnished it should be sized, the size stopping up the pores of the wood and thus allowing an casy and economical application of the varnish.

Size is generally a constituent of good distempers; it has an adhesive effect upon the distemper after it is applied to the walls or ceilings of a building. Size may be jurchased from any colour merchant in kegs; it is then in a jelly or viscous state; but it may also be obtained in a concentrated form in small packets. To render it fit for use it is dissolved by boiling water and applied hot with a brush Wallpapers are sometimes sized so as to obtain a smooth surface for the varnish. See Painting; Paperhanging.

SKATE : How to Cook. Skate should be kept at least one day, and should not be eaten directly after it is caught, but it must never be taken out of season, and is better in tho late autumn and winter. The time for it is from August to the following April. It is advisable to buy this fish reaily ciressed from the lishmonger, as it is a difficult process to crimp it, and even if the tish is to be boiled whole it will need to be skinnexd both sides. The liver is usually removed and made into sauce, or served with the fish as a garnish. The dieections given for crimping and cooking ray may be followed for skate.
The wings or fins of the skate may be made into a breakfast dish. Dry the wings of a large skate, skin them, and cut them into fingers, then blanch them. Put the pieces on
a tin and cook them in a moderate oven till skates used for figure skating. The Ice King is quite tender. Then draw out the bones and a good example, but there are others.

Boots and Accessories. The sliater's boots rub the flesh through a sieve. Melt 3 oz . butter in a stcwpan, add the fish, lemon juice, grated nutmeg, pepper and salt, mix well and dish on buttered toast cut into squares. Pour round it a thick egg sauce. Skate when crimped may be served with some piquant sauce. See Fish; Ray; Sauce.

SKATES : Their Care. For use on ice the skate is made with a steel blade securcd to metal plates or a wooden block for attaching
 are important. Spccial boots are made and sold for skating, but ordinary laced ones can also be worn. They should, however, fit perfectly and should be provided with a moderately thick sole, flat straight heels and fairly stout uppers. They should fit tightly, but when they are first put on the ice it is advisable not to lace them up too tightly; the laces can be tightened after the lirst few minutes on the ice.

The skater should provide himself with covers for the blades of the skates. These may be of leather or rubber. The blades should be kept quite clean and should bc covered with vascline when not in use. The vascline must be thoroughly well rubbed in, and a fairly thick coating left on. The screws and bolts must be taken out and
to the boot. The cheaper kinds are those with a wooden block, with straps in front and at the back, and a screw for the heel; they arc suitable for children and beginners.
To-day in Great Britain most of the skating is done on rink ice and takes the form of tigure skating. Skating on natural ice is only available as a rule for two or three days in the year and sometimes not at all, except perhaps in the north of
Scotland. Many persons, however, go to Switzerland or other countries where during the season there is natural ice in abundance, but therc, too, figure skating is the more popular form.
Types of Skates. Of figure skating there exist two main schools, called the international and the English, and for each there is a particular kind of skate. A good skate of the international type is the Salchow-Meyer, seen in Fig. 1. This has a serrated toe and a narrow blade, which is hollow ground, the depth of the grinding varying with the condition of the ice, as natural ice needs a sharper edge than does rink ice. The point of this skate should touch the boot; in some cases it is let into the boot, a V-shaped nick being made for it.
For the English school of skating a good type of skate is the Club (Fig. 2). This is a skate with a broad obtuse-angled blade slightly hollow ground to a radius of 7 ft . for sizes up to 11 in . and 8 ft . for anything larger. It is the official skate of the English school and is sold in sizes from $9 \frac{1}{2}$ in. to $12 \frac{1}{2}$ in. Another good skate of the same kind is the Mount Charles, which will stand a good deal of hard wear.
The Criterion (Fig. 3) is a good skate for skaters of the international school and it has the additional advantage of bcing made ontirely of Sheflield steel. Somewhat heavier than the Salchow-Meyer, its footplates are bronzed, a feature which adds to its appearance. The fourth skate shown in the illustra. tions is the Junior (Fig. 4), one made specially for juniors and beginners. This is very near the ground and has no serrations on the toe.

For speed racing a different kind of skate is necessary. This is usually quite straight, lacking the curved end seen in most of the

Skates. Four kinds in general use. 1. Salchow-Meyer. 2. Club, official skate of the English school. 3. Criterioa. 4. Junior, suitable for beginners Courles!! of Lill!!whites, Ltd.
thoroughly cleaned or they are liable to rust. Skates need grinding from time to time as the edges must be kept sharp. This can be done at home on an emery wheel or a grindstone, but many persons prefer to send ther. to the maker for this purpose. A skate sharpener that can be carried in the pocket is sold.

Skidding. See Motoring.
SKIMMER. This utensil is employed, as its name implies, to skim the fat from the top of soup, stews, etc. and also to remove the cram from milk when skimmed milk is required. It skims more quickly and thoroughly than a spoon.

SKIMMIA. This hardy evergreen shrul, is about 2 ft . high, and bears white flowers in summer and red fruits in autumn. Male and

Skimmia japonica, a busby plant hearing rreenishwhite flowers and. later. scarlet berries
female tlowers are on separate trees, and care must be talien to plant both kinds to ensure fruits. Fortunei, japonica and Foremannii are the best. These shrubs thrive in a mixture of loam and peat and should be planted in September or October or April. Propagation is most easily carried out by layering.
SKIM MILK. Milk from which the cream has been removed by skimming or separating is known as skim milk, and, although devoid of the natural fat possessed by new milk, it is used for many purposes in cookery. It makes good milk puddings if a small portion of finely chopped suet is added to enrich it, or it may be used in making batters, milk bread, biscuits, or calies.

Despite the absence of natural fat, skim milk is a wholesome and strength-giving food as it retains the casein, and a proportion of fat can always be added if clesired. The finest variety of pork is that obtainerl from pigs which have been fed on skimmed or separated milk. See Cream; Milk; Separator.

SKIN : Its Care. The skin is tough and very elastic, so that it stretches when fat accumulates underneath and returns to its former statc if the fat becomes reduced. As a person grows older this elastic property of the skin diminishes and causes wrinkles.

The skin consists of two layers, the cuticle without and the true skin within. The cuticle, also called the epidermis, or scarf skin, is sub. divided into layers; the outermost is the horny layer, while the innermost contains the pigment cells which give the skin its colour ; the accumulation of this pigment causes freckles, chloasma, etc. The cells of the outer surface are continually wearing out and falling off. Blisters are accumulations of tuid under the outer layers of the cuticle, which have no nerves, so that the puncturing of a blister does not causc pain. Thickening of the cuticle takics place in a large number of skin diseases. I'arts exposed to intermittent pressure may form callosities and corns. See Corn.
The cuticle, when undamaged, is impervious to water and microbes, but if abraderl it admits microbes; some microbes and other fungi can thrive in its gland ducts and on its surface, giving rise to skin eruptions. The cuticle allows certain drugs to pass through when they are nixed with oils or fats and well rubbed in.

The dermis, also called the cutis vera, true skin, or corium, is very much thicker than the cuticle. It consists chietly of interlacing fibres of connective tissue, together with bloodvessels, nerves, glands, etc. The glands are of two kinds, the sebaceous, or oil glands, and the sweat glands. The former manufacture an oily Huid which is poured out on the skin, and keeps it and the hairs soft and pliable.

The sweat glands consist of little tubes about $\}$ in long, coiled at the inner extremity and opening on the surface of the skin. The chief purpose of the sweat apparatus is to help to regulate body heat in the widely differing temperatures in which human beings live. The sweat glands are always active, pouring out water on the skin; this may evaporate at once, constituting what is called insensible perspiration; but when we go through exercise they become much more active, and the amount of sweat is greatly increased and forms sensible perspiration (q.v.). The same happens in hot weather or when one is in a warm room.

Certain conditions interfere with the function of the sweat glands. Thus on a damp, bot day the evaporation is checked, and we feel oppressed by the heat in consequence. Because it prevents evaporation, waterproof clothing is unhealthy. Alcohol increases both perspiration and the flow of blood to the skin. Consequently alcohol is a dangerous thing to take when one has to facc extreme cold.

It is very necessary for health to promote the normal action of the skin by cleanliness,
correct choice of clothing, and exercise. Many skin diseases arise partly from want of care of the skin. Coughs and colds, and diseases such as rheumatism, ctc., find an casier victim in the person whose blood-vessels have no acquaintance with the tonic properties of cold baths.

There is no better means of preserving the elasticity and bloom of the skin than daily brisk exercise in the open air. Even more important is scrupulous cleanliness, not of the exposed parts alone, but of the whole body surface. For those in vigorous health a cold bath every morning and a warm bath once or twice a week are to be recommended. It is often recommended after the bath to rub the skin vigorously with a rough towel. This mensure, howcver, may cause irritation and scratching of a tender skin, with a resulting crop of pimples.

Soft water should be uscd when available and cheap, harsh soaps should be avoided The skin of the borly requires a good quality soap as much as the face. For very irritable skins a superfatted soap may be used, or bran added to the water. The skin is irritated in many people by wool clothing. After a time in addition to the discomfort a crop of pimples breaks out owing to the constant irritation. In these cases the remcdy is to wear silk, or cotton, or very fine wool next the skin. While clothing should be sufficient, the healthy action of the skin will be greatly interfcred with if too much is worn. On the other hand, a person whose feet, or legs, or hands or arms are constantly cold cannot have a healthy skin.

In certain constitutional affections the skin is involved, e.g. in some of the fevers. In a large number of other instances, however, the skin itself is the original site of disease. For purposes of description, ailments which attack the skin directly may be classed as follows. 1. Inflammatory diseases, such as eczema, herpes, psoriasis, ctc. 2. Affections of the glands of the skin, such as seborrhoea, blackheads, etc. 3. Affections characterized by overgrowth or wasting of the skin, such as corns and warts, and types of haldness following on atrophy of the hair-roots. 4. Nervous affections, such as itching of the skin, pruritus. 5. Parasitic diseases, such as scabies. See Benuty Culture; Face.

SKIN EFFECT : In Electricity. This is the property of a high-frequency alternating current whereby the current tends to flow along the surface oi a conductor, in contrast to a direct current, which is evenly distributed throughout the mass of the conductor. The surface or "skin" effect increases with an increase of frequency.
SKIPPING. Skipping is admittedly one of the hest forms of exercise, especinlly in cold weather stimulating the circulation and keeping the muscles firm and supple.

For ordinary purposes the sliipping rope, when held in each hand, ahould be long enough to reach the ears of the skjpper while her feet are resting upon it. This means that when the handles are included the whole should reach to the top of the ears. Unless the rope is this length, the skipper will not be able to keep her knees straight.

For plain skipping the rope should be held so that it almost rests on the ground behind the feet, while the arms are extended to their full width on a lerel with the shoulders. At a given word, or at the commencement of the music, the rope is twisted backwards, while the skipper springs lightly over it with each revolution. Music is a great assistance to good skipping. The feet should be kept together and the knces straight, while the arms must remain fully extended and the head well up. The arms should be practically still, the rope being turned by movements of the wrist.

Cross Skipping. For the cross skip the arms are folded across the chest, while the rope goes
over as casily as if it were straightforward skipping. The arms, however, must not touch the body. It is generally interspersed with plain skipping. two plain and a cross, or three plain and a cross. The double cross is more difficult. For this the arnis a re reversed; that is, if the first cross is performed by crossing the right arm over the left, the second, which must follow immediately without any plain skipping in between, nust be formed by crossing the left over the right. In a yet more difficult form the double cross is the same cross repeated twice.

Another difficult excreise is the double through or double under. To achieve this, the rope has to pass twice under the feet to one spring. Two thinge are necessary for a successful performance. The rope must be worked up to as high a speed as possible and the skipper must spring very high in the air to allow the double passage of the rope. This is not hs a rule possible with atraight knecs. If the knces have to be bent the feet should be Hung backward, as though the performer were ahout oo kneel down, not forward as though she were about to sit. When well done the action should be a steady rhythm, with the double through performed every sixth step. but this can only be achieved with practice, and necds perfect balance as well as extreme agility.

Various dancing steps may be performed with a slipping rope, among which the ordinary gavotte step is popular. Some of the Scottish recl steps and the first of the Highland tling are also effective. The foregoing type of akipping should always be performed to music to ensure perfectly rhythmic movement, and with the rope going from front to back in order to keep the shoulders open and the chest expanded. This adds good breathing to the many other advantuges bestowed by the movements.

SKIRT : Of Beef. This is an inner portion of the buttock, sometimes called the midriff, and is part of the diaphragm. When the skin is removed and the skirt is trimmed, it is cut into pieces and used in place of steak for making puldings and pies Beef skirt is considered very suitable for this purpose because it is always tender.

The skirt is sometimes made into a stew. and if mixed with ox kidney an excellent dish is the result Equal parts of beef and ox kidney are used and the procedure is the same as that described for stewed becf.

SKIRTING BOARD. In house-building this is a thin deal board laid along the foot of a wall to give a neat finish to a room, and to protect the face of the wall from damage. It
 is stained or painted $t$ with the rest of the room. The usual width is 2 to 9 in., and thickness $\frac{1}{2}$ in. to 1 in.

Other forms are made in different sections, as, for example, triangular, $t$-round, and chamfered, these generally measur$b y 2$ in. Other pat.
terns include those with a $\frac{1}{4}$-round hollow, which gives a more
 wall and the floor.

In better-class construction, the skirting board is huilt up from several pieces or sections, properly jointed togather, as in the diagram, which also shows how the skirting is fixed to the wall and the floor. The skirting in this example is composed of two picces, the lower one being practically an ordinary board with a groove ploughed in its upper edge.
The upper part of the skirting is moulded at the top, the lower edge being tongued and fitted into grooves in the lown timbers. The akirting is attached to the wall by mieans of strips of rough wood known as grounds These are generally about $\frac{3}{4} \mathrm{in}$. thick and 2 or 3 in . wide. The grounds are nailed to brecze bricks, wood blocks, or plugs. or even by driving the nails into the mortar joints between the brirks.
The edges of the grounds which adjoin the plaster work are planed up to an angle. so that when the plaster is applied it acts as a key and assists in holding the grounds and the plaster in position. The grounds are carried right around the room about $\frac{1}{2} \mathrm{in}$. or so below the upper edge of the skirting. To support the lower edge a rectangular or other sectioned strip of wood may be nailed to the Hoor to provide a stop or abutment for the skirting, which is then nailed to this rough strip.
When fixing skirting boards, the heart side should lie used as the facc, in order that the lateral tendency of the timber to warp will only cause the top edge to be forced more tightly against the face of the plaster. When a single skirting board is used, it should only be nailed along the top edge; the lower edge should be tongued and fitted into a groove cut in the floorboards, so that the skirting looard is able to shrink and twist without splitting. The depth of the tongue should be sufficient to allow for shrinkage and expansion, without entirely coming away from the joint at the bottom.
Scribing a Skirting. Sometimes, in older houses, when it is desired to fit a new skirting board, it may be found that the floor has settled and is no longer flat. In such a case, the best procedure is to scribe the skirting board to the floor. To do this, it is placed in position and set with its upper edge horizontal. It will then be found to lie resting at one or more places on the Hoor. A pair of dividers is sct so that the distance between their two faces is exactly the same as that between the Hoor and the lower edge of the skirting board.
The dividers arc then used as a scriber by moving them along over the surface of the Hoor, with the upper leg pressing on the skirting board, and keeping the points vertically above each other. By doing this, a line will be scratched on the surface of the skirting looard, and its contour will exactly equal that of the foor. The board is then removed, accurately sawn, and finished, if necessary, with a spokeshave or plane to this scribed line, when, on placing it in position, it should fit the contours of the lloor exactly.

SKITTLES. For this game a slittle alley is necessary. This can bo marle ly laying down a number of planks to form a stretch of level flooring, which should be about I' yd . long and 3 or 4 yd . wide. The game can be played by two persons or by any other even number, provided there are not too many of
them. In the latter case they are divided into two sides.

The game is playerl with a wooden ball and ninepins. The former. called the cheese, is flatsided, and should weigh about 10 lb . The latter weigh from 7 to 9 lb . each, and are set up as shown in Fig. 2. The player stands about 6 or 8 yd . from the pins and his aim is to throw the ball so that it will knock down as many pins as possible. They must be knocked down by the ball itself, or by a pin that it has caused to fall. Any pin knocked down by a rebound is not reckoned as down. The player is allowed one step forward when throwing.
There are several ways of scoring. Onc is $t 0$ make exactly 31 points in the fewest possible throws, each pin knocked down scoring one. If 31 is exceeded the number scored in the last throw is not counted, and another throw is allowed. Another way of scoring is for the players, in turn, to throw at the pins and each one to knock over as many as
possible, the one with the highest score winning at the end of an agrced number winning at the end of an agreed number
of throws. A nother form of the game

Skye Terrier. An active long-coated little doz of affectionate and courageous disposition
dog, with a well-feathered tail, his other points are hidden by his long, hard upper coat, which is perfectly straight and falls to the ground or near it. The head is relatively large, but its form and the face are screcned by the long veil which parts only to reveal the black muzzle. The softly feathered cars may be either erect or drooping : the close-set hazel cyes are all but invisible under the veil. The colour should be either blue-grey-light or dark-or fawn with black points. The total length from muzzle to tip of tail is 40 in .; the height at shoulder is 9 in ., and the weight 18 lb . See Dog; Kennel.

SKYLIGHT. A window or sash fixed in a pitched roof for the purpose of lighting a
is to allow each player three successive throws, his aim being to knock down all the pins in as few throws as jossible. If he knocks down all the pins in one throw, he scores three points: if in two throws, he scores two points : and if in three throws, he scores one point. If the player fails to do this, he scores nothing. The scores are addled up at the end of the game, and the individual or the side with the most to his or their credit is the winner.

There are other skittle games. Some play with only four pins, one at each corner. In Dutch skittles, as it is called, the hall is bowled along the ground, not thrown, grooves being made in the floor for it to roll in. A round ball is used for this game, and the rule is that the centre pin must be knocked down first. This is sometimes known as the king pin, and is often distinguished from the others by its make or size.
SKULL CAP: The Plant. Thesc are uncommon plants of the sage family and hear somewhat helmet-shaped flowers in summer. They are 10 or $12 \mathrm{in}. \mathrm{high}$, for the rock garden or near the front of the flower borde:r. The botanical name is Scutellaria. Some of the chief hardy porennials are alpina, purple and yellow; albirla, white: and baicalensis, purple. Of the greenhouse kinds the best is Scutellaria mocciniana.

SKUNK: The Fur. The dark brown glossy fur known as skunk is obtained from an animal of the same name, closely allied to the otter and weascl. It is of remarkable durability, and is of a soft, thick texture. See Fur.
SKYETERRIER. Although it is naturally a sporting clog, the Skyc terrier as a domestic dog sliows strong affection, faithfulness and obedience. It has a quick ear and warlike readiness to mect anv intruder, large or small. A long-bodied, short-legged
room, passage, or space below is known as a skylight. It must not be confused with a lantern light, which is used chictly in conuexion with a flat roof. See Flashing.
SLAT. This is a name given to a long, narrow and thin piece of wood wider than a lath. The picces of wood forming a venetian blind are called slats, as well as the inovable or fixed strips of wood in an open window shutter. The name is given also to the picces of iron which are fitted from side to side and from end to end on the framework of a bedstead to support the mattress.

# Slates and Slating for Amateur Builders 

## A Practical and Economical Method of Roofing

Matters concerning the roofs of houses are dealt with under a variety of headings in this work, such including Corrugated Iron; Felt; Roof: Shingle; Thatching; Tile. See also Bungalow; Cottage; Girage; Housc; Scatrolding; and ihe articles on the various outbuildings

Slates are used extensively for covering the is used; if the slates are to be fixed on to roofs of buildings, and when properly laid they formi a gool covering, heing comparatively light in weight and ccorronical in use as compared with many other roofing materials, while their expansion is praçtically negligible. They resist fire well. and their power of absorption is not great, which is nn important consideration, because much wet absorbed on

a root means added weight. Good slates, as a rule, should not increase in weight more than $\frac{1}{2} 0$ during rainfall.

Slates are used more in towns than in rural areas, where tiles are often a local product. A roof covered with slates does not need such large timbers as one covered with tiles, and the roof need not be given such a steep pitch as $n$ tiled roof, which is an advantage economically. Slate used for roofing purposes is quarried principally in Wales, Lancashirc, or Cumberland, and is split into standard sizes.
The variet is most frequently used are Duchess, 24 ir . long and 12 in . wide : Countess, 20 in . long and 10 in . wide ; and Larlies, 16 in long and 8 in . wide. Allowing a 3 in . lap, it will talie approximately 122, 180,280 slates respcctively to cover one square, which consists of $100 \mathrm{sq} . \mathrm{ft}$. of roof area.

There are several nicthods of preparing a roof to receive the slates, the most inexpensive being to nail wood battens across the rafters to the required gange. as in Fig. 1. A better method is to cover the roof with boarding and then nail the slates direct on to the boards A more costly method is to board the rooi, cover it with tarred sheet felt, then nail the battens on to this, and fix the slates on to the battens.

Finding out the Gauge. It is first necessary to calculate the gauge, i.e. the width of slate exposed in the course. This depends to a certain extent on the kind of nailing that is to be used, that is, whether the slates are to be nailed at the top or in the centre. For example, if Duchess slates are to be used with head nailing, deduct from the length of the slate the lap (which is generally 3 in .) and 1 in . besides, divide the result by 2 , and that will be the gauge at which the slates are to bo laid, which in the above cxample will be 10 in. For centre nailing the length of the lap only will be deducted from the length of the slates so that the gauge would be $10 \frac{1}{2} \mathrm{in}$. Thus, a slightly bigger area is covercd when centre nailing

The slates may be fixed to the battens with copper, zinc, or composition nails; it is advisable not to use iron nails, hecause they will rust away and the slates wil! fall.

It is neces sary to board or batten the roof before slating is com menced. Bat tens are fixer at the gauge calculated, so that the centres of the battens are the gauge
is used; if the slates are to be fixed on to
battens, the latter, too, will be nailed to the rafters to suit the gauge.

The slates must have the holes punched into them, Fig. 2 The position of the nail hole has to be calculated as follows: Add to the gauge, previously ascertained, the cstimated lap, and to this add another $\frac{1}{2}$. making $13 \frac{1}{2}$ in. If the Duchess slate is used, that means the holes are punched $13 \frac{1}{2}$ in. from the bottom edge, or tail, of the slate. No matter what may be the size of slate, the method of cal-

## culation is the same

To facilitate the marking of the slates for ally to the holing, a simple gauge niay be made from a straight piece of batten to which a stop has been fixed at the proper distance from one end. The trimming of the slates when it becomes nccessary, and also the punching for nailing is carricd out by the use of very simple tools (Fig. 3). A cutting iron is fixed to a piece of timber on which to rest the slate. Another tool, the slater's axe, is like a chopper in appearance, but it has in addition to the chopping blade a spiked piece of metal. which is used for making the holes in the slates. In making the holes the slate should be struck from the under side. The top side, it will be noted, has the edges chamfered.
 proper length, which may be arrived at by adding the length of tho lap to that of the previously calculated gauge.

It is usual to fix under the first course of slates a tilting fillet, formed a piece of 3 in. by 1 in. stuff cut across the

Fig. 6. Slate rip. Fig. 7. How to remove old or broken slates with the tool shown above
forming one feather edge. This gives the slates a tilt so that their tails press on to it when they are securely nailed. Thus each successive course presses on to the former one, and the slates are kept firm and the roof sound.

The second course completely covers the slates that have been specially cut, the tails of the two courses keeping the same line. Great carc must be taken to see that the joints are broken, as in Fig. 5; straight joints will let the water in.

With the double caves courses fixed there need be no further difficulty. The slates have to be cut at the verge or outer edges of the roof, also to fit the hip or ralley should these occur in the roof to be covered. The successive courses of a simple job are illustrated in Fig. 5. It is good practice to put a tilting fillet against the side of any chimney or wall that the roof night butt up ngainst, as this helps to throw
distance apart. If boards arc used, the gauge is marked with a chalk line.

Laying the Slates. The most important point is to start the slating correctly. Slates are laid beginning at the caves, that is, the bottom colge of the roof. There must not be any straight joints, otherwise the rain will find its way througlı the roof. Experience has proved that it is necessary to have a double course at the caves, as in Fig. 4. The first course of caves tiles has to be cut speci-

Slating. Fig. 1. Beginning of slating. Fig. 2. Punching the holes. Fig. 3. Top, slater's axe, for trimming and making holes in the slate; bottom, cutting iron.

the water on to the wain roof. The ridge, valleys, and hips of a roof may he finished with lead, or with slates epecially formed for that purpose. These are bedded on to their positions by the use of cement mortar.

When, owing to breakage, slates have to be removed the tool known as a ripper (Fig. 6) is used. It is thrust up beneath the broken slate and the sharp hook-shaped blade brought against the nail so as to sever it aud free the slate. (Fig. 7).
Sledge Hammer. See Hammer ; Forging.
SLEEP: Its Value. When the body is rowing rapidly more sleep is required. A newborn child should slumber almost continuously for the lirst 6 days of its life, and up to the age of 10 years not less than 12 or 14 hours of s'cep are necessary every 24 hours. From 10 to 15 years, an allowance of 12 to 10 hours should be given and up to the age of 25 it is best to sleep at least 8 hours. After that age the miatter becomes a personal one.
Owing to the growing complexity and strain of morlern life slceplessncss has become a very prevalent disorder. In many cases the remedy is simple, and the hints given under the heading Insomnia will be helpful.

A common form of slecplessucss consists in waking unduly early in the morning. In such cases the sufferer should get up directly he wakes; the hour of awakening will soon become later. The importance of darkness and quiet is well known but it is equally necessary that any cause of irritation, such as a decaycd tooth or a blistered heel, should receive attention. The commonest cause of insomnia is the stomach. Excessive tea-drinking, hurried feeding, and late meals of indigestiblc food account for many a bad night, although no discomfort is present. Finally, never, without medical advice, should drugs for inducing sleep be taken
Sleeping Out of Doors. Many people, especially those who work indoors in large towns, realize the advantages of sleeping out of cloors, not mercly for an occasional camping holiday, but as a regular thing. Those who build their houses can plan for one or more sleeping porches opening from the upper lloor; but there are many simpler ways in which outdoor sleeping may be satisfactorily arranged in an ordinary back garden.

Waterproof shelter is essential, and aspect is important. Outdoor beds should be protected from the east, whence come the bitterest winds and the morning sun, which is apt to wake the sleepers unreasonably early in summer. With a south-west or west aspect the roof must project several fect beyond the foot of the bed, or rain will drive in. A veranda opening out from one of the sitting-rooms makes an ideal improvized sleeping porch, though if exposed to the rainy winds it may need a roof extension. The east or north-east side of an outdoor bedroom, if open, should be filled with glass, wood, or removable screens of canvas, according to the nature of the structure.

For comfortable and regular sleeping out proper bedstcads are essential, and can be moved out from the house. Naturally, expensive ones should stay indoors, the cheaper wooden, iron and camp beds being placed in sleeping shelters. For a veranda which is wanted in the daytime for lounging and afternoon tea, the best equipment is a camp bedstead or light make of divan bed supported on legs with castors.
In clamp weather the person who makes the beds should throw right over them camping ground-sheets, waterproof covers, or a collection of old mackintoshes, to keep out the moisture. Particular care should be taken that the pillow is well protected, though experience has proved that even those who sleep out in winter as well as summer suffer in no way from damp bedclothes. Besides being extremcly
pleasant regular outdoor slumbers have been proved to be particularly beneficial to nervy and anaemic people. See Hammock. In somnia; Nightmare; Slecpwalking

SLEEPING BAG. A sleeping bag is a useful article of equipment for cainpers out, yachtsmen, or even for those who slcep out in the garden during the summer, while for small children in their perambulators it is invaluable. The first type can be procured from most athletic outfitters. It may be made of fur, camel hair, or some waterproof material, and usually has a Hap which can be fastened down over the head of the occupant. This arrangement also enables the bag to be used as a valise when packing up for the next stage of the journcy.

All aḍequate slceping bag may be made by the simple expedient of folding a blanket in two and stitching it up at the side and one end. It is not necessary to cut the blanket for this, which means that it may serve its purpose as a bag for as long as it is nceded, and may then be unstitched, washed, and returned to its normal use. For this purpose handstitching is recommended as being easicr to unpick. The bag should be long enough to come well up to the slecper's armpits, and, if required for really cold weather, only the head should extend beyond the bag. Some people prefer to have the top foot or foot and a half left unstitched, so that they can move their arms frecly, or can turn the top edges down and over if they get too hot in the night.

SLEEPING DRAUGHT. A slceping draught may be prescribed and obtained from the chemist made up ready for use, or the hypnotic ingredient may be prescribed and directions given regarding the preparation of the draught. It is often advised to give the draught in hot milk or gruel, except in the case of an evil-tasting substance like paraldehyde. No patient should make up his own sleeping draught, nor should hypnotics be within his reach, as a patient desperate from sleeplessness might easily take an overdose. See Hypnotic , Insomnia.
SLEEPING SICKNESS. The disordered condition known as sleeping sickness is the last stage of trypanosomiasis, or infection with some trypanosoma. This is a protozoal parasite which first exists in the blood but later finds its way into the cerebro-spinal Huid. The disease is found in West and Central Africa and in Brazil, and is transmitted by various species of tsctse flies.

African sleeping sickness must not bc confused with encephalitis lethargica, the so-called slcepy sickness, outbreaks of which have been noted in Great Britain since 1918. See Encephalitis.

SLEEPWALKING. This troublesome habit is more common among children, and a.s a rule a child grows out of it; but in some cases it lasts on into adult life.
Sleepwalking resembles the hypnotic state The somnambulist has no recollection of what he does when he walks in his sleep. The sleeper gets out of bed and moves about. In most cases he merely gropes around the room, and, partially awaking, returns to bed. Sometimes, however, he leaves the room, and, in rare cases, gets out of the window.

Among the most common causes of sleep walking in children are over-pressure at school, and going to bed in a state of anxiety from this or another cause. Attention should be paid to the diet and to the bowels. These persons should not eat a heavy mcal just before going to bed, nor go with an empty stomach. If there is any costiveness, a dose of aperient medicine should be given. Exercise in the open air is very necessary. The bedelothes should be light, and the room well ventilated.

When a person is found walking in his sleep it is better not to awaken him, but to lead him
quietly back to bed. Danger in awakening a sleepwalker is largely a matter of where the sleeper happens to be at the moment of awaking. The bedroom door should be fixed so that it will not open sufficiently to let the slecpwalker pass through : the windows should be sccured in such a way that they will not open wide. A good p'an is to put a picce of cold ni!cloth at the side of the bed, which may awalien the alceper as be steps on it. When a child is much given to the practice it is always best to takc him to a doctor. See Sleep.

SLICE. This word is used for the silver or silver-plated knife or scrver with a thin broad blade that is employed for serving fish. It is also frequently used to describe the kitchen implement employed to lift fish fricd cggs, rissoles, etc. from the frying pan without risk of their breaking. Such a slice is usually of aluminium or enamelled metal and has a broad, thin blade perforated in order to allow surplus grease to escape back into the pan.

SLIPPERS. 'This term is now chiefly einployed for bedroom slippers, includin" heelless '.eather, felt, quilted satin, woollen and raffia woven footwear and also the types of bedroom slippers known as mocassins, silk or satin boudoir slippers with heels, and the mule, which is simply a toe cap of material attached to a heeled and padded sole. The main thing about this class of footwear is that they should slip on and off easily and be held in place without fastenings. See Mocassin
Slipperwort. This is the popular name of calccolaria (q.v.).
SLOE. This is the fruit of the blackthorn (Prunus communis), the progenitor of the garden plum. A double-flowered kind named spinosa is worth growing as an ornamental shrub.
Sloe Gin. This cordial can easily be made at home from the following recipe : To 1 pint slocs add I lb. sugar. Half fill a bottle with the sugared fruit and fill up with gin. If the slocs have been previously pricked, the liqueur should stand for 2 or 3 months before drinking, otherwise for 12 months. Properly matured sloe gin should be the colour of full-bodied port wine. A cocktail known as sloe gin rickey is made from $\frac{3}{4}$ gill sloc gin with ice and the juice of half a lime squeezed into it. Fill up the glass with cold soda' yater.
The following is another recipel: Take 3 lb . sloes, $\frac{1}{2}$ gallon unswectened gin,, $1 \frac{1}{2} / \mathrm{lb}$. Demerara sugar, and $\frac{1}{2}$ oz. bitter alnouds. Wipe and stalk the sloes, prick them well with a necdle in several places, and put them into a large ston jar. Add the gin and sugar and then the blanched and skinned almonds, cork the jar tightly, and then shake it vigorously. Shake it once daily for about 14 weeks, at the end of which time it may be strained and bottled for use.
SLOP BASIN. This is a basin placed on the table at breakfast and tea to receive the dregs from the cups. Slop basins are usually part of a breakfast and tea service.

SLOP PAIL. In bedrooms not fitted for running water, and where the ordinary toilet service is used, this may include a pail to match. Enamelled pails are used for the pur. pose of emptying slops. These pails are easily kept clean and are less fragile than china ones.

SLUG. This is one of the chief garden pests, and may do immense damage, especially among seedlings and young plants. It is invariably most troublesome in ill-cultivated land; soil which is kept in a good state of cultivation by digging, forking, and hoeing is not, as a rule, badly infested. This pest is most harmful in wet weather. It can be trapped by means of orange peel, bran, picecs of potato or carrot laid down on the soil, and examined frequently.

Scatterings of lime, soot and aluin are useful Ashes placed round about plants when fresh growth is pushing through the ground will often keep away slugs. Zinc collars pressed into the soil are used to protect choice rock garden plants.

The best remedy is to dissolve one pound of commercial aluminium sulphate in one gallon of water and a double handful of lime in four gallons of water. The two solutions are then thoroughly mixed together and applied to the soil infested by the pests.

SLUG WORM. Often called the slimy grub, this larvae of a species of sawfly is destructive to leaves of the pear, and sometimes: attacks the plum, peach, and cherry. The saw Hy itself is shining black with dusky wings, and the larvac a quite small slimy black slug with a large head. Eggs are dejosited on the upper surface of leaves during Junc, hatching ont late in the month with grubs that are white, then yellow, and finally covered with black slime. As soon as grubs are scen they should be given a dusting of powdered lime.

There is also the rose slug worm which restroys the upper skin of leaves, and these may be recognized by their colouring pale yellowish green, orange head, and dark marking down the bacli. Tiwo broods are produced, one in June and another in September, or earlier. The bushes should bo sprayed with hellebore wash or a nicotine insecticide. See Insecticidc.

SMALLPOX. One of the most contagious of all disenses is smallpox, or variola. It is an acute infections disease accompanied by fever and an cruption of papules or pimples on the skin which change into pustules and then into ocahs. The great prevent:ve is vaccination.

Smilax. Greenhouse plant, the long pracelul tendrils of which are much used for table decoration

When the discase breaks out among people who have not been vaccinated it is always vers destructive.
A smallpox patient is infectious from the onset of fever and other symptoms until convalescence. The most dangerous period is from the outbreak of the eruption until the scabs have dried up. The infectious material exists in the blood and secretions, in the exhalations from the lungs and skin, but chictly in the pustules. which dry and fall off in tine particles. It is thus possible to become infected in a railuay
carriage or any public vehicle or place of public resort. Overcrowding favours the spread of the diseasc, and so does had sanitation.

Mistalics are made in dingnosing smallpox because at the outset it often closely resembles chickenpox. If an epidemic is raging, smallpox may be strongly suspected when there are sudden severc pains in the head and back, with vomiting and bigh fever, following a shivering fit.

When an epidemic breaks out it is advisable that everyone should be vaccinated or revaccinated. Smallpox patients should be removed to special hospitals. See Vaccination.

SMELLING SALTS. The inlalation of ammonia has a stimulating effect of much use in the relief of faintness and headachc. The ammonia is derived from ammonium carbonate or from strong solution of ammonia, and the preparation is made agreeable by the addition of perfumes. Sometimes carbolic acid or cucalyptus oil is added to obtain an antiscptic cffect in influenza, common colds, hay fever, etc.
When liquid ammonia is used in the preparation it should be thoroughly soaked up by a piece of sponge, asbestos, or some other absorbent material, as the liquid, if spilt on some coloured fabrics, will stain them. The pungency of strong acetic acid serves the same purposes as smelling salts. See Acctic Acid; Fainting.

SMELT : The Fish. A small, delicately Havoured fish, the smelt needs to be cooked as soon as possible after it is caught. otherwise the Hesh loses its firm. ness. 'To clean it press ont the inside. through a slit made just below the gills, cut off the latter and then wash the fish quickly.

Frying is the usual method of cooking smelts, but they may also be stewerl, and in this form make a good dish. To fry them, clean and dry the fish,

when only the stitches that conncet the pleats can be seen on the right side, the rest of the stitch being run inside.

This form of work is always useful, as well as decorative, on children's clothes, and its popularity never dies out. It is particularly uscful on the wrists nad at the necks of frocks and of small boys' suits, as it is elastic and will stretch easily over the head and hands. Smocks are also excecdingly serviceable as overalls, and for gardening work, when made in holland, linen or heavy Shantung silk.

Methods of Working. Mercerized cottons may be emploved for smocking casement cloth and similar goods, embroidery cottons for mainsook and other white goods, linen cmbroidery threads for soft linens o.nd twisted cmbroidery silk on washing silks.

Smocking transiers can be bought at almost any fancywork shop, and these consist of shcets of paper with dots marked in transfer ink, which are transferred to the material by means of a hot iron. Thesc dots are spaced evenly, about $\frac{3}{i 8}$ in. apart, along the row and the rows ahout! in. apart. If a transfer is not at hand, a card with holes at the correct intervals through which the point of the pencil is inserted makes a permmisent marker. Before using either the transfor or a marker the minter:al should be stretched on a drawing. board and sccured with drawing pins.

To gnther, begin nt the top right-hand corner, and put a good knot at the end of the cotton; make n little backstiteh here to prevent the linnt from going through. These, gathering threads are drawn out after wards, as they only serve to hold the pleats together. Put the needle down through the material again half-way between the first and sccond dots, and out ngain at the sccond dot. 'This will resull in a flat stitch lying over the lirst half of the space between the first and second then coat then lightly with seasoned tlour. Brush over them a little beaten egg, woll them in breadcrumbs, and then fry them in a pan of smolinghot fat until they arc of a golden brown colour. Drain them on paper and then serve them hot, garnished with parsley and accompanied by plain white sauce.

For stewing, cut the heads off the fish and then lay the latter in a small fireproof dish containing enough white stock to cover thent. Add scasoning to taste, put on the cover of the dish, and cook the fish in the oven for about $\&$ hour. See Fish.

SMILAX. These are hardy and greenhousc evergreen climbing shrubs and plants. The long slender trails of smilax (Asparagus medcoloides), so much in demand by florists for decorntive purposes, is a greenbouse plant. It is easily grown from seed, planted in a compost of loam, leaf-mould and sand and trained on string or wires. Of the hardy kinds the chief one is aspera, a vigorous climber suitable for covering a rough fence.

SMOCKING: In Needlework. Smocking is formed by gathers which are drawn into vertical pleats by running gathering threads at certain distances from each other. The latter depend on the design, and arc used as guides for spacing, when the decorative part is begun. The stitches on the surfaec of the pleats are the ordinary sewing and embroidery stitches. They all appear on the surface of the work, except in honeycomb smocking,

Smocking. Fig. 1. Running the gathering threads along dotted lines. Fig. 2. Four different stitches insed, all worked from left to right
dots. Contidue this to the end of the row. Fig. I shows two gathering thrcads completed and the third row with the needle in position. Repeat this gathering thread on all the rows of dots. When they are all finished clraw up the top thread and secure the latter round the pin at the left side ns for ordinary gathering. Fig. 3 shows three of the pins with the cotton twisted round. After drawing up the top row stroke the pleats into position. Draw up, secure and stroke each row, when the work will be ready for the smocking stitches. When the work is bogun the threads can be released a little but must still be fastened round the pins while working. It is necessary to draw the pleats up tight at first to set them in an even position. Fig. 2 shows specimens of four differnnt stitches, from which many pretty designscan be formed.
The top row shows ordinary stem stitch completed and the second row the same stitch in progress, taking up the stitch on the top of a pleat, and bringing the needle out under the cotton. If the work is held sideways the thread is thrown over to the left of the ncedle. Note that the work procecds from left to right. The third row shows crewel outline stitch pleated and the fourth row crewel stitch in progress. The only difference is that the loop of thread is thrown over to the right in working and the needle comes out above the thread. The fifth row of the same figure shows alternate stitch, that is, outline stitch for the first stitch and stem stitch for the second one, repeating these two movements alternately across the row. The last row on the same figure is herringbone stitch, taking the first and second pleats together for the lirst top stitch, and the second and third pleats together for the next lower stitch; for the top part of the next cross take the third and fourth pleats together and continue across the row. For each new stitch take the second pleat of the last pair, together with a new pleat.
In the same way all the feather-stitching patterns can be carricd out in this work, and the 3 stitches in Fig. 2 oan be worked in zig\%ags or waves to form new designs. In Fig. 2 the gathering threads are fastened off at the back of the work for the purpose of illustration, but when they are cut out entirely the smocking expands, causing the pleats to stand up evenly and giving a much prettier effect. The cathering threads should not, however, be removed entirely until the work is completed.
Honeycomb Design. Fig. 3 shows the honeycomb design. After setting the pleats as described a bove, join the thread to the top lefthand pleat, as the work proceeds from left to right, and take a stitch through the second and lirst pleats. Insert the needle in the scoond pleat just where the last stitch was macle, slip the needle down unter the pleat and bring it out on the second line of dots for the big honeycomb or halfway betwcen the two lines for the smaller honeycomb.
'I'be two sizes are illustrated on Fig. 3. This long stitch running through the pleat must be entirely hidden. Take a back-stitch through the third and second pleats, slip the needle under the third pleat and bring it out on the lirst running line again. Take a stitch through the fourth and third pleats, and slip the necdle down through the last pleat to the second line once again. Reference to Fig. 3

broidery stitches. See Embroidery; Feather Stitch Herring-bone Stitch
SMOKE TREE. Smoke tree is the common name for Rhus cotinoides, a hardy rleciduous shrub, otherwise called sumach. It is suitable for the mixed shrubbery or for the lawn, and bears foliage which assumes a rich orange-crimson shade in autumn. There is a similar species, cotinus, known as the smoke bush. and this is perhaps more beantiful. The smoke tree should be planted in good ordinary soil during autumn, and increased by layerings or cuttings of ripened shoots during the sainc period. See Rhus.
SMOKE WOOD. This is another name for Clematis vitalba, the Traveller's Joy of chalky lands and hedgerows. While it is uscful for covering old tree-stumps, banks, and trellises, and is popular on account of its feathery, smoke grey seed heads, its main use is as a stock on which can be grafted choicer kinds of clematis (q.v.).

SMOKING. There are no certain rules as to the quantity of tobacco that should be consumed in a day or a week, as this naturally depends on the individual smoker. Factors to be reckoned with are the condition of his heart, nerves, and digestive organs, the nature of his occupation and the amount of physical exercise, particularly open-air exercisc, which he or she is in the habit of taking. Generally speaking, a fair average for a pipe sinoker is 4 oz. a week: many are satisfied with less.

Where smoking is indulged in to excess, it is most frequently in the form of cigarettes, and if inhaling is practised at the same time the danger to health is very real. Those who suffer from anaemia should be very careful to smoke in moderation, and to avoid inhaling, and if there is any weakness of the heart unlimited cigarette smoking will cause trouble. Cigarettes oller the cheapest form of smoking to those who strictly limit the number they consume in a day, and it is a wise plan to do so.
Strong tobacco may contain as much as 9 per cent of nicotine, but the amount is usually less, and in a mild mixture it may be as low as 2 per cent A person can only judge whether he is smoking too much ly the effects produced. These are indigestion, generally acid indigestion with llatulence: reduced appetite, more or less mental depression, some reduction of the muscular strength and more fatigue than should be after exertion, and perhaps dimness of sight. Sore throat (smoker's throat.), with huskiness of voice and a short irritable cough, is not infrequent.

If the tongue becomes sorc, or the heart palpitates, cease smoking for a time. These are
danger signals that should not be disregarded, and any dimming of the sight is another. People who should not smoke at all are those whose heart or nerves are weak, sufferers from relaxed throat, or a tendency to bronchitis or consumption. Smoking is specially injurious to growing lads.

All smokers should be carcful to wash the tecth morning and night. The tobacco poison clings for a long time to the mouth, and if one goes to slecp without removing it he will swallow some portion of it in the night. The best mouth-cleanser for smokers is water in which bicarbonate of soda has been dissolved, the proportion being a teaspoonful to the pint.

Smoker's Heart. Nicotine in excessive quantities acts as a heart poison, and anyone who smokes immoderately may suffer from unpleasant symptoms.

In extreme cases the action of the heart becomes irregular, attacks of palpitation occur, there is giddiness, and in pronounced cases actually fainting. If the smoking be stopped the heart recovers very quickly, as a rule in a few weeks' time. No other treatment is required in the great majority of cases.

Smoker's Throat. A chronic state of inHam mation of the pharynx, though not very severe, caused by the excessive use of tobacco, is sometimes called smoker's throat. Some forms of tobacco are more irritating than others. Pipc smoking is thought to be chiefly liable to produce it.

The symptoms are a husky voice, frequent hawking, and very often a short cough. The only cure is a reduction of the amount of tobacco consumed. Before going to bed every smoker should gargle the mouth and throat with a solution of bicarbonate of soda in water $\frac{1}{2}$ teaspoonful to $\frac{1}{2}$ pint. See Nicotine; Pipe: Throat.
SMOKING: Of Meat. Whilst meat and fish may be cured by being nerely dried after salting, they possess a superior flavour if the drying is supplemented by smoking them in the fumes from a wood fire. The best results are obtained by burning green birch, beech, or oak wood, oak sawdust or broom tops. Occasionally juniper wood is employed to impart a special aromatic flavour to hams and bacon.

When meat is to be smoked it must be well dried after removal from the pickle, by hanging it in a cool, well-ventilated place; there should be plenty of air, but no direct draught on the food. Salmon is sometimes pickled with a mixture of saltpetre, bay salt and coarse brown sugar before bcing smoked, but after pickling it must be rubbed with common salt and then dried. Haddocks and herrings are merely salted and dried before being exposed to the smoke.

The smoking of butcher's meat or bacon is usually done in places constructed especially for the purpose, but it is possible to smoke sinall hams and portions of bacon at home if a wood fire inay safely be built on the stone or brick Hoor of an outhouse. The meat should be suspended sulficiently high above the fire to smoke without getting cooked. Ham and bacon take from 10 days to 1 month to be properly smoked.
Fish is easier to manage, as the curing may be accomplished in about 12 hours after exposure to the wood smoke. To sinoke small fish a tank or cask with both ends open may be turned on end on the brick floor of an out house and a good layer of sawdust placed inside. Into the sawclust a red-hot iron should be inserted. The fish should then be slung on an iron rod across the top of the cask and smoked in the fumes.

SMOKING ROOM. In many modern houses where smoking is allowed in every room there is no special smoking room.

Where a sitting-room is reserved for this purpose, the chief characteristics should bc cosiness.

Rugs may be preferred to carpets as they can he taken up and shaken frequently to rid then of tobacco ash. Suitable materials for upholstery would he leather, oil baize, or mohair. A wide, deeply padded angle seat covered with some dark material-narrow striped or plaid effects are good, the stripes toning with the colours in the rugs-and a few large, plainly piped cushions to match, make a cosy treatment for a warm corner.
Smokers' tables should be solidiy made: they stand more firmly, and are more useful if shelved after the fashion of a hook table fitted with small cupboard sections. cupboard or cabinet for drinks and glassesin a panelled room this cupboard might be built in-a card table Hat-topped writing desk, four small chairs of solid make and a bookcasc or shelves according to requirements would complete the necessary furnishing. Lights should be sharled, and reading lamps are essential. Pictures are usually confined to a few etchings, engravings and sporting prints.

SMOOTHING: In Wireless. This is the procese of converting pulsating unidirectional currents to pure D.C. suitable for applying to the anodes of wireless receiving valves.

In an A.C. mains eliminator the rectified currents although, unidirectional are not free from ripple. These currents are therefore passed through a smoothing circuit, comprising a combination of inductances and condensers, which eliminates the ripple.

Direct current mains supply has to be treated in a similar manner before the current can be used for high tension supply in a wireless recciver. See Eliminator.

SMOOTHING PLANE. The most usual type is about 8 in . long, which is enough for ordinary finishing purposes. The methorl of assembling and adjusting is much the same as for a jack plane, excejt that to loosen the plane iron the back of the plane is tapped with a hammer or mallet. No handle is required. The plane is graspel at tho back with the right hand: the left hand is placed on the front, and is used at the end of the stroke to pull out long shavings. See Plane.

SNAIL: In the Garden. As a rule snails like green diet, i.e. living plants of all kinds, and are therefore enemies to the gardener. They usually feed at night or at dusk, but in damp weather, or after heavy rain, they may be found in numbers in the duvtime.

Dry dressings of any irritant may be tried to kill them. Of these the hest is a mixture of lime and caustic soda, 4 parts of caustio soda to 96 of lime, well mixed. Other dressings are soot and lime. salt and lime, ant powdered coke. Two or three dress ings sliould be given, the second some 15 or 30 min . after the first. These dry dressings, except powdcred coke, should be applied atter sunset, or clse very early in the morning. Sep Jime; Slug.

SNAKE ROOT. The snake root is an attractive hardyherhaceous yerennial. It grows 3 ft . or so high, and in July and August hears small white Howers on long, graceful stems. They Hourish in ordinary well cultivated land, do not mind slight sharde, and are increased by division in autumn. The best are simplex, japonica and racemosa. The botanical name of snake root is Cimicifnga.

SNAKE'S HEAD. This is the popular the players are under contract to make name of one of the fritillaries (Fritillaria each other laugh, to which end they may meleagris), a charming spring bulh with do anything except speak. In this way the beautifully chequered Howers. Sce Fritillary. player with the most mobile face stands
SNAP: The Card Game. This popular indoor game is played with specially preparcd packs of cards. These are of various sizes, but the general principle is that they shall be in fours, each four bearing the same fig口
special number of players is necesspecial number of players is neces-
sary. Two can play, hut it is better to liave four, five, or six. The cards having heen dealt, the players, holding them face downward in their hands, play in turn. Each places his played cards face upward on a heap in front of him. When two
similar cards are exposed together any player can call smap, and the one who calls first obitains all the cards which lie beneath the two snapped ones. So the game continues until one plaver has secured all the cards.

In case a player calls snap when there is nothing to snap on the table, the cards in front of him go to a pool. There they lie until a card similar to the one on the top thereof is exposed, whereupon, if a player calls snap pool, he receives those in the pool. Special paclis of cards may be bought for this game, or it may be played

Snapshat. Fig. 1. Exposure meter for giving reliable indication whetber light is strong enough for a anapshot with ordinary playing

SNAPDRAGON: The Plant. This is the popular name of antirrhinum (q.v.), a the popular name of antirrhinum (q.v.), a
favourite garden fower grown in British gardens in quantities for summer bedding.
 SNAPSHOT : In Photography. Snapshots may be deacribed as amateur photographs of the more or less limited kind that are possible to the owner of an inexpensive hand camera with only one shutter speed. This is usually about 1-30th sec., though often marlied, if marked at all, as 1-25̃th sec. It is possible, of course, to take snapshots with any camera that has a shutter working at one or more speeds in addition to time exposures, but the beginner in photography is generally limited to snapshots.

So long as the light is strong enough to give a fully exposed film or plate with an exposure of 1-30th sec., the amateur will have little difticulty on this score, but it is essential that he should recognize clearly this limitation. Ony a proportion of subjects which the amateur usually wants to photograph are sufficicards. The former include cards made with ently well lighted to give good bright prints and are usually more popular with children with moderately good lenses, although the than ordinary packs. They have an added faster films available permit somewhat wider advantage in that they save a good pack of playing cards from the rough usage which is almost inevitable in this game. If an ordinary pack is used the snapping will be between cards of the same value; for instance, one two and another, one king and another, and so on. If a more complicated game is required the snapping may be from one to two, two to three, and so on.

The game can be played without any calling of snap. In this case a small object-say, a shell-is placed in the centre of the table and, instead of calling snap, the player places his hand on this. This prevents any doubt as to the winner. In calling it may be difficult to say who called tirst, but only one hand can touch the shelf at once.

Animal Grab. There are some amusing variants of the game, among which may be mentioned animal grab and grimace snap. In the former each player chooses to be some animal with a distinctive cry, e.g. a dog, cat, pig. When two players turn up similar cards, instead of saying smap, each has to make the noise of the other person, and the one who achieves it first wins the cards. As the tendency witl most people is to make their own noise, while scarching vainly in their memory for the one belonging to the other person, the effect is usually very ludicrous.
Grimace snap is extremely simple. Instead of snapping.
latitude in exposure.

With a camera whose lens worlss at about f/11, sunshine, or sunlight with very thin clouds, in the summer is essential to good results. Winter or carly spring sunshine is deceptively hright, as a test with an expozure meter will demonstrate. If the lens is marlied $\mathrm{f} / 8$, bright midday winter sunshine or slightly dulled summer light will give reasonably good results. As the strength of the light is the prime factor in snapshot photographs, the amateur will he well advised to purchase an exposure meter.

The Watkins Fall Meter (Fig. 1), for roll films and other cameras, is inexpensive, and indicates by a simple test whether the light is strong enough for a snapshot. It is supplied with special dials suitable for particular Korlak and other cameras. If the metar shows that the light is too weak, it is a waste of film to attempt a snapshot. The Fall exposure meter is a modification of the general Watkins' meter shown in page 440 . Full instructions for its use are given with the meter.

In snapshot work it is often of importance to know or he able to calculate the speed of moving objects in order to estimate the maximum exposure possible without showing move. ment or hlur in the negative.

Novement relative to the camera's focussing screen is the fundamental consideration. If the object is approaching the camera from the front the movement of the image on the screen will be small relative to the actual movement of the object, while the image movement will increase in proportion to the angle that the object makes with the camera, the maximum obviously being when the object is moving straight across the front of the camera.
Thus it will often be possible to secure a good snapshot of a moving object if the photographer can get into a position at a small

30 ft . per sec. The canmera being at $\mathrm{B}, 50 \mathrm{ft}$. away, the longest exposure possible with a V.P.K. if movement is not to show, is $1-100$ th sec . With the camera at C it would be, roughly about 1.50 th sec. while at $D$, an exposure of 1-251 1 sec. might give rood results

As a basis of calculations of this sort it is to be assumed that during the exposure the image must not move morethan 1-100th in. on the focussing screen if it is not to show blur in the negative. For a lens of in. focus which may be taken as the distance between lens and focussing screen an object 100 ft . from the camera is 200 times the distance from the lens that the image of it on the focussing screen is from the lens, 100 ft . being 200 times 6 in.
Therefore a movement of 1-100th in seen on the focussing screen is equal to an actual movement of the object of 2 in . and this is the maximum movement permissible during the time the shutter is open. Thus we can calculate maximum length of the exposure. At 20 miles per hour the object, say, a inotor car would move about 30 ft . in 1 sec ., or 360 in . As it must not move more than 2 in . during the exposure, the time is $2-360$ th or I-1s0th sec

As the onger the focal length of the lens the larger the image on the screen, and the greater its movement, a short focus lens such as is usually found on shapshot cameras will permit longer exposures. With a small camera of the vest pocket Kodak type where the distance between lens and film is about 3 in., the exposure in the example given will be doubled, i.e. 1-90th sec., or, to be safer, 1-100th scc. These calcu'ations assume that the object is moving across the line of vision, i.e. at right angles to the camera. If other positions can be taken up, as indicated in Fig. 2, the exposure times will be reluced accorlingly.
Mr. Walter Kilbey in his book "Advanced Hand Camera Work " gives the following exposures for certain types of moving objects. With a lens of 5 in . or 6 in . focus the objects being not less than 20 ft . from the camera, for groups standing in the street, childien at quiet play, ete. $1-50$ th sec.; for children actively at play, athletics and less rapid sports 1-200th to $1-600$ th sec.; for rapid games, cycling, racing, horse jumping, 1-500th to l-800th sec.; for divers, football, etc. $1-700$ th to $1-1000 \mathrm{th}$ sec.

The exposures given are of course the maximum possible if movement is not to show and have no relation at all to the aperture of the lens, the strength of the light or the speed of the plate or film. If the camera lens is not fast enough, i.e. of sufficiently large an aperture, for the strength of light on a particular occasion, or the speed of the plate, then a snapishot is hopeless, hecause exposure will be insufficient in order to give a properly exposed negative.

## Sneezewort. See Helcnium.

SNEEZING. The process of sneezing is a provision of nature by which irritating substances are expelled from the upper air passages. Ordinary causes are the presence of irritating matters, such as snutf, pepper,
$\qquad$

53 ft .

angle with it. ln the diagram (Fig. 2) the dust, etc., in the air passages. In hay fever moving object, A , is supposed to be a motor the pollen of grasses produces violent and car travelling at 20 miles per hour, or about distressing sneering.

Sneczing is one of the earliest symptoms of
a cold in the head, of influenza, incasles, and
 When the affection is troublesome and prolonged, it may often be stopped by smelling camphor, sniffing menthol snuff, or fine powder of bismuth carbonate. Pressing the tip of the longue against the back of the central upper teeth sometimes arrests sucezing. This smallish bird is in scason from October or November up to the following liebruary. bird is young, the fcet should be examined, and if these are not soft and tender the bird is old The long bill also will indicate whether the snipe has been liept too long, as it must not be moist. Like many small birds, snipe is best when dressed without removing the trails, but the gizzard should always be taken away before the bird is cooked. It is trussed with the head left on, and when it is plucked the head and neck feathers should be carefully removed, also the eyes must be picked out. The snipe is then singed and trussed.
'To truss snipe, cut off the claws and then twist the legs so as to force the fect behind the thighs. Then run the sharp bill through the thighs and body as if it were a skewer. Pasten a noose of string round the bend of the leg joints, across the lower part of the breast; then bring both ends up to the head, pass round that and the tip of the bill and tic at the back. Cross the fect. Cover each bird with a slice of fat bacon tied on with string, and roast as described under the general heading Game in this work.
Snipe Pie Prepare 4 to 6 snipe and cut them in halres. Chop very finc $\frac{3}{4} \mathrm{lb}$. rump steak and 6 oz . fat bacon, and pass twice through a mincer. Crcam 3 oz. butter, season it, add teaspoonful grated nutmeg, the juice of half a lemon, and the same of orange. Work in 3 oz . line breadcrumbs and 2 yolks of egg. Mix in with these the meat and bacon, and moisten to a paste with white wine. Make this forcemeat into balls. Lay at the bottom of a pie-dish $\frac{1}{2} \mathrm{Ib}$. rump steak and $\frac{1}{1} \mathrm{lb}$. bacon cut in strips and rolled; lay on these the portions of snipe, with the forcemeat balls arranged between. Season well, and threcparts till the dish with stock. Cover over with good rough puff pastry, glaze, and bake $1 \frac{1}{2}$ hours.

Snipe Pudding Make a good crust with kidney suct and tine llour well salted, then prepare 4 snipe and cut in halves. Reserve the livers and the trails. Sprinkle a little lemon juice over the birds and season them with salt and cayenne pepper. Peel and slice a Spanish onion, and try it a light fawn in 2 oz. butter: stir in 1 oz . Hour,
hay fever. If measures be taken against a cold in the head as soon as sneezing occurs, further development mav be prevented.

SNIPE : How to Cook.

To find out whether the
lb . prepared and chopped mushrooms, 1 teaspoonful sifted swect herbs, $\frac{1}{\frac{1}{2}}$ of a chive (chopped), a good pinch of grated nutmeg and seasoning to taste.

Stir all the ingredients in the pan for 2 min ., then add $\frac{1}{2}$ pint of well llavoured stock to which 2 wincglasses white wine have been added. Simmer over the fire for 10 min., then add the liver and the trails. Pass the contents of the pan through a wire sieve into a basin. Line a pudding-basin with the suet crust, add the snipe and the puree, and a !ittle more liquor if needed. Put a lid of paste over the pudding, tie it up and steam for $1 \frac{3}{4}$ hours. The paste for this pudding must not be very thick. The pudding can also be boiled. See Game ; Pastry ; Suet Crust.
SNOOKER POOL. This game is played on an ordinary billiard table. It can be played by two or more persons, either as sides or independently, and is a game consisting of winning hazards, cannons being ignored.

The game is played with 22 balls which are placed on the table in the following fashion: Fifteen red ones are in the form of a triangle, the ball at the apex being on the pyramid spot, and the base being purallel with, and nearest to, the top cushion. Black is on the billiard spot; pink on the centre line of the table, touching the apex ball of the pyramid; blue on the centre spot, brown on the middle of the baulk line; green on the left, and yellow on the right hand corner of the $D$. The remaining ball is the white or cue ball. The values of the balls are: red 1 , yellow 2, green 3, brown 4, blue 5, pink 6, and black 7 .
Having arranged what number of points shall make a game, the players must decide upon the order of play. The lirst player must play from hand with the cue ball. This must strike a red ball, and if one or more of the red balls are pocketed the player scores for each one, and continues his break until he fails to score. At his second turn he must strike one of the pool balls, these being the balls that are not red, and the game is continued by pocketing reds and pool balls alternately.

If the striker fails to score, the player next in turn plays from where the cue ball rests. If the cue ball is pocketed or forced off the table, the next player plays from hand. Each pool ball pocketed or forced off the table must be respotted before the next stroke. It should be noted that un!ike the reds, two pool balls must not be pocketed by the same stroke, nor must they be struck sitnultancously. See Billiards ; Pool.

SNORING. The usual cause of snoring is sleeping with the mouth open, particularly when lying on the back. It results from the Happing of the soft palate between two cur rents of air, one through
 position of snow guard ( 2 ) the mouth and the other cure is to lieep the mouth closed and to sleep on the right or left side ; perseverance is necessary.

In some cases the mouthbreathing which provokes snoring is due to an inflamed and thickened state of the mucous membrane lining the nose, due to chronic catarrh, which must of course be dealt with. Snoring in children is a very common result of adenoids. Sce Adenoids; Breathing.

SNOW. A fall of snow, especially if it should be heavy or continuous, will cause considerable damage to a house unless prompt measures are taken to deal with it. These include

clearing it away trom porch, steps, and paths; preventing it from stopping up gutters and falling on to low roofs and glass roofs. Newly fallon snow can gencrally be brushed away with a stilf broom, but if it has been allowed to get hard, use a spade or some form of scraper. A liberal application of salt is sometimes used to loosen hardened snow, but care must be taken to remove the whole, or a surface of icy smoothness may form instead.
Snow Guards For the protection of low roofs or glass structures adjoining high ones. it is usual to provide a rack, or snow guard. This consists of a wooden rack or wire guard fixed at the edge of the roof. The guard supports the snow and prevents the guttering on the eaves from becoming elogged. It is necessary to provide very strong supporting brackets. The iron brackets should be at least $1 \frac{1}{4} \mathrm{in}$. by $\frac{5}{16} \mathrm{in}$. in section, and although the single supjort, if placed at frequent intervals, will generally be sufficient, high roofs overhanging a greenhouse or a conser vatory should be strengthened with iron brackets as inclicated by dotted lines in the diagran..
The height of the snow guarll need not bemore than from 6 to 10 in ., but the latiens nust be securely bolted on the brackets and the whole structure prainted to prescrve it If the wooden guard is considered unsightly and wire guards are desired, they should be male from a stout gauge inaterial and sup. ported at more frequent intervals than in this case of wooden ones. If the wire is galvanizel after it is made up it will be more churable.
Snow Ball Tree. This is a nother name for the gucilder rose (q.v.).
SNOWBERRY TREE. This name is given to a vigorous bush which bears attractive white fruits in autumn (syinphoricarpus). It thrives in ordinary soil even in shady places. The locst liinds are racenosus and mollis.
SNOW BLINDNESS. Long exposure of the eyes to the glaring light of snow causes inflammation of the conjunctiva. There is a gritty fecling in the eyc, which begins to water, and there is difficulty in keeping the eyes open from the painful effect of light on them, more especially a bright light. The condition can be prevented by the use of smoked glasses.
SNOWDROP. This is onc of the carlicst spring tlower:ing bulbs. It looks best when planted freely in grass. The bulbs should be
set 3 or 4 in. deep in August-September, they flourish in ordinary soil, particularly that of a loamy character. The common snowdrop is Galanthus nivalis; others with la:ger hlooms are Elwesii, byzantinus and plicatus. Snowdrops may be grown in pots in the unheated greenhouse or in bowls of fibre indoors.

SNOWDROP TREE. This is a small family of hardy flowering trees belonging to the genus Ha!esia, and also known as the silver bell tree (!.v.).

SNOWFLAKE : The Flower. The snowllake is a beautiful spring and early summerllowering bult, with drooping, white, greenlipped flowers. It lhrives in ordinary soil and should be planted in September, 3 in. deep. preferably in the rock garden. The spring snowtlake, Lcucojum veruam, is 6 in . or so high; the summer snowflake (aestivum) reacher a height of 18 in . Onc named autumnale has white Howers slightly tinged with rose in early autumn. Snowllakes do not usually bloom freely until well established.

SNOW FLY. This tiny pest, often dexeribel as the ghost Hy, is destruetive to greenhouse plants, particularly tomatoes. The Hy multiplics with great rapidity, erippling folinge by sucking its sap. If dis turbed the tlies aseend in cloudlike swarnis. For aniateurs, the liest remedy is two or three fumigations with a good nicotinc pio. paration, thr first to kili mature flies. and others succersively about threeweeks later. White-fly vapour is и pro.
 prictary preparation that is also used. Sce Insceticide: Spraying.

SNUFF. l'irst said to have been used to ward olf infectious diseases, snuff came into fashion as a sternutatory in the 18th century, a pinch being taken or sulifed into the nose and causing sneezing. As tobacco smoking came more and more in to vogue, the practice
 Their shnpies are often very odd, resembling hoats, tiddles, books and animals. The snuli hoxes lecorated with plaiels in imitntion of the Highland tartans are freguently met with. An example of onc, lating from late ISth eentury, is shown in Fig. 3. Boxes of papier mâché were in common use in the late 18th and early 19th

Snuff Box. Fig. 1. Napoleonic example with embosses wedaution. Fig. 2. Georgian painted box. Fig. 3. Scottish snuff box of the Georgian period. Fig. 4. Box of chased and engraved silver : 19th century Figs 1.3. courlesy of Fribourg \& Treyer
century in England. They are often decorated with mother-of-pearl or Chinese characters in gold and black, or are made to imitate tortoiscshell.
Silver hoxes were fashioned in a variety of shapes and with different styles or ornamentation. The specimen illustrated in Fig. 4 shows a well known type in use through a great part of the 19th century.

SNUFFERS. A pair of snuffers consists of a pair of scissors with a closed box to hold the charred wiek which is cut off. Many of them have three small feet to enable then to stand on a specially shaped tray which often accomprnied the sulfers. They were made in silver, Sheffield plate, brass, and also in plated metal and iron.

Some beautiful examples of snuffers, with trays to match, the trays being piercerl and chascd, date from the early 18 th century. Snutfers are a useful accessory in a modern home if wax candles are employed to light the dining table. See Brass.

SOAKAWAY. A soakaway is a looscly filled cavity in the carth adapted to receive rain or surface water and allow it to percolate into the ground. It is useful in manv gardens and in the vicinity of houses and outbmildings. The water is lirst collected and delivered to the soakaway through pipes, a channel, or some similar systen, which may include the ordinary form of trapped gully. It is most conveniently located immediately bencath the delivering pipe. The size of the soakaway will depend upon the quantity

## Soap and ITs Various Grades

## For Household, Laundry and Toilet Purposes

Reference is suggested to the artic!es on Baby; Bcauty Culture; Face; Hair; Shampoo and also to the many entries that deal with cleansing processes, e.g. Laundry; Spring Cleaning: Washing Up

The quality of soap is an important matter,
whether for houschold or toilet use, and though whether for houschold or toilet use, and though ingredients vary in ditferent soaps, according
to the purpose for which they arc required, they should be free from adulteration.
A good scrubbing soap for household use is light in colour and has a fresh, pleasant odour when pure fat has been uscd in its manufacturc. Extra soda in its composition is an advantage, because it cuts and extracts dirt and grease. Resin is present in yellow bar soaps; a small quantity as an ingredient produces a good lather and gives the soap a clean scent. In large quantity it is an adulterant to weight cheap soaps, and its stickiness prevents the soap from being a good cleansing agent. The darker in colour a bar soap is the lower the grale.

Wrapper soaps sold in bar's of two stamped tablets are free lathuring with a small proportion of resin. Disinfectant houschold soaps to which tar acids are alded are strongly alkaline and only suitable for occasional floor scrubbing or for outhouses, etc.
It is economy to buy household bar soaps in quantity and stock them, as if thoroughly dry before use they last longer. Any scraps cain be saved and put into a large carthenware jar and covered with water. As the soap jelly which forms is used, more scraps and water are arlded. Where there is much scrubbing to do one tablet of household soap dissolved in three quarls of water makes a satisfactory soapsuds solution.
Soap powders make a good lather. They are uscful for washing down paint, and the result is good if care be taken to sponge the soap off at once with clean water. Soap powders are not economical when sold at the price of soap. They contain very little fat, which is the expensive ingredient, and a great deal of soda, which is comparatively cheap.
Laundry Soaps. Laundry soap should be
of water of which it has to dispose. A convenient size is an excavation in the earth to a deptl of about 6 ft ., making the aperture alout 3 ft . square.
In the case of good, solid carth the walls can be left in their natural state, but should preferably be cut or sided to a vertical face. The space is filled at the bottom with gravel, broken brick, clinker, or other hard core well rammed and consolidated. The whole of the cavity to a depth of about 4 ft . is filled with similar material, the top surface being covercd with gravel to the level of the inlet pipe, which should normally be some 12 to 15 in . below the level of the ground. Large pieces of stone, broken brick, or similar material should be placed on the top of the gravel to allow the water to discharge freely from the pipe. The filling is continued on the top of this layer and the whole covered with soil and turfed or otherwise finished.
In the case of very light soil it may be necessary to erect temporary shutlering, wooden supports, or even to line the walls with concrete. If this is done, apertures must be left to allow the water to comc through, especially in the lower part of the soakaway. Such holes can casily be cast by inserting short lengths of agricultural drain pipes prior to pouring the cement between the shuttering.
Where two or more soakaways are arranged in series, to handle a larger volume of water, the first should be filled with coarse material and the others with finer materials. See Drainage.
and terebene (turpentinc) soaps are also used in certain cases, as, for instance, after infectious fevers, for their antiseptic effects.

Soaps are also made containing resorcin, salicylic acid, ichthyol, and many other drugs. In acute eczema, or whenever the skin is greatly inflamed, soap of any kind is exceedingly irritating, and should not be used. The skin can be cleansed by rubbing olive oil on a soft cloth and wiping it off with a dry cloth. Special soaps for washing dogs contain either sulphur or creosote.

Toilet Soaps. As only the highest grades of fat and oil should be used in a supermilled toilet soap, it cannot be bought at a cheap price. Too much caustic soda added to the fats causes the soap to be too free in alkali, which has an irritating effect on delicate skin. On the other hand, soap is cleansing to the skin by virtue of the alkali it contains. When rubberl on the skin a little of the soda separates and unites with the grease of the skin; at the sainc time it softens the superficial waste layers of the skin and allows of their removal by water.
It is important, thercfore, that the fatty acids and alkali contained in a toilet soap, should neutralize each other. Too much alkali can be detected by a simple litmus test. Having anclted a small piece of soap in water and added a few drops of litmus, the colour should be mauve if the soap be properly neutralized; if free alkali be present the colour will be blue. Super-fatted soaps may contain glycerin or an excess of fat and oil, in which case they should not be stored for long as they may become rancid.

First-class toilet soaps are hard, highly polished, denoting the linest texture, and of a pale colour.

English soaps of this quality are unexcelled as complexion soaps. Strong perfumes are only desirable in the best quality of soap, as essential flower oils, balsams and animal scents such as ambergris. musk and civet are costly. Synthetic perfumes and substitutes are used in the cheaper qualitics. Dark colouring nifen disguises a poor grade of fint. The presence of too much coconut oil though a small amount is necessary to obtain a free lather, has an irritating effect on the skin and necessitates the use of a coarse perfume to disguise the strong odour.

The addition of resin in the composition of bath tablets increases their lathering quality, but these soaps should not be used for small children or for the face. Honey soap, which is ycllow soap of a good quality, coloured and perfumed, and curd soaps are suitable for the bath, but are too strong in alkali for complexion soaps. Palm oil is used as an ingredient for cheaper violet soaps as it has the odour of violets.

Soaps having a good proportion of pure olive oil in their composition are the best for a baby's skin. If a child's face is shiny or rough after washing, the soap is too harsh or has been rublied on in excess. Pure whit. Castile soap is usually a satisfactory choice.
Shaving soap should lather freely with a softening effect on the beard, and no irritating effect on the skin. Caustic alkali should not be present or any excess of coconut oil, though some is necessary for free lathering. A creamy lather may be induced by paraffin wax or gum tragacanth, and a considerable amount of superfalting makes it more emollient.
Soap Bubbles. Soap bubbles provide children with an amusement which seldom palls either in the nursery or out of doors. If played in the garden they are usially in even greater joy, because there is more room for the sport, and sun and foliage enhance the colouring of the bubbles. Clay pipes, with the ends well sealing-waxed, are the best implements for blowing bubbles, and the supply should be liberal, as they are very
brittie. The soapy water should be warm und the lather is best made with soap flakes or soft soap.

The pipe should be put into the water with the low downwards. If it is shaken gently up and down once or twice in this position cnough of the water will have been collected to form a goo! bubble without a lot of unnecessary tluid. Each player will have his own methods and fancies; one may set out to blow verv large bubbles without releasing them and letting them liont in the air; another may like 10 blow many small ones and allow them to form a fleet.

SOAPWORT. This group of hardy annual and peremial plants bears rose-coloured Howers in summer. Of the perennials Saponaria ocymoides is a charming trailing plant for the rock garden: another good rock garden plant is cuespitosa. Both flouriah in well-irained rockery soil. A taller kind, which grows from 18 to 20 in . high, and has double rose-coloured blooms in summer, is all attractive border plant. The best of

Soapwort. Prolusion of pink blossoms of the small
species boissieri, a useful rock garden plant
the annuals is calabrica, 6 in., with rosecoloured blooms, which is raised from seeds sown out of doors in spring.

# Socks for Adults and Children 

## Instructions for Knitting Standard Patterns

This article gives detailed instructions for knitting a pair of woollen socks for a man, a pair of woollen socks for a child, and a pair of bad so:ks. Other articles or knitted wear include Bootecs; Gaiters; Stockings. See also Darning; Knitting; Mending; Wool

With a heavy type of shoes or hoots in cold] weather machine or hand-knitted ribbed woolien socks for ment and boys are most suitable. A heavy shoe will quiclily wear holes in a thin sock. For ovening dress plain black sili. and for ordinary town wear, with shoes of medium weight, cashmere socks are worn by most men. These last should be guarantred pure wool and of a firm but soft and even texture.

When buying woollen socks, whether woven or Enitied, it is well to purchase a size too large. Even though guarantred unshrinkable, however carefully washed they will shrink a little. Measuring round the closed fist to ascertain the length of a sock is not infallible. It is better to ask for socks that will fit a size larger than the shoen worn.
lior country wear, well-knitted socks are the most comfortable for much excreisc. Hecls and toes may be strengthencd by double vool or by knitting silk of the same shade. Knitting should be loose enough for the needles to pass through easily, and success depends on an even appearance and upon the skill in turning the hrel and rounding the toe.

Babies' socks are usually made in the softest white wool, and may be knitted in a fancy stitch, or, if preferred, crocheted in a rib-stitch. This is ordinary double crochet, the ribbed effect being obtained by putting the hook into the back part of the foundation cach time a stitch is worked, instead of into the front. For children, best socks are knitted in silk. Mercerized or fine crochet cotton may be used and also fine wool. Boys' socks are usually of a heavier make.

Socks. Fig. 1. Man's sock in soft wool that can

Men's Knitted Socks. A pair of men's woolen socks is illustrated in Fig. 1. They are of average size, and since the leg is not shiped, they can be made cither longer or shorter without necessitating a chunge of pattern. The knitting is done at a tension to produce about 10 sticches to the inch in width: 4 oz of 4.ply Bechive Soft Ḱnitting wool and 4 No. 13 knitting needles are required to make a pair.

Begin by casting on 84 stitches, 28 on each of 3 needles. and work in rourds, in ribs of knit 2 and purl 2 until 4 in . have bcen worked.

Continue in plain knitting until the sock measures 11 in., and then commence the heel as follows: Knit the first 21 stitches of the round on to one needle, and slip the last 21 stitches of the round on to the other end of the same needlc. These 42 stitches are for the heel, and all the others, which make up the instep, should be divided on to two needles.
On the heel stitches purl and knit a row alternately until 4l more rows are worked The first stitch of each row should be slipped, and the last row should be a purl one. To turn the heel, knit 26 , knit 2 together, then turn, purl 11 and purl 2 together. Turn, knit 12, knit 2 together. Turn, purl 13, purl 2 together. Turn, knit 14, knit 2 together. Turn again, and continue in this way unti' all the heel stitehes are worked on to one row again. Then linit 13 stitehes and the heel is

Slip all the instep stitches on to one needle, and on to the first needle knit the remaining stitches of the heel. Knit up 21 stitches at the side of the heel and the first stitch from the instep needle, and with a second needle linit all the instep stitehes but the last one. With a third needle knit the last instep stitch; then linit up $2 l$ stikehes at the other side of the heel, and the other 13 heel stitches. Knit one round without shaping, and then decrease thus for the instep in the next round Knit to the last four stitches of the first needle; knit 2 together, knit 2. Knit the stitches on the second needle without shaping, but on the third, knit 2, knit 2 together, and through the back of the loops knit to the end of the necdle. Repeat
the last 2 rounds until only 20 stitches remain on each of the first and third needles. If a 10 in . foot is required, work without shaping until the sock measures $6 \frac{1}{2}$ in. from the side of the heel where the stitches were linitted up; for a $10 \frac{1}{2}$ in foot, work 7 in . from the side of the heel, and $7 \frac{1}{2}$ in. for a foot measuring 11 in.
Shape the toe thus: * Knit to the last three stitches on the first needle, then linit 2 together and linit 1 . On the second needle, knit J, knit 2 together, and then linit to the last 3 stitehes; then linit 2 together, and linit l. On the third needle, knit 1, knit 2 together through the back of the loops, and knit to the end of the row. Knit 1 round without shaping, and then repeat from * until only 24 stitches remain on the round. Knit the stitches on the first ncedle on to the third, and close the toc. by the procedure kinown as grafting.

To do this, place the two needles logether, and having threaded the wool into the bodkin, work in the following way. Place the bodkin in the first stitch of the front row, as for knitting, slip the stitch off the needle, and draw the wool through. Then put the borkin in the second stitch of the front nerulle as for purling, and draw the wool through, but do not slif the stitch off the needle. Pass the bodkin under the front needle, put it in the first stitch of the back row, as for purling. draw the wool through and slip the stitch off the needle. Then place the bodkin. in the sceond stitch of the back row, this time as for knitting, and draw the wool through, but do not slip the stitch off the needle. By this it will be seen that the action of the bodkin is reversel on the back needle. Reperat until all the stitches are worked off, and take care not to draw up the wool too tightly. When the last stitch is reached, pass the woot through it and fasten it off securcly on the wrong side.

Child's Socks. Woollen socks with striped coloured tops, Fig. 2, for a child of about 6 years of age, can be made accorting to the following directions. The socks incasure $8 \frac{1}{2}$ in. from the top to the ankle an: 7 in from the back of the heel to the point of the toe, and the work is done al a tension to produce about 10 stitches to the inch in width. The materials required are $1 \frac{1}{2}$ oz. of Beehive 3 -ply Scotch fingering wool in white or grev. and $\frac{1}{2} 0 \%$ of the same kind of wool in any other colour for the turnover or striped tops, with four No. 14 sted kinitting needles.

With the coloured wool east 24 stitches on each of 3 needles, and working the top in a rib of knit I and purl 1 , do 4 rounds in the coloured wool and 4 rounds in white. then 1 round in colour. 4 rounds in white, 4 rounds in colour. 4 rounds in white. This completes the top, and as both sides are the same it doces not require turning if the socks are to be worn with a turnover top.
Knit the next round in plain knitting and increase one stitch at the beginning of the round by picking up a loop of t!ic previous round and knitting it as an ordinary stitch. Now begin the shaping for the leg in the next round. * Kinit 1 etitch, knit 2 together, knit to the last 3 stitches of the round, slip 1 . knit l, pass the slipped stitch over the knitted, linit l. Knit 4 rounds withour any shaping. Repeat from * 3 more tinses, then do another decrease round, making 5 decrease rounds and 10 stitches decreased away all together. Work 54 more rounls to reach the anlile. Extra rounds are worked here for longer sock.

Now begin the heel. Kinit the first 16 stitches of the round on to one needle, slip the last 16 stitches of the same round on the other end of the same necrlle; these 32 stitohes are for the heel flap. Divide the remaining 31 stitches on 2 necdles and leave them for the instep. Now work on the heel stitches, always slipping the first stitch, purl 32, turn, finit 31, turn, purl 30, turn, knit 29, turn. Continue
in this manner until 9 stitches are left at each side of the heel, the last now being purl 14.
Turn and knit 14, lift up the right-hand side of the loop just before the 15th stitch and knit the 2 stitches together to prevent a hole. Turn, purl 15, lift up the oop just be fore the 16th stitch and purl the 2 to gether. Coninue in this manner working one extra stitel on to each rowtillall the 32 stitches are on the ne row The last row will be a purl row. Knit back 16 stitches and so complete the heel. Slip the instep titches on to one needle
Now on

Socks. Fig. 2. Cbild's sock hand-knitted in wool, with coloured tornover top
needle knit the remaining 16 stitches of the hecl, knit up 2 stitches at the side of the heel, and knit the first stitch from off the instep needle. With the second needle knit the instep stitches: with the third needle knit up 3 stitches from the side of the heel and the other 16 stitches. Knit one round plain, then decrease for the instep in the next round as follows: Knit to the last 3 stitches of the lirst needle, then knit 2 together, knit l, linit the second needle without any shaping, on the third needle knit 1, slip 1, knit 1, pass the slipred stitch over the knitted one, then knit to the end of the needle. Repeat the last 2 rounds 3 times. Now work 56 rounds without any shaping for the length of foot required before shaping the toe, allowing for the latter to add another $1 \frac{3}{4} \mathrm{in}$.
Shape the toc as follows: * Knit to the last 3 stitches of the first needle, knit 2 together, knit 1 ; on the second necdle knit 1, slip 1, knit l, pass the slipped stitch over the knitted, knit to the last 3 stitches of the same needle, then kiit 2 together, knit 1: on the third need!e knit 1, slip 1, knit 1, pass the slipped stitch over the knitted one, knit to the end of the needle. Knit 2 rounds without shaping. Repeat from * until there are only 28 stitches in the round, then knit the stitches of the first needle on to the third needle.
Place the two needles together, and knit a stitch from each needle at a time, and when 2 stitches are on the right-hand necdle slip the first one over the second stitch, and so on
until there is only one stitch left, then cut the wool, draw it through the last stitch, thread the end in a darning needle, and fasten of verv sccurely on the iprong side of the sock. Casting off the toe nan also he done by grafting which is a much neater method and more comfortable in wear (sce page 669)

Bed Socks. To make a pair of hed socks of average size for a woman, 24 oz . of some such soft wool as Baldwin \& Walker's 3-ply Lady ship Flossella Wool will be required and also $1 \frac{1}{2}$ yards of ribbon, and three No. 7 needles Commence at the top by casting on 53 stitches, and work the first 24 rows in ribs of 2 plain and 2 purl, always knitting the first two stitches at the coinmencement of every row and purling the last three stitches of every row.

Now cbange and work in moss-stitch (l stitch plain and the next stitch purl, alternately to the end of the row, then on the return row reverse the order of the stitches so that a plain stitch comes over a purl stitch of last row) for 4 inches, increasing 1 stitch at the beginning of the first row in order to bring the stitches up to 54 .

To make the holes for the ribbon. work 2 moss-stitches," make l, take 2 tog., 4 moss stitches ; repent from * to the end of the work, ending with 2 moss-stitches. Now work again in moss-stitch for 12 rows. then the stitches will be divided for the foot.

Work in moss-stitch over the first 16 stitches, on the next 22 stitches work backwards and forwnids in moss-stitch for 40 rows (always slipping the first stitch), then break off the wool and join to where the 16 stitches were left and with the same needle pick up 20 stitches along the side of the instep flap and also 11 stitches across the toe. With the spare necdle work across the remaining 11 toe stitches and pick up 20 stitches along the other side of the instep flap, also the 16 remaining stitches on to the same needle. Work across all the stitches for 10 rows; then decrease 1 stitch at both ends of both needles for 5 rows. Then cast off or leave the stitches for grafting. Join up the scams and through the holes at the ankle thread the ribbon

SODA. Soda is a valuable agent for quickly and thoroughly removing grease and dirt from pots, pans, and other kitchen uten sils, accessorics, and cloths. These should be thoroughly rinsed in clean hot water before they are dricd. Soda should not be used for cleaning aluminium and enamelled vessels.

Household Uses. If the houschold water is very hard, common soda is frequently added to it when boiling green vegetables, or it is used for the purpose of restoring the colour of the regetables when they have been closely packed and curriod to market. It is, however, preferable to sacrifice appearance and omit it altogether, for on some constitutions it has a deleterious effect, particularly the common or washing soda. At all times the quantity should be strictly limited, und bicarbonate of soda should be substituted for the washing soda, as much as will lie on a sixpence being quite sulficient to soften each gallon of water.

Bicarbonate of soda is used as a raising agont in the making of bread, cakes, and scones, and for cakes it has almost-superseded yeast. Sometimes cream of tartar is added to the soda in order to prevent it from darkening the llour. Bicarbonate of soda is the most important ingredient of baking powder.
Uses in Medicine. Soda is largely employed for medical purposes in the form of various salts of sodium

Sodium bicarbonate, 2 drams to the pint of water, is a useful lotion to apply to the skin in cases of mild itching. Made into a paste with a little water and applied to insect bites and stinge, it often gives immediate telief, as also in burns and scalds before blisters have formed.

Internally sodium bicarbonate is constantly prescribed in various kinds of indigestion
The phosphate and sulphate of soda and tartarated soda are widely used purgative salts. Most of the natural purgative mineral waters such as Apenta, Rubinat, Hunyadi Jànos, Carlsbad, ctc., derive their characteristic action from one or more of these sadium salts
Sodium chloride or common salt is one of the natural ingredients of the tissues, and thercfore is an essential article of our dietary. In large doses it acts as an emetic.
Sodium citrate is often added to the milk of babies bottles to make it more readily digest. ible. One grain of sodium citrate dissolved in a teaspoonful of water is added for each ounce of cow's milk in the bottle. The effect is to render the curds of the milk which form in the infant's stomach less tough. See Salinc.
SODA CAKE. For making this cconomical cake the ingredients are 1 lb . flour, $\frac{3}{2} \mathrm{lb}$. sultanas, $\frac{1}{4} \mathrm{lb}$. chopped peel, 6 oz . butter ol margarine, $\frac{1}{4} \mathrm{lb}$. granulated sugar, a little grated nutmeg, 2 eggs, 1 tcaspoonfui bicarbonate of sodn, $1 \frac{1}{2}$ gills milk, pinch of salt. Sift Hour and salt together, rub in the butter, add the sugar and dried fruit. Put the bicarbonate of soda in the milk and add it to the eggs, which have been beaten. Pour this on to the dry ingredients and leat all thoroughly before putting the misture into a baking tin lined with paper and baking it in a moderate oven for about $2 \frac{1}{2}$ hours.
SODA WATER. The name soda water is rather misleading, for commercial soda water consists usually of water charged with carbonic acid gas. Occasionally soda is present in small quantities, about 5 gr . of bicarbonate of soda to the bottle. It should properly contain 30 gr . to the pint of acrated water. Soda water can be made at home, the acrating process being accomplished with sparklets. See Sparklet.

SOFA. Through its predccessors the day bed, courting scat, settee, and the couch of the Regeney period, the sofa has a very long pedigree. As seen to-day it has a head at one end and sometimes a back. The frame is of vood, which may be mahogany, deal, or one of intermediate valuc. Many sofas are fitter with a loose cushion and a bolster for the head.
In Vietorian days a sof:a was made and sold is part of a suite of furniture. and these suites were seen in dining rooms, drawing rooms, and other living-rooms. To-day the sofa is less popular, its place having been taken to a large extent by the divan, modern versions of the settee, or the Chesterlield.
It may be remembred that, in common with many other pieces dating from the first half of the 19th century, well-made sofas increase in value and interest as people begin to collect furniture of this period.

Repairing a Sofa. The back of a sofa is composed of a shaped top rail as at A, F:g. l. two ends $B$, a centre picce $C$, and a bottom rail D. These parts are generally secured together with dowels, as shown, and if loose they can be replaced and the joint glucd ip again. An alternative method of strengthening the frame is to screw on angle brackets at the corners as at E . This method should not be employed in the case of a badly damaged frame.

The frame itself is usually dowelled to the seat frame and screwed to the scroll ends. The seat frame shown at Fig. 2 is sufficiently strong to resist the strain of wear, but it is possible that the cross or end rails may have become loose or broken; in this case the method of repair is to fit a new rail across, as at $F$ or $G$, the latter being additional, to strengthen the frame or remove a twist cansed by a warped length.
The legs are usually secured with doweis, the repairing being generally a matter of fitting new dowels. It will be scen from Fig. 3, which
shows a plan of the framing directly over one of the legs, that two of the dowels are fitted in the outer rail and one in the oross rail. In renewing them, a larger diameter dowel should be providod, and the old ones bored qut: in addition the two flat surfaces should be scraped quite clean so that tbe glue will hold up tight. The leg with dowelş is shown in Fig. 4.

Castors may have heen replaned two or three times and worked loose again, or the wood may have split. In the former case it is adviseble to fit a slout dowel in the leg as in Fig. 5 ; the end can be shaped so as to fit in the castor. If the leg has been split at the bottom, it will he as well to hind it with wire, suitable grooves being cut as in Fig. 6i. By using an ondinary wood filler the wire binding can be entirely covered and wil! not bo noticed. The scroll ends are !iable to work loose or break off at the tenon joints, as at H, Fig. 2, alid K in Fig. 7. Allhough they can be glued up again, it is gencrally more satisfactory to cut the tenons off, fill up the mortises with suitable blocks of wood, and replace with a dowelled joint, as in Fig, 8. The dowels should enter both pieces for at least 11 in .

If the ends are not very loose, the joint ean be strengthened by blocks of wond screwed to the inside of the frame. as at L, Fig. 9, but it will prohably be necessary to fit in thin blocks cach side, as at $M$, to bring the inside of the scroll upright to the same distance as the seat rai!. Further strengthening may be necessary in dealing with the scroll ends by renewing the rails $P, R$, and $T$. These are placed there as much for upholstery purposes as for strengthening the construction. As a rule, they are secured by glued blocks, as at N, but in better class work they are housed in the sides.

Breakages in the short grain of the wood are not unusual, cither at the bottom, as at $W$, Fig. 7, or as in Fig. 10. In dealing with a break as at $W$ ', the best way is to screw on a suitable strip of hardwood, as shown. Breakages at the top are repaired with a narrow strip screwed on as in Fig. 10, but the hroken edgea, particularly if they are of long standing, must be thoroughly cleaned and glued together. Re-glued joints should have newly planed surfaces, but if this is impracticable, the surfaces must be scraped to remove old glue ; where it is impossible to use a scraper, the wond should be cleaned with hot water and a

 easily worked, the opof the softwoods are the coniferous trees such heavy soils. as the pine, fir, larch and ycw. They abound in resin and yield turpentine and pitch. Sce Deal ; Hardwood; Larch; Pine; Wood,

SOIL : The Varieties. The chief kinds of garden soil are heavy, loamy, peaty and light. or sandy soil. The nature of each can be modified by artificial treatment to suit the conditions of the garden and the requirements of the plants that are to be grown therein.

Of the four chief kinds of soil, a heavy soil consists almost entirely of stifi clay, and nust be lightened by decp digging and throwing

stiff hrush, See Castor ; Chesterfield ; Divan; Dowclling; Settee.
SOFFIT: In Building, There are numerous applications of the soffit in domestic architecture. Externally it is the covering applied to the underside of the eaves of a house ; on internal parts of the building the term soffit refers to exposed ccilings such as those found beneath some forms of staircase.
The term is applied to the inner face of an arch and to some forms of ceiling formed into panela and otherwise treated, and often found on projecting or bow windows. Soffit lining is the covering on the underside of lintcls for a window or door, or arch opening, or the linings covering the undersicle of an exposed Hight of stairs. See Ceibing; Eaves: Rafter; Roof.

## Soft Water. See

 Water Softener.SOFTWOOD. The timbers that are classed as softwoods are those that are light in testure and are

the subsoil open to disintegration by the action of frost during the winter months. It may also he further lightenod by the admixture of sand, wood astbes, burnt weeds, grass, and other bonfire material. Road sweopings, where they can be obtained free from the taint

Soil. 1. Soil stack : turves interlaid with lime (a) and manure (b). 2. Lightening beavy soil : $a$, bottonn spit well dug; $l$, manure $; c$, top siol with lime and sand lorked in (d). 3. Base for same: $A$, fire ; $b$, draught passages; $c$ bricks; $d$, soil, etc.
$B_{u}$ special arrangement witl Amateur Gardeninu posite kinds being the hardwoods. The chief of petrol refuse, are excellent for lightening

A loamy soil is the best for all general purposes, and is the one in which clay and sand are found naturally mixed. A peat soil is very dark in colour, due to the preponderance of decayed lenves in its composition. It is invariably found in the neighbouthood of woods and forests, and should be mixed with other soils to obtain the best results.
Sandy soil is casily recognized by its dry and powdery nature. It is composed chictly of silica, and alone is unsatisfactory and unproduotive. It is best improved by the addition of clay, animal manure, decayed vegetation, and anything that helps to bind the particles of sand together.
If the soil is sicli, and grows moss and sorrel, it contains too much acid, and requires a good dressing of lime. In making a new garden liming is always necessary. About 10 lb . to a square rod will he sufficient.

Health and the Soil. The nature of the soil on which $n$ house is built may have a great dea! of influence on the health of the inhabitants. It often happens that a person who suffers from rheumatism, neuralgia, lung troubles, etc., finds himself much better on changing his residence to another neighbourhood. There may be other reasons, of course, for the improvement, but in many cases the chief cause is removal from a damp soil or low location to porous, dry, and warm ground.
The most porous or permeable soils are gravel and sand. Through theso the rainfall percolates frcely, passing down until it meets an impermeable stratum, puch as clay or rock. The next most porous is a chalk soil. Any of these furnishes a dry site for a house provided it is situated on a slope. Limestone is only slightly porous; the water will How away over it if the site is on a slope, but otherwise it is apt to keep the surface wet.
Hard rocks and clay soil are almost impervious to water. A rock site on a slope forms a very healthy foundation, as the water flows away quickly. Clay is nearly always cold, and on a dead leve!, or in a hollow, it forms a
recy wet, bad site, both the ground and the exterior of the building uir being damp. When sandstone or chalk is present in a mixture with clay, it is likely to be damp unless the slope is stecp enough to allow the water to run away frecly
Two important points have to be considered in connexion with soil, namely, ground water and ground air. All soils, except those that are quite impervious, contain water and air. The water consists of the rain which bas passed through the upper porous layers, and at a greater or leas depth, is prevented from sinking further by an underlying impervious stratum. Thus if we dig down we always reach water. In some low-lying, wet places this ground or subsoil water comes up close to the surface in rainy seasons; in marshy districts it may be level with the surface; in other places it may be hundreds of fect down.

Ahove the !evel of the ground water the interstices of the soil are filled with air, the ground air. When the water level is close to the surface a great deal of it goce off into the outer air liy evaporation, making the air around the house damp. The level is constantly varying, and each time the ground water riscs it forces out the air contained in the soil abovo it.
If the soil is pure this air is harnless. If the soil is contaminated, the air will be impure, and when foreed into the basement of a house it may cause injury to health. The soil may be contaminated by its contents of decaying vegetable matter, or by drainage from manure hraps. cesspools, middens, farm buildings, leaking drains, graveyards, etc. Not only does a rise of ground water force gases into a house unless there is a thick concrete foundation, but it may contaminate wells.
The points to consider in connexion with this matter are the nearness to the surface of the ground water and the greater or less Huctuations of level which take place. If the ground water is not more than ten feet below the surface, the site is not a good one for a dwelling-house; probably the level should be fifteen or twenty. Likewisc, if there are great and frequent changes in the level of the water, danger arises from the gases forced out.

In Great Britain the building by laws of most local authorities now require the provision of a ground layer. This usually consists of six inches of concretc over the site of the rooms, and effectually prevents any movernent of ground air inside the bouse irrespective of the !evel of the ground water. It also protects the immates of the house from contaminated ground air which is detrimental to their health See Housc : Ventilation

SOIL PIPE. This name is given to an impervious pipe connceting the w.c. with the manhole in a drainage system. The requirements of the local authorities must be strictly observed when putting in, repairing, or in any way dealing with soil pipes.
In most districts it is a requirement that these pipes be of good grade cast iron treated on the interior with Dr. Angus Smith's solution to render then immune from the attack of acirls, water, and foul matter gencrally. All joints must be properly mado and absolutcly airtight. Customarily an air vent is provided from the highest point reached by the soil pipe and taken from that some distance above the roof.

The lower end of the soil pipe discharges into the first manhole adjacent to the house. This manhole has also to be ventilated with fresh air in conmon with other parts of the sewage system. The result in a properly devised system is that the soil pipe is normally empty and is ventilated throughout by a steally current of air. The exterior of the pipe should be kept in good condition by the frequent application of paint, and all cars, lugs, straps, etc., used to fix the pipe to the
extcrior of the building
should be examined from time to timc. See Drains; Sani. tation.

SOLANUM. This is the botanical name of a group of shrubs and plants which inc!udes the potato and several linds of ornamental value. The bitter swcet of the hedgerows, of which the rod berries are poisonous, is Solanum dul. camara. Solanum melongena is the egg fruit or aubergine whieh is raised from seeds under glass in spring and grown in large Hower pots or on a sumny horder. The winter cherry (Solanum capsicastrum) is a favourite window and grcenhouse plant which bears orange-red fruits in winter and is raised from sceds or cuttings under glass in opring. Sola. num crispum, mauve and jasminoidfes, white, are vigorous climbing plants suitable for a wall in mild districts, or for the greenhouse elsewhere. Solanum Wendlandi, which must be grown under glass, is a climbing plant with large mauve blooms.
SOLAR FLOWER. A Hlower that opens and shuts cluring the day about certain hours is known as a solar Hower. 'Thus the goatsbeard is open from 3 to $\overline{5}$; the dandelion from 5 to 6 ; the pimpernel ahout 8 ; day lily from 10 to 11 : and the tiger lily robout 12. low temperature is known as soldering.

The requirments for amateur work consist of a soldering iron or copper bit (Fig. 1), some solder, Hux, emery paper, an old file or two and an odd knife for scraping the metal clean. In addition there must be some means for heating the iron, and preferably some sacking or rough cloth with which to wipe it clean

The size of the iron and its type will depend on the nature of the work For domestic use a plain bit weighing about $\frac{3}{3}$ to 1 lb . will suffice, and this may be the ordinary adjustable type of iron with a wooden handle. The term "iron" is misleading, for the actual beating element is a pointed or hatchetshaped piece of copper. The most useful form of solder is timman's solder in bars about

## SOLDERING FOR THE METAL WORKER

## Enabling the Handyman to Undertake his own Repairs

This prccess is recessary for a numter of mending and constructional operations described in
our work. The reader should therefore consult Aluminium ; Bent Iron Work; Copper ; I caded Lights; Napkin; Piercing; Silver Work. See also Blow Pipe; Flux; Pumbing

The process of joining metals together by $\frac{1}{2}$ in wide and $y_{n}$ in. thick, sold by weight. means of another metal that melts at a relatively Blow-pipe solder, which is harder, is oold in long, thin strips; this is best used with a large copper bit or a blow pipe. Tinman's solder also can be purchased in narrow strips

The soldering acid or flux may be powdered resin, killed spirits, that is, hydrochloric acid in which a number of small pieces of zinc plate have bcen dissolved, or one of the proprietary brands. A combined solder and flux in paste form is useful for small jobs, as the surfaces can be coated with the paste, held or wired together, and united by sweating, using a blow pipe or lamp, as later described. In an awkward corne the point of the soldering iron can be introduced to heat the joint.

The heating medium for the soldering iron

Solanum. The winter cherry (Solanum capsicastrum), a greenhouse Closing times vary with particular plants. Solar towers are sometimes used to compose a oral clock.
SOLAR PLEXUS. Lying behind the stomach and in front of the norta, or chicf blood vessel of the ahdomen. is that part of the sympathetic nervous system known as the solar plexus. It consists of two large ganglia, and of interlacing nerve fibres. It reccives branches from the right vagus nerve and supplies branches to the liver, stomach and other abdominal organs. The disabling effects of a blow over the solar plexus are well known

[^9]

is preferably a gas heatet of some kind. a regular soldering stove, or a powerful blow. lamp when gas heating is not available Irons arc made that are self-hcating (Fig. 1) Some derive their heat from a self-contained gas burnct, and others fron in electric heating device, or a petrol blow lamp forming a part of the soldering iron itself
Mending a Kettle As in example of the methods of soft soldeling, suppose a leak is to be mended in a tin liettle. The lirst step is to clean the surface to be repaired. The best method is to scrape or polish the metal with an old file or knife, as in Fig 2, and finish with rough emery paper. Then wipe the metal clean with a piece of clean cloth to remove the dust and chips.

The iron is heated over a gas ring or any clear, hot, bright fire until the copper is almost. but not quite red hot. Now talie the bit from the firc and wipe it quickly with a cloth to remove any surface dust. Next rub the tip of the copper with in file, as in Fig. 3, resting the iron on an orld bit of wood or metal to prevent scorching the bench.
The next step is to tin the bit, that is, to cause a film of solder to run on to and adhere to the point of the bit. If the bit has cooled in tho cleaning process it must be reheated. Place a spot of flux on the centre of the clean piece of tinplate and dip the point of the hot iron into the fux for a moment. Then, holding the iron in the right hand and the strip of solder in the left, place the point of the iron on the tinplate and apply the solder to the edge of the iron.
The worker turns the iron over as the solder melts (Fig. 4), moving it about and rubbing it into the little pool of molten metal until the solder adheres to all the four sides near the point of the iron. The appearance of a well-
timed bit is shown in Fig. 5, and it is in this state that the iron is fit to use. The iron need not be reheated until it fails to melt the solder freely. When this point is reached, take care not to overheat the iron and melt off the tinning, as if this is done it will have to be clcaned and retinned as alreaciy described If carefully used the iron should not need tinning except at long intervals.

Presuming the iron to be stil! hot. the next step is to talie a small dist of tinplate and place it over the hole on the cleaned part of the work in hand, to which flux will previously have been applied, adding a touch of flux to the edges. Press the iron on the edges of the tinplate disk and apply the colcier to the side of the soldering bit, nelting oll a few lumps or blobs as shown in Fig. 6, and proceed to flow the solder all round the edges of the disk At the ame time press the soldrong iron on the centre of the disk to assist in lieating it, and also to draw the solder we!l under the metal and ensure a sound joint Finish by running the iron around the joint to make the surface of the solder neat and tidy, as shown in Fig. 7

It is well, when the solder has been run round the patch, to press on the latter with the point of an old file or some similar object, so as to hold the patch firm until the solder cools. If the file is held upright on the centre of the patch the soldering iroll can be worked round the edges of the patch 10 miake a neat andeven joint. The kettle should be firmly supported so that both hands are free.

Exactly the same processos are followed in soldering any tinplate article, the steps being to clein the surfaces, apply llux, see that the iron is well tinned and sufficiently hot, flow the solder round and undel the joint, and finish by smoothing with the point of the iron. Any small lumps of solder aie removed by the iron

or can be filed away, the use of the soldering iron being preferable.

Tinning a Joint. For brass or copper the same procedure is adopted, except that it is necessary first to tin the surfaces to be united This is accomplished by rubbing with the point of the tinned copper soldering bit and at the salne time flowing on a further supply of solder. The surface is gencrally made smooth and bright by wiping it over with a clean rag while the solder is still hot and molten. This ensures a better ultimate joint, as the two faces can then be brought into more intimate contact
Wrought iron and steel can be soft soldered by first tinning the surfaces: they are, however, more often brazed together, as there are few occasions for the use of soft solder when steel has to he employed, since this metal is used on the grounds of strength. A soft soldered joint is not naturally strong unless the parts to be joined are fitted into one another, or otherwise made secure against external stresses
Sweated Joints. Another mothod of soft soldering is known as sweating, and this does not call for the use of a soldering iron The typical procedure can be illustrated by the case of a brass ferrule forming part of a pipe union for attachment to a gas fitting. The first steps in this case are to clean the surfaces thoroughly and then to tin thein by holding the parts in the flame of a blow lamp; as soon as the metal is hot, apply a trace of flux and press the end of the stick of solder on to the metal It should then flow over the surface and partly adhere. The tinning is completed by wiping the surface with a clean rag

The parts are then placed in position, the flame of the blow lamp directed on to the joint, and the solder melted into place. The end of the joint should be pressed against some suitable object, the heat being concentrated on the outer pait of the joint, remote from the lip, as the solder will always run towards the heat. If the greatest heat is at the inner end where the joint begins, the solder will be more difticult to flow into place. Small jobs can be carried out by using paste solder combined with Hux. Sometimes the objects to be united can be held over the flame of a gas ring, spirit lamp, or Bunsen burner.

Zinc is soldered in the usual way, but with the use of killed spirit as a flux. Aluminium can be soldered, but only with specially prepared solders and a suitable flus There are several proprietary brands on the marliet, and they should be employed exactly as the makers direct Methods of soldering lead are dealt with in this Encyclopcilin under the heading of plumbing.

Hard Soldering To carry out hard soldering, or silver soldering, a blow lamp or blow pipe (Fig. 8) is essential, or some other form of easily controllable heat giving a long clean blue flame. The soldering is effected with silver, the metal being alloyed with a small proportion of brass, to lower the inelting point. Articles made of silver can thus be united with the solder without danger of fusing them This method is used by silversmiths and jewellers, and has the advantage that the joints are particularly strong and durable for small work, being in many respects superior to brazing. There are several tinds of Hus that may be used, but probably the best is borax in lump form, which is reduced to a paste with water by rubling the borax on the surface of a slate. The solder is obtainable in several grades, melting at different temperatures. To use it, the netal is cut into strips of suitable size and fed up to the job while playing on it with the blow-pipe flame or the jet of a blow lamp.

As an example, suppose it is desired to solder in a boiler end to a model boiler, the barrel being formed of seamless tube, as

Soldering. Fig. 8. Implements used in bard soldering. A, bench gas burner. $\mathbf{B}$, holder ior small objects. C, gas blow pipe. D, mouth blow pipe. E, charcoal block
Courlesy of H. W. Hurn d. Co.
described in the article on Enginc. After the The methot of silver soldering jewelry and surfaces of barrel end and disk have been similar objects is somewhat different. The cleaned the boras paste is applied to the joint worker places the articles to be united on a with the point of a small camel-hair brush. charcoal block (Fig. 8, E), or a soldering "wig," One or more of the strips of solder are bent and after applying the borax plays on the around and placed on the borax flux. After this the flame of a blow lampor gas blow pipe is directed on to the work. The clean part of the Hime must be liept on the joint. This is generally a little distance from the tip, at a spot where the inner cone of flame is visible as a slightly different coloured cone. If the dirty part of the Hame is used the work may be oxidized and the result prove a failure. As the metal is heated the borax will froth and turn white and finally melt. Soon the metal will appear to be red hot and the strip of silver will melt and flow around the joint.

The crus of the operation is to make the silver flow properly, and only experience can give the requisite skill to accomplish this. It is largely a matter of correct temperature and correct iosition of the Hame : the metal will always follow the heat of the flame, and can be diawn, as it were, to the desired spot. If the work is at all delayed the flux may all be burned, but this can be remedied by application of a further supply from a spoon made from a piece of thick iron wire beaten to a spoon-like end. If this is placed nenr the Hiame of the blow lamp it will keep hot. and when dipped into the boras some of the latter will adhere, and it can then be conveyed to the desired spot.
When properly made, a silver-soldered joint is nearly as strong as the metal to which it is applied, and for all small work it is preferable to soft solder. 'The resulting scale on the work can the removed by filing and finishing with emery paper.
Should it be desirable to unsolder an article, the sweating process is perhaps the best when it can be carried out, the metal being heated, a small amount of Hux applied, and the parts pulled asunder while the solder is molten. After any soldering process all traces of the flux or soldering acid must he removed by scouring the article in hot soda water or by the use of emery paper.

Some of the appropriate implements for hard soldering are illustrated in Fig. 8. The gas blow pipe ( C ) is used in conjunction with a small bellows of the kind shown on page 502. The gas burner (A) has a swivelling tube: when this is turned at right angles the fiame is reduced to a tiny jet.
oint with a small blow pipe (D). The solder is cut into small picces and placed in position

Solitaire Board, showing the thirty-three boles, arranged in the form of a cross, for the marbles
with a pair of twee\%ers. The jobs are small, of course. and the heating source can be a spirit lamp or a Bunsen burner. The parts to be soldered arc fastened together with binding wire. For quite tiny objects one can use a holding device (Fig. 8, B) consisting of a pait of clips mounted on a rod which is held in the hand or a vice. The clips have universal joints, so that the parts, when gripped by them, can be brought into contact and ire held fast while being soldered.

SOLE : The Fish. A llat fish with firm, white tlesh and an excellent llavour, the sole should be cooliced as soon as possible after it is canght, but in cold weather may be kept for a few days without harm. There are two kinds of sole, known respectively as the lemon and the real sole. The latter is superior in flavour and thercfore dearer. Steaming between two p!ates over a saucepanful of water is the best way of preserving the delicate llavour of fillets of sole. The fillets of the fish should be seasoned with pepper and salt and lemon juice.

Fillet of Sole. To bake fillets of sole, wash them well, removing the white skin, and roll each one into a round. Stand them in a greased pic-dish, add $\frac{1}{2}$ gill mill, and salt and pepper to taste, and place a small piece of butter on each fillet, using about 1 oz in all. Cover the dish with a plate, and bake the fish in a moderately hot oven for about 18 min . In the meantime prepare $1 \frac{1}{2}$ gills white sauce and brown some breadcrumbs. When the fillets are cooked, take them from the oven, roll them in the breaderumbs, and then stand them in a line on a dish. Pour the sauce round and garnish the top of each fillet with a thinly cut slice of lemon.

A nother method of baking sole is described in the following recipe: Skin and fillet a small fish, season it and then fold each fillet in two, doubling the thin end over towards the thick. Lay thein on a baking-tin greased with butter, add a tomato, cut into quirters, then cover the whole with a piece of greasell paper, and bake it for about 8 min . Serve the fish on $a$ hot dish with the picces of tomato placed round it.

Baked fillet of sole may also be served with white sauce to which two hea ped tablespoonfuls of grated cheese have been adderl. Some more grated checse should be sprinkled over the fish after it is cooked and then browned under a gas griller.

Either whole or tilleted, sole may be fried as directed in the article on Fish.

Sole may also be grilled, and a pat of maítre d'hôtel butter is a good garnish. Finely chop 1 teaspoonful parsley, add a squeeze of lemon juice and incorporate with sufficient butter to make a round pat. Place one on cach portion of grilled sole when ready to serve. See Carving; Fish; Lemon Sole: Sauce.

SOLIDAGO. These vigorous herbaceous perennials bear yellow Howers in September and October. They flourish in ordinary soil and are casily increased by divisiou in autumn and spring. The best kinds are Golden Wings, Shortii and canadensis, all about 5 ft . high. Onc, Canadensis nana, is only $2 \frac{1}{2} \mathrm{ft}$. high.

SOLITAIRE. This game for one is played on a circular board containing 33 holes, each made to hold a marble. They are arranged in the form of a cross, each line containing 7, as shown in the illustration. Marbles are placed in the holes, except the centre one, and the object of the player is to remove them one by one until only one is left, and that one in the centre hole. The removing is done by taking one oft the board when another is moved over it into an empty hole beyond, as in draughts. Moves can only be made in a straight line, not diagonally. It is by no means easy for the beginner to succeed in his task, as one false move will leave him with three or more marbles in such positions that they cannot be taken.

SOLOMON'S SEAL. This is an excellent hardy plant for shady places. It grows 3 ft . high and has arching leafy stems bearing

Solomon's Seal. Showing the rows of greenishwhite bell-like flowers which hang from the undersides of the stems
numerous greenish white flowers in May. It sproads rapidly and thrives in ordinary soil. Roots may be potted in autumn and placed in the greenhouse for spring blooming.

SOLO WHIST. This card game, generally known as solo, is played by three or four players with an ordinary pack of 52 cards. If only three play, either one suit entircly is omitted or only three hands are dealt, as the players agrce. The cards are dealt three at a time to each player in turn, and the last round consists of a single card to each player, the final card, the dealer's, heing turned up for trumps.

Each player cither says " I pass " or makes a call. The lowest call is proposal, usually contracted to "prop." A player who props docs so in the belief that his hand is good enough, if backed by a reasonably good ono by annther player, to make 8 tricks in the partnership. Any other player may tako the proposal, pass, or make his own call

The next highest call is solo. This is a call by a player when he undertakes to make at least 5 tricks, playing a lone band against the other three. Above the solo call is misère. When a player makes this call he undertakes to lose every trick, despite every effort on the part of the other three players to make him take $n$ trick. There is no trump suit in the misère call. Above misère comes abundance in any suit except trumps. A player declaring abundance undertakes to take at least 9 tricks, playing a lone hand against the other three. Abundance in trumps calls over abundance in a plain suit.

Above the last call comes open misère. When this call is made a player undertakes to lose every trick, his hand being exposed upon the table after the first trick has been played. The highest call of all is abundance declared, when the player, naming his own trumps, undertakes to win all 13 tricks against the other three players. A player making such a call has the right to lead.

When players are playing prop and take, or prop and cop, as it is more generally known, they may be sitting together or opposite one another, and in those positions they remain. No player may bid after once passing with the exception of eldest hand, who has the privilege of accepting a proposal.

In three-handed solo a player is sometimes allowed to bid a 6-trick solo, in which he names his own trumps and must talie at least 6 tricks. Except in abundance declared eldest hand leads and players should follow suit. If not, a player may discard or truinp. The winner of each trick leads for the next. See Whist

## Somnambulism. See Sleepwalking.

SOOT. In summer, when fires are infre quent, soot accumulates only in small quantitics, but in winter it forms a thick coating inside the chimney and it is most important to have it thoroughly swept and to arrange for the periodical visits of a sweep.
Garden Uses. Soot which has been exposed to the air for a few weeks is an excellent fertilizer for plants and may be scattered on the soil round about them. If placed in a bag suspended in a barrel of water soot makes a useful liquid manure for ferns, chrysanthemums and other pot plants. Fresh soot cither alone or mixed with lime is a good soil insecticide; it should be forked in the ground, not left on the surface.
SOOTHING SYRUP. The practice of dosing fractious and restless children with soothing syrups, soothing powders, and similar preparations is strongly to be deprecatited. It may malie things easier for the nother or nurse, but this may be at the expense of the child's welfire. If a dose of castor oil, or some other simple purgative, does not improve the child's temper, consplt a doctor. See Aperient; Child; Teeth

Sorrel. Hardy evergreen shrub ranch used in
SOPHRO-CATTLEYA. This name is given to a bigeneric orchid raised by crossbrceding hetween Sophronitis granditlora and cattleya. It Howers during winter, and may be grown in well-drained pots, or hang. ing baskets. The cultural requirements of sophro-cattleya aro very much the same as for cattleyas. See Orchid.
SOPHRONITIS. This is a small group of dwarf-growing evergreen orchids. The favourite is grandiflora with orange-scarlet blooms: it should be grown in pans or baskets suspended frow the roof of the intermediate house. Sophronitis needs a mixture of peat, moss, and charcoal, and flourishes in a temperature which may vary from $55^{\circ}$ to $70^{\circ}$, according to the season of the ycar. See Orchid.

SORBET. This is a water ice flavoured with fruit and liqueur. General dircetions for the making of water ices and the serving of sorbets will be found in the article on ices (q.v.).

Sore Throat. Sce Laryngitis: Pharyng. itis; Throat: Tonsillitis.

SORREL : The Herb. The leaves of this herb are used as an ingredient of salars and soups. Seed should be sown in March in drills 6 in . apart, and the rows thinned out during the following month. The name sorrel is frequently applied to species of the genus Oxnlis. See Oralis; Spinach

Use in Cookery. Sorrel is used in cookery chiefly for a soup and a purée, the purée being employed as a means of dishing and also as a garnish for entrées. It is especially suitable for serving with lamb, veal, or swectbreads, and also as a garnish for poached eggs in place of spinach.

Sorrel must always he thoroughly cleansed, and it is better to use a hair sieve for making it into purée. Soda should never be put with sorrel when cooking it, on account of the acid contained in tho leaves.
Sorrel Purée. To make the purée, pick and wash 2 lb . of sorrel and boil it in about $\frac{1}{2}$ pint of water until quite soft, then drain it on a hair sieve until all the water is out of it. Clean the stewpan in which it was cooked, dry it and melt in it $1 \frac{1}{2} \mathrm{oz}$. of butter. In this
fry to a light brown 1 pecled and sliced onion, then add 1 oz. of Hour, 1 dessertspoonfui of brown sugar, and $\frac{1}{}$ tesspoonful of grated nutmeg. Stir all together for 2 or 3 min ., then put in the sorrel and $1 \frac{1}{2}$ gills of brown sauce. Season well and pass through a hair aicve.

Sorrel Soup. Sorrel soup may be made as a clear vegetable soup or it may be thickened by mixing in the yolks of 2 or 3 eggs to each quart of soup. If it is to be serred as a vegetarian soup water must be substituted for stock. For the thin soup clean and shred line 2 lb . sorrel, the best part of a large lettuce, 12 sprigs chervil, and 4 or 5 sprigs parsley. Sauté these in 2 oz. butter in a stewpan, then add 2 pints well flavoured rich clar stock, : lumps sugar, and scasoning to taste. Boil up and simnice for 20 min ., then clear the soup of fat, pour it into a soup tureen and serve with dice of fried bread.

For the thickencd soup proceed as for thin soup, but when the whole is boiling, whisk up 2 or 3 yolks of eggs and add to them by degrees about pint of the liquor of the soup. Stir theso till all is just ready to serve, then draw the pan back from the fire and stir in the thick. ening. Cook for 2 or 3 min . without allowing the soup to come to the hoil, then add a good s)ice of fresh butter, stir this in and serve.

Souchong Tea. Souchong is a black China tea of a fine flavour suitable for everyday consumption or for blending. See Tea.

SOUFFLE. The meaning of this word is something puffed or blown up, and in cookery this condition is obtained through using the stiffly whipped whites of coggs and preparing the ingredients in such a manner that they rise upward nas soon as the heat penctrates them. Baking powder is never aclded to give lightnces, success depending on skill in preparation and the beating of the eggs. The delicacy of a soufflé renders it a most wholesome and favourite dish, and one which may be safely offered to invalids.

A souffé is cooked directly it is mixed and served immediately before it has time to sink, It may be baked, in which case the oven must be cxactly of the right moderate heat and kept at a steady temperature during the process of cooking; or it may be stcamed, in which case the water must be boiling in the saucepan before the souffé tin is placed in it. Bakerl souftés are served in the dishes in which they are cooked.

Befors: serving a steancel souffé it is usually turned out on to a dish from the tin mould with straight sides in which it has been cooked. Tbe mould is prepared by brushing it over with pure salad oil or clarificl butter. A double band of white kitchen paper deep enough to stand 3 or 4 inches above the lop of the mould arid long enough to fold right round and overlap should be also greased and tied round the outside of the mould. A round of paper is then greased ready to cover the top. The soufté mixture should only fill three parts of the mould to allow for rising. The mould is then put in a pan of boiling water. Sce that the water only reaches half-way up tin.

For baked souftlés lireproof earthenware chinn or glass souffé dishes are used. Oven table glass ware is an aid when making a soufflé, as the process of baking can be clearly seen. When serving, lireproof dishes are placed on another dish covered with a paper duily, unless the souffle dish is provided with a plated or silver frame. Individual soufflés are balied and served in small paper or china cases. Any dishes or cases used must be first well greased. When threc piarts tilled with a soufté mixture, they are placed on a baking-tin and cooked until well risen and firni. Aroid any unnecessary opening of the oven door, as a sudden draught of air inight cause the souffé to sink. It should never be
left in either steamer or Laking dish after jt has finished cooking.

Swect fla vourings are added for light souffie puddings, while cheese or fish, game and white meats make this quickly cooked disb into a savoury, a light luncheon course, or entréc. The main ingredients consist of four, milk or stock, and new-lnid eggs. Any fish or meat used should be firsit pourided and passed through a sicve. Checse should be grated. Fruit is not very suitable for sweet souffé making, the best flavours being chocolate, vanilla, colfee, almond or a dclicate essenoc. Swoet souffés may be steamed or baked, cheesc souffés are baked, while fish and meat souffćs are steamed.

Cheese Souffé Melt 1 oz . butter in a saucopan over the fire, stir in $\frac{1}{2}$ oz. flour, and when the mixture is smooth add 1 gill milk, stirring the whole over a gentle heat until it thickens. Then take the pan from The fire and mix in $2 \frac{1}{2}$ oz. grated cheese. When the mixture is slightly cooled stir in, one at a time, the yolks of 2 cggs . Season the mixture to taste, afterwards folding in lightly the stiffly whipped whites of 3 eggs. Hall fill a greased and fireproof soufflé dish with the mixture, and bake it in a quick oven for 10 or 12 min . Sprinkle about 2 teaspoonfuls grated checse over the top of the souffle, and serve it immediateiy.

Chicken Souffle. Make this by laking the Hesh from a chicken and, after removing the skin and gristle, cutting it into amal| pieces and pounding them well in a mortar. Season them with salt, pepper, and a grating of nutmeg, and add $1 \frac{t}{2}$ gills good white sauce and the yolls of an egg before passing the mixţure through a fine wire sieve into a clean basin. Then work in lightly, but thoroughly, $1 \frac{1}{2}$ gills cream, partially whipped, and the stiffly whisked whites of 2 eggs, pour into a preparod souffé tin, and steam gently for about 50 min . Let the souffle stand for a minute to shrink slightly, then remove the paper from the tin and turn out on to a hot dish. Serve at once with béchamel sauce. Game or rabbit can be used for this souffé in place of chicken.

Chocolate Souffle. This souffé can be made from $\ddagger \mathrm{lb}$. breadcrumbs 2 oz . sugar, 1 oz . grated chocolate, 1 pint milk, $\frac{1}{2}$ oz. butter, and 2 eggs. Boil the milk, chocolate and sugar together, then add the breadcrumbs and butter and stand the mixture in a cool place. When it is cool, add a few drops of vanilla essence and the yolks of the eggs, afterwards stirring in the whites, whipped to a stiff froth. Pour the whole into a well-greased glass or other fireproof souffé dish, and bake it for 20 min . in a moderate oven until it is of a golden brown tint.

Fish Souffle. To make this soufflé melt 2 oz. butter in a saucepan, stir in the same quantity of flour, and mix them together over the fife for a few minutes. Then add 1 gill milk or fish stock and stir until the sauce thickens. Put it into a nortar with $\frac{1}{2} \mathrm{lb}$, of any white fish and pound them well together, adding 3 eggs, one by one. Scason the inixture carcfully, rub it through a sieve, and mix it with 1 gill whipped cream. Put it into a prepared souffé tin and stearm for

Fish Souffé. Dish made from any white fish
$\$$ hour, then ccat it with some good white sauoe and decorate top with chopped parsley.

Lemon Soufflé. This sweet soufflé may be stenmed. It is made by rubbing together a heaped tablespoonful of castor sugar and the grated rind of a lemon. Nolt a lump of butler about the size of a len's egg in a small pan over the fire, add a heaped tablespoonful of llour, and mix the two smoothly. Cool them for a few minutes, taking care that they do not brown; then pour in a gill of milk and stir the whole over the fire until it leaves the sides of the pan. Move the lattor to the side of the fire, add the sugar and rind, and a little lemon juice, and then beat in separately the yolks of 3 cgge. Whisk the whites of 4 eggs , together with a pinch of salt, to a stiff fpoth and stir them into the mixture, blending the two well together.

Have ready a prepared souffic tin, and decorate the bottom of it with halved glace cherries. Pour the mixture in and cover it with anotber picce of greased paper. Plaoe the tin in a pan of boiling water and steam the souffé for about $\frac{1}{2}$ hour, or until it is wel! risen and firm to the louch; then turn it on to a hot dish and serve it with lemon sauce. Orange may be used to flavour the souffé and sauce instead of lemon.
Liqueur Souffé. Any kind of liqueur can be used to Havour this souffé. Mako it by melting a lump of butter rather smaller than a hen's cgg and then mixing in a wellheaped tablespoonful of flour. Stir the two over the fire until they are smooth, but do not let them brown. Pour in 1 gill milk; continue stirring for a fow minutes, and draw the pan to the side of the fire before beating in separately the yolks of 2 eggs.

Add 1 tablespoonful castor sugar, a pinch of salt, and enough liqueur to flavour the whole to taste. Just before turning the mixture into a greased soufflé dish, stir in the stiffly beaten whites of egg. Place the dish in a tin of hot water in the oven and cook the souffle until it is frm and risen. If a sweet sauce is served, it may be Havoured with the same liqueur as that used for the souffle itself,

Oyster Souffé. To make this souffé, blanch and beard a dozen oysters and cut ench into threc or four pieces. Melt 1 qz . butter in a stewpan, stir in smoothly 2 oz. flour, and mix then well together over the fire. Pour in 1 gill ovster liquor, and stir the whole until the Hour loses its raw flavour and the sauce thickens. Talse the skin and bones from $\frac{1}{2} \mathrm{lb}$. whiting, then put it into a mortar with the sauce and pound the two together, adding

Oyster Souftle, coated with white sauce, and decorated with half slices of lemon
the yolks of 3 eggs, one by one, and salt, pepper, and cayenne to taste.
lub the mixture through a hair sieve, then stir into it the oysters and the stiffly whipped whites of 4 eggs. Pour the mixture into the prepared souffé tin, and steam it gently for about $\frac{1}{2}$ hour, or until it feels firm. Serye it with a good white sauce poured over it, and garnish it with lines of finely chopped parsley or slices of lemon.
Potato Souffé. To make this dish, rub $1 \frac{1}{2} \mathrm{Jb}$. cooked potatoes through a sieve, add to them loz. butter, previously inelted in a pan, and put in also 2 tablespoonfuls milk, the yolks of 2 eggs, and scasoning to taste. Mix these well, then take the pan from the fire and stir in lightly the stiffly whisked whites.
Turn the whole into a prepared soufflé mould and steam the soufflé for about 40 min. in a saucepan containing enough hoiling water to reach half-way up the mould. Turn it on to a hot dish, pour some white sauce over it, and garnish it with chopped parsley or the yolls of a hard-boiled egg rubbed through a sieve. If preferred, the soufflé can be baked in a china souffle dish in a moderate oven for about $\frac{1}{2}$ hour.

Rice Souffé. An excellent rice soufflé can be made by washing $\frac{1}{4}$ b. rice and boiling it in 1 pint milk to which has been added 6 oz. butter, and the same quantity of sugar. When these are cool, stir in the yolks of 4 eggs and add a little vanilla essence. Whisk the whites of the eggs very stiffly, then fold lightly into the rice, and pour the whole into a well-buttered mould decorated with angelica and cherries. Steam the souffle gently for about $\frac{3}{4}$ hour, and serve it with jam sauce. See Eggs; Egg Whisk; Entrée; Fireproof Ware; Ham ; Mould; Omelette; Sauce.

Sound Box. See Gramophune.

## Soups: Clear and THICK KINDS

## Many Recipes for the Staple Itcm of the Dinner Menu

This contribution, which describes the making of various kinds of soup, may be read in connexiopn with the articles on Dinncr; Luncheon; Supper. See also the entries on Artichoke Soup; Beef Tea; Browning; Clarifying; Croûton ; Menu; Mutton ; Sauces; Scotch Broth; Stozk, etc.

Soup is prepared by boiling meat or vegetables with water. It may be thickened by the aid of starchy substances or the admixture of beaten eggs. It precedes the fish and meat courses at meals.

To make nourishing soups good stock is essential and directions for preparing the various kinds are given in the artiole on stock, Directions for browning or caramel used for colouring soups are given in page 155, and for making roux to thicken brown and white soup in the article on Sauces. Soups may be divided into five classes: Clear Soups, Broths, Thick Soups, Purées, Vegetarian Soups.

Clear Soups. Clear soup or consommé is prepared from first stock, and if that is ready and made according to the rules laid down, all that is necessary is to provide extra seasoning, and a garnish.

The foundation of clear soup is always the same, the various names given to it on a menu
being merely dictated by the garnish. Spring soup, for instance, is clear brown stock gar-
nished with delicate spring vegetables, in cluding asparagus points, green peas, forced French beans, or new carrots, the two latte cut small.
A good clear soup is made by the addition to any clear stock of minced beef and vege. tables. An onion and a carrot, cut into small pieces, should be allowed to $\frac{1}{2} \mathrm{lb}$. beef and 4 pints stock. These should all be put into a saucepan, with 1 or 2 peppercorns, a sprig of mixed herbs (parsley, marjoram, and thyme), and the white of 1 egg. The soup should be whisked over the fire until frothy. After it has boiled it is left to simmer for about 30 min ., then strained through a scalded teacloth.

Consommé royal is made from brown stock with the addition of a savoury custard, cut into fancy shapes. To make the custard, 1 egg is allowed to 1 tablespoonful milk or white
slock 'The egg is beaten with satt and pepper to taste, and stirred into the hot milk or stock The custard is then stenmed in a small greased basin for about 15 min . and allowed to cool When it is cold the custard should be sliced with a knife which has been dipped in hot "ater, and then atamped into fancy shapes. These should be placed in the soup turcen and the boiling consommé poured over

Clear soup can be garnished with cooked regetables, shredded very finely, or with cooked vermicelli or macaroni, or small force ment balls fried and well drained
Julienne Soup. This favourite clear soup is made by the addition to 3 pints of clear brown stock of 1 carrot, 1 onion, $\frac{1}{2}$ large turnip, 1 strip celery, 1 tablespoonful green peas (cooked), pep per, salt, $\frac{1}{2}$ oz. butter. The prepared vegetables are cut into fine strips like matches. Melt the butter in a saucepan and fry the vegetables in this with the seasoning for a few minutes shaking thein to prevent them from scorching Drain them from the butter, add them to the hot stock, simmer for 30 min . keep wel skimmed. The vegetables may be parboiled in salted water instead of frying in butter if preferred before simmering in the stock till quite tender. French beans, cooked and cut into thin strips, may be added instead of or with the peas.

Paysanne Soup. This clear vegetable soup is made by cutting into thin rounds about the size of a sixpenny-picce a carrot, a turnip; 2 leeks and a stick of celery. Fry these lightly in a saucepan containing a little butter; then add a pint of chicken or veal consonmé, and let the whole cook gently until the vegetables are tender. Just before serving, remove any scum that may have risen to the surface, and add a little chervil.

Broths. For this class of soups the stock is usually made by saving the liquor from meats boiled whole for table. The liquor should be strained through a hair or tammy sieve, akimmed frec from fat and well seasoned. It is generally thickened with rice or pearl barley and a few fresh vegetables cut small and cooked in it. At the finish a small quantity of chopped parsley may be added. Sheep's head broth, mutton broth, Scotch broth or veal or chicken broth are some of the varieties of this description of soup or bouillon. Boil some vegetables in the liquor while cooking the meat to flavour the broth.
Pot au Feu. Pot au feu is the name given to the French national broth. To prepare it, put 1 lb . brisket of beef in a large saucepan with 2 quarts water, bring the latter to the boil, reniove all scum from the top, and add salt to taste. Simmer all for $\frac{1}{2}$ hour, and in the meantime prepare 2 carrots, 2 leeks, 3 sticks of celery, a cabbage, 2 turnips, and a parsnip

Cut the cabbage into tivo, tying the halves together, and peel and slice an onion. Cut up the carrots, turnips, parsnips, lecks, and celery, using only the white portion of the two lastnamed, and at the end of the $\frac{1}{2}$ hour add them to the soup, together with the onion, cabbage, 10 peppercorns, and a bunch of herbs. Simmer the whole with the lid on the pan for $1 \frac{1}{2}$ hours, then strain the soup and slim off the fat from the top. The soup should then be served in a hot tureen. This broth is often termed Croutte-au-pot when French bread is cut into thin slices and placed in the tureen just before serving, the meat and vegetables being served as a separate course at another meal.
Veal Bouillon. Take 2 lb . scrag of veal and cut it into small pieces. Then put them into a saucepan with 1 quart boiling water and $1 \frac{1}{2}$ oz. of well-washed rice, boil up, and simmer gently for an hour Add an onion, carrot, and 3 sticks celery cut in neat pieces. Cook until these are soft, and just before serving sprinkle in two tablespoonfuls of picked ehervil. Skim and remove all fat before adding the chervil to it.

Thick Soups. These may be cither white or brown according to the white or brown roux employed to thicken them, or to the nature of the stock used. Thick brown soups should be made with good stock and Hlavoured with vege table They may be thickencd either with a brown roux, or with rice. If rice is used as a thickening it should be cooked previously and boiled up in the soup.

All brown soups should possess a rich deep brown colour, whether made thick or thin To improve the appearance of the soup it may be necessary to add a little browning, but this should be done with discretion.

In making either white or brown thick soups the quantities required for thickening are im portant, and the following may be noted From 1 to $1 \frac{1}{2}$ oz. flour will thicken 1 quart liquor About 2 tablespoonfuls rice, etc., should be allowed to 1 quart stock and 2 to 3 eggs and 1 gill cream will make a sufficient thickening for about 2 or 3 pints of white soup. When eggs are addcd as a thickening, the soup must only be simmered and not allowed to boil up again, or the eggs will curdle.

The garnish for thick soups should not be neglected. If vegetables are to be used they must be neatly cut and freshly boiled. If no vegetable cutter is available the roots may be shred or shaped evenly in dice. Small picces of carrot take about 7 min . to boil. turnip 5 min .

Chicken Soup. A nourishing thickened white soup is made by cutting up an old chicken into small picces, and putting the whole, together with the bones, into a suucepan containing enough cold water to cover it. Bring the bird slowly to the boil, skim the stock well, and add a carrot, a leek, two small sticks of celery all cut into small picces, a bunch of mixed herbs, and $\frac{1}{2}$ teaspoonful salt. Simmer the soup for about 5 hours, remove all traces of scum, and then strain through a fine sieve. Let the liquor stand in a hasin till it becomes cold, then pound some of the chicken meat in a mortar, moisten it with a little stock, and rub it through a sieve. Make a smooth white roux by melting a small lump of butter in a saucepan and mixing with it $\frac{1}{2}$ oz. flour, then add the liquor and pounded meat, and boil up the whole. Finally add $1 \frac{1}{2}$ gills boiled milk and seasoning, and serve.

Giblet Soup. To make this thickened brown soup the giblets of a goose or turkey, or of a couple of clickens or ducks, are needed Cleanse and cut them into small pieces; then melt 1 oz. butter in a saucepan, add the giblets. together with 1 lb . lean beef, and a small onion $\frac{1}{2}$ a carrot, and a stick of celery, all cut into small pieces. Fry all these a pale brown, then add 3 pints stock or water, a bunch of parsley and mixed herbs, and salt and pepper to taste. Bring the soup to the boil, skim it well, then put the lid on the pan and let its contents cook gently for about 2 hours.

The giblets, etc., may then be strained out and the liquid poured into a clean sauccpan. Mix $\frac{1}{2}$ oz. flour smoothly with the butter in which the vegetables were fricd, brown and add half a glass of sherry or a little cold brown stock, ald it to the soup, and hoil up the whole. Put in 2 or 3 in . of coolied macaroni cut into thin rings, and stir it over the fire for a few minutes. Before serving the soup add more seasoning if desired.

Macaroni Soup. Boil 1 quart white stock, then add to it 2 oz. cooked nuacaroni and simmer for $5^{5} \mathrm{inin}$. Mix together the yoll: of an egg and 1 gill unsweetencd condensed milk, and add 2 tablespoonfuls grated cheesc. Take the pan containing the macaroni away from the fire before adding the egg mixture, and then stir all over a gentle heat until the soup thickens. Season to taste, add 1 dessertspoonful of chopped parsley, serve with sippets of toast and then hand round grated cheese.

Mulligatawny Soup. To make this thick brown soup, fry 1 carrot, 3 onions, cut small, with a head of celery cut into dice, in 4 oz . fat or butter until the onion begins to look clear then add 2 tablespoonfuls curry powder and the same of flour. Fry all till the onions brown then stir in by degrees 2 quarts good stock. Let all simmer till the scum has risen well and the vegetables are quite soft.

Pass the soup through a hair sieve, return it to the saucepan, adding a dessertspoonful of curry pastc and scasoning to taste. Squecze in a little lemon juice. The curry paste should be rubbed smooth with some of the liquor and dissolved before being added to the soup. Rice should be handed round with it

Mushroom Soup. A quart of bone stock and lb . each of ox lidney and mushrooms are needed to make this brown soup. Cut the kidney into small pieces and roll them in Hour, mixed with a little pepper and salt. Melt 1 oz butter in a saucepan and fry the mushrooms, pecled and cut into small pieces. Add the kidney and the stock, and simmer for about 2 hours. Make a brown roux from a tablespoonful of Hour stirred into a tablespoontul of melted butter and thicken the soup with this. Bring it just to the boil and serve it very hot.
Tripe Soup. For this white soup take $\frac{1}{2} \mathrm{lb}$. tripe, a turnip, a carrot, 3 onions, 2 table spoonfuls cornflour, $\frac{1}{2}$ pint milk, 3 pints water and a little sweet herbs, parsley, salt and pepper. Scald the tripe in boiling water and then cut it intosmall pieces. Having prepared and sliced the vegetables, put them in a saucepan with the tripe and water and simmer them for $1 \frac{1}{2}$ hours. Mix the cornflour to a paste with a little cold milk, add to the soup, and stir all well together. Just before serving add the rest of the milk, the herbs. parsley, salt and pepper, and serve the soup hot with croûtons of fried bread.
Turkey Soup. This soup provides an excellent method of using up any cold cooked turkey. To make it, cut up the remains into small pieces and put these, together with the chopped bones, into a stewpan. Add a bouquet garni and a small blade of mace, a sinall pecled onion, 2 quarts white stock or milk and water mised in equal proportions, and scasoning to taste. Put the lid on the pan, simmer its contents gently for about 3 hours, then strain the soup, and after rinsing out the pan pour it back again. Mix $1 \frac{1}{2}$ oz. ground rice smoothly with a little cold milk, stir it gradually into the soup, then bring the latter to the boil and let it boil gently for about 10 min . Have ready 2 oz. fieshly boiled macaroni or spaghetti, cut it into short lengths, and heat it up in the soup before serving.

Purées. This class of soups is made by rubbing the meat, fish, vegetables, etc., through a sieve after cooking. For vegetable purées, beans, carrots, pens, artichokes, potatocs, chestnuts, tomatocs, or celery are used. These are prepared and, if necessary, cut in small pieces. They are then tossed in butter for a few minutes and cooked in boiling stock. When done they are passcd with the liquor through a sieve, then returned to the stewpan, boiled up, seasoncd, and scrved in a tureen, with dice of fried bread handed round
Vegetable purces are often white no when potatocs or artichokes are used. White stock must then be added instead of second brown stock and a small quantity of milk or creain must be boiled with them when finishing the soup in order to blanch it. White soup.s usually are scasoned still further with a dash of mace or nutineg.

Carrot purce should be an orange colour and only the red pirts of the carrot be used for it. Green pea soup nay be made with second stock, and an economical version of it can be prepared by cutting up the pea shucks and adding them with the peas to the liquor, increasing the amount of stock in proportion to
the quantity of shucks. The shucks will hoil quite tender if the peas are young, and the flavour after the vegetables have been passed through the sieve will be found excellent. A bout 2 lb . fresh vegetables to 3 pints liquor is the arerage.

Dricd pulse vegetables make good and nourishing soups, and water may in all cases be substituted for stock. The pulse is soaked overnight, then washed and picked. It should be stirred. with a few fresh vegetables to give it flavour, notably onions, in butter or fat for a fow minutes over the fire; the water is then added cold, and the whole boiled up together and cooked until the pulse is perfectly soft. The soup should be passed through a wire sieve or colander, and afterwards returned to the saucepan in which it was boiled, well seasoned and thoroughly heated ready for serving.
A bacon bone or one or two rashers are often added to lentil soup. The bone is removed before the soup is sieved, but the rashers, if minced small. will pass through the sieve with the lentils. To pea soup ham or bacon bones are sometimes added and boiled with the peas; they must be removed as soon as the peas are soft enough to sieve. For soup made from split peas it is better to use the liquor from salt beef after it has been boiled, but first ascertain that it is not over-salted. The liquor from any boiled nieat may be used, or a weak stock. Plenty of fresh vegetables must in. variably be cooked with dried pulse to give the right Havour.

Haricot beans make an excellent white soup, but only celery and onions are suitable for adding as a vegetable flavouring. This soup should be finished with a small quantity of milk. The amount of pulse required for each quart of water is about $\frac{1}{2}$ pint ; $\frac{1}{2}$ pint milk is the usual quantity for finishing 1 quart white soup. Fish puree is made with fish stock, thickened with white roux, seasoned and linished with milk or cream. The fish is cut up and flaked, all bones and skin removed. cooked in stock till tender, and then passed through a sieve before adding the cream.

Parmentier Soup. A good creamy potato purée can be made by slicing 3 large potatoes and the white part of 3 medium sized lecks, frying them lightly in a saucepan containing 1 oz. butter, and then adding 1 pint veal or chicken stock. Cook the whole gently until the potato is tender; then rub it through a fine sieve. Reboil it, and before serving add scasoning to taste, 1 gill cream, 1 oz . butter, and a little chervil.

Parsnip Purée. The ingredients consist of 1 pint milk, 1 quart bone stock, 4 parsnips. 1 onion, 2 sticks celery, Hour and scasoning. Clean and slice the vegetables, fry them in dripping, and then add the stock: Let the whole simmer until the vegetables are tender, then rub them through a wire sieve and return the pure to the stewpan. Add the milk, seasoning, and the flour mixed smoothly with a little nilk, and cook the soup for about 5 min Serve it with croutors of fried bread.

Sp:nach Soup Cook the spinach, make it into a purce, then stir it in butter for $\mathbf{i} \mathrm{m}$ min and add boiling white stock and a little cream The quantities required are 2 lb . spinach, 13 pints stock, 2 oz. butter, it gills cream. Fla vour with lemon and nutmeg, and add the stock to the purce by degrees.

Tomato Purée. Trim and wash three !ceks, holding them under running water so as to rid the inner leaves of grit, then cut them into small pieces, and fry them gently without browning them for a fow minutes in a pan containing loz. fat.

Add to them $\frac{3}{4} \mathrm{lb}$. tomatoes previously wiped and cut into quarters: fry these also until they are tender, and then pour over them $1!$ pints stock. A bunch of mixed herbs should
a lso be added, and the whole boiled up rapidly Then season it to taste, and after cooking it slowly for abour $\frac{3}{4}$ hour rub it through a fine sieve.
In the meantime rinse out the saucepan, then pour the soup back, add a teaspoonful milk, and reheat the whole. Just before serving the soup add a lump of butter a bout: the size of a hen's egg, and, if necessary, a little more seasoning.

Vegetarian Soups. The recipes for the pulse soups given may be adapted for vegetarian soups by using vegetable stock, milk and water or milk in place of meat stock. For other vegetable soups the vegetables are cut thin, fried in butter as for a purée, before adding the liquor Onion soup and leek soup should he thickencd with white roux. For white soups the vegetables must only be stirred long enough for the butter to be absorbed if the soup is to be brown they must be well fried. After they have been cooked in the butter, they are boiled and passed through a sicve. Onions, leeks, and a touch of garlic are necessary for these soups to increase the flavour. They are seldoin thickened except with dried or baked pieces of bread.

Another class of white vegetable soup is made by shredding lettuce, the hearts of spring cabbages, cucumber, spring onions, and various salad herbs. These shreds are stirred in butter for 8 min . without colouring them They are then moistened with regetable stock, a little nutmeg is added, also seasoning, boiled up and simmered for 15 min . Just before serving the soup is thickened with a liaison of eggs and cream. Bomne femme soup is made much like the foregoing; 4 lettuces, 1 cabbage. and a good handful of salad herbs being required. and about 3 pints vegetable stock and 2 oz . butter.

Vegetable Bouillon. A purely vegetarian broth is made from the following vegetables prepared, cut up into small pieces and placed in 4 quarts boiling water to make 2 quarts soup after simmering for 4 hours: 8 oz . carrots, $1_{2}^{\frac{1}{2}} \mathrm{oz}$. haricot beans, $\frac{1}{2} \mathrm{oz}$. lentils, 4 oz potatocs, 4 oz . turnips, 3 oz . leeks or onions. Add salt to taste.

SOUR MILK : Medical Uses. Poisonous substances resulting from the putrefaction of protein food in the bowe! have been blamed for eausing or aggravating various disorders, such as acne, boils, cczenia, enteritis, neurasthenia, and arterio-sclerosis. It is often attempted by the use of soured milk to diminish or prevent this auto-intoxication. The lactic acid bacilli contained in sour milk multiply in the bowel at the expense of the putrefactive bacteria. A pint of soured milk is taken daily, in two or three portions, at meals, or preferably between meals. Thi soured milk is taken for threc wecks at a time, and should be persevered with even if constipation ensucs, which it frequently does.

Ordinary buttermill: is sometimes used, but milk artificially soured by the Bulgarian bacil lus is better, as this bacillus appears to be more active and more resistant than the ordinary lactic acid bacillus found in but termilk. Solid and liquid preparations containing the Bulgarian bacillus are on
the market, but it is better to use the products of a good dairy, when these can be had. It is very important, when undergoing the treatment, to avoid meat extracts of all kinds, white of egg, fat meat, and high game, as these form a good food for the putrefactive bacteria which it is desired to destroy.
 flour, $\frac{1}{2}$ teaspoonful cream of tartar, $\&$ pint sour milk, $\frac{1}{2}$ teaspoonful bicarbonate sodn, 1 teaspoonful golden syrup. Add salt to flour, then mix in all dry ingredients. Add the syrup to the sour milk, pour into flour, etc., and mix lightly. Turn on to a floured board, and knead quickly until smooth. Roll out into a round $\frac{1}{4} \mathrm{in}$. thick, divide into four or six pieces, and cook in a hot oven or on a girdle until well risen and browned. The cones should be scrved hot.
Sour Milk Cheese. Allow the milk to become very thick and curdled, then put the solid curds in a piece of clean muslin. Tie this up and suspend it on a hook in a cool place wherc all the moisture can drip from it When it is dry and crumbly take the bag and dip it quickly into boiling water. Do not let it stay in the water more than a minute or so. Let it dry again, then put the curds in a basin and beat up with salt and pepper to taste. Press into a mould or make into a pat, and cover with greaseproof paper. The cheese will keep several days in a cool place. See Milk.
SOUTHDOWN MUTTON. A fine special breed of sheep fed on the Sussex downs is noted for the quality of its meat, which is known as Southdown mutton. A leg of this mutton, in particular, is considered a delicacy, but the chops and cutlets are also estcemed. See Mutton.

SOUTHERNWOOD. This is a shrubby plant. Artemisia abrotanum, which grows 3 ft . high and bears fragrant greyish leaves and yellow flowers in late summer. It flourishes best in light or well-drained soil and is increased by cuttings in a frame in August. Other names for this plant arc lad's love and old man.

SOWING: Of Garden Seeds. The commonest crrors made in sowing sced are to sow too thickly or too deeply, and to allow insuffi cient drainage to sceds sown in pots, pans, and other receptacles. As to depth of sowing. it is a good practice to cover seeds about twice their own depth

Vegetables as a general rule are best sown in drills shaped like a $V$ to the desired depth by means of a hoc, but in the case of beans and

Sowing. 1. Home-made drill rake. 2. Drills drawn and labelled. 3. Triangular drill. 4. Flat drill for beans, peas, etc. 5. Economical group sowing. G. Seedbox with klass covering. 7. Drainage holes for same. 8, Seed-bozes and pots in frame. 8. Pot prepared for sowing : $a$, crocks ; $b$, soil flbre $; c$, chopped turi : $d$. good soil ; $e$, fine soil and sand. io. Soot sprinkiler
pens it should be fint or saucer-shnped, as pictured. Always use $n$ tnut garden line when chopping out or drawing drills, to cnaure straightness. Sufficient seed should be placed to provide good rows, an old garden maxim being one for pests, one for the weather, and one for the harvest crop.
The following quantitics, in portions of ounces or pints, will be found ample for goorl rows of vegetables 100 ft . long: Broad bcans, French beans, and scarlet runners, $\frac{1}{2}$ pint; broccoli, Brussels sprouts, cabbage, cauli. llower, leek, kale lettuce, onion, savoy and turnip, $\ddagger$ oz. ; carrot, parsnip, radish, and swede, $\frac{1}{2} \mathrm{oz}$; beet chervil, and spinach, 1 oz ; peas, 1 pint

Hardy annuals are usually sown out of doors in March and April where they are to bloom in summer; many may be sown in August-September to provide late spring and early sumner flowers. Biennials, e.g. sweet william and Canterbury hell, are sown in May; hardy perennials under glass in spring or out of doors in early summer. See Frame; Hotbed; Propagation; Seed.

SOY. This sauce is usually bought ready prepared. Its chicf ingredient is the soya bean, which is imported from China, Jnpan and Manchuria. Japanese soy, made from soya beans, coarsc barley meal and salt in equal weight, is usually the most popular. It should be brown in colour, of a thick consistency and clear. Chinese soy contains varying amounts of sugar, mace, ginger and pepper, and has a sweet. treacly flavour. Japanese soy is largely used in the mnking of store sauces. See Sauce.
SPADE. There are several varieties of spade, and many fancy shapes, but the one with the simple, broad, straight edge is the

Spade. Correct position in which to hold the spade before thrasting it into the earth
best for general purposes in the garden. The handle grip usually fitted is of the type known as the eye handle, and is strengthened with a rivet through the gripped part. Another type (illustrated in use) is T-shaped, having a short length of rounded wood attached at its centre to the end of the handle.
Much labour is wasted in digging if the spade is not properly used. The spade should be held nearly vertically over the ground where it is slesired to dig, the left hand being a good way down the handle. The right hand grips the end of the handle. A sudden downward
motion follows this. Having pushed the spade as far as possible into the soil with this downward thrust, the right foot is planted on the blade on the right side of the handle. The

Spaniel. Field spaniel, the well-known sporting dog. Above, silky-coated Blenheim toy spaniel
sink the blade still lower into the ground. Using the unbroken ground at the back of the opade as a fulcrum, the carth is prized up on to the blade of the spade by a downward and backward movement of the right hand. If this operation is found very difficult the earth may be loosened by noving the spade backward nnd forward before attempting to prize the mass. To turn the carth over or to thirow it to any desired place, the left hand is used for raising the blade end of the spade. The last operation consists of turning over the earth, the spade being tilted over to the left to frec it from the earth. See Dibler ; Digging.

SPAGHETTI. A particularly fine make of macaroni, spaghetti is casily digested and can be given with safety to invalids.
Savoury Spaghetti. To prepare savoury spaghetti melt 1 oz . butter in a sauccpan, nnd fry in it for a few minutes 1 lb . sliced tomatoce and a peeled and sliced onion. Then add $\frac{1}{2}$ pint stock and $\ddagger$ teaspoonful of mixed herbs tied in muslin; bring the whole to the boil, adding seasoning to taste, and then simmer it until the vegetables are tender. Break $\ddagger \mathrm{lb}$. spaghetti into small pieces, wash it well and cook it in boiling salted water until it is tender. Take out the herbs from the tomato sauce, rub the latter through a sieve and then put it back into the saucepan, thickening it with $\frac{1}{2}$ oz. cornflour previously mixed with a little cold water.

Boil the whole for a few minutes, kecping it sell stirred, nnd then mix in the cooked and drained spaghetti. Grease a pie-dish, cover the bottom of it with 2 oz . grated checse, then pour in the tomato and spaghetti mixturc and over the top sprinkle another 2 o7. grated cheese. Heat the whole in the oven, and then brown the top beneath a griller before sending it to the table. See Macaroni.

SPAN. As a measure of distance this is 9 in., which is approximately the distance between the tip of a man's tliumb nnd little finger when his hand is outspread. In architecture it is the spread of an arch between its a butments.

SPANDREL. A spandrel is the corner space between an arch and its surrounding frame. If the arch is in a colonnadel oak bedhead, therc are two spandrcls, one on cach side of the arch. If a circular panel is used in a door, there are four spandrels, each roughly triangular, occupying the space between the ring and the enclosing frame. Spandrels are found in inlaid sideboards of the Sheraton and other styles.

SPANIEL. The generic name of spaniel is applicd to seven of the most useful varieties of gun-dogs. 'They are the clumber, cocker, English and Welsh springers, ficld, Irish water,
and Sussex. The cockers and springers are most used, per. forming the dual function of springing and retrieving the game. They are generally docile and friendly of disposition, the exception being the clumber, who does not readily lavish his faroure upon strangers. Another spaniel, the Blenhein!, was used in the fiedd, but he is mainly a toy dog. See Clumber; Cocker; Dog; Japancese Spaniel; Kennel; King Charles; Mange, etc.

SPANISH BROOM. This beautiful hardy shrub (Spartium junceum) bears slender, rushlike branches. and yellow flowers in summer. Spanish broom will thrive in ordinary garden soil, especially if light and sandy. It does not care for stiff, heavy soil. Propagation is by sceds, sown in the open in autumn or spring, or by cuttings of young shoots raised in frames in the summer-time.

SPANISH CHESTNUT. This is a bardy, suinmer-leafing tree (Castanea sativa), 20 ft . to 50 ft . in height, which flourishes in ordinary soil and a sunny position. The nuts are ripe in late autumn. Propagation is by sowing the nuts in early spring, and transplanțing the secdlings when they arc one ycar old. The timber is of value to the woodworker, as it is hard and hcavy and js sometimes used as a substitute for oak, See Chestnut.

## Spanish Fly. See Cantharides.

SPANISH FOWL. One of the oldest brceds of poultry known to British breeders is the Spanish fowl, which is an excellent layer of large white eggs averaging $2 \frac{1}{2} \mathrm{oz}$. and in some strains even more. It is a moderately large bird, with a fair quantity of white flesh, and nlthough it is a black plumaged bird its skin is delicately white.
A single-combed breed, the Spanish fowl carries large white lobes that spread over its face until they meet bencath the wattles. The comb and wattles are red, the plumage rich, glossy. green-black, legs and feet slate blue. See Fowl; Poultry.
SPANISH IRIS. The common name for Iris xiphium is Spanish iris. It is one of the most useful bulb plants for display in the

Spanish Iris, popularly known as the poor man's orchid and invaluable for providing cut blooms
garden, and for nroviding cut flowers of many shades of colour. It has been called the poor man's orchid. Spanish irises should be planted 3 in . deep and 6 in . apari in carly autumn. See Bulb; Iris; Planting.

SPANISE OMELETTE. To make this, fincly ohop a shallot and a clove of garlic, fry them to a pale brown colour in 1 oz butter, and then add 4 stoned olives cut into small dice. Beat up 4 eggs, add 2 tablespoon fuls sherry, and seasoning to taste, and pour them on to the mixture.
Stir the whole over a good fire until the eggs begin to set, then tip up the pan and shape the omelette to an oval form. Tho upper side inay be lightly browned cither by turning the omelette or holding it before a clenr fire. Serve it with a little hot Espagnole sauce. See Omelette ; Sauce.

SPANISH ONION. This is the name of $n$ large variety of onion. Spanish onions are consiclered to be better than British ones for serving as a vegetable, but not for flavouring. They are also very uscful as a cure for certain complaints. See Onion.
SPANNER: For Nuts and Bolts. There are two main kinds of spanner in general use. Within its limits the adjustable type can be made to fit alinost any nut as occasion deınands; the fixed or key pattern is rigid but can be obtained in various sizes.
Cycle spanners, or wrenches, are perhaps the most common of the first type. Theso can be adjusted by menns of a nut, which is generally in the handle of the tool. The fixed size spanner is often double ended, the two ends differing in size by about $\frac{1}{8}$ inch. In box-type spanners the recess is capable of taking the whole thickness of the nut to bc unserewerl. reducing considerably the risk of the spanner slipping off the nut. Some are tubular in form, with a T-hnndle, a cranked arm, or just a hole through which a loose "tominy" bar can be put to give leverage. The tubular type is usually supplied in seta, the smaller sizes nesting inside the largest one. Since they are often double ended, a complete set takes up quite a small space.
Ratchet spanners arc handy and take two main forms. In onc sort the spanner itself is box shaped, fitting into a holder to which is attached a ratchet handle. In the other kind the spanner resembles the ordinary Hat double raded type, but the jaws are disk shaped, interchangeable, and formed with ratchet tecth on the periphery. There is a pawl in the handle which engages with $n$ tooth of the jaw and forces it round as the handle is moved forward and backward.
The cone spanner is for tightening up cones, as on an ordinary bicycle, without removing the wheel. Being made of thin material the spanner can be placed on the cone, and the latter turned the required amount, if the spindle nut is slackened sufficiently. Another handy type for a cycle is the spoke spanner. It fits over the nut on the rim ends of the spokes, and can bo turned without taking the spanner off the nut, thus adjusting the tension of the spoke.
In using an adjustable spanner the open end of the jaws should face in the direction of the turn. There is then less tendency for the spanner to ulip over the nut. If the nut is exceptionally tight, it should bo remembered that a sharptap, or series of sharp taps, on the end of the handle of the spanner is more likely to effect a movement than prolonged pressurc. In some casces it may even be necessary to heat tho nut before it can be unscrewed. See Wrench.

SPAN ROOF. The common form of roof for a dwelling-house is the span roof. It is formed by roof plates fixed to the walls, common rafters and a ridge board, all framed
ogether to cover thi spaco between two walls. Such a roof can take a span of 12 ft .; if a greater span is to be covered, purlins will have to be introduced, or principal rafters in the form of a truss. See Purlin; Roof,

SPARAXIS. These bulbs, which hear brilliantly-coloured flowers on slender stems 15 in. high in carly summer, may be potted

Sparaxis, a gaily fowering bulbous pot plant
in autumn or carly apring and grown in the greenhouse, or they may be planted out of doors in well drained compost of loam, leaf-mould and sand, in a sunny sheltered position. In wet weather in winter a temporary glass covering is beneficial. The bulbs may be left undisturbed for soveral years. There are many named varieties,

SPARKING PLUG. In nll internal comlustion engines the high tension spark from tho nagneto is convoyed to the inside of the cylinder by means of a sparking plug and caused to jump across a gap, thereby firing the mixture

Plugs can be purchased for long, short, or medium reach, the distance from the point of the central electrode to the seating of the plug varying according to the type of engine to which it is to be fitted. The end of the plag should be approximately level with the inside surface of the combustion head or the face of the valve cap, as shown in the diagram.
The sparking plug consists of a stcel shell screwed into the borly of the cylinder or the inlet valve cap. Inside this shell is fitted the contral electrode, which is surrounded by a stoutcasing of some in-
sulating material, such as porcelain, mica or steatite, and thus insulated from the outer shell. At the bottom of the outer shell is a small projection so placed as to be close up to, but not touching, the central electrorle. The high tension current that flows from the nagneto via the high tension lead and the central electrodo
Sparking Plag used in an Internal combustion engine
 jumps across this gap.
returning to the magneto vis the outer shell of the plug and the metal work of the engine.
In order to ensure a gas-tight joint between the insulation and the outer shell, a brass gland nut is generally employed. When a plug has been in use a considerable time it is often possible to tighten the gland nut down a little owing to the fact that the gland packing will havc contracted. This adjustment should only be made while the pluga are warm, and it will necessitate also the checking or resetting of the gap or amount of space between the points of the plug.

The proper setting is highly important, especially in regard to the starting up of an engine, because the wider the points arc apart, the stronger is the current required to jump across. In other words, a greater initial speed will have to be given to the engine before a high tension spark of sufficient intensity can be reveloped. The correct gap) for magneto systems is 0.020 in . ( $\mathrm{s}^{2} \mathrm{~s} \mathrm{in}$.) ; for coil ignition it is $0-025 \mathrm{in}$. ( $\frac{1}{6} \mathrm{in}$ ).

Testing Ignition. Sometimes a fault in the ignition is put down to the magneto, becausc a test of the plugs has been made by turning the engine over very slowly, while placing n finger on the terminal of the plugs and noticing whether a slight ahock is felt. This procedure is wrong, because it in no way proves that a current is passing across the points. Further, it is possible for a plug to function properly at a low voltage, and yot to ahort badly on n high voltage through insula. tion failure, such as a cracked porcelain body.
Onc way to test for insulation failure is to take the plug out of the enginc and lay it on some metal part with the high-tension lead attached. The motal shell must be touching some mctal engine part, but care must be taken that the plug terminal is not in contact with, or too close to, any metal. Then, by revolving the enginc at a good speed by hand or by the self-starter, the sequenco of sparks at the points can be noted. The spark should be regular and of $n$ uniform intensity, otherwisc the insulation is at fault, assuming the plug is perfectly clean.
better niethod is to use : neon tester, consisting of a smalltuhc containing hcon gas. With this dovice the plug need not be removed. The tester is suitably protected, nnd

Spark Tester. Tube containing neon Ras, a device for testing isnition which obriates removal of plug has a terminal
 has a ternuinal which is placed in contact with the lerminnal the plug to be tested. If the plug is sparking characteristic red glow is seen in the tulse.
For other details about sparking plug troubles and their romedy the reader should refer to the article on Motor Car, especially. pars. 1 and 2 of the section dealing with the parc of the car. Sce Internal Combustion Engine; Magneto.

SF'ARKLET. Plain water can be converted into sode water by the use of metallio
capsules known as sparklets. They are sold by glasses, which may chemists, and acrate the water or charge it with carbonic acid gas. See Aerated Waters; Carbonic Acid; Soda Water.
Sparling. The name is sometimes given to the smelt (q.v.). Occasionally a young or very diminutive herring is called a sparling.

SPATCECOCK : In Cookery. Spatchcock chicken is prepared by splitting a young bird down the back, brushing it over with some warmed and melted butter, and then coating it with a mixture prepared from a little madc inustard mixed with 2 tablespoonfuls Worcester sauce, a lump of butter about the size of an cgg (previously melted), and sensoning to taste. Sprinkle the chicken with breadcrumbs, then coat it with some more melted butter, and grill it over a slow fire. Serve the bird with piquant saucc. The neat appearance of spatchcock chicken is gained by breaking the legs and wings at the first joints and fixing them in a flat position with skewers. See Chioken; Sauce.

SPAVIPI. This is a discase alfecting one or both of the hocks of horses, cobs and ponies, and it is exceodingly common. A swollen condition of the hock, especially after the animal has been standing in the stable, following upon active work, is spoken of as bog-spavin. The hock is swollen and puffy, imparting a soft or boggy sensation to the lingers when these are prcsscd upon it, particularly at the front and sides. This conditio.. does not actually constitute discase, unless it amounts to a considerable degree of distension, thus interfering with feecdom of movement of the hock. Apart from this, it does not render the nnimal in any way unsound. Bonc apavin is regarded as constituting unsoundness. No one should purchase a horse without having it examined previously by a veterinary surgeon. See Horse.

SPEAR GRASS. Spcar grass, which is sometimes called the bayonet plant, is the hardy rock perennial Aciphylla. There are threc species in cultivation, lyallii, colensoi, and squarrosn, all about 6 in . high. Spear grass is best planted in rich sand loam, during spring or autumn, in an open part of the rockery. See Rock Garden.

SPEARMINT. The fragrant herb ealled spearmint is sometimes known as lamb mint, and has lance-shapol leaves of pungent odour. Other familiar kinds are peppermint and pennyroyal. Of the several kinds of garden mint, spenrmint has the finest flavour.
Spearmint is sonictimes used as a flavouring for milk or batter puddings, and can be regariled as suitable either for sweet or savoury dishes. Sec Mint.

SPECLAL LICENCE. This term is used for a marriage licence issued by the arch. bishop of Canterbury. It permits n marriage to be celebraterl at any place, with or without previous residence in the district, and at any time, hut the reasons given on nppliention must be regarded as eatisfactory by the archbishop's advisers. The fee for a special licence is $£ \sum 5$, and application for one must be made to the Faculty Office, 23, Knightrider Street, Doctors' Conmons, London, E.C. See Marriage; Wedding.

SPECTACLES. The principal usg of spectacles is to corroct errors of vision. The particular type which should be worn is highly important. Much harm results from wearing spectacles or glasses of any kind which do not fit properly, or arc not accurately suited to the purpose in view and the sight of the wearer.

The type of spectacles required can only be detormined after slilled examination by an oculist or a sight testing optician. It is always falsc economy to obtain glasses without-having the eyes properly examined, or to buy cheap
glasses, which may even more serious and lasting trouble. The shape of the bridge of the nose ofton decides whether spectaoles or cyeglasses should be worn.

Nothing but spectacles should be worn by children, and the framc should be of steel nickel plated, or solid nickel, with curl sides which hook behind the ears. The bridge of the frome should not bear directly upon the bridge of the nose; the weight should be bornc by attachments which bear only on the sides of the nose. The lenses should be of such a shape that the child cannot easily look over or under them.

For adults the irame may bc of platinum, gold. rolled gold, tortoiseshell, or other material, or oven without any frames around the glasues. Speccontinuously. protect the cyes. straightened by an optician. Lonking Glass (q.v.).
tacles with curl sides are beat adapted for object of speculation. those who require to wear their glasses
Whene bright light irritates the eycs, spectacles made of Crookes' glass may be worn. It is made in four tints, the two paler ones leing most beneficial for absorbing the ultra.violet rays; the two darker tints are suitable for bright sunlight and tropical climates. Decply tinted glasses are also largely used in factories where there is a very bright light. These glasses are usually fitted up in the form of gogglos, with fine gauze around the edges, to protect the eycs from flying particles of metal. Goggles of various forms are also used in strong winds and in sandy districta to

Spectacles require great caro in handling. They should not be put on or taken off roughly, and the greatest care should be exercised in closing down the sides lest the joints be damaged or the frames bent; when not in use they should always to placed in a casc. When the fraincs become bent, the defective vision is not properly correcterl. therefore it is essential that they should be

Glasses should be wiped with a piece of clean old linen, or with special cleaners, which provent the glasses from stcaming, and give a bright, clean polish. If they are much soiled, they ahould be washed in warm water with soap, to which a little ammonia may bo added. See Eye; Eyeglass; Sight Testing.
Specularia. This hardy annual with purple, bell-shaped flowers is called Venus'

SPECULATION : A Card Gance. This is a cand game for any number of perwons, and is played with the full pack of 52 cards, each player contributing an agread number of counters to the pool. The dicaler puts in twice as many counters as other players. He dealay
threc cards face downord to cach player and
highest trump for the time loing is excopted from turning up any more of his cards. If all carda are turned up without it being beaten he takes the pool. If his card is benten he continues with the other players to turn over his cards one at a time in his turn. Any player turning up the acc of trumps at once takes tho pool.

Any player may buy any of the unexposed cards from another player, in the hope that they contain the winning trump. If any card ii) his hand is accidentally looked at by a player, save the actual cand ho is turning up, all his cards arc immediately thrown face upward in the middle of the table, and the player must then pay a penalty into the pool.

SPEECE: Its Defects. Human speech may le nffected more or less scriously by a large number of complaints. When there is any blocking of the air passages, as by chironic catarrh of the nose, adenoils, nasal polypi, etc., the patient pronounces the letter Mi as EB, and N like ED. Treatment is to clear out the obstruction so that the child may breathe properly. After this, lessons in correct pronunciation should be carried out. Lisping mosy be duc to carcleasness in tenching the child to talk; the defect is well within his power to control.

Deafness coming on after diserse in childhood, liefore speech has been solidly acquired, may end in deaf mutism. Paralysis of nerves may be the cause of the defect. Another rerious defect is aphasin, which is interference with the thought processes of speech and is due to some injury or discase of the brain.

Stammering and stuttering are not due to actual defect in the epeech mechanism but to inability to control it on account of emotional disturbance. It is an expreasion of anxiety hysteria, and an attempt should be made to cure it by finding out the enotional disturhance that underlics the hysteria. Voice exercises, as in declaiming, and Lreathing
exercises may be bencficial by giving the patient confidence. See Deafness; Larynx Tongue: Voice.

## Speedboat. See Boat

SPEEDWELL. This name covers a group of evergreen shrubs and hardy herbaceous plants of great garden value, known botanically as veronica. They flourish in ordinary soil. The hardiest shrub is Veronica Traversii. 4 ft . high with white flowers in summer Veronica speciosa, of which there are varieties with purple, erimson, rose or white flowers. 3 to 5 ft ., is less hardy: it does well in seaside gardens and in mild districts or may be grown in pots in the greenhouse.

Among the herhaceous border plants the best are gentianoides, 18 in., with palc blue fowers in May: longifolia and subsessilis, 2 or 3 ft ., blue, in August, and spicata, 12 in ., blue, in June. Veronica rupestris is a lovely low-growing blue-flowered rock garden plant. The shrubby kinds are increased by cuttings in a frame in July, the others by division, or sceds in spring
SPERMACETI. The fatty substance obtained from the sperm whale, and called spermaceti or cetaceum, is quite a common basis of ointments. The ointment of spermaceti is made up of spermaceti 10 parts, white beeswax 4 parts, benzoin 1 part, and almond oil 36 parts. These ingredients are heated for 2 hours. Spermaceti may be applied alone to inflamed, irritated surfaces for its emollient action. Pron. Sper-ma-see-te.

SPHAGNUM. Sphagnum moss, which is commonly found on peat bogs, is used extensively in the potting of orchids. Being extremely retentive of moisture, it keeps the Heshy roots of plants in sound condition, whilst its open, spongy character allows air to be admitted freely. Sphagnum does not decuy like other mosses, a peculiarity that adds a good deal to its usefulness. See Orchid.

SPICE. Aromatic seasonings obtained from plants of tropical growth are used in cookery and as foorl preservatives, and some have certain medical properties. They are known as spices, those chiefly employed in cookery being cinnamon, cloves, ginger, mace, nutmeg, and pepper. Allspice or Jamaica pepper conbines the flavours of cinnamon, cloves, and nutnicg.

In addition to their use in cookery, cloves are employed to Havour wine, cough mixtures, and confectionery, while cinnamon is a popular Havouring for liqueurs, and has certain properties that justify its inclusion in many tablets and mixtures sold to cure colds. Grated nut meg is added to junkets and puddings, and ginger is a valuable stimulant. Various spines, such as turmeric, coriander, and ginger are contained in curry powders and pastes. Condiments such as pickles and sauces owe some of their piquancy to spices.

Spices shou!d be bought in small quantities as they deterioratc rapidly if exposed to the air. They are best stored in special spice boxes. S'e.e Allspice: Cinnaınon: Clove: Curry : Flavouring, etc.

Spice Bush This is an alternative name for the plant known as lindera.

SPIDER: A Crochet Pattern. This all-over pattern derives its name from the solid centre-picce of double crochet, from which long chains branch out in different dircetions. The foundation chain on which the work begins should be a multiple of 14 with 5 stitches orer. In the small piece illustrated there are 47 chain stitches, worked as follows
lst row: 1 double crochet in the llth chain from the hook, 1 double crochet in each of the next 2 stitches, * 5 chains, miss 5 stitches, 1 double treble in the next stitch, 5 chains, miss 5 stitches. 1 double crochet in cach of the

Spider. The crochet stitcb which goes by the name of the spider pattern
next 3 stitches. Repeat from * until only 6 stitches are left, then make 5 chains, miss 5 stitches, 1 treble in the end stitch, 7 chains Turn

2nd row : * 3 double crochet on 3 double crochet, 5 chains, 1 double treble on double treble 5 chains. Repeat from * across the row ending with 3 double crochets, then 5 chains, 1 treble in the 6th chain of the loop at the end, l chain. Turn.

SPIDER WEB: In Embroidery. This pattern is used in two different forms of work. one as a solid whitc or coloured linen embroi. dery for decorative purposes: and the other to fill in an empty corner where threads have been drawn

In the lirst case fancy canvases and coarse linens are used, where the threads can be casily counted to form sections. In the illustration coarse linen is scen. worlied with coarse sylko cotton giving bold relief to the pattern. Here 40 threads are counted each

Spider Web, a pattern which is much used in solid embroidery, and also for flling up a corner in drawn thread work
under and over as in ordinary darning, missing 2 threads at the beginning of each new round, so that the thread that was passed over in the previous round will be passed under in the sccond.

The change of round can be seen easily in the working, when the ncedle passes a sccond time ounder the same thread. To ensure an even weave, it is best to put the matcrial in an ordinary round embroidery frame when working the corner picces, that is, when the remainder of the work is being done over the fingers. See Drawn Thread Work; Embroidery.

SPIDERWORT. This is the popular name of tradescantia, a group of hardly and greenhouse plants. The best of the hardy kinds is Tradescantia virginica, called Flower of a day, which thrives in shady places and bears purple-bluc blooms in summer Those suitable for a warm greenhouse are quick growing trailing plants with green and colourd leares. They :are useful for planting bencath the staging, or if grown in pots make a suit able edging; they look well also in suspended baskets. They are easily increased oby cuttings and thrive in a compost of loam, leaf-mould and sand.
SPILLIKINS: The Game. This game is played with a number of thin pieces of bone or ivory. These pieces, the spillikins, are cut into queer shapes and each has a number, the numbers usually running from õ to 40.
The spillikins are taken in the hand of one of the players and dropped in a heap on the table. The players then take turns at trying to remove one of them from the heap without disturbing the others. This is sometimes done with the fingers and sometimes by means of two small hooks provided for the purpose.
When the game is over each player adds up the numbers on the spillikins he has taken, and the one with the largest number wins. Sometimes, instead of the players taking turns to remove on spillikin, one player continues to remove them until he disturbs another one, when he loses his :turn.
SPINACH. There are four chief kinds of this useful leaf regetable. Summer spinach is sown at intervals from February to April in drills . 1 in . deep and 12 in apart; rich deep soil is necessary to ensure quick growth. Winter spinach is sown in August-September in a similar way: the seedlings of both crops should be thinned to 6 in. apart. The round spinach is commonly sown in spring and the prickly spinach in August and September
New Zealand spinach is a vigorous tender plant which should be sown out of doors in May, or raised in pots in a frame. The plants must he 3 ft apart. The tips of the shoots

Spinach. Leaves of the round variety, the best summer spinach
are gathered for cooking. Perpetual spinaoh or vegetable which should be sown in spring and again at the end of July to provide a long cession of proluce
How io Cook. Spinach is one of the most wholesome and readily digestcd of vegetables. It is scrved cither as a vegetable or as an entréc. Spinach sometimes accompanies fried

Spinach. L. Soil preparation : $a$, manured soil ; $b$, fine soil. 2. Rows separated by rain channels (a). 3.,Catch. crops between peas or beans 4. Winter spinach sheltered by beaps of bracken or straw. 5. Spinach beet between shrubs or under trees. 8. New Zealand spinach in pots: $a$, crocks and rough stuff ; $b_{0}$ decayed
manure ive fine rich soil. 7. Box similarly prepared. 8. Pots and boxes sheltered in cold frame or covered box

and 2 tablespoonfuls white sauce, also 1 teaspoonful castor sugar. Serve it on round crouttes of buttercd toast with a garnish of fried half-moons of pulf pasiry or of bread.

A savoury dish of spinach miay be prepared in the following manner: Boil 3 lb . spinach as dirceted in the second recipe. Chop it slightly, and fry it in 2 oz . butter, with 4 anchovies, washed, boned, and chopped fine.
or grilled ham, and a favourite dish is poached eggs on spinach.

The leaves require very thorough and careful clansing, as they are always gritty. They should be well pickerl over after heing washed, and the stalks removed. Salt is required in varying quantitics according to taste. No soda must be added to it while cooking, and no water is required save that which clings to the leaves after washing. One of the simplest methods of preparing a plain dish of spinach is to put about 4 l . of the leaves in a large saucepan. sprinkle over them a tablespoonful of salt and a teaspoonful of white sugar. Bring slowly to the boil and boil them for about 12 min ., or until they are soft, stirring them in case they cling to the bottom of the pan. When cooked, strain and press out the water until the spinach appears dry, then turn it on to a board, chop it, and return it to the sauccpan. with a litle butter, lemon juice, pepper and salt. Dish it on toast.

For an entré, prepare 4 lb . spinach, then boil it in the drippings from the lcaves, adding salt. Stir frequently, and when it is cooked strain and press it free from moisture. Now immerse it in cold water and leave to cool but do not separate it. When quite cold, drain, and once more squceze out all water. Chop it fine, and pass it through a wire sieve. Melt in a stewpan 2 oz. butter, add the spinach, and stir it round, then season it with salt, cayenne, and $\ddagger$ teaspoonful of grated nutmeg. Pour in 1 gill thick cream cloth. Pour all people hold the ends of the a small saucepan, place it on the fire, and, as it curdles, scrape the curds out on to a sieve to drain off the water. After draining put the greening into a covered jar in a cool larder till the sance is ready. Hone-prepared greening is best for sauce or mayonnaise, but for colouring sweets it is more convenient to purchase liquid spinach green colouring. See Kitchen Garden. Pron. Spin-aje.

SPINDLE TREE. This is a small British tree (Euonymus europaeus) valued for its highly coloured ornamental fruits in autumn. It thrives in ordinary soil

SPINE. The spine, or backbone, makes it possible for the body to assume and maintain an upright position and at the same time act as a protective covering for the spinal cord, which, with the brain, forms the main part of the central nervous system. It is made up of 24 vertebrae, which allow a certain amount of movement one on the other, and two terminal bones, the sacrum and the coccyx. The bodics of the vertebrac are separated by thin layers or disks of cartilage. These not only allow the bones to move without grating, but also act as shock absorbers.

When standing in the erect posture, the spinal column forms a series of natural curves from before backward. Thesc curves balance each other, with the result that the general line of the spine is practically vertical

Curvalure of the spine is dealt with under that hcading. Injurics to the spine by blows, twists, and other forms of violence may result in sprains or strains. There is local pain and tenderness, and perhaps slight swelling. Cold applications may relieve suffering, but it is often necessary to-rest for some weeks. The result of an injury niay, however, be much more severe than this See Curvature; Fracture.

SPINET. Being smaller than the harpsichord, the spinet dors not possess a double keyboard, and the tone was usually a fifth

Spinet ol wood and jory ornamented with jasper and other stones, made in Milan $\ln 1577$ Bu permission of the Director. Victoria \& Albert Museum. Soyth Kensington
closed at each end and almost filled with liquid. A small air bubble, however, remains visible in it, and when the tulve is in a horizontal position, the bubble will always be exactly in the middle of the length of the tube, and at the top of it. A spiri level is calibrated and tested at the time of embedding the bubble tube in the frame, and thereafter should not be disturbed otherwise the instrument may be thrown out of truth. To facilitate the reading and to increase the accuracy of the result, two lincs are generally marked on the top of the tube, in such a position that when the ait bubble is exactly between then, the instrument is perfectly horizontal.
whecls made in the late 17 th and 18th centuries were copied in most European countries, and the spinsters of England, Scotland, Wales, and Ireland used wheels which in design were very similar to those of Flanders. What is still known as the Dutch wheel is collected assidu. ously by interested people, though the name is used to designate one of Irish manufacture.

The whecls employed in English cottages for the purpose of spinning
for a living were fre. quently of elm, ash, or birch. The lly-wheel of these was heavier, and the turning of the spokes, spindles, and legs much coarser in detail than was the case in the walnut and mahogany spinning wheels of more expensive make. Round the distafl, which is secn on the left above the wheel in the illustration, the treadle, which is also clearly shown.

A unique collection of spinning wheels is that of Mr. John Horner, of Belfast, where theso old machines are housed in the Municipal Art Gallery and Museum. Various museums in Yorkshire, notably Hull, also possess examples showing local characteristics, and a few specimens are preserved in the Victoria and Albert Museum, South Kensington.

SPIRAEA. Both shrubs and herbaceous plants of decorative value in the garden are included in this group. Some of the shrubs are very handsome when in full bloom: they thrive in ordinary well-tilled soil. The best aro Thunbergi, arguta and canescens, which bear white flowers in spring and early summer, and grow 4 ft . or so high ; Lindleyana, Aitchisoni and discolor, which bear plume-like clusters of white or cream-coloured flowers in late summer and reach a height of 10 ft . or more ; and japonica, bumalda, and Anthony Waterer, which have red flowers in JulyAugust, and are from 2 ft . to 4 ft . high. Propagation is by cuttings or sceds.

Of the hardy herbaceous spiracas the noblest is aruncus, a vigorous plant 5 ft. or so high, with cream-white flower plumes in summer. Filipendula and ulmaria (the common meadowsweet), with whitish flowers, and palmata, red, are other useful kinds. They are all good waterside plants, for they thrive best in moist soil. Propagation is by division in autumn and spring. Spiraca japonica, white, is a favourite plant for the greenhouse. Pron. Spi-ree-i.

SPIRIT LEVEL. A spirit level is an instru. ment for ascertaining the level or adjusting the level of an object in relation to the horizontal

Essentially, the instrument comprises a wooden or metal frame containing a glass tube
is loosely wound the raw fibre. This is spun Fig. 1, will suffice. It is here seen- in use off by the spindle. The fly-wheel is driven by to level two adjacent planks. These levels

Spirit Level. Fig. 1. Testing level between two pieces of material As an example of its nse, suppose that a floor joist has to be set in a horizontal position. All that has to be done is to place the joist approximately in position, rest the spirit level upon it, and raise or lower the ends of the joist until the air bubble is exactly between the two lines marlied on the tube. The joist will then be level. For ordinary purposes the regular carpenter's level, shown in are available in various sizes, but one about 10 in long is very convenient. Practically all levels with a woolen body, or frame, have a brass plate at the top and brass tips at the bottoni, to strengthen the wood and increase the durability of the instrument. For carpentry or building purposes a longer level measuring about 24 in . will be found to be preferable. A useful type has two tubes, one at right angles to the other. The second

Spiraea. Spray ol S. astilboides, a Joly blooming plant with long teathery spikes of white flowers
tube is set near the end ol the frame in a vertical position, so that the instrument can be used for plumbing uprights. When the bubble is in the middle of the tube it indicates that the object which is being tested is perfectly upright, as shown in Fig. 2. See Plumb Bob; Plumb Rule.

SPIRITOFSALT. This strong acid, known alternatively as hydrochloric acid, has valuable cleansing propertics. It may be used to take stains from lavatory pans and washing basins, and when diluted with 20 times its volume of water, it removes rust marks from clothes without danaging the material. Thorough rinsing is essential, otherwise the acid may canse the fabric to rot. See Hydrochloric Acid.

SPIRITS. This term is used for certain liquids used for drinking purposes that are obtained by distillation. Such include brandy, gin. and whisky. See Alcohol: Brandy; Gin; Rum. Whisky.

SPIT : For Roasting. A spit is a pointed rod with a handle at the end, and mounted so that the meat

Spirit Level. Fig. 2. Use ol spirit
level in testing lor the vertical

Splints are most conmonly made of wood, but a great variety of other materials are also used, such as poroplastic, gutta-percha, netal, celluloid, and cotton. linen, or Hanuel, stiffened with plaster of Paris, starch, or gum. Straw matting rolled up and cut to a suitable length forms an excellent splint in an emergency. Other materials with which, in an emergency, splints may be made are laths. a broom-handle, a walking. stick or umbrella, a small straight branch of a trec, a few folded newspapers, a rifle, and a scabbard.

Padding must be donc carefully, so that there shall be no lumps and that the splint shall fit evenly against the limb; extra padding should he placed over bony prominences, e.g. at the ankle. Probably the beat material to use is sheep's wool, but cotton wool or tow serve very well. In emergency some old flannel, or a number of handkerchiefs, may be used. A splint should fit the limb nccurately: for a broken thigh bone it should reach from the armpit to below the ankle. For other broken hones it should extend far cran supported on the spit and rotated cnough on cach side of the fracture to afford from time to time in front of the fire good support and secure perfect rest. See Roasting.

Spitchcock. This is a method of cooking ecla. They arc salted, then fricd in batter and breadcrumbed. See Eel.

## Spitting. See Expectoration

Splat. This term is used for the broad, Hat, upright portion of n chair back. See Chair.

SPLEENWORT. This is the common name of an extensive genus of ferns, hardy, greenhouse, and stove, botanically classified as Asplenium. Amongat hardy kinds the scale, maidenhair spleenwort, and wallrue are suit-
 able for growing on old walls ; the lady fern in moist shady corners or bordors; whilst othera are uscful for planting in the rock garilen. The bird's nest fern is exten. sively grown for market purposes. See liern. SPLINT. More or less rigid materials used as sup. ports for a broken or otherwise injured limb form splints. Their purpose in cases of fracture is to keep the ends of the bone together and to keep the $\operatorname{limb}$ in a natural position to prevent deformity.

When first aid is being rendered one person should hold the broken limb in an extended position while the other ties on the splint. First tic above the fracture, then helow. If a leg is liroken, tie both legs together after the aplint has hicen applied. Handkerchiefa may he used for tying if handages are not available. The splint should he tied on firmly, but not too tightly, lest the circulation of the blood be interfered with. Make the knots over the outer splint. See Bandage: First Aid.

SPLINTER: How to Extract. Thorns. necdles, and splinters of wood which penctrate the skin should he removed as sooll as possible, for if allowed to remain until intlammation begins, they become more firmly fixed in the swollen tissucs; needles also sometimes wander far from their point of entry. If the splinter is visible, the opening through which it entered should be enlarged with a carefully sterilized needle or a sharp-pointed knife. The sterilization can be done by passing several times through a spirit lamp llame. The splinter should then he worked out by pressure with the tips of the lingers. If the splinter lics deeply, it is better to consult a doctor at oncc.
SPLIT BALUSTER. This is the name of a form of decoration used on simple styles of oak furniture especially towards the end of the 17th century. It consists of a spindle which, having been turned between two points on a lathe, was cut lengthways into

Spokeshare. Right pattern with wooden stock and tanged ateet cutter.
Left. type with malleable iron atock and a fat blade clamped to the and Left, type with malleable iron stock and a fat blade clamped to the atock off by solidly gilded handlea and rims. iwo or more parts and applied to ornament a frieze or horder on a chest or dresser.

SPLIT PEAS: In Cookery. Split peny are amongst the cheapest and the most nutritious of vegetables. Their principal use is for soup-making, nind they can be cooked in the same way as lentils. To be quite digestible they need long cooking after being soaked in cold water for 12 hours. See Lentil; Soup.

SPODE : The Ware. Josiah Spode was the founder of this firm of Stalfordshire potters, which was one of the leading houses in the trade. After an apprenticeship to Whieldon and Josiah Wedgwood, Josiah Sporde started a factory in 1770 . His services rank next to Wedgwood's, and his black hasaltes and jasjer wares are in high esteem. He was the first to apply transfer-printing to the willow pattern. and his printed waie was ofterl finished by hand with enamel colours. The improvements made by his son helped to establish the supremacy of English boneporcelain and opaque china.
Siode porcclain is a translucent paste with a soft glaze and good print. ing. Dinner services wereat first made with a medium.blue decoration, set

Victoria \& Albert Muxelt S Kensington stamped in the paste or pencilled on the glaze. The name was afterwards placed within a seroll, or across a square seal with the worla

Partnership hetween the younger Sporle and William Copeland led to the factory pasaing ultimately into the family of the latter. For a time the mark was Spode \& Copeland, then Copeland \& Garrett late Spode, and afterwarda Copeland late Sporle, a mark which atill survives. The present factory continues to produce many of the old Spode designs hecause of their popularity, but the modern ware is alvays distinguishable by the mark. See

SPOKESHAVE : How to Use. A spoke. shave is a two-handed wood-working implement. consisting esesentially of a stock or holder and a cast steel hlade or cutter. Tiwo $t$ ypical examples are illustrated. The origimal and astill extensively used spokeshave has a wooden stock. Into the middle portion is litted a stcel cutter having two tangs at right angley to the plane of the blade and located at eachend of it.

The prongs of the spokeshave arc presserl into holes cut in the wood, and as both hole and tange are tapered. the blade holds firmly when tapped hoinc. The other
type has a nalleable iron stock and a flat blade something like a plane iron. This is held to the stock by means of a clamped plate and a thumbscrew which goes through a slot in the blade. The cutter can be adjusted by pushing it in or out, and when in its correct position it is secured by twisting the thumbscrew. In the case of the wooden stocked spokeshave, the cut is regulated by tapping the cutter closer to or farther away from the working face of the stock.
The essential purpose of the spokeshave is to work curved surfaces, either externally or internally, so as to bring them to a correct and uniform curve. The work should be firmly held cither in the vice or supported by blocks temporarily screwed to the work bench. The operator stands facing the work, and grasping the spokeshave in both hands, his thumbs pressed across the back part of the cutter, but clear of the work. The implement is presscd firmly on to the wood and pushed forward. The cutter must never be worked against the grain, or the wood fibres will be torn.
Some spokeshaves arc provided with an adjustable fence or guide, and with variously shaped blades, so that some form of moulding and reedings can be produced. See Plane; Router Plane; Rustic Work.

SPONGE. The soft, porous article known as a sponge is a form of animal life brought up from the bottom of the sea by divers. For toilet use it is indispensable, and, on account of its absorbent properties, it is also employed to bathe cuts and other wounds. Sponges vary in quality and price, the cheaper kinds being liable to tear after a few weeks' use.
The finest sponges are the Turkish, which are much favoured for babies and facial use because of their softness. All sponges should be soaked in cold water for 24 hours before being taken into use. This gets rid of any sand and enlarges the sponge, by about onethird, to its working size.
Sponges may be kept clean by occasiona ${ }^{1}$ washing in strong, hot soda water. If allowed to hang in a sunny window, where the air has free access to them, they will last longer and require less washing. Old sponges are useful for washing paint work.

If sponges are used for washing wounds, or mopping up blood in operations, they should be sterilized by soaking then in corrosive sublimate before use. After use they should be washed in borax soap powder, and then kept in a 5 per cent solution of carbolic acid A sponge should not be boiled. Sterilized gauze, it may be said, is a much safer and better material to use than a sponge for wiping wounds. See Bathroom; Toilet.
SPONGE CAKE. To make, break 3 eggs into a basin, whisk them with 6 oz. castor sugar for about 15 min ., and then lightly fold in $\frac{1}{4} \mathrm{lb}$. sieved flour. Grease the inside of some small sponge cake tins, coat them with a mixture of sugar and flour, shaking out any that does not adhere, and then put in the

Sponge Fingers fitted together in pairs and served for afternoon tea. See article above
sponge cake mixturc. Shake a little castor charlottes, can be made from the same mixture sugar over the cakes and bake them in a hot oven for $10-15 \mathrm{~min}$. Sponge cakes are used extensively in the making of trifles and other sweets.

## SpOONS FOR COLlecting AND FOR USE

## Their Development from Antique to Modern Shapes Illustrated

The reader is referred to the article on Dessert Spoon; Electro-Plate: Fiddle Pattern: Ladle; Pewter: Rat Tail: Silver:' Table Laying

The earlicst form of spoon was a shell hand held up in the act of blessing. A with a cleft stick as handle. The cleft was 14 th spoon was added to the collection represlipped over the edge of the shell and tightly senting St. Paul. A specimen is illustrated bound behind the join. Wood, bone and in Fig. 4 carrying his emblem, the sword. horn spoons followed, and these materials are Complete sets of these spoons are extremely still in use to-day for salad, salt and kitchen rare, and when a set comes into the market it spoons, while mother-of-pearl shell is also still usually fetches a high price. employed for condiment spoons.
Fig. 1 shows a Roman spoon of about the 4 th century, which was found in England. Fig. 2 shows the coronation spoon, which can be seen with the regalia in the Tower of London.

The transition from the knops to plain ends occurred after the reign of James I. In Commonwealth days the stump end (Fig. 5) was introduced, to be followed by the cleft-end and ornamented lobe ends in the reign of The date of this gold spoon has been a subject Charles II. In this new variety the stem end is more or less cleft into three parts, and the ower part of the stem is continued to a length which extends more than half-way down the back of the bowl. This continuation of the stem at the back of the bowl is the commence
pous. ris. 1. komal spuon, the ceatuay, wuen was ound in England. Fig. 2. Coronation spoon in gold, an example of 12 th century work ; it is part of the English repalia Fig. 1, courtesu of Spinte \& Son, Ltd ment of the rat tail form. Fig. 6 shows a for discussion; in general, however, it is spoon of this style bearing the London hall accepted as an example of l2th century work. mark for 1680 , and the back of the bowl Silver spoons were made in this country in bears the characteristic scroll decoration, also early Tudor times and designs were copied in found on the front end of the spoon. base metals.

The chicf source of information concerning spoors is gathered from inventories, wills, and other old documents. That spoons of silver must have been somewhat scarce is proved by the careful way in which they are described, and the probability is that among the lower classes of society they werc practically unknown, spoons made of pewter, wood, or latten, a nixture of brass and tin, being in general use.
In Tudor times the bowls of spoons were fig-shaped. The handles terminated in various fantastic shapes, such as a whirled knob, a diamond point, an acorn, a kind of fir-cone knob, or knop, while some were made with a seal top end, as illus. trated in Fig. 3. Others had a figure on the end, a representation of the Virgin Mary being one of the earliest, known as the Maiden Head knop, followed by what are called Apostlc spoons. These spoons bore at their ends representations of the twelve Apostles, each figure having its distinctive emblem, by which it can be recognized. Accompanying a set of 12 spoons was the Master spoon holding an orb in the left hand and with the right

tried; these include leaving the eentre of the blocked window open and moving sitter and reflector about. An arrangement which may be tried in an ordinary spuare room with two windows is shown in Fig 2. This a!so will afford basis for experiment which may conveniently be carried out on an inanimate object.

A more convenient and adaptable metliod of spot-lighting, such as is used on a large scale by professional portrait photographers, is the lantern form of light (Fig. 3) tor use with elcetric lamps. It is fitted with a condenser lens mounted on a spring bracket which enables the light to be directed at any angle. The lamp-holder is ad justable to permit focussing with the con denser, and the light is controlled by means of a movable ditfusing screen, and also a hlue lavourite ornament at the end of reign of terized by fine workmanship and artistic form. lilter, used separately or together. The light George II was the bead-edged handle, while Kitchen spoons include the ever uscful wooden a little later many handles were engraved. ones in various sizes, perforated aluminium After the accession of George III new patterns spoons for lifting eggs, etc.. from boiling water of spoons were introduced, but these differed only in the manner of ornament, the main design remaining the same, until the fiddle pattern appeared in the Victorian cra.

Modern Spoons. To-day, unlike our ancestors, who were often content with one single spoon, which was carricd about wherever they went, we have in common use a wealth of spoons for particular needs. Table service contains table: goup, dessert, tea, coffce caddy, sugar, egg, salad, fruit, orange, and ice cream spoons.

The orange or grape fruit spoon illustrated in Fig. 10 shows the bowl conveniently shaped and the handle of conventional Old English pattern, as seen in Fig. 9. Designs for spoons and forks are usually based on the old patterns. Bead or reeded edges are seen on some handles, on others ornamentation takes the form of shells and fluting. Plainer Puritan designs are liked, and the fig-shaped and ovate bowls are reproduced in modern soup spoons, and in fruit and salad service spoons with Hat-shaped handles.

The knop ends are often adapted to collee spoons and to jam spoons. Salt spoons and mustard spoons usually match in style the containers they accompany. Egg apoons

Fig. 10. Modern orange apoon may be attached to a silver or plated stand or be bought separately to match the tea and other service spoons in use. Silver or plated ladles for sauce or soup generally match the tablespoons. Very ornainental spoons arc seldom used, but fruit servers are designed in which there is a decorative connexion between the plain silver handle and spoon bowl charac.
poons for lifting eggs, etc.. from boiling water, sets of attached measuring spoons, of live
different sizes, and teaspoon infusers for making single cups of tea

SPORE. This is the name given to those cells or bodies which are found on the backs of fern fronds and other flowerless plants and by means of which propagation is effected. The spores are gathered when ripe by shaking the fronds over a sheet of paper ; they are sown in flower pots or pans of sterilized soil in a propagating case under glass and kept moist and shaded.

Spot: On the Skin. See Blackhead Pimple; Rash; Skin.

SPOT-LIGHT. In many modern professional portraits attractive and artistic results are obtained by use of a spot-light, an arrangement by which a beam of light, natural or artificial, is projected on to a face or profile or other part of the sitter, in addition to the ordinary illumination. By this means striking high-lights arc obtained, or parts which would be without detail in the photograph are given pleasing tone and balance.
In taking portrait photographs by natural light spot-lighting effects can be obtained in a room lighted by two windows, especially if a bay window is available. One arrange. ment is shown in Fig. 1. Ordinary lighting is given by window A and the reflector. Spot lighting from above, or top-lighting, is given by window B , all but the top part about lo in. or 18 in. square. being blocked up. This will give a soft and not too obvious lighting of the face from above. Otber arrangements can be

Fig. 2. Arrangement in a square room, with one of the windows partly covered

must not be placed too neal the sitter. Experiment will slow the best positions for the light and the exposure to be givell. As a basis the amateur should try the spot-light about 6 ft . or 7 ft . from the sitter. The lamp is also useful in getting effects with daylight portraits, in addition to or in place of a reflector. See Portraiture.

SPOTTED FEVER. This is the popular name of cerebro-spinal meningitis, an inflamniation of the covering membranes of the brain and spinal cord caused by a germ. These germs invade the thront in the first place, and are often found in the throats of people who have had the disease and also of others who do not themselves suffer from it,

Spot-light. Fig. 1. Arrangement in a room in wich the spot-light is given by the window $B$
but who can communicate it to others. In any community there are a'ways "carricrs" of spotted ?cver, and this danger increases in a marked degree when people are crowded together. Epidemics of the disease are therefore liable to break out in barracks, camps, ctc. Dirt and bad sanitation play a contributory part.

Children are most frequently affected. Severe headache and

Spot-ight. sis. S. Spot-ngat connected up and alight. ready for making an exposure. See page 1190 Courtesy of Ensign. Litd
vomiting, followed by a painful rigidity of the muscles at the back of the neck, are carly symptoms. The doctor should be called at once. This is a notifiable disease and the patient must be isolated. Those who have been in close contact with the patient should use antiseptic gargles.

SPOTTING: Of Negatives. Negatives frequently require spotting because of the presence of small holes in the film, called pinholes, due to dust on the plate before exposure or somewhat larger holes due to hubbles of air adhering to the plate during development. T!ese holes are iransparent, and therefore print black. They are most noticealile in the high lights, i.e. the dense parts of the negative, and may spoil the appearance of the print or the enlargement.
Prevention is, of course, the best remedy and will be achieved by taking great care to keep the interior of both camera and dark slides free from dust. Do not attempt to brush off possible dust with a camel-hair brush from the negative prior to develop. ment. In a dry atnosphere the brushing will slightly electrify the film of the negative, and attract much more dust than it removes. Glass negatives may be sharply tapped on the hack with the thumbnail, or the edge tapperl on the table.
When pinholes appear they must be filled by spotting with Indian ink or other pigment. The secrets of neat spotting are to use the pigment nearly dry and not to attempt to work it on the film. One touch in the right place is all that is required. More will only spoil the result. Spotting is a simple and effective process if a little care is talien. Lamp black or ivory black, mixed with water containing a little gum arabic or Indian ink, may be employed. Use a finc brush, preferably a No. 1 cames hair. Give it a good point by twisting on paper or hetween the lips, and take a very small quantity of pigment, mixed with sufficient water to make it of the consistency of cream.
Try the brush on paper, twirling it as when giving it a point until it hardly seems to mark. Then immediately touch the pinhole once, making a line dot, and leave it. If the hole is a large one, a scries of dots may be required, but they must not be allowed to run into one another. Allow the first to dry, if necessary, before making another By this ineans, if care is used, spots in the prints will be entirely avoided. and with a little practice it will be found that a number of pinholes in a negative can quickly be spotted out. When a negative which is to be enlarged contains a number of very small pinholes, it
will be found that by throwing the negative slightly out of focus the holes will be practically unnoticeable in the enlargement without reducing its quality.
To spot prints, a pigment or water colour to match the colour of the print is chosen, mixed with gun water, and spotting carried out as for negatives. Large black spots may he removed with a touch of Farmer's bleacher as used for intensifying (potassium ferricyanide with plain hypo). A spot of the bleacher is applied with a canel-hair brush, eft for a minute or two to set, and then sponged off. The resulting white spot is touched with pigment to match See Negative.

SPRAIN. Whenever a joint is wrenehed the bones may be displaced or fractured, but when the injury stops short of this and consists merely of stretching or tearing of the ligaments and tendons it is called a sprain. Even this may do damage, cause pain, and hamper movements of the joint.

Blceding takes place from torn blood vessels, and this is quickly followed by inflammatory reaction in the injured tissues. These things combined lead to more or less swc!ling and discoloration, and when in the course of a few days the shed blood breaks down, the familar changes of colour from red or black to green and yellow occur.
Cold compresses should be applied at once. They relieve pain and help to diminish bleeding. Later hot applications may be used for the pain and to promote absorption. Rest at first is necessary, and splints may be used to this end, but early massage and passive movements are necessary to prevent stiffness. See Ankle; Bandage; First Aid: Joint.

SPRAT : How to Cook. The sprat is seasonable from November to March, and should be caten very fresh. After being cleaned it should be rubbed in a cloth to remove the scalcs. The condition of this tish is easily ascertained by the appearance of the eycs; if these are bright it is fresh, also the skin of the fish should have a silvery look when washed. Dried sprats may be bought in bundles. As nuch as possible of the dried skin should be removed by placing the tish in boiling water and then wiping them dry on a clean cloth. The sprats are then heated in the oven in a greased baling tin.

After being cleaned and rubbed sprats may be dressed by being dipped in scasoned flour and fried in boiling fat, a frying basket being used to kcep the fish together. The fat should be smoking hot or the fish will be sodden. If no frying basket is at hand the sprats must be lried in a frying pan, using plenty of fat. The fat cannot be used again for anything except lish. Another method is to dip the fish in seasoned flour and egg and crumb them, using very line white breaderumbs

Pickled Sprats. Sprats may be pickled to keep. Clean the fish and boil them, just covered with water. When cooked drain off the liquor and pack them tightly but evenly in jars. Fill up the jars with equal quantitics of strained fish liyuor and vinegar. Set them by for a few days, and if the vinegar has become reduced fill up the jars. Tie down closely.

Sprats au Gratin. l'repare 2 lb . sprats and arrange them in a well. buttered lireproof clish. Scason them with salt and cayeme pepper, and pour
over them the following mixture $\frac{1}{2} \mathrm{lb}$ mushrooms, prepared. cut in strips and blanched in $1 \frac{1}{2}$ gills stock, 2 good wineglasses sherry or white burgundy 2 peeled and chopped shallots, and a grate of nutmeg. Pour this, including the liquor in which the mush. rooms were blanched, over the lish. then place at intervals about 1 oz. butter in small pieces. Scatter over 1 tablespoonful chopped parsley and coat with browned breaderumbs. Bake for about 20 min . See Fish . Sardine.

SPRAY: Medical Üses. In affections o the nose and throat the use of a spray is often preferable to other methods of applying medicaments. The liquid is converted into a fine cloud by means of a rubber ball which. when compressed, sends a current of ait across the inouth of a tube that dips into the liquid. The spray is sater than the nasal douche for a cold in the head, and more effective than gargles for a sore throat. Cocainc, menthol, carbolic acid, iodine and other sedative and antiscptic drugs are used and the vehicle may be water or !iquid paraffin. See Douche.

SPRAYER. For domestic purposes a sprayer can be used for scent and for fixing charcoal, pencil, and other drawings by covering them with a tinely distributed film of varnish. Larger forms of the same appliance are employed for spreading whitewash, distemper, and paint, and in the garden disinfectant and insecticide are sprayed on potatocs and on fruit and rose trces. The principle is quite simple, and consists in passing a current of air over the top of a tube which is immersed in a liquid.

The simplest form of sprayer consists of two lengths of glass tube fastened together with a hinged elip, so that they can be set at right angles. One tube passes through a cork and reaches almost to the bottom of a bottle containing the liquid to be atomized. When air is blown through the horizontal tube the liquid is drawn up from the bottle and projected as a fine spray. The essential feature of the appliance is in the relative positions of the ends of the tubes, for the end of the horizontal or air tube must be so put that it directs the air across the top of the liquid tube. In the scent spray for the dressing table the air is sup. plied either by a rubber bail or a piston, the former producing a continuous spray.

The com-

Courtesy of Richard Mclhuish, Ltd.
sprayer for insecticides has an action similar to that of the tubular sprayer described above. It consists of an air tube in the form of a pump, and similar in action to a syringe. A nozzle at the end is directly over the liquid tube. which is attached to and fits in a receptacle holding the liquid, this container being filled through an opening covered by a screw cap. This type is used also for spraying rose trees and fruit bushes.
The spraying of distemper, paints, cellulose finishes, etc.. requires a more powerful air pressurc. In commercial work a power driven air compressor is used, but a substitute for bome use is available in the form of a foot pump in combination with an air reservoir. A portable sprayer is shown on page 1191. Machines suitable for garden purposes are described in the succecding article.
SPRAYING: In the Garden. Various iiquid mixtures which are administered by spraying are widely uséd for destroying insect and fungus pests on fruit trees, rose trees, and other flowers, as well as on certain vegetables; for instance, potatocs. Spraying is most effective in dry weather. If it is followed quickly by heavy rain it must be repeated as soon as the weather clears. Early morning and cvening are the best times of the day for spraying.
A hand syringe with a spraying nozzle is usually sufficient for treating potato plants, small fruit trees, rose trees and flowers, but for large trees and stretches of potatocs a mechanical sprayer is advisable.

Sprayıng Machine. Where there are a good many trees concerned a machine sprayer is used. One of the best is known as the knapsack being so called because it is carried on the back. This is suitable for spraying all kinds of fruit trees, as well as potatoes and other vegetables.
In these machines the containcr, which holds about $3 \frac{3}{4}$ gallons of the spray, is usually made of plain or tinned copper. The former is less expensive. but it cannot be used for a lime sulphur wash, for which either a tiuned copper one must be used, or onc with a container made of an alloy that is chemically resistant. Fitted to the container is a short length of hose, and attached to this is a brass lance about 3 ft . long, the nozzle being fitted to the end of the lance. For spraying large trees a lance, 5 or 6 ft . long.. can. if necessary be fitted. All spraying machines are fitted with strainers. When it is necessary to spray an orchard of large standard trees, a type of small wheel manual machine is recommended

Winter Spraying. For spraying fruit trees in winter the tar-oil washes are recommended ; they not only cleanse the trees of moss, lichen and other impurities, but help to destroy hibernating pests among the branches. Limesulphur. nicotine and Bordeaux mixture are commonly used in early spring before the blossom buds open, and again at summer strength later on if necessary. Arsenate of lead paste in solution, if sprayed on the trees as soon as the blossom has fallen poisons the food of caterpillars. During the summer months one of the concentrated insecticides sold under various patent names will keep down aphis and other common pests. See Apple; Bordeaux Mixture: Fruit; Insec ticide ; Potato. etc.

SPRIG: In Lace. In lacemaking this word refers to one of the separate pieces of lace fastened on a ground in appliqué lace. Material embroidered with sprigs, or which has sprigs in the pattern, is known as sprig embroidery or sprig muslin. See Lace.

Spring. See Door; Lock.
SPRING: In the Garden. For the amateur gardener spring is the most delightful scason of all, particularly in the open garden, and it is also a busy time. The results of hard
work during the dark, cold, wet and frosty days show themselves by the arrival at perfection of many beautiful subjects, particularly Howering bulbs. First of all come the snowdrops, which are closely fcllowed by crocuses, scillas, anemones, hyacinths, narcissi daffodils, and tulips. later on flowering cherries and almonds put forth their beautiful pink and white blossom. fresh young buds and foliage begin to appear upon trees, shrub.s and perennial plants.

Strenuous work must be done out of doors in order to obtain the best results later on. This necessitates care in the sowing of seeds of hardy annual flowers, which, in snall gardens, may be done safely in between the clumps of spring flowering bulbs already in bloom and the groups of established perennial plants which begin to indicate their presence for the season. Many questions of pruning, propagating, dividing, and other technicalities arise at this time of the year.

As the official period of spring is from March 21 to June 21, information regarding the constructional part of gardening work will be best derived from the tabulated information given in this work under the headings of the different months. See April ; Autumin; June : March; May; Summer.

SPRING CABBAGE. This is a valuable vegetable which supplies produce in spring and early summer. Seeds are sown on a reserve bed during the third week in July and early in August in southern districts, and carly in July in northern countries. In September the plants are put out where they are to remain at 15 to 18 in . apart. Some of the best varieties of spring cabbage are Harbinger, April, Ellam's Early, l'lower of Spring, Mein's No. 1, and Emperor.

SPRING-CLEANING. The housewife who starts to spring-clean with a definite plan of action generally manages to renovate the home with the least possible amount of fuss or disturbance of its other inmates, and with the best and most economically accomplished results. The plan includes arrangements for essential repairs outside (in the case of the owner's house) and inside ; also getting rid of rubbish, storing away winter things, inaking at home anything in the way of new covers, lampshades, curtains or cushions that are required, or getting them madc, and sending away carpets and other soft furnishings which need professional cleaning or dyeing.

It is wise to make out the plan a good fort. night before the cleaning begins. Obviously any external repairs needed to roof, gutters, windows, etc., should be done first; then when the carpets are up any repairs to gas fires or other installations which may be required indoors. Should any room or rooms have to be redecorated it is advisable to remove everything portable, and have that work finished before proceeding with the other general spring cleaning. In the meantime small things can be attended to ; cup boards can be thoroughly turned out, winter goods protected from moth by ccdar chips, naphtha or lavender, stored away safcly wrapped in newspapers, and rubbish disposed of : china can be mended and also rugs and carpets which need fresh binding or darning with rug wool. Any odd jobs of carpentry or putting up shelves, etc., should be done before cleaning starts. Mattresses or pillows which require re-making should be sent away, and stock can be taken of the linen, glass, china and kitchen utensils.
Method of Procedure. In the case of a house it is best to start from the top downwards. The sweep should be engaged to clean in turn any chimneys in rooms where there have - been coal fires. Having decided the rotation of cleaning, prepare a room for the
hangings, ctc., and covering the rest of the furnishings with dust sheets and newspapers.

An electric vacuum cleaner is a great aid to the housewife where electricity is installed; it is not only useful for cleaning ceiling, trieze, picture rail and walls, but also for mattresses, stuffed chairs, divans, settees and soft furnishings generally. Once the sweep has finished, the special attachment to the vacuum cleaner should be used for ceiling and walls, or, failing this aid, a long-handled soft ceiling broom. After this the floor is dealt with, scrubbed or washed over with soda water and repolished, if parquet, or if of stained boards which are worn, restained with equal quantities of Brunswick black and turpentine, giving as many coats as are required, leaving them to dry in turn and then treating with floor polish.

When linoleum, rubber or cork carpet is the floor covering, use a little disinfectant in hot, soapy water with a clean Hoor cloth, afterwards dry thoroughly and wax polish. Japanese or fibre matting can be scrubbed, using a little soap and water, and working the way of the weave. The matting should be dried with a soft cloth immediately. Paintwork is best lightly treated with a tepid solution of borax and water, dried and polished with a soft rag on which a few drops of paraffin are sprinkled. Windows should be thoroughly cleaned and blinds, if any, scrubbed with a brush wrung out so that it is merely damped with soapy water and afterwards the blinds must be well dried. All furniture and fittings are next cleaned. Polished wood that requires particular attention should be washed in tepid vinegar and water and then rubbed over thoroughly with linseed oil and left for a few days; after this it should be well polished with furniture cream. Other furniture should have the woodwork washed over with a damp cloth and polished, and any upholstery well brushed or treated with the correct vacuum cleaner attachment.

## Cleaning Firepiace and Mantelpiece

All pictures and mirrors should be cleaned, all drawers and cupboard shelves washed over with a damp cloth wrung out of hot water with a little disinfectant added to it and, when dry, relined with clean paper. Brick fireplaces, which should be rubbed down weekly with warm water to which a little paraffin has been added, may be further cleaned with a preparation sold for cleansing unglazed bricks. White marble curbs and mantelpieces which arc stained should be rubbed with half a lemon dipped in salt. Leave the application on for a few minutes, wash off and dry the marble thoroughly.

China and glass, ornamental or useful, should be washed in soapy water with a little ammonia in it, using a hoghair paint brush for finely-modelled pieces and for getting the dirt out of crevices. Fittings of brass, copper, etc., and ornamental pieces should be cleaned and the opportunity taken to apply a trans. parent lacquer to any suitable pieces, which will save further cleaning for a considerable time. Piano keys and other ivory can be best treated with a paste made from sal volatile and olive oil, rubbing it on with a wash leather and leaving till dry, when the paste is polished off with a clean soft cloth. All books should be, thoroughly dusted and old papers and magazines discarded if uscless. See Brushes; Carpets, Clothes Moth: Labour Saving; Paint: Polishing: Vacuum Cleaner.

SPRINGER: The Dog. The breed of sporting spaniel known as the English springer is a very symmetrical dog, weighing on the average from 40 to 50 lb . He is possessed of a long head, square muzzle, longish Hat coat, long ears, straight front legs, good strong feet. and a general look of activity.

The colours are various. Among sporting dogs the springer's extra size gives him greater pace than the cocker, and he is able to retrieve a hare. See Dog.
Spring Mattress. See Divan: Mattress
SPRING ONION. To prepare these for table, wash them well in cold salted water, so as to draw out any insects from the leaves, cut off the roots, and trim the green tops The outside leaves, if withered, may he peeled off. Serve the onions either whole with salt, or cut them up and add them to a mixed salad.

Spring onions are sold in small bunches. The leaves should be upright; any tendency to droop being an indication that the onions are not fresh. See Onion; Salarl.

SPRINKLER : For Clothes. Any vessel which has a perforated top that will serve ns a sprinkler may be used to damp clothes hefore they are ironed. The large enamelled tins, with handle and detachable tops, sometimes used as tlour dredgers, make good sprinklers, and enable the dainping process to be done more evenly and thoroughly than would otherwise be possible. See Ironing.

SPROCKET : The Wheel. A toothed wheel of any diameter suitably designed for chain drive as distinct from gear drive is a sprocket. The shape, width, and pitch of the teeth will vary in accordance with the pitch and width of the chain to be used.

In its true form the sprocket wheel is always employed for pedal cycle work in conjunction with the block or roller type of chain, the roller chain being the most popular. A sprocket used with the silent chain is in appearance identical with the ordinary pinion, the teeth being much the same in shape. This pattern is always employed where chain drive is incorporated in the design of a motor vehicle. See Bicycle; Internal Combustion Engine; Motor Cycle.

SPRUCE : The Tree. 'This is the common name of a group of conifers among which are valuable timber and ornamental trees. Deal is the wood of the common spruce or Christmas tree (Picea excelsa). The blue spruce (Picea pungens glauca) is a beautiful lawn tree, and others of decorative value are the Hinalayan spruce (Picea morinda); Engelmanni, the Servian spruce (Picea omorica); and the Sitka spruce (Picea sitchensis); the lastnamed is an excellent tree for wet land. Propagation is by seeds.

Uses of the Timber. Spruce or white deal is one of the cheapest and commonest woods, imported into Great Britain from N. Europe and N. America. It has a white, clean appearance, with distinct annual rings and with numerous small hard knots, the latter making it rather difficult to work, as they dull the cutting tools, otherwise the wood is fairly soft. It is light, elastic and resonant, the
latter quality making it a suitable wood for sounding-boarls and for violins.

As a-tree spruce is tall and straight, yielding poles which are suitable for masts, spars, scaffold and telegraph poles, and for ladders when split. Builder's planks and temporary constructions are generally of spruce, and it is used for piles, packing cases, and similar rough work, and also for making paper pulp.

Its cheapness and clean appearance are reasons why spruce is employed for flooring, matchboarding, kitchen dressers and tables, and much other interior joinery. It is used also in bnat-building and for oars. The Christmas tree is a small spruce. See Wood.

SPRUCE BEER. This is a beer flavoured with $\pi$ decoction of the young shoots of the spruce fir. 'To make it, dissolve 4 lb . treacle in 2 gallons water by heating them in a large pan over the fire, then strain the liquor into a cask and add to it 2 gallons cold water and about 2 tablespoonfuls spruce esscnce.

Let the whole stand until it is just lukewarm, and then stir in $\frac{1}{2}$ gill fresh yeast. Place the cask in a warm place, and when fermentation ccases bung it closely and leave it until the following day, when its contents may be hottled. Sprucc beer made in this way is ready for drinking in a week's time. Essence of spruce is made by boiling the tops of the hlack spruce in water, then taking them out and boiling the water again so as to concentrate the lecoction

SPUD : For the Garden. This is a long handled tool with a sharp, straight, narrow hlade which is used for digging out hardrooted weeds such as thistles or burdock. Smaller types are convenient for cradicating lesser weeds on lawns, paths and between cultivated crops. See Spade: Weeds.

SPUR : For Horses. Nickel or electroplnted spurs are those in general use. Each spur consists of the branches for the heel, neck, and rowel, blunt or sharp, with a strap to go below the boot and one to fasten around the instep, with a leather pad to keep it in position on the boot and to prevent undue pressure on the foot. Spurs are used for

Spur Valerian. Rose-red flowers of a bardy plan for a sunny or shady border. See article above
enlivening a jaded horse or as an aid to guiding the animal in crowded thoroughfares, or to force a horse up to its bit when necessary. When applied with riscrimination they are considered essential for breaking and making good hacks and liunters. After use the straps should be removed and the leathers carefully sponged. See Horse ; Riding.
SPURGE. This is a large genus or group of plants, but few of them are of much value to the gardener; the botanical name is Euphorbia (q.v.).

SPUR VALERIAN. This is a uscful plant (Centranthus ruber), suitable for sunny or shady borders, walls and the wild garden. It grows about 2 ft . high and bears rose-red Howers in summer. It spreads rapidly by means of self sown seeds. The variety coccineus is a better colour and the white variety is attractive. See illus. below
Sputum. See Cough: Expectoration.
SQUAB PIE. To malic, fill a pie-dish with alternate layers of fairly thin pieces of uncooked mutton, sliced onions, and sliced apples. Over each layer of meat and onions sprinkle salt and pepper and a pinch of chopped herbs, over the apple a little white sugar. If the mutton is very lean, a few small pieces of bacon fat should be added. When the dish is full pour over it about $\frac{1}{2}$ gill water. then cover it with a good thick short crust and bake the pie slowly. It should be served hot. See Pastry.
SQUARE MEASURE. This is employed for measuring land, walls, floors, and surfaces of all kinds, being essential in all building operations. It is as follows

| 144 square inches | $=1$ square 1oot |
| ---: | :--- |
| 9 square fret | $=1$ square yard |
| 304 square yards | $=1$ square rod, pole, or |
| 40 square rods | $=1$ perch |
| 4 roods | $=1$ acre |
|  | $=1$ |
| 640 acres | $=1$ square mile |
| See Arehitecture : Bungalow : Measure- |  | Architecture

Bungalow
Measurement; Rule, etc
SQUEEGEE. The simplest form of squeegee is the flat type, consisting of a strip of thick india-rubber mounted in a wooden holder. When passed over a wet sheet it drives out excess of water from both upper and under surfaces of the shect.

Large flat squccgees mounted on broom handles are much more effective than a broom or mop for sweeping water off concrete or cement floors and paved courtyards.
Squill: The Bulb. Squill is an oldfashioned popular name for the spring-flowering bulb scilla (q.v.). See Bluebell; Hyacinth
SQUINT : How to Treat. Strabismusor squinting is mostly due to errors of refraction, hut may also be the result of paralysis of a muscle of the eve. Squinting from long sight or hypermetropia may apjcar at a verv carly age. When a child makes a strong effort to bring near objects to a focus there is undue contraction of the muscle, and a squint is produced. In short-sighted squint there is weakness in turning the eye. An inward squint is commonly due to paralysis of the muscle, which turns the eye outward.

For the squint caused by paralysis the treatment will vary according to the disease on which the paralysis depends. In the forms of squint arising from errors of refraction, the child should be at once taken to an oculist, who will prescribe suitable glasses. If this is done in time the squint may he cured in many cases. But if one eye is weaker than the other, efforts must be made to strengthen it. The usual measure is to cover the stronger eye with a shade, so that the weaker one may bo strengthened by exercise. The same object is obtained if some atropine ointment is applied daily to the better eye. The treat ment should be given a full trial for at least a year. See Eye; Sight Testing ; Spectacles.

SQUIRREL: The Fur. Squirrel fur is grey in colour, the clear paler shades being most valued for making up into coats and wraps. It dyes well and the darker skins can be treated to imitate Kolinski or sable. Squirrel is also dycd to match mole and flat brown furs as a trinıming. Unfortunately, it is not a durable fur. See Fur.

SQUIRREL PAINT BRUSH. To a great extent brushes of squirrel hair have taken the place of the camel hair brush for oil and water colour painting. They are made in a variety of sizes and are obtainable at artist's colour shops.

SQUIRREL'S FOOT FERN. This is the common name of davallia, a greenhouse fern. Its rhizomes are often trained round objects of various shapes and sold as fern balls. The most popular kind are the squirrel's foot fern (hullata) and the hare's foot fern (canariensis). Davallias are well suited to cultivation in suspended baskets. They like moist, warm, shady conditions. A suitable potting compost is two parts of fibrous loam with one part each of sand, peat, and charcoal, potting being performed in spring.

SQUIRREL TAIL GRASS. The ornamental grase known as maned barley or squirrel tail grass belongs to the genus Hordeum, and the only noteworthy species is H. jubatum. This is an annual growing about 2 ft . high, the bearded awns of which form a kind of mane. It may he sown in spring or autumn and will thrive in any open space.

SQUIRTING CUCUMBER. This is a curious half-hardy annual climbing plant with oblong, cylindrical fruit somewhat resembling small cucumbers. When ripe these fruits open and discharge their pollen. They should be grown in a heated glasshouse in a mixture of loam and leaf-mould and may be trained up the sides of a sunny greenhouse and on to the roof. Potting up must be done in early spring in large pots.

Propagation is by sceds sown in pots parly in the year, in a temperature of from $60^{\circ}$ to $70^{\circ}$. The flowers of the squirting cucumber are yellow in colour. The botanical name of the family is Momordica, while other popular names are balsam apple and apple of Jerusalem.

STABLE. In building a stable the points that must be principally borne in mind are that the horses should have plenty of light, plenty of air, and that the floor upon which they stand should be dry and well drained. A stable may be built of any material convenient, either stone, cement, bricks, or timber.

The stable walls should be 8 or 9 ft . high, so as to give plenty of hearl room, and the floor
should be raised at least 9 in . above the sur. rounding soil. The common practice of building the hay loft above the stable is not a good one. It leads to bad ventilation and to dust and clirt in the stable beneath, while at the same time the ammoniacal vapours rising from the stalile tlo not improve the hay.
Ventilation should he provided in the ridge of the roof and also in the walls, but the ventilators in the walls must be set above the lieight of the horse or horses' heads. If set iower, draughts will be cansed and the horse will suffer. Stalls are frequently made too narrow ; 6 ft . is the ininimum width to be allowed for an ordinary horse. The slope of the floor should not exceed 1 in 50. There is nothing worse for a horse than to be compelled to stand on a stcep slope with the greater part of its weight upon its hind legs.

## Points about the Floor

The floor of the stall or loose box is generally made of cement concrete slabs, which are roughened so as to give firm standing. Blue bricks grouted in cement make an excellent floor, but it is more costly than cement. Stone setts can be used if laid on cement and grouted with cement mortar. Cement alone will not stand the hoofs of heavy horses and nsphalte is too slippery, while wood absorbs moisture and cannot be kept clean. Good Irainage is allimportant, for if a horse is allowed to stand on foul and wet bedding its feet will certainly suffer. Under-floor drains, like stone causewayed floors, are now out of date, the drainage to-day being usually carried out of the stall.

The modern hay rack is usually of iron, and set at a much lower level than the old wooden rack. The feeding trough is either of cast iron or of fire clay, and is set not more than 3 ft from the floor of the stall. Water is usually provided in the stall, the water pot being set at a little distance from the manger, and providcel with a supply pipe and tap. It should be of a shape easily kept clean, and water should not be left in it. The woodworl: of the stall should be clean dressed and varnished, and all iron work painted three coats.

The stall should be provided with suitable windows. It is cruel as well as foolish to keep a horse in a dark stable, and particularly when it is opposite a blank wall. The windows should be of the sash varicty, and made to open and shut. The best for stable purposes are made with iron frames. A window in the wall must be protected with iron bars on the inside. It is well to remember that an ordinary 15 -hand horse can reach up to a height of quite 7 ft .

The hamess room is usually part of the same building as the stable, and is provided with tittings for holding harness and saddlery. These, as a rule, are made of iron, but wood is a preferable material. The harness room is provided with some method of hrating it, cither a stove or an open tireplace, for although there is no necessity to warm the stable itself, it is essential to have mcans at hand for drying wet harucss, and for maling hot gruel or bran mash for the horses.
Shelves are required for holding harness soap, oil, and polishes, and a few veterinary medicines can be kept
in a smali cupboard. In a small establishment the corn chests may be kept in the harness room. These are made of galvanized iron, and they are usmally separated into two or more compartments, to hoid oats, beans. maize, bran, etc.

It is necessury that water be laid on to the stable, and the tap must be one that will takc a hose pipe. The manure pit should in no circumatances adjoin the stable. All inanure should be removed cacb day to a pit in the garden, or at some convenient distance from the house and stablc. See Drainage; Groom; Harness; Horse; Manure; Roof.

STAFFORDSHIRE CHINAWARE. The qualities which characterize this china, both in its usefu! and in its ornamental forms, are durability, whiteness, and translucency. It has had as much to do as the coarser pottery and stoneware with spreading the renown of the Five Towns, Burslem. 'lunstall, Hanley, Longton, and Stoke, whose activity was greatly enhanced by their amalgamation into the county borough of Stohe-upon-Trent, which possesses five great public museums. Among outstanding names are Sjode, Davenport, Min!ton, Neale, Mason, Ridgway of Cauldon Place, Adans, Copeland, Treen, and Browntield.

Collectors of old china regard the immature and uneven productions of Wiliiam Littler, of Longton Hall, for a few yours after the middle of the listh century, as the beginning of Stafforilshire china. The mark was nade up of two L's crossed, and examples are now rare. But it was Josiah Wedgwood who intro!uced into the manufacture of fine earthenware those new methods of potting, firing, and decoration which revolutionized the industry.

Somewhere about the year 1800, Josiah Spode, the younger, adopted at Stoke-uponTrent a mixture of china clay, felspathic rock, and bone ash, with a lead glaze, which resulted in a true porcelain. His example was followed not only in his own neighbourhood, but ultimately also in the great rival factories found elsewhere.

The result was to abolish the old 18th century distinction between hard paste, as represented by Dresclen, and soft paste, as wrought at Sèvres, and virtually to establish a standard composition for English hone-china throughout the kingdom. As the proportion of bone-ash may be as much as $\frac{2}{5}$, the resulting body differs radically from that of the Chineso porcelain, and has become the chief model for modern china manufacture in all countries.

In the early years Spodo and Davenport turned out tea and other services in old Japan patterns, sometimes on rose or celadongreen grounds, with gilt feet. Davenport also made at Longport vases and other picces with raised floral ornaments enclosing delicate landscape panels.

After the mid-Victorian art revival, Mintons did some outstanding work, and the Crown Staffordshire Porcelain Co., Ltd., successfully rivalled the enamel tints used by Chinese potters in the famille verte, famille rose and powder-blue groups. Perhaps the highest achievements in this diroction are the flambe glazes wrought by Bernard Moore. See China; Davenport Ware; Minton Ware: Pottery: Spode; Wedgwood.
STAG BEETLE, The visits of stag beetles to the garden on summer evenings often gives rise to unnecessary alarm. They are perfectly harmless, in spite of the formidable appearance presented by the antler-like development of the male beetle's jaws. These are neither offensive nor defensive in their function, being, in fact, mere ornaments. The smaller, inconspicuons jaws of the female are of a far more practical character; but they are used only for crushing soft shoots in order to suck up the sap. As the attack is made chietly on oak trees, no appreciable harm is done. The grubs

Stag Beetle. Male and female of this harmless garden insect
is to sew rings on a tape running diagonally across each curtain on the side away from the audience. For a stage with a $12 . \mathrm{ft}$. opening the rings would start from the upper right and left inner corners respectively, and be continued down to a point on the edge of the curtains, where they
spend the full period of their existence feeding in the decayed wood of old stumps, and are in no sense garden pests.
STAGE. When a stage is required for amatcur thentricals or concert in house or carden, it may either be hired from an entertainment caterer with its accessories of proscenium, curtains, and lighting arrangements; or else it can be made at home in a simple but satisfactory way.

Presuming that the performance is to bc in the house, the size of the available room must be considered first, as the smallest stage requires a room not less than 14 ft . high: 20 ft . wide, and 30 ft . long. Of the last measurement 14 ft . is required for the depth of the stage and the remaining 16 ft . for the accommodation of the andience, who are too near the players unless 4 ft . be left between the stage and the first row of seats.

The bare stage floor measuring 20 ft . by 14 ft . scems a good size, but when the marginal space of 4 ft . has been allowed at cach side, and at the back for standing room, cxits, and entrances of the actors, the passing bchind the scenes required during the performance, and the necessary support for scencry by stage braces, the acting portion of the stage is reduced to a $12-\mathrm{ft}$. wide opening and a depth of 10 ft . Though workable, it will be seen that this size somewhat limits the scope of the productions. If the entertaininent be given with screens or Irapery as a bacliground instead of scenery, the same amount of marginal space would not be reguired on the stage, and a smaller room could be used.
Making the Cortains. The curtains may be made of dark coloured Bolton sheeting, and should part and fall easily. A simple plan
ome together in the middle, 6 ft . from the top.
A line is threaded through these rings and over a pulley at cach top corner, which will draw the curtains up into a festoon. Weights should be sewn along the bottom hem. This method requires a person on either side to raise or lower the curtains.
The Scenery. The scenery is usually hired from one of the scenic studios, where a speciality is made of small scenes for home entertainments to suit the size of stage described. Exterior scenes are usually formed by a back-cloth, wings, or side pieces, and borders of top picces of trees or sliy. Interior sets are, as a rule, made up of tlats and ceiling borders. Flats are straight pieces fastened edge to edge by means of cleats and lines and held up by wood or iron braces heavily weighted with counter-weights.

A few details as to simple stage effects may be found useful, though most of them require practice, because if badly done they may spoil a serious scene. Horse-hoofs are imitated by two half coconut shells tapped against the wall. For wind, a special wind machine can be hired at a theatrical store. The effect of steain from a railway engine can be obtained by rubbing two pieces of sandpaper together in imitation of short or long escapes.

For lightning on a darkened stage a mag. nesium flash may be used. Thunder is suggested by blows on an iron sheet suspended by two ropes; the roll of thunder is suggested by holding the iron sheet at the bottom and shaking it. Rain effects are worked by pouring dried peas through a long wooden tube studded inside with nails; the slight or the marked tilt produces a shower or heavy rain. See Theatricals.

## Stains and THE STAINING OF WOODWORK

## Rules for the Application of this Decorative Finish

Useful both to the householder and the woodworker, this article deals not only with methods
of staining but with the preparation of the varied surfaces so reated See also Floor;
Graining; Oak; Paint; Pokerwork; Varnish, etc.

The object of staining generally is purely decorative, but certain stains have preservative qualities and thus answer a double purpose. By the use of a stain inferior woods may be made to resemble those of a finer quality, and hardwoods may be darkened to any shade for the purpose of enhancing their appearance.

While painting forms a completely new surface upon the wood, thus hiding the grain, a stain percolates into the grain, changing its colour without forming a fresh surface. There are many different varieties of stains, the chief difference being in the medium with which the colouring properties are mixed. This may be water, spirit, oil, wax, or varnish.

A useful wax stain is sold under the name of Sitainax. It is applicd with a brush, dries in a fcw hours, and results in a durable wax finish, which can lee polished with a brush. It is ohtainable in a number of shades.

Anotler method of staining is by the use of chemicals such as permanganate of potash, ammonia, and bichromate of potash. There is another class of chemical stain, the use of which involves two procerses, a priming and a colouring coat. The solution combines with the wood to form pigments which are fast, and the colour may take a couple of days to develop.

Stains may be either purchased ready naade in liquid form, or obtained in the form of paste powder and crystals. They are usually named according to the woods they represent, as light and dark oak, mahogany, walnut, and ebony, or in direct colours, as blue or green
For outdoor work it is neccssary to obtain stains which are weatherproof, as ordinary types are apt to fade quickly and develop a
patchy appearance. For cabinct work or indoor fitments the wood should be first planed smooth and llat, and then well glass-papered with, first, No. Middle 2, and finished off with No. $1 \frac{1}{2}$, using a cork rubber on which to hold the glass paper, and working it always in the same direction as the grain of the wood. If the glass paper is rubbed transversely to the grain, this will roughen the surface and cause any such parts to become darker than the remainder when the stain is applied.

Where it is desired to stain existing woodwork, care should be taken to ensure its being clean and free from grease marks, as thesc parts will be lighter than the remainder when the stain is applied, and will give a spotted and patchy appearance. Such places should be treated by rubbing them with a rag soaked in benzine. Any dirty marks can be removed by the use of glass paper.

When staining wood of poor quality, it is sometimes advisable to dress the surface so that the stain may lic evenly. The clressing consists of a coating of size applied fairly thin and left to harden thoroughly before staining. Sizing is necessary before the application of varnish stains to new woodwork, as otherwise the porous nature of the grain will soak up the quick-drying liquid before it is possible to work it.

All nail holes and other indentations must be filled in before staining. If water stain is to be used, the stopping is made up of plaster of Paris, or of wax mixed with suitable colours. Ordinary oil putty is used if the work is to be treated with oil or varnish stains. Care must be taken to avoid marking the surrounding woodwork with the putty, as this may leave such places lighter than the rest when the stain is applied. The holes are rubbed down level with glass paper afterwards.

The brushes required vary according to the nature of the work. For intricate parts of the work, such as mouldings and carvings, a narrow flat brush is the most suitable. A toofully charged brush is apt to give a streaky appearance to the wood, and there is the danger of the stain dropping from the brush on to the work.
The stain should be kept in airtight bottles, sufficient being made up to finish the whole of the work in hand, so that the colour will be uniform throughout. When required for use, it may be pourcd into a shallow vessel. Before applying the stain to the wood, it is advisable to test the colour on a spare piece of similar wood.
How to Use the Stain. The stain is applied by drawing the brush from one end of the work to the other in the same direction as the grain, working across from one side. It is essential that the edge of the colour should not be allowed to dry before the adjacent portion is stained, as this would result in a series of streaks ; hence it it is necessary to procecd smartly, cspecially when working on a large surface. A hot, dry atmosphere should be avoided, as one brushful will dry before the application of the next. It is a mistake to begin at the centre and work outward, as this necessi. tates working two edges of colour.

Having covered the whole surface, the brush should be pressed out to remove all surplus stain and lightly drawn to and fro over the work in a series of parallel strokes in the same direction as the grain. This will have the effect of removing any excess of stain in any one part. Some
workers prefer to finish off with a piece of enough to require special treatment may be muslin folded into a rubber, which gives a more even finish and removes all brush marks. Rub evenly and with only a moderate pressure, as otherwise the stain will be rubbed off in patches.

When staining a piece of panelling or a door, the panels are first attended to, working across from one side to the other in parallel strokes, taking the brush well into the corners and into the quirks. Any inner members of the framework are stained and then the rails, finishing off with the stiles. By this means the treatment of each successive portion of the work will clean off any stain inadvertently overlapping at the joints, as the brush can be drawn cleanly in a line with the joints in the same direction as the grain. The mouldings are finally stained, using a small brush and being careful to avoid touching the panels, especially when working on mouldings running transversely with the grain of the panels. The brush should be sparingly charged to prevent the accumulation of stain in the quirks and corners.
If a particularly dark colour is to be applied to a light wood, it is generally advisable to give two or more coats of a weaker stain rather than one heavy coat, as the latter is apt to dry
rubbed with a cloth ball. The latter, being partly composed of fuller's carth, acts as an absorbent and is therefore specially effective in removing grease spots. Various patent preparations are sold for removing either acid or grease stains, but before using them on delicate materials they should be tested on an odd piece of the same colour and texture.

Preparations of benzine, though labelled improved ' or ' non-inflammable,' still require care in use, and should not be applied near a naked light. The article treated should be aired by an open window until the smell of the cleansing has disappeared.

Stains on alabaster ornaments can be removed with a pastc made from whitening, soap and water. The paste is left on till quite dry and then removed with a soft cloth. A little powdered pumice is sometimes effective for the removal of obstinate stains. Stains on marble slabs, chimney pieces, etc., are best treated with half a lemon, dipped in salt. Wash of thoroughly and polish with a soft cloth.

Grease Stains. Stains on clothing caused by the spilling of gravy, oil, etc., should be sponged iminediately with hot water, or rubbed

Ink Stains. An ink stain on a white fabric should be sprinkled with salt at once, and then rubbed with a cut lemon. Rinse and warh off both cleansers at once. This method should not be used for coloured things as it may shift the tint; instead, try the following method:
Soak the stained part immediately in slightly warm milk, This should remove the mark if it is a fresh one, and the marked area can be rinsed, dried, and smoothed with a warm iron. Another method is to rub the stain with half a ripe tomato. then soak it in cold water, and the remains of the mark will disappear entirely after the next laundering. Tomato juice is satisfactory on dark woollen material if afterwards well sponged with cold water.

Old ink-stains which have dried in can only be removed from white fabrics with care, as the strong remedies necessary will spoil coloured goods. There is also always a risk of the cleanser eating a hole through delicate fabrics. Spread the stained part over a shallow dish or bowl half full of boiling water. Moisten the mark with water, and place a tiny pinch of salts of lemon over the stain. The latter must be carefully handled, as they are very poisonous. Leave the salts about a minute, then pour a thin stream of boiling water through them and the stuff. Repeat if necessary, rinsing off all trace of the acid immediately.
When ink is spilt on a carpet, take up the moisture immediately with blotting paper, then rub the place with a rag dipped in milk, preferably boiled, and dry with a dry cloth, rubbing hard. Or salt may be sprinkled on the stain, and rubbed with a cloth moistened in warm water.
Tea and Coffee Stains. For obstinate coffee stains on linen or cotton, a bleaching liquid made from $\frac{1}{2} \mathrm{lb}$. chlorinated lime, $\frac{1}{2}$ gallon boiling water, and 2 tablespoonfuls ordinary washing soda is effective. Turn the lime into a clean basin, pour the boiling water over it and then add the soda. Stir the whole with a wooden spoon, breaking up any lumps, and working vigorously to help the water to draw out the chlorine. Careful straining is then necessary to remove all the powder and leave the liquid clear.

The latter should on no account be used stronger than one part of bleaching liquid to 4 parts of hot water, and in the case of old or fragile materials, one part of liquid to 6 parts of hot water, or an even weaker solution, is advised. The article should be soaked in this for a short time, and taken out as soon as the stains disappear. A soaking in cold water and a thorough washing to remove all trace of the chemical are then necessary.

This bleaching liquid should never be used on silk or wool. Tea stains may be removed in the same way.

Grass Stains. Grass stains on fabrics which are too delicate to be washed should be treated with methylated spirit dabbed on with a clean cloth. If the material can be laundered, however, the stained part should be soaked in cold water, then covered with a little cream of tartar and left in the sun. Finally rinse with more cold water, and if the marks have not disappeared, repeat the treatment. For grass stains on linen or cotton goods, javelle water (q.v.) will be found effective. See Cloth Ball; Clothes; Dry Cleaning; Floor; Irons; Mildew; Paint; Petrol.

STAINED GLASS. The introduction of stained glass in a window for hall or landing depends for success on architectural features, the design and shape of the window and ita useful purpose. When there is an ugly outlook, or one on to a blank wall, a well-chosen stained glass window may be a charming piece of decoration, which screens without seriously obstructing the light. The best effects are usually obtained by concentrating the design to a border and a top panel or central motif, and using rippled or muffled white glass for the rest of the window. This is a successful

Stained Glass : its decorative use in the home. Fig. 1. Two examples of rouadels and reproductions of 15 th century quarries introduced into the leaded light panels of a living room window
to be specially designed for the style of furnishing in use. Lighting effects can often be improved by tinting white glass pancls in fittings with amber or red glass stain. See Glass Lead Art Craft; Leaded Lights; Window.

STAIR CARPET. Whatever the indiv:dual choice of colouring and pattern may be, it is poor ceonomy not to put down a type of stair carpet that will yield lasting wear. Goo! qualitics of relvet pile and hair carpet are always suitable, and for the country cottage coconut matting has much to be said in its favour, as besides its durability it does not retain the dust. Thick felt pads should be placed under the carpet on each tread and an extra yard of carpet should lee allowed for each flight to enable the carpet to lee shifted at least two or threc times a year.
Stair carpet is usually stocked in three widths, 18 in ., $22 \frac{1}{2}$ in., and 27 in . In a few nakes, colours and patterns it is obtainable in 36 in . width. When deciding on colour, and whether the carpet is to be plain or patterned, the width and lighting of the staircase, the wallpaper and the hall should be talien into consideration. Where a number of persons use a stairense it is often considered better to have a patterncd carpet.
Where an oriental rug is placed in the hall the pattern of the stair carpet should blend in tone and be of the same type of design a a small conventional pattern is satisfactory with a tiled hall, the ground of the carpet repeating a note of colour in the tiles. Where it can be used, the patternless carpet is easier to bring into an cllective decorative scheme. It may The decorative use of quarrics and roundel for the home window is seen in Fig. 1. In this instance the shapes of the patterned picces be all of one colour, possess a plain contrasting do not correspond to those of the plain glass, border, or show a narrow line of colour a few but break the uniformity of the leadel light inches from each edge. The last two varieties panel by the pleasing namner of their inscrtion. are usually to be found in hair carpet. Hints Fig. 2 shows a lozenge-shaped quarry with on the economical laying of stair carpets will the initials of Henry VIII and Katherine be found in the article on Carpet (q.v.). llanking the Tudor rose surmounted by the crown. In Fig. 3 the charining effect is scen of two rectangular quarrics set in panels made up of glasses of similar shape. Again royal emblems arc chosen of the lion, unicorn, rose and standard. The heraldic shicld which is seen in the lozenge-paned light on the left of the picture is another pleasing example of the discrect use of coloured glass. Reproductions of quarries and roundels can be obtained to order at the Victoria and Albert Museum. They can also be sometimes picked up in antique shops. While large panels of old stained glass are expensive, small quarrics have been bought for a few shillings, and finely reproduced roundels are obtainable for about thirty shillings. Panels and roundels with good geometrical or conrentionalized pat terns have been introduced successfully into sash windows, but require

Stained Glass. Fig. 3. Discrest use of stained glass by the inclusion in a charmingly designed window of two rectangular quarries and an heraldic shield

## Staircase: Planning and Decoration

## With a Survey of its Architecture at Various Periods

This contribution deals with one of the essential features of the house, and is therefore dis cussed to some extent under such headings as Cothaze; Hall; House; Landing. See also Baluster; Colour; Dado; Floor; Panclling; Stain, etc.
Few parts of a house require more careful horizontal members which rest upon the risers planning than the staircase, which provides a and receive the wear and tear of the stairs means of access from the ground lloor to the The nosing is the front of the tread. As a floory above, and at the same time offers rule it is rounded off or moulded, and projects great scope for decorative effect. It will almost always be found that a house with a well-designed staircase is easier to manage from the housewife's point of view than one in which the stairs are badly lighted, too narrow, or in some way out of keeping with the style of the house.
Economy of space is another leading consideration, and the location is very important. The severcly geometrical designs essential to the construction of staircases admit of little variety in form, but in the materials used and in decorative details there is scope for original treatment. Some of the principal types of staircase are dealt with in this article. which also describes the conuponent prarts and constructional details of a simple form.
The materials used in stairmaking are generally either wood, brick, concrete, stonc or iron. The stairs are made up of the following parts : strings, risers, treads, nosings, winders, landing, newel, handrail, balusters. The strings are the side members that receive the ends of the treads and risers, the latter two being housed and wedged into the former. If the stains are fired against a wall, that nearest to it is called the wall string, the other the outer string.
The risers are the vertical members which are placed across the stairs to receive and support the treads. They are housed into the immediate lower tread. The treads are the

Staircase. Fig. 1. Diagram showing positions of the various parts that malke up a fight of stairs

## beyond the riser about $\frac{3}{3} \mathrm{in}$.

Winders are those steps or treads that form an angle, if such exists, on a staircase. Their shape on plan is similar to that of a kite Winders should be avoided if possible, and be substituted by a quarter landing, that is, a rectangular space the same width as the stairs both ways. The rise of the stairs is the vertical height from the surface of one tread to the other, and the going is the name given to the horizontal distance between the faces of the risers.

The newels are picces of timber generally $\ddagger$ by 4 in . in section. They are placed at the botton, top, and at any change of direction of the stairs. The head and the pedestal of the newel are generally worked. The newels eccive the handrail, the latter being tenoned into the former and pegged. The handrail is the member that spans between the various newels. It is ronnded or moulded. If lixed over the outer string, balusters are placed between them, tenoned into the string and handrail respectively. They arc placed about 4 in. apart, two balusters being gencrally allotted to each tread. The handrail is fixed about 2 ft . ! in . above the string.

In addition to the strings, thic treads and riscrs should be supported by carriers; 4 by 3 in . stuff is generally used for these, and they are so arranged that each slep is supported by either onc or two carriers.

## Rules to Determine the Pitch

The pitch of the stair is governed by the available space and height. It should generally be arranged so that the rise multiplied by the tread will produce 66 or thereabouts, e.g. 11 by 6 , or 9 by 7. These proportions give very good results in practice. The former would be used in the best class of work, while the latter would be applicable to the ordinary dwelling-house.

When the amount of rise and going bas been determined, a gauge or pitch-board is made. This is a triangular piece of wood, the two sides forming the right angle being the gauge of the rise and tread respectively. By the assistance of the piteh-board and the plan of the stairs the newels and the strings are set out.
The housings for the treads and the risers are cut on the tajer, in order that wedges may be driven to complete the fixing together of the stringe, ticads, and risers. The tenons and nortises are prepared on the newels, these latter being pinned to the strings during the lixing of the stairs. The width of the stains should not be less than 3 ft . outside measurement. Stairs are often narrower than this, but it is undesitable, and in many instances very inconvenient.

Although in some of the newer small houses metal and concrete are utilized for staircases having steps of white or coloured composition, with rail and supports of metal tubing, the most common type is the timber staircasc. Of these the two forms most used are the well and the dog-leg staircase. The latter consists of two or more Hights so arranged that the outer string of each successive llight is immediately above that of the preceding one, the bottom newel of the upper flight acting as the top newel of the lower one. This form is chiefly used to economize space, and is seen in many terrace town houses. It is also the cheapest form of simple staircasing. Fig. 2 shows an elementary type of such a staircase.

Fig. 3 is an example of a well staircase. This type of stairy is probably the most dignified in appearance and consists of two or more flights built so as to cnclose a space. The example given is constructed round three sides of a well, each of the flights being straight and having two quarter space landings, thus obviating the necessity of using winders. The handrail is of heavy proportion, but being in combination with the hold newcls it docs not appear out of place. The upward curve to be seen at the head of cach rail is known as a ramp and is used to bring the rail up to the required height for the beginning of the succeeding member.
Tudor and Jacobean Staircases. In the early Tudor buildings the most used type was known as the solid newel, and consisted of a central upright or newel from which the treads and risers radiated in a spiral fashion. These werc usually of stone and of crude construction, and were dangerous, owing to the treads necessarily tapering to a point towarls the central newel. With the advent of the Renaissance, although stone. stair; were still constructed, wood stairs arranged in straight Hights came into use, these being the forerunner of those in use in modern times. The carlier specimens were often composed of a series of solid blocks huit into strings of similar heavy formation, but these were later superseded by a lighter form of separate treads and risers housed into the stringe. A

Fig. 2. Open type of dog-leg staircase, simple form chiefly used to economize space
notable feature of Elizabethan staircases is the treatment of the newel, which was carried above the handrail and was usually surmounted by a capping or carved finial. This treatment is found in many later oak stairways and in adaptations of Tudor and Jacobean styles. An example may be seen in Fig. 2, page 574 , while in its simplest form such a newel post is shown in page 608.

A variation from the usual balustrading of turned spindles was that consisting of a series of pierced pancls carved in scroll and leaf work in the charicteristic style of the time.

The later Jacobean staircases were of similar formation to the Elizabethan, except

Staircase. Fig. 3. Well staircase of modern construction; a simple and dianified arrangement
that they were rather lighter. The turnings, ir place of the heavy bulbous type, were slighter, the handrailing of smaller proportions, and during the lirst half of the lifh century the newel was still carried above the handrail. This feature is probally a development of an earlier form, when the newel was continued from floor to Hoor in one continuous line, a style also found partially adapted to the modern stairway, as may be scen in Fig. 6.
Our next illustration, Fig. 4, shows a 17th century Loudon stairease of unrivalled beauty. This is situated in Ashburnhan House, now part of Westminster School, the building of which has been assigned to Inigo Jones, between 1633-1640, or to his pupil Welbl in the period between 1660-1670. This staicease is considered to have been planned and designed with consummateingenuity and art. Its wide, shallow treads, carved talusters, Huted Ionic columns, and its elliptical dome (not seen in the illustration) supported hy a series of twel ve columns, give an effect of great dignity and spaciousmess. The lovely 17th century panelling should be noled.

Staircases of the 18th Century. For the more intimate and cosy type of house which camo into firshion in the reign of Qucen Anne staircascs were planned of much lighter construction. The heavy balusters and massive handrails disappeared in favour of a lighter and more elegant style. Thee finely twisted balusters were sometimes found on each wide tread, and carving "as discreetly limited to a delicate nersel at the bottom of the staircase, and sometimes to brackets helow the treads on the outer side which enriched the appearance of the flight when seen from the hall. In other 18th century staircases a railing of scroll work in hent iron "as utilized in place of wooden balusters. This is yet another stylo adopted to day, in some cases all

Fig. 4. Beautiful 17th century staircase in Ashburnbam House, Westminster School, with Ionic columns, carved balusters and panelled walls. Fig. 5. Georgian staircase with gracefully turned balusters and carved mahogany rail courles!! of Countr!! liire

Wallpapers and carpets with very pronounced patterris are, therefore, not a good cho:ce The modern liking for varnished paint and riarnished marbled papers in pale tones oi yellow. beige. green or grey for hall and staircase is to be recommended fortwo reasons The lirst s that a pale, shiny surface reflects the light, and the yecond that such surfacus especially when mottled, do not show dirt or marks, a considera tion on a family stainway

Sometimes the balust tade is accentuated by being painted in a daiker colour to stand out against light walls, as in F?g. 7; in other cases, as in Fig 6, the woodwork is of the

Staircase. Fig. 8. The cupboard under the stgirs in some houses is a dark biding-place lor unwanted things. Not so in this case, where an electric light reveals its useful contents at a glance same colour as the walls In the latter example the dark rich little to maintain in good order. For the tones of the stair carpet are particularly type of staircase shown in Fig. 3, brown valuable A good effect has been also woodwork has an excellent effect, and renders obtained by painting the treads and hand- carpeting unnecessary if the treads and risers rail black, while the risers and rest of are of oak. Deal docs not stain very well the woodwork were painted white. A grey- for this purpose, but British Columbian pine green carpet with a decper toned border and has a beautiful grain and, though dearer than pattern, and the green marbled wallpaper deal, is worth the extra cost, which is com t.eatment, with the applied landseape motif, illustrated in page 575, completed an inexpensive scheme for a town house. Another staircase was decorated in shades of grey The walls had a dark grey dado with dove-grey paper above, and allother woodwork, including stairease doors, was in two medium shades of grey 'Thestair carpet was also grey, but colour was introduced by rugs, window curtains, and a set of llower prints framed in lead (see Lead Art Cra!t).

While paint is most usual on a staircase, stained woodwork has much to recommend it. It is permanent, neutral in colour, and costs

Fig. Painted staircase planned for a labour-
saving house. The solid construction of the wooden saving house. The solid construction of the wooden balustrade does not barbour dust "lunphre," of Vera Joel paratively little for the staircase and accompanying woodwork in a small house. The hatural colour of the wood combines with a preservative stain to give a beautiful effect when wax polished A scheme which included a dado of this wood, boney coloured walls and ivory ceilings would place no restrictions on the decora tions of the rest of the house, and yet would be warm and inviting in itself. Sucha scheme is, however, only possible for new "oodwork when the choice of decorations rests with owner or leascholder. Stains, especially those of a preservative kind, which give the best effect besides preserv. ing the timber. not only penetrate the wood \{unlike paint, which merely coats the surface) and are diff. cult to remove, but also have a destructive effect on paint should it be wished afterwards
to make a change in the decorative scheme.
Stair Cupboard. In many houses there is a cupboard under the stairs which ean be most convenient if its contents are easily seen and properly arranged. When used as a housemaid's cupboard and not as a hiding place for unwanted things it can be fitted with ehelves, a broon rack and apace left for the vacuum cleaner, etc It is also a good housing place for gas and electric meters. Where electricity
is installed a light which reveals the content.s of the cupboard at a glance is well worth the extra point Fig 8 shows a stair cuploard fitted in this way. Note the wall socket at the foot of the stairs for radiator or vacuum cleaner.
STAIR ROD. The long, thin rod placed in the angle between the tread and riser of stairs to secure the carpet or linolcum is generally made of wood or metal In selecting stair rods, it is well to bear in mind that those which are niade of polished metal call for conslant attention to keep them bright and in good condition, whereas only an occasional polish with furniture polish is needed for wooden rods The good effect of oak stair rods is illustrated in Fig. 6 of the previous artic!e. An oak rod with an oxidized metal eye or bracket is a useful fitting The brackets are simply screwed to the tread and riser respectively.

To kicep any type of brackets used at a uniform distance apart, it is a good plan to cut a stick or piece of wood of sulficient length to lit neatly between the two sides of the staircase or stringers of the stairs, and to cut two notches in one edge of the stick exactly where the metal brackets are to go. By using this stick se a guide and placing the brackets according to the notches, uniformity in line is ensured.

Instead of rods, clips or holders are often now used A simple switching of the holders is all that is neccesary to relcase or fix the carpet. There are no loose parts to be taken away and replaced. Such holders are tinished in oxidized brass, copper or silver.

STAKING: In a Garden. This is all important detail in the cultivation of trees and plants. Standard trees must be supported by strong stalies or the head of branches may cause the stems to break. Suitable ways of supporting herbaceous border and other plants are shown in the accompanying diagrams. llant supports ought to be as unobtrusive as

Staking. 1 Good knot tor garden work: a, details of tying 2 Same knot incorrectly tied at $b$. 3 and 4. Two useful' supports of wood and string. 5. How to stake a tree securely: $a$, stakes ; $b$, twisted ligature: $c$, knot as shown above. 6. Stake farred or creosoted above and below ground 7. Method tollowed in staking a pot plant 8. General utility stake for border purposes
By special arrangement with Amateur Gardening
possible, and they must be inserted in good time, for if the stems become bent the flower display will be spoilt. The metal coil stakes are commonly used for carnations; they are of spiral shape and tying is unnecessary. See Beans: Carnation; Fruit; Pcas: Swect Pea.

## Stammering. See Specch.

STAMP : On Documents. Certail docu ments, in order to be valid, need stamps, the value of which varies with the value of the
trausaction for which the document serves. is $1 /$ - for every $£ 100$ or part of $£ 100$ above that have been supplied originally to collectors

For instance, a contract note for the sale or purchase of any stock or marlietable security must bear a stamp. This is 6 d . for contracts between $\mathfrak{f} 5$ and $£ 10$ in value: $1 /$ - for those between $£ 100$ and $£ 500$; 2/- for those between $£ 500$ and $£ 1000$, and so on, until a stamp of $£ 1$ is needed for sums in excess of $£ 20,000$.
Stamp duties are also payable when land or houses or other property of that kind is conveyed or is sold. These are at the rate of one per cent. When the value of the transaction does not exceed $£ .50$ ), the rate is one half per cont. The stamp duty on a mortgage is $2 / 6$ for every $£ 100$. or fractional part of $£ 100$, with smaller amounts for those below $£ 100$.

A promissory note must bear a stamp. it is for less than $£ 10$ the stamp is 2d. It rises to $1 /$ - for a note between $£ 75$ and $£ 100$, and
amount. Stamps must also be put upon all life insurance policies. This is Id. if the sum does not excecl $£ 10$. From this the scale rises by (id. for every $£ 50$ or part thereof until on policies exceeding $£ 10(1)$ in value it becomes $10 /$ - for every $£ 1000$, or part of that amount. All agreements except (1) an agrecment in some matter under $\mathfrak{£ 5}$; (2) an agreement for the sale of goorls: (3) an agreement for the hire of any serrant, and (4) certain agreements relating to hire of sailors on board ship, must bear a 6d. stamp. An adhesive stamp may be used if it is allixed and concelled at the time of the agreement, or a stamp may bc impressed at Somerset House without penalty within 14 days of the agreement. An agreement may be after-stamped at any time on payment of a penalty. Sce Land; Mortgage.

## Stamp Collecting

## Practical Advice on a Popular and Educative Hobby

Devotees of other collecting hobbics will find in this work articles on the various subiects in which they are interested, e.g. Brass Collecting; Buttertly; China; Coins; Pewter Collecting
Whether he intends ultimately to specialize should be handled carefully and, after retain or not, the beginner should make himself thoroughly acquainted with the willer aspects of the hobby in the realms of geography and portraiture, cartography and industry, transport and navigation, history, currencies, languages, and many other subjects. A collection comprising one or more of these groups will be a source of constant interest to its owner and to his friends, whether they are stamp collectors or not.
Whether the tiro intends to be a philatelist or to remain a stainp collector only, he should start on general lines, laying the foundation of his collection either by means o! the gift of specimens, by the exchange of duplicates with other collectors, or by purchase from dealers.

Except in the casc of the commonest examples, stamps have a recognized "catalogue" value. that is, the price at which they are quoted for in the dealers' annual lists; hut it is not necessary for the beginner to buy then separ atcly. Many lirms make a speciality of packets ranging in price from a fow penco to $£ 50$ or more, according to quantity and quality. Whole scries of these art available, the contents so graded that no stamp is duplicated, the whole forming a nucleus for a general collection.

Each stainp, no matter how common, should be studied carefully, both as to its design and philatelic components and its status and value according to the catalogue. The purchase of mixed variety packets from different firms will, of course, result in the accumulation of duplicates; these will be useful for exchange purposes.

After a groundwork has been achicved by the packet system, the beginner is recommended to build up his collection by means of the sets of various countries. These sets may be representative of the whole output of the country in question, or they may be of one series only, and are sold in great variety from a few pence upward. The next step is to write to dealers for selections on approval. These are the speciality of many firms, who invariably offer a discount off the catalogue prices. Approval selections are mounted on sheets or in small books, with the price for each stamp clearly indicated. Such selections

ing any specimens required, should be returned for those that are retained.

A standing order may bo left with a dealer for selections to be submitted from time to time, according to one's specific requirements, clearly stated on what is technically known as a "want list."

If the collector intends to concentrate on the stamps of a certain country or issue, he should keep his eyes on dealers' announcements in the philatelic press, wherein special. ized collections are occasionally offered for sale intact. If, on the other hand, he prefers to collect on general lines, and $w$-ishes to keep his album up to date, he cannot do better than join one or other of the several new issue services which exist for his convenience. Through their agences, and
in this way
Stamp auctions by reputable firms are a familiar feature of the trade: they are held every week from early September to the and of the following July. Many bargains can be picked up in this way, and when the collector has gained a working knowledge of market values, etc., it would be worth while applying to one or other of the auctioneers for a sale catalogue, in which the lots to be disposed of arc listed in single stamps, sets, or collections according to scarcity.

Exchange Clubs. These provide another means for the economical extension of the collection, while also being a useful channel for the disposal of one's unwanted duplicates. Numerous clubs are in existence, their primary object being the circulation of a monthly packet containing sheets of stamps submitted for sale by members, each of whom has the opportunity of seeing the preket in rotation in accordance with a postal list supplied by the club secretary, who is charged with the settlement of the sales and the return, in due course, of unsold stamps to the owners.
The stamip collector must learn to buy wisely if he hopes to sell to advantage. Condition is of vital importance. Each specimen inust be examined to see that it is not damaged or defective, that its colour is true. If it is a used stamp, it should be refused if the postnoark is very heavy, unless it is a really rare example. If it is a perforated stamp the perforations must be intact, unless it is a bona-lide variety such as that termed partly perf. On no account should a damaged stamp be mounted in an album unless it is a very rare specimen.

In the ordinary way the collection should be limited to adhesive postage stamps. Nonadhesive stamps printed on postcards, envelopes, letter-cards, and wrappers are seldom included, nor fiscal or revenuc labels, unless they have been used for postal purposes. Stamps available for both postage and revenue fiscally cancelled should be rejected alto-

Stamp Collecting : some of the requisites. Below, star perforation gauge with sixteen variations, each in a space of 2 cm . Above, left to right: tweezers with rounded ends; same with pointed ends; pocket magnifler
should also not be mixed $u_{p}$, with the ordinary postal issucs in the album.

Necessary Accessories. Apart from the album there are three essential accessories which the collector should obtain at the outset, viz a box of mounts (small strips of thin, transparent paper, gummed on one side for folding in the form of a hinge), a pair of tweezers, and an up-to-date catalogue. As he progresses with the study of stamps he will need a magnifying glass, a perforation gauge, and a watermark detector. Several sorts of magniliers are made expressly for stamp collect ors, with specially powerful lenses.
A watermark detector is a small black tile or japanned tray, on which a stamp, the watermark of which is undecipherable when held up to the light, is placed face downward, and a spot or two of pure benzine applied to its back. Used in this way, benzine is quite harmless for all ordinary philatelic purposes, but it is advisable to procure the rectified brand A few issues do not lend themselves to this treatment, being printed
in lugitive colours, some of which disappear when plunged in the benzine bath.
In cases such as this, where the watermark is not apparent on ordinary scrutiny, risk of danage can be avoided by recourse to a simple photographic process, in which the stamp is used as the negative
Other Requirements. Less important acces. sories include a surcharge measurer, which is a device like a pair of dividers, opening and closing with a screw adjustment, a chalky paper tester, and a mount damper or fountainbrush for moistening stamp hinges. The testers consist of a fine silver point held pencil. wise, which, if the paper be chatky, will leave a slight black mark. The determination of the question of a slamp's surface, as to whether or not it is on chally paper, frequently affects its value. Any piece of clean silver will serve as a lest, which should be carried out in the margin of the stamp, if possible, rather than on the stamp itself.
Peroxide of hydrogen is useful for restoring the original freshness to oxidized colours. but
no attempt should be made to expunge postmarks by means of chemicals. A pocket collecting-book and a supply of transparent envelopes are practically indispensable components of the outfit of even the most humble 1,hilatelist.

Varieties in the perforation of such stamps as were not issued imperforate must be represented by separate specimens in a specialized collection, but they need not concern the general collector. One of the principal objects in the philatelist's outfit is a perforation gauge. This is a printed card bearing a scale of clots of various sizes, ranging from 7 in the space of 2 centimetres ( 20 millimetres) to 17 in that width. By passing the edge of the stamp over the dots, it will be found that one or other of the 20 lines of holes will fit these, the figures at the side of the row indicating the gauge of perforation

A stamp which has more than one gauge of perforation is said to be compound perforate, and in classifying such a combination the measurement of the top row of holes is placed first. Thus the current postage stamps of Great Britain will be found to be perf. 15 ly 14 . If the perforation varies on all sides, which seldom happens, the sequence of naming is top, right, bottom, left-that is, the direction of the hands of the clock.

Apart from measurements, therc are a good many kinds of perforation, as well as of roulette, all of which are separately classified by the specialist, but need not concern the general collector. The main diflerence between perforation and roulette is that, whereas the former punches out the holes, the latter merely cuts the paper but does not remove any portion of it.

Mounting the Stamps. Before mounting stamps in an ilbum, any pieces of paper or old hinges adhering to their backs should be carefully removed. This can be done by floating the stamps face upward on tepid water, or by moistening between damp shicets of clean, white blotting paper, a dry sheet heing laid out ready to receive them, face lownward on removing them from the water: Stamps printed in aniline inks should not be inmersed in water, nor should those on enamelled or challsurfaced papers, which would quickly sulter if damped. Stamps should not be kept in a very warm place, as they are apt to curl up.

In the early days of the hobby it was the practice to fasten unused stamps into all album by means of their own original gum, and 10 gum or paste on the used ones. This has robbed the world of specimens which would have been well-nigh priceless to-day had they been mounted by the method now in usc. The modern method is as follows: Take one of the special hinges referred to a bove, fold back about $\frac{1}{4}$ in. of one end, gum side outward, lay the stamp face downward, slightly moisten the turned back portion of the hinge, and fix it to the back of the stamp just below the top edge. Then moisten the other
fold of the mount and attach it to the album in the place chosen for it. Do not use stamp edging or ordinary gunmed paper for the purpose, as this will probably ruin the stamps.
l'eelable mounts are easily obtainable, the advantage of these being that they can be readily renoved from the stamp or the album, or both, without damage 10 either. It should be borne in mind that occaaion may arise, from time to time, to examinc the back of the stamp as well as the front, and the use of the special hinges makes this a simple matter. There is no need to wet the mount all over; a mere touch on both the folds is sufficient to make it adhere safely and to simplify its instant removal when required.

In mounting or unmounting, sorting or classifying, always use the twcezers; there is never any necessity for the collector to touch his stamps with his fingers.

Arrangement and Annotation. If using a printed album, the stamps should be arranged in catalogue order, that is, chronologically, spaces being left for specimens which it is hoped to acquire later, If a blank album is used, due regard should be had to the artistic arrangement of the collection. Single slamps look well when arranged in straight, horizontal rows, varying in length in order to obviate monotony, as shown in p. 1202.

The stamps should be equidistant one from the other. This is facilitated by the faint ruled squares of the blank album pages. Each row should have the tops of the stamps level. Where blocks, pairs or strips are being mounted, a different plan must be adoptcd. A block of four or more look best at the top.

Completing the Album. Whether the colJection is a general or specialized one, the pages of a blank album should be embellished by brief, neatly written, historical notes appertaining to the various issues displayed, showing the date of their appearance, the artist responsible for their designs, the engravers, printers, mode of production, kind of paper, water-mark and perforation, if any, and any other relcvant. notes of special interest. "Writing up" is an art in itself, and in highly specialized collections it may be elaborated considerably.

In such collections each issue, perhaps even one value of an issue, occupies several pages of the album, illustrating various stages of its career, shades, varieties, etc., a nd including examples of original sketches, essays, proofs and colour trials, and so forth. Used copies should not be mounted on the same page as unused ones, and separate pages should be reserved for those on entire, i.e. the original letter.

As a safeguard against damage by friction 1 ransparent envelopes, made of mica, may be had from many stamp dealers. These envelopes are as clear as glass, and atd to, rather than detract from, the beauty of an artistically arranged album page. They are made in various sizes, for the accommodation of a single stamp, small or large, a pair

Enlarged reproduction of penny red stamp of 1858-1879, showing plate number 177 at sides. This plate is journals, one to keep him least to date stamp the philatelic news of the day, and the other as an aid to the extension of his scientilic knowledgc. In any event, a current catalogue should be his constant companion.
Advanced Specialization. Specialization may be extreme, that is, calling for every possible variety in all colours, shades, papers and perforations, or it may be modest, in which the very minor trivialities are rejected.
It is open to every specialist to introduce individuality into his collection, and this is often done by the process of "graingerizing," in which the collection is enriched by a variety of evidential matter and extensive notes such as postal decrees, originals of and essays for stamp designs, etc. The practically unlimited scope of the hobby is one of its chief charms. Plating, that is, reconstructing a sheet of engraved or lithographed stamps in the form in which it was originally issued, is the most advanced phase.

A knowledge of the various processes involved in the production of stamps is very desirable: indeed it is essential if the hobby is to be pursued on scientific lines. Gencrally speaking, stamps are produced cither by line engraving (intaglio), lithography or surface printing, the last-named being by far the most commonly used. When the philatelist has mastered the rudiments and technicalities of his hobby, it should be comparatively easy for him to separate line-engraved stamps from lithographed or surface printed specimens.

A Useful Test. The following is submitted as a test for determining an engraved stamp. Take a thin sheet of tinfoil and place it over the stamp.

Standard Lamp. Fig. 1. Floor lamp fitted for gas. The supply is obtained from the plug point in the skirting through the flexible metal tubing. Fig. 2. Handsome standard lamp of gilded wood fitted for electric light.
The carved decoration is of eastern design
provided with a solid, well-balanced base. Ahout 5 ft .6 in . is a good average height.
(has standard lamps with flexible metallic tube connexions are ohtainable in good designs. An example is shown in Fig. 1 of a wooden floor standard with a fringed and dome-shaped silk shade. The wood is painted with brush cellulose lacquer picked out with silver metallic paint. Placed in the position indicated in the illustration there is little likulihood of a sudden pull on the lamp by anyone tripping over the flexible connexion.
Electric floor standards may be either severely plain in construction or highly decorated like the example seen in Fig. 2, a handsome gilded wooden lamp carved in an Eastern design and carrying a bcautiful shade correspondingly ornamental. Equally beautiful lamps can be decorated in lacquer work.
l'olished wooden standards in oak, walnut, or mahogany either suggest enlarged wooden candlesticks with twisted, fluted or baluster stems and heavy round or square bases, or are frankly modern in design, with base and sten formed of cubes, or of oval and square shapes combined. Metal is often utilized, either oxidized brass or copper, chromium steel or untarnishable white metal, or older styles are reproduced in iron work. See Bent Iron Work; Lacquer Work; Lampshade.
STANDARD ROSE. There are three types of roses usually included under this heading, the half-standard, standard, and weeping standard. They are budded on the common wild briar or dog rose, or on the Japanese briar (Rosa rugosa); the latter is being used increasingly as a stock for standurd roses. The stem of the half-standard is about 2 ft . high, that of the standard 4 ft ., and of the weeping standard from 5 to 7 ft . high. Ranıbling and climbing roses are used to form weeping standards, and tea roses do exceptionally well as half standards.. See Rose; Rose Garden : Stock.

STANLEY PLANE. This is a combina tion plane extensively used by practical workmen, and it has many differ rent uses. It is sup). plied with a large number of cutters. By using tho various parts and adjustments, the plane can be used for rebating, ploughing grooves, beading, reeding, and fluting, for rounds and hollows, for making all shapes of moulding, for matching, chamfering, sash and dado, as a fillister, and a slitting cutter. See Plane.
STAPELIA. Possessed of quaint, fleshy flowers, which emit a strong, disagreeable odour, the stapelia, in its native halitat in S . Africa, attracts carrion Hies, hence its alternative name of carrion tlower. The stapelia is suitable for culture in the greenhouse, the species grandiflora, shown in the illustration, being probably the finest. It should he potted in sandy loam.
STAPRYLEA. This is a hardy summer-leafing and Howoring shrub, from 4 ft . to 10 ft . in height. Staphyleas are suitable for sunny borders or shrubberies, in any ordinary soil. The flowers are white and are borne early in summer. The best is S. colchica, an early Howering sort, which may also

Stapelia. Curiously shaped flower of this greenhouse plant, sometimes known as the carrion flower

Staphylea. White blooms and pointed leaves of
bc forced for greenhouse purposes. Propagation is by cuttings in autumn.
STAPLE. This name is applied to a U. shaped fastening device. Another application is to the loop shaped fastener used in conjunction with a hasp and padlock. The small staples in common use, which are known as nctting staples, are made of tinned or galvanized iron wire, and may be purchased for household use in tho form of packets rontaining about a gross. Various sizes are available, ranging from $\frac{1}{2} \mathrm{in}$. to $1 \frac{1}{4}$ in. long. The gauge of wire generally employed in their manufacture is No. 17 to No. 14.

A stronger lind is the fencing staple used for attaching wires to fence poles. These staples are generally from 1 in. to 2 in . long, and are made from bright wire of No. 10 to No. 6 gauge. Very strong staples are made with a pair of long thin points. Usually a thick gauge of wire is used, and such staples are handy for attaching a chain to a wall. Flectric or telephone staples are made from llat wire,
and when protected by a thin piece of fibre are know $n$ as insulating staples. See Gate; Latch; Padlock.

STARCH. Laundry starch is made from potatoes or, in better qualities, from rice. The potatoes are pulped and water run over them to carry off the starch, which is then washed and dried. Rice is treated with caustic soda to burst the starch cells, and when the starch is freed it is washed, dried and ground, washed again with soda, and finaily with clean water. Starch is in soluble in
cold water. It inmproves the appearance of certain fabrics by making them smooth surfaced, the better to resist dirt, and stiff to avoid a limp, untidy look. It is used with hot water for muslins, linens and cotton materials which require slight stiffening, and with cold water for collars, cuffs and shirt fronts which are to be hervily starched. For the former purpose $\frac{1}{2}$ teaspoonful of borax and a few shreds of wax are added to 2 tablespoonfuls of starch, which has first been smoothly mixed to liquid form with cold water, and boiling water is stirred in untilthe starch and other ingredients become semi-transparent. If boiling water is added to dry starch the result is lumpy.

For cold water starch 1 teaspoonful of borax is dissolved in a little boiling water and added to 2 tablespoonfuls of starch, already mixed with cold water, and a few drops of turpentinc. The last named improves the gloss and the iron runs more smoothly on the fabric. The mixture is strained. left for a few hours and well stirred before it is used.

In laundry work the process of starching follows blucing. The strength of starch varies with the article and its reçuired stiffness. For laces, muslins and cottons, boiling water starch is used of about equal parts of the made starch and water. For slight glazing rather than stiffening, about l part of starch to 15 parts of water is required and for table linen about 1 to 8. Cretonnes and coloured prints should be starched in equal quantities of starch and cold water used to dreserve the colour. A slighter stiffening for lace or muslin can be obtained by using water in which rice has been nooked. .

Collars and cuffs are steeped in cold water starch, and then it is well worked into the fabric, wrung out and rubbed from the surface.

Staple. Left to right : Type for the support of straps around a box ; strong wire staple with finely pointed ends ; lencing staple for attaching wire to poles

The articles are rolled in a clean cloth and left for about an hour before being ironed; they are then spread wrong side up on the ironing sheet and any loose starch is removed before a hot iron is passed lightly on the wrong side to set the starch. When starching a shirt, the starch must be well rubbed into the front, neckband and cuffs, while care is taken not to starch the body of the shirt, which should be ironed first.

Medicinal Uses. As a food starch belongs to the group known as carbohydrates. Its value lies in the fact that it is easily converted into a readily digestible form of sugar. The starchy foods are digested by the ferments contained in the saliva and in the pancreatic and intestinal juices. Any sfarchy food should be cooked thoroughly to swell and rupture the granules and should be well chewed.

In medicine starch is largely employed as a basis for dusting powders and insufflations. Mucilage of starch is also employed to suspend insoluble oils or powders. For inflamed skin surfaces the following powder is suitable: Zinc oxide powder, 1 dram; boracic acid powder. 1 dram ; starch powder, 1 oz . To be thoroughly mixed. The powder should be placed in a cardboard or metal box, over the mouth of which a piece of gauze is stretched as a dredger.
The making of a starch poultice is described under the heading Eczema. See Diet; Food; Ironing; Laundry.

STAR OF BETHLEHEM. This is the result in the handle being pulled out of the popular name of a spring thowering hardy bulb operator's hand
(Ornithogalum umbellatum). It shovid be It is a dance
(Ornithogalum umbellatum). It shouild be It is a dangerous practice to attempt to revolve the starting handle barrel-organ fashion, unless one is abnormally strong or the engine is easily turned over on compression. Unless the speed is fairly high, there is always the likelihood of a backife, and should this occur during the down stroke of the handle the consequences might be very scrious.
As all inodern cars are equipped with some form of self-starter, the starting handle is detachable and is carried on the car as a unit of the tool lit. This frequently means that the self-starter is employed as the starting medium for the engine from cold, which is a bad practice. The proper method is first to give the engine a few turns by hand, before switchplanted in autumn, will thrive in shady places ing on, thus overcoming the resistance caused and bears greenish white Howers. Other kinds by the cold oil and allowing a charge of gas to bloom in summer and should be planted in enter the cylinders. Then the starting motor sandy loany soil in autumn in a sumn place. Some of the best are nutans, greyish green; pramidale, white: and pyrenaicum, greenish yellow. Thicse bulbs may also be potted in autumn for spring Howering in the greenhouse.
STARTER: For the Motor Car. With all types of internal combustion engine some form of starting device is required to transinit the initial novement to the crankshaft. In motor car design the starting handle is litted for this purpose. It consists of a cranked handle, with about a 10 in . leverage, nounted below the radiator in front of the car, and engages with a short extension of the engine crankshaft. A compression spring liecps the starting handle normally out of engagement as shown at A in Fig. $]$
There are three points to bear in mind when using the starting handle. The first is to sec that the ignition is not too far advanced. The second is to let the handle lie snugly in the hand, as at $B$ in the illustration; the third point is to sec that all the control levers are corrcetly set and the petrol turned on.

On no account should the startin! handle be gripped tightly with the thumb, over the top, as shown at C. T'o hold the handle incorrestly is 10 courl disaster should the engine baclifire. A brohen wrist or a dislocated ellow is an acicident by no means unlikely to occur.
Befure switching on the ignition, revolve the engine three or four times slowly. Switch on the ignition, engage the starting handle. and turn it slowly until the compression is felt just hefore bottom dead centre is reached. Then swing the handle past the bottom dead contre and finish with a very smart pull up. If the engine fails to start. engage the handle again and repeat the process. The greatest effort should be applied during the pull-up period only, because should a buckfire occur it will only

Starter Fip. 1. A, principle of design: and $B$ and $C$, right and wrong ways of holding the handle

Electric Starters. These are of two main types. In the first the apparatus serves a dual purpose, functioning as a dynamo to generate current for the batteries, or as a motor to supply the initial impetus to the engine for starting, current being taken from the batteries in the latter case. In the second type of apparatus, shown in Figs. 2 and :3, an independent starting molor is used and brought into engagement with the crankshaft when necessary.

The type of starter motor that is a combination of charging dynamo and motor is called a dynamotor. The unit is permanently driven off the engine crankshaft or somewhere else in the engine line, usually by silent chain gear, and is controlled by two switches, charging and starting. With the charging switch on, the unit works as an ordinary dynamo, but with the charging switch off and the starter switch on, the unit becomes a starter motor, thus rotating the crankshaft. A very notable advantage of the dynamotor is silence in operation.

Of the independent starter motor little need be said. Current is supplied from the accumulators to the windings of the armature, thus causing it to rotate. The chief point of interest lics with the automatic means by which the pinion mounted on the armature is caused to engage and disengage itself with the toothed ring on the llywheel of the engine. This is carried out as follows : Cut on an extension of the armature shaft is a quickpitch square thread, on which the pinion is loosely screwed, and retained when out of use at a definite position against a coiled spring. When the armature is caused to rotate, the pinion, being a free menber, is drawn along the threaded portion of the shaft. thus bringing it into
engagement w'th the toothed ring of the flywheel. The duration of time between the commencement of rotation of the armature and that of the pinion is just sufficient to cause the pinion to screw itself along the shaft far enough to engage the teeth of the toothed ring. The moment this occurs, the pinion by being held stationary, is readily drawn into full engagement.

To disengage the pinion the order is reversed Current is switched off from the armature. causing it to stop, and the toothed ring on the rotating Hywheel, now being turned by the engine, drives the pinion, thus unscretving it off the armature shaft and out of engagement. Owing to the large gear reduction that must be used to avoid the necessity of employing a big, heavy starter motor, the pinion is thrown out of engagement with considerable force, and brought to rest without damage by the buffer spring.

With the ordinary electric starter motor the rapid acceleration causes considerable noise as the pinion teeth come into engagement. Moreover, the fu!l power is applied on the teeth before they are right home. To overcome these drawbacks some types of starter motor effect the engagement of the pinion before it is causer to revoive, or while it is rotating slowly, the full current being switched on by a further movement of the control.

Faults with
 electric starters are very rare, and for this reason the carbon brushes, the commutator, and the varions connexions ale liable to be

Starter. Fig. 2. Typical method of mounting an electric starter motor. Fig. 3. Showing quickpitch screw, pinion and buffer spring
Courlesty of C. A., Vandervell dit Co . L/d., and of
neglected. All these should be looked to occasionally and kept perfectly clean. What is of most importance is to see that the carbon brushes are clean and working freely, and that the commutator is perfectly smooth and free from any deposit of carbon and oil. A breakdown from any other cause in the nıajority of cases will be a job to be dealt with by the makers or an experienced man.
Starting Difficulties. Although, when the engine is warm, there is no harnı in $\breve{a}$ limited use of the starter, such is by no means the case when starting from cold, because the gummy nature of the oil renders the engine very stiff, thus calling for considerable effort from the starter motor to turn the crankshalt at a sufficient speed. First of all, before switching on, revolve the crankshaft by means of the starting handle. A few turns, given slowly, will very considerably reduce the amount of current drawn from the accumulators during the starting process. If this precaution is not taken, it is probable that the efficiency of the accumulators will sutfer Serions daınge, such as a buckling' of the plates and loosening of
the paste from the grids, can of ten be traced to inconsiderate use of the starter
Should the engine be properly warmed up and yet refuse to start, do not persist in the use of the starter, but make sure all is in order, petrol turned on, ignition switched on, carburetter flooding properly, and extra air shutter closed, if one is in use

Trouble experienced in starting the engine in cold weather is generally attributable to faulty carburation, assuming of course that the ignition is in order and that there is nothing wrong with the engine mechanically

The proper grade of lubricating oil recommended for winter use should be employed, the sump being emptied of the summer grade and recharged on the approach of cold weather. Other likely sources of trouble are neorrect tappet clearances, worn valve stems or guides, and anything producing an air leakage into the induction system. Thus a leakage may be brought about by wear on the throttle valve bearings. The sequence of tests given in the fault-finding chart in page 812 should be carried out.

When starting from cold the throttle should first be opened a little more than is necded with a warm engine If, however, the carburetter is fooded to access and the engine raced, the surplus petrol washes away the oil film from th- piston, cylinder walls, and other parts, and impoverishes the oil supply by dilution. When the engine starts from cold the oil, owing to its viscosity and the resistance it offers to movement, is not circulating properly, so that the working parts are almost dry. It is not until the oil gets warmed up that it can reach and effectively lubricate the different parts of the engine. It is cleap, therefore, that for the first few minutes at least the engine should be run slowly, until it warms up. See Carburetter ; Motor Car: Tappet; Valve.

Starwort. This is another name for the Michaelmas daisy (q.v.) or perennial aster.

Statics. See Atmospherics: Valve.
Statys. Name sometimes used for the plant popularly known as the sea lavender (q.v.).

STEAK: How to Cook. The term steak usually implies beefsteak, but in a general sense it may be applied to any thick slice of fish or meat. Beefsteak, which is boneless, is cut from the best parts of the animal, and includes rump steak, fillet steak, buttock steak. For grilling the steak should be of the finest quality.

The largest steaks are cut from the round, but are less likely to be well Havoured and tender; therefore they are best stewed in a casserole. Fillet or tender loin steaks are from the undercut of a sirloin.

A steak which looks like a large chop, about $1 \frac{3}{4} \mathrm{in}$. thick, taken from a sirloin of
beef with an undercut, is known as a Porter house steak. It should be Hattened with a cutlet bat, trimmed, brushed over with melted butter, and seasoncd with pepper, and then allowed to stand for half an hour before being grilled over a clear firc. The grilling should take about 15 min .
Rump Steak. This is a thick slice cut from a large three-cornered joint of beef known as the rump. The latter is that portion which lies behind the sirloin at the end of the back and reaches a short way down the leg in a slanting direction. It is seldom cooked whole, being usually cut into small joints.

Rump steaks are generally grilled, but may also be included in meat pics and puddings. For grilling, they should be at least $1 \frac{1}{2}$ in. thick. The middle and end cuts are best.
Stewing is a popular method of cooking steak. The directions given for stewed beef under the heading Beef should be followed.
Steak is also cxcellent when minced, made into rissoles, or, with the addition of kidney, into a beef stcak pudding.

Grilled Steak. Stcak à la Française provides a good dish, but before the stcak is grilled the garnish of carrots should be prepared. To do this, scrape and wash a carrot, cut it into small squares, and cover it in a pan of boiling salted water until it is tender. Then strain off the water, melt 1 oz . butter in a saucepan, and toss the carrot in it.
Split 1 lb . thick fillet steak into 2 or 3 slices, each about $\frac{3}{4} \mathrm{in}$. in thickness. Make the slices into neat rounds, trimming off the fat, Hatten them with a cutlet bat or a large knife, sprinkle them with pepper and salt, and pour over half teaspoonful of salad oil and 2 teaspoonfuls of vinegar. Let them soak for about 15 min . Press 1 oz . butter out on a plate, work into it $1 \frac{1}{2}$ teaspoonfuls chopped parsley, and 2 teaspoonfuls chutney, cut into small dice and leave in a cool place.

Grill the steak for about 10 min ., turning it frequently, and at the same time grill some of the fat that was trimmed off, first cutting it into small rounds. Arrange the fillets down the centre of a hot dish, with some of the grilled fat between each, and garnish them with small heaps of carrot and a few dice of the prepared butter.

A simpler way of grilling a rump or fillet steak about $1 \frac{1}{2} \mathrm{in}$. thick is first to trim it and beat it a little to make it more tender; then rub each side with a little butter. Grill it on a well-heated gridiron, allowing 5 min . to each side of the steak; then turn it again and give it 5 min . more. Put a small pat of maitre d'hôtel butter on the top, just before serving. Scrve it garnished with small baked tomatoes or a little watercress.
Beef steak is less digestible when fried, though this particular method of cooking is
often more convenient than grilling. To fry, heat a little butter in a frying-pan so that the bottom is just covercd, and put the steak in this, frying both sides as rapidly as possible. When brown, continue the cooking more slowly, and turn the meat frequently. Serve the steak either with a little butter spread over the surface, or with gravy. Jried onions, cut into rings and cooked in butter or dripping, are a favourite accompaniment. See Beef; Becf Stcak Pudding : Casserole : Diet : Food; Mince.
STEAK AND KIDNEY PIE. To make this very popular dish, take $1 \frac{1}{2} \mathrm{lb}$. buttock steak or topside of bcef, also about $\frac{3}{4} \mathrm{lb}$. bullock's kidney. Remove any skin from the meat and cut the lean into neat slices about $\frac{1}{3} \mathrm{in}$. thick; cut the fat into dice and lay on one side. Trim the kidney, removing skin and hard part, and cut into neat pieces. Mix on a plate some pepper, salt. and flour, dip each slice of steak into this, and roll it up with a portion of kidney inside. Arrange these pieces in a pie-dish and scatter over them a chopped shallot and parsley, also add the pieces of fat. Almost fill the dish with water or stock, and then cover with a rich short crust rolled thick. Make a hole in the centre of the lid to allow the stcam to escape, brush over with egg, and bake from $1 \frac{1}{2}$ to 2 hours in a good oven. See Pastry.
STEAMER : For Cooking. The most satisfactory way of steaming food is to cook it in a patent steam cooker, but if this is not available, a plate placed on top of a pan of boiling water, or a double cooker, such as that used for porridge making, can be utilized instead. Steamed puddings are usually cooked in a basin or mould placed in enough boiling water to reach about two-thirds of the way up the sides.

A special steam cooker is obtainable in which a pudding can be mixed and cooked at once without a pudding cloth. Fruit can be cooked in this way without water and thus the juices are retained.

Another sniall steamer which is on the market is divided in half by an adjustable compartment so that two vcgetables can be cooked in it at once. The compartment can be removed should it be desired only to stcam one vegetable or other article of food.
Steamers can be bought in several sizes, but for family use the larger kinds with three or four containers are the best. The lowest container holds boiling water, and from it a pipe conveys stcam to the vessels above. The stcam can be regulated by means of a controlling valvc. The strongest steamers are of tinned sheet steel with copper bottoms, but cheaper kinds can be had in aluminium. The illustration shows an electric steamer in which four dishes can be cooked at once. Steamers are cspecially useful in flats and small houses, since a whole dinner can be cooked over one pan of boiling water. See Pressure Cooker.
STEEL: Grades and Uses. Made from iron in a variety of ways, steel is used in many forms in the house, and it is employed in nearly every craft. Stcel is classified into three grades, mild, medium and hard, depending on the amount of carbon, which varies from 0.15 per cent to 1.5 per cent. It is made by melting the iron, driving from it by various processes its contained carbon and impurities, and then adding pure carbon. The softer steel contains less carbon than the harder varieties.

Soft steel is used for the manufacture of articles requiring a ductile metal, which may be beaten or pressed to a desired shape ; medium steel for constructional purposes where comparative hardness is required ; hard steel is employed for all cutting tools, for fire irons, and every purpose where great strength is needed. Chrome steel contains a
sinall percentage of chromium ; it is intensely hard and is used for safes. Nickel stcel contains a small percentage of nickel, which renders it very ductile. Manganesc steel, containing a large parcentage of manganesc and carbon, is very hard but ductile, and cannot be softened by heat.

Steel can be hardened by heating it to a red heat in a clear fire, and then dipping it into cold water or oil. Steel is tempered loy first hardening it and then polishing the surface quite bright with emery cloth. It is then heated up again until it assumes a certain colour and again cooled. Methods of hardening and tempering are fully dealt with in the articles Case Hardening and Hardening.
The difference between iron and steel is not readily apparent without some knowleclge of their propertics. The easiest test is to drop the metal on a stone floor. Cast iron has a dull, dead sound; wrought iron has a higher tone and a dull ring. Mild stecl is similar, but it has a slightly higher tone. Tool steel has a much higher tone and a well-toned ring, and the harder the sted the higher the tonc. The best tool or high speed steel cannot be filed, and ordinary carbon stecl is not in any way affected by the file when it has been hardened

The difference between mild steel and wrought iron can be seen if a strip is bent over on itself and hammered; the steel will not breali, but the iron will. If fractured, the grain of wrought iron is of a fibrous nature, the outside being of a dull black with a reddish scale. Cast iron has a dull grey granular appearance. Mild steel is somewhat granular in appearance, but it is a greyish white intermixed with bright sparkling grains. The outside is brightish black in colour. Tool steel is similar in appearance, but the grain is finer and the outside is a bright blue black.

Oil and soapy water are used as a lubricant in turning or shaping steel, and also to prevent the cutting edges of lathe tools from getting too hot; the lubricant is also used when cutting threads by hand.
Stainless Steel. Containing a percentage of chromium, this is used not only for table catlery, but for many purposes where a hard cutting cdge is not required. Saucepans and other kitchen utensils, dish covers, trays, hot-water jugs, spoons and forks are all ohtainable in chromium steel, while excellent use is made of this stainless metal for door furniture and bathroom fittings. Tungsten stecl is hard, and is employed for metal cutting tools. Mild stecl can be hardencd by the process known as case hardening, which leaves a hard outer surface with a soft interior. See Brazing; Forge: Hardening: Labour Saving; Lathe; Metal Turning; Metal Work.
STEEL: For Sharpening. This name is given to an instrument used for sharpening knives, especially carving knives. A stcel is usually sold with carving knife and fork, the handles and finishings being alike. See Carving.

## Steering Gear on Motor Vehicles Principles of Operation and Method of Handling

Other articles that deal with allied subjects will be found under the headings Differential Gear ; Front Axle; Gear; Live Axle. Sec also Motor Car; Motoring

From the joint of safety, apart from the brakes, the steering gear is the most important mechanical part of a motor vehicle, and the primciple of its operation should be thoroughly understood.
There are two classes of steering gear, namely the adjustable and the lixed. The former ter:n denotes that the stecring wheel is adjustable for height, usually carried out by mounting the stcering hox on a swivelling bracket. The locking device consists of either a quadrant plate with nut and washer or a elip lug. With the lixed type steering, a specially shaped bracket is cast as a part of the steering box and bolted to the chassis side member.

In the majority of cases the steering gear is designed on the irreversible principle, which means that, although the front whecls may be casily turned by the steering wheel, a reversal of movement from the wheels to the stcering wheel is not possible. In actual practice this is only carried out up to a point, and n most cases, if considerable effort is applied against the front wheels, the stcering wheel is caused to rotate. This is as it should be, other wise the castor action of the wheels that tends to straighten out the course of the car after a turn has been made would be lost; also the slightest movement of the steering wheel would definitely deflect the car's direction.

Apart from stcering gear design the castor action of the front wheels is of great importance to easy steering, as it tends towards kecping the car on a straight course. Castor action is provided by cither setting the stub axle bchind the centre of the steering head, or by very slightly canting the stcering head backwards. The result is to bring the projected point of contact of the stcering head slightly in advance of the wheel's point of contact with the ground, as shown in Fig. l.

For the 4 -wheel motor vehicle the stecring gear lay-out is commonly on the Ackermann principle, shown in F'igs. 1 and 2, a rigid axle being litted with a swivelling stcering head at each end. These heads carry the stub axtes on which the wheels revolve, and are connceted to each other by a track rod, usually adjustable for length. The stecring wheel controls the movement of the stecring hearls via the steering box and tho steering arin. Movement of the steering arm must be

Fig. 1. Diagrammatic lay-out of the Ackermann steering Rear. On the left two methods of suppling casto action for the front wheels
provided for in all directions. Therefore ball and socket joints are always litted, and in the case of stcering heads that are set outward at the bottom, i.c. are not parallel to each other, it is necessary to employ some form of universal joint at each end of the track iod as well.

Owing to the fact that when the car is turning through part of a circle the outside whecl will be moving through a larger radius than the inside wheel, it is necessary to set the steering arms so that the correct angle is given to each whecl at all points between their limit of movement. This is carried out by setting the steering arms so that their ends cross imaginary lines drawn from the centre of the stcering heads approximatcly to the centre of the back axle, as shown by the dotted lines in Fig. 1. The same rule applies whether the steering arms are fitted in front or are fitted behind the axle.
The steering box is very strongly constructed, as the whole of the road shocki imparted to the wheels have to be withstood by this unit. Fig. 3 shows the type in common use. It consists of a worm, mounted on the end of the stecring column, that engages a worm wheel on the shaft on which is mounted the drop arm. The latter, by means of the stcering arm, controls the direction of the wheels. Reference to the diagram shown in Fig. 2 will make this clear.

Although some makers still fit a worm segment, it is common practice to fit a full wheel as shown. As wear takes place the whee can be turned a quarter revolution, thus bringing fresh teeth into engagement, it being understood that only one quarter of the worm wheel is ever engaged for a full movement of the stecring gear. Plain bearings are cm ployed for the worm, and single thrust bearings at each end, the latter lieing adjustable to take the load.

The screw and nut type of gear is characterised by simplicity of construction and saving of weight. A screw on the lower end of the stecring column worlis in a nut. the latter engaging two levers attached to the operating shaft. As the nut moves along the screw the shaft oscillates and so operates the drop arm fastened to its outer end

In the cam type of steering gear the specially cut worm engages and moves a pin set in the end of a short arm commected to the operating

Steering Gear Fig. 2. General arrangement of steering mechanism on the Ackermann principle. Fig. 3. Worm gear employing complete worm wheel. Fig. 4. Another type of gear in which the worm on the steering column swingsa rotating ring mounted on an arm fastened to the operating shaft
shaft and thus to the drop arm. causing the latter to oscillate in accordance with the movement of the steering wheel. Another type is shown in Fig. 4 Here the worm on the steering columm engages and swings a rotating ring mounted on the forked end of an arm fastened to the operating shaft. In order that the ring throughout its swing shall be properly engaged by the worm, the diameter of the latter increases towards its ends.
Care of the Steering Gear. A periodical overhaul should be given to all parts of the steering mechanism. It cannot be too much emphasized that all the hearings must receive regular and sulficient lubrication. The steering box and its attachinents should be looked to tirst in the case of noticeable slackness, because it may be found that the fixings have worked slack owing to vibration and shocks transmitted from the wheels. The ball joints connecting the drag link to drop arm and steering head respectively should be examined, as they are equally affected by any strains imposed The joints should be well packed with greasc and the same applies to the joints connecting track rod and steering levers. The track rod can be adjusted if it becomes necessary to correct the

## Stencilling and its Possibilities

A Decorative Medium Affording Scope for Originality
This article belongs to a group that describes various ornamental handicrafts. Others are Lacquer Work; Painting on Textile Fabrics; Pattern Printing; Pokcrwork; Raffia Work. See also Fricze; Lampshade : Lettering; Monogram; Screen

A stencil is a plate made either of metal or cardboard on which a design has been traced and cut out for the purpose of transferring it to linen, cloth, or other material. The transfer is accomplished by brushing over the stencil with oils, water-colours, waterproof inks, or stain
Almost any material can be stencilled. The best fabrics are probably casement cloth. velvet, satin, Arras cloth, and hessian Chiffon muslin, and similar thin fabrics can be treated successfully, but they must be stippled and not rubbed Glass, china, wood, leather, imitation vellum, and cardboard all lend themselves to stencilling. The process is also employed in house decoration for friezes and panels, and other forms of ornament The outfit required consists simply of the colours and brushes together with a piece of plate glass or marble for cutting plates, oiled manilla papcr, a stencil knife, and a drawing board or table. Any good oil-colours may be used, but there are special stencil watercolours, and liquid oil-colours are sold in small bottles. No medium is required with watercolours, but for cils a stencilling medium is used Inexpensive outfits are obtainable in any good art department.

When working in reveral colours on a oneplate stencil, it is advisable to use a piece of blotting paper or oiled manilla to cover up the design where the colour is not to go. This is called masking 'The piece of paper is moved about to form a screen as the work proceeds. In doing very large quantities of any design
P-

a plate is generally cut for each colour, as one can work quicker, but for ordinary use a small mask is sufficient.

A separate brush should be liept for each colour, if possible. In working, the brush should be of a size suita ble to the design that is to be transferred. If it is too small it makes the surface streaky, while too large a brush is apt to cover more of the design than is desired, and to necessitate masking. In Fig. I, a boghair brush, a knife, and (lowest) a Japanese stencil brush are illustrated. Before using a new brush soak it in cold water After the work is finished clean the brushes with a little turpentine on a rag and then wash them with soap and water.
Cutting a Stencil Plate. Many people prefer to buy stencil plates, but it is not dilficult to cut out the designs at home, and in this way original work can be designed or attractive patterns copied. The beginner should choose a simple design first If a copy is desircd. make a tracing or rubbing of the design on a suitable piece of oiled manilla, which is the best paper for the purpose. leaving at least 1 in margin al! round for small things, and 2 or 3 in for large plates, or finely cut ones.
Place the plate on a piece of martle nr glass, and, holding a well-sharpened stencil knife at an angle of about $45^{\circ}$, cut out the clesign, working from the weak part of the plate towasds the stout (Fig. 2). Never cut towards any part of the work if there is risk of breaking the ties, which are the portions of the plate left in to hold the clesign together.

In cutting a flower the centre should be cut out first, then the petals cut from the centre outwards. Always cut the side of the petal next to the one already cut. Do not cut the opposite side and then attempt to cut the petal after both sides are weakened. When a corner is eached, cut across it both ways, so that the piece comes out ; never pull the pieces out, as this will make the edges
alinement of the wheels. Instructions for ensuring proper alinement and lints on the correction of steering effects are given in parathe article on Motor Car, P. 814

Wheel wobble is a condition in which the wheels get into a state of side to side vibration; in shimmy, another similar trouble, rapid vibrations are set up in the steering gear. and so transmitted to the driver's hands. Wheel wobble occurs at fairly low speeds whercas shimmy arises when the car is travelling at high speed. Both conditions are a source of danger, as even a small dellection of the wheels from the straight-ahead position may bring about a disaster when running at high or even moderate speed
The cause of the troubles mentioned is obscure. Attention should be directed to lubrication and alinement, and any excessive slackness in the mechanism must be corrected. In some cases the fitting of a steering dampcr, which introduces a certain amount of frictional resistance to the movement, will afford a remedy. Wheel wobble can sonnctimes be stopped temporarily by a sharp turn of the stopped ten
hand wheel ed is rou flower round and round, gradually working in this way until all the petals are coloured in

The prettiest effects in stencilling are ohtained by working one colour over the other For leaves, use yellow on the tips, green from the base, and draw the two together with a little brown, blue, or red according to the leaf that is being coloured. When stencilling on a woven fabric is finished, allow it to dry, then place a slightly damp cloth on the right side, and iron on the wrong side of the material. Remove the cloth and press well. This is only necessary for lixing the coiours. and need not be done otherwise

Velvet nust not be ironed. If necessary, cover the iron with a damp cloth, and pull the velvet over it. When working on a dark material it is necessary to kill it first, otherwise light colours will not show on it. It is possible to remove colour from the background with a preparation called Jarello. The design is stencilled in the ordinary way, with this and then put aside and washed. 'The design will then be bleached and pale colours may be stencilled on top of it For a malerial which is unwashable. paint the whole design in white or a very pale shade of the colour to be used. When this foundation tint is dry, the stencilling is done over it in the ordinary way.

When stencilling on thin materials, do not work up and down, but stipple and gently pat the designs, holding the brush upright. as in Fig. 4. Use blotting paper underncath, and work with the brush as dry as possible. Lift the matcrial off the blotting paper now and again, and it may be found that most of the colour is on the blotting paper, and very little left on the fabric. This usually means that the brush is either too wet or too hard. A Japanese brush, such as that illustrated, is best for very thin materials.

Stencilling on China. When stencilling on china, place the vase, bowl, or other article in a large pan of cold water, and the latter must be brought slowly to the boil. This process serves not only to temper the china and
render it less likely to break, but also removes In working stencils on any stains that might disfigure the result. curtains or covers the Once the water has boiled, talic the pan from corners must always be the fire and leave the china in it until it is cold : taken into account. If then dry it thoroughly, and, in order to guard possiblo work all the against the possihility of a greasy surface, corners first, and then wipe it with a rag dipped in methylated spirit. The presence of grease will not only make the application of colour very difficult, but will also affect its permanency.
In working round any curved article it will be found necessary to snip the stencil plate top and bottom. Use the brush very dry and the colours sufficiently thick to prevent any white patches from showing throingh. Stippling is the best method, as the plate is difficult to fix and will be inclined to slip. When the design is finished, take off the plate, and with a clean rag wipe off any surplus colour. Begin drying the worls in the arrange the centres of the sides. The other way is to place the centre of a design in the exact centre of one side and then arrange the corner. Never work up to a corner or the centre without find ing out whether the plate will fit. If not, it will be necessary to find some portion of the design which can be repeated to fill in oren, and when it almost dry hold it in stencil work for a the steam of a fast-boiling kettle This fixes the colours so that washing does not affect them

When stencilling on glass use oil tube colours with quick drying medium or special coloure for painting on glass (see pages 53!, 540). The article to be decorated must be polished with methylated spirit to remove all grease. Hard surfaces such as wood, metal, china, or glass re. quire a dry brush as all the colour remains on the surface Wood stnins may be used for stencilling unpainted wooden articles. When finished and dry. the work may be varnished or wax-polished

Florescan Stencilling. A very attractive form of stencilling which resembles the Florentine work of the 17th century is known as Florescan stencilling. Handsome cushions, and has a matt appearance when tinished medallion in the corner

Stencilling. Fig. 2. When cutting a stencil, hold the plate firmly with the left band, which should be above the knite to avoid any rigk of cutting the band should the knife slip

Courlestl ol Winsor \& Newton

Hanters, fans, curtains, etc., can be made by curtain is seen in Fig. 5 . In this particular stencilling suitable designs on velvet, satin, case the corner was stencilled firstand made to leather, suede, gauze, or georgette. Florescan lie well inside the hem. The latter may bc colours are sold in tubes and used with a used as a guide, provided that the edges of the medium. If required to wash or when paint- stencil-plate are true The use of a skirting on leather, the washable medium must be board is an advantage, because it allows a used. Japnnese brushes shonld be employed good deal of the curtain to be pinned down at Stencilling Curtains, Casement cloth for once. Stencil up the whole length of one short curtains takes the colours very well, side and along the bottom, arranging tbe

To get the best resulta the stencilling sloould be done before the top is gathered. The material will then lie fintter, and can be more easily ironed Any colour scheme can be used so long as it tones with the room in which the curtaine are to be hung. As soon as the stencilling is finished, cover it with a slightly damp cloth and iron first on the right side and then on the wrong side. This makes the curtains washable, and also fixes the colours. Thick stencil. ling should be avoided, for thin material hangs badly if much colour is used.

Decorating Cork Mats. Cork table mats may be successfully stencilled. The three examples shown in

Fig. 3 (below). Showing the correct way to hold the brash lor stencilling. with oil colour on thick material. Fig. 4 (ahove). When stencilling on thin materials use a Japanese stencil brush and stipple the colour Courlasy ol Winsor \& Newton
-

Stencilling. Fig. 8. Three stencilled designs on cork mats for table use Colouring should match the dinner service Courtes॥ of Winsor \& Aewton
stencil plates should be cleaned as soon after use as possible. Rub them with a piece of paper or rag, then clean them with turpentine. Hang them up to dry. or lay them between piects of newspaper.

STENODE. This is a system of wireless rcception for obtaining an extremely high degrec of selectivity. Use is made of the superheterodyne principle and the intermediate amplifying stages are sharply tuned to provide a degree of selectivity sufficient to separate stations working $4 \frac{1}{2}$ kilocycles apart.
In one version of the Stcnode a "crystal gate " is employed, the output from the intermediate amplifice being passed through a piezo-quartz crystal, a device which will not respond to frequencies more than a few hundred cycles above or below its natural frequency of vibration. This method enables an even greater degrec of station separation to be obtained.
The output from the second detector of the Stenode gives a preponderance of low notes the high notes being weak. A corrected lowfrequency magnifier is, therefore, usell to restore the balance of tonc, the corrector circuit being so designed that its amplification increases with the frequency. See Superheterodyne.

STEPHANOTIS. The hothouse evergieen climbing plant called stephanotis hears fragrant and beautiful white flowers nearly all the year round. Steplan not is can be growil in pots, or it may be planted out in a well-drained hed consisting of turfy loam, one-third cach of decayed manure and peat, and sand.
Very little water is needed in winter. An average temperature of ahout $70^{\circ}$ is the most suitablc. Weak growths should be thinned out from time to time. A limited number of strong, thinly-disposed shoots are best. Propagation is by cuttings of the previous year's shoots in the propagator in spring. See illus above.
STEP LADDER. The difference between a step ladder, often referred to as a pair of steps, and an ordinary ladder is that in the former the feet rest upon Hat pieces of wood, or treads, and in the latter upon rounded ones, or rungs. Another difference is that the step ladder is made in two pieces, a front and a back, which are hinged together so that when opened out it will

Step Ladder tor nousenold purposes, proviaed with a trey for a bucket, etc. He treads all flat automatically when the ladder is closed, as shown on the right Courtesy of J. H. Healhman \& Co.. Ltd.
especially if it has not been very well made or has been left outdoors exposed to the weather. The joints may become loose, the ropes may rot, and the hinges get rusty and breali. Frequently, too, the top step is knocked off or loosened.

To repair a laslder that has reached the state described the steps should be extra nailed with

Stephanotis. The rragrant watte nowers of an evergreen greenhouse climber. See article below
$2 \frac{1}{2} \mathrm{in}$. oval wire nails, and, if possible, gluc should be run into the trenched joints. There will usually be roon for two new nails at each joint. The heads should be punched down and the holes filled up with putty. The top step should also be extra nailed, as should the hack hinged board. Care should be taken when nailing into the elge or straight grain of top and bottom. Chain is preferable to rope, when nailing into the elge or straight grain of
as it is not liable to stretch and lasts longer. the wood, which is likely to split ; holes should as it is not liable to stretch and make sure that the legs are firmly
placed on the ground before it is make sure that the legs are firmly
placed on the ground before it is ascended. Now and again the rope
that connects front and back ascended. Now and again the rope
that connects front and back should be examined, as this may become frayed and so give way.

Repairing a Ladder. The step ladder occasionally needs repair, *
 when they are put vidual steps will fold up hand pole at the top. Some are double, having steps on both sides, while others have a special platform on which a bucket may stand while cleaning operations are in progress. Other steps, again, are so made that the worker can sit thereon in comfort.

The steps most commonly used are those with a hinged back and rope stays. They are made of deal, and are obtainable at a low price. When purchasing, it is advisable to exanainc the woorl, particularly in the treads, to see that the grain is fairly straight and free from large knots. The treads shoulll be set well in the knots. The treads slould be set well in the
sides, and if possible provided with iron bolts first be pierced with a bit. If one of the treads is damaged, it can be rencwed without disturbing the others. Saw the old tread in two places with a tenon saw well away from the nails, and then pull the end portions away from the groove. Tap the points of the nails and withdraw them with pincers. The new tread should be planed up from a piece of straight grained sound wood, and cut to the exact length between the two grooves. The groove and the ends of the tread should be coated with glue, and the piece pushed into its placc. In nailing, use new positions on the outer piece.

The mortise and tenon joints of the back strut frame should, if loose, be reglued and wedged. If the tenons are broken it is best to make a new rail. A less satisfactory way is to glue the pieces together and fix a new rail across both joints with glue and line nails on the outside. The hinges can be replaced by a new pair. The rope should be of strong window sash cord, and care should be taken that it is the correct length to give the right spread to the ladder, making it stand firm and level on the floor. The knots should be on the outer side of the wood. A step ladder should be painted to keep it in good condition. See Ladder.

## Steps as a Garden Feature

## Viewed from both Practical and Ornamental Standpoints

The construction of a flight of steps is by no means a diificult task for the amateur worker. For
further information he should consult the articles on the various materials, e.g. Brick; Cement;
Concrete; $S$ one. See also Crazy Paving; Garden; Path; Paving; Pier; Rock Garden
Where the garden slopes gently a very bricks used. Commonly, the dimensions for pleasing arrangenient of steps, as illustrated in measuring purposes can be taken as 9 in . Iong, Fig. 1, can be adopted, which combines the $4 \frac{1}{2}$ in. wide, and 3 in. thick. When the plan has function of a path and that of a llight of steps. been settled satisfactorily the ground shoult! The whole is constructed of crazy paving, and be marked out with pegs and lines, and a the steps arc comparatively low and the trench excavated on cach side to reccive the breadth considerable. Fig. 2 shows a method foundations for the wing walls. The excavauseful in small garclens and positions where tion need not be carried down beyond the there is a drop from the garden level to that point at which the ground is tirm and solid, of the ground floor or sub-basement. The so long as a depth of about 4 in . of concrete steps here illustrated are made partly with crazy paving, but the nosing or edge of the treads is finished with hewn flagstonc.
When it is possible to use rough-hewn stone of the type generally known as rubble masonry, a very handsome type of steps can he constructed somewhat as shown in Fig. 3. Retaining walls are built at the sides, and the steps are formed of roughly hewn llagstones set in rough masonry and emberlded in cement mortar on foundations of broken brick.

Flight of Brick Steps. Fig. 4 shows a flight of six steps with brick wing walls and brick piers. The path from the top step to the doorstep is laid with brick. The doorstep is llanked on cither side by low piers of brickwork, those at the entrance being topped with capping stones.
The difference in level between the approach to the house and the carriage drive is 27 in . This height or its equivalent on any other job has to be divided between any number of steps that can conveniently be built with bricks, plus the difference in level duc to the fall of the path. In this case a fall of 2 in . is allowed from the door to the uppermost step. Each of the five treads of the steps has a fall of $1 . \mathrm{in}$. the five brick courses of bricks set on erlge are cach $4 \frac{1}{2} \mathrm{in}$. high, thus making up the required total, namely 27 in.

When details of this kind have been settled for any particular job a drawing of the steps should be worked out, such as that shown in Fig. 4. taking particular care to dimension the courses properly. according to the number of
best be achicred, by the amateur worker, in first preparing the foundations for the lower part of the wall at a reasonable level, placing a couple of briclis on end on the concrete, and laying in a bed of concrete to the level of the top of the top brick. This forms the stepped foundation, the height of the step being proportional to the height of the bricks, thus avoiding much cutting and making up with mortar.

Care should be taken to plumb up the piers and the walls as the work proceceds, and to drive up the bricks by tapping them with the end of the trowel. The second step should then be laid with bricks as before, well embedding them in cement mortar. The ground between the wa!ls is cleared away leve!, some hard core rammed into it, and the foundations for the next step made by filling in with concrete to placerl on another foundation of broken brick or stone. A trench sliould be dug to reccive the foundations for the bottom step This should also be filled with concrete and roughly levelled off with a shovel, as in Fig. 5.
The first proceeding is to lay a bed of mortar on the foundations for the front step and the two entrance piers, and commence by laying three courses of bricks at each pier. The bricks which are to form the step are embedded in mortar and should exactly fill the space between the two piers; ihey should fit tightly and mav be driven home with the handle of a heavy haminer, as in Fig. 6. Six nore courses of bricks are set on cach of the piers, and the side walls built up. These may be laid in the ordinary Flemish bond, the arrangement the level of the previous step, as is visible in of the bricks by this method being clearly shown Fig. 8. The work then proceeds in a similar in Fig. 7, where the headers and stretchers manner as before, ly laying another step in are clearly distinguished. The worker should brickwork, giving the bricks a gradual fall to refer to the article Brick for further details of ensure that water does not lic on them, and the method of bonding.

It should be noted that as the normal surface of the ground rises, the trench, with the levelled concrete in it for the foundations of the side walls, need not be kept in one main level, but may be stepped up. This result can

Fig. 3. showing tae cnarm of a đugat or shallow steps made of hag stone and rubble masonry flanked by retaining walls

Steps. Fig. 1. Picturesque effect achieved by the use of crazy paving for a path which rises rradually in shallow steps. Fig. 2. Steps connecting different levels in a small garden ; they are of crazy paving finished on the edges of the treads with hewn flagstone

Steys. Fig. 4. Sectional view showing method of construction of a flight of six steps with brick wing walls and brick piers
body e.g. the noise produced by broath. ing and by the action of the heart. In disease these sounds are modified or added to, each change having a diagnostic significance.

## STEW. A stew

 can lie made with either becf mutton, or veal as the main ingredient, and lirections for making such be set on the side walls as shown in Fig. 9. This stews will be found under the respective gives a tinish to the work. headings. The ingredients needed for a The last remaining steps are then !aid, and mixed stew are $\frac{1}{2} \mathrm{ll}$. becf kidnev, $\frac{1}{2} \mathrm{lb}$. pork if the work has been properly done the top (not too fat), $\frac{1}{2} \mathrm{lb}$. mutton, $1 \frac{1}{2} 1 \mathrm{w}$. veal, $1 \frac{1}{2} \mathrm{lb}$. Hight of steps will be exactly the same level potatocs, $1 \frac{1}{2} \mathrm{lb}$. onions, and ! lb . carrots. as the top of the hender course on the two side Green peas might be userl instead of thecovered vesse!, generally with very little alded liquor. By this method tough portions of meat are rendored catable, and very little heat is reguired to maintain the proper tomperature after the food has been boiled. Nonc of the juices of the meat are lost, and the fool can be kept hot without deteriorating.
A stewpan, a casserole, or an earthenware jar may be used, and it is placed in the oven or on the top of the stove. Before starting the slow process, meat to be stewed must be well boilen up, or it will soir. A stew is nearly always thickened, and meat stews should be made with fresh, not cooked, meat. The stew may be white, as in the case of Irish stew, or brown, as in stewed ox-tail or skirt of beef. Vegetables are usually stewed and served with meat. Fish may also be stewed; trout or eels make excellent stews.
Stewed Fruit. Stone fruits are much more digestible when stewed, and if served with some accompaniment of a milliy nature they are less likely to disagrec with children or those persons whose digestions are weak or impaired. For this reason it is the custom to serve cream or custard with stewed or cooked fruit, and sometimes milky puddings or blanemange. One advantage of strwing fruit consists in being able to cook any that is not actually ripe or is in the green stage. Gooselurries, for instance, when quite unripe, are excellent for stewing, hut are not fit for this purpose
walls. This result is only accom. plished by the constant checking of the level between the two side walls, by resting a batten across them aud then testing with a spirit level.

The brick path is laid in the usual way, two smal! piers built by tho doorstep, and the entrance picrs completed in readiness for the capstones. These can lie obtained from a mason's yard, or may be moulded in concrete.

STERILIZATION. The process of making certain substances free from germs of all kinds is usually called sterilization. A large number of different methods are used, the choice depending in any case on the materials of which an ohject is composed and also upon
 the uses to which it is to be put, etc.

One of the simplest means is to raise the carrots when in season. material to a high temperature at which no The vegetables are first germ life can exist. For example, the hoiling sliced and the meat cut of milk is the most thorough and reliab!e up into neat picces, method of destroying any germs which may then all should be put be contained in it. Pasteurising is a useful in layers, in a stewpan. method which will destroy almost all the germs vigetables making up likely to be found in milk. It has an alvantage both top and botton, over boiling in that it has a less marked effect layers. Season plention the taste of the milk. The process consists fully with salt and of raising the milk to a temperature of $145^{\circ}$ to $150^{\circ}$ and keeping it there for not less than half an hour. See Antiseptic; Bottling; Disinfectant; Milk; Pasteurisation.

STERNBERGLA. These hardy bulbs hear yellow, crocus-like Howers. They are suitable for planting in sunny places in the rock garden or at the foot of a house wa!l. The winter daffoclil, or lily of the field (lutea), which blooms in September, should be planted in July, and Fischeriana, which is in Hower in April, ought to be planted in October.

STETHOSCOPE. An instrument known by the name of stethoscope is used by doctors for listening to sounds producel within the in slow boiling in a

STEWING: In Cookery. One of the most economical methods of cooking is wing, which consists
 How side walls are bonded together. Fig. 8. First two steps completed. Fig. 9. Heading course set on side wall and steps nearing completion
when ripe. Certain kinds of plums stew well, also apples and a hard sort of pear

The simplest method for stewing fruit is to put it in a stewpan with sugar and a little water, and cook it gently over the fire or in the oven until it is quite soft, and the sugar and water have thickened. The fruit must be in sound condition; before stewing it should be picked over, and all damaged portions rejected, then it should be rinsed with cold water in a colander.
The amount of sugar necessary is about the same quantity that would be required for making the fruit into a pie. Fruit must always be amply sweetened while cooking, as no amount of sugar alded afterwards will arail to remove the tart taste. The quantity of water to be added also varies with the kind of fruit ; for very juicy fruits the drippings of water after washing should create sufficient liquor for the stew.

A secondmethod is to prepare a syrup, and, after heating it to boiling point, drain the fruit until no moisture is left, and turn it carefully into the syrup. About 1 gill syrup should be enough for each lb. fruit, and it must be strong, as it will be thinned considerably when the juice boils out of the fruit. Cook all until the fruit is tender, shaking the pan occasionally to prevent the contents from burning. The heat employed must only be moderate.

Another method is to lay cach piece separately in the stewpan in a single layer, pour a strong syrup over it, and cook gently on top of stove or in oven until soft. Each portion or whole fruit will then be found entire, and can be properly arranged in a dish. The syrup when cool should be ladled over and round.

Rhubarb, if possible, should be treated by this method, and will make a superior dish, especially if a little syrup from a jar of preserved ginger is added while stewing. Strawberries are not suitable for stewing by any mothod, although they may be heated and softened in syrup for the purpose of filling tartlets and flans. The same applies to oranges, all pips and pith heing removed, and also to fresh pincapples and bananas, and tinned fruits, such as cherries, peaches, pears, etc. One dessertspoonful of lemon juice should be added to the syrup made with a 2 lb . tin of peaches or apricots. Many varietics of dried fruit are excellent when stewed, and full directions arc given in page 391.

Stewpans. Except for size, stewpans are in most instances identical with ordinary saucepans, and in the avcrage household the latter are used as substitutes. Pans used for stewing should have tightly fitting lids and the power to retain heat. Casseroles and other earthenware utensils have this latter property, and are therefore specially well adapted to this method of cookery.

Tinned copper, tinned irou, and enamel pans are also excellent for stewing, but care should be taken to see that the lining of copper pans is undamaged, otherwise poisoning may result. Double saucepans, such as those used in making porridge, are also suited to stewing, for they minimize the danger of burning. See Beef; Casserole; Dried Fruit; Pressure Cooker; Saucepan; Steamer.

## Sticking Plaster. See Adhesive Plaster.

STIFF NECK. Muscular rheumatism, or fibrositis, may result in a stiff nech. It is more common among children than adults. Generally the stiffness is confined to one side, the muscles in front and at the side of the neck being most often affected. Persons subject to this painful affection should take the greatest possible care to avoid draughts and exposure to cold.
Usually the only treatment required is the rubling in of some warning, stimulating liniment, and then covering warmly with a pad of cotton wool to prevent chilling. The
following are two prescriptions for liniments that are suitable for external use in cases of stiff neck:

## See Fibrositis; Rheumatism.

STIFFNESS: Of Muscles. The painful stiffness in over-used muscles may be removed by a hot bath and sufficient massage; stiffness remaining after a night's rest is generally dissipated by brisk exercise.
Painful stiffness is a feature of muscular rhcumatism or fibrositis, and here, also, heat and massage are good remedies. Stiffness and rigidity of the muscles of the abdominal wall are found when there is underlying inllanimatory mischief, as, for cxample, appendicitis. See Fibrositis; Massage.
STILE : In Carpentry. This is the term used for the outer upright pieces of a frame into which the rails are tenoned. In cabinet and other double doors, the two inner stiles arc known as meeting stiles, and the meeting edges are cither rebated or one stile provided with a projecting beading to cover the space. See Cabinet Making; Door.
STILETTO : For Needlework. This is a small, sharp-pointed instrument used for piercing eyelet-holes. Stilettos can be bought cheaply from all art needlework shops. Carc should be taken to keep them free from rust. See Eyelct.

STILL BIRTH. When a child is born dead the occurrence is spoken of as a still birth. It is important to remember that still births, as well as others, must be notified to the medical officer of health within 36 hours in districts where the Notification of Births Act has been adopted.

Sometimes a child is born very pale or blue in the face, making no attempt to breathe or move, but with the heart beating faintly. The nurse should sprinkle the child's face and chest with cold water; this stimulates it to breathe. If that does not succeed, she should raise the child by its heels and tap its body smartly. Should this be unsuccessful, artificial respiration sliould immediately be practised.
STILL ROOM. In large houses there is often a housekeeper's pantry or still room, as it is called. Though apart in its uses from the butler's pantry, it is furnished in much the same way with cupboards, shelves, and sink, and there is usually a gas stove or range and large kitchen or cook's table. Where a great deal of confectionery is made in the house a special still room maid often assists in this branch of cookery.

STILTON CHEESE. In the true stilton the milk with which it is marle is enriched by a certain proportion of creain, alded when making the curd. The cream is first scalded by a small quantity of boiling water being poured upon it. The best season for making stilton is from July to October, giving the cheese time to ripen for Christmas fare. Although the outer crust has a rough, pitted appearance, the interior is milky white with sireaks of dark green.

Stippling. Fig. 1. Stippler for paint. Fig. 2. Larger brush for use with distemper
cheese scoop, and in the hollows which are made wine or ale should be poured. By degrees, if this process is carried out, the cheese will acquire a morc matured flavour, while it will be kept sufficiently moist inside. See Cheese.

STIMULANT. A stimulant means any drug or agent which increases the activity of any organ or tissue; thus there are heart stimulants, brain stimulants, skin stimulants, and so on. Popularly, the word is used for something which invigorates the body, generally alcohol.

As a matter of fact, the stimulating effects of alcohol are transitory, and the main effect is narcotic. Small doses of alcohol, repeated if necessary, ought to be given instead of large ones in the treatment of collapse.

Ammonia is a good general stimulant, and may be given in the form of the aromatic spirit or sal volatile, in doses of a tcaspoonful in a wineglassful of water. Tea and coffee are also good general stimulants.
STING: How to Treat. The poison introduced by an insect sting is usually formic acid. A solution of ammonia is the best remedial application, but solutions of bicarbonate of soda or of potassium permanganate are also useful.

Fresh tobacco ash is a simple remedy for stings. It should be applied to the affected part with moisture to form a paste, and then rubbed in gently.

A few drops of oil of geranium rubbed behind the ears and over the neck and ankles will generally afford protection against the stings of midges and other summer pests. Babies and children should be especially protected, as insect stings are not only painful, but may be dangerous when they occur on the lips or eyelids. If the oil is not rubbed on the skin, it may be used to soak small pads of cotton wool sewn to the clothing

## See Bee Sting.

Stipa. This is the botanical name of the ornamental grass known as feather grass (q.v.).

STIPPLING. A flat effect is obtained with ordinary paint or distemper by the method known as stippling. The stippler used for paint is shown in Fig. 1, and Fig. 2 shows a larger brush for use with distemper. Both are made from hog-hair, and after use should be washed in lukewarm water if used with distemper, or with turpentine in the case of paint.
Stippling should be done while the paint is wet. The methor is to apply the paint or distemper evenly; the direction docs not matter as long as the surface is cvenly covered. The stippler is then dabbed on the wet surface. The surface to he stippled should not be more than 1 sq . yd. at a time. Broken surfaces require considerable care, and it is ofteu necessary to use a small sash tool as a stippler.
It is more difficult to use the stippler in applying a Hatting paint. Only the tips of the hair should be used, and the brush must be kept clean by dipping it from time to time in turpentine and cleaning it on a piece of paper. Care should be taken not to drag the stippler over the surface, but to apply it with the hairs at right angles to the surface, and with a light touch. See Brush; Paint.

STIRRUP. Steel or nickel-plated stirrups are a necessary part of the rider's equipment, though not essential when learning the rudiments of horsemanship.

The use of stirrups is to assist balance and to form a support. Some riders drive their feet right home into the stirrups, but the
disadvantage of doing this is counterbalanced by a lighter grip with the sole about its middle. The adjustment of stirrup leathers is always a matter of prime importance. If they are too long the rider does not get the requisite support, and sore back may result. The best method is for the rider to sit in the saddle and test the length by putting his feet into the stirrups.
There is another use for the stirrup, and that is the left stirrup iron serves to receive the left foot during mounting, aided by the grip of the hands of the pommel and cantle of the saddle.
Cleaning Stirrups and stirrup leathers require clcaning after use : the former with metal polish and the latter with saddle soap. As the leathers are liable to perish with use it is necessary to examine them frequently, and replace worn portions. See Horse.

## STITCH: In Needlework. Of the

 various kinds of stitches used in necdlework, running is cmployed for gathering, and also for joining materials, and hemming for turning down raw edges, while tacking, whichis a temporary stitch, holds the fabric in position while the permanent stitches are put in. There are also fancy stitches, such as cross-stitch and herringboning, which are employed for decorative purposes. See Appliqué ; Basting: Cross Stitch; Dressmaking. Embroidery ; Feather Stitch; Hem ; Hemstitch; Herring-bone; Laill Work; Necdlework: Overcasting : Running ; Scam : Sewing Machine ; Smocking ; Tapestry Needlework.

STITCH: In the Side. The sharp, stabling pain felt sometimes at the side of the chest, and popularly referred to as a stitch in the side, may result from running or any violent exertion after a meal, or from prolonged laughing, coughing, or sneezing. It may be due in these cases to a cramp-like spasm of muscle fibres in the midriff or the chest wall. and no treatment is neccssary, as the pain passes off almost at once on resting.
Sometimes, however, this form of pain is a symptom of a broken ril), or lobar pneumonia, of pleurisy or of some disorder of the liver. The application of a hot bag is a useful temporary nieasure.

## Stock for Soups and Sauces

## Recipes tor Clear. White, Bone and Vegetable Varieties

## This article is in close connexion with those in Sauce and Soup. See also Beef; Bouquet

 Garni; Gravy; Mutton; Veal, etc.The foundation of most soups, sauces, and Mutton is difficult to clear on account of its also of gravies used for made up dishes is stock. Impoverished stock will make a very poor soup, and no added Havour of vegetables or herbs will successfully disguise its original weakness.
Scraps of food, trimmings of meat and boncs, which would otherwise be thrown away, can be added to the stockpot and turned into useful material. Almost any oddment provided that it is suitable to augment or clear the stock, may lie added from time to time. Egg-shells assist in clearing the liquor, and even hard crusts have their use in helping the scum to rise. Stock requires careful skimming when it boils up and whenever scum collects.
The more continuously the stocl: is allowed to sinmer the better and richer it will be, but it is advisable to strain it out at night into an earthenware pan to prevent souring, especially in summer. Vegetables, particularly turnips, if left in the stockpot are liable to sour the liquor. Potatoes should not be put into the stockpot Meat bones can be loiled again for a second and third stock, but vegetables should not be used a second time. Stock should not be left in the larder after the second day without being boiled up, and in stormy weather it should be boiled daily. A thundery condition of the atmosphere is alone sullicient to spoil the stock entirely.

If fresh meat is added to the pot, skimming must take place as soon as the scum rises, for if the scum is allowed to boil down in the liquor it will be impossible to clear it properly, and a thick and cloudy appearance will result. Never place a pan of liot stoc! on a slate or stone slab, or it will cool too rapidly ; if obliged to set it away hot, place under the pan 2 or 3 pieces of wood to support it.

Chickens, rabbits, or meat intended to be served as a boiled dish may be cooked in the stockpot and will add to the strength of the stock, and they will be flavoured and enriched by it. Chickens should be wrapped in buttered paper or a loose cloth, which will prevent sediment or small pieces clinging to them.
lish stock is made from lish or the bones and trimmings of fish. boiled with or without vegetables. A recipe is given in the general article on Fish.

First Stock. Clear soup is always mhde from first stock. This is composed of fresh meat or bones and flavoured with vegetables.
allowy fat, and pork is too fat for any stock Beef, veal, calf's head, ox-tail and ox-cheek make the best. lirst stock. Vegetable and bone atocks can also tie used, but must be carefu!ly strained, and clarilied with white of egg if necessary. Peppercorns should be used for first stock, as ground pepper would make it cloudy. The salt should be added to the water when cold, as it helps the scum to rise, and care should be taken to remove the scum just as the stock is on the point, of boiling. to prevent it sinking into the liquor. Before the vegetables are added all scum must be removed, and the vegetables should te put in by degrees to prevent dropping the temperature of the etock too suddenly. Never add marrow bones to stock intended for clear soup, as marrow fat cannot be entirely skimmed away
There is no occasion for concern if stock made principally with beef docs not make a strong jelly. For clear soup a meaty flavoured stnck is more nocessary than one which is very gelatinous, and the meaty stock will be bright as well as clear.

White Stock. White stock for white soups and sauces is always made with white meats. Knuckle of veal, carcasses of chicken, or an old hen are the most usual meats for this purpose. The llesh of the hen need nol be wasted, as it can be worked up into some side dish.
The ingredients for a good white stock are a knuckle of veal weighing about $2 \mathrm{lb} ., \frac{1}{4} \mathrm{lb}$.

stock pot maye in atunimum. The tap ahow, the liquid to be drawn oft quickiy after the stock has been heated up
lean ham, 2 onions, 2 sticks celery or $\frac{1}{4}$ tea spoonfu! celery salt. $\frac{1}{2}$ turnip, 18 peppercorns, 1 blade mace bunch of herbs, 4 in . lemon tind, 2 teaspoonfuls salt, 3 quarts water

Chop bones and meat small and put into stockpot with sal! and cold water bring to boiling point, skim carefully, then boil for three hours, skimming frequently. Add vegetables, carefully cleaned and peeled and chopped small, together with the flavourings, and simmer for two hours. Strain through a hair sieve, and remove fat when cold Use bones and meat for second and third stock.

Brown Stock. For this use 2 lb . shin beef, 1 lb knuckle of veal, \& lb raw ham, 1 oz. dripping, I teaspoonful salt, " onions, $\frac{1}{2}$ turnip, 2 sticts celery. or $\frac{1}{4}$ teaspoontul celery salt, a bouquet garni, 2 quarts water.

Put prepared meat and !ones in the stoclipot with cold water and salt. bring slowly to the boil, being careful to remove all scuin in the process. Simmer. gently for threc hours. Slice onions tinely and fry in the dripping until brown. Drain well, add to stock with remainder of ingredients and simmer for two hours. Strain through a hair sieve and remove all fat when cold. Reserve meat and bones for second and third stock.

Bone Stock. A good recipe for bone stock requires the following ingredients: 4 lb . raw or cooked bones, 1 carrot, 2 onions, $\}$ of a large turnip, 2 stalks celery or $\frac{1}{4}$ teasponnful celery salt, $1 \frac{1}{2}$ teaspoonfuls salt, bouquet garni, 3 quarts water

Chop bones small, place in stockpot with cold water and salt and bring to boiling point, skimming carefully all the time Boil for threc hours, skimming frequently. Clean and cut up vegetables, and add to stock with the herbs, boil gently for 3 hours, then strain. Remove fat when cold.

Vegetable Stock. Vegetable stock is made from mixed vegetables. To 1 quart water allow 1 lb . mixed vegetables. Carrots, turnips and onions are the most used, and, if liked, celery, tomato, leek, and a little parsley can also be added. Four peppercorns are used for seasoning, and 1 or 2 cloves can also be aclded. The vegetables are washed and cut into small pieces, and then fried gently in about 2 oz . fat for about 15 min . in a covered pan. The water, herbs, and a sprinkling of salt and the peppercorns are added to the vegetables, and the whole brought to the boil. The stock is then left 10 sinmer for about 2 hours in a covered pan and straincd. Variety can be given to any of these stocks by the addition of other vegetables, sma! $p^{i}$ ece of cooked meat. poultry, game, or macaroni, vermicelli boiled rice, sago, or semolina

Vegetarian stock is sometimes made by boiling bran with water for $1 \frac{1}{2}$ hours. then straining off the liquor and letting it settle. Oatmeal also is used for this purpose.
Straining Stock. When straining stock remember that pressure should not be resorted to if the stock is desired to be clear. The liquor should be allowed to drain until all is through. then the sieve is lifted off with the solid portions. By straining liquid stock it can be rendered free from grease, although it is usually more difficult to clear this stock from fat than that which is in a jelly. When perfectly cold pass the stock through a hair sieve or piece of muslin stratched over a basin, after removing solid fat with a broad flat knife. The hair or material will effectually retain any particles of fat, but the stock must be rea!ly cold; if merely lukewarm the fat will be liquid enough to pass through very fine meshes. Jellied stock may be cleared by the fat being taken off in a cake and the top washed with warm water.
Stockpot Any pan or vessel reserved for the preparation of stock may he described as a stockpot. In the home, a large saucepan is
generally reserved for this purpose. but pots specially designed for stock-making can also be bought in a variety of metals. Some of the larger kinds are fitted with taps. An example is illustrated in the opposite page, which is made in alumin. ium. When its contents have been heated, the tap allows the stock to be drawn off quickly.

Unless the stock. pot is of earthenware, stock should never be allowed to remain in it overnight, neither should it be left standing at the side of the fire for an indefinite time. Stockpots should be scoured and dried thoroughly immediately after they have been in use.
STOCK : The Flower. The stock is a delightful fragrant garden flower of which there are several types. By cultivating a suitable selection the plants will supply flowers during the greater part of the year. Ten week stocks are raised from seeds sown under glass in March, the seedlings being planted out of doors in May; they bloom in summer and autumn, and bear flowers in many beautiful colours. The Brompton stock is grown as a biennial, seeds being sown in June to provide plants that will flower early the following summer. If the garden soil is clayey and becomes sodden in winter it is wise to pot the plants in autumn, keep them in a frame and plant out in spring.

Intermediate stocks raised from seeds in summer are very useful for greenhouse decoration in spring. If raised in a warm greenhouse in January they will bloom out of doors in late summer and early autumn. The East Lothian is a favourite strain of the Intermediate stock. Winter flowering stocks are splendid plants for the greenhouse. Seeds are sown in a frame in August. The secdlings are potted in small pots and subsequently into others 5 or 6 in . wide and brought into a slightly heated greenhouse in autumn.

Stock. Queen stock, a bushy variety with white, crimson or purple ${ }^{\text {flowers }}$

Stock Cultivation. 1. Seedlings sown in box ready for transplanting. 2. Suitable transplanting. 3. Brompton stocks sown in pot $: a$, drainage; $b$, braken turves : $c$, fine rich soil 4. tood type of seedling potted in small pots. 5. Type of seedling which often produces single flowers. 6. Plants pushed on in frame : $a$, ashes ; $b$, decayed manure or leaf-soil: $c$, ordinary soil ; $d$, fne rich loam: $e$, block for ventilating

Favourite varieties are Christmas Pink, Beauty of Nice, All the Year Round, and Empress Elizabeth. The night-scented stock (Mathiola bicornis) is a hardy annual raised from seeds sown out of doors in April ; the
flowers are very fragrant in the evening. See Night-Scented Stock.

STOCK : For Trees. The named varieties of fruits and roses are invariably budded or grafted on stocks, i.e. closely related trees or shrubs. Well developed trees are obtained more quickly in this way and in some cases the growth of the tree is controlled by the stock. For instance, standard apple trees are budded on the crab stock; they come slowly to maturity, but eventually form large trees. Apples budded on the broad-leaved paradise stock make less vigorous growth and bear fruits earlier. Thus the choice of stock on which a tree is budded is one of importance.

Similarly, pear trees on the pear stock grow more vigorously and come to fruit bearing later than others on the quince stock. Those whose gardens are restricted in size should plant apple trees budded on the broad-leaved paradise or other dwarfing stock and pear trees on the quince stock. Rose trees are budded chiefly on wild briar and the Japanese briar. The first named is considered the best for dwarf or bush roses, and is also used for standard roses, but, owing to the difficulty of obtaining suitable briar stems, the Japanese briar, Rosa rugosa, is now often used instead. Stocks for roses and fruit trees are raised by nurserymen or imported annually in large numbers. They are planted in autumn and budded the following summer.
As stocks for plums, the most popular are the Mussel, the Brompton, the St. Julien. For the cherry the most popular stocks are the

## Stocks and Dies for Screw Cutting

## How to Form External and Internal Threads on Metal

This contrib ttion explains the method of cutting an external screw threal by the use of a die, and also the tappin: of holes. The mechanical process of screw cutting in the lathe is dealt with in an earlier artic.e on Screw Cuting. See also Lathe; Metal Turnirg; Screw Plate
In choosing stocks for serewing purposes adjusted to cut to the desired diameter. Screw the first consideration should be the nature it on to a clean piece of metal that has already of the work. For small diameter screws, a been threaded to the proper size, then adjust stock for use with circular dies is suitable. the die until it is stiff to move by hand. Such a stock would measure about 8 in. in For steel set the dies a shade closer, and for length, and contain a circular socket or aperture for the small size die measuring $\frac{1}{1}{ }^{3} \mathrm{in}$ in. diameter. This is suitable for screwing in brass up to $\frac{3}{8} \mathrm{in}$. diameter or thereabouts. and rather less on steel
For work from about $\frac{1}{4} \mathrm{in}$. to $\frac{1}{2} \mathrm{in}$. diameter one of the engineer's type of stocks should be used, with a pair of adjustable (two-part) dies. For gas-fitting purposes, larger stocks employing separate dies are generally used.
External Threads. The function of a screwing die being to cut a screw thread upon the outside of a circular piece of metal, the interior of the die is fashioned in the form of the screw thread. Parts of the diameter are cut or ground away to form a cutting edge, and the threads themselves are ground away at the front or entering edge, to facilitate starting the screw thread.

Most circular dies have a small set screw which, when screwed in, expands the die slightly and thus increases its effective diameter. Two-part dies are adjusted for diameter by means of a set screw or screws in the body of the die stock. It is important that the die be

Stocks and Dies. Fig. 1. Small circular die stock used in cutting a screw thread. Fig. 2. Adjustable circular dies. Fig. 3. How large die in atock is employed for screwing gas barrel
 on the tap, cutting away portions of thescrew thread. The shape of the
flutes is designed so that one of its walls forms a cutting edge. The opposite end of the tap is usually left plain, and finished with a square-shaped portion. The tap is turned by a lever or bar, known as a tap wrench, which may consist of a piece of metal with a square hole through it of a size to lit the square on the tap. A more convenient pattern is adjustable, having a pinching screw which clamps the shank of the tap.
The cutting part of the tap is shaped in various ways apart from the ordinary fluting. A set of taps for any particular size includes a taper, second, and plug or bottoining tap. In the case of the taper tap the screw thread portion is ground away for about ${ }_{3}$ of the length of the screwed part, so that it becomes tapered. In the second tap the tapering is restricted to a very slight amount at the end,

| 1 | 27/32 | $2{ }^{2}$ | 3 9/39 | 10 | 53-55 |

the bulk of the screwed portion being of full diameter. In the plug, or bottoming tap, no part of the thread is ground off.

Before the hole can be tapped it must bo drilled out to a certain size, dependent upon that of the screw thread which is to be formed within it. Suppose, for instance, the screw which is to be inserted into the tapped hole is $f$ in. diameter. The hole will then have to be drilled out about $I^{3}$ in diameter. The correct size of drill to use is most quickly determined with the aid of a drill and tapping gauge, an instrument consisting of a metal plate with a series of numbered holes through it. The hole marked $\frac{1}{4} \mathrm{in}$. (tapping size) will actually measure less than $\frac{1}{4}$ in., and denotes the correct size of drill to employ to prepare the tapping.
Gauges are generally based on the assumption that the Whitworth system of screw
hole, or by jamming it on the bottom of the hoie. When tapping iron or steel the tap should be well lubricated with light machine oil.

It is important that the tap should be rotated about its own centre line; if allowed to swing from side to side in even the slightest. degree the hole or the threaded portion will be enlarged or distorted. Special care is needed when starting the tap.

Whatever size of tap is used. the same method is followed in all cases likely to be met with by the amatcur. It is exceedingly important to use a tap of the correct dianneter and thread form for the screw which is to be fitted into the holc. This, however, presents very little difficulty in practice, as bolts and screws mostly used in the home, for such work as the repair of a stove, mangle. garden implements and the like, are generally screwed on the Whitworth system. Small work, such as that in wireless receiving apparatus, scientific instruments. and the like, is generally screwed on the B.A. system, as regards the small size, up to about $\frac{3}{4}$ in. Larger sizes are often cut in a lathe.

Threads used in the home for screwing iron pipe, either for gas or hot water purposes, are always screwed on one of two systems. Iron pipes are screwed with gas threads, while copper and brass pipes are usually screwed with brass gas threads. Taps and dies for this work are obtainable at most tool shops. The size of the tap wrench varies according to the size of the tap.

As taps can be purchased separately, the anateur will be well advised to buy those needed for any particular job, and gradually accumulate a stock as circumstances necessitate. To prevent them becoming rusty they should be wiped over with a greasy rag.

STOCKFISH. Large fish, such as cod or hake, were at one time extensively cured by being split open and dried in the air until very hard, no salt being used. The fish before being cooked was beaten with sticks in order to soften it. The name is now often applied to salt cod, ling, hake, etc., and is a term of commerce. See Cod; Fish.

STOCKINETTE. A wool or silk knitted fabric of elastic texture, stockinette is employed to make frocks, cardigans, and other sports wear, and underwear.

Stockinette needs the samc care in laundering as other knitted inaterials. No wringing or rubbing should be done, the dirt being removed by squeezing the garment in warm soapy water. It should be pullerl gently into shape while still damp. left to dry on a that surface and ironed with a cool iron. When holes appear in stockinette they should be darned at once, otherwise they will form ladders.

## Stockings of Several Textures

## With Directions for Knitting Two Standard Types

Other articles in this work that describe the variolus items of footwcar include Boorees; Boot; Mocassin; Sock. See also Artificial Silk; Knitting; Silk; Wool

The correct choice of stockings for women and girls depends chiefly on footwear and costume, silk being worn with light shoes and silk and wool, lisle thread or all wool textures being selected for sports or country wear with a heavier type of shoe.

In choosing silk stockings the hand should be run through inside from top to toe to see that the fabric is clear of Haws. Stone rings should be removed before doing this, or they may ladder the silk. Attention should also be paid to the fashioning, whether full or slight, of the leg and the width round the top. A top which is too narrow cuts in an uncomfortable way, and if not full enough the stocking will split or ladder at the back seam. In some makes the heel piece runs up to a
fine point or twin points at the back of the ankle, insuring a better fit.
Stockings of a lighter shade than the shoes worn make the feet appear smaller, but they are not helpful to thick ankles. Very dark brown or gunmetal grey silk stockinge have the most slimming effect. With gold and silver shoes the silk stocking should match as nearly as possible in tone. Grey shoes and stockings should match exactly. Sports stockings for winter wear are smartest when handknit in thick silk or fine wool. Some display patterns of contrasting shade up the leg instead of ribs. Such patterns gencrally have a thickening effect on the ankles.

The usual sizes for women's stockings are $8 \frac{1}{2} \mathrm{in}$. and 9 in . for sizes 3 and 4 in shoes, $9 \frac{1}{2} \mathrm{in}$.
for sizes 5 and 6, and 10 in. for sizes $6 \frac{1}{2}$ and 7. Some people reinforce the toes and hcels of new silk stockings by cutting out pieces of fine mesh of silk veiling to fit the required size and invisibly catching them on the wrong side of the stocking foot. Woollen stockings can be lightly darned in the same places with fine wool of the exact shade before being worn. Hand-knitted stockings can be strengthened by using a finer wool, in addition to that used for the rest of the stocking, linitting the two together for heel and toe.
No stockings can equal in durability those that are made by hand, whether they are knitted with wool, coarse or fine, or with silk. There are many patterns and styles, one of the most popular being the plainest of all.
For closer fit there are the ribbed hose, which are even stronger than the plain, and are specially suitable for sports wear. By way of a standard, a plainly knit stocking has been illustrated and fully described so that when once the making is thoroughly understood others can be modelled in a different style and with slight variations in size.

Plain Knitted Stockings. To make the stocking shown in Fig. 3, 8 oz. of 4 -ply fingering are required and four steel needles, No. 14. Some workers will like to rib the top of the stocking with needles No. 16, as the finer knitting affords a closer grip. The model is planned for wear with suspenders. Should garters be worn, the leg should be about 3 in. longer to allow for rolling over.
The wool must be wound very loosely, 2 or 3 fingers being taken in with every 16 or 18 windings round the ball. A quick knitter will like to have several yards of the wool pulled off the ball at once to lessen the number of unwindings.

For this stocking, cast on 80 , arranging 26 on one needle and 27 stitches on each of the other two needles. Make the welt by knitting 2 and purling 2 alternately all round for 30 rounds.

An excellent and durable top for a stocking to be worn with suspenders takes the form of an ornamental hem. After casting on, knit 11 plain rounds. 12 th round: Make 1 by bringing the wool round the needle, knit 2 together. Work thus all round. Work 11 plain rounds. Take an extra needle and with it pick up the cast-on stitches opposite those on the working needle. Fold the work so that this needle is at the back and those last knitted are in front. Knit a plain round, taking up a stitch from each needle, and work them off together as one stitch. Continue thus all round.
Take care that the stitches are exactly opposite one another, or the hem will be twisted. The 12 th round forms a series of tiny scallops at the edge of the stocking. The 25 th and 26 th rounds are purled. For the 27th round make 1 and knit 2 together all round. Purl the 28th and 29 th rounds.
Now begin the leg. In the next round raise an extra stitch in the middle, and purl this as a seam-stitch in every row till further notice. Knit plain for 80 rounds-that is, as many rounds as there were stitches cast on.
In the next round, begin to decrease to
> knit 2 together, knit the rest of the round plain. Knit 8 rounds without decreasing. Repeat from * 8 times, thus reducing the number of stitches to 63. Knit 63 rounds plain for the ankle, that is, as many rounds as there are stitches on the needles.
> Divide the stitches ready for the heel.

3 stitches of the on to the needle with which the loops up the seam-stitch, ${ }^{*}$ slip l, second edge of the heel-flap are to be picked knit l, and draw the up exactly as before. Knit with this needle slipped stitch over to the centre of the heel where now future it, knit 1, purl the rounds are to be begun. Knit all round to seam-stitch, knit l, get the stitches arranged in their places.

Place 31 stitches on one needle with the seam-stitch in the middle. Put 15 stitches on to each of the remaining 2 needles. Leave these stitches for the present, as later on they will be wanted for the instep. Work in rows backward and forward (purl at the back and knit in front), always slipping the first stitch of a row. When 24 rows are done, decrease exactly as in the leg, and purl back. Repeat this row twice.

Knitting the Heel. The heel is now ready to be worked off thus: Knit to the seam-stitch. knit that and the next together, knit l. Turn, slip 1 . purl 2 together, purl 1. Turn slip 1, knit till the little hole is reached that was made by the decreasing of the preceding row, knit 2 together (the stitches on each side of the hole), knit 1. Return in the same way, purling instead of knitting. Continue thus till all the stitches are worked off.

The following directions make an excellent heel, with rather more spring in it than the former. When the flap is finished, knit to the seamstitch, then purl 1, knit 5, knit 2 together. Turn. Slip 1, purl 11, purl 2 together. * Turn. Slip stitches are left, knit 2 knit 11, knit 2 together. Turn. Sip Sip 1, together, knit l. On the last needle, knit l, 11, purl 2 together. Repeat ${ }^{2}$. , purl slip 1, knit 1, draw the slipped stitch over till all and knit to the end of the needle.

Next, the stitches must be arranged for the instep. Pick up and draw the wool through the double loops that run down the side of the heel flap. After every third stitch increase by knitting and purling 2 in the edge of the work. When all have been picked up, slip 3 stitches on to this needle from the instep pin. Work across, and slip the last 3 stitches

Knit one plain round. Repeat from ** till about 20 stitches remain. Keep 10 of these on the one needle, and slip the other 10 on to a single needle. Close the opening by turning the stocking wrong side out, take the stitches alternately from the 2 needles with the end of wool and a rug.needle. Fasten off by darning the wool on the wrong side. f grafting is preferred, proceed thus with

Stocking. Fig. 4. Pattern ior a boy of 14 years. The turn-over top can also be knitted in three different colours, as shown in Fig. 5

3 cardinal, 1 grey, and 1 cardinal, and fasten off the latter colour. From this point 3 rows of check are worked in grey and Lovat mixture.
For the 1 st row of checks do 4 stitches in one colour and 4 stitches in the second nolour alternately. Do 3 more rounds as the last one. For the next $t$ rows reverse the colours, then do 4 more rounds as the lst 4 . Join on the cardinal wool again and do 1 plain round, then 1 grey, 2 sardinal, 1 grey, and l cardinal. Fasten off the cardinal securely. as this is not required again. and complete the turn over with 2 rounds of Lovat mixture. Fasten off the latter the end of wool threaded on a large rug needle. colour and resume with the grey for the rest Put the two needles logether: for the front pass the needle as if to knit through the tirst stitch and slip it off the needles, put needles into the second stitch, as if to purl, but only draw the thread through without slipping it off. For the back purl and slip off, then put the needle into the next stitch as if to knit, but keep it on and draw the thread through. As the stitches are slipped on to the wool, draw this up closely, to make the seam invisible.
When tinished the woollen stockings should be laid wrong side out on an ironing board covered with a thick blanket. A damp cloth should be spread over them, and pressed with a moderately hot iron till diy. The stockings will then look like well-finished woven hosiery.

Boys' Stockings. A popular type of stockings for men and boys are those with turn-over tope. A pair of ribled stockings of this kind suitable for a boy of 10 to 14 years of age can be knitted from the following directions. These inchude a turn-over top in three colours, as shown in Jig. 5, as well as a turn-over in a different ribbing from the stocking, but in the same colour of wool, as in Fig. 4

The stocking measures $24 \frac{1}{2}$ in. from the top to the bottom of the heel flap, including $3!2$ in. on the turn over. The foot is 9 in . long from the back of the heel to the point of the toe, but the length of the latter can be varied in the centre of the foot before shaping the toc. The length of the leg can be altered in tivo places, either between the welt and the first decrease, or between the last decrease and the heel Hap. The materials required to knit a pair are 6 oz of 4 -ply White Heather Scotch fingering wool in grey, with a set of 4 No. 12 steel knitting needles. For the 3 -volour top 1 oz . of Lovat mixture and 1 oz . of green or cardinal wool will be required as well as the grey.

To begin the work tast 26 stitches on each of 2 needles and 28 on the 3 rd needle, to make 80) stitches in the round, and if making the turn-over in one colour do $3 \frac{1}{2} \mathrm{in}$. of single rib, that is, knitting and purling a stitch alternately all round. For tho 3-colour turn-over begin with the grey wool, cast on the same number of stitches, and work 12 rounds in rib of knit 4 and purl 4 alternately. Here take the Lovat mixture, and, leaving the grey wool hanging, work 2 rounds in the new wool

In the next round do 2 stitches in grey and 2 stitches in Lovat mixture, letting the wool not in use pass behind loosely so as not to contract the work. Work another round the same as last round, keeping the respective colours over each other so that a dark square is formed, then work 2 more plain rounds of Lovat mixture. Take the cardinal wool, and work 1 plain round, then 1 grey round,

## of the stocking. <br> Now turn this top insice out so that when

 the stocking is completed the right side of the turn-over will be uppermost.Knit the next round plain, as this will form the turning-edge of the top, and in that round increase 7 stitches by knitting in the front and back of a stitch at equal distances in the round to make 87 stitches. Having fewer stitches on the stocking top will give a firm grip and keep the stocking in place.

Decreasing the Leg. The stitches should now be arranged 30 on cach of 2 needles and 27 on the 3rd, so that each needle ends with a completed rib. as the rib continues in the pattern of knit 2 and purl 1 alternately all round. Continue in this pattern for $14 \frac{1}{2} \mathrm{in}$. from the lst round, when the work will be long enough to begin the leg decreases, thus: * linit tho lst 2 stitches together, continue in the rib up to within 3 stitches of the end of the round, then linit 2 together through the back of the stitches, and purl the last stitch. Knit 6 rounds without shaping, but taking care to keep the continuity of the rib after the decreasings. Repeat from * until 9 stitches are decreased at each sicle and 18 stitches less in the round.

Continue ribbing on these stitches until the stocking measures $21 \frac{1}{2} \mathrm{in}$. from the top,

Stocking. Fig. 5. Turn-over top for a bos's stocking, which can be knitted in three different colours by following the directions in the text
counting the turn-over. This brings the work to the top of the hecl-flap, so more rounds can be worked here for a longer stocking before begimning the heel. In the last round knit together the last 2 stitches.

To work the hecl knit the first 17 stitches of the round on to one needle, slip the last 17 stitches of the same round on to the other end of the same necdle, making 34 stitches for the heel. Divide the other stitches equally on 2 needles, and leave them for the instep. On the heel stitches purl and knit a row alternately until 33 more rows are worked, always slipping the first stiteh; the last row will be a purl row.
To turn the heel knit 20 , knit 2 together, tum. Always slip the lat stitch after the turn. Purl 7, purl 2 together, turn; knit 8, knit 2 together, turn ; purl 9, purl 2 together, turn: knit 10, knit 2 together, turn. Continue in this manner until all the heel stitches arc knitted on to one row again, then knit back 10 stitches and leave the heel stitches on 2 necdles. Slip) all the instep stitches on one needle, so releasing one as a working needle.

For the Ist needle knit the remaining 10 stitches of the heel, and knit up 17 stitches at the side of the heel. For the 2nd needle knit the instep stitches, and on the 3rd needle pick up and knit 17 stitches on the other side of the heel and the remaining 10 heel stitches. Knit one round plain, then decrease for the instep in the next round thus: Knit to the last 3 stitches of the lst needle, knit 2 together, knit l. Knit the and needle without shaping. On the third noedle, knit l, knit 2 together, through the back of the loops, knit to the end of the needle. Repeat the last 2 rounds until only 17 stitches relnain on each of the lst and 3rd needles, working the rib pattern on the znd needle only.
ffer the instep shaping is finished, work one more round, increasing 2 stitches on the 2nd needle to bring the stitches up to 70. Then continuc on these stitches, ribbing only the 2nd needle, for 58 rounds, or until the toe is reached. The heel, sole, and toe will be in plain knitting. Extra rounds can be worked here before shaping the toe if a longer foot be desired, allowing for nearly 2 in . more to finish the toc.

The toe proceeds in plain knitting, and in the lst round the 9 th and 10 th stitches are knitted together, then 2 rounds are worked without any decreasing, and these 2 plain rounds ara worked after every decrease round. In the 4 th round knit every 8 th and 9 th stitch together; in the 7th round every 7th and 8th stiteh ; in the 10th round, every (ith and th stitch ; in the 13th round, every Jth end (jth stitch; in the 16th round, every 4th and 5th stitch.

Runa double thread through all the remaining stitches, and darn in the end very sceurely. An alterna tive method for finish ing a toe is by the processknown as grafting

## STOKESIA. This

 is a hardy perennial, 18 in . high, with large nster-like blue flowers in late summer. It should he planted in well-drained or light soil on a sunny border. I'ropagation of stokcsia is loy dirision in spring or by seeds in the spring or summer.STOLE. To make a fur scarf or stole from on suddenly with a troublesome hiccough. several skins, first arrange the latter so that all the fur lics in one direction, and number each slin in order on the back before starting to join them. The careful matching of the skins, not only in colour, but also in both texture and length of fur, is most inportant.

Having matched the skins, cut a paper pattern as large as the largest oblong that can be contrived from the smallest of the pelts. Cut them all out by that, placing each pelt fur downward on a deal table and marking round the pattern in pencil or ink upon the lather side before procceding to cut through the lines. Holding the skin taut between the tingers, cut it with a very sharp penknife. To join them, place the cut edges back to back, fur inside, and threading a special 3 -sided fursewing needle with stout No. 30 cotton, overcast them together, firmly and strongly enough to hold the skins side by side, but not no closcly or tightly as to draw the cut edges up into a ridge. In sewing smooth the fur doirn and away from the cut edges which are being joined by means of passing the needle betwcen them.

When the skins have all been joincd line the stole with silk or satin or brocade that inatches or tones with the fur, with or without an inter lining of domet or llamel, or a thin layer of wadding. Any interlining should reach harely to the erlges of the fur, while the lining proper should be cut at least 1 in . wider all round, to allow for a good turning. The interlining should be attached with a few invisible stitches to the fur, before starting to line it.

STOMACH. The shape of the stomach varies according to the degrec of distension, but is somewhat like a pear, with the large end to the left just below the heart. Hence, when the stomach is distended by gases in indigestion, the action of the heart is often interfered with, and there may be difficulty in breathing.

The capacity of the stomach in an adult is roughly from 3 to 5 pints. In the fceding of children it is important to know how much the infantile stomach can comfortably hold. At birth the quantity is very small, and even when at the age of 12 months a child will be made uncomfortable if it gets more than $\frac{1}{2}$ pint of milk at one time

The duty of the stomach is to digest protein matter and to help in pulping the starchy material of bread and vegetahles. It contains a variety of glands, which manufacture pepsin, the ferment which digests meat, eggs, cheese, etc.; a Huid that clots milk immediately it is swallowed; and hydrochloric acid. This last substance serves to prevent fermentation of the food, and is necessary for the action of the pepsin. The muscles keep the stomach in constant movement after a meal so as to ohurn up the food and mix it with the digestive juices. When the mass is ready for discharge into the intestine, the muscular wall contracts and forces it through the communicating valve in little spurts, repeated until the whole meal is passed through. The spasm of dyspepsia is a violent contraction of these stomach inuacles.
Diseases of the Stomach. One of the commonest of the disorders and diseases of the stomach is atony, or loss of power in the muscular wall. The food remains too long and fermentation occurs, causing flatulence

Inflammation of the stomach lining, or gastritis, and gastric uleer are treated under their own headings.
Cancorr of the stomach occurs mostly between the ages of 41 ) and 70, and is sometimes preceded by a chronic ukeer. It has heen pointed out that its most frequent site is the spot likely to be affected by hot liquids, and by alcohol when this is swallowed raw.
The size of the stomach is increased by dilatation, which in an acute form may eome

Chronic dilatation is of two kinds. In one the outflow of the stomach's contents is obstructed; the cause of the other is atony, often the result of cating very large meals or drinking a great deal of fluid habitually, such as beer. The chicf symptoms are flatulence, constipation, vomiting, sleeplessness, and occasionally cramp in the calf of the lcg. In the atonic cases rest in bed improves the condition, but the cure is slow. Efforts should be made to improve the general health and so restore the tone of the stomach muscles. In the cases arising from ohstruction an operation is necessary for complete relief. See Acidity; Digestion ; Gastric Ulecr ; Gastritis; Indigestion.

STOMATITIS. Inllammation of the mouth, or stomatitis, is of scveral varieties. Simple stomatitis may arise from smoking hot tobacco, drinking raw spirits, and other causes. Aphthous stomatitis, in which small whito blisters form, chiclly attacks ill-fed children.

In thrush patches of white membrane form on the soft palate, tongue. and elsewhere in the mouth. In the ulcerative form sores form on the gums about the tecth. Gangrenous stomatitis is practically limited to children who are underfed and live in squalor
The diet must be contined to bland liguids, which must not be given hot. Kicep the mouth clean by washing it out with solutions of boracic, potassinm chlorate, ctc

## Stone as a Building Material

## Durability and Grace in Domestic Architecture

Related information will be found under such headings as Crazy Paving; Steps; Sundial; Wall. Sce also Building; Conerete; House; Path; Paving; and other entries that deal with contructional matters

The stones used in building are sandstone, limestone, slate, and granitc. All stones are porous, some to such an cxtent as to render them unfit for domestic purposes. A very porous stone absorls much rainwater, cspecially when the face of the building is cxposed to the prevailing wind and weather. Granites should not absorb much more than about 1 per cent. of their volume of water, limestones 17, and sandstonc 10 , after 24 hours' immorsion. The weight of the stone has also to be considered. Heavy stones may be used for buttresses or quoins, but lighter stones are cquired for vaulting and similar work.
In selecting stone for building, the colour is often attractive, but some highly coloured stoncs are not so durable as those of a duller colour. The hest stones are those: which are free from hands or spots of colour, and are of a uniform colour in structure. This, of course, cloes not apply to marble. Stone when freshly quarried contains a certain quantity of moisture, known as quarry sap. The stone is preferably cut to size and shape as soon as possible after quarrying, as it is more easily worked, but it is then set aside to scason,
gaining considerably in hardncss and clurability. Artificial stone is a term applied to slabs of concrete, with differing forms of aggregate, often sold under proprictary names.

The stone employed in building work may be one of the many freestones that can be tooled readily, but generally the choice is governed by the material available locally. On this material will depend to a great cxtent the style of the work and the nature of the ornament. For cxample, in certain districts a soft and easily worked stone is associated with tine tracery and delicate carving, whereas when a hard and intractable stone is a vailable the nature of the building is quite different. When a coarse sandsione hias to be used, the mouldings are bold and large, but on granite the style is broad and simple

In the article on Loggia, p. 742 is illustrated the sto ne-built loggia of a Wiltshire house. This is carried out in local stonc. We show in this and the following pages other pictures of typical stonework, indicating different methods of surface finishing.

The amateur constructor should ascertain the kind of stone a vailable in his district. the

Stone. Beautiful 17th century stone-built house at Broadway, Worcestersbire, showing the steep pabled roof and mullioned windows which are typical fealures of the Tudor style of architecture

The lacing course of bricks adds longitudinal and transverse strength to the wall. When this is done, the stones are preferably set in mortar, and the wall is often composed of smaller stones worked with the smoothest and straightest faces sct outward. The spaces between the two sets of stones are filled in with small pieces and grouted with mortar.

Another method, particularly applicable to buildings, is to set rubble stones in front of a backing wall of brickwork. This has the effect of providing a smooth and durable inner face. Jiach course is set in mortar, and the stones arc arranged to break joint. Usually only the face stones are sct in mortar, the spaces between the irregular stones and the brickwork being filled in with hearting or small stones, and grouted in with liquid mortar poured from a pail. The mortar should not be allowed to run on to the face of the stones.
All the forcgoing wallings can be put up by the amatcur if reasonable care be taken to bed the stones well and to work a bonder or through stone about every yard square of the wall surfacc. The bonder is a stone of sufficient proportions to pass through the wall from face to face, and act as a stiffener to tie the whole together.
Cutting Stone. The preparation of bonders will probably necessitate cutting the stone, which is by no means easy until the knack has been acquired. One way is to score a shallow groove along all four faces of the stone by chipping a line, with a cold chisel nnd hammer, as shown in Fig. 3, afterwards striking it a few blows with the mallet, delivering the blows through a board set vertically over the groove. A stone severed in this way would be sulliciently smooth and straight for random rubble work. The working or tooling of stone and the arts of the mason are hardly to be acquired by the amatcur, but a few simple exercises in trueing a stone will aid in the completion of such work as the cutting and shaping of capstoncs for walls, ctc.

In order to produce a llat surface on a block of soft sandstone, the inethod slown in Figs. 4 and 5 may be followed. The lirst step is to cut the stone roughly to shape and size, and to select the llattest surface or bed. The corners of this part of the stone arc chipped away with a chisel
cost of transport, and the amount of work in a more or less that will have to be expended on the stones before they are fit to use. Some of the extensively used grades of stone are stocked by merchants, such as York stone for paving, and some of the West of England stone for general work in rock gardens and the like, otherwise the supplies have to come direct from a stone quarry. Should it have to be drawn by road, the cost per ton, inclusive of handling, should be agreed at the outset with a contractor equipped for the work.
As turned out by a country quarry, the stone is split into thin slabs or sawn to shape in pieces suitable for building. It is possible to obtain stone in $n$ rough form, comparatively small in size, but thick and solid, such being suitable as regards size for walls and constructional work of an elementary character. Thinner pieces generally of larger size are used for paving purposes, and also for some walls and roofs, and the stonc can also be obtained cut to any reasonable shape and size.

York stone is largely used for crazy paving in pieces about 2 in . thick and of random shape. It is quite admirable for paths, steps, and the floors of outbuildings. When the material is delivered, the best plan is to sort out roughly those pieces which have at least one edge straight or nearly so, and to set these pieces aside for the edges of the steps or for other similar work.

Methods of Walling. The chief structural difference between one class of stonework and another lies in the arrangement of the stones, which is known as walling. This is cither carried out in courses like brickwork, or
indefinite manner known as randon rubble. Walls of rubble are built of thinly bedded stones of irregular shape, generally 9 in . deep or less. Varieties of rubble include coursed and squared $r u b b l e$. Block stone masonry is composed of squared blocks set in regular courses, or random formed of different shaped blocks.
The easiest walls for a novice to build are those of random rubble set dry, as seen in Fig. 1, where the wall is composed of substantial blocks of rough stone set without mortar. The foundations may be of concrete, or a course of stout stones set with the greatest width across the wall and bedded to the solid earth. For the sake of sccurity two courses breaking joint should be employed, and the walls erected upon them. The stones are roughly selected for height and width, and arranged to tit into each other as tightly as possible. They are kept in line by setting them by a cord stretched from end to end of the wall. The top is finished with stont stones set upright, and often bedded on earth to keep out rainwater.

Another type of wall consists of several courses of stonework and then a few courses of brick, as shown in Fig. 2, finishing with other stoncs and upright pieces on the top.
 to form two flat surfaces at the front side; one such place is formed similarly at the back. blocks of wood of uniform height are placed on the front flats and a batten rested on them. The purpose is to raise the batten above the level of the rough parts of the stone. A block is also placed on the one flat at the back, and another on the untouched back corner. The second batten, as shown in Fig. 4, is rested on the blocks at the back, and the last corner is cut away as much as necessary until the tops of both battens appear level or parallel when viewed by looking across them. The same test is applied after the front and back edges of the block have been chiselled in order to make them level (Fig. 5).

There are thus two level surfaces along the front and back edges respectively, which are known as chisel drafts. The intermediate stone betwcen these drafts may be cut away with the chisel and hammer, or the stone may be finished with chisel-drafted margins. The method is applied to the preparation of

Stone. Fig. 6. Part of an old Sussex house with a picturesque roof consisting of thin slabs of Horsham stone
good weathering qualities, and is set on massive oak roof rafters. The stones are laid ill random courses, decreasing in size from the eaves upward. The slabs are hung on oak pegs driven into holes in the head or narrow part of the stones In modern work the stones are often set on a boarded and felted roof cover. ing, and secured with brass na!!s or screws. Another plan is to cover the rafters with expanded metal lathing, covering this with a bed of mortar, setting the stones thercon and pointing the joints as the work procceds.

Any attempt at rigid regularity of shape robs the stone roof of much of its charm Roughness and unevenness in the stones also assists the lrying out of moisture, which is important, as any dampness in the roof, by admitting frost, accelerates splitting of the stones. The valleys are generally swept, and the ridges finished with a half-round ridge tile or by sawn stones A hipped roof is rare, and calls for great skill in cutting and fitting the stones
capstones for the top of a low garden wall. Capstones may be used for decorative effect as well as for protection of the brickwork or other walling material, such capstones being set preferably in cement mortar.
When stone is used for building purpose the walls have to be much thicker than they would be if made of brickwork, and, unless built in random rubble set in mortar, will have to be well fitted together, and secured where necessary by means of dowels, cramps. or other fasteners.
Stone has been largely used for rooling purposes. and a roof covered with Horsham shalo is illustrated in Fig. 6 . This is a thin stone of

Stone. Wing of stone-built house showing both tooled and rough surfaces. Windows are stone

STONE: The Weight. This useful measure of weight consists usually of 14 lb . avoirdupois, although there are stones of other kinds. The Smithlichl stone for dead meat is only 8 lb . ; that of wool is 24 lb ., and of hay 22 lb . See Avoirdupois Weight.

Stone: The Disease. Seє Calculus; Gall Stone.
STONECROP. These hardy Howering plants are chicfly suitable for the rock garden and the wall. One, however, the Japanesc stonecrop (Sedum spectabile), is a valuable border plant, 15 in . high, with grey succulent leaves and large flat bunches of carminerose blooms in Scptember which attract the buttertlies and bees. It thrives in ordinary border soil, and is casily increased by division in spring. Low growing stonecrops suitable for the rock garden flourish in sunny places in soil with which sand and old mortar rubble have been mixed
They are increased by division in early autumn or spring. The common yellow stonecrop is Sedum acre ; it is a creeping plant with yellow flowers in summer. Choicer kinds are Ewersii, rose purple ; kaintschaticum, yellow; lydium, pink: middlendorfianum, yellow, and spatulaefolium, yellow.
STONE MARTEN. This fine fur is obtainel from a species of marten (a genus of carnivorous mammals of the weasel tribe) which derives its name from its liking for rocky places. The best skins come from Asia, ancl are of a soft, fine texture, the underfur being almost white and the tips resembling sab!e in colour. In some respects stone marten bearsa great likcness to the latter fur, and is sometimes dyed to imitate it. It has the arlvantage of being both hard wearing and attrac tive. See Fur; Marten.

Stool. Walnut atool with carved cabriole legs and splay feet, covered with woolwork. Early 18th century
B", permission of the Director, Victoria \& Alvert Museum

STONEWARE. This term is used for a cortain kind of pottery. It is less fine than chinaware, and is widely used for domestic croclicry. Stoneware was first made in Germany, and later in England, where certain districts, e.g. Staffordshire, earned a reputation for it. After a period of decay its mannfacture was revived, chiefly by the firm of loulton, whose artistic stoneware was a notable contribution to English pottery. Ser China; Doulton Ware Nottingham Stoneware ; Pottery.
STONING: Of Fruit. Many varieties of stone fruit when made into jam or marmalade are stoned. To do this the fruit should be split in half and the stone removed without tearing the fruit. Special cherry stoning devices for domestic use can now be: obtained, which may also be userl for olives and damsons. The sceds of raisins should be extracted brfore this fruit is added to puddings or cakes. When large quantities are to bo stoned the operation is done by menne of a

Stone. Circular window, an interesting combination of tooled stone with rock-faced stonework
machine, but for smaller numbers the secds are removed by hand
It is well to have a small basin of warm water on the table when starting to stone raisins, but recourse should be had to this as little as possible, as the added moisture detracts from the flavour and richness of the fruit. To stone, split the raisin in half lengthways with a sharp cook's knife, but do not actually divide it. By pressing the knife against the stones which are exposed they will rise, and can be removed without wasting the pulp. If the fingers become sticky, dip them lightly in the water and wipe them on a damp dish cloth before again commencing operations.

When using sections of oranges for jellies or pastries the seeds should be removed. This is best done by feeling for the pip and pressing it out with a quill, in order to avoid injuring the appearance of the fruit or allowing the escape of the juice

STOOL. A stool is almost the oldest form of seat. Early examples are of the milkmaid's stool type on three legs, but in the l6th century they were made with four, and a certain amount of decora tion was intro. duced into the simple design. Sometimes they possessed a box seat with hinged top. In
the late 17th century they were upholstered, but about the same time they began to lose popularity owing to the greater comfort afforded by the chair. Specimens, however, continued to be made, and the legs of these were cabriole, and showed the carved knees and the claw, lion's paw and claw and ball terminations of the period. Qucen Anne stools were often covered with petit-point embroidery. An example of one with a tapestry needlework covering is illustrated in the previous page.
The stool most valued by collectors is one of the joint stools, as they are called, of the 16 th century. They are of oak and rest on four legs, which are joincd together by stretchers. The legs are turned, and in some examples there is carving on the sides of the seat. Many of them are inlaid with box and ebony in alternating triangular pieces, placed in the rails just below the seat. Sce Camp Stool; Chair; Dressing Table; Jacobean Style, etc

STOOL OF REPENTANCE. To play this round game one person is sent out of the room and the others then decide what shall be said about him or her, these criticisms being noted down by the leader. A stool is set for him in the centre of the players, and he is called in to occupy it. When he is seated the game proceeds.

The leader reads out each criticism in turn, thus: Somebody says you are irritable, or conceited, or good-natured, and the victim has to guess the name of the critic. If he guesses a sufficient number correctly he is released from the stool of repentance and allowed to take his place in the circle, while another player goes out to endure the ordeal; but as the game would cease to be amusing if the same person were dealt with twice running, he is usually considered to have earned his relcase whether he guesses correctly or whether he does not. See Children's Party.

STOP: In a Camera. The amount of light which passes through the lens of a camera is controlled by a stop or diaphragm placed behind a single lens or between the components of a compound lens. On the size of the stop used depend both the length of the exposure required and the degree to which sharp definition of detail can be obtained throughout the picture.

The most usual form of diaphragm or stop in the modern camera, known as the iris diaphragm, consists of a series of thin metal tongues working on points in a ring in the lens mount. Each tongue has a curved slot. cut in it, so that as the ring is rotated the metal tongues move uniformly towards or from the centre, making an adjustable circular aperture as seen in the photograph. The apertures at which the stop or diaphragm works are indicated on the lens mount and are known as $\mathrm{F} /$ numbers.

The larger the stop which can be used with any particular lens the shorter the exposure, while the smaller the stop the greater is the effective depth of focus of the lens, and the sharpness of detail. The process of using a smaller stop, which is known as stopping down, is used far too frequently by the amateur photographer. In doing so, he not only lengthens the exposure unnecessarily and thereby destroys the principal quality which makes a lens both good and expensive, but also produces photographs that are lacking in artistic quality.
The whole tendency in modern photography, and this is particularly the case in landscape,
figure study, and portrait work, is so to increase the aperture of the lens, and therefore the size of the stop which may be used with it, as to shorten more and more the period of exposure. while producing softer and more artistic photographs in which the different planes of vision are separated.

Many of the better quality modern roll film cameras are fitted with $f / 4 \cdot 5$ lenses, and full advantage should be taken of the opportunities they offer. It is chiefly a matter of knowing what stops to use and when to use them.
The amateur should not be misled by instructions which he may find on inexpensive fixed-focus cameras as to using different stops for different subjects. These instructions are a necessary compromise, due to the lack of focussing adjustment, and also to the fact that the shutter has only onc speed. With a fixedfocus, single-speed shutter camera it $=$ will be necessary to stop down to get foreground subjects into focus (since stopping down deepens the field of focus), and also to cut down the light passing through the lens when shorter exposures are required, since the shutter speed cannot be increascd.

The larger the aperture of the lens the shallower is the field of focus. This means that while objects in the foreground may be sharply defined those in the middle distance will be softened, while those in the background may be so far out of focus as to be unrecognizable. This gives the photographer considerable opportunities for artistic work, especially when differential focussing is employed. by which the object that is of principal importance in the picture is more sharply defined.
For portraits and similar studies the largest stop available should be used, but with landscapes, which include a wide field of view, a medium stop, such as $f / 6 \cdot 8$ or $f / 8$, may be required. At the other extreme the smallest stops are required when copying prints or in photographing specific objects. such as furniture.
The effect of using different stops is best studied carefully on the focussing screen before rather than after cxposure. For this purposc it is essential that the screen should be well shaded. In general it may be said that the proper use of lens stops indicates the skill of the photographer. Always bear in mind that the exposure varies according to the square of the stop used, f/ll requiring twice the exposure of $\mathrm{f} / 8$, and $\mathrm{f} / 16$ four times. See Camera; F/Number ; Focus; Lens.
STOP COCK. In its most general application a stop cock is any principal tap used to cut off the supply of liquids or gas to a build ing or to some section thereof. In the home the term is restricted to the main water or gas tap that is fitted in the run of the main supply pipe.

The water company generally fits a stop cock of substantial pattern at the nearest point to the main water pipe where the branch is taken to the huilding, and generally it is operated by a long-handled metal rod or key. It is an advantage to have another stop cock fitted inside the house on the rising main, c.g. beneath the sink in the kitchen. See Pipe.

STORAGE BATTERY. This is an appliance which acts as a reservoir for electrical energy: Usually it consists of a series of cells or accumulators, and is intended to yield a higher voltage or greater volume of energy than is feasible from a small portable accumulator.

For house-lighting. purposes the units are usually fitted with open-top glasis cells, and,
instead of having the ordinary type of terminals, the lugs terminate with a bolt and nut, and are connected by means of lead strips which are bolted to the lugs on the plates. The cells are usually arranged on a wooden stand so as to raise them from the ground and permit of inspection and necessary attention.
Any unit or cell composing a storage battery holds nominally not more than 2 volts. Actually, however, this figure rises slightly when the cells are fully charged, and may drop slightly below 2 volts when they are almost discharged. Consequently, if it is required to provide a nominal voltage of 25 volts, it is necessary to have at least 13 and preferably 14 cells, with some means of controlling the voltage, such as by a resistance or by temporarily disconnecting one of the end cells. In other words, to find the number of cells required the voltage is divided by two and one extra cell added to the total.

In arranging for the erection of a storage battery it is desirable to choose a cool, dry place, well ventilated, and situated where the fumes given off by the cells cannot affect the surroundings. A small brick-built outbuilding with a ventilated roof, and used only for the storage battery, is the best, but if the battery has to be housed indoors it should be located away from the foodstuffs and as far from the living-rooms as possible. It must be partitioned off from the rest of the room and provided with some independent and direct ventilation to the open air.
Charging and maintenance instructions are issucd by the makers of the battery, and the information contained therein should be carefully followed. See Accumulator.

STORAX. The white-flowered, deciduous and hardy shrub storax requires a dry position in light ordinary soil, preferably under the shelter of a south wall. It is worth some attention, and will benefit by incorporation of peat in its root run. The most suitable planting. period is from October to February. It is propagated by layering of shoots. Two good species are japonica and obassia, natives of Japan.

STORE ROOM. In some larger households, the accommodation provided for holding food stores, ctc., in the larder, kitchen and pantry is supplemented by a special store room.
This room should have a north or eastern aspect, and the nearer it is to the kitchen the better. It is essential that it should be thoroughly dry and airy, and have at least one window covered with perforated zinc or wire gauze, the walls and ceilings being whitcwashed or coated with sanitary paint. The floor can be left with plain, well-scoured boards or covered with linoleum. Every little crack in flooring or walls should be carefully filled to prevent the entrance of mice, beetles or other vermin.
The store room must be well fitted with shelves, preferably of graduated sizes. If all are very wide, there will be a tendency to pack each with several rows of articles instead of a single row, and so small objects may easily be hidden behind large ones and overlooked. Each shelf should bc neatly covered with oilcloth held in position by drawing-pins. The stores must be grouped according to their character, i.e. all the jams together, all the seasonings in another group, different kinds of sugar together, etc. Cercals are best kept on one shelf, each stored in a separate tin. There should be a few shelves set apart for soaps and cleansing materials, not too near foods such as flour. Soap can be kept in bulk, as it hardens with keeping and is thus rendered more economical. Certain stores such as cheese, coffee, etc., impart their flavour to other foods, and therefore should be stored in airtight tins. Tea also
tends to lose its aroma unless kept in an airtight container.

A slate and pencil or writing tablet is generally liept hanging in the store room for noting down any supplies that need replenish. ing. If preferred a store indicator can be bought for a few shillings. This gives a printed list of stores and a system of removable pegs to indicate which are needed.

STORING : Of Vegetables, Fruits, etc. Beetroot, carrot and turnip should be lifted in autumn when growth is complete and stored at the foot of a wall or fence. A covering of earth, sand or old ashes will provide protection from frost. Or they may be stored in boves containing one of thase materials and placed in a shed. Potatoes are lifted when the tops have died down, and after having heen exposed to the air for two or three hours to dry the skins they are placed in boxes or tubs or in heaps in a frost-proof shed. Care should be taken to store only sound tubers, and it is wise to scatter a little lime on them.

Parsnip, salsify and scorzonera are dug as required. To enable the roots to be lifted in severe weather the soil should be covered with bracken or straw to prevent its being frozen. Onions when fully ripened should be tied in bunches, as in lig. 4, or made up into "ropes" in an airy shed or even on a sunny wall. Savoy and other cabbages, kale and Brussels sprouts are very hardy, but broccoli, when fully developed, should be lifted and hung, heads downwards, in $n$ shed.

Roots and Bulbs. Flower roots of a tuberous nature which rannot be left in the open ground during winter should he lifted as soon as the first frost has touched their foliage. Their stems should be cut down. After they have been in a cool place under cover for excess sap to drain away, they should be stored in boxes of sand, as in Fig. 7, in the shelter of a frost-proof shed. Bulbs such as dattodils and tulips should be left in the soil until their foliage has become yellow, drying them slowly in a shaded, airy place, and storing in boxes away from frost : the foliage must be thoroughly ripened before storing.

Gladioli corms and others should be lifted before winter sets in, tied in bunches, and suspended in a cool place until their foliage has withered, when they may be stored in boxes of sand. Geraniums and other bedding plants must be taken indoors in autumn, potting then up after trimming. A simple and common method of dealing with geraniums in the winter months is illustrated in Fig. 5.

Stove. Fig. 1. Slow combustion coke-burning stove, with piping passed through roof Courtesu of Smilh \& Wellstond. Lld.
Apples and Pears. Apples and pears should be graded according to size and quality, storing them, if possible, in a rack of trays, as shown in the diagram. Where the quantity is small, scparate fruits may be suspended to beams or rafters in a cool and airy place, as in Fig. 2. Grapes will kecp in bottles of water containing a few pieces of charcoal, the bottles being fixed at a slight angle in a dark and cool place. Nuts must be gathered when fully ripe and should be stored in boxes of sand which are set in a cool, dry place. A cool shed with an earth floor is the most suitable store for apples and pears.

Storage cupboards constructed as explained below are probably the best solution of the problem, since the fruit is stored on single shelves and can easily be examined, any which show signs of deterioration heing removed for immediate use.

Ordinary packing cases or Tate's sugar boxes may, for the sake of cheapness, be used, hut it is better to make the boxes a certain standard size. so that all shelves are interchangeable. Ordinary cheap whitewood may be used 4 ft . by 2 ft .6 in . by 2 ft .6 in . The boxes themselves are made from 1 in. by 8 in . tongued and grooved
wood, and the sides may be joined together by a simple dovetail. At suitable distances inside each box, six $\frac{1}{2} \mathrm{in}$. grooves are cut, into which $1 \frac{1}{2} \mathrm{in}$. strips of wood are screwed. The inch which projects into the box forms convenient runners along which the trays slide.

Stork's Bill. See Pelargonium.
STOUT. A dark brown malt liquor. stimulating and nourishing, stont is a superior kind of porter. It is brewed in much the same manner as ale, with roasted malt to give it colour. Oatmeal stout is also made.
Stout is a drink which blends very well with cheese or a cheese savoury. It is also good with oysters. On account of its somewhat heavy qualities some people prefer it mixed with bitter beer, half and half. It should be served in a pewter or silver tankard.
lirom a medical standpoint really good pure stout, like other good beers, is certainly the most nourishing of all alcoholic drinks, but still it contains only a very small quantity of mutritions material. With some people flatulent indigestion is a very common rosult of drinking it, and when nursing mothers take it their babies may have their digestions upset. See Beer; Diet.

STOVE : For Solid Fuel. A stove differs from a fire because the fuel and heat are enclosed in an iron or some other kind of ensing.

The principle on which many stoves work is that known as slow combustion. There is nn enclosed furnace in which the rate of fuel consumption can be controlled by regulating the quantity of air supplied to the fire.

A stove of useful and simple type is shown in Fig. 1. It consists of a cylindrical iron casing lined with fireclay, and the fire is laid on the solid clay bottom at the base, there being no fire bars. Though sometimes a little troublesome to light, stoves of this type are efficient and economical in use. The kindling wood and other lighting material should be dry, and the stove should not be filled until the fire has taken hold. Coke or anthracite is suitable fuel. Stoves of this kind are commonly fixed in school-rooms, halls, or workshops. It is best to kecp the stove pipe inside the building, if a brick flue is not available, as condensation sometimes causes trouble when the pipe is taken through the wall and carricd up outside.
Of the many patterns of coal stove, the varieties that burn anthracite or similar fuel have many advantages, and are readily fitted to a fireplace in place of $n$ existing grate.

Stove. Fir. 2. Stove flted to an existing Hrepace. It burns anthracite nuts or coke, and is ftted with automatic ventilating check valve and gas tube Courtesy of inilh \& Wellstood. Itd

Storing crops and plants. 1. Potato clamp. 2. Suspended pears. 3. Parsnips or carrots in box of sand. 4. Suspended onions. 5. Geranium in winter. 6. Winter radishes in sand : $a$, turves, grass uppermost ; $b$, soil. 7. Storing dablias. 8. Apple or pear rack in section: $a$, fruit ; $b$, trays; $c$, tray supports

Stove. Fig. 3. Slow combustion atove which fits into a fireplace recess. It has an ashpan regulator, and a slide damper in the flue at the back

To take full advantage of this class of stove it should be kept burning continuously during the cold weather, so that the room is always at a comfortable and cquable temperature. Figs. 2 and 3 show representative patterns.

Fuel Consumption. The fuel consumption of a stove suitable for use in a room 20 ft . by 12 ft . would be approximately 1 cwt. anthracite per week (continuous burning). This is based on the maintenance of an average indoor temperature of $62^{\circ}$ to $64^{\circ} \mathrm{F}$., with a minimum outdoor temperature of $32^{\circ} \mathrm{F}$. Coke can be used, the kind known as washed nuts No. 2 being suitable. Owing, however, to its tendency to choke and hang up in the stove, and its greater ash deposit, coke is not so good for continuous service as anthracite.

Stove Brush. For cleaning the fireplace in the home a strongly made brush is required, with stout grip-handle screwed on to the back. and there is a varied selection of oval and oblong shapes. The chief consideration should be a well-flled bristle surface with the knots securely drawn into the stock with wire.

The hair is trimmed level, which with a curved stock means longer knots at the ends than in the middle; some have distinct wings or tufts at the ends to facilitate getting into corners, and negotiating uneven surfaces. Very stiff bristle is not necessary, but a brush of pure bristle, or a good mixture of fair length, will outlast several inferior articles. See Anthracite Stove; Boiler; Brush; Burner ; Cooker; Oil ; Range.

STOVE HOUSE. A stove house or hothouse is a glazed structure in which a high temperature can be maintained, thus permitting the forcing of fruits and the cultivation of plants native to tropical climates. Such .structures require skilled attention and maintenance, and are only suitable for market growers, specialists in exotic plants and ferns, and amateur gardeners of ample means. For the average gardener a cold or warm greenhouse will be found more economical, and, within limits, will be of greater all-round
utility. The construction of a stove house for amateur purposes can follow very largely on the lines described for greenhouse and conservatory building. Usually the temperature is kept at $60^{\circ}$ to $65^{\circ}$ at night. Consequently the arrangements for heating the stove house must be fully adequate to the demands made on the system.
The section of a simple stove house is shown in Fig. 1, partly cut away to reveal details of construction. The lower part of the walls is built in 9 in. brickwork with ventilating or air bricks at intervals. There are skylights or openings in the roof, and by control of the inlet and outlet the desired temperature and ventilation are maintained. The air bricks can have shutters to close them, and these are controlled by a long handle or rod, the end reaching to the front of the tiers of hot-water pipes.
The pipes will have to be of adequate capacity to maintain the heat, and may be in one continuous system, or in two or more distinct sets, each controlled by separate valves. The average size of these cast-iron pipes is about 4 in. diameter. The heating surface of such a pipe can be reckoned roughly as 1 sq . ft. per foot of length.

Heating Capacity. Thus, if a stove house were to be, say, 18 ft . wide and 50 ft . long, with 6 pipes a side, there would be roughly $1,344 \mathrm{sq}$. ft. of pipe area if the pipes were set on the three sides of the house, leaving one end free for the door and entrance. The boiler would therefore need a heating capacity equal to about $1,300 \mathrm{ft}$. run of pipe 4 in . diameter, and would probably measure about 5 ft . long, 2 ft . wide, and 3 ft . high. These sizes are approximate and vary with the make and type of boiler.
The side staging can be made of wood or preferably of stone or slate, which may be set into brickwork as shown in section in Fig. 2. The stages or tables can be covered with a layer of coarse sand or other material to a depth of 2 or 3 in . whereon to stand the pots. The purpose is to absorb moisture and give it out again for the proper development of the plants. See Conservatory; Greenhouse: Orchid.

STRAIN. Muscular strain is particularly common in people who go in
for games and exercises without the necessary
preliminary training, as may be noted at the preliminary training, as may be noted at the sports seasons. In most cases of severe strain some of the muscular fibres are torn, and unless proper care be taken the muscle may remain weakencd for a long time. Rest is the cure, while cold, heat, or other anodyne applications will be useful at first. Slings, bandages and strapping help to secure absolute rest.

Heart strain is a popular name for dilatation of the heart, usually caused by excessive muscular exertion. It may come on suddenly from a single great effort, as in lifting a heavy weight, or the heart may dilate more gradually in consequence of repeated efforts beyond the person's strength. Cycling up hills is a common cause, being especially injurious to growing boys and girls. Week-enders who lead a sedentary life from Monday to Friday, and then start on a long walking tour, hillclimbing, rowing, etc., are frequent sufferers from heart strain.

When this occurs the patient may feel considerable pain in the region of the heart, he suffers from palpitation, may faint from slight causes, and is liable to sleeplessness. For sudden or acute heart strain absolute rest is necessary. In more severe cases, rest in bed with mustard plasters to the feet and legs, anc ice over the heart, will usually give relief. A very important factor in predisposing the heart to strain is some temporary weakness due to recent influenza or some other infection. A day's rest in bed is the best means of allowing an overworked heart to recuperate. People who have difficulty in getting through the week should therefore make a habit of taking such a rest periodically, and this applies not only to those with damaged hearts but to the aged. See Exercise; Heart; Sprain.

STRAINER. The shape of a strainer for culinary purposcs may be round or conical.

The round strainer in appearance is somewhat similar to a metal pan with slightly sloping sides, the kase being perforated or composed of metal wire. The conical pattern is perforated all round the sides with the exception of a broad band of plain metal encircling the top. A handle extends from one part of the edge, in both shapes. by means of which the strainer can be held in place over the receptacle into which the liquor falls. In larger round strainers two short handles, one on either side, replace the one in the smaller.
An excellent strainer may be devised by using a piece of muslin. The material should be held or fastened over a bowl and the liquor poured through it. Hair or wire sieves and colanders may be used as strainers. A very small strainer shaped like a tiny bowl and perforated or fitted with fine silvered woven wire is often used to retain the leaves when pouring out tea. Some lemon squeezers art fitted with strainers which keep back the pips and portions of pulp, leaving the juice clear. Gravy strainers are convenient for small quantities of soup, for finishing sauces or for coating purposes, and also for pouring sauce or custard round a dish. For this purpose the conical form of strainer should be used. When larger quantities of stock have to be dealt with a sieve is inverted on a bowl on which it will rest firmly and the stock is poured through
quickly. A hair sieve should be used for the more delicate varieties of stock, but a wire sieve is suital,le for any ordinary kind. For straining completed soups, if only a small quantity has been made, a conical strainer is best, but larger quantities must be strained through a sieve into a bowl and then re-heated.

To strain sauces, use a hair sieve and pass through as much of the solid matter as will he absorbed by the liquid. No acid satuce should be passed through a sieve fittel with brass wire.

There are many liquid or semi-liquid cookery ingredients which require straining. Milk is better strained before bcing used and sometimes it is necessary to strain it after it is hoiled. Liggs when beaten should be strained to remove the thead. This hard piece will be quite apparent in a pudding or custard if not strained out. Strain the eggs when sufficiently mixed but before they are entirely beaten, and continue the whipping after straining. When using yeast and after the liquid has been added to it, let it be strained, using a finc conical strainer. See Fish Kettle; Jelly Bag: Labour Saving; Soup; Stock; Vegetables.

STRAINING POST. A particular type of post is adapted to take the strain of fencing material. In a wire fence, for example, the wire must be at a good tension, and this is ensured by specially braced posts being placed at intervals in the fence so that the slack of the wire may be drawn up tightly. See Fence ; Post.

STRAMONIUIM. The dried ripe secds and the dried leaves of the thorn apple furnish the preparations of stramonium, which has an action closely resembling that of belladonna. Stramonium is chietly used to relas the spasm of the bronchial tubes occurring in asthma.

For this purpose the drug may be given internally in the form of the tincture, or cigarettes made of the leaves may be smoked, or the fumes of a burning powder containing the dried leaves mixed with powdered nitie, ctc., may be inhaled. Tincture of stramonium is given in doses of 5 to 15 minims. Stramonium sometimes has a slight effect on the beart, rendering its beating less ragular and cven producing palpitation. See Asthma.

STRAP. Odd straps may be bought from leather stores, and it is worth while buying a goorl one, for cheap leather wears rapidly and sometimes stretches. When it becomes necessary to make new holes in a strap, use a sharp skewer, holding the leather over it and pressing the point through. This is nore satisfactory than cutting the strap with a penkinife.

When straps have been laid aside for some time, and are to be used again, make certain that the buckic is firm. If the leather has become hard, soak it in hot soapy water for $n$ few hours, and then hang it up in an airy place to clry. Finis' by rubbing it vigorously with a soft rag dipped in linseed oil. See Harness; Leather.

STRAPPING. A few strips of adhesire plaster may be applied to an injured or dis. cased part for the purpose of giving support and securing rest. In some cases ordinary allhesive plaster suffices, in others something stronger will be required and calico plasters are employed. See Arlhesive Plaster.

STRAPWORK. This is the name of an ornament used on furniture and metalwork. It is formed by narrow strips of wood or metal, as the case may be, crossed to form a lace-like pattern. See Guilloche; Jacobean Style Tudor Style.
STRATHSPEY: The Dance. This Scottish dance is a type of reel, the difference lying more in the time than in the actual steps.

In common with the reels the Strathspey tunes are clivided into two parts of 4 bars cach, but Strathspey music is played more slowly, the steps being energetically rendered and with jerky effect, in contrast to the more
gliding movements of the true reed. The jerkiness is due to the fact that the notes of most Strathspey tunesarealternately a clot ted quaver and semicjuaver, the bar frequently terminating irt a crochet. In the modern Scottish reel pari of the dance is often in Strathspey time.

Typical steps include the setting step, in which the right foot is placed behind the left; the daneer sinks and hops on it and then the same morement is repeated with the left foot behind the right. Another step is known as cross passes. The dancer springs to one side with the right foot, immediately passing the left across it, hopping, and crossing again, which finishes one step. It is repeated, beginning the spring with the left foot.

A constantly recurring step is the open step ; beginning with the feet in the sccond position and then with straight knees the dancer makes a smart spring upon the toes to the fifth position and docs a like spring, being careful to let the foot which was before in the first spring be behind in the sccond. See Reel.
STRAW. Consisting of the dried stalks of wheat and other grain, the uses to which straw is put are manifold. In building it is employed for thatehing roofs; in the loome it is scen in the form of baskets, bags, and matting; and it is made into hats of all colours and shapes, as it dyes and bleaches well in both fine and coarse varieties.

# Strawberries and Their Culture <br> <br> And Various Ways to Cook and Serve Them 

 <br> <br> And Various Ways to Cook and Serve Them}

The directions given here on growing this fruit are followed by information about serving it,
after which come recipes for various strawberry dishes. See Layering; Netting
This fruit is grown most successfully on grown nowadays; they have been super-well-tilled land which does not dry out in seded by others of less delicious fiavour but summer; it is not satisfactory on very light better constitution. Royal Sovercign, Bedforit sandy soil unless old turf and manure are dug Champion, Fillbasket, Sir Joseph Paxton, in freely. The best time to plant is in August The Duke, Givon's Late Prolific and King or early September, using sinall plants which George are favourite sorts. Viscomtess de werc layered in pots of soil in Junc and July. Thury, which bears heavy crops of rather If this practice is followed there will be a small fruits, is an excellent strawberry for fair crop of first-rate fruits the following jam-making. The perpetual-fruiting strawsummer, an abundant crop of good fruits berries St. Fiacre and St. Antoine de Padoue the sccond year, and a heavy crop of smaller bear fruits both in summer and autumn.
fruits the third year. It is the usual practice To obtain an early crop of strawberries to destroy the strawberry bed after it has under glass in May, runners layered in small borne threc crops and plant a fresh one, but pots of soil in June should be repotted in the old plants may be left for another year 6 -in. pots in August, in a compost of loan or two if desired, though they will produce with which a little decayed manure and sand only sinall fruits. Strawberry plants should be set from 18 to 24 in . apart according to the vigour of the varicty.

In late summer dead and discased leaves should be removed together with all weeds, and a dressing of manure put on the soil. strawery Before the blossoms open in spring, straw should be spread among the plants; it will kecp the fruits clean and frec from soil splashed up during rain. The mats specially sold for this purpose are now used in many gardens instead of straw. The plants must be covered with fish netting to prevent the fruits bcing damaged by birds.

The best Havoured strawberries are Dr. Hogg, Countcss, 13ritish (Queen, and The P'resident. British Queen needs to be layered every year, the bed being replanted each autumn. These varictics are rarely

both old and young fruit, covering it with a of lemon jelly in $\frac{3}{4}$ pint hot water, then pour white mildew, and causing the older fruit to decay. Though often observed only on the fruit, it develops first on the under surface of the leaves, a point which should be noted, as it is only in the early stages that remedial measures can be satisfactorily applicd. The mildew usually appears in May.
As soon as it has been discovered the plants should be dusted with flowers of sulphur or black sulphur, and the treatment repeated if necessary. A small pair of bellows, called a sulphurator. may be used for this purpose, but if one is not available the sulphur may be shaken out of a loosely woven bag attached to a stick.
Leaf blight, in the form of red spots which run and spread on the leaves, also occurs, usually after the fruiting period is over, but with a weakening effect upon the subsequent health of the plant. Another pest, which can be dealt with in the orthodox way, is green fly. The fruit may also be attacked by slugs, which are best combated with soot or lime or with traps of brewers' grains. Red spiders may attack plants grown under glass if the air is allowed to get dry, but proper syringing will keep this under.

An insect known as the strawberry tortrix moth is at times very destructive. The damage is done by tho caterpillar, which eats the foliage in May and June. The only satisfactory treatment is to pick over the plantation by hand on the first appearance of the pest. To keep the plant clear of another destructive insect, the strawberry blossom weevil, all dead leaves, wastc straw, and the like, should be removed from the vicinity of the beds, as the adult weevils dwell therein in the winter, whence they issue forth when the strawberry blossoms are beginning to open.
How to Cook. Freshly picked strawberries may be served with cream or included in fruit salads, compotes, trifles, and other sweet dishes. They are also made into jam, wine, ices, flans, and pies. If fresh berries are not obtainable, the bottled or tinned kinds may be uscd instead. Those preserved in tins are sometimes lacking in flavour and almost always lose their bright, attractive colour. For the latter reason they are unsuited for garnishing, but for other purposes the colour may usually be restored with a little cochineal. Strawberries combine well with raspberries and several other kinds of soft fruit, and make an excellent filling for fruit shortcakes.
Strawberry Charlotte. Either fresh or tinned fruit can be successfully used to make this sweet. Prepare "it by dissolving a pint packet
of lemon jelly in $\frac{3}{4}$ pint hot water, then pour
a little of it into the bottom of a mould and leave it to set. Stalk and wipe a few small strawberries, dip them in jelly, arrange them in a ring in the mould, and in the centre put a

Strawberry Charlotte, made with iresh or tinned fruit, lemon jelly and sponge fingers
few diamond-shaped pieces of angelica, also previously dipped in melted jelly. Leave these to set, then cover them with a little more jelly.

While this layer is setting, cut the ends from a few sponge fingers so that they will stand upright, then place them round the sides of the mould, standing them on the jelly. They should reach just to the top of the mould, and if they are too long they should be cut. Mix a few biscuit crumbs with 2 table. spoonfuls of melted jelly, and if there are any cracks between the sponge fingers, fill them up with this paste. Set the whole aside in a cool place.
Make $\frac{1}{2}$ pint of strawberry puréc by rubbing some fruit through a hair sieve. Add 3 oz . castor sugar and 1 teaspoonful lemon juice to the puree and mix them $w \in$ ll. Whisk 1 gill French leaf gelatine dissolved in $\frac{1}{2}$ gill hot be served with it.
water or strawberry syrup. Stir the mixture Strawberry Pie.
water or strawberry syrup. Stir the mixture over ice until it begins to thicken, then turn it into the mould and leave it to set.

When ready, turn it out on to a dish and garnish it with a few strawberries. If tinned fruit is used, the garnish should consist of strips of angelica, and glacé cherries.

Strawberry Fool. Wipe and stalk 1 lb . strawberries and then rub them through a hair sieve, adding to the purce 3 oz . castor sugar and 2 teaspoonfuls
cream until it thickens, then add the fruit until all the fruit and jelly are used; then purce to it gradually, and lastly strain in $\frac{1}{2}$ oz. leave the whole to set. Whipped cream may lemon juice. Mix with a pint of rich custard and whisk well.

Strawberry Fritter. Only the large, firm strawberries are suitable for fritter making. Dredge them well with sugar, sprinkle them with kirsch and leave them in a cool place for about $\frac{1}{2}$ hour. Then dip them in batter and fry them for a few minutes in a dcep pan of smoking hot fat. Drain them thoroughly, dish them on lace. paper and serve them sprinkled with more castor sugar.

Strawberry Jam. In making strawberry jam, $\frac{3}{4} \mathrm{lb}$. to 1 lb . sugar should be allowed to every lb. of fruit. Stalk and wipe the
strawberries, put them into a preserving pan and cook themslowly until some of the juice has been extracted. Then add the sugar and continue cooking slowly until it has dissolved. The jam should then be boiled steadily for an hour, when it may be put into pots and tied down.
Strawberries and gooseberries together make an excellent jam. To prepare it, top and tail 6 lb . gooseberries and pick over an equal quantity of strawberries. Put them into a preserving-pan with $1 \frac{1}{2}$ pints water, add 10 lb . sugar and cook the jam slowly until the sugar has dissolved. Then bring it to the boil, boil it for about 1 hour, and turn it into pots.

Strawberry Jelly. A tin of strawberries in syrup, $\frac{3}{4}$ pint hot water, a pint packet of strawberry jelly, and a few pieces of angelica are needed to make this sweet. Dissolve the jelly in the hot water and add to it a gill of strained syrup from the tin of strawberries. Rinse out a mould with cold water, set a little of the jelly in it, and then decorate it with the angelica dipped in jelly.

When these are set, pour over a little more jelly, let it set, and then add a layer of strawberries. Continue with these strawberry layers

Strawberry Jelly, made with tinned strawberries, and decorated with small

Strawberry Pie. To make this, line a greased pie-dish with some short-crust pastry, then fill it with strawberries, strewing these thickly with castor sugar. Put on a top crust, make two or three slits in it with a knife, so that the steam may escape, and bake it in a hot oven till it is lightly browned. When it is done, dredge the top of the pie with some more castor sugar. It should be served quite cold, accompanied by whipped cream.
Strawberry Pudding. A cold strawberry pudding can be made by lining a puddingbasin with sponge cakes, filling up the centre with strawberries, gently heated in syrup, and then covering then with more sponge cakes. Cover the pudding with a weighted dish, and leave it to get cold before turning it out and serving with cream.

STRAWBERRY - RASPBERRY. This plant is often wrongly described as a hybrid between the two fruits, but it is a bramble or rubus. The plant is very attractive with its bright green leaves, white blossoms, and red fruits, but the latter are most palatable in a cooked state. See Raspberry.

STRAWBERRY TREE.
The hardy evergreen strawberry tree produces white or blush-coloured flowers in spring and summer, followed by globular reddish fruits somewhat resembling strawberrics. See Arbutus.

STRAWBOARD. Strawboard is a form of cardboard commonly brown in colour which is chiefly used in the home for packing purposes, as, for instance, in sending pictures or other articles through the post.

STRELITZIA. This striking plant is suitable only for a large heated greenhousc. It has broad leaves and the blue and yellow flowers are on stems 5 ft . or more high. Owing

Strelitzia. Curiously shaped blossom of the greenhouse perennial plant that is sometimes given the name of Bird of Paradise flower
the botton corners, or coats buttoned up and with the sleeves turned in could be used in the same way. Where it is available a light door or gate, which can be taken off its hinges easily, makes a good stretcher in an emergency.
In carrying a sick or wounded person on a stretcher, certain rules should be observed. The bearers do not keep step, the front man stepping off with the left foot and the rear with the right. The object of this is should be 5 or 6 in. long and about $\frac{1}{2}$ or $\frac{3}{4} \mathrm{in}$. to diminish the swing wide. It is forked at boith ends so that the of the stretcher. The string can be wound upon it. This shoukd patient is carried feet he tied very tightly and only a little at a time foremost cxcept when so that the needle will slip casily through going up a hill or up the loops.

The work consists of netting, which is a series of loops linotted cvenly. To begin with, the worker should make a foundation loop with a separate piece of string. This should be about 10 in . long, and its curls knotted together. It should then be slipped
cup), for example, string or tape is irequently tied around it to keep the pieces together until the cement sets. The same use is made of string in glueing together $\Omega$ box, the leg of a table, etc. For mending or for making sacks, string threaded through the cye of a specially large needle is used. See Macramé ; Netting; Parcel.

STRING BAG : How to Make. A string bag is fairly casy to make. To make one that will hold six tennis balls, the only requisites are a ball of string, white string, strong but not too thick, being the most suitable, a netting necdle (see pagc 846), and a piece of woorl, rescmbling an ordinary rule. i.c., about 12 in . long and 1 in . wide.

The netling needle should bo of woorl or bone. The needle, or mesh, as it is called,
to their brilliant colouring the strelitzia is stairs. If, however, a . Hower. It may be grown in large pots or in a trunk. A stretcher must never be carried bed of soil; a suitable compost consists of loan with sand and decayed manure or leaf-mould. Propagation is hy division.
STREPTOCARPUS. This is the name of a family of dwarf, greenhouse perennial plants that bear comparatively large Howers of many colours-blush, crimson, purple, rose and so on. They are raised from seed sown in early spring in pots or boxes of loam, leaf-mould and sand, and kept in an average temperature of $50^{\circ}$ with plenty of inoisture during the months of summer and autumm. Young plants may be placed in a cold frame during the summer. As soon as the seedlings are large enough they should loe shifted into 3 in . pots, and a further shift may be made later on, if the young plants thrive and are sturdy. Flowers are produced, as a rulc, about 6 months after sowing. See Greenhouse ; also illus. below.
STRETCHER: How to Make. stretcher may be improvized by taking two poles, broom-handles, or something of the sort, and rolling each up in a side of a blanket till they arc about 2 ft . apart. The blanket is fixed in this position, and two pieces of wood are tied across the poles, one at the head and the other at the feet, to prevent the poles coming together. Instead of a blanket two sackis will serve if the poles are pushed through

Streptocarpus. Greenhouse plant with petunia-like flowers in pink, white or blue. See article above
on the shoulders or over a high wall, as one of person thrown off. See Bandage ; First Airl

## STRETCHER

## In Woodwork. In

 woodwork stretcher is a piece of wood joining two rails which is used for st rengthen ing the framework of cabincts, tables, chairs, and other forms of construction. See Cabinet Making; Chair: Sidehoard.STRING. There are so many uses for string in every household that it is generally a good plan to keep a ball of medium thick twine in a box, or in a canister with a hole in the lid. Many housewives keep a string bag, often hanging it on the back of a hall or kitchen cupboard door, in which they
lengths of string removed from parcels.

If parcels of some weight have to loc carried any distance it is a convenience when tying them up to make a handle. The string is passed twice round the longest side and scveral inches apart, and around these two a length of string is passed across and across three or four times. The loose end of the string is then twisted round the strands, and between them and itself to form a handle, closely covered with buttonhole stitch.

With a heavy parcel it is best to start as above, but to twist the string round a number of times. A piece of intout, pliable cardhoard as wide as the handle should be wound over the strands and made fast with gum.

Kitchen Uses. In the kitchen fine string is most needed for tying down jam jars, trussing fowls and preparing joints for the oven. For tying down the cloth over a pudding basin a stouter string will be required, also for tying to gether the feet of a turkey, goose, ctc., that it may hang in the larcler. Snall ends of string can be utilized to make loops with which to hang up litchen utensils to hooks, etc. A picce of fine string will cut a bar of soap.
The use of string in mending is usually

Stretcher : how it may be improvised. Two poles about 8 ft . Iong are rolled into the sides of a rug or blanket till they are about 2 ft . apart. The cornera of the rug are then tied to the poles and cross-pieces of wood are fixed on to prevent the poles being drawn together by the patient's weight
over the knob of the chair, or on a nail, or any thing else that will allow it to be pulled at a height convenient to the worker. Having arranged the foundation loop with an ordinary knot, the worker should fasten it to the end of the string that has bcen wound on to the needle.

Then, taking hold of the mesh with the left hand, he should wind the string, marked A in the diagram, from the needle once round the mesh and pass it through the foundation loop. He next draws the mesh up to the foundation loop, and places the first finger of the left liand upon the string $B$, at the point $C$. He next casts a loop of the working thread and passes the neerlle to the right of the foundation loop, hetween it and the mesh and through the loop which has just been east. This enables the worker to form a knot which he can then draw tight against the first finger, which sloould be kept on the string $B$ until this is done. It is important to bear in mind that the string is drawn towards the worker, not upward.
Fifteen stitehes or loops should be cast in this way on to the foundation loop. The mesh may then be slipped out and removed, while a complete turn is given to the foundation loop on the nail. The work is turned over so merely temporary. In mending a broken that the work is begun on the left-hand side
finished off on the right. This strip, ready turned for the first stitch on a new row, will be seen on the bottom of the diagram. The next row is continued in the same way, but a
again, but at the same point at which it was gathering, thus giving a much neater effect. surface. At the present day it is mainly Before stroking can be dune, the gathering thread must be drawn up tairly tight and wound round a pin inserted in the material at the left end of the gathering. The cotton restricted to cal

## mixture of sand.

Stucco was once used extensively for internal decorative plastering, such as for forming cornices or mouldings, and de-
 coration of ccilings. It was composed of pulverized narble and gypsum, mixed with fine sand and clean water, and it hardened gradually, thus giving opportunity to work it into the design, which the plasterer did with the aid of small sted tools.

This kind of stucco has been superseded in Great Britain by stick and rag work. Mouldings are cast into the shape required and kept rigid with the aid of canvas; after these are placed in position, the joints are made
scparate loop instead of the foundation thread should be taken up.
The whole bag is made in this way, row after row of knotted loops being worked from left to right. The work must be turned on the nail after cach row. After about $2 \overline{5}$ rows it will be found that the strip of netting, when it has been doubled in half and joined up at the sides, will be long enough to make the bag required. To finish it off slip the mesh out of the last row and neatly cut off the necdle string. Then take out the foundation loop and join up the sides as though they were being sewn, using the fingers as the needle, poking the string through the loop, and joining with a knot top and bottom. The bag is then complete except for the draw-string at the top. This should be threaded through the loops which form the moutll of the bag. It should be about 20 in . long and of stouter string than the bag itself. The ends should be knotted after it has been threaded through the loops at the neck of the bag. See Netting.

STRING BOX. For holding string, boxcs are obtainable in wood and netal. The wooden box is turned from hardwood, generally provided with a cutter. Metal boxes are composed of two half-spheres hinged together: some are provided with a ring for hanging and others have a metal base to stand upon. Boxes in wood pulp and papier mâché are obtainable which can be decorated by stencilling or other forms of painting. See Italian Renaissance Work: Lacquer Work; Pattern Printing, etc.

STRINGING. Stringings mean very thin lines of inlaid wood put round panels and the edges of constructional parts of furniture. Satinwood stringing on mahogany is used to give a light line on dark wood, and cbony to give the opposite effect. Stringing was much used by Sheraton and other makers - at the end of the 18th century. See Inlaying; Parquet; Sheraton.

STRIPPING KNIFE. The knife used for stripping off old wallpaper and paint consists of a broad blade with a straight handle, the blacle being so tempered as to give slightly when pressure is brought to bear upon it. After first wetting the wallpaper the linife is inserted under it and the paper peeled off in strips. With old paint this knife can only bo used on large areas, when a good deal of ground can be covered in a short time. The paint is scraped off with the knife after it has been burnt with the blow iamp. The stripping knife must be used in the direction of the grain of the wood. See [ainting; Paperhanging.

Stroke. See Apoplexy ; Paralysis.
STROKING : In Needlework. This process consists in placing side by side, in even folds, the little Hutes made in material by
must not be broken off, as the gathers are afterwards released to the size required.
Take the material in the left hand, with the right side of the fabric towards you; then take a needle in the right hand, with the point upward. Beginning at the left hand end of the work, raise each gather gently with the point of the needle, and stroke down into the little ruck which lies between, moving it gently to the left, so that it is placed under the thumb. Repeat this process until all the gathers are stroked under the thumb; then release the cotton at the left end, to make the gathering the desired size, and fasten off.

Care must be taken to stroke the portion of the material above the gathering thread, as well as below it, and

to use a blunt-pointed tapestry embroidery needle for the stroking. See Gathering.

STRYCHNINE. The action and the medical value of nux vomica, the dried seed of an East Indian plant, depend almost entirely upon the strychnine which it contains.

Strychnine is one of the ingredients of Easton's syrup, and is valuable in many tonic digestive mixtures, acting as a stomachic and carminative. It is largely employed in the treatment of chronic heart disease and is an ingredient of expectorant mixtures in inflammation of the lungs or bronchial tubes. Strychnine should never be taken except under a doctor's immediate supervision.

STUARTIA. Growing up to 10 ft . in height, the beautiful shrub stuartia has nearly oval, toothed, pointed leaves and large white flowers in summer. It thrives out of doors, but should be planted in a sheltered sunny position. Ordinary soil can be made suitable by adding leade-mould and peat. Propagation is most casily carried out by sowing sceds, but layering may be done in late summer. The best kind is Stuartia pentagyna, which bears large white flowers stained slightly with red.

STUCCO. This term has been applied in a general scnse to the plastcring of walls with any material designed to produce a finished
good with plaster of Paris, in a mastic state.
The materials used for trowelled stucco, that is, the kind that is used as a finishing for 3 -coat plastering, are lime-putty mixed with clean washed sand. 'Such materials form a setting coat, having a smooth and hard surface, and should always be used in the case of ceilings that are to be treated with distempers. Where a rough surface is desired, the stucco may be brushed over with a wet distemper brush just before it sets. It is not advisable to use this kind of stucco externally. See Cement; Plaster.

STUD : In Engineering. A stud or studbolt is a headless bolt with a screw thread formed at each end and an unscrewed portion between. It is screwed tightly into some fixed member, and the projecting end, in conjunction with a nut, serves to hold in position some other part, e.g. the detachable cylinder head in an internal combustion engine. See Bolt ; Nut.

STUDY: Its Fittings. When it is possible a light, airy room on the quiet side of the house should be chosen for the study. There should be a good heating arrangement and convenient artificial lighting, as it is difficult to do the best mental work when handicapped by any degree of discomfort.

With regard to the treatment of decoration and furniture most people would wish to aim at harmonious repose for the former and comfortable efficiency for the latter. Some would feel keyed up to work in a bright but austerely furnished study, while others would prefer the more conventional style illustrated in Fig. 1.

A restful room of this type could be treated with dove-grey walls and ivory woodwork and ceiling, a deeper grey carpet with purple border, and the windows curtained with purple velours and ivory net. Touches of dull pink and yellow could be introduced in the cretonne covers.

A brighter room might have walls of duck egg green and furnishing fabrics in autumn leaf tints. A cretonne in old English needlework design would then be a good choice for curtains and any loose covers.

Some people prefer the bureau type of writing desk because of its more charming appearance in a room, but the flat-topped desk is more comfortable to work at than a bureau.

In many cases the owner of a study requires more than one or two small shelves for the accommodation of his books, and a bookcase with glass doors, which keep out the dust, is added to the furniture.

The second illustration shows the very business-like study of Mr. Edgar Wallace. Comfort and colour are supplied by the rich tones of carpet and rug, the floor cushion, and the velvet furnishing fabrics. The modern note is well emphasized in the two chairs with

Study. Fig. 1. Spacious and well-lighted study with conveniently placed desk, roomy bookshelves and comfortable chairs for moments of relaxation
tubular steel frames, in the writing table and in the severely plain bookshelves.
There are wull-designed tables and ornamenal covers for typewriters to be had which will harmonize with most furnishing schemes. A filing cabinet is often required and a cupboard with shelves in which to stow away stationery. The desk chair is $n$ matter of individual taste, but a comfortable armchair in which to sit while reading, a fair-sized, solidly made table, and a good reading lamp may be considered essential.
Over a desk or low bureau, placed to the right of a window, near a corner of the room, an angle arrangement composed of two shelves which allow the requisite depth between them for reference books makes a useful corner treatment and a pleasing one if an attractive piece of china is placed on the top shelf. A small c:uphoard let into the wall near the desk is convenient for the telephonc. See Bookcasc Library; Writing Table.
STUFFING: In Cookery. Stuffing is a savoury compound which is combined with meat, game, or lish in order to impart a rich or special Havour. Stuffing may be used to fill hollows, it may be laid between two Hat portions of food, or, on the other hand, it may be converted into a coating.
If meat is boned it is often stulled, while if made into a galantine a certain quantity of stulling is mixed with the other ingredients which help to form the filling. Stulting also is added to meat and poultry served whole. Veal is accompanied hy what is known as veal stufting, or forcemeat, and pork by sage and onion stufling; poultry and game may be stuffed with a lage variety of forcenkats, flavoured and seasoned in a suitable manner, but always made very savoury.
In meat the stuffing is inserted by raising up the skin covering a hollow or convenient place for pressing in a sulficient quantity; the position varies according to the nature of the joint, but the stufting must be so placed that there is a possibility of equal distribution when carving takes place. It must be entirely corered when in the joint and fastened in place serurely, or it will escape in the dripping pan.
In poultry or game the stufting is pressed under the breast from the neck end of the bird. Sometimes a portion of it is inserted through
the vent under the lower part of the breast Hares and rabbits are stuffed where the internal organs have been removed, and the hole should then be sewn up.

The practice of cooking stuffing apart from the food it is intended to flavour cannot be rccommended, as the meat is prevented from absorbing the savoury ingredients while it is cooking. Stuffing made up into balls is added to meat pies to enhance the flavour.

Most varictics of fish may be stufferl. If the fish is whole the stuffing is inserted where it has been gutted, the opening is sewn up, and usually the fish is trussed round or in the shape of an S. Sometimes the stufting is used as a lilling for fillets, and often two small fish may

they are soft, in enough water to cover them. They are then rubbed through a sieve and mixed with a lump of butter about the size of an egg, and a sprinkling of seasoning. Sec Forcemeat; Goose; Turkey; Veal; etc.

STUPOR. In coma the patient cannot be roused by any means, but in stupor bo may be roused by speaking londly to him, or by some other form of stimulation.

A large number of causes may give rise to this condition, c.g. concussion of the brain, as a result of a blow or a fall; compression of the brain, by a fracture or a tumour ; epilepsy, abscess of the brain, meningitis. asphyxia; poisoning by opium, chloral, alcohol, and other narcotic drugs.
One of the most difficult cases to diagnose is that in which a man is found in a state of stupor, and smells of alcohol. The tendency is to suppose that the man is very drunk, but he may have taken only a little alcohol, while his condition is due to some one of the causes enumerated above. Mistakes are sometimes made with serious consequences to the patient. When there is the least doubt the person should always be assumed to be ill, and be treated accordingly. See Coma.

STURGEON : How to Cook. The flesh of the sturgeon is solid, white, and not unlike veal. When fresh the veins and gristle have $a$ blue appearance, and the grain of the ilesh is even ; if the veins are brown or dingy in colour the fish is not good. The roe is preserved, and in the form of caviare it is highly valued as hors d'oeuvres. The isinglass manufactured from the air bladder is superior to gelatine for the purpose of stiffening jellies and creams.

After cleansing, the skin of the sturgeon should be loosened with a sharp knife, starting from the backbone and dealing first with one side and then with the other. The skin is then laid over the fish again and fastened with string or tape. It is better thus to loosen the skin before cooking the fish, as it is uot good served with it, and loosening facilitates dishing.
To boil sturgeon, take half a small fish and put it into a fish kettle, just cover it with water, add the rind of half a lemon, 20 black peppercorns, a small stick of horse-radish, and 1 gill of vinegar to each quart of water. Cook from $1 \frac{1}{2}$ to 2 hours very gently, then drain the fish, remove the skin and serve with a good piquant sauce.
A favourite method of cooking sturgeon is to roast it. Cleanse 3 lb . of fish and remove the skin, but do not replace it. Dust each side of the flesh with salt and pepper and then lard it closely or cover it with thin slices of fat bacon, which should be tied on. Butter a thick sheet of white kitchen paper and lay over it 2 prepared and sliced onions and 2 carrots, also prepared and sliced, 1 dessertspoonful sifted dried sweet herbs, and 1 tablespoonful chopped parsley.

Wrap the fish completely in the paper and secure it. If the paper is not very thick it would be best to use it double. Melt 3 oz . butter or good beef dripping in a baking tin, lay the fish in the tin, and balse it from 1 to it hours, basting frequently. It must cook rather slowly. To serve the fish remove the fastenings and paper, and if it is not well coloured return it to the oven to brown, then brush over the top with glaze and serve it very hot. A well-flavoured brown sauce may be handed round.

Sturgeon may be roasted like veal, stuffed with a good veal forcemeat. Let it be well basted with butter and served with thick brown gravy. One way of dishing it is to pour over it when dished a good brown sauce. Garnish with cut lemon and little rolls of bacon.
Sturgeon is sometimes cut in small steaks, and these should he broiled. Prepare and
cut the steaks, which should be about $1 \frac{1}{4} \mathrm{in}$. thick. Cover each with egg and fine seasoned crumbs, wrap them in buttered paper and broil them over a slow, clear fire. Serve them with anchovy sauce. A little chopped parsley may be added to the breadcrumbs.
For fillets of sturgeon prepare about 2 lh . of the fish and cut it into fillets. Melt 2 oz . hutter in a saute pan. put in the fillets and cook them very slowly. When done on one side turn them and cook the other side: they will take about 20 min ., but much depends on how thick they are cut. When tender, take them up and serve hot with a good brown sauce or Genevoise sauce. See Caviare; Forcemeat; Isinglass; Sauce: Veal.
STYE: In the Eye. Inflammation of a little gland at the root of an eyelash results in a hordeolum or stye. This is a painful swelling which soon suppurates, the matter, if it bc left to itself, finding its way out, usually through the inner lining of the lid. It will shorten suffering, however, if the affected lash is pulled out and the little abscess opencd as soon as matter has distinctly formed. Until then hot applications, for example boracic fomentations, should be made.
Not uncommonly one stye is followed by a succession of others. The eye should be washed regularly with boracic lotion for some time after a stye. A lotion or drops of sulphate of zinc is also sometimes required. The general health may be depressed and require tonic treatment, and constipation if present must be corrected, as a habit of this kind may be responsible for styes. See Conjunctivitis; Eye.

STYPTIC. A drug or other agent used to stop capillary bleeding by contracting the blood vessels and furthering clotting of the blood is called a styptic. Very hot water has the same effect. Amongst the drugs used in this way are perchloride of iron, tannic acid, the salts of copper and lead, calcium chloride, hazeline and adrenalin. Cobwebs applied directly to a wound act as an effective styptic, but should never be used in view of the danger of poisoning the wound. See Bleeding.
STYRAX. This hardy shrub thrives in well drained loany soil with which leaf-mould has been mixed, and in a sunny sheltered place. One of the best kinds is styrax japonicum, 15 ft . or more high, with white flowers in summer. Styrax Obassia, a japanese white-flowered shrub, is also beautiful. The gum resin called storax is obtained from styrax officinale.

SUCKER. To the gardener a sucker is a shoot rising from the subterranean stem of a trec or bush. Such can be used for propagation purposes, as in the case of the raspherry. The suckers which develop on the stocks on which roses, fruit trees and certain shrubs are grafted or budded ought to be pulled up and destroyed. See Apple Sucker; Plum; Propagation; Pruning; Raspberry.

SUCKING PIG. Usually the pig can be purchased ready for dressing, but, if not, it must be thoroughly cleansed, particularly the nostrils and ears, as the head is served at table. Cut off the feet at the first joint, loosening the skin and leaving enough to turn under. The pig should then be stuffed with sage and onion stuffing as for roast pork. Scw the stuffing up inside the body of tho pig, then roast it as for roast pork.

To cook this dish to perfection the Hesh should be basted first of a!l with brine, then pour it away, and baste thoroughly and frequently with butter. Serve with rich gravy well flavoured with lemon juice, and hand round apple sauce.

The sucking pig should not be more than 3 weeks old, and it will take about 2 hours to cook. It is served split in half. And the snout and jaws should be trimmed off, leaving
only the cheek and cars and the outline of the snout and jaw. Sucking pig is sometimes stuffed with the chestnut stuffing used for turkey. See Pork; Stuffing.

SUEDE. Obtaincd from shcepskin dressed soft and finished on the flesh side with a very fine nap, suède can be sewn and worked for all purposes just as easily as velvet. Suède is utilized largely in the manufacture of gloves, shocs, handbags, belts, hats and sports coats. Artificial Howers are made from it, and it is dyed to many different shades.

Care of Suède Shoes. Wet suède shoes should be placed on shoe trees or stuffed tightly with paper and left to dry. They should not be dried in front of the fire, as this causes the leather to split. If they are mudstained, they should not be brushed until they are thoroughly dry. Like all other suede goods, they may be cleaned with petrol (see page 935 ), the latter being applied with an old toothbrush. The pilc or nap may be restored with sandpaper or with a small wire brush which is sold for the purpose.

The best micans of cleaning coloured suèdes that have become soiled in wear is by the use of the many coloured dry cleaners marketed for the purpose. Grease and other stains are best removed by rubbing briskly with a piece of suèle, or a piece of chanois leather, used dry without any lubricant at all. Glass paper is also useful for removing obstinate stains. The employment of petrol, benzine, and other spirits is not advised for red and otller brightly coloured suèdes. They will remove the stain, but may also cause the dye to fade and so give the leather a patchy appearance. Suède so treated will need to be redycd in order to restore its original colour. sce Cloth Pall; Glass Paper; Gloves; Leather.

SUET: In Cookery. The fat which lines the loins and kidneys of sheep and bullocks furnishes the suet which is indispensable in cookery for making puddings and for other purposes. The best is that which surrounds the kidneys, and is commonly called kidney suet.

When suet is received from the butcher it should be examined to see that it is frce from taint, as the slightest defect of that kind will probably spoil a whole dish. To prepare it, the skin is first removed and the suet is sliced up into flakes. It has then to be chopped finely. The success of the cooking depends to a groat extent on the skill and thoroughness with which the chopping is done. Suet graters can be bought and do the work more quickly than it can be clone with a knife.

Suet should be firm enough to chop without the necessity of adding flour during the process, but if the weather is close and the fat scems unduly soft, flake it, then add the whole quantity of flour needed for the pudding and finish chopping. By adding small quantities of flour, as is often done when chopping suet, the fat is merely worked into a paste and cannot be successfully mixed. It should be remembered that extra flour added for chopping purposes destroys the proper proportions and takes away from the quality of the dish.

To keep suet for a few days the best plan is to remove the skin, chop the suet and put it into a dish, covering it with flour. The fat must be entirely covered, and an account must be kept of the amount of flour used. The practice of burying a lump of suet in the flour tub, unskinned, is not good. The skin quickly becomes tainted and it then contaminates the flour.

SUET CRTST. For making dumplings and roly-poly, and also for covering meat or fruit puddings, a suet crust is made as follows: Chop finely 10 oz . suet, and mix it lightly with 1 lb . household flour which has been sifted, with $\frac{1}{4}$ teaspoonful of salt. Work these
ingredients into a tairly stiff paste, using about $\frac{1}{2}$ pint cold water. Some housewives add baking powder to suct crust (see Apple Pudding), others considor that any raising agent should be avoided in the niaking of this crust.
The pudding should be perfectly light if the suet is properly ehopped, the dough skilfully handled and not made too moist. A pudding may either be cooked in a greased pudding basin, covered with a greased paper, or as in the case of a roly-poly, tied up in a floured pudding cloth. The pudding is plunged into fast lioiling water and kept boiling the whole time of cooking. When inixing, pour the water

## Sugar: Its Uses in the Home

## Consideration and Comparison of Kinds and Qualities

This coneribution is connested with a great number of other entries in this Ensyclopedia, nolably the cakc, preserve and sweet making recipes in which sugar is used. See Chocolate; and sweet making recipes in which sugar
Diet: Food; Jam; Sweets; Toffee, etc.

For home consumption sugar generally consints of loaf or lump sugar, granulated, castor, icing, and the varied forms of yellow or brown sugars. The very first consideration when buying any of these should be to ensure quality ; the purchasc of an inferior article is no economy in housekeeping, as inoist, sticky sugars, ceven if slightly cheaper in price, are heavier in proportion to the pure crystals, while their swectening power is considerably lower. The white crystalline sugars are the purest, and usually are frec from the impurities frequently found in loose or brown sugar. Loaf sugar is not often adulterated, and the quality is easy to detect from the appearance. It should lee clean looking and sparkling.

One or two rulcs for distinguishing good sugar from inferior may be useful. A gond white sugar should look very dry and highly crystallinc, also when rubbed lietween the finger and the thumb it should be free from any feeling of stickiness, and should never appear clammy. Good cane sugar should be casily soluble, and may be tested with water. If dissolved in half its weight of cold water, and found to be free from sediment of dirt or pieces of foreign matter, it is absolutely pure.

White Sugar. Lump or loaf sugar may with advantage be employed not only for table use. but for a! the most delicate kinds of calies and sweets. For use in cookery it needs, unless it can be dissolved in liquid, to be pounded in a mortar and passed through a finc sieve, and the rougher portions which remain must be pounded again and sifted until the whole is a finc powder.

White sugar should always be used for making jams and marmalade; not only is a greater degree of sweetening principle obtained from it, but the jans will be clearer and a hetter and brighter colour. In some country districts moist sugar is used for jam making, but the preserve then has a rough taste as well as looking cloudy. Of course, something depends on the quality of the sugar. Summer and invalid drinks, also home-made wines, should be sweetened with loaf sugar. The more delicate kinds of toffees should be made with this sugar, and jellies should be sweetened with it.

Granulated sugar is a purer variety of white sugar than inferior castor sugar, but for some cookery purposes, also for table use, it is rather coarse, and not so easily or so completely soluble as loaf sugar. It may be employed for swectening fruit in pies, in puddings, for large cakes, and it is often used for making jams and marmalade. A large white crystal sugar is specia!ly sold for use with coffec.

Castor sugar, which is a pounded form of lump or loaf sugar, should have a bright, dry appearance, and the tiny crystals should also be well defined and even, as in granulated sugar. It is most suitable for table use, and also for swectening delicate cakes where a spongy consistency is needed. It is likewise
into the centre of the basin and work in the four round the sides as quickly as possible till all is mixed, but take care that the whole is smooth and the ingredients properly incorporated. The paste should he firm and no moisture should appear when it is cut or rolled. If a richer crust is desired the quantity of suct may be slightly increased.
The time required to cook plain suet or rolypoly puddings varies from $1 \frac{1}{2}$ to 2 hours, according to size. Fruit puddings take aloout the same time. See Apple Roly-Poly ; Dumplings; Plum Duff, etc.

Suffocation. See Artificial Respiration; Asphyxia; Drowning.
sugar, but is readily digestible by infants, and has a slight diuretic and laxative effect.

Malt sugar, or maltose, is obtained by treating the starch of barley with the ferment diastase. It readily undergoes alcoholic fermentation. It is impossible to lay down any general law as to the amount of sugnr which should be includerl in any particular individual's diet. A point to be remembered is that sugar has a cloying or satislying effect, and therefore it should be caten at the end of a meal.

A proportion of sugar must be maintained in the blood and, as neccssary, glycogen is changed back into glucose and added to the blood stream. The proportion in animal blood is from 0.08 to 0.04 per cent. If the amount in the blood is too high sugar appears in the urine; but in the condition known as kidney diabetes sugar is apparently able to pass into the urine although the proportion of blood sugar is not raised. Sugar appears to take
the place of alcohol and to diminish the tendency to build up a taste for the latter.

The handling of sugar sometimes produces dermatitis of the hands and forearms, a condition which among grocers is called groeer's itch. When unrefined sugar is being handled it is thought the irritation may be due to the sugar mite, an insect which resembles the itch mite, and which occurs in such sugar. Fat children who take an excess of sugar nay suffer from cezema, and symptoms of rheumatism are also sometimes a result of excessive use of this food.

SUGAR BASIN. The receptacle for sugar may be an ordinary basin, but it is usually more claborate when sold separately or as part of a tea service. Sugar basins are made in glass, china, pottery, plated metal, or silver, in old and modern styles.

Often they are made in plated metal or in silver to match a milk jug and teapot in reproductions of Queen Anne and other classic styles. An carly form of the sugar hasin is the glass bowl sometimes found in a tea caddy. Sugar basins in antique silver and Sheffield plate are valued by collectors. Some early picces are embossed. Others of a somewhat later date are adorned with pierced and fretted trellis work, a decoration which necessitated a glass lining. This was usually blue in colour, but occasionally crystal. An example of such a basin, or basket, is illustrated in Fig. 1. It has a swing handle and a head erlge. In page 1144 a round basket of the same period, but made in Shefficld plate, is shown. Some fine examples are supported on conomy in buying it, as the sactharine principle is very deficient and the quality altogether inferior. Foots sugar is the moist syrupy sugar which lies at the bottom of the hogsheads of raw sugar. It was at one time used for toflee. At yellow crystal sugar, not unlike sugar candy, is preferred by some people to the white crystal sugar for swectening coffec.

Food Value. From the medical standpoint sugar is one of the most valuable foods, because it is a source of body hent and energy. Canc and grape sugar are composed of carbon, hydrogen and oxygen. Cane sugar, although ohtained chiefly from the sugar cane, is also manufactured from bectroot, carrots, and the sugar maple. Glucose, grape, and starch sugar are found in various fruits; they are prepared artificially from cane sugar, starch, and dextrin. Glucose has not the same rlryness as canc sugar, and will attract and absorb moisture. When cane sugar is moist it is often due to the presence of grape sugar.

Milk sugar, or lactose, which is found in nilk, and nay be separated from it as a tine white powder, is much less sweet than ordinary
used in making meringucs, custard and whipped cream mixtures, whips, some glazes, and is

A nother form of white refinell sugar is icing sugar. This is white sugar pulverized until it resembles a fine powder, and the greater the extent to which it is pulverized, and the finer the powder, the higher the quality of the icing sugar will be, and the better the use which can be made of it for cooking cakes and for decorative icing. However good the sugar, it must always be treated by further sifting before it is used for cake icing. A fine hair, tammy, or silk sieve should be used for the purpose.
Brown Sugars Of all brown sugars Demerara ranks the bighest. It should be a golden brown colour, and the erystals should be dry and separate. It makes a good porridge sugar, and is sometimes used for coffec. It is useful for sweetening lunch, rich large calies, and many varieties of puddings. Demerara is occasionally adulterated, a kind of yellow crystal sugar being sold as a substitute for it which is made from bect sugar and dyed.

Barbados is a rich moist sugar, hrown in colour. It is, when pure, very good for mixing in with dark coloured puddings, or any description of gingerbread : it is also used for clark toffees, in the pickle made for snlted and spiced meats, and in chutneys. It is not suitable for sweetening fruit when cooked, as it imparts an unplcasant syrupy taste, and also spoils the colour of the juice.

A cheap sugar called white moist is sometimes sold, but there

Sugar Basin. Fig. 1. Example in pierced silver work, lined with blue glass, 1785. Fig. 2. Fluted sugar basin on ball feet Courlesy of Chapple \& Muntell
ball and claw feet, or on lion's paw or ball ammonia, lime, and potash, are of great value fect. Sometimes the basins were made with covers. Fig. 2 shows a fluted sugar basin, with gadroon border, scroll handles, and ball fect. dating from early in the 19th century.
SUGAR CANDY. Being a pure and wholesome sweetmeat, sugar candy consists of sugar crystallized and dried in an even, hot temperature. The crystals are formed on strings, but as special vessels are necessary 10 do this, it is scarcely possible for an amateur to attempt making it.
SUGAR CASTOR. A sugar castor or sugar dredger is employed to sprinkle castor sugar over fruit tarts, stewed fruits, etc., after they are brought to the table. It is usually very similar in shape to a muffineer (q.v.) or pepper pot, though larger, and, like a inuffineer, is provided with a conical or round, screwed-on, and perforated lid.

Sugar castors are frequently made entircly of silver or silver plate. Sometimes the lid alone is of silver, the rest of the castor being cut glass or china. Collectors' examples in silver date from the end of the 17 th century. Queen Anne shaped castors were often octagonal, the picrced top surmounted by an octagonal knob.

SUGAR SIFTER. This is a spoon used for scrving sugar. The distinctive point about the article is the pierced bowl which enables the sugar to be sifted as it is put on to the food. Sifters, which are usually of silver or electroplate, can bo purchased either separately or with a sugar basin.
SUGAR SOAP. This is the name given to a soap in powder form used for washing down paintwork before repainting. It can be had from an oil and colourman. See Paint.

SUGAR STICK. This sweetmeat can be varied by changing the colour and flavour, and needs to be stored in airtight bottles. l'repare the sticks by dissolving ${ }^{\text {a }} \mathrm{lb}$. granulated sugar in a little more than $\frac{1}{2}$ gill water, and then adding 3 oz . glucose. Stir the whole in a pan over the fire until the glucose has melted; then boil it up to $300^{\circ} \mathrm{F}$. and pour it on to an oiled slab. Flavour with cinnamon, add a little saffron for colouring purposes, and fold the hot candy over and over with a flat wooden spoon, afterwards pulling it out with the hands until it begins to harden. It is then ready to be cut into sticks.
SUGAR TONGS. The pair of tongs which often accompanies a sugar basin is usually of metal, silver and electro-plate being freely used. They arc made with a slight amount of spring, so as to grip the sugar when pressed. A shape often scen is one resembling two spoons fastened together.
SUIT CASE. The lighter types of suit cases consist of a p!ain frame covered with morocco cloth, vulcanized fibre, brown canvas, green drill or some other material of that kind. The licavier ones arc of leather.
A very light weight case has a soft top. Such suit cases are lined with a fnncy material or cotton moirette and are made of leather grained cloth or black or coloured oil baize. Expanding cases are serviceable in reliable and stouter makes. Another type is here illustrated. It is covered with vulcanized fibre, lined with strong material, and the top is fitted to hold six dresses. The bars come forward, for hanging them. The lower portion of the case is deep enough for shoes and other nsticles of clothing.

Suit cases are fastened by snaps or loclis or both. They are made in a variety of sizes. simall ones are 18 in . long, $13 \frac{1}{2} \mathrm{in}$. wide, and $5 \frac{1}{2}$ in. deep, and they can bo bought as large as 30 in . long, 17 in . wide, and 8 in . deep.
SULPHATE: The Fertilizer. Salts that are formed with sulphuric acid are termed sulphates. In the garden, three sulphates,
ammonia, lime, and potush, are of great value
in fertilizing crops. Ammonia can be ayplicd to all kinds of soil, except those containing chalk. It is particularly uscful on cold, heavy ground. It should be applied to the soil before planting, but may be used as an after stimulant in liquid form in the proportion of $\frac{1}{2} \mathrm{oz}$. to a gallon of water.

Sulphate of lime, sometimes called gypsum, is an excellent fertilizer, its action being to liberate silicate of potash for the feeding of crops ; it has the power of fixing ammonia, and is used on manure heaps for that purpose. Sulphate of potash is very soluble, and this quality, in conjunction witl its feeding value, makes ít invaluable for pot plants, flowers, etc.
One of the poisonous winter washes for the cure of black spot, mildew. scorch, and rust, is made with sulphate of copper, also called blue stone. It is mixed with water, in the proportion of 1 oz . to 2 gallons, and carefully applied with a syringe or pneumatic sprayer when growth is dormant. See Bordeaux Mixture ; Lime; Potash.
SULPHIDE. Amongst the sulphides the one known as sulphide of potassium, or liver of sulphur, provides an excellent remedy for mildews in garden and greenhouse. It is simply prepared by mixing 3 oz . sulphide of potassium with 4 oz . soft soap, dizsolving both separately in water, and adding further water to make up to 10 gallons. The solution must always be used when perfectly fresh. It is applied to mildewed plants during summer. See Mildew; Spraying.
SULPHUR: Medicinal Uses. Sulphur is widely used in medicine as a parasiticide. In scabies or itch sulphur ointment is a very valuable remerly; or the drug may be applied in the form of Vleminckx's solution. In the treatment of other skin discases, notably acne and dandruff, it is also a valuable merlicament. Internally, sulphur acts as a gentle laxative, and is often prescribed for children.
Compound liquorice powder, a useful and reliable laxative, owes its action partly to sulphur, which it contains. Sulphur lozenges, containing 5 gr . of precipitated sulphur, one to two at bedtime, are often taken in order to correct constipation, or by the subjects of chronic rheumatism.
The sulphur waters of the natural springs in various parts of the world are used inwardly and as baths for the cure of chronic rheuma tism, skin diseases, and a large number oi other conditions. A su!phur hath at home is made by dissolving 6 oz . potassa sulphurata in boiling water and adding to a full bath, that is to say, about 30 gallons of water.

Suit Case in vulcanized fibre, lined and fitted with bar attachment, over which drasses and akirta may be hung and held in place

SULPHURIC ACID. Oil of vitriol or sulphuric acid is a heavy, oily, lighly corrosive liquid which will destroy any animal tissues and many other substances with which it comes in contact.
Sulphuric acid as used medicinally is always very greatly diluted. Externally dilute sulphuric acid is sometimes used to check slight bleeding. Internally dilute or aromatic sulphuric acid may be used to check acute diarrhoea. It is often given as a daily dose, well diluted for those who work in lead, painters, colour grinders, ctc., as the acid combines with any lead which has been taken into the system, forming sulphate of lead, which is insoluble and harmless. In general debility, diluted sulphuric acid, either alone or with other tonic duggs, sometimes acts as an effective alterative, improving the appetite and generally bracing up the system. It should not be allowed to come in contact with the teeth.
On account of its violently corrosive effect. poisoning by sulphuric acid is a most painful as well as high!y dangerous condition. Violent burning pain, from the lips down to the stomach. with vomiting of bloorl and corroded shreds of tissuc, and collapse, are the chicf symptoms.
While awaiting the doctor, inagnesia, chalk, or soda should be given at once, if obtainable, in water, milk, or olive oil. If these substances are not at hand, crumbled-up plaster from a wall, soapsuds, or mortar, mixed with water or milk, should be given. An emetic should not be given. For the pain, poultices or fomentations are applied to the abdomen. If breathing is difficult put cloths wrung out of hot water round the throat and moisten the air with steam by means of a bronchitis kettle.

Afterwards demulcents, such as white of egg, or olive oil, should be given to soothe the inflamed stomach.

SULPHUROUS ACID. On account of its strong deoxidizing action, sulphurous acid is used as an antiseptic, a deodorant, and a disinfectant. The acid is sometimes applied locally in parasitic skin diseases, e.g. ringworm. Sulphurous acid is sometimes given internally to prevent gastric fermentation. The dose is $\frac{1}{2}$ to 1 Huid dram.

SULTANA. A small scedless raisin with a thin rather light-coloured skin, the sultana is much used in cookery for adding to puddings, cakes and scones. It is considered to possess a delicate Havour, although it lacks some of the full rich taste of the larger secded raisin. Sultanas give better results when mixed with other dried fruits except when a plain fruit cake is desired.

Sultana Bread. This is made by sieving together $1 \frac{3}{4} \mathrm{lb}$. flour and a pinch of salt, rubbing into them 1 lb . margarinc or butter, and then adding and mixing in 5 oz. picked and cleaned sultanas and $\ddagger \mathrm{lb}$. sugar.
Put 1 oz. yeast into a small warmed basin, mix it with 1 teaspoonful castor sugar until it is reduced to liquid and then add $\frac{3}{4}$ pint warm milk. Strain these into a well made in the centre of the four, etc., mix in a little of the latter from the sides, then cover the basin with a cloth and let it stand in a warm place for 20 min .
When this is done, mix in all the flour, adding more warm milk if required. Turn the dough on to a slightly floured board, knead it for about 8 min., then put it back into the basin, cover it and leave it to rise in a warm place for about $1 \frac{1}{2}$ hours. Turn it out and knead it again for a few minutes, then put the loaf of dough into a greased and floured bread tin.

For the third time, let it rise in a warm place for $20-30 \mathrm{~min}$., then bake it in a hot oven for about $\frac{3}{4}-1$ hour. When cooked, brush the loaf over with a glaze made from castor sugar and
milk, putting it back into the oven for a few sceonds in order to dry

Another recipe, in which yeast is omitted, is as follows: Sieve together $1 \frac{1}{4} \mathrm{lb}$. flour, $\frac{1}{2}$ teaspoonful each carbonate of soda and cream of lartar, and $\frac{1}{}$ teaspoonful salt, then add 2 oz . cleaned sultanas and mix the whole with enough water to make a fairly soft dough. Turn this into a greased tin and bake it in a fairly hot oven for $\frac{3}{}$ hour. The bread is improved if buttermilk can be substituted for the water

Sultana Pudding. To make this pudding take 6 oz . sultanas, 5 oz . each of margarine or hutter and of sugar, a lemon, an egg, $\frac{1}{2} \mathrm{lh}$. breaderumbs and some milk. Grate the rind of the lemon and stir this into the breadcrumbs. Wash, pick over and dry the sultanas and beat the sugar and the margarine or butter to a cream ; to these add the cgg. which should be stirred in quickly and beaten for a few minutes. Mix the breadcrumbs and sultanas, adding a little milk as required, and stir the whole well logether.

Put this misture into a greased pudding basin, cover it securely with a well-greased paper, steam it for about 2 hours, and turn it on to a dish. This pudding should be served with syrup sauce. To make this, take 3 tablespoonfuls golden syrup and one tablespoonful each of strained lemon juice and water. Place these three ingredients into a saucepan and boil them together for a few minutes. See Bread; Cake; Scone.

SULTAN FOWL. This is a quaint looking white-crested fowl with cheek mufflings and a beard. It is heavily feathered on the shanks, the feathering being carried right down to the toes, and is vulture hocked like the Brahma: it possesses five tocs, and thus may be akin to the Houdan. The comb is horned The Sultan is not a large fowl, the males when full grown weighing 5 lb . to 6 lb . and the hens $3 \frac{1}{2} \mathrm{lb}$. to $4 \frac{1}{2} \mathrm{lb}$. The hens lay a white egg which weighs slightly under 2 oz . The chiclis, which are creamy white, are very hardy, and show the leg and foot feathering immediately they le we the shell. See Fowl ; Poultry.
Sumach. This is the popular name of a group of ornamental hardy shrubs, linown botanically as rhus (c.v.).
SUMATRA GAME FOWL. No fow approaches the black Sumatra game fowl in the richness of its colour, which is dense black. with a glossy beetle-green sheen. The head is sinall and rather short, the eye large and bold, the somb small aud pea shaped. The booly is broad, with a full-round chest.
The body feather is close fitting, but the bird has long llowing saddle hackles, nud the cockerels have a very long drooping tail, with immense side hangers and sickles, which almost sweep the ground. The hens have a large fan-shaped tail. The eye should be red, but is often brown or black, the face comb and lobes are black, the beak and legs olive green. The hird often shows double spurs. The hens are layers of tinted eggs which woigh $1 \frac{7}{8} 0 \%$. to $\mathbf{2} \mathrm{oz}$. The Sumatra is a fairly good table bird, the tlesh being delicate and having the Havour of game. It thrives best on free range. See fowl: Game Fowl ; Poultry.
SUMMER : In the Garden. Summertime for the gardener officially extends from Junc 21 to Sept. 29. It is cluring this period of the year that the fairest llowers, roses, carnations, and lilies, to mention only a few, are in bloom; turf is at its greenest, summer beds are at their brightest, the trees are at their leatiest, and many of the most delicious fruits and choicest vegetables are available.
The summer is also a period for observation. birrors in the lay-out of beds and borders, mistakes in colour schemes, and incongruities in the arrangement of plants should be care-
fully noted, and plans made for alteration or improvement when autumin comes. l'lants, the Howers of which show any outstanding qualities in the way of size or beauty of colour or perfume, should be carefully noted for special care and attention when the season for propagation arrives. Indoors the chief troublc is with insect pests, various methods of battling with which are given under many headings throughout this work. See August: Border Garlen; Insecticide; July : June.
SUMMER CHAFER. This pest of the rose is similar to the common chafer or May bug, and it feeds in the evening, attacking both the foliage and petals of Howers. The on!y way of dealing with chafers is to seek the pests, during dull days and evenings, amongst

Summer Chafer slightly reduced
the petals of blooms, im. mediately destroying all that may be found.

Scek also in the ground for their fat white grubs that feed on fibrous rootlets, as well as on the skin of large roots, apply. ing a little sulphate of iron to the soil during late autumn and carly spring. If beetles are sern in light around trees, give a spraying with arsenate of lead wash. Regular warfare must be waged against all garden chafers and their white larva. See Rose: Spraying

## RUSTIC AND FORMAL

## Points to Remember in their Construction and Situation

The amateur is herein told how to construct a summer house, a choice of styles being offered. Other useful information will be found under such heıdings as Arch; Garden Furniture; Rustic Work; Steps; Thatching; frellis
In a variable climate a well planned and of the garden Fig. ] illustrates the charming built summer house provides the necessary shelter for long hours to be spent in the garden. Many days, even in winter, can be thus enjoyed, especialiy if the summer house is of the garden-room type, with easement windows and glass panclled door: Where there are children the summer house forms a delightful playroom or nursery, in which they can have the henctit of fresh air in safoty, and in hot weather the shelter may be litted up as a sleeping room or serve as a dining room. Such in summer house to be practical should measure from 8 to 10 ft . square.

The furnishing of summer houses should be plain or rustic in character, according to the nature of their structure. Painted wood or cane, or natural teak wood furniture, fabrics which will not fade or deteriorate with damp, and cottage earthenware or rough pottery meal scrvices are always suitable. while wicker and rustic wood benches, tables and seats arc appropriate for the simple type of structure illustrated in l'igs. 1 and 6.
The placing of the summer house in the garden is of great importance, not only from the point of view of getting shelter from north and east winds, but also because a pleasing structure of this kind can enhance the design
of the garden Fig. I illustrates the charming
placing of a thatched slielter on a southern slope with a background of trees and a foreground of stone steps. The summer house is covered with wavy-edired elm boarding, is rustic in appearance, and in perfect accord with the rock garden which surrounds it

Delightfully chosen for its surroundings is the summer house pictured in Fig. 2. This is of serviceable size and solid construction. particularly suitable to the formal Dutch garden which it enhances The tiled roof is supported on stucco-covered brick pillars, the side windows are glazed and the floor is bricked A charmingly designed garden seat furnishes the interior, but there is plenty of room for other chairs and a table Such a dignified type of shelter is suited for a town garden.

For a more open setting Fig. 3 shows another type of equally picturesque summer house, also of quite substantial construction, thatched with straw. The opening is framed by the rough hewn posts which support the front. The sides and back are filled in with rustic work. There is a brick floor, and the semicircular space in front is paved with rough hewn timbers.

Another summer house with an open front is shown in Fig. 4. It is built with a reloated

Summer House. Fig. 1. Thatched summer house of rustic appearance, well suited to the rock garden which surrounds it and to the stone steps which approach it

Huniphre! \& Vera Joel

Summer House. Fig. 2. Set in a Dutch garden, this formal aummer bouse with its red-tiled roof. brick foor and stucco-covered pillars is an admirably chosen shelter for a town garden lumphrey \& Vera Jopl
framework to allow the weatherboarding to be nailed flush with the outer corners of the uprights, and is supported on a suitable brick or concrete foundation. Hinged casement windows are fitted in front and at the sides. The roof is boarded to overhang in front and at the back and sides, and is supported by rafters fitted against a small ridge hoard and finished with a capping planed on both sides to the roof angle.

The Hoor is boarded with 1 in . tongued and grooved boards, suitable joists being placed at intervals of not less than 18 in . The construction can be arranged in sections with a separate Hoor, to which the front, back, and the two ends, as complete sections, can be bolted. The roof in this case is made in two halves, and bolted to the top framing and joined on top with a cepping.

Stock Models. Fig. it shows a house which is huilt up on a square floor supported on a stout foundation providerl with a revolving gear The newest form of this is similar to that employed for locomotive turntables and does not stick through rust or wear. The whole building can be casily turned to catch the sun or to avoid bitter winds. The revolving gear is to be found in the less expensive types of summer house, as well as in the larger structures. The roof of this example is thatched, but though this material is coolest and most picturesque to use, weatherboarding or oak shingles could be substituted. The front of the summer house is provided with two windows (shown shuttered) and a door with glazed upper pane!s. There are also windows at either side.

Stock models can be obtained of shelters which will suit most gardens. Walls are made of deal or of wavy-edged elm hoarding, or for a. lighter type of shelter are of woven reeds. Some houses are made on a multiple unit system. IJy this means it is possible to order a shelter which will be of the exact size required when constructed. The units are obtainable in 4 -ft. and $6 \cdot f \mathrm{ft}$. lengthes and in two heights Each unit can be used as a plain wall, or with a window or door, and multiples or combinations of the units permit. of putting up a structure to meet any requirement. Roofs also admit of a variety of treatment. Existing structures may be afterwards extended at small expense and with very little trouble by means of this unit system.

Rustic Summer House. A rustic shelter can be constructed with ordinary poles, such as may be purchased at small cost in most country districts. A simple structure is shown in lig. 6 . It measures some 7 ft . in wilth and 6 fft . in breadth, the height of the corner posts being 6 ft .6 in . clear ahove the ground. It is roofed with thatching employing faggots made up from young willow. Alternatively the roof may lie covered with straw or thaiched with heather.

Rough drawings giving the leading dimensions are prepared and used as a guide while the work is in progress. The plan of the building is marked out on the ground with the aid of pegs and lines, after which seven upright poles are ciected. These should be well embedded in the ground, and the tops linished off level. C'ross-pictes are nailed to the tops of the three uprights on either side
of the shelter. The cross-picces should project about ! in . heyond the corner posts. They are fitted by making little llats on the undersides of the cross-pieces, chipping away the round part and sccuring the cross-pieces with 4 in. or ${ }^{6}$ in. nails.

Rafters for the roof can be fixed by first setting uptie liars across the back and front pairs of uprights, and erecting a temporary upright in the middle of them to support the ridge pole, afterwards nailing the rafters to the ridge. The horizontal members are nailed, one near the ends of the rafters, and one in the middle of their length. The work is completed by fixing short uprighis from the crosshar to the rafters at cach end of the building.

The rool may be covered next. The faggots are most casily fixed with soft galvanized iron wire, wiring the bundles of faggots to the cross-pieces on the roof. The exact method of covering the ronf will have to be modified according to the material employed, but if ordinary brushwood is used it can be laid with two layers of faggots. Each faggot is separately wired to the roof, and the whole secured with a further turn of wire. The end of the faggots should be trimmed ofl with shears or a bill hook.

The cross-picces between the uprights are fixed at ahout the middle of their height, and pieces should be nailed from post to post on all three sides, leaving the front open. A crosspiece is titted near the ground to act as a support for the lattice work which forms the walls or sides. This may consist of poles about 1 in. diameter, niled to the uprights and cross pieces with $2 \frac{1}{2} \mathrm{in}$. wire nails. They are set diagonally, each panel running in opposite directions, as shown.
Seats are provided on three sides by making gallows brackets. These are spilied to the uprights, one being tixed to each. The brackets in the angles of the building should be set at an angle of $45^{\circ}$ to the side walls to form a support for the poles used for the seats. The top of these seats should be about 18 in . off the ground. The poles are nailed to the tops of the gallows brackets and overlapperl slightly at the angles or corners to give the effect of a mitre.
The back and sides of the summer house can be completed in trellis work, set diagonally. The whole may be treated with wood preservative stain or varnished. In the latter case

Fig. 3. Summer house with thatched roof and heavy rourh-hewn surports averooking aunk rarden in Sugsex. The sides and back are of rustic work and there is a brick floor Humphrey \& Vera Joel

Summer House. Fig. 4. Attractive structure of stained weatherboarding, open at the front and with casement windows at front and sides
the registrar of the blind roller as described for indoor blinds county court. It is Japanese rush blinds, in some shade of greon, procured by going to can be fitted in exactly the same fashion. the office and filling in a form which will be thore supplied, which states what the sum. mons is to be in respect of. There are two kinds of these, ordinary and default. The ordinary summons is issucd merely on request and is served by the bailiff of the court. If the bailiff says he is unable to find the defendant, the plaintiff himself, or his solicitor, may ask to be allowed to serve it. See Debt.
SUN BLIND. Sun hinds a re blinds fixed to the outside of a window and brought into use cluring days when there is a good deal of sun. They are the bark will have to be stripped off the timuer also used for the same purpose to protect before it is erected. Some of the harder woods doors and in conservatories and greenhouses are quite satisfactory if the hark is left on generally. Rooms, especially those that are them; with others it is desirable to remove it ; exposed to an abundance of summer sun, need but there is no hard and fast rule for this the protection of sun blinds, hoth to keep them part of the work, and it is largely a question cool and to protect their wallpapers, curtains, of appearance. Useful hints will be found in the articles Arch and Rustic Work. The same method of construction can be used for a more claborate structure, taking care that the principal supports have the requisite strength.
SUMMER PUDDING. This is a pudding made from bread and stewed fruit. It is a good way of using up stale hread, and any fruit in season miay be used. It is advised specially for those who arc unable to eat pastry with fruit. To make it, cut some stale bread into slices rather more than 1 in. thick. 'Trim off the crusts. Cut one of the pieces of bread inth a round to fit the bottom of a greased hasin. Measure the depth of the basin and cut pieces of bread to fit. Odd bits can he fitted into any spaces as may be necessary. Cut a second round to fit the top of the basin.

When the hasin is lined with bread, pour in sulticient hot stewed fruit to fill it. Any kind will do, but it must be nicely sweetened nand not too much of the juice used. Lay the second round of bread over as a lid and put a on it to press the bread down. Leave it until is strong and durable. It is attached to the it is cold, then turn it out on to a dish and serve it plain, or with custard or cream.

SUMMONS. The usual method of compelling a defendant to appear in court is to issue a summons, which he if lound to answer. It is usually issued by the magistrates courts and county courte. Anyone who wishes a summons to he served upon another person to answer n charge should go before the magistrate and make a complaint, which may or may not he taken down in writing and required to be signed loy the somplainent.
The summons is scrved by a warrant ofticer, who is usually a policeman. It orders the defendant to be at the court on such a day at such an hour to answer the chargo preferted against him.
A county court sumimons must be issued nt the oflice of

Fir. 5. Revolving summer house that can be turned round so that the front windows, bere shown shuttered, may face the sun Courtesy of Boulton \& Paul, Lld

A sun! porch or entrance door is easily shaded, either with a plain or a spring roller blind attached to the top of the framework over the fanlight. The blind should be long enough to reach at an angle from the fanlight to the front of the porch, where it is secured by a crossbar of wood or metal. inserted through a pocket formed in the material. This rod slides into two eyes or staples let into the brickwork when the width inside the porch is greater than at the entrance. Otherwise it is secured with short lengths of light brase chain. The blind may hang down beyond this rod as much as desired. The rod must be at least 6 ft . above the ground so as not to inconvenience passers-by.
The term sun blind is also used for a rectangular piece of material that is hung in front

Fig. 8. Summer house constructed with ordinary poles roofed with a thatching of willow faggots
of a door during hours of sunshine to protect the paint. For this a strong fabric should be selected, prefcrably onc with green stripes, and the colour should be guaranteed not to fade in the sun. Having beel cut and hemmerl to the required size, it can be hung by fastening a ring at each of the top corners and placing these upoil two hooks put in position above the door. See Awning; Blinds; Window
SUNBURN. It is not the heat of the sun, but the chemical action of the violet and ultra-violct rays which causes sunburn. It has been found that the condition is mozt likely to result from the early morning sunlight or from the rellected liglit from water or snow-covered ground. A dry wind also favours its occurrence, as it deprives the skim of its natural moisture. l'air-haired people are affected more readily than darls people.
In the most common form there is nothing worse than browning of the slin, which acts as a protective from the heat of the sun. In scverer forms the face becomes red, painful and perhaps swollen. There is tingling and itching, nid $n$ few days after exposure the skin peels off. In sunburn of a still greater degree blisters are formed. When people are daily exposed to the powerful rays of the hot sun for a long time the skin is likely to become dry and wrinkled.

For the redness and irritation cooling and soothing lotions should be applied. In the slighter cases a little eau-de-Cologne mixed with three times its quantity of water is ver: effectual Rosewater and elderflower water
are also used. Sometimes an astringent lotion, such as Goulard's water, dabbed on the face and allowed to dry is most serviceable.

The following will be found an admirable cooling application for the skin after returning from an outing in the sun. It should be dabbed on the face with a piece of lint or very clean rag :

Almond mixture
Rosewater, enough to make
1 dram.
1 oz
2 oz.
2 oz.
8 oz.

A simple but very efficacious cooling application for sunburn is freshly-sliced cucumber lightly rubbed on. See Complexion ; Dermatitis: Face: Freckles.

## Sundials: How to Erect and Set

## A Picturesque Feature for Gardens Large and Small

The earlier part of this article descrites the building of a sundial, while in the latter our readers are told how one should he set. See Brick; Cement: Concrete; Stone; and other entries that deal with the tools an's materia's used by the amateur worker; also Flower Garden; Garden

A sundial may be fixed vertically on a wall, ' as Fig. 7, but it is generally found in a horizontal position, mounted on a pillar or some form of pedestal like that illustrated in Fig 1. This is set up in a sunny spot in the garden, in such a position that at midday the shadow of the gnomon falls exactly on the 12 o'clock mark on the dial.
Making a Brick Pillar. Brick is perhaps the best inaterial for the amateur to use. First of all the foundation has to be prepared. If the site selected is in a grass plot, the top soil must be removed until firm ground is reached. This is made up with broken brick or hard core, and coated with concrete floated off to a level surface. The centre panel may be made up with crazy, or random flagstones laid in cement mortar, or the whole of the area can

Fig. 1. Skilful placing of a pedestal sundial in a long and terraced path be covered with brick. work.
The crazy paving can be surrounded by a brick border. The centre of the site is ascertained $h y$ driving four pegs, one at each corner. and stretch. ing a line tightly between them, the point of intersection of the two lines exactiy marking the centre. A scale drawing should bc made of the pillar showing the number of courses, the positions for the tile creases, and any other structural details. Tho drawing given in Fig. 2 is that from which the pillar shown in the accompanying illustrations was constructed.

The worker should refer to the article on bricks for details of the making up of mortar, method of laying the courses, etc. The first course is laid and levelled, and the second course is then set upon the first, half a brick's width less in size, so as to form a stepping.

Sundae. See Glassware Ice
SUNDEW. There are three native species of sundew, which is an insect-eating plant and a hardy perennial. Of these the best linown is Drosera rotundifolia, a low plant with roundish, reddish, radical leaves covered with sticky, shining, glandular hairs, which glisten in the sun. It is found in parts of Great Britain, Ireland and the Channel Islands in boggy places.

Although hardy, it is sometimes grown in pots as an interesting greenhouse object. A compost of peat and sphagnum moss is suitable. Propagation is by sced or division. There are several other species.

The buik of the pillar measures 14 in . square, and is easily built up by arranging the bricks alternately, one brick lengthways and the next at right angles to it. This operation is repeated for three courses, and then the tile creasing is laid in a similar manner. consisting of two courses.

A further three courses of bricks are laid on the tiles, and another tile creasing course. The tiles should be tapped up level to the sides of the shaft by striking them lightly with the handle part of the trowel They should be well bedded in mortar and pressed down firmly, as indicated in Fig 3. Two courses of bricks are then laid, to complete this part.

The over-sailing course of bricks remains to be laid on the top of the pillar so that they project over 1 in . beyond the face of the shaft; for this purpose it is necessary to cut a closer, that is, a short piece of brick, to fill the gaps between the whole bricks. The overhang can be measured with a rule or gauged with a sinall wocden gauge having a notch cut in one edge to represent the amount of overhang. The bricks should be bedded in a thick bed of mortar and well tapped home with the end of the trowel, as shown in Fig. 4.

The capstone can be a piece of thick, flat stone or paving stone, 18 in . square and about 2 in deep. or in its absence an excellent suhstitute is obtained by first preparing a rough wooden mould and casting a capping piece in concrete. To provide a means of attachment for the plate of the dial four rectangular pieces of wood are arranged in the centre of the mould before the concrete is filled in. The mixture is poured into the mould box in a moist condition, and the surface should be trowelled off large, so that there is room for adjustment.

Setting a Sundial. The dial is attached to the top of the pillar by screwing it down with four screws to the wooden blocks embedded in the concrete capping The gnomon should point north and south, with the highest part pointing towards the north.

A sundial made for one particular place is quite useless for another place in a different latitude. Before setting a sumdial it is essential to know whether the sun is fast or slow of the clock. Sundials show apparent time, whilst clocks measure equal or mean time, so that if a perfectly regulated clock were set to apparent solar time it would agree with the sundial only on four days of the year. Fig. 2. Showing aumber of four days of the year.
brick courses and position of
tile creases in sundial pillar dar is the
illustrated below between two succes$s$ ve returns of the sun to the meridian. The moment the sun reaches its highest point in the heavens, that is, the highest point above the horizon, it is true noon. Sonetimes the sun is as much as 14 min .28 sec . after the clock. and at others 16 min .18 sec . before the

Fig. 2. Showing vumber of brick courses and position illustrated below

smooth. Instructions for moulding concrete are given in the article Concrete.

The concrete must remain in the box for a week or more until it has set thoroughly hard, after which it may be removed and placed upon the top of the column, first covering the latter with a thick bed of mortar. When placing the slab, it is important to get a uniform overhang on all sides of the shaft, and to lay the slab flat on top of the brickwork The slab should immediately be levelled up, by laying a large spirit level diagonally across it., first from one side and then the other. as depicted in Fig. 5, tapping the upper surface of the slab and gradually working it home until it is quite level. It is highly important that the capstone should be perfectly level. The dial itself should be procured before dealing with the capstone, so that the correct position of the wooden fixing blocks can be determined. In the case of a brick or stone capping, lead or hardwood plugs are inserted for the fixing screws Leave the plugs full
.

Pig; 6. courlesy of Francis Barlier \& Sons, Ltd
clock, at XII o'clock noon. Mean time is that shown by clocks generally, the day of 24 hours being obtained by taking the average of all the solar days of the year. Place the dial upon the platform and move it about until the shadow cast by the gnomon on the dial shows the correct time within a few minutes.
To read the time by sundial, stand on its north side. The forenoon or morning hours will then be on the right-hand side of the dial, whilst the afternoon hours will be on the left. At noon the shadow of the gnomon will fall within the space between the two lines at XII o'clock.

When the dial is in the correct position mark the platform or capstone through the holes in the dial for the fixing screws. Finally adjust and fix the dial at XII o'clock noon. Of course it can be fixed at other times, but XII is the best As before mentioned, the sundial and clorek coincide only four times in a year, about April lis, June i4, Aug. 31, and Dec. 25, and it will be found convenient to lix the dial on or near one of these days. provided that the sun is shining
Set a watch to the mean time of the place where the sundial is to be tived, and ascertain on the day the sundia! is lixed the difference between mean and solar time. Say the dial is to be fixed on April 10-the watch having previously been set to the correct mean time of the place, by adding the difference fast or slow of Greenwish-it will be seen that the watch is faster than the time shown on the sundial by 1 min Move the dial about on its platform until the space between the two lines at XII o'clock is filled with the shadow cast by the gnomon and the watch shows exactly 1 min . past XII o'clook. When correct, firmly serew the dia! to its platform.

If the dia! is lixed during the period in which summer time is in force. it must be remem bered to make the necessary allowance

SUNFLOWER. There are both annual and perennial sunflowers of considerable value in the garden. The latter plants llourish in ordinary soil and spread rapidly. They ought to be lifted, separated into small pieces, and replanted every autumin to keep them under control. Some of the best are multiflorus, 4 ft .; rigidus and its variety, Miss Mcllish, 6 ft . ; Golden Monarch, (i-8 ft.; and Solcil d'Or, double, 4 ft .
The annual suntlower (Helianthus annuus), which bears enormous circular flowers on stems, 6 to 8 ft . high, is a familiar plant in

cottage gardens, but the newer sorts, 3 or 4 ft high, with smaller yellow and reddish flowers which are morc valuable, are less grown. The annual sunflowers are raised from seeds sown in spring. See Prairic Sunflower.

Sunlight: In Medicine. See Heat Stroke Light; Rickets; Tuberculosis.

SUNROSE. This is the popular name of a group of low-growing, hardy flowering slirubs known as helianthemum. The Howers are white, yellow, red, pink or crimson, throughout spring and summer. They like sunny banks, borders, or rock gardens, and are raised from seed sown in springtime or by cuttings in summer.

Sunstroke. Sec Heat Stroke.

## SUPERHETERODYNE RECEIVER

This is a wireless recciver based upon the principle of beat reception. The oscillations fromi a local oscillating valve are superimposed upon the carrier-wave frequency to which the receiver is tuncd, and the beat
frequency so formed is then rectified and passed through an intermediate frequency amplifier. The frequency to which the intermediate amplifier is adjusted is constant and is always equal to the beat frequency The amplified signals are then rectified by a second detector and either applied directly to a pair of telephones or further amplified by a low-frequency magnifier to a strength sufficient to operate a loud speaker.
Superheterodyne receivers are normally used in conjunction with a frame aeria!. and are highly sensitive and selective. When the local oscillations are applied to the grid circuit of the first detector, a superheterodyne should not be connected to an outdoor or indoor aerial of conventional type, because of the danger of interference with neighbouring sets. For each frequency (wave-length) to which the frame aerial tuning condenser is adjusted there are two settings on the oscillator condenser which give the desired beat frequency. In practice either of these settings may be used.

One of the difficulties in the design of a superheterodyne receiver is in the choice of an intermediate frequency or wave-length which will ensure frecdon from continuous-wave and other transmissions that may cause inter ference. It is usual to screen the intermediate frequency transformers in order to prevent the direct pick-up of long-wave transmissions

A high-frequency amplifier operating at the fundamental frequency may precede the lirst detector and will give still greater selectivity and sensitivity, but this complicates the design and increases the number of valves. The conventional arrangement, comprising first detector, oscillator, screen-grid intermediate frequency amplifier, second detector and low-frequency magnifier provides all the amplification necessary for normal broad cast reception. Sec Heterodync.

SUPERPHOSPHATE. In garden parlance this is the valuable manurial preparation superphosphate of lime. It is obtainable in three qualities, viz., ordinary, containing about 25 per cent soluble phosphates concentrated, embodying up to 45 per cent. of the same essential plant food; and double. a grade in which soluble phosphates as high as 80 per cent often appear. For ordinary

Sunflower. Left, dark-centred blooms of the common annual sunflower. Right, double perennial variety
suitable. The concentrated may be used for more exacting culture, but for special classes or specimen plants the double grade is best.

As superphosphate contains only phosphoric acid, other essential plant foods must be supplied by using potash and nitrogenous manures, and when used in suitable quantities the mixture gives the best results on general crops in most soils. A good average quantity to use is 2 to 3 oz . per sq. yd. Unless required for immediate use superphosphate should not be combined with nitrate of soda; and it is not advisable to apply it to acid soil. See Manure.
SUPPER. In many households where a hot dinner is cooked in the middle of the day, and usually on Sundays, supper is served in the evening in place of a more formal meal. Except in warm weather, when all cold food may be preferred, soup and a hot fish or savoury dish are generally liked, with a cold joint, meat pic or galantine and a salad on a table or sideboard for those who want a more solid meal. Any cold sweet, such as a jelly, stewed fruit and custard, blancmange or pastry, is suitable for supper, with cheese and biscuits to follow, unless the savoury chosen contains cheese. Coffce is sometimes liked, or the usual cold family beverages.
Entertainment suppers are nearly always cold, unless hot soup in cups is served, or there are facilities for cooking special hot dishes as required. Mayonnaises, game, poultry, galantines and terrines, salads, cold savouries such as stuffed olives or caviare prawn croûtons (see page 208), creams, fruit jellies and other sweets, all kinds of ices and every variety of dessert are suitable refreshments. When served at a big party, the dishes are placed down the length of the tables in the dining room in order that the guests may help themselves, servants, or waiters engaged for the occasion, standing behind the table to assist as required. Cocktails may be a feature at the opening of the party. Champagne and other wines are provided at a smart supper, and various cups, other iced drinks, and hot coffec.

Where a number of guests are entertained and the staff is small, the buffets and tables should be well arranged so that many people can help themselves at the same time without a scramble. A good idea is to have all the cutlery laid out on a first table with plates piled in their respective sizes. The guests take what they require and proceed to the buffet where the food is laid out within easy reach. J)rinks and glasses are placed on another table, and service is further facilitated if there are a number of small tables and chairs placed well apart from the buffet to which people may retire to eat what they have chosen.
Small Suppers. More ințimatȩ, sit-down suppers for a small number of guests may be given after a theatre or on a Sunday evening. A prettily decorated table is an important factor. A summer supper for such a party might consist of grape fruit, salmon mayonnaise, galantine of chicken, cold veal and ham pie, strawberry trifle, meringues filled with ice cream, hock or cider cup. A winter menu could consist of soup, oyster patties, hot cutlets and vcgetables, or salmis of game or chicken en casserole, with some cold meat dish and celery salad, little fruit jellies and cheese straws. Any cold savoury or sweet should be prettily decorated and arranged on a suitable dish.

A chafing dish is an admirable aid at such a party, as it enables the hostess to cook a varicty of appetizing little dishes at the table. Omelettes of any kind, various fricassées, scrambled eggs with anchovies laid across the top, and other savouries can be ready in a few minutes. If food has been prepared and cooked beforehand it can be kept hot on a food warmer, the necessary heat being supplied
through a flexible tube connected to a gas point. An electrical contrivance is a table cooker which can be put over a large plate on which has been previously placed the sausages, cutlets or anything else of the kind which it is desired to cook. The current is then switched on to cook the food. When done, the food can be left under the cooker to keep hot for some time after the current has been switched off. The cooker can afterwards be inverted to stand on its insulated feet and the hostess can then boil a kettle on it for coffee.

Every evening suppers for children should be light. Party suppers-except for quite small children, when the simplest of the suitable dishes are usually selected-are served on the same lines, without the wines but with claret cup and iced drinks, as are those at grown-up entertainments. See Chafing Dish; Cocktail; Salad; Sandwich; Table Laying.

SURNAME. A surname is the name which a person has or adopts in addition to his Christian name which was given to him at his christening or which he was registered as possessing. Anybody may adopt any surname he pleases without permission, except an alien, who may not change his surname without the leave of the Home Office.
Nobody has any right to adopt a surname with intent to deceive. If he does, the true owner of the name, if able to prove damage or likelihood of damage to himself or his busi ness, may obtain an injunction. See Name: Naturalization.
SURTAX. This is an additional income tax, and in Great Britain is levied on all incomes, whether carned or unearned, that are in excess of $£ 2,000$ a year. In estimating the total income of an individual for purposes of surtax, the amount taken is the full gross amount of the income without any deductions for earned income and other abatements, and before deduction of income tax proper. This means that a man with an income of $£ 2,100$ must pay surtax, although, owing to allowances, he is only liable to pay income tax proper on perhaps $£ 1,700$.
The rates of tax as revised in 1930 arc given below. To obtain the total amount due 10 per cent must be added, this being the increase levied in the budget of Sept., 1931.

Thus a man with $£ 7,500$ a
ycar pays £859 7s. 6d., made up as follows

See Income Tax
SUSSEX FOWL. The most popular fowl among British poultry breeders is the Sussex, and it has gained its position by sheer merit. Sussex fowls have secured the chief awards in the dead table-fowl classes at the Dairy and Smithfield shows and in the principal laying competitions. There are four colours in this breed-light, red, speckled, and brown. The first-named are the most popular among both utility breeders and exhibitors. The browns
are the largest of all, and with the speckleds are held in great esteem by those who breed and fatten for the market.
Sussex are large-bodied birds, broad in back and deep in breast, very white in skin and flesh, and carry an abundance of fine quality white meat. The hens are good winter layers and careful mothers; the chicks are hardy and grow quickly. Full-grown males weigh from 8 lb . to $10 \mathrm{lb} .$, hens 6 lb . to 8 lb. , the browns generally going 1 lb . or 2 lb . hcavier. The eggs are brown and average 8 or 9 to I lb . See Fowl ; Poultry.

SUSSEX PIE. To make this, take 2 oz. sultanas, 2 oz . currants, 3 oz sugar, 8 oz . cooked apples, and a pinch each of cinnamon and mixed spices. Make a little short-crust pastry and line a pie-dish with it. Having washed the sultanas and currants, put them, with the apples, sugar, cinnamon, and spice, into the dish, cover it with pastry, and bake it in a moderate oven for an hour. See Pastry.

SUSSEX WARE. The mellow charm of the hand made roofing tiles and flower-pots of unglazed red earthenware for which Sussex is famed is due to centuries of traditional skill working with good material. There can be no doubt that, since at least as far back as the coming of the Huguenot refugees, domestic utensils also were produced in the neighbourhood of the coast ports. These were wrought with mixtures of the fine, light, local clays. and 18th-century examples may be found here and there, although they arc not easy to identify, because they are generally undated and unmarked.

A ware of a semi-faience type, which has a red body covered with tiny stamped ornaments embedded in a white slip and leadglazed, was made at Chailey and Rye in various small potteries for about half a century after 1793, and comprised pipkins, pitchers, flasks, stands and other useful forms. More than 100 years ago a factory was established at Crowborough for the production of glazed and unglazed brown crockery, including the Sussex pig used for rural wedding toasts.
After the mid-Victorian art revival attention was turned, both here and in Rye, to more ambitious forms, such as jugs and vases, candlesticks, and other decorative objects. Upon these foliage was moulded in simple, natural designs and covered with a brilliant brown or green glaze, not unlike that of some Devon ware, and sometimes rivalling old Rockingham in effect. Cream-coloured clạ!s

Sussex Fowl. A typical speckled cockerel Courtesy of the roultry World
were uscd for basketwork and other styles of greater delicacy, and out of this industry has arisen a distinctive type of art pottery known as rustic wasc. See Pottery.

SWAG. In fur. niture a swag is a garland or fostoon suspended between two points. It was used liy the Arlam brothers and thoir successors on carvel, inlaid, and painted pieces of furniture, and is scen a great deal in all kinds of decorations of the latter part of the 18th century. Many chair backs by Hepplewhite and Sheraton have sw time. See Adlam Style; Queen Anne Style.
SWAGE. When linishing iron while it is hot blacksmiths use $\Omega$ tool known as a swage. There are several forms, but essentiplly they all consist of $\Omega$ form of hammer head or some other face which has a $\frac{1}{2}$-round groove across it. Swages are gencrally used in pairs. Onc, known as the botiom tool, has a shank which fits into a hole made for that purpose in the anvil. The uppler tool is held with an iron rod handle, which is grasped by the smith in the right hand while the work to be swaged or rounded is held in the left hand
The metal is brought up to its proper heat, and roughly rounded by hammering in the ordinary way, somewhat as described in the article on forging (q.v.). After this treatment it is reheatel. if necessary, and rested in the groove in the bottom tool. The top tool is then placed into position on the upper side of the worl:, and an assistant strikes the top too a heavy blow with a sleclge or other hammer, according to the size of the work. At the same time the smith partially revolves the metal between each hammer blow, thus ultimately rounding off the metal and work. ing it up to a smooth surface. If carefully done, tolerably good rods can be obtained.

Instead of using the botton tool, a large rectangular block is often utilized which has grooves across its cdges. It is lonown as a swage block.
SWALLOW WORT. The colan. dine (Chelidonium majus) has been given this name because its Howers open about the time when the swallow arrives, and the drying-up of the plant takes place vhen the bird is departing for warmer climes. It is useful for shady garden comers.

It has an old reputa. tion as a cure for warts, and as a remedy for scorbutic eruptions.

SWANSDOWN. Because of its extreme softness the down or under plumage of the

Sheraton have swags, and swags are also a the water until it is clean, and requent ornament on painted tables of that the fire, shaking it all the time to

Swansea Ware. Bough-pot of "apaque porcelain," a species of white earthenware. with a painted design of birds and foliage

swan is the most popular minterial for powder pulls. but it is also used for trimnling purposes on dressing gowns and jackets and on babies honnets. It can be hought in white and pale colours and is obtainable in picces of a suitable size for puffs or as a trimming by the yard in narrow strips.

Swansdown should be washed in warm soapy water. The lather is hest produced with soap iclly; for, like many other delicate materials, swansdown suffers if rubled with soap. Squecze it gently in the firc, shaking it all the time to restore its original Iluffiness.

SWANSEA WARE. All linds of pottery and soft paste porcelain fabrics were produced at Swansea for more than a century down to 1870. During the 18 th century the styles included salt-glaze, cream ware, black basaltes, gold and ruby lustre, and printed ware, which was done both in dark and in light bluc, and also in both black and brown.

A so-called opaque porcelain or china decorated with tine bird and flower paintings is highly prized by collectors. This opaque china is not true porcelain but a fine whitc carthenware fabric. An example is illustrated of a bough-pot with a beautifully painted floral pattern. A bough pot was $\Omega$ vase originally intended to hold llowering hougha, and the term is also speit bow-pot and used for a pot on which a floral design was painted.
For a few years a translucent porcclain was made. The decorations resemble those of contemporary Staffordshire fabrics, but the body contained no felspar, and was consequently very soft. Later on the paste used was llarker, at first with a grcenish tinge, and afterwards a dead-white glaze.
Some of the pieces decorated at Swansea by Nantgariv painters were marked Nantgarw. At a second factory, established at the same time, cow milk-jugs and milkmaid figures were
$\square$
turned out and exported in large quantitics to France. Etruscan ware, so marked, was minde of a local red clay, with classical figures in enamel colours. Another factory turned out useful services in pure white.

It was at Siwansea that the Cambrian ware was produced. The usual mark, stamped or stencilled, comprised one or two tridents, with the place-name and sometimes the potter's name, such as Dillwyn \& Co., or Bevington \& Co. Pottery is still made in the neighbour hood of Swansea. See Cambrian Ware.

Sweat. S'ee Perspiration.
SWEATER. This heavy type of jersey is made in various sizes both for men and boys, the chest measurement being the usual standard. Sweaters are made as a rule of white wool, but sometimes colour is introduced at the neck and as a border. Sweaters in variegated colours are occasionally seen and they are made with club or regimental colours at neck, wrists and waist. These are worn by members of cricket and football clubs. As regards pattern, some are made with a collar and some without. The collar may be of the roll or turn-down variety.

The knitted garment known as the pullover is a kind of sweater. This is worn by men and boys and is sold in a variety of coloars. Most of them have two pockets, some have a decoration around the neck and elsewhere, while others are quite plain. They are also made in check patterns in two colour mixtures, in three colour stripes, and in other patterns. Stockings to match may be knitted, or are sold with many of these garments.

How to Knit. To knit a useful, standard type sweater with a V-shaped neck the requisites are 18 oz . of Beehive fleecy wool, two No. 7 and four No. 10 bone knitting needles, pointerl at both ends. The garment should be worlied at a tension to produce about 5 stitches and $7!$ rows to the inch measured over the plain portion. lior the back, cast 96 stitches on the No. 7 necdles. lst row: Knit 4, * purl 2 . knit $\because$. Repeat from * to the end of the row, always slipping the first stitch through out. Repieat this row 20 times. 22nd row Knit plain. 23rd row : Knit 2, purl to the last 2 stitches and knit 2 . Repeat these last 2 rows until the work measures 30 in . from the beginning. Cast off $\geq 6$ stitches at each end and leave the 44 stitches at the centre on p No. 10 needle.

The front should be worked exactly like the back until it measures 22 in ., finishing with a purl row. Then begin to shape the neck as follows: lst row: Knit 45 and then turn. Leave the remaining stitches for the sccond half of the neek. Continue in the pattern, decreasing once at the neck end of the needle in every third row until only 36 stitches remain; then cast off. Taking the needln where the stitchos are left, slip the first 6 stitches, at the centre of the front, on to a No. 10 needle, and, on the remaining stitches, knit the second half of the neck to correspond with the first.

To make the sleeves, cast on 76 stitches. 1st row : Knit 4,* purl 2, and knit 2. Repeat from * to the end of the row. Repeat this row 30 times. 32nd row: K nit plain. 33rd row : Kinit 2, pur! for the last $\underline{(2}$ stitches and knit 2. Repeat these last two rows throughout the sleeve and increase at the beginning and end of the 7th, then every following (ith row until there are 7 increasings at each side of the work. Then knit without shaping until the underarm seam measures 18 in . without the cuff and cast off loosely. To make up the sweater, press each of the pieces carcfully. Sew up the shoulder and side seams, leaving 9 in . for the armiholes. Sew up the seams of the sleeves and then fix these latter in the armiholes, placing seam to seam.

To make the collar, with the No. 10 needles knit the 44 stitches that were left at the back

Swede. 1. Soil preparation : bottom apit broken and manured (a). 2. Raised drills (a) for sowing. 3. First thinning. 4. Second thinning. 5. Final thinning 6. Swedes prepared for storing by wrenching off tops (a) and cutting of tap-roots (b). 7. Properly prepared clamp: a, sand: b, soil: c. straw : 8. 8 wedes covered with fine ashes ( $a$ ), through which green tops sprout "!/ special arrangement with Amateur ciardeming
with melted butter sauce.

To serve swedes mashed, boil them in the same way, then rub them through a sieve. Empty the saucepan of water and put into it a piece of butter the size of a walnut. When this is melted stir in a little flour then, before it browns, add the mashed swede, well seasoned with salt and pepper. Stir this a minute or two, and it is then ready to serve. See Sauce Turnip.

SWEEP. When chimneys require sweeping the sweep should be notified some days beforehand, especially in the spring, when he is in much demand.
of the neck. Follow on with a second needle. It is usually found most convenient to select and knit up 29 stitehes at the side of the an early hour, and to make the necessary neck and 3 stitches off the extra needlc. With preparations overnight. The sweep often a third needle knit the next 3 stitches and knit up 29 stitches at the other side of the neck. Knit 16 rounds in rib of knit 2 and purl 2, increasing 4 stitches in the first round at the centre of each of the second and third ncedles. Cast off loosely. The collar can be made to look very effective by introducing stripes of a scond colour. See Knitting; Wool.

Sweating : Of Metals. See Soldering.
SWEATING POWDER. In commencing colds and other feverish disorders 5 or 10 gr . of Dover's powder may cause more or less profuse perspiration, and thus diminish the fever. This may sometimes bring the malady to an end. The best time to take such a powder for a cold is at bedtime, and great care should be excrcised next day to avoid exposure. Other drugs, such as phenacetin, antipyrin, and antifebrin, also act as sweating powders and reduce temperature, but they are not safe remedies for this purpose, on account of their deprcssing action on the heart. See Fever.

SWEDE. The Swcdish turnip has been generally accepted as a farm crop, but its value as a winter vegetable is now recognized, and seedsmen offer selected strains suitable for srowing in the vegetable plot. Its cul. ture is the same as for turnips, but owing to stronger growth rows should be 18 in. apart, keeping the soil well hoed and free from weeds rluring summer.

How to Cook. As a vegetable the swede is usually boiled in the same way as ordinary turnips, after being peeled and cut into quarters or smaller pieces. These are put into a saucepan of hot salted water and allowed to boil until tender, which may take anything from 30-60 min. Serve in a tureen, covered

Swede. Fine roots of this variety of turnip, a useful winter vegetable

They must now be wiped and pressed between two plates, as pressing them will improve the shape and give greater facilities for neat dishing.
To roast sweetbreads, take a pair of calf's sweetbreads and prepare them according to the foregoing directions, then brush them over with beaten egg and roll them in seasoned breadcrumbs. Have ready melted in a sauce pan 1 oz. butter, and sprinkle this over the coating of crumbs, then roll the sweetbreads in breadcrumbs a second time. Put them into a baking tin in which 2 oz . butter have bcen melted, and place them to roast in a moderate oven. They will take 30 min . to cook, and must be basted frequently with the butter in the pan. Jish them up garnished with fried parsley, and serve with them a good white or béchamel sauce.
Another entrée may be made by the follow ing recipe : Prepare a pair of calf's swectbread and cut them in rather thick slices. Put these in a stewpan and just cover them with white stock. Add scasoning of salt and cayenne and sprinkle in a little powdered mace. Add 2 oz . butter and a wineglass of sherry, also l teaspoonful lemon juice. Stew very gently till the slices are cooked, then beat up the yolks of 4 cggs with a nother glas of sherry or $\frac{1}{2}$ gill cream. Add these to the contents of the saucepan and stir over the fire till the whole thickens without letting it boil. Serve very hot garnished with a border of cooked green peas, and just before sending to table squeeze over the strained juice of an orange.

Sweetbread Fricassée. A very good fricasséc can be made with either calf's or lamb's sweetbread. If calf's breads are used procure 1 pair; if lamb's breads, buy fron $\frac{3}{4} \mathrm{lb}$. to 1 lb . Prepare the breads by soaking parboiling, and pressing, then cut them into neat slices. Have ready 1 pint white stock, add 1 onion, 1 carrot, and a bouquet garni The onion and carrot must have been prepared and cut up small. Stew the swcetbread in this for 20 min
Meanwhile melt 2 oz. butter, add $1 \frac{1}{2}$ oz. Hour, and cook together without browning for 4 min . Remove the slices of sweetbreads from the stock in which they were cooked, then strain it, and add it by degrees to the white roux in the pan. Make it into a smooth sauce, then whiten it with a liaison of 1 gill cream, or milk and cream mixed, and the yolks of 3 eggs beaten together. The sauce must not be allowed to come to the boil after the eggs are added. Mix in the slices of sweet bread, scason to taste, add a pinch of powdered mace and 1 teaspoonful lemon juice, and serve garnished with croûtons of fine bread and small rolls of fried bacon.

If no stock is available, cook the pieces of swectbread in water, and in another pan put I pint milk with a prepared and sliced onion and carrot, a bouquet garni, and scasoning Stew these gently while the sweetbreads are cooking, and then strain the milk and use it for making the sauce in place of stock.
Sweetbread Fritters. Lamb's sweetbreads make excellent fritters. First prepare them as already directed, then cook them in a little stock or milk, well Havoured with vegetable and seasoned. Then cut them in slices about $\frac{3}{4}$ in. thick, dip each piece in a very light batter, and fry them a golden brown in deep fat 1)rain well, and garnish with fried parsley.

Sweetbread Omelette. To prepare this. make a plain omelette according to the directions given under the heading omelette, and before folding it over put some sweetbread, broken into small pieces and reheated in a little béchamel sauce, in the centre. Serve at once in a hot dish. See Sauce.

SWEET BRIAR. Flowering in June, rose pink in colour, with brilliant red berries in winter, the sweet briar or eglantine is

Sweet Briar. Beautitul delicate pink single blossoms of the fragrant Penzance briar
noted for the spicy fragrance of its leaves. The perfume emanates from the glandular hairs on the underside of the serrate leaflets and is particularly fragrant after rain. Botanically the plant is Rosa rubiginosa,
The sweet briar grows wild in the challs hills and heaths of S. England as well ns in scotland and Ireland. It forms a delightful herlge for an inner garden. The beautiful large-llowered Penzance briars were raised by cross-breeding between the sweet briar aid other roses. See Rose.

SWEET CHESTNUT. This is an altermative description for the Spanish chestnut. The chestnut wool used for furniture and other articles is obtained from this tree, not from the horse chestnut, and the same tree produces the nuts which are the chestnuts used for food. See Chestnut; Spanish Chestnut.

SWEET CICELY. This plant is a species of myrrh native to England, known botanically as Myrrhis odorata. It is a fragrant perennial herb, with graceful feathery foliage and large umbels of creamy Howers. Ordinary soil in any position suits it, and if planted during spring or autumn it will thrive in the shrubbery or wild garden.

SWEET GUM. The hardy, summerleafing tree that is known as swect gum or liyuirlambar has handsome, lobed, maple-like leares that assume a brilliant colour in autumn. The kind best suited to gardens in this rountry is Liquidambar styraciflua. It thrives in ordi.
nary soil and is increased by seeds or layers. The swect gum tree attains a height of 50 ft .

SWEET HERB. Parsley, bay leaves, marjoram, thyme, sage, savory, mint, and basil are the sweet herbs most frequently used in cookery. When, as in recipes for stews, etc., the use of a bunch of sweet herbs is recommended, only the first four, tied together with the parsley on the outside, are usually chosen. Sweet lerbs can be used fresh from the garden, dried and stored at lome, or purchased in packets and bottles. See Mint; Sage ; Thyme.

SWEET MARJORAM. This is the culinary herb botanically known as Origanum majorana. The common marjoram, Origanum vulgare, is correspondingly fragrant, and is greatly favoured as a bee flower. Swcet marjoram thrives in rach soil where the position is sunny. Shoots for drying may be gathered just when they are a modern frilled variety they are coming into flowe dictamnus, which bears pink hop. Origanum sary to protect them from birds by means and is known as pink phow號, is a very pretty through the soil.
SWEET PEA. This is the See Marjoram. Some of the most beautiful modern varieties
SWEET PEA. This is the loveliest of all are the following: Model, white; What Joy, hardy annual flowers and a great favourite for cream; Valentine, blush; Pinkie pink: cutting. It is grown in immense quantities Mrs. A. Scarles, cerise; Youth, white with for market, and is an ideal Hower for amateur pink edge; Magnet, cream-pink; Blue Bird, gardeners. If well grown it will yicld four- purplish-bluc; Warrior, maroon; Huntsman, bloom stems throughout many weeks. In scarlet; Mammoth, orange scarlet; Sextet recent years numerous beautiful varictics Queen, white; Gleneagles, lavender; Wemwith frilled Howers of delightful colouring have been raised.

Seeds are sown in pots or hoxes in a frame during October, or in a slightly heated greenhouse in January. Juring the cold weather the seedlings need only to be kept safe from

Sweet Peas. 1. Sowing in matchbox: end removed at a. 2. Inner box with seedling ready for planting out. 3. Large boz with removable divisions ( $a$. a) for sowing. 4. Strips of turf (grass downward) for use in same, showing seedlings lifted and ready for planting. 5. Seed grown in eggshell : drainage bole at $a$. 6. Sowing seed in large pot. 7. How to place supports. 8. Ideal compost for sweet-pea seedlings

off; this causes fresh basal shoots to develop which will produce fincr flowers than the original stem would have done.
After having been well hardened the plants are set out late in March or early April in soil that was dug deeply and manured in winter. To ensure longstemmed blooms and four on each stem the plants must be set at 8 or 9 in . apart and restricted to one stem (unusually vigorous sorts to two stems), all side shoots being rubbed off. Each plant is ticd to a tall bamboo cane.
For ordinary garden decoration seeds are sown out of doors in late February or March at 2 to 3 in. apart, and the seedlings should be thinned out to 4 to 6 in . from each other. The seedlings must be supported by twiggy stick. as soon as they are well through the soil, and subsequently by ordinary pea sticks. It is usually neces-
outer skin, slice and toss in butter or mash and fry in doat hot fag and breadcrumbs with butter, season and serve hot. They can be boiled as ordinary potatoes.

Sweet Potato Fritters Pecl, boil and mash 1 lb . potatoes, add to them 2 oz . warmed butter, 2 tablespoonfuls flour, 3 eggs, and a little salt. Mix stiffly and form into round,
sprinkle with castor sugar and powdered cinnamon. Serve hot as a sweet.
SWEET ROCKET. The o!d-fashioned hardy perennial plant Hesperis is also known as rocket, dame's rocket, double rocket ans dame's violet. See Rocket.

## Sweets and Sweet Making

## Recipes for Some of the Most Popular and Wholesome Kinds

In connexion with this general article on candied sweets are those on the two important confectionery sections of Chocolate Making and Toffee. There are as well supplementary articles in our work, e.g. Almond Rock; Fondant; Fudge; Marsh Mallow; Nougat, etc. See also Browning; Crystallized Fruit; Essence ; Icing; Sugar ; Syrup; Vanilla

The word sweets, or candies, is used to In boiling sugar strict cleanliness is essential describe a great variety of small confections in which boiled sugar is the main ingredient. The materials include flavouring agents such as almond, peppermint lemon, and coconut, while use is also made of fruit juices and nuts. Colouring matter, which in the case of the cheaper swects may be injurious, is employed. One large group of confections falls into the class known as chocolates (dealt with under the heading Chocolate Making) ; others may be classed in a number of ways, such as toffees, fudges, nougats, fondants, fruit jellies, etc.
Sweets should not be given just before meals, or they may spoil the appetite for plainer, but very necessary, forms of food. It is not a good plan to give children sweets just before going to sleep, for the reason that the sugar clings to the mouth throughout the night and encourages the growth of bacteria which may damage the teeth.
It is necessary to add that there is one type of child from which sweets should be withheld, or at most given very sparingly, and that is the fat, flabby child showing a tendency to eczema. Again, if a child exhibits a capricious appetite or suffers from indigestion, a doctor's advice should be obtained as to the propriety of allowing sweets. The sweets given to any child should be of the purest quality.
Outfit for Sweet Making. Very little initial outlay is involved in making sweets at home. All that is required to start with is 2 or 3 pans sufficiently deep to boil the requisite amount of sugar, a stirrer or spatula (these may be had in various sizes in wood and metal, and are flat-shaped without a spoon-bowl), a few shallow dishes or tins into which to pour the finished confection, a sugar-boiling thermometer graduated to 400 deg ., a small marble slab, and a pulling hook for rock making.
In the trade, copper pans are mostly used, owing to their high conductivity of heat, but quite good results can be got with aluminium pans. Do not use enamelled ware, as the high temperature at which sweets are boiled may crack the enamel. Tin-lined copper pans should not be used as the tin may be melted during the process. A tin or aluminium scraper for cleaning the slab, an extra spatula or two, and a large pair of scissors will complete a good working outfit. For making moulded fondants it is a good plan to invest in a rubber fondant mat. Small rings can also be obtained for peppermint creams, and a dropper made of tin. The latter is shaped like a funnel with a band of copper round the nozzle end, and a stick to fit it, which is lifted for a fondant mixture to drop out in the quantity required to form each sweet. The stick is replaced and the dropper quickly moved to fill the next mould or ring.
Sugar Boiling. Only the best-grade sugar, gianulated or loaf, should be used. If inferior sugar is employed, there will be much scum during boiling, and a tendency for the batch to grain, i.e., to come back to its original state of crystallization. Any scum must be removed. Good sugar should show next to no scum, and should boil clear and sparkling.

In boiling sugar strict cleanliness is essential. The pan should be well scoured, and all utensils carefully washed. Place sugar in the pan at the rate of 4 lb . to every pint of water. This will be found thick enough in consistency for most sweets, but a rather larger proportion of sugar is allowed for fondant mixtures by some sweet makers who use 4 lb . sugar to $\frac{3}{4}$ pint of water.

Wash down the sides of the pan with a small brush to remove all adhering sugar, and set the pan and its contents over a very low fire so that the sugar will melt slowly and com. pletely. Now bring it quickly to boiling-point. remove it from the fire, carefully stir in cream of tartar or glucose, as in the recipes, wash down the sides as before, and place the pan once more with the lid on over a quick fire or gas-ring. The lid should be kept on for about 10 min ., so that the steam may thoroughly wash down any adhering crystals. Remove the lid, insert the thermometer gently. Too much importance cannot be attached to the necessity of removing any scum during the boiling process, but there must be no movement of the pan after boiling point has been reached. The more rapid the boiling after the sugar has dissolved the better will be the quality of the sweets.

Before inserting the thermometer, it should be warmed in hot water and not put directly into the boiling syrup; then leave the thermometer undisturbed in the syrup until the temperature reaches 240 deg ., if the sugar is required for fondants or similar sweets. A slightly higher degree is necessary for tablets. At 310 deg. if a little sugar is withdrawn and dipped into cold water it turns quite hard, and cracks between the teeth with a snap without sticking. This is the highest degree advisable to attempt. It is known as the crack. the degree for all hard sweets and rocks.

When the sugar has reached the desired degree, take the pan carefully off the fire. The thermometer should be removed and gently

placed in a jug of hot water. The syrup is left to become per fectly still and the air bubbles must cease before proceeding with the sweet making.
Flavouring and Colouring. Next after sugar in importance come flavour and colour. These must be carefully chosen, for,

Sweets. Fig. 1. Coconut Iee, made with a fordint mixture and desiocated coconut. Fig. 2. Coconnt
other things being equal, they determine the quality and attractiveness of the sweets. Both colour and flavour should be very delicate for creams and bonbons. It gives them an unprofessional appearance to be over-coloured, and too much flavour is out of character. Essences and essential oils are the chief flavouring ingredients. The former are not satisfactory unless highly concentrated, so that those specially prepared for sweet making must be used.

Essential oils are most suitable for highboiled candies, but there are many inferior makes on the market, and only the more expensive brands should be used. Cheap essen tial oils are very impure, require a larger quantity than the better grades to flavour the sugar, and leave a harsh, unpleasant taste in the mouth. Special colours in all shades are prepared and, like the flavours, can be purchased from any bakers' sundriesmen, or in a good grocery department.
Sweets with a Fondant Basis. In a large class of swects the basis is fondant. Take 2 lb . best granulated sugar, put it in a clean aluminium saucepan and add $\frac{1}{2}$ pint cold water. Proceed as directed for sugar boiling, adding 1 dessertspoonful warm liquid glucose to the boiling syrup, stirring it well, and replace over the fire. Do not allow the flames to come up the side of the pan, but keep the heat well below. When the syrup has reached the temperature 240 deg . remove the pan from the fire, take out the thermometer and allow the syrup to settle, and then gently pour it in a thin sheet on to the marble slab, previously wetted with cold water. Sprinkle the fondant with a little cold water and allow it to cool slightly. In hot weather this takes several minutes; in cold the mass will require creaming almost at once.

Scrape it into the middle with the scraper and then take a wooden spatula and work the sugar backwards and forwards. Hold the scraper in the left hand and the spatula in the right so that as the spatula works the scraper collects the spreading mixture. The syrup will gradually turn into a thick cream and then suddenly to a solid white mass. Experience is needed to get the exactly correct temperature at which to start creaming the syrup. If worked too hot it will cream easily, but the resultant fondant will be coarse If too cold, or with excess of glucose added to the syrup, it will be difficult to cream.

When required for immediate use, the fondant should be further kneaded on the slab with the hands until quite free from lumps and a smooth, creamy mass. Fondant made in this way will keep for weeks if placed in an airtight jar and stood in a cool larder. The fondant should be left on the slab for 15 min . covered with a clean cloth before being put into the jar. It is really better when allowed to mellow for a day or two before being moulded or used as a basis for other sweets.

Where fondant has been stored it some times requires to be thinned down with boiled sugar syrup, and it is well to have some in stock if sweets are to be made often. To 2 lb . granulated sugar in a saucepan, add 1 pint cold water, $\frac{1}{2}$ teaspoonful cream of lartar and 1 dessertspoonful glucose. Boil as directed before but re move from the fire when the syrup reache; 220 deg. Pour it into an airtight jar and store for use.

Coconut Ice. For this sweet (Fig. 1), take 1 lb . fondant mixture and put it into a saucepan. Stand this in a larger pan of hot water and stir the fondant with a wooden
spatula. A few drops of the thinning syrup may be added, butcare must be taken not to get the fondant too thin. Continue stirring until it is the consistency of thick cream, divide it into two equal portions, and colour one pink by adding a few drops of cochincal and kneading well in. Work into both portions on the slab enough desiccated coconut to make them fairly stiff. Avoid excess of coconut. Press out each piece to $\frac{1}{2}$ in thickness, and place pink over white. Place a weight on top and allow the cream to sit till firm, then cut it up into bars. For variety, lemon colour and flavour might be used instead of the pink. 'To make coconut kisses (Fig. 2) the mixture is rolled into little balls and left to cool.
Peppermint Creams. Care must be taken in melting the fondant for peppermint and other areams with this basis. It should be made just so hot that the linger cannot be kept in it for more than a second or two. If underheated, the sweets will not set properly; overheated. they will turn quite hard. When adding thinning syrup be guided by the condition of the fondant. In hot weather it will te inore creamy and easier to stir while being reheated; in winter a few extra drops of syrup will be required. Add favouring (colouring also when necessary) when the fondant is warmed through and the syrup has been thotoughly stirred into the mass with a wooden spatula For pepperinint creams add a fow drops essential oil of peppermint to $\frac{3}{4} \mathrm{lb}$. warm fondant mixture. This will be sufficient to fill 24 peppermint cream rings. (luickly pour the fondant into a "armed dropper, and till the rings one-third full. When cold turn each ring upside down and gently tap it and the cream will drop out.
Bonbons and Creams. The basis of a number of fancy bonbons is almond cream, which can be made thus: To 1 lb . warmed fondant Havoured with vanilla add 4 oz . ground almonds, working the latter in thoroughly. Variations are produced from this basis by adding chopped fruits, figs, dates, glaué cherries, or nuts, Barcelona, pistachio, etc.
Neapolitan creams are made by taking four equal portions of almond cream and colouzing one pink with cochineal. another with saffron,

Sweet 3. Fig. 3. Walnut creams, consisting of balls
of almond cream surmounted by balf walnuts
another with pale green or coffee colour. and leaving the fourth white. On to a piece of wased paper on a board press out a piece of the pink fondant to a square 1 in. thick, and then procced to place a square of the same size and thickness of each of the other coloured fondants on the top. Gently press them together. Take a sharp knife and cut the mass into strips. Use a sawing movement while cutting. The strips should be further cut into cubes. Almond cream may be used to stuff French plums or dates. The stone is removed, a roll of the cream neatly inserted, and the fruit pressed together. The almond cream may also be shaped into balls and half a shelled walnut placed on top, as illustrated in Fig. 3. Bonbons (Fig. 4) are made by dipping almond cream contres in fondant using a dipping fork. The tops may be decorated with lines, twirls, etc., or with split pistachios, angelica, or coloured sugar. The article on Chocolate may be consulted for further ideas on suitable centres for bonbons.

Moulded Fondants. To make prettily shaped fondants a rubber fondant mat is a good investment. The mats arc obtainable in several sizes. They must be used quite dry The slightest damp or remains of former fondants will prevent the new hatch of sweets from turning out properly. When the fondant has been reheated, thoroughly stirred, Havoured and coloured, as already described, pour it gently but quickly into the warmed dropper and till each impression or mould just level in the fondant mat. When cold the sweets come out easily if the mat is very slightly bent upwards. Should a sweet stick, remove it with a tiny spatula, but do not use that impression in the mat again if refilling the mat for the rest of the batch. The mat should be quite clean and diy to refill several times without washing if the fondant is of the right consistency and each sweet has come out of its impression cleanly After use the mat should be washed in warm water with a small brush, rinsed in several clean waters and dried on a rack over a low fire before putting a way. By means of the ends of two teaspoons fondants can be shaped. Take small portions of the hot fondant and drop them on the slab, quickly pressing the portions into shapes.

Tablets. Tablets may be made as follows : Boil 2 lb . sugar with $\frac{1}{2}$ pint water to $245^{\circ}$, stirring in a pinch of cream of tartar just when it reaches the boiling point. Allow it to settle for a minute or two after removal from the fire, add flavour and colour, and, with a meta spatula, vigorously rub sinall portions of the syrup against the sides of the pan, and stir these in till the whole becomes cloudy. This is called graining. Add desiccated coconut, almonds, walnuts, etc., as desired, then quickly pour into frames, previousl y lined with wased paper. An unlimited variety of tablets may le produced in this way (Fig. 5). Colours and flavours should harmonize.
For ginger tablet add finely chopped ginger, flavour with gingerine, and colour a light brown with kitchen browning (burnt sugar). For raspberry tablet flavour with raspberry essence and colour with carmine. For chocolate ta blet Ilavour with vanilla, colour with melted chocolate or with chocolate powder well stirred in. Chocolate macaroons are easily made. Cut up plain white coconut tablet into bars, dip these into melted chocolate, well thinned down with co:o-butter, and roll the bar in line desiccated coconut.

Mexican Kisses. The candy known as Mexican kissas is made from 3 breakfastcupfuls best Demerara sugar, 1 cupful milk, 1 lb . chopped walnuts, a piece of butter about the size of a hen's cgg, and I teaspoonful vanilla essence. Boil the milk and sugar together, then add the butter, and continue boiling until the mixture hardens slightly when tested in cold water. Reat the whole well for 3 min ., add the walnuts and ranilla, and beat the mixture again before turning it into a buttered tin. Mark it into squares before it cools.
Sweetmeat Jellies. The sweets that are known as jellies can be made at home and without the aid of special confectioner's tools if a plain cube shape is not objacted to. Two recipes are given, one for making them with gelatine and one in which agar agar or Japanese gelatine is used. This can be purchased at any of the large stores or at a chemist's.

in. 4. Honbons, tor wnicn various centres are dipped in fondant and the tops decorated with coloured surar, etc.

To make the jellies with plain gelatine take lb. any stoneless jam, I gill water, $\frac{1}{2} \mathrm{lb}$. loaf sugar, and $3 \frac{1}{4}$ oz. best leaf gelatine. ${ }^{2}$ Boil the jam with the sugar and water for a few minutes, then strain through a hair sieve. Return the mixture to the saucepan and add the gelatine, which should have been previously dissolved in 2 tablespoonfuls warm water. Boil up and skim, and if desired add colouring or extra flavouring. Pour the mixture into bright, shallow tins lined with wased paper and leave them all night. In the morning reverse the tins to release the jelly, and remove the paper by wetting it. Cut the jellies into small pieces. They look more attractive if rolled in granulated sugar.

To make jellies with the variety of gelatine known as agar agar soak $\frac{3}{4}$ oz. overnight, using 2 pints cold water. In the morning dissolve it over the fire by gentle heat and keep it warm while the syrup is being made. Put the sugar into a strong unlined pan with 1 pint cold water, let it melt, and then boil it till, on a little being dropped into cold water, it will break in a brittle manner, but it must not be coloured. Remove the pan from the fire and pour the gelatine into the sugar. Mix it well.
The jelly can now be flavoured and coloured as desired, or it can be divided and the flavour and the colouring can be varied. Procecd as

Fig. 5. Tablets, made from a boiled sugar ayrup. variously flavoured and coloured, and desiccated nuts
in the former recipe to mould. A large pinch of cream of tartar should be added to the sugarwhen at boiling-point.

Pulled Sugar. Sugar boiled beyond 250 d dg. and allowed to cool turns into a hard crystal. line mass. The addition of some acid substance, as cream of tartar, or of some non-crystallizable substance, like glucose, causes it to be very pliable while hot, and quite transparent when cold. The pliability of hot sugar is a very important point in the making of rocks, and the transparency is essential to appetizing boiled swects.
In pulling sugar for rock maling, a large metal hook, about ( 6 in . across, is used. It is fixed on a wall, level with the chin. The marble slab must be well greased with butter. The hook and a metal scraper or knife used to work the sugar should also be thoroughly greased. With the scraper gently fold over the edges of the inass, raise it a little at a time, and continue folding over towards the centre until the sugar mass is sausage-shaped and just cool enough to be held in the fingers. Before doing this, grease the hands or the sugar will stick. Keep the sugar as much as possible on the fingers and not on the palms of the hands. Fling it on the hook so that the sugar mass is suspended in the middle and drawn by its two ends towards the operator.

When pulled out several feet, the ends are placed together and held by the right hand. while the left is moved till only a foot or two below the hook and laid over the sugar. The left hand is then drawn downward so that the sugar forms an S , and almost simultaneously both are thrown towards the hook, so that the sugar is doubled over on itself. This is repeated over and over again until the requisite amount of pulling has been accomplished. The sugar will probably take about 15 min . to pull. During this process air is enfolded in the hot
sugar, which increases in volume and very perceptibly changes in colour, colourless sugar becoming snow-white, red changing to pink. and black-brown to cinnamon

Rock Making. The beginner must remember that in all rock making quick handling of the sugar is essential. If it cools too much and is difficult to work, heat it over a gas-ring. To make Edinburgh rock, take 2 lb . granulated sugar, $\frac{3}{4}$ pint water, and a good pinch of cream of tartar. Boil to 260 deg. and pour sugar on to the oiled slab. As it sets round the sides, turn these right over into the centre with the greased scraper or a palette knife, so that it will all cool evenly. Add colour and fla vour, fold the sugar over on itself once or twice, and pull it on the hook as already explained. When removed from the hook place it on a board well dusted with icing sugar, roll it into sausage shape, then pull it out to the thickness required and cut the strip into suitable lengths, and let them lie for a day or two to granulate.

Peppermint Rock. Plain peppermint rock may be made with $3 \frac{1}{2} \mathrm{lb}$. white sugar, $\frac{3}{3} \mathrm{lb}$. glucose, 1 pint water, a few drops of oil of peppermint. Boil to 310 deg., the crack degree. Pour sugar on the oiled slab and turn in the edges as it cools. Sprinkle over it 2 or 3 drops of peppermint. When fairly firm, but still very hot, pull the sugar over the hook till it has a white satin-like appearance. Knead it up a little on the slab, make it into a thick sausage, then set it on end and pull it out into rope-like strands. Keep rolling these till they firm up, or cut them with a pair of scissors into short lengths.
For striped peppermint rock (Fig 6), boil up the sugar as before. Have a little red colour powder made up with water into a thick paste,

Sweets. Fig. 6. Striped peppermint rock, a
favourite and wholesome sweetmeat for children
and well stir a little of this into a corner of the hot sugar on the slab. While turning in the edges take care that the coloured portion is kept apart. The other portion, which should be the bulk of the sugar, is pulled as before, and rolled into sausage shape. The coloured sugar is well kneaded, then drawn out into long ropes, which are laid along the white in twos or threes, at wide intervals apart. The sugar is then made into a cone, and the narrow end drawn out as before into a thin rope. The result is a peppermint rock with very thin stripes of red, the artistic effect depending almost entirely on the good taste of the maker.
Cough rock is made from the same recipe as that for peppermint rock, but with oil of aniseed as the flavouring. Here about onequarter of the whole is pulled on the hook, the rest being coloured black and strongly flavoured with aniseed. This latter is rolled into sausage shape, while the white is flattened out and made to enclose the black completely. A cone is formed as before, and drawn out, giving a rock with black centre and thin white case.

Some candy makers do not use a hook, but simply take the two ends of the sugar (when cool enough to handle on the greased slab), pull the strip evenly, then putting the end in the right hand into the left, fold the roll over and pull. Continue in this way until the sugar is firm enough to cut up.

Boiled Sweets. The various rocks, while still pliable, may be cut with scissors into

Sweet Sultan, a hardy annual with fragrant flowers in white, rose, purple or yellow
lengths of about $\frac{1}{2} \mathrm{in}$., and rolled between the palms of the hands to form balls, striped or plain. These balls are known as boiled sweets.
Acid balls are made by boiling 3 lb . white sugar, with $\frac{1}{2} \mathrm{lb}$. glucose and 1 pint water, to 310 deg . l'our the sugar on oiled slab, turn in the edges as it cools, and add a good pinch of tartaric acid and a few drops of oil of lemon. Knead it well. Draw it out as for rock, cut it with scissors, and roll it into balls. Ingredients for making cinnamon balls are the same as for peppermint rock, but the flavouring is cinnamon. Pull the sugar on the hook till it is of the proper colour. Draw it out, cut it with scissors, and roll it into balls. To make cushions, cut the strip across and give it a half-right turn, which brings the point, of a cushion up. Clip it off and then give the strip a quick half-turn left and cut off. Each time the half turn is reversed so that the strip is not twisted. Any pulled sugar sweets may be thus formed into cushions and wrapped in waxed papers to make them look quite professional.

Crystallizing Sweets. Even high-boiled sweets rapidly deteriorate when kept in con tact with the atmosphere. It is customary to crystallize many of the finer varieties, so that they may be immune from atmospheric influence. Sweets. treated in this way arc greatly improved in appearance.

The sweets to be crystallized are set on little wire stands, similar to those used in baking, but on a smaller scale, and these are placed in shallow tins. A deep tin is often used, and the trays, with their rows of sweets, are set one upon another inside it. These trays should have legs about $\frac{3}{4}$ in. long. The sweets on top are covered with another flat wire tray, to keep them from floating in the syrup. The trays thus arranged, the crystallizing syrup, made from the recipe given below, is gently poured in, and the whole allowed to remain untouched for 8 hours, by which time a coating of crystals will have formed. If the coating is not heavy enough, a little longer immersion will be effective.

When removed from the syrup, the sweets are set out on wire trays in a warm, dry room to dry thoroughly. Sweets crystallized in this way will keep for many weeks, even
when exposed to the air. The spent syrup can be boiled up again for tablets or rocks.
The recipe for crystallizing syrup is as follows: Boil 4 lb . sugar with $1 \frac{1}{2}$ pints water, using no cream of tartar or glucose, to 218 deg . Cut out of soft brown paper a piece to fit exactly the top surface of the syrup. leaving a small hole in the centre of it, The syrup should be set aside to cool, and disturbed as little as possible.

SWEET SCABIOUS. This hardy and useful garden plant is also known as the pincushion flower, the species including perennial and annual kinds. The former includes the very beautiful Caucasian scabious. See I'incushion Flower; Scabious.

SWEET SPIRIT OF NITRE. Spirit of nitrous ether, popularly called sweet spirit of nitre, is commonly prescribed in slight feverish attacts, colds, etc.. on account of its diaphoretic action on the skin. It thus tends slightly to reduce the temperature. The drug also has a marked diuretic effect on the kidneys, and is therefore often an ingredient in mixtures prescribed in kidney, heart, and lung troubles, where it is desired to increase the flow of urinc.

SWEET SULTAN. This is a heautiful hardy annual (Centaurea noschata) with fragrant flowers in white, rose, purple, yellow. The modern named varieties have large handsome blooms, and the plants are from 18 to 24 in. high. Seeds may be sown out of doors in spring or in September. Sweet Sultans nced well dug friable soil and a sunny situation.

SWEET WILLIAM. This is a charming old-fashioned garden flower (Dianthus barbatus) of which splendid new varietics have been raised. Two of the most striking arc Scarlet Beauty and link Beauty. The auricula-cyed varieties of mixed colouring are also attractive. These plants are grown as biennials, secds being sown in boxes of soil in May; the seedlings are planted on a

Sweet William. Four varieties of this richly coloured flower, familiar in cottage gardens
reserve border for the summer, and in October are set out where they are to bloom the following year. They should be destroyed after flowering: and a fresh stock of plants raised from seeds. Sweet Williams can also be grown from cuttings in summer.

SWELLING. In inflammation swelling is accompanied by redness, heat, and pain. A dropsical swelling of the skin has the peculiarity
that firm pressure with the point of the finger leaves a depression or pit which takes some time to fill up. Tumours form fairly welldefinel swellings as a rule, at any rate at the beginning. A swelling in the groin or elsewhere on the abdominal wall may be due to $n$ rupture or hernia.
The nature of a swelling should be determined before treatment is undertaken as poultices or rubbing, which have their uscs in appropriate cases, in others may do damage. See Abscess; Sprain.

SWIFT MOTH. Being a nocturmal moth that tlies after dusk, the swift moth is seldom scen, except by the entomologist, gencrally during the month of June. Its grubs, however, are more familiar, and may be recognized by their brown heads and bristly creany-white bodies, about ld in. long. These are some- must do to combat the disease.

## SWINGS FOR NURSERY AND PLAYGROUND

## How to Construct an Outdoor Type

This is one of the entrics in this work that deal with the recreatiors of children. Sce also
Nurscry. The .builder of a swing will find other valuable information in the articles that describe the various tools and woodworking processes

Siwings that are in the form of a chair to may be erected in a garden or courtyard. which ropes are attached are sold for indoor Fig. 2 shows a front elevation of the framework, usc. These can be fastencd to the top of a a side view being given in Fig. 3. The parts are door, so that the child can swing through the marked with a distinguishing letter, those opening. This arrangement is suitable only marked with the same letter being similar in for a small child. The hooks by which it is size and shape. suspended from the door lintel should be Any kind of sound timber which is neither securely lixed. Another lighter type which liable to split nor warp may be used. Well. can be bought has netted sides, tho chair scasoned pine, larch, ash, or clm planks are all being enclosed except at the front, making suitable, and can be obtained planed and it safe and comfortable even for an infant. trimued to size. The quantitics and sizes of
Fig. 1 illustrates a type of swing such as timber reguired are given in the following

Swift Molb. Natural size roots of potatoes, beans, reference.
as paragus, dalilias, peonies, alll other crops. A good remody is effected by the digging in of naphthalene and lime during the autumn or winter months.

SWINE FEVER. This disease is often very destructive to pigs. It is also very contagious and is therefore one of the diseases that are notiliable. This means that in case of an outbreak the ollicials of the Ministry of Agriculture must be informed at once. They will then tell the owner what he
times found derouring list, each piece being named and lettered for

[^10] letter are of similar size and shape. Fig. 4. Front and side views of top of upright, showing position of slots and holes. Fig. 5. Details of shape of upright top
nailed to the upper side of the cross-beam, as in Fig. 2. The spar is shown in Fig. 9.
Stays D D D D are cut as in Fig. 8, a $\frac{1}{2}$ in. diameter hole being bored through the thickness of each stay. The tic-beanis E E have three $\frac{1}{3}$ in. diameter holes bored through them as in Fig. 9. The corners and edges of the seat-board G are rounded as shown in Fig. 10, the positions of the seat-irons being marked out. The bars for the seat-irons P P P P are bent to shape, as in Fig. 12. The centres for three $\frac{1}{4}$ in. bolt holes are marked with a centre punch on each bar, at the point given in diagram A, then the lines from which the bars are bent to shape are marked off from the measurements in B. These lines should be slightly incised with a cold chisel, so that they may show clearly when the irons are heated.
After the bends have been marked, the corners of the bars are cut off with the chisel and the ends filed to the semicircular shape in C. The bars must be heated before they can be bent to shape. Some trouble can be saved if the irons are taken to the local blacksmith to be bent. If the worker prefers to do the
work himself he can procced as set out in the article on Forging.
Three $\frac{1}{4}$ in. diameter holes are drilled through each seat-iron from the points previously marked with a centre punch. The irons are then placed in position on the seat and tested. The plates $Q$ Q, which are fixed beneath the seat-board, are prepared as shown in lig. 13. Four $\ddagger \mathrm{in}$. diameter holes are drilled through each plate from the points given in the diagram, then both ends of each plate are rounded in the same manner as those of the seat irons. Both pairs of seat-irons are now placed exactly in their positions, as in Fig. 14. The positions for the holes for the bolts $R$ are marked on the seal, then the irons are removed, and a $\frac{1}{4} \mathrm{in}$. diameter hole bored through the seat from each point.

After the irons are replaced, the small bolts R are fitted into the holes in the lower angies of the irons and partly into those in the scat, then the 2 plates $Q Q$ are placed in position on the underside of the seat, and the holes brought in line with the bolts. The bolts are driven in until their ends project throagh the holes in the plates, a nut being fitted to each

Sections, showing Recess \& fitting of Eye-bolt

Swing. Fig. 6 ${ }_{\text {Sase }}$ Swing. of ${ }^{\text {Fig. }}{ }^{6}{ }^{6}$ showing checks cut to receive the stays. Fig. 7 Measurements and details of crossbeam and eye-bolt Gxing s. Fig. 8. Plan and side view of seat-toard$\stackrel{\pi}{\text { in }}$ in.
projecting bo!t and tightly screwed up with a spanner.

The woodwork of the swing is assembled by first fitting aud bolting the tic-beams and stays to the uprights, then bolting the crossbeain in position, and finally attaching the ground plank F (Fig. 11) to the lower ends of the uprights. Lay the two uprights A A on the ground and place a tic-bcam E across each of their lower cuds. Bring the hole in the centre of each tic-beam in line with the hole at the lower end of each upright. Next insert a 5 in . bolt L (Figs. 2 and 3) into the hole in each tie-beam, and pass it through that in each upright. A washer is placed on the projecting end of each bolt, and a nut fitted and tightencd up.

The stays D D D D are fitted to the ticbeams and uprights in the following order. A stay is bolted to the right end of each ticbeam, then the upper end of each stay is placed in the check in the right side of cach upright. The upper end of each left stay is fitted into the check in the left side of cach upright, and the lower ends of the stays are bolted to the left ends of the tic-beams. The 5 in . bolts should be fitted with washers, and the nuts screwed firmly home. The upper ends of the stays are sceured in thie checks by means of the 6 in. screw bolts $M$ Each screw bolt is fitted as follows: The centre of the thickness of each stay is found and marked, at a point 2 in. from the upriglit. A $\frac{3}{8}$ in diameter hole is then bored from each centre point at right angles through the stay, and into the upright to a depth of 4 in . The holes are slightly enlarged with a $\frac{1}{2} \mathrm{in}$. rose-bit for a depth of about $1 \frac{1}{2}$ in. Each serew bolt is fitted with a washer and inserted into the hole, and screwed in with a spanner until each stay is firmly bolted in position.

The cross-beam B is placed in the mortises in the uprights, and the 2 holes at its right side brought in line with those in the right upright. A 7 in . bolt K is driven through each alinement of holes, then a washer is placed on the projecting end of each bolt, and a nut fitted and tightencd up. The left end of the cross-heam is bolted to the left upright in the same mannor The ground plank F (Fig. 11) is attached to the tic-beams and lower ends of the uprights by large nails. Care must be taken to sec that the uprights are the correct distance apart before the ground plank is fitted.

The cross-beam and those parts of the uprights and stays which will be above ground when the framework is erected are given se veral coats of varnish paint. The seat may be given a varnish finish or painted Creosote oil or hot tar is applied to the lower portions of the uprights and stays and to the tic-bcams and ground plank.
After the framing and scat have become thoroughly dry, the chains S S are attached to the cye-bolts in the cross-beam. The pins are unscrewerl and partly withdrawn from 2 of the shackles T, then the shackles arc placed on the cye-bo!ts. The upper end link of the right chain is placed on the pin in the right shackle, and the pin screwed home. The left chain is fitted to the left shackle in the same manner. Jetails of the chain, eyc-bolts and shackles are given in Fig. 8. Thesc should be of the dimensions specified.
The ground where the swing is to be situated is dug out to a depth of 2 ft .6 in ., Fig. 15 showing the measurements and shape of the excavation. After the earth has been remored, the bottoms of the trenches should be well rammed. The framework is then lowered into the excavation and uprighted. If the uprights are not perpendicular, the
ground beneath the tie beams and ground plink whole of a building must be removed until they become so. on to the focussing
The framework has to be tested with a screcn; but this plumb line and the spirit level, and any crors causes distortion, unof position rectificd. Large slones negative itself vertior old bricks should be arranged round cal. If the camera is both uprights and firmly driven into the soil. tilted upward, buildThe chains are attached to the seat-irons inge will appear to
 seat-irons, and the pin fitted through the sliackle and holes in the irons and firmly screwed up. The shackle on the left chain is then fitted to the left pair of seat-irons and the pin tightened up, and the swing is complete.

The seat will be about 14 in . from the ground, that height lucing conrenient for general usc. but it may be raised if necessary by moving the shackles to higher links on the chains. Onc-inch diameter ropes can be substituted for the chains, but they rannot be compared with the latter for strength or durability.

SWING-BACK: In a Camera. When photographing buildinge, strect scenes, and other subjects where it is not possible or convenient to get sufficiently far away to include the top of the subject, a rising front gives a useful means of adjustment.
The amateur in surb circumstances is empted to tilt his camera in order to get the

Swing-back. Fig. 1. Field camera in which both hack and front can be swung in order to tilt camers without distorting vertical lines in the photograph Courtesy of Ensign, Ltd.

Swing. Fig. 11. Ground plank. Fig. 12. Diagrams showing bow the bars for the seat-irons are bent to shape. Fig. 13. Plates for securing seat-irons. Fig. 14. Method of securing seat-board. Fig. 15. Shape and dimensions

P P by placing be falling backward in the photograph, and the top of the building, the plate holder, C D, a slackle in the to be falling forward if the camera is will be tilted as well, so that the vertical lines end link of each tilted downward. of the building will converge together in the chain. then the The rising front is the simplest adjustment photograph, giving it the appcarance of falling shacklo on the and is one fitted to most hand cameras. At backward. right chain is the top of the U-shaped lens front a milled The remedy is shown in Fig. 3. The camera placed on the screw will be found on many patterns of is tilted, but by the use of the swing-back the right pair of cameras. When this is rotatod the whole of plate holder is still vertical. The whole of
 the lens mount rises or falls. As it rises it will the building is included, but the axis of the be found that the amount of foreground is reduced on the focussing
reen.
This adjustment should not be used more than is absolutely lens, $A$, to the plate, as shown by the lines C D. This means that the top of the building is slightly nearer the plate, while the bottom is farther away. The lens therefore must be stopped down until all parts of the image are seen sharply in focus on the screen. It is impossible to use either swing. back or swing-front without using a focussing screen.

The same results can be obtained more conveniently by the use of the swing. front, as shown in Fig. 4. Here the front of the camera less the lens lia good covering power i.e. Will cover evenly a plate a good deal larger than that used in the camera, there is a risk of uneven lighling, since the optical axis of the lens is moved from the centre of the plate.
The swing front or swing back adjust. ments, either or both of which are fitted in good fifld and other cameras designed for architectural and landscape work, permit the camera to be tilted while leeping the plate vertical.

Fig. I illustrates an ordinary field camera whose adjustments permit back or front to be swung with a wide range

Fig. 4. Same result as that shown in Fig. 3 achieved by use of swing-front of variation, while the baseboard can be
tilted and the front raisol a considerable is tilted, while the back and the plate holder amount. In the smaller varieties of folding remain vertical. As before, it is essential to pocket or hand cameras the swing front alone stop down the lens until sharp focus is olis usually fitted.
In Fig. 2 the camera is so placed that it i impossible to inclucle the whole building on the power considerably exceeding the minumum lines. If the camera be tilted so as to include the ordinary central and vertical position. A
reference to the diagrams will show the neces. sity for this.
The practical advantages of the swing-back are demonst rated in the photographs Figs. 5 and 6, which show the Bush Building in Kingsway, London, photographed with and without this adjustment. It was impossible to include the whole of the building on the plate without

Swing-back. Fig. 5. Showing distortion of vertical lines due to tilting the camera without use of swing back. Fig. 6. By use of swing-back or awing-front. the camera is tilted but distortion is avoided
tilting the camera. In Fig. 5 this was done switches are made for various purposes, without the swing-back, and bad distortion resulted. Bringing a swing-back into play, as in Fig. 6, the distortion was aroided, but longer exposure was needed owing to necessary stopping down. See Camera; Stop.
SWISS CREAM. This sweet is made by heating up 2 brcakfastcupfuls of fresh milk with the thinly peeled rind of a lemon, placing the pan at the side of the fire so that the process may be slow enough to let the milk absorb the fiavour of the peel. Add $\frac{3}{4} \mathrm{oz}$. isinglass, 1 gill cream ; boil up the whole, strain, and leave to cool at the side of the fire. Stir in the well-beaten yolks of 3 cggs and sugar to taste, put the pan back on the fire and continue stirring until its contents thicken Then let the mixture cool again, and add to it a few blanched and split. almonds and some small pieces of preserved ginger before turning it into a mould to set.

Swiss Roll. See Chocolate Roll ; Jam Roll.
SWISS TART. These small sugar-covered tarts can easily be made from 6 oz . Hour, $\frac{1 \mathrm{lb}}{} \mathrm{lb}$ margarine, 2 oz . castor sugar, water to mix, and a little jam. Sicve the flour into a basin, rub in the margarine, and then add the sugar, mixing them well. Add about a tablespoonful of water, mix it in, and then divide the mixture into six equal portions, forming each into a ball.

Grease 6 small cake tins, put a ball into each, and in the centre of each ball press the little finger, making a hole almost to the bottom. Drop a little jam into the hole, and decorate the top with a knife, making sharp cuts from the centre round the tart.

Bake the tarts in a moderately hot oven for 20 min ., or until they are of a light brown colour, then leave to cool on a sjeve, and, before serving, sprinkle the top with icing sugar.

SWITCH: For Electric Light. The purpose of $a$ switch is to interrupt an electric
circuit, or to close it at will. Switches are made in a great variety of patterns.
In the tumbler switch the centrally placed lever, when depressed, forces the contact blades into contact with the copper brushes connected by set screws to the conductors. Turn switches have a knob or button which is partially rotated to effect contact. Two-way
of purpurcum are purplish. Propagation is by seeds sown out of doors in autumn.
Uses of the Wood. The timber obtained from the sycamore is close, compact, and easily worked, and it takes a smooth, glossy surface from a finely set planc. If it is properly scasoned and sawn on the quarter it will not shrink or twist to any extent. It is nearly white in colour with a yellowish tinge. Owing to the method of conversion the surface shows a pretty figuring, particularly when the wood is cut nearly parallel to the medullary rays.

The wood is much in demand for general turnery. It is used for rollers of mangles and washing machincs, (lairy utensils, and bread boards; it is also employerl for violin backs. Owing to its close grain it is adapted for inaking wooden bowls, and for the same reason it is suitable for wood-carving and particularly for chip-carving. It takes stain well, and can be used as a substitute for cbony. It can be obtained in boards over 12 in . wide, and is also procurable as plywood.

SYLLABUB. A very old-fashioned country dish, syllabubs formerly were made with new milk drawn straight from the cow on to the spiced and sweetened wine in the syllabub bowl. To-day they may prove a highly successfu! addition to thie refreshments at an evening party if made according to one of the following modern recipes.

For a " Farmhouse" sy!labub dissolve in a bowl 3 oz . castor sugar by stirring it with $1 \frac{1}{2}$ gills sweet home-niade winc and $1 \frac{1}{2}$ gills sherry. Add the grated rind of a lemon and $\ddagger$ of a grated nutneg. Put into a large carthenware teapot l pint new milk warmed to the degree of freshly drawn milk, and hold the pot ligh above the contents of the howl and pour with a circular movement on to the wine. Strew over the top a little grated nutmeg. Let the whole stand for some houra, then cover the top with clotted cream.
A Staffordshire recipe is to put 1 pint cider with a wineglass of brandy into a bowl, add about 6 oz . pounded lump sugar and $\frac{1}{2}$ teaspoonful grated nutmeg, then stir until the sugar is quite dissolved. Warm 1 quart new milk, and put it into a jug with a sharf spont, or, better still, an carthenware teapot. Pour it round and round on to the cider; grate more nutmeg on the top, and let it stand for some hours. Serve with whipped cream.

A lemon syllabub has an excellent flavour. Grate the rinds of 2 lemons and stir them into $1 \frac{1}{2}$ pints sherry or Madcira; also dissolve in the wine llb. lump sugar. Strain the juice of 6 lemons and 1 full-flavoured orange, and arld these to 1 pint pure thick cream. Now put both wine and cream into a decp but not very large basin, and beat with a whisk for $\frac{1}{2}$ an hour. Let nll stand for 2 or 3 days, and the night before it is required for table arrange it in sundac glasses or custard cups.

A very cconomical syllabub may be made by dissolving 2 oz. lump sugar in $\frac{8}{3}$ pint homemade raisin wine, then add the grated half of a nutmeg, and pour on to the wine 1 quart of warm new milk from an carthenware teapot.
To make good syllabubs it is most important to use pure fresh cream or nilk and the finest white sugar. Lump sugar is the best. When beating, work evenly and in one direc. tion. It is a mistake to start in a hurry ; begin and continue with slow, steady strokes.

SYNOVITIS. Inflammation of the synovial membrane of the joints, or synovitis, may follow sprains or other injuries.
The reute condition is usually accompanied by pronounced swelling, heat, and pain. It is treated by rest and cold applications. Later the joint is massaged, and a woven clastic bandage is put on to maintain pressure and assist in the absorption of the fluid in the joint. In chronic cases iodine or som? other
counter-irritant is used to reduce the swelling, and a bandage is worn during the day. See Bandage: Joint.

SYPHILIS. Syphilis is due to the entrance of a minute organism beneath the skin or mucous membrane through an injury to the surface, which may be excecdingly small. In the great majority of instances the infection is conveved by sexual intercourse.

The discase begins with a sore, which develops most frequently upon some part of the organs of generation, usually about 4 weeks after infection. During the next 6 wecks to 6 montlis there may be fover for a few days, headaches, and rheumatic pains in the joints. Rashes of various sorts appear on the skin, and the throat and inside of the mouth become ulcerated. In the later stages tumours known as guminata may appear in ally organ or tissue of the body, extensive ulceration of the tissues may take place, the bones may be croded, the arteries thickencd, and aneurism may develop.

Locomotor ataxia and other forms of paralysis may occur, and mental changes such as general paralysis of the insane. In women iniscarriage and abortion are common. A particularly sad form is seen in infants when one or other parent has the discase.

Great efforts are now being made to eradicate syphilis and other forms of venereal discase from the community. In the United Kingdom methods for prevention and treatinent are advocated by the Society for the Prevention of Venereal Diseases, 6, Holborn Viaduct, London, E.C.I.

Parents can assist by giving their children sound, healthy teaching in matters pertaining to sex, and by impressing upon young adults the langer of promiscuous intercourse. The provision of carly and efficacious treatment is also of great importance, and centres have been established in all large towns where those who have acquired the disease can obtain treatment with the assurance that strict privacy will be maintained.

In its primary stage syphilis can be cradicated by treatment with arsenical compounds combined with mercury or bisinuth. Treatment should last for at least two years.

SYPHON: For Mineral Waters. Soda and other mineral waters may be obtained in syphons which consist of a glass container with a metal top. A glass tube fixed at one end in the top passes down inside the container, extending almost to the bottom; it must not touch the hottoni, otherwise the action of the syphon will be obstructed. The top is fitted with a spout or tap and a small spring lever in the form of a handle which operates a valve. When the lever is pressed down the valve opens and the mineral water in the syphon is forced up through the tube by the pressure of the gas which it contains, and discharged through the spout. The quantity is regulated at will instantaneously by depressing or releasing the handle.

Freshness of Contents. The advantage of the syphon over the ordinary bottle therefore, is that small quantities can be drawn at any time without detracting from the freshness of what remains in the container. Syphons are filled through the spout by a mechanical process which cannot be carried out at home. They can be obtained from any chemist or dealer in mineral waters.

In warm weather syphons should not be kept in a living-room, but should occupy the coolest position in the larder or cellar. For table use they may be cooled by the aid of ice. but should not be placed in direct contact with it. Some refrigerators are so constructed that a syphon may be placed on a shelf right above the ice, or it may be cooled in an ice cave. If the house does not contain these means of cooling food it is best to put the syphon into a wooden vessel and pack the outside of
the wood with ice, placing a tray on the top with ice on it. It is not safe to im. mersc a syphon in ice as it might burst.
Syphon Stand. This is an ornamental container for the ordinary mineral water syphon. The pattern illustrated is made throughout in silver, and comprises a tube-like body ornamented with a band of piercing in a simple design, and provided with handles. See Piercing.
SYPHON : For Transferring Liquids. A syphon which can be made at home consists of a glass or metal tube bent to a $U$ shape, with the limbs of differing length. It provides a simple means of transferring tiquid from onc vessel to another. The difference in the lengths of the tube is essential to the action of the syphon, the shorter length being placed in the liquid that is to be drawn off.
If suction is applied to the long leg of the tuhe the liquid is raised in the syphon and flows out until the level drops below the end of the short leg, or, if the long leg dips into a vessel, until the level of liquid in both vessels is the same. As sucking by the mouth may be inconvenient when the syphon is not fitted with a suction pipe, the same effect can be obtained by inverting it and filling it with the liquid. Then, stopping both ends with the fingers, or corks. the short tube is placed into the liquid and the ends unstopped, when the liquid will flow steadily until it falls to the lavel of the lower end.
Syringa. This is the botanical name of the lilac, but it is often wrongly used to describe the mock orange or philadelphus.
SYRINGE : For the Garden. A syringe is invaluable in garden and greenhousc. but it must be of a good type, provided with spare nozzles and roses capable of impelling water in volume or fine spray. It should be kept properly packed to prevent leakage ; for pacling, use tow and grease if available, otherwise substitute darning wool. As a general rule plants with hairy leaves or ripening fruit should not be syringed. See Insecticide ; Spraying.

SYRINGE: In Medicine. Various kinds of syringe arc used in the treatment of different disorclers. Direction for syringing the ear are given in the article on Deafness (q.v.). Syringing the nose is often dangerous and should be left to a doctor. See Douche; Ear.
SYRUP : In Cookery. Syrup is a solution of sugar in water heated until, when poured from a spoon, it drops like oil, or by the sugar thermometer to $220^{\circ} \mathrm{F}$. It is used for sweetening various foods, as a means of preserving them, and also as an article of diet in itself When properly prepared it can be stored in bottles, and will keep in perfect condition for a considerable period.

The syrup may be merely a simple thick liquid, it may be flavoured, or it may be medicated; but the process is the same: Only the purest refined sugar and distilled or filtered water should be employed; if there is any doubt as to its purity it should be clarified.

To clarify, have ready a perfectly clean, thick steel or aluminium pan. Dissolve the sugar in the water, placing both together in the pan, and allowing $\frac{1}{2}$ pint water to evary lb . sugar. The water must be accurately measured. Whip up the white of half an egg with 2 or 3 tablespoonfuls of water until light. then pour it into the syrup and place the pan over slow heat. Beat until a good froth forms, then skim the surface carefully and brush the sides
 when taken out of store. Use loaf sugar in preference to granulated sugar, as it will be found to be cleaner. To test the syrup, if no sugar thermometer is at hand, pour it slowly from a spoon or drop a little on a plate, and if it lifts with a thread it is boiled enough.
If syrup is bottled when alinost boiling, and at once tied down with portions of bladder or some covering equally in pervious, it will keep better and appear brighter. If fermentation should take place, put the bottle into a pan of boiling water; this will usually clear it.

Fruit Syrups. Any flavour added to syrups must be perfectly clear; if at all cloudy it should be clarified. When making a syrup with a fruit juice, either fresh or taken from a tin of fruit. no clarification is necessary. The juice should be strained through a hair sieve, the sugar added, also a little lemon juice, and then the whole should be simmered in a bright saucepan to the required consistency.
Sweet jellies are brighter and clearer if syrup is used in place of raw sugar. but the proper proportions of liquid must be adhered to. Many excellent summer drinks may be made with syrup and flavouring if aerated water is added For stewed fruit, flans, and pastry fillings, syrup is both useful and necessary as a sweetener, and the housewife will find it a great help always to keep a few bottles of different fruit syrups in the store cupboard.

Another kind of syrup much used in cookery is golden syrup, which can be substituted for treacle in any of the recipes given under that hearing. It can also be used instead of jam in the making of roly-poly puddings, tarts, etc. Golden syrup used for tart-making is usually thickened with breadcrumbs. This syrup is also much used instead of sugar for sweetening porridge and similar foods.
Syrup Cake. To make a good syrup cake, sieve together 1 lb . flour and $\frac{1}{4}$ teaspoonful bicarbonate of soda, rub into them 7 oz . margarine, and add 6 oz . sugar, and ? lh . ground almonds, mixing all well. Beat up 2 eggs in another basin, add to them 1 teacupful golden syrup, and whisk the mixture well before stirring it into the dry ingredients. If necessary, the syrup may be warmed slightly. Add also about 1 gill milk, then beat the whole for a few minutes before turning it into a greased cake tin lined with greased paper. Bake it in a moderately hot oven for about $1 \frac{1}{2}$ hours.

Medical Uses. Certain drugs are dissolved in syrup for the sake of making the medicine palatable to the patient. Various tonic mix tures are prescribed in this form, including syrup of the phosphate of iron; Easton's syrup, or syrup of the phosphate of iron with quinine and strychnine, and compound syrup of phosphate of iron, or chemical food. See Compôte; Flan; Treacle.

TABLE. One of the oldest pieces of fur- ornamental nature. Reference may be made niture and one of the most common. From the original table that was but a square or oblong piece of wood, standing upon trestles, was evolved, the one supported by a leg at each corner, and from the latter a greal variety of styles has developed.
In England, at a later date, were made the massive oak tables, with legs supported by a stout frame. To the Jacobean age belongs the draw table, which, with improvements, has come into favour again as a dining table in the 20th century. The dressing table and also the work table developed on their own lines, and special tables, suited for specia! purposes, were produced, as the wine table, now a valued antique, and the card table, with its mor. abie top. Folding tables are of considerable age and from thesc were developed, in Cromwellian days, the gatc-leg tables still so popular and, later, Pembroke tables. Many beautiful examples of walnut tables were made in the reign of Queen Anne, with cabriole legs oftc n having shell ornaments carved on the knees. Later Chippendale made many tables, including varieties fo specific uses.

Fig. 1 shows an artist's table with square legs and a typical Chippendale design in the strapwork carving. Hepplewhite and Sheraton also made and designed a variety of tables, and readers are referred to the entries on the styles of these great English designers. During the period of the Regency style (q.v.) sofa tables were developed from those of Sheraton on the lines of the example illustrated in Fig. 2, which shows the yoked fect and brass inlay so characteristic of the early 19th century pieces.

Articles on how to make the principal types of table will be found under the headings Afternoon Tea Table; Bed Table; Card Table; Dining Table; Dressing Table; Folding Table; Gate-Leg Table; Kitchen Table; Trestle Table; and Writing Table. These contain working drawings and full instructions showing how the home worker with a little skill in earpentry can construct tables of a useful or

Table. Fig. 1. Chippendale artist's table in mahogany with strapwork carving ; late 18th century

TABLEAUX VIVANTS. This form of entertainment may be given in a some. what ambitious or in an extremely simple manner; but there are certain general rules which should be observed in either case.

The tableaux should be in charge of three persons: a producer, to sclect, cast, and rehearse the pictures; a stage manager, to attend to the lighting, any scencry or furniture, and the curtain or scieens; someonc to supcrintend and assist with the dresses, to inspect the performers before they go on the stage, and to help generally with difficulties in both makicup and costume.
The succession of pictures must be carefully worked out. Pcople who are appearing in more than onc picture must be given time to get ready for the next character while pictures in which
they do not appear are being shown. Copies of this progranme should be pinned up in any dressing-rooms, behind the scene, and in the stage manager's corner at the left side of the stage. He should have a bell as a signal for the commencement and close of each tableau.

The pictures remain before the audience for two or three minutes. It is difficult to preserve absolute stillness in some poses, and it is better to display the tahleaux for a shorter time than to spoil the illusion by movement. Where there are a number of people in the picture the most brilliant and striking dresses are placed in the foreground and those in neutral tones at the back. Good colour schemes are a great help towards success. In selecting subjects, those with strongly marked dramatic contrasts will be the most successful.
Use of a Stage. More elaborate presentation requires a stage a bout 12 ft . square, with a proscenium screen painted to represent a picture frame, across which a close black gauze, 8 ft . wide by $7 \mathrm{ft} . \mathrm{high}$, is stretched and nailed hehind the frame. Behind this gauze, which is stationary, curtains which can be drawn or closed are fixed on a roll, and there is a complete frame of electric light, hidden by the proscenium screen, round the tableaux. The black gauze has a softening effect and keeps the whole picture remote from the audience; otherwise, it is not seen when the lights hehind it are full on.

At the beginning of each tableau the stage manager rings a hell and the lights in that part of the room where the audience sits are switched off. The stage curtain would have been down while the tableau was arranged with the lights up behind; when the setting is complete he switches off the stage lights and the curtains are raised in the darkness. Then these lights are switched on and the picture is disclosed behind the gauze screen.
The frame of light is not required for all tableaux. A well-known painting may be copied in which there is a glow of firelight, or a sunlight effect from an open door in a darkened interior. In that casc the lighting wonld be supplied from the side with the hclp of a lime box and coloured slides. Any special lighting effects would have to he tried beforehand. The whole background may be black; it may be of black velvet, or any light absorbent material; the stage cloth should also be black. Sometimes the sides of the stage are draped with dark curtains, and different back cloths are used for different pictures.

A simpler method, with or without stage, in a large room is to manage with curtains only. or with sereens plain!y covered in a dark colourSome of the picture illusion is lost withont the framed gauze, but the tableaux, if well arranged, can be quite effective. The lighting in this case is from the top and sides, or from the sides only. When screens are used, twe people in fancy costume, as pages or theatre attendants. draw back the front screens at a signa' from the stage manager.

Garden Tableaux. Tableaux vivants may be given in a garden. A raised terrace with wall or shrubbery background, or at the top of a shallow flight of steps, below which there is a space which can be utilized for the audicnce, is a good place to choose for the entertaiument. Screens can again be utilized for the change of picture. Sometimes children are rehearsed to form up in a senicircle in Iront of each picture after it has been sloown, holding big branches of foliage to mask the stage, parting when the next picture is ready : or grown-ups with stencilled banners, which they unroll to form a complete screen. These last methods are particularly good when the curtain makers act as a chorus for nursery rhyme tableaux or for illustrations of old songs. In selecting a series of tableaux the question of costumes inust be carefully thought out. Simple dresses can be made at home and special or historical costumes can be hired, but this last expense may be considerabic if many elaborate dresses and wigs are nceded in the pictures.
A fairy story such as Little Snow-White and the Seven Dwarfs or The Slecping Beanty, illustrated by a dozen tableaux, with someone to tell the story as it is shown, is a good item on a programme. Tableaux introducing famous characters from Shakespeare, Dickens Jane Austen, and other writers, topical cartoons, well known advcrtisements, -and dramatic ballet groups, in poses which cam be held, are all effective.

A man and woman dressed in fancy costume may be stationed in front on each side of the tableau stage to introduce the pictures, or for the children's entertainment a fairy godmother may tell the story and appear to control the picture with her wand. See Make-up: Theatricals.

TABLE CENTRE. This style of mat especially designed for the centre of the table, and formerly either placed on the dining table when not laid for meals, or as a decoration. over the white cloth, is now usual only as the centre piece of a luncheon or dessert set of table mats. On festive occasions, such as a Christmas party, a special centre is sometimes devised to enhance the decorations. For instance, a gold or silver tirsel square or circle might be outlined with artificial holly leares
nad berries, or a square of ivory gauze stencilled with red Howers and silver leaves might form a table centre, to be surrounded with fancy swect rlishes and cruckers.

TABLE CLOTH. For the dinner table it pays to huy good damask, not only because of its apprarance, but also because it wears well and launders better than the cheaper kinds. For family use such a table eloth should be on the large side. There is no objection to its hanging down nearly to the Hoor at sides and ends, and if an extra leaf has to be put in the table the cloth will still be large enough. Some people favour table
cloths with drawn-thread borders or a hem stitched or lace elge. It may be said that a fine damask necis no further ornament than an embroidered initial or monogram, but a less valuable one is sometimes improved by a little ornamentation, not too clahorate, and lace crochet introduced into a linen dinner table cloth gives it a handsome appearance.
Table cloths for use at other than meal times are not often seen, owing to the liking for polished or painted surfaces and the hygienic dislike for anything that accumulates dust. See Appliqué Work; Breakfast; Drawn Thread Work; Embroidery: Jinen.

## TABLE LAYING AND Decorating

## Attractive Settings for both Everyday and Formal Meals

Other useful information on this subject will be found in the articles on Breakfast; Dinner; Luncheon; Supper. See also Christmas; Cocktails; Dining-Room ; Flowers; Glass Ware ; Hors d'Oeuvres; Napkin; Silver Ware; Sfoon

The art of good table-laying is one which enhances the reputation of the houscwife and hostess. Fond can only be enjoyed when nicely served and with pleasing surroundings. More attention than ever is paid to the im portance of colour, freshness and ordered arrangement of the table appointmenta, since it has been recognized that these things in themselves create a sense of personal har mony which is helpful to good appetite and digestion. On the decorative side it is easy to give either a charming, amusing or festive air to the table with inexpensive accessories and flowers to suit the season and occasion.
A few preparations have first to be made in the kitchen or pantry. The knives are wiped, the silver polished and special attention paid to the condiment containers, as an attractive table is impossible unless salt cellars are evenly filled, pepper pots are showing no trace of pepper dust, and mustard pots are supplied with freshly-made mustard. Any glasses on the table should be quickly polished with a clean cloth, and water jugs, etc., require the aame attention before being filled. For the breakfast table it is most important that the butter and jam or marmalade dishes ahould ook inviting.
The housewife decides whether she prefers a table cloth, table mats, or a sort of combination of the two by means of a linen runner and mata to correspond. The last arrangement is a favourite one for breakfast or luncheon and looks particularly well in coloured linens to harmonize with the table ware. All-over striped linen cloths are a good choice for the family breakfast table with napkins to match. There is great beauty about a plain danask cloth for the dinner table, but lace-edged mats will look more festive if the china ware and other appointments are simple. When a cloth is used the table should be protected by underlying baize, serge or felt: protective mate must be-provided under linen or lace table mats. These protections can be dispensed with when a cold supper or luncheon is served.

An example of a wise choice of plain damask cloth is shown in Fig. 1. Here the table is laid for a small formal dinner party. Unity is achieved by the plain background to the ornamental glass, silver candlesticks, sweetmeat and salted almond dishes, the patterned dinner service and the central llower arrangement of roses and gypsophila. Lace mats would make so much detail fussy and the appearance of the table less dignified. The possessor of Sheffield plate candlesticks, and a cake basket in which a glass bowl could be placed to hold the Howers, conld use these appointments with equal success in such a setting.

A complete change of surroundings and ware makes Fig. : an equally striking and successful example. On a table with polished wooden top and netal lega, the soup bowls
are of the square shape that some English makers are favouring, and the mats are of glass. The centre-picce is of glass and stecl and the two ibises on either side of it are of silvered glass, while a tiny cactus is placed in a silvered pot at each corner. The inenu cards arc on heavy glass stands, the table silver and gold-rimmed drinking glasses are slightly less severe in design than the rest of the appointments, but the whole effect is bright, a musing and sparkling.

In a Queen Anne or Georgian style of room with a fine mahogany table surface, nothing conld be in better taste than the setting illustrated in Fig. 3. Cut crystal glasses and llower bowl are the features; the condiment holders are of pierced silver with glass liners, and the mats of beautiful linen Madeira work. The simple luncheon tahle shown in Fig. 4 is
quite as charming with its oblong linen place mats, covered soup howls, pot of hyacinths and silver wire bread hasket

Laying for Dinner. Where the carving and serving are done at table, a carving cloth should be spread at the end. This may be an embroidered affair or a plain dinner napkin of good size. The sideboard is covered with a cloth, and also the dinner wagon or butler's tray.

In setting the table for dinner the place for each person can be marked out by a napkin. The necessary supply of cutlery, silver, etc., is placed on a small tray, which is carried round the room, so as to arrange each place correctly. Each person should have a large knife on the right hand, a large fork on the left hand for use with the meat course, with space left between to take the plate. A dessertspoon and fork may be placed horizontally in front, the spoon on the outside with the handle towards the right and the fork on the inside with the handle towards the left. Alternately, and more usually when etcertaining, the dessertspoon and fork are placed with the other cutlery on either side of the plate. If a fruit salad or ice is to be served in individual glasses, a small spoon is often put beside the glass on the plate when handed to each person, and no dessertspoon and fork are laid.

If fish is to be served, the fish linife and fork are placed outside the large knife and fork. For soup a tablespoon, or special soup-spoon, is placed on the extreme right of the knives; a cheese knife is placed inside the other knives, or on the checse plate, as shown in Fig. 1. When grape fruit is served a grapefruit spoon or a teaspoon is provided and a small fork or knife and fork for a savoury.

Table Laging. Fig. 1. Table laid for a formal dinner party, with a white damask cloth to set of the beauty of the patterned china, the glass and the flowers.

Table Laging. Fig. 2, A polished table surface is further enhanced by plass mats, steel and glass centrepiece surrounded by cacti in small pots and a pair of silvered glass ibises

Eaci person is given a tumbler for water and clear water, a fruit knife, and a forli and spoon. one or more wine glasses if wine is offered. A sugar bowl lilled with castor sugar should Jach ferson may be given a small slice of be in readiness whenever fruit such as oranges, bread or a roll placed on the left hand, or the strawberries, etc., are being offered. Before bread may be cut and placed on a salver or dessert is laid on the table the used glasses, basket. Somctimes toast is served in one or tivo sinall racks.

Carvers and kilife rests are placed at one end of the table in front of the persoll who does the caring and outside his own complement of knives and forks. Spoons and forks for serving the sweets, etc., are usually laid at the opposite end of the table Fish slice and fork are placed outside the meat carvers and the soup ladle next to these. A sufficient number of salt cellars, etc., should be provided and placed at the corners of the table, as illustruted in ligs. 1, 4, or in the ease of a small round or square table may flank the centre piece.

Cbecse, butter, biscuits may be
placed in readiness on the sidehoard and cheesc: plates. etc., are removed and the also fruit dishes. etc:, if dessert is to be offered, and in this cuse there should also be put ready a dessert plate for each person, with a fingerbowl containing aboul, one-third of its depth of

Fig. 4. Luncheon table, with small individual cloths, covered soup basins, and heavy cut-glass tumblers
cheon table, with small individual cloths, covered soup basins, and heavy cut-8
crumbs are taken ofl the cloth with a crumb scoop, kept in readiness on the sideboard. Coflce making equipment may also be placed there, as indicated in Fig i.

Table Decoration. The choice of effective table decorations is almost limilless, and can therefore alwavs be regulated by individual taste and means. For those who possess flower gardens, the problem of expense is practically non-existent except during a few winter months.

Any scheme for decorating a dining tiable should be inlluenced by the colouring of the room in general, and of the dinner service, lamp or candleshades in particular. When only two or three people are dining at a long table, and onc ched is not occupied, an im-portant-looking decoration is a pleasant change when placed at this end instead of in the middle; otherwise a long or oval table is best with all extended treatment, a round or square table with a more compact one not too high to obscure the view across the table.

For luncheon or breakfast table pale yellows and blues are charming, but they are apt to lose their effect by artificial light. Violets, purples, and deep blues. also, are not good night colours. When shaded candles are used to light the table, Howers of somewhat more deciled tones ill harmony with the shades should be chosen for the decoration. Very large blooms are difficult to arrange, except when the size of the table allows of a somewhat massive decoration. Even then they are better when some lighter flower or fcathery folinge is mingled with them in order to avoid a heavy or crowded appearance.

Fig. 3. A simple old-world atmosphere is suggested by water lilies in a faintly tinted glass bowl, gleaming silver and cut glass reflected in the polished table; graceful period chairs complete the harmonious effect

Coloured glass is often a deciding factor in a successful scheme. Cherry or ruby red glass on a white lace-trimmed cloth is enhanced by flowers of the same shade; while amber or pale green glass is beautiful with mauve. In early spring, on a mahogany table, with mats instead of a cloth, so that the polished wood is seen, a bowl of yellow tulips Hecked with orange and arranged with red-brown berberis is a simple and harmonious decoration.

Shirley poppies, daisies, and grasses are attractive for a luncheon table, and vellow roses in a sapphire bluc bowl, lightly arranged with plenty of leaves, are a good choice with a dinner service which is patterned with green. For a hot night, coolness is suggested by pink roses in small cut crystal vases set round a block of ice in a large bowl, the table lit by pinkshaded candles in silver or glass candlesticks.
In winter, when flowers are expensive, a dish of fruit in contrasting colours is a good centre-picce for small vases of llowers or trails of autumn foliage. On a polished table, a pair of brightly coloured china birds or Chelsea figures are sometimes used at either end of a dish of fruit. Glass birds or animals set on a piece of mirror glass form a bright decoration round a vase of glass flowers or a little green glass tree. Old silver-gilt em bossed spoons and small glass or silver dishes for sweets and salted almonds can also help towards the decorative scheme.

A miniature Japanese garden (see page 646). sct in round or oblong pottery, with lacquered
candlesticks and corresponding shades, is a change from flowers or fruit. A good Christmastide decoration has for centre-piece a black Wedgwood bowl containing flowering bulbs of scarlet tulips and white Roman hyacinths, surrounded by holly leaves and berries, and groups of searlet and silver crackers.

TABLE MAT. Protective table mats for meal service on polished tables are miade of rubber, rush, raffia, linoleum, asbestos, cork, composition, glass and wood. Otnamental mats to be uscd over these are of embroidered linen, either white or coloured, wholly of lace or crochet, or linen trimmed with lace or crochet. In some cases the protective mat is also decorative, as for example when made of iaffia dyed in bright colours, of cork stencilled with a pattern, of painted glass, or of wood treated with bronzes and brush lacquer colours.

With transparent lace the colour of the protective mat underneath is important. Gilded composition or cork is used with good effect, otherwise the under-mats are best when unobtrusively matching the colour of the table. For ordinary use rubber mats afford excellent protection: also they have the advantage of bcing thin, and the linen mats over

## Table Tennis: The Rules of the Game

## A Popular Indoor Pastime for Winter Evenings

A number of articles in this work describe various indoor and outdoor games that are suitible for the home. Such include Billiard; ; Lawn Tennis
Table tennis is a development of ping-pong, these halves being known as courts. The one which became popular in Great Britain about 1900. An association was formed, but after 1905 the popularity of the game waned and this ceased to exist, although there were pingpong leagues in various parts of the country, including Plymouth and Exeter. Each of these leagues, however, had its own rules. In 1921 the Ping Pong Association was revived and under its auspices national championship matches were held. In 1924 the term ping-pong, as it was a trade name, was abandoned and table tennis was sub. stituted. The Ping Pong Association was dissolved and its place taken by the Table Tennis Association.

Table and Implements. Tables specially made for the game of table tennis can be purchased. A useful type is a light table, coloured green, that can be laid on the top of an ordinary table.
The table should be rectangular, 9 ft . by 5 ft . in size, of solid hardwood, or of such material as will yield a uniform bounce over its entire surface of at least 8 in . when a ball of standard size is dropped from a height of 12 in . The net must be $6 \frac{3}{4} \mathrm{in}$. high, and should be dark green in colour, with a white band along the top. It must fit close to the table and to its supports. and must be exactly in the midd!e of the table's length.

The average weight of the celluloid balls that are used in this game is 13 to the oz. ; they must not be heavier than 121 1 to the oz. nor lighter than $13 \frac{1}{2}$. They should measure between $4 \frac{1}{2} \mathrm{in}$. and $4 \frac{3}{4} \mathrm{in}$. in circumference.

Almost any kind of light racquet may bo uscd, the surface being of any material. To day the best players use rubber racquets, with which they can get an astounding amount of speed on the ball.
Scoring. The method of scoring is by games, 21 points making a game. Each player in turn serves until five points have been scored by the two players together. If the score reaches 20 all, it continues to 25,30 or more points, on the principle of lawn tennis that one side must be two points ahead of the other before game is called.
Rules for Serving. The game is usually played by two persons, but it can be played by four, two against two. In the former case each player deiends one half of the table.
them do not slip when plates are removed. his court and then touches any object apart A set of protective table mats usually from his racquet or the hand holding it.

The ball is dead or no longer in play and the point counts against the player who made the stroke in the following circumstances: when the returned ball strikes any object, apart from the net or its supports, prior to dropping on to the opposing court; when the ball, having been played, touches the player's court before going over the net (this does not apply to the service): when the ball, after passing over the net, goes beyond the limits of the table without dropping on it.

If either player touches any part of the net or its supports with the racquet or any part of his body while the ball is in play, the ball becomes dead, and he loses the point: when a ball drops on the proper court and screws back over the net, the player whose turn it is to strike may reach over the net and play the ball, so long as he otherwise makes a good return. If he fails to play the ball, his opponent scores the point notwithstanding the fact that the ball has returned over the net. A player loses a point if he touches the table with his free hand while the ball is in play.
The phrase table surface is to be interpreted as including the top edges and corners of the table top, and a ball in play which strikes these latter is therefore good and still in play; though if it strikes evidently the side of the table top below the edge. it becomes dead and counts against the last striker.

Finger spin may be imparted to the ball in service by projecting it by hand into the air and then striking it; it may not be imparterl by holding the ball and rubbing the racquot surface against it before it leaves the hand.
The Game for Four Players. These rules are also applicable to the game in which four persons play, but for this there are certain other regulations. The table must be divided down the centre at right angles to the net by a line or tape, ${ }_{4}^{3} \mathrm{in}$. wide, so that the table is divided inco four courts. Wach of the four players defends one court.
The pair who have the right to serve the first five services in any game shall decide which partner shall do so, and the opposing pair shall then decide similarly which shall first be striker-out.

The first five services shall be delivered by the selected partner of the pair who havo the right to do so, and shall be received by the selected partner of the opposing pair. The second five services shall be delivered by the striker-out of the first five services and received by the partner of the server of the first five services. The third five services shall be delivered by the partner of the server of the first five services and received by the partner of the striker-out of the first five services. The fourth five services shall be delivercd by the partner of the striker-out of the first five services and received by the scrver of the first five services. The fifth five services shall be delivered as the first five services, and so on, in sequence, until the end of the game or the score is 20 all. Then the sequence of serving and striking-out shall be uninterrupted, but each player shall serve only one service in turn until the end of the game.

TABOURET. A tabouret is a seat or stool with neither arms nor back, the top being stuffed and upholstered. Tabourets are chiefly stools of the period of William and Mary and Queen Anne, 1688-1714.

TACKING. The stitch known as tacking is a temporary one, being used to hold a hem, seam, or other part of a garment in position while the permanent stitches are put in Coloured cotton should be used for tacking white materials and whitc cotton for dark matcrials, so that the stitches can be easily distinguished.

Begin the tacking by knotting the cotton at one end and pushing the needle straight
through the material. Work from right to bear large, round, lemon or orange-coloured left, and make the tacking stitches about $\frac{1}{2} \mathrm{in}$. flowers which make a striking display in the long and to lic a little above the line where herbaceous border. There are both tall and the permanent stitches are to be made. After pushing the needle through to the wrong side, bring it out again $\frac{1}{4} \mathrm{in}$. further on in a line horizontal to that where it was put in, and continue to the end of the work in this way.

Tacking should be finished with a backstitch. When removing tacking stitches, care should be taken to see that the material is not torn or puckered. See Basting.

TACSONIA. These climbing plants are suitable for the hothouse or moderately heated greenhouse. It is of vigorous growth and is suitable for training on a trellis beneath the roof glass. They belong to the passion flower family and bloom chiefly in summer and autumn. The plants may be set in large tubs or flower-pots or in a well-drained border ; a compost of loam, leaf-mould and sand is suitable. A minimum winter temperature of 55 degrees is necessary. The finest sorts are insignis, reddish-violet; manicata, scarlet,and Van Volxemii, scarlet.
TAFFETA. The most popular variety of this cloth is silk taffeta, which is crisp, with a peculiar dull lustrc. Silk taffetas, because of the methods used in making them. are, however, inclined to split in wear, and for this reason they cannot be regarded as hard-wearing. Wool taffeta makes an excellent shirting, and is a superior fine flannel inade in tasteful patterns. Cotton taffetas are especially good as shirtings, and are generally dependable in colour and wear.

TAGETES. This is the botanical name of the French and African marigolds, two valuable summer and autumn flowering plants. They are grown as half hardy annuals and raised from sceds sown in a heated glasshouse in February. The secdlings are transplanted into boxes of soil to give them room for development and are hardened off and planted out of doors early in June. The African marigolds grow 2 ft . or so high and

Tallboy. Queen Anne tallboy in beautifully grained walnut with inlays in the botlom drawer representing riys of the sun. Height 6 ft .2 in . Courtesu of Gill \& Reigate, Ltd.
dwarf French marigolds, the latter being very useful as edging plants; the double and single flowers are various shades of ycllow, or yellow marked with reddish brown. Legion of Honour, yellow and brown, is a favourite dwarf varicty.

TAIL PIECE: On Chairs. This term is used for the continuation of the seat backward seen in Windsor chairs. It forms a necessary attachment to the diagonal spars in a stick-backed type of chair. It is usually quite short and of the thickncss of the seat. The diagonal spars fixed to it are useful for stiffening the piece. See Chair.
TALCUIM. There are a number of uses for talcum or talc, which is a soft, greasy mineral, varying in colour from silvery white to yellow and green; it is a magnesium silicate. The name is also applied to mica, and it is used as chimneys for gas burners and for windows in some kinds of heating stoves. Another use for tale in the home is in the crushed or powdered form as toilet powder. Powdered talc is employed as a lubricant, and, mixed with varnish, makes a shiny coating for wallpapers.

When crushed, talc has the property of reflecting light, and when spread over a comparatively large area it imparts a certain lustre to the material. This effect is made use of in the preparation of a number of fabrics with a shiny surface, the result being obtained in some cases by the use of a special talc preparation. Talc is also employed under the name of French or Spanish chalk.

Medical Uses. Talc has also certain medical uses. On account of its smoothness, prepared talc is often used as a dusting powder for babies; boracic acid powder is generally added and a trace of perfume. Venetian talc, which comes from Tirol, is especially soft and smooth. Lassar's paste, a protective and soothing application for irritable and inflamed skin disorders, may be made with talc as follows : Zinc oxide powder and powdered Venetian talc, of each 2 drams : vaseline or soft paraffin, $\frac{1}{2}$ oz.; salicylic acid powder, 10 gr . Mix into a paste and spread on soft linen or surgeon's lint.

TALLBOY. A tallboy is made up of a double set of drawers, one upon the other. This piece of furniture was first made in England in the latter half of the 17 th century. The carly ones are of walnut, beautifully grained wood being sclected to veneer the picces. A finc example is illustrated, which shows the characteristic Queen Anne features of burr walnut vencer, brass handles and discrect use of marquetry, the bottom drawer alone being ornamented in this manner.

The tallboy belongs to the walnut period of furniture at its best, but at a later date was made in mahogany. The typical piece has 3 or 4 long drawers in the lower part, and 3 in the upper. In the upper there are also usually 2 smaller drawers. The piece rests on 4 short club legs, and beneath the drawers is an arched shaping. The upper part is usually narrower than the lower, from which it is separated by a simple moulding. The decoration is not elaborate, taking only the form of deep moulding at the top and chamfering or reeding on the front angles. See Chest of Drawers; Queen Anne Style.

TALLOW. Tallow is an animal fat largely consisting of stearin, palmitin and olein. The highest grades are used commercially for the making of candles and the lower grades in the manufacture of soap and dressing leather. Tallow can be used to some extent as a lubricant in cases where rope or cord runs over a pulley. Jishing and other lines are rendered
more or less waterprooi when rubbed with tallow.
Tow impregnated with tallow can be ent ployed for the making of joints in the stuffing box or gland of pumps, etc. See Tow.

TAMARIND: The Fruit. The fruit of the Tamarindus indica is imported from the E. and W. Indies in the form of a reddish brown pulp mixed with sugar. It has an agreeable taste, contains a large quantity of citric and tartaric acids, is a refreshing drink for fever patients, and is slightly purgative.

For children tamarind spread on bread and butter is a good laxative medicine. A refreshing beverage for the sick may be made by boiling 1 oz . in a pint of water. Tamarind whey is made by boiling 1 oz . in $1 \frac{1}{2}$ pints of milk, or stirring it into boiling milk. The dose of tamarind is 2 to 8 drams. It is usually used with other purgatives ; for example, in confection of senna.

TAMARISK. This is a hardy flowering shrub with slender, graceful, leafy stems and rose-pink flowers in early or late summer. It

Tamarisk. The feathery heads of small rose-pink fowers of the Tamarix pentandra
reaches a height of from 4 to 8 ft . or more The tamarisks are particularly suitable for planting in seaside gardens, where they are often used as hedges. The common taniarisk is Taınarix gallica. It bears pale rose-pink Howers in May. Tetranda, which Howers at the same time, is more beautiful ; both should be pruned after flowering if necessary. Pentandra (Hispida aestivalis) is a charming shrub with rose-coloured inflorescences in late sum mer; the shoots should be pruned in spring. Tamarisks thrive in ordinary soil and are increased by cuttings inserted in sandy soil out of doors in autumn.

TAMBOUR. This is a method of constructing a lid or shutter to a writing-table or bureau. It was used among others by Hepple white and Sheraton. The sliding lid of a rolltop desk is an elaboration of it. Sheraton made bookcases in this style. The lower part is enclosed in a sliding shutter composed of beads made to slip in grooves.

TAMMY CLOTH. Sauces and soups that depend for success upon their smoothness are usually passed through a tammy cloth made of
fine woollen muslin. The cloth is spread over a basin or other receptacle, its edges gathered in the hands to form a well in the centre and the mixture poured in. The two ends of the cloth are then twisted in opposite directions intil all the mixture has been forced through. If the latter is especially thick and cannot be tammied in this way, it may be rubbed through the cloth with the aid of wooden spoons.

Immediately after use the tammy cloths should be washed in warm water to which a little soda has been added, rinsed well, wrung out, and dried in the open air. See Jelly.

TANGERINE: The Fruit. The amall Tangerine orange is used as a dessert fruit, and also for various forms of swects. It makes an excellent marmalade, and the juice is used to flavour fondants, icing, sweets, and a delicate filling for cakes.

The filling for cakes may be made from the following recipe: Boil 3 egge hard, then pound the yolks fine with 3 oz . butter, 4 oz . icing sugar, the grated rinds of 2 tangerine oranges, and sufficient of the strained juice to form a soft cream. Spread this filling between two sponge sand wiches and dust the top with icing sugar. This cream spread between shortbread biscuits is delicious.
Meringues may be flavoured with tangerines. Gratc the rind of one or two tangerines and add them to the sugar which is used to sweeten the whipped cream for the filling.

Tangerine Chips. These make an excellent garnish for cakes, biscuits or fondant sweets. To preparc them, remove the peel from several Tangerine oranges and shred it in long, narrow pieces, then place these in a basin, cover them with water and lay them aside till the next day. In the morning strain and weigh them, and take an equal weight in castor sugar.

Put the chips into an unlined, bright metal saucepan and strew the sugar over them as they warm, shaking and tossing them about over a moderate heat until they appear perfectly dry. Store in a dry place and keep the chips covered up tight. The pulp of the oranges should not be thrown away : it may be used for other sweets.

Tangerine Drop Cake. Tangerine peel may bc used to flavour light drop cakes. Rub $\frac{1}{2}$ lb. lump sugar, lump by lump, on the outside of 3 Tangerine oranges until the sugar has absorbed the zest, then pound the sugar in a mortar until it is a fine powder. Separate the yolks and whites of 4 egge, beating both by themselves and then together, then by degrees beat these into the flavoured sugar until spongy.

Tango. Fig. 1. Showing the six ateps of the reverse turn. See text for full description

Mix in very lightly $0^{\frac{1}{2}}$ oz. fine sifted flour, to which has been added a pinch of salt. Drop this mixture with a teaspoon on to a tin lined with grease proof paper. Bake in a fairly quick oven, decorate each cake with a Tangerine chip attached with a little marmalade jelly, then cool on a wirc, and store in a covered tin. See Fondant: Marmalade.

TANGO. The tango differs from other modern dances in that the dancers walk the steps instead of gliding them, the knees consequently being more relaxed, although they should not be bent; also the man holds his partner a little farther to one side (on his right hip), his left forearm being bent in more. Both dance with the right side of body alightly in advance of the left, consequently the right foot is turned in a little and the left turned out to the same degree.

There are two rhythms to be followed in this dance, the slow (S.), in which each step occupies one beat of the music, and the quick, pies one beat of the music, and the quick,
quick, slow (Q.Q.S.), in which the quick steps
take balf a heat each and the slow step one beat. The basic steps are as follows: (1) The Walk: (2) Progressive side step (Fig. 2): (3) Reverse turn (Fig. 1) ; (4) Side promenade (Fig. 3) : (5) Back corté (Fig. 4).
The Walk (S.). The walk forward consists of natural length, ordinary walking steps, the weight of the body being kept over the front foot. The back foot is left behind until the last possible moment before stepping forward with it. The step is counted "slow" and takes one beat of music. The body being held with the right side a little in advance of left, contrary body movement (C.B.M.) is consequently used when stepping forward with the L.F. For the walk backward swing leg well back from the hip, going on to ball of foot and keeping weight on front foot. As step continues weight is carried between the feet and the toes of front foot should leave the floor so that all pressure is on front heel. Weight is then transferred on to ball of back foot. The back heel should not be lowered until the front foot passes it. The front foot should remain in front until the last possible moment before stepping back with it. The right side of the body being held in advance of left, the contrary body movement position occurs when stepping back with the R.F.
Progressive Side Step (Q.Q.S.). Following a walk forward with the R.F., the man steps forward and across slightly to R. with L.F., takes a small step to the side with R.F. and steps forward and across slightly to $R$. with L.F. The girl, having taken a walk back with the L.F., steps back and across slightly to L. with R.F., takes a small step to side with L.F. and steps back and across slightly to L. with R.F. In this step the contrary movement position occurs on the first and third steps for both man and girl (Fig. 2).
Reverse Turn (Q.Q.S., Q.Q.S). The man steps forward with L.F., turning on it to L., takes small step to side with R.F., still turning, and erosses L.F. over in front of R.F.; steps back with R.F., turning on it to $L$, takes small step to side with L.F., and closes R.F. up to L.F. The girl steps back with R.F., turning on it to L., nearly closes L.F. up to R.F., still turning. and closes R.F. up to L.F. ; steps forward with L.F., turning on it to L., takes small step to side with R.F., and closes L.F. up to R.F. On the first three steps half a turn is made. On the last three, a quarter turn (as shown in the diagram) or no turn at all (Fig. 1).

Side Promenade (S.Q.Q.S.). The man steps to side and very slightly back with L.F.

Fig. 2
Fig. 4
Tango : three of the basic steps. Fig. 2. Progressive side step ; it usually follows a walk forward with right foot. Fig. 3. Side promenade, in which thy dancers cross one foot over the other. Fig. 4. Back corte. Throughout the dance the right foot is turned slightly in, and the left foot slightly out
crosses R.l., well over in front of L.F., takes a small step to side with L.F., and closes R.F. up to L.F. The girl steps to side with R.F., crosses L.F. well over in front of R.F., takes small step to side with R.F., and closes L.F. up to R.F. Contrary body movement is used on the second step (Fig. 3).
Back Corte (S.Q.Q.S.). The man steps back with L.F., back with R.F., turning rery slightly to L., takes small step to side with L.F., and closes R.F. up to L.F. The girl steps forward with R.F., forward with L.F.: turning very slightly to $L$., takes small step to side with R.F., and closes L.F'. up to R.F. Contrary body movement is used on the second step (Fig. 4).

In the accompanying diagrams the R.F. is shaded, the left shown in outline only. The dotted outline indicates the ultimate position of foot. It will be casier to follow diagrams if the dancer faces the direction in which the toes are pointing and turns the diagram at the same time. See Dancing : Foxtrot: Quickstep: Waltz.
Tank. See Cistern; Gallon.
TANKARD. The modern tankard is a plain drinking vessel usually large enough to hold a pint of liquor and made of silver, pewter, glass or earthenware. They are cither open or with lids. Genuine antiques and tankards reprorluced from old sty!es are nearly always lidded. The tankard is shaped somew hat after the stylc of the flagon (q.v.), but the latter is an earlicr type of drinking vessel, and whereas tankards vary from about 6 to 9 in . in height, 7 in . being usual, Hagons were as much as $15 \frac{1}{2} \mathrm{in}$., and more cumbersome picces.
Tankards are sometimes found in old Sbeffield plate, but more fŕcquently in silver and, copied in the plainer styles, in pewter. The lid and hinge are the chief points of interest: in the older examples a thumbpiece on the hinge strap is placed so that the lid may be easily raised. Both handle and thumbpiece were often artistically decorated. The latter was cut in two main shapes, a horizontal corkscrew, and bifurcated. Fine tankards occasionally have a lion thumbpicce and in later examples this is sometimes fluted.
Dating from the end of the 16 th century to the reign of Charles I, tankards were straightsided, but often richly chased and ornamented with repoussé designs. Very plain styles with flat lids followed in Puritan times. Restoration tankards were massive with cylindrical bodies, Hlat lids and engraved with coats of arms and

Tankard in ailver dating from 1830, when these pieces were richly ornamented Courtesy of chapmle \& Mantell
crests. Queen Anne tankards were for the most part fairly plain but clegantly shaped and often embellished by gadroon ornament to edge the lid and base. or by reeding round the body of the tankard. A knob appears on the lids occasionally. This disappeared on the domed lids of Georgian tankards (sce page n54), many of these pieces being bellied and the thumbpiece, or purchase, well in evidence. The tankard illustrated dates from the reign of William IV and shows the reappearance and claboration of the knob into a floral ornament, the bellied body, spreading foot and lavish raised decoration of the perind. It will be noted that the thumbpiece is absent from the hinge strap, the knob by this time having been substituted for it.

What are known as peg tankards have small pegs fixed inside in a line with the handle; the object being to regulate the quantity of liquor to be drunk on ceremonial occasions in honouring each toast. See Pewter; Silver.

TANNIC ACID. Oak galls are the source of tannin or tannie acid, which is a brownish powder with a strongly astringent taste. Common preparations are : glycerin of tannin, suppositories of tannic acid and lozenges of tannic acid.

Tannic acid is an efficient astringent, lessening the discharge of Huid from any ulcer or mucous surface to which it is applied. It is also a powerful hacmostatic, as it clots the blood Howing from a vessel. The powder may be used as a snuff to check blceding from the nose.

Internally tannic acid is used in the form of an infusion to check diarrhoca. It may be used in a douche to check leucorrhoea. The glycerin of tannin, 1 part to 8 parts of water, is an efficient astringent gargle in sore throat.
TANSY. This is a small family of hardy herbaceous perennial plants. The average height is about 2 ft ., and the yellow, daisy-like Howers are borne in summer. Seed should be sown in spring in ordinary soil. The value of the ordinary tansy, Tanacetum vulgare, is in

Tansy. Leavea of Tanacetum vulgare, a valuable addition to the herb garden
its leaves, which are used for Havouring pud dings, and also for decorating dishes. Cost mary, T. balsamita, is grown for the salad value of its leaves. Tansy tea is also an oldfashioned country remedy. All kinds may be increased by division of the roots in autumn. See Herb Garden.

TANTALUS. A tantalus is a small upright wooden stand used as a receptacle for spirit bottles, in which the latter are locked up but visible. The bottles arc of cut glass and generally number two or threc.

Tap: For Screw Threads. See Stocks nd Dies.

## Taps: The Household Types

## Hints for the Handyman on Fitting and Repairs

This article describes the leading forms of domestic water tap. The articles on Frost and Water
Supply should be consulted for further information. See too Bath; Hose Pipe; Hot Water Supply should be consulted for further information, See too Bath; Hose Pipe; Hot Water Supply; Sink; also Pipe; Plumbing; Soldering

The water taps in general use in the home are of two classes, known as plug and screwdown taps.
The plug tap consists of a body and a plug. the body having a passage-way through it which is crossed at right angles by a second passage-way tapered in shape. This is occupied by a similarly shaped piece of metal known as the plug. The plug has a hole through it lincable with the first or throughway hole. When the plug is turned in its socket so that the hole in the plug is opposite that in the borly, the liquid passes through. When the hole in the plug is at right ang!es, the through-way is closed and no liquid can pass, if the pluy is a perfect fit in the socket. This kind of tap is used for water at low pressure. A similar type is used on gas pipes.

The screw-down tap consists of a handle and screwed rod which turns in the upper part of the body and has at the lower end an enlarged portion known as the jumper. This can be raised or lowered under the action of the handle, the function of the jumper being to cluse or open an aperture between an upper and lower water-way formed in the !ody of the tap. The construction is clearly indicated in Fig. 1, which illustrates a stop cock. Fig. 2 shows a bib cock with the jumper nut and washers removed. A pillar valve for baths and lavatory basins is illustrated in Fig. 3.

Screw-down taps are generally used on all water fittings in connexion with public sup-
plies, as they are durable and reliable in use and tend to minimize wastage of water. It may be noted that some considerable pressure of water is needed to operate the screw-down tap, so that it is useless fitting this type to a rainwater tank, for cxample. A plug tap should be employed for such purposes.

In Figs. $\simeq$ and 3 the component parts are indicated as follows: A, handle and barrel. $B$, jumper. $C$, jumper nut. $D$, washer. $E$, joint washer. F , borly. G , cap. H , fixing nut. J, union piece and nut.
The tap usually fitted to wator pipes for domestic purposes (Fig. 2) is known as a

Tap. Fig. 1. Sectional view, showing principal parta of the acrew-dow type of atop cock
screw-down bib cock. The compononts are clearly shown, as they bave been taken apart in their proper order. The hody is seen at the bottom. right; above it is the washor which makea the joint between the body and the barrel watertight. Next ahove the washer is the jumper washer (top, right), and jumper with retaining nut (bottom, left). The jumper seats on to a valve face within the body, and is praclically the only part that is likely to give trouble. It is replaced when needed with a new washor, which can he obtained in various sizes from ironmongers. A washer of a special material is needed for pipes on the hot-water system. As soon ns the pipe commences to drip, and water is not easily turned off, a new washer should be forms of domestic work. as, for example, when fitted. Sometimes the jumper nut gets cor- a small part has to be securely attached to a roded and will not unserew : in such a case it base plate or other part. The screw passes is best to fix a new jumper and washer complete. through a clearance hole in the part to lie

The barrel at the top consists of a stuffing box to keep the joint between the screwed part of the handle and the barrel watertight. The lower part of the barrel is threaded to screw into the top of the body. Usually this part is screwed left-handed, that is, the barrel is unscrewerl by turning it backwarl, or against the clock. It is sometimes fitted with a setscrew to prevent it unscrewing. This should be looked for at tho start, removed if present, and the barrel can then be unscrewed with a large spanner applied to the bexagonal part at the botton of the barrel.

The same principle is adopted with stop cocks and other taps, including the pillar types of bath and lavatory basin valves, an example of which is illustrated in Fig. 3. The internal structure and arrangements are similar to the foregoing, but the outlet from the body is set at an angle to enable the tap to stand in a vertical position. This has the adrantage that the pipes can be more readily erected and are less obtrusive, as they can be hidden to a large extent behind the basin or hath.

As will be evidnnt from an inspection of Fig. 1, there is a right and a wrong way to fit a stop cock, the correct way being with the lower of the waterways towards the direction of flow of the water. This is because the water as it passes the jumper and washer is then able to lift it of its seat, and thus there is a minimum of friction in passing. If the tap be arranged the other way round, the water will tend to force the jumper down and thus partially choke the waterway, and there will be much more pressure needed to force the water through the stop cock. On some makes of tap the jumper is positively attached to the spindle by a Hoating joint, and this joint automatically lifts the washer and jumper from the valve seat.

TAP BOLT. Alternatively known as a stud bolt or cap screw, the tap bolt, which has a square or hexagonal head, is employed in metal work when an ordinary bolt and nut cannot be used. Examples are found on many
attached, and bites in a thread cut into the main part of the apparatus. See Bolt : Nut.

TAPE. It is not always best to buy cotton tape in mixed packets. A small assortment in varying widths is useful, but the stock bundles usually include a proportion of the less necrled sizes, and
Tap Bolt for use in metal work
 these take up room in the workbox.
Linen tape is naturally stronger and more durable than cotton tape, and, although nsually unbleached, it whitens in the course of washing. Tape makes an excellent sub stitute for twine, especially in packing stationery and books. Stationers sell special tape for such use, as well as red cotton tape for tying documents and narrow green silk tape for batches of typewritten shects.
Special tape is also made for heading and gathering curtains, which pulls out flat for washing. These headings ensure good pleating and are supplied in all colours and in various widths.

TAPE GRASS. The half-hardy, ornamental grass with small white flowers, which is known as tape grass, is suitable for indoor pools, aquaria, or water basins. It should be potted up in a small receptacle filled with rich garden in springtime It a the wate temperature of about $60^{\circ}$. Tape grass is also known as eel grass. There is only one important variety of it.
holder in Sheffield plate, about 1800

Taper Holder. Wax-jack type ol

TAPE MEASURE. A good tape measure is an indispensable adjunct to the workbasket. It is, as the name implies, made on a strip of material which looks like tape, usually about $l \mathrm{in}$. wide, and is finished off at one end either with a metal tab or a loop. The length is usually 60 in . and is divided into inches on one side and centimetres on the other. The whole can be rolled up neatly and put away in the workhasket without taking up raluable space. Similar measures are made in narrower widths in a box or reel which contains a spring. This draws the measure back automatically when the end is released and involves no winding.
TAPER. Wax tapers bought by the dozen are useful in the house for lighting up purposes, especially with incandescent gas. They are obtainable in colours and in white. The hearier make of white tapers can be inserted in a brass holder which can be adjusted to the length of the taper, and prevent it curling up at the end when a few inches have been burned

Such a holder is convenient when hung near the gas cooker for lighting one burner from another with the taper contained and for preventing the fall of drops of wax.
Taper Holder. This antique was designed for holding a tiny candle or a coiled wax taper when the introduction of sealing wax made some device for melting it a necessity on the writing table. Good specimens in silver and Shefficld plate are greatly valued to day by collectors. The holder took three main forms, a stick, a box, and a jack. The stick resembles a small candlestick and is also to be found in brass. These pieces followed the standard candlestick patterns. Some have a chimney glass as a protection for the flame against draughts.
The box is a small, rounded canister, about 3 in . across. It has a loose lid, through the centre of which is a tube which holds the taper. An extinguisher is often attached to it, as it is to the candlestick. The jack is a less familiar picce. Sometimes it, too, was supplied with an extinguisher. The example illustrated has a cage of flat wire work and a side handle, by which it was held. The ring is fixed to the taper bar round which the long wax taper was coiled, except the small portion in use which comes through the hole in the top. Another type of wax-jack without the cage is illustrated in page 1144. See Candlestick; Sherlield Plate.

TAPESTRY. The word tapestry is used to cover a range of decorative patterned fabrics, the design rather than the texture determining the classification. Thus a type of machine-woven furnishing materials, carpets, wallpapers and needlework, are all spoken of as tapestry. The real thing is confined within the limits of its handwoven texture, of which the design forms an integral part. It may be woven on an upright or a horizontal loom, but the resulting fabric is the samc. Tapestry was woven in Egypt many centuries b.c., while beautiful fragments exist of ancient Greek work. Although made in France from the 14th century, important manufactories were first established in England in the 17th.

A textile is not tapestry in the strictest meaning of the word, even when handwoven on a loom in which a double warp (vertical thread) is used and the shuttle carrying the weft (horizontal threads) is thrown between the warps to their full width, the interlocking of the textile being accomplished by use of

Beauvais were also flourishing, and at Mortlake in England fine work was being carried out.

Designs are classed under two broad headings, verdure and personnages. The former may be of massed foliage only, or also introducing flowers and fruit ; the style known as mille fleurs, in which Howers and leaves are scattered in profusion over the ribbed ground: the landscape designs, for which the workshops at Beauvais were particularly famed. Mille fleurs and landscape designs often introduce figures and animals, but the main interests of flowers and foliage class them as verdure.
Personnages designs, as the name implies, are figure pieces, battle and hunting scenes, cartoons and copies of pictures in which people are the chief intercst. Heraldic or armorial tapestries were usually surrounded by borders of verdurc. In old tapestries made for mural decoration borders were an important part. Pancls are completely bordered by a narrower design or on three sides with inscriptions at the bottom, while lengths, originally part of hangings which covered whole wall surfaces, usually display a border top and bottom.

Besides this broad classification based on type of design, which embraces all periods,
the treadle, which brings first one set of warp threads to the top, and then the other.

Real tapestry is bobbin woven. One set of warp threads only are used, and the bobbin passes the weft by hand in and out of each warp thread alternately. Only the weft threads are seen on the surface, presenting the design with the ribbed or rep appearance, exactly the same on both sides, which distinguishes the genuinc fabric. In the article on looms a simple tapestry pattern is shown being woven on a string warp, and the principle of the weaving is demonstrated by the illustration.

Of all textiles, tapestry is the most durable, as this complete interlocking of warp and weft produces a web which is almost indestructible in ordinary usage; but it will be readily understood that even modern real tapestry must be a costly production when it is considered the time, patience, and artistic skill required to produce a yard, copying the forms by use of the number of colours and shades which go to the making of a fine design. Old pieces fetch prices beyond the purse of the ordinary buyer, except by some lucky chance. Anyone possessing genuine tapestry which has been cut'or torn should have it repaired at a tapestry studio; otherwise it may be irretrievably spoiled.

The three great epochs and corresponding centres of tapestry making were, in the 14 th and 15 th centuries, Arras (the name of the town becoming a synonym for tapestry hangings); in the 16 th, Brussels ; in the 17 th, Paris, when the Gobelins workshops were assisted by Louis XIV to become the finest centre of the art. At this period the ateliers at Aubusson and
tapestries are also classed as Gothic, Renais-
sance and Later French, and these terms are often used by modern decorators in speaking of various patterns. The Gothic designs of the Middle Ages, which are considercd the fincst, are flat in drawing and almost without
perspective. Fewer gradations of colour were used, and in consequence the patterns have stood the test of time, while subtler shading has become blurred in more recent work.

Some of the loveliest Gothic designs, copied to-day for mural punels or to upholster valuable chair-frames, are the mille fleurs. In the Renaissance designs attempts were made to copy the lifelike style of the painting of this period. The Later French period tapestry, often spoken of as Louis and sometimes as Aubusson, where a great deal of it was made, chiefly shows the charming designs inspired by the paintings of Boucher and Watteau; dainty and delicate in colour and treatment, these are largely reproduced to-day for covering white and gold or gilt frame chairs and settees.

Simulated Tapestry. In the machine-made jacquard tapestries effects are well reproduced at a moderate cost. This fabric is made in panels to copy tapestry pictures with verdure borders, varying in size from big wall-pieces to cushion covers. It is also made by the piece, repeating the all-over verdure design, and sold by the yard. It has splendid wearing qualities, and its texture looks better next to a polished wooden surface than a dull one. The charming effect in a hall of such tapestry in a pictorial form is shown in the illustration. Block printing by hand of a good tapestry design on a horizontally ribbed material, simulating the real tapestry texture, is another form of imitation for mural purposes. The colouring and designs used are good, and at a little distance the effect is rich and pleasing. Above a dado carried out in oak block printed rep looks its best. Pictorial and other tapestry effects are carried out in needlework, using the stitches described in the subsequent article.

Painted tapestry in imitation of the Gobelin tapestries has a foundation of corded or rep canvas over which the designs are painted. Its resemblance to the genuine tapestry is duc to the particular kind of canvas of which it is made, for the real Gobelin tapestry has also a corded ground, though the designs are woven, as already described, instead of painted. The painting is done by experts, and the finished article is therefore somewhat expensive.
Tapestry carpets are imitations of Brussels. In tapestry wallpapers the verdure designs are copied in pleasant colourings. Sometimes figures are introduced, or landscapc panels. See Living-Room ; Louis Style; Loom.

## TAPEstry Needlework: Stitches \& Designs

Embroidery for Chair Seats, and Other Canvas Coverings
This article explains the practical application of this decorative needlecraft in the home. See also Bag; Cross Stitch; Embroidery; Laid Work; Queen Anne Style: Rug; Stool ; Victorian

Included under the heading of tapestry needlework are all the canvas embroideries in which the stitchery covers the whole groundwork of the fabric and in which the work is done on countcd threads. This type of embroidery was done in England in early Tudor days and continued in use for wall and bed hangings until the end of the 17 th century, and on, when it became the fashion for chair, settee and stool seat coverings. In Victorian days it was much used also for firescreens, draught screen panels, footstools and tapestry pictures. On stools and chair coverings, opaque white and crystal beads were frequently introduced as high lights on the patterns. In some examples of older work silk thread is used for the same purpose and some needle tapestry is embroidered entirely in silks.

Materials Required. One of the most fascinating things about the work for furnishing purposes is that designs can be obtained or evolved which suit any type of room and furniture, but in which the same simple stitch or group of stitches are employed,
however intricate the appearance of the work when completed. Another immense advantage is durability. It is therefore wise to use the best wools for embroidery, and canvas for foundation. Materials, including designs with colour charts, canvas already traced for working, or with the patterns outlined and colours suggested by painting them on the fabric, wool and silk embroidery threads, canvases in a variety of meshes, needlework frames and needles are stocked by all good art needlework shops and departments in stores. Work can also be reshaped if pulled, or mounted when finished if required.
Tapestry wools vary in thickness according to the nature of the work, canvas and design. For a large piece of work such as a chair seat, which will be required to withstand constant wear, a heavier type of thread is required than for a bag design embroidered on finer canvas. Among other excellent makes of wool Pearsall's tapestry and crewel wools, Whitc Heather Embroidery Wools, Penelope Crewel Wools, and Copley's " Darnart " Embroidery

Wools are all made in a wide range of colours and are obtainable in small skeins.
Silk threads should not be used for upholstery covering as they do not withstand wear. In several old pieces where silk threads have been introduced into portions of the original work the wool worlied portions are unimpaired, but the silk ones have perished. Silks are lowever useful for brightening smaller designs for pole lire screens, cushions, cosies, blotters and purses. Artificial silks, owing to their brilliancy, are often liked for this purposc. For very fine work Filo and Filoselle threads are recommended as the strands can be split and any thickness used that the worker requires. Mercerized embroidery cottons such as Sylko are sometimes employed, and wear well, but nothing can beat the beauty of wools for this form of embroidery. Tapestry wools are best used for heavier work, light crewel wools for fine petit-point embroidery on such articles as bags.
Tapestry is worked on either a single thread canvas, or double thread Penelope canvas, and a variety of meshes are ohtainable according to whether the design requires a fabric having many holes to the inch or comparatively few. For instance, there might be 120 stitches across a design, and if the work was wanted to measure 12 inches across when finished, the canvas should have 10 holes to the inch. Double strung canvas is best for covering furniture. The canvas is obtainable in single and double widths when bought by the yard. Special blunt pointed tapestry ncedles should be used for the work.
For large pieces of embroidery it is wise to use an embroidery frame, but this is not necessary for a smaller piece. A frame simplifies the task as there is a tendency for the work to pull crookedly. Should this happen the remedy is to damp the work thoroughly on the wrong sidc, place it face downward on a piece of clean cotton cloth on a board and tack it flat to the board, testing with a ruler to sce that the work is stretched to the exact shape required when finished. and leave it to dry.
Colours and Designs. For all fine needle tapestry it is essential that colours should be subtly gradel. The richness of pattern is obtained by the use of 4 or 5 shades of one colour in proximity and by the contrasted plain colour of the solid background. Expert workers get wools specially dyed according to their colour charts. When copying some of the older designs it should be remembered that colours were originally brighter and probably cruder. This is especially the case with greens. The lovely bluc-grcens of the old Jacobean work are to a great extent the result of accident. The blue dyes employed endured, while the yellow were fugitive. The most delicate pinks and yellows in many Queen Anne period pieces have in some places faded to indeterminate whitish shades.
Artistic workers use undyed tapestry wool for these, the natural tint of the wool giving exactly the right tone when used as the lightest member of a group of greens, reds and pinks, blues or yellows. Another hint which can be applied when embroidering a cover for a period chair or stool is to change the pale shades slightly in the repeats of the pattern to give the partially faded eflect of inellowing age. The result is to make the new cover belong to the frame instead of proclaiming its modernity at a glance. If in spite of careful choice of "old" colours to suit period pieces the result is still too crude, the tapestry may be dipped in tea and then tacked to a hoard or frame to dry and preserve the required shape.

While art needlework shops supply designs elaborately prepared there are many pieces of heautiful work which can be done directly on the canvas by counting stitches and follow-
ing clear charts of clesigns and colours. The pattern motifs are always worked first and the plain backgrounds put in afterwards.
Period designs are obtainable in Florentine, Cluny, Gothic, Gobelin, English 17th century, Queen Anne. Chippendale, Adam, Victorian, and: also in Louis styles. The last are often used for embroidering beautiful bags, and a typical one is illustrated in Fig. 11, with its landscape motif surrounded by a scrolled frame and floral pattern. A great help to anyone who wishes to work a cover for an antique stool or chair is to visit the Victoria and Albert Muscum and study the necdlework covers of furniture in the collections there. For the most part earlier designs show a tendency to all-over patterns, which have again appeared in tapestry work for quite modern pieces, particularly Florentine patterns consisting of vandylies or wavy lines in which the rich effect is gained by use of varied colours. Many of the later designs were composed of central floral or pictorial motifs, either surrounded by fancy borders or a plain continuation of the background stitchery.
The Stitches. The stitches most used in needle tapestry are petit point, gros point, cross-stitch, straight Gobelin stitch and mosaic stitch. Whole pieces can be worked
 is offen known as tent stitch, finest elfects being gained by it on a small-meshed, singlethread canvas. This stitch is worked diagon. ally over one thread of the canvas and is actually worked from left to right upward diagonally, but the row always progrcsses from right to left, as shown in Fig. 1. For alternate rows the work is turned upside down. Fig. 2 shows the same stitch on double thread canvas.
Gros point is worked in the same way, but over two threads or two scts of double threads on a dunble-thread canvas. This stitch is greatly used for chair seats and for groundings. A padded effect is gained by laying a thread, as shown in Fig 3, between the threads of a horizental line of the canvas. and working the stitch over it. Do not pull the wool tightly when working over a coarse canvas as it is a sign of bad stitchery when the canvas threads show through. Some workers use double wool for heavier types of designs on coarse meshes. Do not thread the needle with more than ahout 20 in . of working thread.

Cross-stitch for tapestry is usually worked over 2 vertical and 2 horizontal single or double threads of the canvas. To ensure an even look stitches must always be crossed the

 in tapestry. Fig. 5. Straight flling stitch. Fig. 8. Mosaic stitch
same way. In a pattern each stitch should be finished singly, but when working a grounding it is permissible to work the first half of the stitch along a row and return crossing. In Fig 4 the stitch is enlarged to illustrate detail

Straight Gobelin stitch is worked in horizontal rows for groundings. The thread is carried vertically over ? threads of single.

Tanestry neeulework. Fig. 7. Queen anne style chair with a drop-in seat covered by a piece of tapestry needlework in a design of the period Courtesy of Bartholomew \& Fletcher
thread canvas (or 2 double threads of doublethread canvas), len ving each time one thread of material between the stitches. As clearly shown in Fig. 10. the effect is rertical and not diagonal. This stitch is used to imitrte the ribbed grounding of Gobelin woven tapestries. A straight filling stitch shown in Fig. 5 and a wide oblique Gobelin stitch are sometimes used.

Fig. 8. All-over pattern of a single conventional floral motif repeated at regular intervals, a suitable design for the chair shown on the left
The latter covers 2 vertical and 3 horizontal single or donble threads of the callvas, and advances one thread of the canvas at a time. Mosaic stitch makes another useful grounding, as shown in l'ig. 6. It is worked along the Ist row with a long slanting stitch and a short one alternately. The 2nd row completes this by adding the second short stitch. The 3rd row is like the lat and the 4th row like the 2nd. The final row is all of short stitches. A stitch used in Florentine patterns is worked in slanting lines, the thrend being carried a!ternately over 2 and 4 crossings of the canvas, the stitches in the $2 n d$ row being short where those in the previous were long, and so on to cover the canvas. There are many othel

Fig. 9. Lircuiar prece ot tapestiy woiked 102 a siool uovering. Fiz. AU. Yoruon ol same design snoming detail of petit point atitches used for pattern and straight Gobelin stitch for grounding
stitchea which the experienced worker uses occasionally. Sometimes stitches seem to evolve of themselves to suit the particular pattern, but the beginner is advised to use the simple ones until proficiency is gained in keeping the work flat and the stitchery even

To secure the first stitch when a laid thread is not used, a knot is made at the end of the wool. the needle passed through the canvas from the right-hand side about \& in. from the starting point. As the work proceeds from left to right after a few stitches the end of wool is caught in at the back. Afterwards fresh lengths of wool are darned in at the back of the stitches. When using a number of shades of the same coloured wool. knot the cut slieins loosely on to a wooden curtain ring, keeping al! the greens together, all the pinks, etc.

Furniture Coverings. The Queen Anne style elbow chair in Fig. 7 shows the beautiful effect of a needle tapestry covered seat. The design is an all-over foral one of the period, worked in petit point in wool on a doublethread canvas. A cover for a chair or stool with a drop-in seat ie easier to make up than one for an overstuffed frame. When the work is finished, the loose seat is taken out, the tapestry stretched over it, and brought smoothly down to the underside. Tacks with large heads are obtainable, which are plared at frequent intervals to secure the worts to the under frameworls of the drop-in seat. This is then neatened with a piece of hessian, the edges of which are turned in under itself. It is important, when measuring the canvas to be embroidered. to allow agood margin forturning.

A conventional floral pattern is shown in Fig. 8 which could be used with any style of furniture. but would look best for

a chair of the style illustrated. It is carried out in gros point on a double-thread Penelope canvas with 12 threads to the inch, using tapestry wools. Sufficient canvas should be bought to allow a 4 -in. margin all round. This pattern has only one motif, so that the beginner becomes quickly used to working it, and in each alternate row of motifs the colours are the same. Thus the lst row of these oonventional flowers could be done in two shades of pink, with a yellow centre, outlined with maroon, and pale green used for the stem. The 2nd row of flowers have dark gicen stems and are outlined with the same shade, filled in with deep rose and crimson brown and yellow centres. It will be noticed that part of the centres of a row of flowers are worked at the top of the illustration,
repeating the colours of the 2nd row underneath The centre of the canvas is first marked and an upright line drawn through it. The rest of the fabric is then spaced out into squares, the size of each recurring motif The grollnding is put in last, also in petit point, and could the in stone colour, of a dull fawn or black according to the colour acheme of the room.
Acharming central Horal design is shown in Fig. 9. This is worked on single-thread canvas in petit point for the pattern. and in straight Gobelin stitch for the grounding, and could be used for a round stool or, by filling out the canvas with the grounding stitch, could be used for an oblong or square stool. The delicacy of the pattern is greatly enhanced by the different stitchery employed. Fig. 10 illustrates a portion of the design enlarged to show the detail. The roses, carnations and leaves are worked first in natural colours on a stone-coloured or grey blue background. central flower. About 30 Begin with the wool are required for a footstool.

Bags and Pochettes. For bags worked with beautiful designs in petit point the finest canvas is used, and in some cases sill: Filoselle is employed for the design and in others fine wools. Occasionally silks are employed for portions of the design only. Pochettes are of ten worked on rather coarser meshed doublethread canvas and with tapestry wools, as they are more handled and used for ordinary occasions, while the bags in finest embroidery are reserved for the evening.

A bag in petit point with a simple floral wreath or posy would require $\frac{3}{8}$ yd. of 23 -in. wide single thread canvas, a bag frame about $t i$ in across, and silk for lining. The shape of the front of tbe bag is marked out on the canvas, making it the width of the frame across the top, 8 in. deen and curving out the sides with rounded corners at the bottom The design on the front inight require about 20 skeins of coloured silks, while the back of the bay and the grounding would require a bout 12 skising of the same shade. A bag of the same shape as the one just described is illustrated in lig. 11, but a heautiful design of this type requires to be traced for working. Such designs on canvas ready for working can be bought in a number of patterns.

In gros point or petit point conventional patterns of stripes, triangles, encroaching squares and circles are all easily worked, and patterns can be copied from modern woven fabrics for pochettes and larger bag coverings. Shaded vandykes worked in wide Gobelin stitch or in a straight stitch taken vertically over 3 holes are most effective for bags with wooden frames. It may. however, be remembered that no stitchery is so durable as petit point or cross-stitch on a medium nieshed canvar. The longer the otitch the greater tho possibility of threads being caught and pulled out of shape in handling and wear The making un of bags and poshettes is described in the article Bag. They can also be made up in needlework shops. Some workers mercly damp their finished embroidery on the

Tapestry Needlework. Fig. 11. Bag in which a Louis style design is worked in petit point with silks on fine canvas
wrong side and tack it on to a covered board to stretch it bank to the required shape when finished; others find that it is best to press the tapestry with a moderately hot iron, placing the work face downward on a thickly padded ironing board

## Tapeworm. See Worms.

TAPIOCA. In cooking, tapioca, which is obtained from the roots of the cassava plant, is used to make puddings, soups, and jellies, and also forms a good thickening agent. It is nourishing and easy of digestion, and therefore may be included in invalid diet. Tapioca requires long cooking, and should not be placed over too fierce a heat. The grains vary in sizc. The fine kind may be cooked in the same way as semolina.

A cold sweet that requires little preparation is orange tapioca. To make it, put $\frac{1}{4} \mathrm{lb}$. smallgrained tapioca into a pan with a little more than a pint of water and the grated rinds of two large or three small oranges. Simmer the whole until it clears, then draw the pran to the side of the fire and add $2 \frac{1}{2}$ oz. sugar and the strained juice of four oranges. More sugar nay be used if the fruit is sour. before turning it into a deep glass dish, and serve with cream or custard.
Tapioca Cream. A good sweet with tapioca and desiccated coconut as its main ingredients can be made in the following way : Wash 3 oz . tapioca, then let it soak for 12 hours or more in a pie-dish containing 1 pint water. Any water that has not been absorbed when the soaking is over should be poured off. Mix in 3 oz. sugar and 2 tablespoonfuls desiccated coconut, add 1 quart milk, and
it to the boil and then cooking it slowly tor $1-1 \frac{1}{2}$ hours. This can be done by lowering the temperature of the oven once the mixture has reached boiling point.

Serve it cold, with 1 gill slightly whipped cream on top, and 1 tablespoonful desiceated coconut sprinkled over the cream. Apricot sauce (q.v.) may be served separately.

Tapioca Pudding. To prepare this, wash 3 tablespoonfuls tapioca, let it soak for an hour in $1 \frac{1}{b}$ pints milk, and then turn it into an enamelled saucepan, adding a lump of butter about the size of a hen's egg, $1 \frac{1}{2}$ tabiespoonfuls sugar, and the thinly peeled rind of a lemon. Boil these up slowly, and then simmer until the tapioca grows clear. Take out the lemon rind and let the inixture cool at the side of the fire before stirring in the vo!ks of 2 eggs, and then the stiffly beaten whites. Pour all into a greased dish, and bake it in a moderately hot oven until it sets, and the top is lightly browned. A tapioca and apple pudding can be made in the same way as sago and apple pudding (see page 1098). Diet; Food; Scmolina.

TAPPET. In internal combustion engines of the side valve type the tappet, which is a part of the valve gear, is fitted between the end of the valve stem and the face of the cams of the camshaft. A similar device is used on some overhead valves operated by push rods, though a pivoted lever is often used which carries a roller at its free end, the roller bearing against the operating cam. Diagrains illustraling both systems are given in the article on Valve.

Owing to the fact that the face angle of the cam as it makes contact imparts a thrust sideways during the initial stage of raising the tappet, the guide is eventually worn oval. To overcome this fault, anti-friction devices, as shown at $C$, are frequently enıployed that provide a rolling instcad of a sliding contact.

The feature of the adjustable tappet, which is most commonly used, is that the amount of clearance between the end of the valve stem and the head of the tappet may be definite!y set and fixed. This malies it possible irre spective of rear of the parts, to maintain the valve gear. in respect of tappet noise, in good order. Although tappet noise is primarily due to faulty setting of this amount of clear ance other contributory causes are worn cams, worn tappet rollers, and slackness of the tappet in its guide.

The method of adjusting tappet clearance is illustrated on page 813. The gap of a few thousandths of an inch can be tested by a feeler gauge of the correct si\%e. The maker's is: structions should be followed on this point, but as a guide it may be noted that the clearance for most water-cooled engines is about -004 in for inlet

 tor overhead valve operater mixture cool overhead valves the clearance is generally a little more. Tappet clearance should be adjusted when the engine is hot.
Valve gear would be almost silent but for the fact that the varying !ength of the valve stem, caused by engine temperuture, makes it impossible to provide permanent contact of the tappet with the face of the cam and the stem of the valve. Tappet noise can be reduced to a negligible quantity, however, if careful attention is given to the adjustment at a time when the engine is thoroughly warmed up. See Cam ; Motor Car; Valve.

TAR : Its Domestic Uses. Tar is ob- be carricd out in warm weather and only old tained by the destructive distillation of coal, clothes should be worn wood, and bituminous naterials such as

shale. The black semisolid mass left as a residue after further distillation of the tar itself is commonly known as pitch. Tar can be had in a semiliquid state or as a solid material. Liquid tar is applied cold, but may require slight heating in cold weather. Solid tar or pitch is broken up into small pieces and can be put in an old iron bucket, supported on bricks, and a fire kindled underneath to melt it, as in Fig. l.

This must be done in the open and well undersides are tarred and a film of tar be away from anything that is likely to catch fire. On no account should a vessel containing tar be heated over a gas ring or a fire indoors.
The tar should be heated just sufficiently to render it Huid enough for use. If it catches fire tar burns fiercely and emits volumes of pungent smoke; it can be extinguished, though not without difficulty, by smothering with damp sand.
The use of tar in the household is due chicfly to its waterproofing qualities, which render it particularly suitable as a protective covering for wood and metal. This property is taken advantage of in the coating of wooden roofs and other wooden structures which are exposed to the weather; but care should be taken to apply such a coating only where there is no particular risk of fire. Iron fences are often coated with tar to protect the metal from rust, and a fence treated in this way. looks well and also lasts for many years if additional coats are applied from time to time. On account of its waterproofing qualities tar is also employed for dampcoursing.
Liquid tar is applied with a specially made stiff-bristled brush : this is shaped somewhat like a short-haired sash tool, but the bristles are spread out at the ends. One pattern is made with a short single handle; the other variety has a long handle, and the brush head is set at an angle to it. The tar stock brush is made with 1,2 , or 3 rings or sets of bristles, which are mounted on a cross-piece of wood and attached to the handle in much the same way as a garden rake.

Roofs and walls of outbuildings are often covered with tarred felt or similar material which has to be tarred frequently to keep it in good condition. This can best be done with a goorl grade of liquid tar or one of the preparations having tar as a base. It is applied with the long-handled tar brush as shown in Fig. 2, and the worker should stand so that the brush can be manipulated at one side of the body, as this tends to keep the person reasonably clean. Tarring operations should

Tar is applicable in uch a paste to floor covering beneath a boarded floor. In such a casc the tar is mixed with the aggregate, which may be very small pieces of clean broken brick or ash well worked into a stiff mass and laid in a similar way to a cement or concrete floor. This takes some weeks to set, and then the floor boards can be laid directly on it. If the
brushed over the floor surface the result will be as nearly as posaible damp-proof.

Tar can be employed effectively in the top treatment of a path. A simple method is to prepare the surface of the path, which is assumed to be of ashes or gravel. The top is then brushed clean and the tar applied hot, and well brushed into the surface. This is followed by a sprinkling of sand or fine grit, and as the tar sets the surface is well rolled. A damp sack should be rolled up and rested on the framework of the roller, and secured to prevent it becoming displaced. The sack is placed so that it rests on the top surface of the roller, and acts as a brush to keep it clean. It should be damped from time to time. Tar with stone dust can be used as a substitute for asphalte in laying a path. The nethod is described in the article on Path.

Medicinal Uses. Wood tar and prepared coal tar are both used in medicine. Wood tar is a blackish. aromatic-smelling semi-solid substance containing oil of turpentine, creosote, phenols, resins, and other constituents. Juniper tar oil or cade oil and birch tarare used in chronic skin diseases, usually incorporated in ointments. Tar ointment is used in the treatment of chronic eczema and psoriasis.

The diluted oint. ment is also often used with success as a means of check ing the very intractable itching of pruritus. Wood tar is prescribed as a stimulating expectorant in chronic bronchitis or winter cough.

Coal tar is the source of a large number of drugs, such as antipyrin, etc., and numerous disinfectants are manufactured from it.

TARNISHING. The best way to prevent tarnishing is to have the objects lacquered when such a course is possible, as this, when
wcll done, is invisible if a clear or crystal lacquer be employed.

To remove tarnish stains from silverware wash the objects in hot water with a trace of ammonia in it, following this with a good washing with clear hot water and finishing with a rouge polish. Tarnished brass and copper ware can usually be cleaned with a very weak solution of sulphuric acid in water. Add the acid drop by drop to the water. Only a trace of the acid must be used, as it is very violent in action and would speedily corrode the metal. The articles should be thoroughly washed afterwards in hot soda water to neutralise the acid bath, and then polished, and, if desired, lacquered.

Another method of treating tarnished silverware is to rub it well with a solution of powdered magnesia and follow with a polishing with the dry powdered magnesia, finishing in the usual way. Steel and iron are best cleaned with a mild abrasive. For slightly affected pieces this may be a light sprinkling of fine emery on an old stocking moistened with a few drops of lubricating oil. When the tarnishing is severe the best plan is to use the finest old emery paper and finish off with a good metal polish. See Lacquer; Polishing.
TARRAGON. This is a hardy perennial herb belonging to the Artemisia, or wormwood, family. About 2 ft . in height, it is raised from young roots planted about 1 ft . apart in spring. The shoots will be ready to cut down in autumn and store away for future use. Roots may also be started in the heated greenhouse in October for winter use. Propagation is by division of old roots, which should be done annually.
Tarragon is used in conkery for flavouring soups and vinegar, and forms an ingredient of many sauces. The whole leaves serve as a garnish for cold dishes. See Vincgar.
TARSO. This is a method of cutting a design on wood which gives it almost the appearance of inlay. It is a modern form of the old intarsia and affords a simple method for the amateur to decorate such surfaces as screen panels and trays. For the latter, when glazed it would be almost indistinguishable from marquetry. Many pokerwork designs can be adapted to this work by those who have no outfit for the former craft. More or less conventional designs can be carricd out effectivcly, and the outfit is of the simplest, consisting of a tarso or cutting knife, a supply of stains in various colours, and some polish.

The satisfactory appearance of the finished tarso depends largely upon clear, even outline, and therefore it is best to work on a flat panel. A box should not be taken for a first attempt unless books are built up alongside !evel with
the top to provide a sup-

something sma!l and fairly simple in design, such as the tray in Fig. 1, which shows a branch and leaves in tarso work wi:h a full moon, which is filled in with liquid whitc enamel. Another good design is illustrated in Fig. 2, which would be equally suitable for an empty grate screen panel or for a blotter. The colours used would be dark brown, green.

Tarso Work. Fig. 2. Panel asowing a boldly outlined
black and white. The incision should be about $\frac{1}{32}$ in. The design must be followed very carefully, and the various lines cut correctly. Cut anything that lies underneath first, and the rest of the design later. When all the lines are incised, the panel should be sandpapered, working with the grain, never against it. Finish off this stage by giving a final rub with the back of the sandpaper.

The next step is to colour the design by painting in water stains with a brush. The stains must be used almost pure, and made to look even and solid. It is an excellent plan to add 1 drop of ammonia to the stain before using it to prevent the colour from spreading. No shading must be attempted, the aim being to make the design look as though it is inlaid and not painted on. The background is left uncoloured. The colours are left to dry; if not sufficiently dense, any part that needs strengthening should be coloured again. After rubbing lightly with a very old piece of sandpaper, the work is ready for polishing.

A very high polish is required (see Polishing). First the whole surface of the wood is covcred by applying a coat of wood filler with a brush, and this is left to dry thoroughly. If the surface is not sufficiently covered, a second coat may be applied and left to dry. Then put some fine glaze polish into a pad, and body in until a good covering is obtained. Oil polish should not be used for this work. It is well to avoid working too long on the surface; the moment it becomes tacky it should be put on one side and work started on another piece. As soon as a good body of polish is obtained, take a clean pad, put 1 drop of glaze on it, and rub the surface hard, working up and down as quickly as possible until the whole surface is absolutely bright and free from any disfiguring appearance of streakiness. See Poker Work ; Tray.

TARTAR: On the Teeth. The deposit of tartar which tends to form about the roots of the teeth consists of phosphate of lime and other mineral substances. mixed with some organic matter. This tends to favour the activities of microbes and provoke decay of the teeth. Tartar is more likely to accumulate when food is soft than when a fair amount of it requires energetic mastication. See Tceth.

TARTARE SAUCE. This snuce is made by adding $\frac{3}{4}$ dessertspoonful each of chopped parsley, capers, gherkin, tarragon, and chervil to $1 \frac{\mathrm{t}}{2}$ large breakfastcupfuls mayonnaise. Keep it in a cool place until required.

TARTARIC ACID. The crystals of tartaric acid irritate the skin and mucous membranes. Obtained from grapes, tartaric acid closely resembles citric acid, and is used similarly chiefly as a refrigerant or cooling medicine in fevers. The dose is 5 to 20 gr .
It is used in making effervescing preparations; 20 gr . of the acid dissolved in oz. of-water will saturate, in an effervescing mixture, 24 gr . sodium bicarbonate dissolved in 1 oz . water. It may be used instead of citric acid for lemonade (q.v.).
TASSEL. This form of trimming is frequently used for pelmets, lampshades, cushions, to weight corners of work bags, panels, and other ornamental furnishing and dress purposes. There are many kinds, made of silk thread of any colour, of fine braid or ribbon, of gold or silver thread, of wool, beads, or leather. They are employed as a finish to girdles for dressing gowns and sometimes to edge scarves. Another use for a silk tassel is for a necklet. The necklet itself is frequently a silken cord, upon which is suspended a large, decorated bead or amulet, from the base of which hangs the tassel, of the same colour as the cord.
To make a woollen tassel, such as might be used to finish the ends of a girdle for a dressing gown, take a small piece of card, as wide as the required length of the tassel, and bind the wool round it several times, the number of threads in the tassel depending entirely upon individual taste. These strands of wool are tied tightly together at one edge of the card and are cut at the other, all that remains to be done being to hold the ends in one hand and twist a strand of wool several times round just below the point where it was tied. Sce Curtain ; Cushion; Fringe; Pompon.
TATTING: In Needlework. An oldfashioncd kind of fancywork, tatting can be worked in crochet cotton or in purse silk, a tatting shuttle and a crochet hook or bone pin bcing also required. The shuttles are made of bone, tortoiseshell, ivory, and of cbony inlaid with mother-of-pearl, and have a block in the centre, pierced with a hole, through which the cotton is passed.
To fill the shuttle, thread the end of the cotton through the hole, tie it, and then pass it through the ends of the shuttle round and round the block until it is level with the ends of the shuttle. The cotton should then be cut off, about 1 yard of it being left to hang loose. Workars should note that the crochet needle or bone $p^{\text {in }}$ is necded when joining the loops.

In learning the stitch, the chicf thing tc remember is that the thread over the hand is to be kept loose, while the thread from the shuttle is drawn tightly. The work resembles the buttonhole-stitch used in making a loop for buttons, the thread from the shuttle corresponding with the loops of the button loop, and the thread over the hand corresponding with the buttonhole stitch worked upon them. Take the end of the thread in the left hand, between the thumb and the finger. and pass it over the fingers of the left hand; then bring it back to the thumb and finger again so that there is a ring of thread round the fingers.

With the shuttle in the right hand, throw the thread from the shuttle round the back of the left hand and pass the shuttle under the thread round the fingers; then draw it back over that thread and pull it out tightly, letting the loop over the fingers become slack. This forms a loop on the shuttle string, tightened by expanding the fingers.
The first half of the stitch is now completed, but in making the second half do not throw the shuttle thread round the left hand, as previously, but simply pass the shuttle over the loop round the fingers and draw it back under it, thus reversing the process of the first half. Make quite certain after each stitch that the shuttle thread will draw, for if it will not an crror has been made, and the stitch must be unpicked. When twelve stitches have been made, draw up the shuttle thread until the stitches form a ring, the first and last stitch mecting. Leave about $\frac{1}{4} \mathrm{in}$. of thread between this and the next ring, which should be worked in the same way.
These rings are joined together by the picot stitch, which is made by leaving a short length of cotton between the stitches, which, when the ring is joined up, forms a little loop. In a large piece of work the rings arc sometimes sewn together, but ordinarily these loops provide the best means of joining them. Begin by making 4 stitches, and leave a small length of cotton between these and the next stitch. Some practice is necessary in judging the right length, for all loops must be of the same size. Then work 4 stitches and another picot, 4 more stitches and a picot, finishing with 4 stitches and then drawing them up into a ring. There is now a ring with 3 picots, and the following ring must be joined to the right-hand picot.

Begin the next ring in the same way, and when 4 stitches are made insert the crochet needle in the picot of the last ring, and draw the cotton which is round the fingers partly through the picot; pass the shuttle through this loop, and then pull the finger thread tight. Proceed with the same number of stitches and picots as in the last ring.

## TAXIDERMY FOR THE AMATEUR

## A Simple Example Described Step by Step

Herewith are detailed instructions by means of which the nature 'over can preserve and mount in natural positions not only bir sand small animals, but also reptiles and fish. See Arsenical Soap

The work of the taxidermist, which consists in preserving the dead bodies of animals, in their natural forms, is well within the scope of any careful amateur. The following tools and materials are required : A pocket-knife, a pair of small scissors, round-nose pliers, flat cutting pliers, 3 -cornered file, iron wire of various sizes, plain and coloured glass eyes, thread and fine string, tow and cotton wool, clay, pins, preservative soap and powder, camphor. Glasseyes and preserving soaps and powders can be purchased at a taxidermist's or naturalist's shop.

The preservatives used are generally highly poisonous.
Skinning a Squirrel. Supposing that the animal to be preserved is a squirrel, the first step is to place it as nearly as possible in the attitude in which it is intended to remain
when stuffed, Fig. 1. Carefully study the formation and contours of the body, and note down on paper any little details likely to be of use in obtaining a natural appearance. The squirrel is now placed on a board large enough to spread the limbs. The lower portion of the limbs should be tied to the board, holes being bored through the board at convenient places. The specimen is then placed in a good light and at a suitable height, and the skin opened with the large blade of the knife. The cut should be commenced about the middle of the breast and continued down into the lower part of the body, the separated skin being opened out and secured by bent pins attached by pieces of string to a nail.

Proceed to skin the body by first working out the hind legs, cutting the leg bones, under

Taxidermy. Nig. 1. A squirres tast nas been stuffed in a natural attitude according to the instractions given in this article
the skin, at the large joints. Use the cutting pliers to sever the joints. Carefully strip the skin off the lower part of the body, at back and front until the tail is reached, the flesh and small bones of which are pulled out from the skin. The operator is now able to proceed with the removal of the skin from the back and breast until the forelegs are reached, the bones of which are cut away 'ike those of the hind egs.
The neck and head are skinned down to the inner edges of the mouth and nose, and great care must be taken to avoid cutting the outer portions of the ears, eyelids, nose, mouth, and lips. After severing the skinned body from the head, remove all the flesh, the brain, and the eyes from the skull, which will now be attached to the skin by the inner edges of the mouth and must be handled carefully. Clean away all the flesh from the bones of the legs, and the skin is then ready for treatment.

Turn the skin completely inside out and scrape off any adhering flesh or other matter, and then apply a good coating of preservative soap, working it well in with a smal! brush. The skin is now turned fur side out again and hung up for 48 hours to dry and let the soap act. At intervals during the drying period the skin should be gently stretched and worked to keep it soft and supple, and at the end of the 48 hours it should be turned inside out and scraped clean with a blunt knife. Then a liberal application of the preserving powder should be thoroughly rubbed in

Modelling the Head. The interior of the skull, as at Fig. 2, should be filled with tow, saturated in a solution of camphor dissolved in a little pure turpentine. The first step in stuff.
ing is to bring the head to shape, and this is done by placing clay and tow on those parts of the skull from which the flesh was removed and modelling them to the required form. The skull is then replaced in the skin of the head, the glass eyes having been set in the eye-holes. The clay should be used as dry as possible and allowed to harden before placing the skull finally in the skin. Parts that are too low can be raised by pressing in a small quantity of cotton wool under the skin of the head and directing it to the required place by means of a piece of blunted brass wire.
A strong iron wire, about 10 in . long, is pointed at one end and bent to the shape of the backbone It is then tightly bound round with tow to the shape of a long narrow body, and placed in the interior of the skin, the pointed end being inserted well into the skull. A pointed wire, about 8 in . long, is thrust through the sole of each hind foot, and forced well into the tow body and the enda bent over. After the wires have been inserted. the ends should project for nearly 2 in . from the soles of the feet.
The leg wires and bones should be clothed with tow and clay and modelled to shape after the wires are in position. The fore!egs are wired by forcing a 6 in . pointed wire through the underside of the claws of each paw, the ends being thrust into the body and clenched over. Bend the forelegs to the desired position and bring to shape with tow and clay as already described. A thin iron wire. pointed at both ends, and about 12 in . long, is passed througb the cartilage of the tail, inserting the wire at the root and carefully pushing it up to the tip. Secure the lower end of the wire by pushing it into the body and bending over.
The body and legs are now bent into their permaneut positions, and modelled to shape by the addition of more tow or cotton wool until the natural contours are obtained Powdered camphor should be mixed with the
stuffirg material. The opening in the skin is lastly neatly sewn up with tine thread, and a piece of wood about 5 in . by 4 in by $\frac{1}{2} \mathrm{in}$., obtained for a stand
Mounting the Specimen. The stand (Fig. 3) will look better if its sides are irregular, and they can easily be made so by indenting and rounding them with a sharp knife. Bore two small holes for the wires of the feet through the surface of the stand, tuin over, and cut a narrow groove. radiating like an arm of the letter Y, from each hole, as at Fig. 4. Apply a coating of hot glue to the top surface and sides of the stand. and dust on fine sand until all the glued portions are thinly covered, when it should be set aside to dry.
The leg wires are passed through the holes in the surface of the stand, and allowed to project for about 1 in after which they are bent over at right angles into the grooves and clenched into the wood, as shown in Fig. 2. A piece of thin brown paper is cut to the shape of the bottom of the stand and glued thereto to give a neat finish. The tail is bent to a natural curve and a nut placed between the claws of the forefeet, holding it in position by the projecting ends of the wires.
The fur is finally cleaned by gently rubbing it with wadding soaked in benzol, afterwards dusting on fine plaster of Paris, which, when dry is beaten out with a bunch of feathers. The cleaning is best done out of doors as the benzol is highly inflammable. Use a fine tooth comb and brush to bring the hairs of the fur into their positions and folds and arrange the tufts on the ears and the whiskers with a fine wire. The specimen is now complete, and should invariably be kept in a dry place

Fish and Reptiles. The instructions given above are equally applicable to birds, fishes, and the larger reptiles. With patience and perseverance and the aid of a good text book on taxidermy, large specimens also may be attempted

A considerable amount of artistic skill and particularly neat workmanship is required in mounting birds, especially when it is desired to show them with open wings. It is worth while spending time and care on the wiring of the legs. The wire for this part of the work should be of a stouter gange than that used for the body: it should be long enough to lock into the body and be sharpened to an acute point at the end. There is only one position in the scaly part of the leg down which the wire will pass freely without damaging the skin, and that is on the inside of the member on the actual sole of the foot, immediately at the base of the hind toe. The actual position

Taxidermy. Fig. 2. Sectional diagram showing arrangement of wires and stuffing. Fig. 3. Diagram of irregularly shaped atand, showing position of holes for wire attached to the lega. Fig. 4. Underside of stand showing grooves cut from each hole for wire
of the legs should be decided on and the bird buns comprise the usual nursery menu, with a box or metal canister with a close-fitting lid, mounted on a suitable base, such, for instance, either weak tea or milk, and sometimes with or else in a tea caddy.
as a piece of thoroughly.dried peat or a piece of virgin cork
The general shape of the bird is now ad. justed, and if the wings are closed the work is simple, two short pointed wires being required for each wing. For open wings a long wire should be passed, right down through the interior of the wing, into the body and then locked in position For small birds the single wire will generally bc sufficient, but with large specimens the principal wire must be stout, and a second wire passed between the wing feathers close to the base. When the final shaping has been effected, the plumage should he worked into position, for it is very little use to attempt it before. The most suitable tools for this work are a pair of fine tweezers and a needle mounted in a convenient wooden handlc. All the feathers should be carefully looked over, and in places where shot holes have disarranged them it is often advisable to pull them out, stroke them flat, and replace them with a touch of paste at their hases.
TAXODIUM. This is the botanical name of a beautiful conifer, the deciduous or leaflosing cypress, Taxodium distichum. It is a graceful tree with light green leaves which become attractively tinted before they fall in autumn. It will attain large climensions in the course of time and thrives best in moist soil ; it is a good waterside tree.
TAZZA. The silver drinking vessel callerl by this name consists of a silver bowl, in shape not unlike that of a champagne glass, supported by a short stem and a small foot. Originally niade to hold drink, they were afterwards used for fruit and cakes. The word is used sometimes for glass and china dishes of this shape, and also for those made in other metals. Examples in antique silver are rare and fetch high prices. See Silver.
TEA: The Meal. As a general rule, in householls whore dinner is served in the cvening, afternoon tea is a very slight meal. In households where the children's dinner is taken at mid-day, tea is usually quite substantial, combining both tea and supper Bread and butter, jam and simple cakes or ruit in season.
For high tea, which is a rather more solid meal in place of supper for the family, the

Tazza, witu lid, in wrongut iron, inlaid witu silver in a floral design. Modern Belgian work
table is laid much as it is for brcakfast, with knives and forks, as well as the accessories of tea proper, and very often ham or meat of another kind is offered. Eggs, boiled or cooked in other ways, grilled tomatocs, bacon and kidneys, sardiacs on toast, special salads, or sometimes a larg meat pie or a fish dish, are served. while cakes and jam follow. See Afternoon Tea Table; Breakfast; Bridge Party ; Pienic ; Sandwich; Service Wagon; Tray.

## Tea: Its Qualities and Blends

## With Hints on the Best Methods of Infusion

Other entries that bear on the matter include Blending; Bre ikfast; China Tea; Diet; Pekoe;
Souchong. See also Kettle; Teapot; Urn, cte.
Tea owes the properties which have made it so popular a beverage to a volatile oil and to theine, an alkaloid which has a gently stimulating effect on the nervous system. It also containe a proportion of tannin, or tannic acid, which is liable to cause indigestion when tea is not properly male or is allowed to stand too long so that it becomes overdrawn. The proportion of tannic acid varies in different kinds of tea; it is usually from 10 to 12 per cent. The proportion of the volatile oil is about $\frac{1}{2}$ per cent., and of theinc 2 to 4 per cent. A cup of fairly strong tea contains l gr. of theine and 2 gr . of tannic acid.
Of the tea imported into Great Britain nearly 90 per cent is produced within the Empire, chietly in India and Ceylon. The balance is grown mostly in China. China tea contains less tannin than the Indian product. On the other hand, there is a larger proportion of theine in Ceylon tea than is usually found in the Chinese varietics.
There are two classes of tea, namely, green and black, with many varieties of each. The difference lies chiefly in the mode of preparation, green tea being rolled and dried, while black tea is also allowed to ferment. The best green tea comes from China.

Of black China tea the chief kinds are Pekoe, Souchong, and Congou, which arc
practically three qualities of the leaf. Pckoc consists of the bud and the first leaf; it is the first-fruit of the plant, and is named after the young shoots, the word Pekoe signifying white down. Soucnong is obtained from the next leaves after Pekoe, and Congou is the third sclection. Among the varieties there are flowery and orange Pekoes, and others which are largely employed in blending.

Practically all kinds of tea arc a blend of several different sorts, the reason being that it is very rare indeed to find the requisites of flavour, strength, and colour combined in any single kind. Some varieties are highly fragrant, being scented with flower petals, notably jasmine. Bohea, a name once applied indiscriminately to all teas, and sometimes used to-day for a poorer late-grown leaf, is a variety grown in Fu.kien prov., China, which is also noted for red leaf Congou.
Buying and Storing. Tea is sold in packets weighing from $\not \perp \mathrm{lb}$. upward. It should be kept in a dry place and protected from the air. This is particularly necessary whore tea is lept in a store or pantry in the neighbourhood of other commodities, especially fruit or spices, as they may communicate some of their flavour to the tea, the dried leaves of which are very susceptible to the surrounding atmosphere. For this reason tea should be kept in

As a rule a chest of tea contains 84 lb . and a half chest 50 lb . Indian and Ceylon chests contain about 100 lb . These cases are furnished with a protective lining of sheet lead
In buying tea the housewife has a wide range to choose from. Generally speaking the Indian varieties are stronger than the Chinesc, but black teas of all kinds are obtainable, and the purchaser must be guided by her own par ticular taste. Black blended teas are the most numerous. Most firms sell a household blend of medium strength and good flavour for ordinary domestic use A fuller and richer flavour is provided by mixtures of Ceylon and Assam.

The addition of a small quantity of China tca in some blends makes for a more pungent tasting beverage, and occasionally a flavouring of Oolong is added Unblended Indian teas, of fine and expensive quality have a delicate and slightly pungent taste. Darjeeling is fragrant and full-flavoured.
How to Make. In making tea many people think it is best for the flavour of the beverage to use an earthenware teapot. The water used should be quite fresh, that is to say, it must not have been boiled previously and reheated, nor have bcen standing some time. The kettle should be emptied and filled fresh from the tap every time that tea is to be made Soft water is always best for the purpose where the supply to the house is a hard water, a very little carbonate of soda may be put into the teapot along with the tea, care being taken not to put in more than a pinch, otherwise the tea may have an unpleasant flavour.

It is essential that the water should be actually boiling. A second point to note is that the teapot should be heated. A little water from the kettle is poured into the teapot, and the latter can then be allowed to stand until the kettle boils, when the teapot can be emptied and the tea dropped into it.

An old rule as to the quantity of tea required is to allow one teaspoonful for each person and one for the pot. One good teaspoonful, however, should be enough to make two cups of tea easily; with some teas a teaspoonful will make three cups. Much depends on the quality of the tea.

After the tea has been put in, the pot should be filled up as soon as the kettle boils, pouring the water slowly over the tea leaves. The most usual method is to fill the teapot half full, but some people fill it three-quarters full.

The filled teapot should then be allowed to stand for 3 or 4 min . so that the tea is properly infused. This is much more satisfactory than to stir the contents of the pot with a spoon, as is often done to save time. China teas require to be thoroughly infused, and some may be allowed to stand for 8 or 10 min . without any risk of deterioration. Some tca drinkers allow the tea to stand for 2 or 3 min . and then pour it into a second teapot which has previously been heated. In this way the infused liquid is obtained without the leaves, and there is no risk of tannic acid spoiling the tea if it should be left standing.

Another method of making tea is by putting it into a teaspoon infuser. Many persons, especially those who suffer from indigestion, prefer to have their tea made in this way, because it produces an absolutely fresh cup with no possible excess of tannin.

Tea cannot be said to have a food value, except when it is taken in conjunction with milk and sugar. Tastes differ considerably in this respect. Some persons enjoy their cup of tea with milk alone, some only take sugar, and there are others who take neither, while some choose lemion in preference. Even when reinforced with milk and sugar, tea is inferior in nutritive value to cocoa, and also to coffec
madehalf with milk, but neither coffec nor cocoa possesses the refreshing propertics of tea.

From the medical standpoint theine, the active principle of tea, clears the brain, stimulates mental action, and removes feelings of fatigue and drowsiness. The best times to take tea are at breakfast and in the afternoon: for most people twice a day ought to be sufficient. It is well not to give tea to young children, or at least not more than a tablespoonful in a cup of milk.

People who are in the habit of in the habit of S. hensington drinking too much tea, or taking it too were also made of figures. Caddies strong, may suffer sooncr or later from in- painted black, and decorated in the Chinese digestion, palpitation, loss of appetite, sleeplessness, depression, constipation, or nervousness. The remedy is to stop drinking tea till the symptoms disappear.
TEA BASKET. A basket made to carry materials for a pienic tea is very similar to a lunch basket, being of wicker, provided with a lid, and straps for security and as a means of carrying it. Cases are more used thin baskets. The fittings for either consist of cups and saucers, plates and tea knives for two, four, or six people, a larger knife, and several cake plates, a bottle for milk, and tins for holding sandwiches and cakes. They also include cither a vacuum flask or a spirit kettle and stove, teapot and tea caddy. See Picnic.
TEA CADDY. The carliest caddies were of Chinese porcelain shaped like a ginger jar. These were made in great variety hy the English potters, a common type being one of blue and white chinaware. They are often in pairs, one for green and one for black tea.
Soon they were made in silver, brass, pewter, and tortoiseshell, and in the 18th century fine silver pieces were produced. Some of these are chased with pastoral figures, flowers and scrolls. They had slip-in, pull off, or hinged lids Some are shaped like a vase, while others are oval, silver bead edging being found on some of the latter type. Shefficld plate caddies were sometimes hexagon in shape, but the more usual type to be picked up to-day are oblong or oval with beaded or gadroon borders. The hall marks should be on the side or bottom.

The wooden tea caddy was evolved from the metal one. It became usual to encase two of them in a wooden box, and in the 18th century wooden caddies were largely made. These usually contained threc receptacles and were shaped somewhat like a small chest. At either end was a lidded well, one for green and the other for black tea, and in the centre was a receptacle for sugar. The finer woods were used, chiefly mahogany, rosewood, and satinwood. Some were mounted on brass. and many were beautifully inlaid. Knobs of ivory, ebony, and silver are found on them. Specimens of the older caddlies enclosed in a box are sometimes met with. An example is a sct of three silver ones fitted in a rosewood case. Shagreen was occasionally used for the case.
Tea calldies were made by Chippendale and Hepplewhitc. Mahogany was the wood chiefly used by both. Chippendale made some of his caddics rather in the shape of caskets with richly carved lids and feet, the claw

Tea Caddy of harewood and satinwood, with marqueiry of satin and other woods
3!) permission of the Director, Victoria and Albert Museum,
and ball being much used by him. The outlines of Hepple. white's caddies were straighter than those of Chippendale. Instcad of feet he often fitted a plinth to them, and while mahog. any was frequently uscd, delicate veneers were much favoured.
An example of late 18th-century workmanship is an oval box of painted wood, on which is represented Howers, crests, and allegorical scenes, vividly coloured. Some of this type are painted with festoons in the Adam style or medallions revealing Grecian figures. Caddies manner or with mother-of-pearl, etc.
In aldition to the above, which may be regarded as the chief styles, another type of caddy was introduced early in the 19 th century, the decoration of which consistcd of rolled paper filigree work. This consisted of a box, usually hexagonal in shape, which had faces slightly recessed. In the recesses were fitted many coils of paper cut in narrow strips, cach placed on edge and arranged so as to form an claborate pattern consisting of scrolls, leaves, festoons, and gcomictrical figures. The inner edges were glued to the wood, the coils were twisted so that rough handling could hardly move then ont of shape, and the surface was protected with glass. Sometimes the parchment paper scrolls were left ivory colour, sometimes gilded. The eflect was that of fine carved ivory, or, when the strips were gilded, of metal filigree, while some of the tinted work was like Indian lacquered wood carving.
For use with caddics a special kind of spoon was designed in Sheflield plate, silver and other metals.
TEA CAKE. Tea cakes can easily be made from 1 lb . flour, $\frac{1}{2} \mathrm{oz}$. solid yeast, 2 oz . margarinc, a flat teaspoonful of castor sugar, an cgg, a pinch of salt, and milk and water to mix. Sieve the flour and salt into a basin, rub the fat into them until the mixture resembles fine brearlcrumbs, and make a well in centre. Put the yeast into a small, warmed basin, noon tea table spread with an embroidered or lace and linen cloth, and also for a cosy to accompany a dining-room breakfast scrvice of handsome and formal design. Conventional shapes are used in smaller sizes for the cosies which form part of a set for the breakfast tray, with egg cosy, and tray cloth to match. Quaint shapes are seen in the cottage designs worked in various materials and in developments of the same illea, such as "The Old Curiosity Shop," Noah's Ark and house
add the sugar. and mix them together until they form a liquid. Then pour in thent warmed milk and water, mixed in equal quantities, strain the whole into the flour, cte., and mix all to a stiff paste. Turn the dough on to a floured board, knead it until it is smooth and pliable, and then divide it into two or three portions, shaping each into a round. Put these on to a greased baking sheet, cover them with a cloth and leave them in a warm place for about 50 min ., or until they have risen to twice their size.

Bake the cakes in a hot oven for 20 min ., and just before they are ready to be taken out brush them over with a mixture of milk and sugar. Leave them for a few minutes so that the glaze may dry. The latter can be made from $\frac{1}{2}$ gill milk and 1 dessertspoonful castor sugar. For currant tea cakes add 1 oz . picked and cleaned currants to the above.
Smaller tea cakes made with baking powder instead of yeast can be prepared from lb. flour, 1 oz . margarine, 1 teaspoonful baking powder, half an cgg, and about a gill of milk. Sieve the flour with the baking powder into a basin and rub the margarine into them. Beat up the egg and add it to the flour, etc., pouring in also sufficient milk to mix the whole to a soft but not sticky con-

Tea Cake. Small cakes wnich may be served cold or cut open and toasted before buttering
sistency. Roll out the mixture on a floured board until it is about $\frac{1}{2} \mathrm{in}$. thick, then cut it into small rounds, brush these over with milk, and bake thein on a greased baking sheet for $10-15 \mathrm{~min}$.

Tea cakes niay be buttered and served cold, but more often they are sliced in half, toasted and buttered, put together again, and then cut in the same way as an ordinary cake. See Crumpet; Girdle Cakc; Sconc.
TEA CLOTH. The phrase tea cloth has two distinct meanings. In one it refers to the cloth laid on the afternoon tea table, and in the other to the cloth, similar to a glass cloth, which is used for drying the tea things after they have been washed up. Ideas for embroidering and decorating afternoon tea cloths are given in the articles on Drawn Thread

## Tea Cosies Conventional and Quaint

## Directions for Making These Table Accessories in Various Fabrics

The reader is referred to the article on Raffia Work for instructions in covering a tea cosy in that material. See also Appliqué Work; Embroidery ; Felt; Laid Work; Leather W'ork; Patchwork; Painting on Textile Fabrics; Quilt; Ribbon Work; Tapestry Needlework; Woolwork
A tea cosy in common with every other boat notions. These are particularly suitable well thought out accessory should be chosen in company with cottage breakfast ware with due regard to its surroundings both in for nursery or dining room, or for garden style and colour. As a rule a conventional tea tables. There are also hen, duck and shape is best for the dainty cosy on an after- a fcw other animal shapes designed to cover
the nursery tea pot.

Making the Padded Lining. Although padded interlinings can be bought inexpensively in several sizes at art needlework shops, some people prefer to make their own. It is really simpler and wiser to have an independent lining for most cosies of conventional shape, and to slip the cover over it when the latter is completed. In the case of suède or a silk or satin cover which has been hand-painted, stencilled, or very delicately embroidered, it
is sometimes desirable to have the lining particularly dainty renewed, or cleaned separately. In the casc when of pale colours of a washable linen cover of ina colour worked in stranded this will require laundering separately. When the cover is of white linen decorated with drawn-thread work or lace motifs and insertions, the lining which will show through should be of a colour to suit the table ware so that the effect of the needlework is enhanced. A scparate lining can be attached to the cover by a few stitches to keep it in place.

Cosins vary in size from those designed for individual teapots to the large covers for family breakfast teapots. A very small cosy cut in conventional semicircular fashion measures about! in. across the bottom and is 7 in . high at the centre of the curve. A medium size is $14!$ in. by 8 in., while a larger one has a height of 10 in . and a width of 16 in . Whatever the size required to fit the outer cover, allow 1 in . all round for turnings when cutting the lining fabric. The wadding for interlining must he cut exactly to the size of the cosy when finished and no turnings allowed. Sateen is a useful material for linings, but for better cosies. silk and crêpe-de-Chinc are used for the inside of the lining next the teapot, while a cotton material serves for the outer lining naxt the cover, unless this happens to be decorated with openwork.

Cut four semicircles of the lining fabric and two of wadding (some workers use this in double thickness), sew the two semicircles for the outside of the lining pad together face to face, stitching firmly all round except at the bottom. Turn them inside out and then stitch the two inner lining pieces togrether in the same way, but do not turn. The two pieces of waddling are now sewn together round the top and sides with long tacking stitches. If the edges of the wadding are overcast they will not fray out. Slip the wadding inside the outer lining, catch them together with a few tacking stitches to hold the wadding in place, and thien push, smooth and stitch the inner lining into position. The bottom edges should now be neatly sewn together all round to complete the lining pad. An inner lining of silk or satcen to match the cosy cover is marle and adjusted to a wadded interlining when the latter is bought covered in white cotton material.

Afternoon Tea Cosies. Whether a cosy cover is a scparate allair or at one with the paclded lining, any embroidery or painting is done before the fabric is made up. Linen cosics are

Tea Cosy. Fig. 1. Cosy of rose pink crêpe-de-Cbine suita ble to accompany a dainty tea service. The design is quilted by band mployed to cover a

Fig. 2. Cottage cosy made of felt. The lattice windows, rose trees and flower border are worked in bright coloured wools and easy stitches whole canvas foundation, or for a motif the handle at the top. It is very intercstto be applied to a cloth, silk or satin tea ing to work out quilting patterns for oneself cosy. Decorative patchwork makes attractive with the aid of an original drawing or cosics in silk, velvet or suède. For these suitable embroidery transfer for the centres fabrics a gooll finishing touch is a cord sewn of the front and back of the cosy, drawing along the bottom and outside edges. This the border for this, diagonal lines and outer should be done with silk of the same colour as border for quilting, directly in pencil on to the the cord and after the cover has been joined. fabric after taking a few measurements for Take up a tiny piece of the fabric and a correct spacing. few threads of the cord and pull them together; then run the needle under the covering material for the longer stitches and take small stitches in the cord. The ends of this must be neatly finished off. 'To form a handle a loop of the cord should be twisted and left in the middle of the top. Tinscl cords are often used when silver or gold thread is introduced into the embroidery. Thonging is sometimes employed as a finish when suerle is the matcrial of the cover. (See Leather Work.)
Nothing could be more appropriate for a cosy than fancy quilting. The example of this work illustrated in Fig. l was carried out in rose-coloured crêpe-deChine, quilted by hand with back-stitching in silk thread to match. Instructions for fancy-quilting will be found in page 1030 . Italian quilting can be equally well used to decorate a cosy for the drawing-room tea table.

As quilting is done on fabric with an interlining, the inside lining of the cosy made of the same material as that quilted is usually attached to the outer cover, an extra layer of wadding being inserted between the two. Such cosies are pretticst in delicate colours and require to be dry-cleaned. The semicircular edges of the one illustrated are finished with a sclf-piping and strap handle. Sometimes the piping is twisted into a looped bow to form

Cottage Shapes. Felt, raffia cloth, linen. crash, blanket cloth and embroidery canvas are all used as foundation materials for the building of cottage cosics. It is not difficult to evolve one's own patterns out of brown paper, cutting the roof portion scparately, a back and a front piece of the same size, and two side pieces. The chimncy which forms the handle is a straight piecc doubled over and sewn on to the middle of the roof.

The cosy illustrated in J'ig. 2 is made of feit. The thatched roof is of brown, the chimney of brick red, the walls of fawn and the door of dark gicen felt. The height including the roof should be about $10 \frac{1}{2}$ in. when flat. A piece of brown felt measuring about 9 in. deep by 11 in . wide would be sufficient to form the roof, back and front when doubled, and the front and back walls of the cosy would be each 7 in . docep (to allow for joining to the roof), and 10 in . wide. The roof projects slightly at either side. The sides are about $4!$ in. wide and 10 in . high, being cut up to a point between the back and front of the roof. The door is a scrap of green (or other colouved) felt buttonholed to the wall picce. The design of windows and flower bed, ctc., can easily be drawn on the felt with a coloured crayon.
Bright coloured wools are used for the embroidery. The windows are done in chain stitch, the wondwork to match the donr and the lattice in darl grey. The rose tree is in stem stitch, brown for the stalk, single stitches in green for the leaves and a French knot for the centres of the pink roses. The groups of smaller flowers are worked with single upright stitches, small ones crossing these in green to form the leaves and stems and the flower heads put in with lazy-daisy stitch, buttonhole rings and French knots for the buds. Any other stitches can be introduced which the worker fancies, and the flower embroidety can be continued at the sides

Tea Cosy. Fig. 3. Plusa duck cosy tor the nursery teapot. Scraps of the plush left over can be made into ducklings to keep eggs warm

TEAK : The Wood. This The best metal teapots are of silver, but they is a heavy hardwood, dark are also made of Sheffield plate, electrobrown in colour, sometimes plate, aluminium, and enamiel ware. Often with a greenish shade. Like oak and some other woods, it darkens with exposure and age. It is oily, docs not suffer by contact with iron, and is durable under water. Its grain is straight and rather coarse, with a dull surface. When freshly cut it has a peculiar smell, something like leather. Though not very difficult to work, it contains a phosphate of lime which soon dulls the edges of cutting tools. When well seasoned it does not crack.

Teak is largely used for furniture in India, its native place, but only to a small extent in Great Britain, its dull appearance and its weight being against it. It is used occasionally for floors, stair treads, window and door sills, and similar purposes. See
in one group and a few brown stitches to represent the earth of the bed. The back can correspond with the front, but leaving out the door and the rose tree. The cottage walls when embroidered are tacked together and made up by firmly buttonholing the edges with wool to match the felt. Begin at the bottom so that a!l the edges are even at the base. Lay the roof in place over the four sides of the cottage, and stitch it down with long running stitches. It is a good plan to buttonhole the points of the side walls and catch the roof through to the buttonhole stitches. Ruttonhole the little piece of brick red felt for the chimney in the same colour, and attach it in the position shown.

Cottage cosies are obtainable, shaped in canvas, and ready to be embroidered in tapestry needleworts. Transfers can also be bought suitable for linen or raffia cloth covers. Details vary for roofs, windows and garden effects, but in the main the shapes are much the same.
Nursery Tea Cosies. Linen cosies with applied or cross-stitch designs of animals or figures from nursery rhymes are more commonplace than the plush duck tea cosy which is illustrated in Fig. 3, with the duckling as a miniature egg cosy. For the tea cosy $\frac{1}{2} \mathrm{yd}$. of 36 -in. wide woolly plush is allowed, the same amount of sateen for lining, a sheet of wadding for interlining, two black shoe buttons for cyes, and a small piece of orange cloth or felt for the beak
The cosy is cut in duplicate, each side in one piece, shaping it with a smaller portion for the head, slightly waisting the shape below this and then widening out to form the semicircular lower portion. The wings are cut out in 4 pieces roughly diamond shaped and the beak is simply 4 semicircular pieces, 2 for the upper part and 2 for the lower. The lining is cut in duplicate semicircular pieces.

Join the two halves of the plush covering with the right sides facing and stuff the head part well with cotton wool. Pad and line the cosy. Join up the two pieces of the Wing, leaving an opening at the base a that the work can be turned right side out. Scw up the opening and attach in position on cosy. Make the other wing in the same way. Join up the two pieces for the upper beak, turn, join up the other two pieces, and sew in position. Sew in the buttons for the eyes.

Teapot. Two Georgian silver teapots, one of them standing upon ball legs, and both with ebong handles Courtcs/l of Chapple \& Mantell
as well as repoussé work. Two typical ex amples of late Georgian teapots are illustrated. That on the left dates from 1787 and has a fine thread erlge and an engraved shield. Teapots of this shape often were made with stands to match on four feet. The teapot shown on the right dates from 1827 , and lias the four ball feet which makers began to put on at the beginning of the 19th century to obviate the need of the separate stand

About the end of the 18th century some beautiful teapots were made in Sheffield plate Existing examples, which have been largely reproduced, are very retined, hoth in shape and in rlecoration. In these subtle curves, plain surfaces and handles of flowing scrolls are skilfully combined, while the adornment takes the form of pierced ribbonwork and delicate rosettes.

Electric Teapot. A feature of the nickelplated electric teapot illustrated is the "tea ball." This perforated cage is filled with tea and suspended by a chain in the water after it has boiled. It can be raised when required, and the chain has a weighted knob which holds the tea ball out of the water so that the tea cannot be stewed. Connector, Hexible cord and lamp-bolder adaptor are supplied with the teapot.

Teapot Stand. A teapot stand is often necessary on polished wood tables and trays. For a silver teapot a small salver is sometimes used. Many different types of teapot stands are sold. In shape they are usually circular or square, and they are made of glazed earthenware, various kinds of metal and stone. The metal ones, because of their heat-conducting properties, are usually raised on wooden fect. See Salver; Urn.

TEAPOY. This word has two meanings. In one it is a small table supported upon a tripod or upon four legs, and used chietly for holding a tea service or an urn. In the other it is a receptacle for holding tea. These teapoys were the early form of tea caddy and were made of china or earthenware.

TEA PUNCH. This good summer beverage is made in the following way: Make a gallon of fairly weak tea, cover it and let it stand for $\bar{a}$ min. before straining and sweetening it to taste. When it is cold, half fill a punch bowl with cracked icc and add the tea and the strained juice of four lemons. Smal pieces of pincapple, a few stoned cherries, some sliced banana, a handful of mint, and, if required, a little more sugar, should be added just before serving. See Punch.

TEA ROSE. This is a group of garden roses, descended originally from the China rose, Rosa indica. They are distinguished by slender and somewhat spreading growth and are rather less hardy than the hybrid teas and hybrid perpetuals. They bloom in summer aid in uutumn and flourish best on a sunny, sheltercd border. See Rose.

TEASEL. The dearl flower-hearls of the teasel or fuller's teasel, owing to the stiff, spiked hracts that cover them, are employed in textile manufacture to raise the nap on cloth. The ordinary household use of this plant is purely decorative, the close oval heads of mauve flowers, each rising from a circle of long spines, on straight, stiff stems, making it an excellent cut plant for a tall vase. Teasels last well in water, retaining their bcauty even after the Howers are withered. They are raised from seerls sown out of doors in May, and the plants will bloom the following year.
Owing to use of teasel heads for teasing cloth, the name teasel wool is given to a kind of wool, the surface of which is raised with a wire brush after it has been knitted or crocheted.
TEA SERVICE. People who possess old china tea services rarely care to use them every day. Exquisite reproductions are obtainable from the modern Worcester, Minton, Wedg.
woord and other potterics, for those who like their tea tables to present an old world appearance and possess the great advantage that each piece is replaceable in the event of breakage. Many are moderately priced. A service for 6 people, for instance, is sold in modern Wedg. wood ware for less than 30s, and there are other makes of Staffordshire china reproducing the old designs to choose from at equally reasonable prices.
Slightly more expensive are the modern designs and delightful shapes of the china services from the Shelley and Newport pot-

Tecophilaea cyanocrocus, the Cbilian crocus, a beautiful spring bulb with blue fowers. It needs a warm, sheltered situation

TEA TABLE. Usually of light buitd and of small size, a tea table is generally about 27 or 28 in . high. It is obtainable in a !arge number of shapes with single and folding tops, and is made in both wood and wicker. On account of its uneven top the latter kind is only suitable for use with a tray.

Tea Wagon. See Service Wagon.
TECOMA. This is the name of a class of evergreen and leaf-losing climbing plants. Some may be planted against a sunny wall out of doors, while others inust be grown under glass. The two kinds suitable for a wall are grandillora and radicans, both with reddish, tube-shaped flowers. Both are vigorous climbers and will reach a height of 15 ft . or more. They should be pruned in spring by shortening the side shoots.

Of those grown in a heated glassbouse capensis, orange-red, jasminoides, white, and valdiviana, orange yellow, are the best. Pron. Te-cō'ma.

TECOPHILAEA.
These are blueHowered bulbs which may be grown in a border at the foot of a sunny wall or in pots in the greenhouse. They are not hardy enough for the open garden. They like sandy, loumy soil and should be planted in autumn 3 in. deep. teries. In semi-porcelain there is a great choice Cyanocrocus, blue, and Leitchlinii, deeper blue, of old and new patterns. In plain colours are two beautiful kinds; both fower in spring. such artistic services as those in Mooreroft The popular name is Chilian crocus. powder blue ware have much to recommend them. Combination breakfast and tea sets are useful, as in this way space is saved and larger cups are at hand to match the tea cups for those who prefer them. In many patterns teapots, hot water jugs, toast racks, cake plates, muffin dishes, butter and jam dishes can be obtained to match. Particularly bcautiful is the ware with a honcy-glaze ground.
A silver tea service is conıposed of teapot, cream jug and sugar basin. Sometimes a tray and spirit kettle or hot water iug are included. See China; Silver.

TEASPOON Teaspoons may be of silver or electroplate. They are ofters sold in sets of 6 or 12, or form part of a set of table silver. In larger sizes they are used with breakfast cups for tea or coffec. For afternoon tea and after dinner coffee ornamental designs in smaller sizes are specially made. The ordinary teaspoon is used as a measure for liquid Havourings in cookery. It is equivalent in this sense to $\frac{1}{8}$ of a Huid ounce. See Silver; Spoon.

Fig. 3

Fig. 2

TEE SLIDE. Used in securing dining- there is constipation fluid magnesia in the table slides, the tee slide is uscful because no mornings is a useful remedy, and the best cross-rails are required under the table when remedy for diarrhoea, at any rate at the bethis form is fitted. The table slides are first worked to the correct shape by special planes and the tee slides are shaped to fit and are let in, glued and screwed
ginning, is a teaspoonful of castor oil. Earache may be treated by applying cold cloths to the car. As the child salivates very frcely, it may soak the garments over the front of the chest,

to the adjoining slide. The amateur will find some difficulty in planing the groove, but with lardwood the table slide can be built up with 3 pieces of wood, as in Figs. 1 and 2. A suitable groove is cut in the thicker piece, and then the two thinner pieces are glued and screwed on. Accurate workmanship is needed to ensure easy running, but if this is attended to the method is preferable to any other. To prevent sticking, the inside of the groove should be coated with blacklead. See Dining Table.
TEETH. A tooth exhibits a crown, a neck and one or more roots or fangs. The coots are composed of dentine, or ivory, and this exists also beneath the crown, surrounding a hollow in the centre of the tooth, described as the pulp cavity, which is continucd down into the roots. In this cavity is the pulp, consisting of blood vessels, nerves and loose connective tissue. The crown is formed of an intensely hard substance known as enamel ; it forms a cap of varying thickness for the tooth and may have two or more eminences, or cusps, on its biting surface.
Teething. The process of cutting teeth is called teething or dentition. There are two dentitions. The first of the milk teeth to appear are usually the lower central incisors, and this generally happens in the 6 th month. In a short time the upper central and all the lateral incisors ernerge. and then follow in order the first molars in the 12 th month, the canines in the 18th month, and the second molars in the 24 th month. Variations of these times occur even in healthy children, and in rickets dentition may be much delayed.
The second dentition begins about the 6 th year, with the appearance of the first permanent molars, and each year after this the other permanent teeth are cut-the central incisors, the lateral incisors, the first premolar, the second premolar, the canines and the second molar. The third molar tooth may appear about the 17th year or not until the 25 th , and is also called the wisdom tooth : sometimes it does not erupt at all.

The first teething is sometimes a trying event for the infant and the gums may be swollen, hot and tender, and the child is feverish and restless. The digestion may be upset, and there may be constipation or diarrhoea. Sometimes there is earache, indicatcd by restless movements of the head and erying. It is not uncommon also for a child to suffer from bronchitis while teething. Another possibility is that the child may have convulsions (q.v.).
A child that is being suckled should not be taken off the breast while it is having difficulty in tecthing. Cool, boiled water may be given frecly to cool the mouth and relieve thirst. If
and care should be taken to prevent this.

The use of a baby's comforter creates a danger of infection, because the comforter may be dropped on the floor and be put back in the baby's mouth without being sufficiently cleansed, but there is this further count against it, that it may cause malformatiom of the jaws.
It is desirable that an infant should begin gnawing at crusts or rusks when it it is about six months old. as this practice helps to develop the jarss, and insufficient development may be due to the child not having been given firm food to gnaw ; but this is quite a different thing from a baby keeping a comforter stuck in the side of its mouth more or less constantly.
There is rarely any trouble with the second dentition. Sometimes the teeth are overcrowded and are placed irregularly. When there is no hope of their settling into a correct position one or more should be extracted. Unless teeth are efficiently cleansed there is a tendency to the deposition of tartar about the neck of the tooth, and this may separate the gum from the tooth, giving access to bacteria and possibly leading to pyorrhoea. Morenver, carbo-hydrate foods, such as sticky fragments of bread, may lodge in the crevices between the teeth, and ferment, giving rise to acid substances which attack and dissolve the tooth-substance. That is the beginning of caries.

The natural method by which teeth are cleaned is by chewing crisp foods and such as require a good deal of mastication. The teeth should also be brushed, however, twice a day at least. The motion of the brush should be up and down and it is necessary to hold it vertically when brushing the backs of the teeth. Parts which cannot be reached by the brush can be cleansed by drawing a strand of dental floss between the teeth.

A smooth dentifrice should be selected, as erosion of the teeth has followed the use of a gritty dentifrice. The tooth is worn away at the gum margin and decay is encouraged. A common cause of erosion is the little metal clip often used by dentists to keep a small denture in position. This should be avoided whenever possible, and so far as the upper jaw is concerned the use of a sufficiently large plate may make clips unnecessary.

As soon as decay begins the parts should be cleaned out and stopped, and it is only prudent to have the teeth examined perıodically by a dentist so that the first beginning of caries may be discovered and dealt with.

The importance of keeping the teeth sound cannot be over-estimated. Apart from the digestive troubles that proceed from deficient or defective teeth an enormous amount of illness is caused by the absorption of poisons from defective teeth.
Pain in a tooth, or toothache, is dealt with under that heading. Excessive bleeding after the extraction of a tooth may be arrested by folding a part of a bandkerchief into a pad and biting on it, or by plugging the socket with cotton wool.
Artificial Teeth. Artificial teeth must be kept scrupulously clean. They should be taken out at night and brushed with tooth powder, and then be left in water containing some antiseptic. For a vulcanite plate this might
be hydrogen peroxide, but for a metal plate it may be necessary to use a weak solution of chlorinated soda from time to time in order to keep the metal bright. A removable denture is much to be preferred to bridgework, as juices may lodge beneath the bridge and decompose. See Caries; Dentifrice : Pyorrboea: Tartar: Toothache.
TELEGRAM. Telegrams are divided by the Post Office into two classes, those sent within the United Kingdom and those sent without. For inland telegrams the charge is ls . for the first 12 words, including the address, and ld. for each additional word. Telegrams to the Irish Free State are treated as inland telegrams, but are charged ls. 6d. for 12 words. Telegrams handed in on Sundays, Good Friday, and Christmas Day are charged 6d. extra in England and Wales. In Scotland this extra charge is made on Sundays only.

Telegrams in plain language in any modern European tonguc or in Latin or in Esperanto are charged for according to the number of words. All words not forming part of any modern European language or of Latin or Esperanto, and all unintelligible combinations of letters, are charged for at the rate of five letters to a word. With the exception of words that are ordinarily written as one, such as father-in-law and twenty-six, no combination of words is countcd as a single word. Double names like Rivett-Carnac, although connected by a hyphen, are counted as two words. Abbreviations, such as can't and won't, on the other hand, are counted as singie words.

Figures are counted at the rate of five to a word. For example, 67243 counts as one word, but 567566 counts as two. Fractions are similarly counted according to the number of figures employed, the mark of division being reckoned as one. Thus $\frac{3}{4}$ counts as one word, but $288_{\text {IT }}^{y}$ as two, because there are six figures and marks therein. When a figure or a group of figures is followed or preceded by a letter, e.g. 716 A , the letter counts as a word. Initial Intters arc counted as a word each, with certain exceptions. For instance, the initials of the London posta! districts, e.g. W.C., are counted as one word, as are the abbreviations, a.m., p.m., and H.M.S.

Certain names of places are counted as one word each, irrespective of the number of words of which they are composed. These are : All names of towns and villages in the United Kingdom and the Irish Free State: the naines of railway stations and other places not in towns at which telegraph business is transacted; the names of districts in towns when such are used in addresses in addition to the names and thoroughfares, e.g. High Street, Camden Town. Here Camden Town counts as one word.

Telegrams should be written on the proper forms, which can be obtained free of charge if unstamped. Forms with embossed stamps can be bought for 1 s . each. A book of 20 can be bought with a sheet of carbon paper for copying, for 20s. 3d. A rcceipt for the charge prepaid upon a telegram can be obtained for Id. A certified copy of a telegram can generally he obtained on application to the local postmaster for 6d.

Delivery of Telegrams. Telegrams are delivered free of charge within three miles of the delivery office nearest the address. When that office is a head post office no charge is made for delivery within the town postal delivery area even if the distance exceeds three miles. In the Irish Free State the limit of free delivery is one mile: beyond that porterage is charged at the rate of 6 d . a milc or part of a mile, the extra distance being calculated from the limit of the free delivery.

The cost of a reply telegram, not exceeding 48 words, can be prepaid. In this case a reply form will be handed to the addressec, who is
at liberty to use it for any inland message at any time within 12 months. If the form is not used its valuc will be refunded. Reply telegrams, handed in on Sundays, Good Friday, and Christmas Day will be charged 6d. extra, unless this has been prepaid by the sender of the original telegram, in which event the reply form will be marked on the back "Sunday rate prepaid." If the telegram is addressed to a place in Scotland, the extra chargc must bc prepaid on Sundays only.
The address of a telegram should be sufficiently full to enable it to be delivered without difficulty and without reference to directories or other sources of information. An address ordinarily used for letters is not necessarily correct or sufficient for telegrams.
Telegrams can be redirected to a second address, either by an official of the post office or by an agent of the addressee. There is no charge for officially recording instructions to redirect telegrams for a period of threc months. For any period in excess of three months the charge is a guinea a year. Telegrams redirected on Sundays, Good Friday or Christmas Day are charged 6d. extra, excepting when the redirection is from an office in Scotland, in which case Sundays only are charged for.

The sender of a telegram may have in structions, such as confidential, written on the outside of the envelope. Such instructions
are charged for as part of the message. Telegrams intended for delivery to callers at a tclegraph office should contain in the address the words " poste restante " or " to be called for." Such tclegrams are kept at the office for two days only. Tclegrams for railway passengers should be addressed $\mathrm{c} / \mathrm{o}$ the station master. The post office is not liable for any loss or damage which may be incurred by reason, or on account, of any mistake or default occurring in the transmission or delivery of a telegram.
Foreign Telegrams. Telegrams can be sent to places abroad, the charges varying with the distance and other considerations. A full list of these will be found in the post office guide. Special forms are provided for these telegrams. They are accepted without restriction to most places abroad, but a-few countries maintain restrictions on them. Particulars of these restrictions cau be obtained from any post office.
Telegrams may be written in any of the principal European languages and in certain others, including Esperanto, provided they are written in Roman characters. The maximum number of letters allowed to pass on foreign telegrams at the charge for a single word is 15 . Any excess is charged at the rate of 15 letters to a word. A reply of any length can he prepaid, but the minimum payment is 1/3. See Postage.

 <br> <br> Regulations for Subscribers and Methods of Installation}

This artic'e is divided into two parts. The earlier is for the benefit of those who have or wish to have, a post office telephune In their bomes. The sciond part describes how a man of mechanical turn of mind can fit into his bouse a telephone service connecting onc room with another. Sec Battery; Bell; Micropho c

Anyone desiring a telephone line to his house must apply to the post oflice. The work of installation will be carricd out by the post oflice oflicials after the neccssary documents have been signed. The subscriber must not interfere in any way with the telephone mechanism; if anything gocs wrong he must tell the authorities, who will put it right. Every telephone line is connected with an exchange and is given a number.

The charges for these telephone lines fall into two classes. There is first of all a quarterly rent. This varies to some extent with the district and is somewhat more for business premises than it is for private residences. For the latter, if the telephone is in London and is not more than two miles from an exchange, the rental is $£ 1$ l2s. 6 d . a quarter, or $£ 610 \mathrm{~s}$. a year. If the telephone is in Glasgow, Birmingham, Liverpool or Manchester, and is not more than $1 \frac{1}{2}$ miles from an exchange the rental is $£ 110 \mathrm{~s}$. a quarter, or $f(f$ a year. If it is in any other part of the country and is not more than $1 \frac{1}{2}$ miles from an exchange the rental is $£ 17 \mathrm{~s}$. 6d. a quarter or $£ 510 \mathrm{~s}$. a year. In case the telephone is more than the stated distance from an exchange, a charge of 5 s. is made for each furlong of the excess distance.
Call Charges. The second charge takes the form of so much per call. This is ld. for every call to a subscriber whose exchange is within a radius of 5 miles from the one to which the caller belongs, and 2ll. a call for those made to an exchange that is more than $\bar{j}$ miles and less than $7 \frac{1}{2}$ miles away. These distances apply to most cases, lut in London and the four large cities, Glasgow, Birmingham, Liverpool and Manshester, there are certain extensions. In the case of the metropolis, calls can be made at these rates to any exchange within an area which in January, 193:, was extended to reach from Dorking on the south to Hatfield and St. Albans on the north and from Gravesend on the east to Eghamı on the west. All calls) beyond these distances are trunk calls, and are charged as such.

Telcphonc rentals are payable in advance, on Jan. 1, April 1, July 1, and October 1. A subscriber is required to deposit a sum suflicient to cover two-thirds of a quarter's account for local, trunk and telcgram charges.
An Extension Line. Occasionally it happens that a person wishes for an extension line carrying the telephone to another part of his house or outbuildings. For instance, a man may want an extension to his garagc. Provided this is part of the same building as the house, one of these lines will be iustalled and a small rental charged. This ranges from 6s. a quarter upward, according to the length of the extension.

One method of securing a telephone is for two persons to join for a single line, and the post olfice has a system by which these lines are provided. This privilege, however, is restricted to subscribers in the provinces whose premises are more than a mile from an exchange. The rental in this case is $£ 1$ a quarter for each of the two subscribers, if the premises are not more than 2 miles from the exchange. If this distance is excecded a rental of 5 s . per furlong for the extra distance rental of 5s. per furlong for the
is charged. The fees for calls are the same as in the case of lines which are used by one household only.

Co-operative telephones are provided on another plan Rural party lines, as they are called, are intended to afford a cheap service for residents in country districts. Under this arrangement several subscribers share the use of one circuit from the exchange. Their calls arc distinguished by a code of rings. Thus, if the bell rings once it is for Mr. A's house-
$\qquad$

hold; if twice, for Mr. B's. and so on. In these cases each subscriber in the ordinary way pays $£ 1$ a quarter. To secure this rate the number of subscribers must average not less than one for every $\frac{1}{2}$ mile of the circuit beyond a radius of $\frac{1}{2}$ milc from the exchange, and there must be a minimum of three. Thus, if the line is 5 miles from the exchange there must be at least nine subscribers.

If sufficient subscribers cannot be found to comply with these conditions, the rental is fixed to produce $£ 2$ per quarter for each mile of circuit beyond the $\frac{1}{2}$ mile radius from the exchange. Thus, if there are five subscribers and the distance beyond the lirst $\frac{1}{2}$ mile is 3 miles, the rental must produce $£ 6$ per quarter, being $£ 2$ for each mile. In this case cach of the five subscribers must pay \&1 4s. per quarter. Calls made by subscribers to party lines are charged for at the same rates as to other subscribers, except that in the case of these party lines the rental covers all calls made to other subscribers on the same exchange. These telephones will not be provided for persons who live within mile of the exchange, or in districts that are not rural.

The post office is prepared to open a new exchange in places where there are a number of persons wishing for a telephone. Applications for new exchanges in small areas remote fron existing exchanges are entertained favourably, provided that the cost of connecting them with the existing exchange system is not excessive, and that a minimum of eight new subscribers, each renting an exclusive circuit, is forthcoming.
Trunk Calls. Subscribers who wish to speak to persons at a distance must make use of one or other of the trunk lines that are available for this purpose. By trunk lines are understood those exchanges, except in London, Glasgow, Birmingham, Liverpool, and Manchester, that are more than $7 \frac{1}{2}$ miles from the one to which the subscriber belongs or from which he speaks. In London a trunk call :s one to any exchange outside the London telephone area. In the other four cities the distance varies, but broadly speaking there is no need for a trunk call when a subscriber within the city is required
The charge for a trunk call varies according to the distance and the hour of the day or night. It costs most between $7 \mathrm{a} . \mathrm{m}$ and $2 \mathrm{p} . \mathrm{m}$. is somewhat cheaper between 2 p.in and 7 p.m. and is still cheaper between $7 \mathrm{p} . \mathrm{m}$. and 7 a m The fees range from 3d upwards. This allows for a conversation of 3 min . If more time is wanted an extra fee must be paid.

Call Offices. For persons who have no telephone in their homes, or are away therefrom, public call offices are provided, these being usually in post offices and railway stations. The fice for the usc of a call office, in cluding communication with any exchange within a radius of 5 miles, is 2 d for each 3 min or less during the day, and for each 6 nim. during the period between 7 pm and $7 \mathrm{a} . \mathrm{m}$. The charge for a call to an exchange between 5 and 7! miles distant is 4 d . for conversation of 3 min. during the day and of 6 min. at night. In the metro polis the distances are much greater. Persons can also use a call oflice to get on to a trunk line by paying the necessary fee and the usual $2 d$. for the use of the call oflice.

Overseas Calls. Telephone commu: nication can also be obtained with most of the countries in

Europe, including the Irish Free State, and alao with Canada, the United States, Mexico and Cuba. It lias also been established with Australia, and with certain places in Argentina Brazil, Chile and Uruguay, as well as with
Java. Mor occo and places in Indo-China telephone service is also available with certain ships that crose the Atlantic, these including the three great White Star liners, Majestic, Olyınpic and Homeric. For these services full charges are in force during the day, hut reduced during the night. These are roughly three-fifths of the day charges.

Private Telephone Wires. The above remarks apply to the service of telephones operated by the post office, which department has control of all wires leading to the various exchanges There is, however, nothing to prevent a private individual from installing a telephone of bis own and using it for communication between one part of his premises or estate and another ; for instance, between one room and another, between house and garage or stable, or hetween house and the cottage of a gardener or chauffeur
A person who possesses, or contemplates possessing, such a telephone line must carefully note one or two matters. He must remember that he cannot use his own line to communicate with any house or premises that only possess a telephone attached to the public system He must, too, take great care that his own line is not linked in any way with any wire that is part of the public service. With these limitations, however, a private line may serve within its own sphere a very useful purpose.
Simple Domestic Telephone. The circuit for a telephone is shown diagrammatically in Fig. 1, the different parts being indicated When a receiver is lifted off its hook the latter automatically makes a contact and places the apparatus in circuit. Normally, with the receiver at rest on its hook, the telcphone line is connected to the bell. The simplest type of telephone system for domestic use is shown in Fig 2. The apparatus consists in the main of two parts. At the top is a push, similar to a bell push, with a hook fitted to its underaide and a plug projecting from the top. Wires from this plug are taken to the lower instrument, which is the actual telephone. At the upper end is the receiver, beneath which is a handle incorporating a switch, while at the bottom is the microphone. The whole instrument is conveniently shaped so that it fits the ear and mouth.

The connexion of this instrument with another of identical design is shown in the diagram. This scheme enables the Mne to he worked in one direction only. That is, station A will only he able to ring station B. Station B can reply, but cannot originate a call. Such an arrangement is useful in the home when $A$ is situated in the dining room and $B$ in the kitchen Ringing is accomplished by pressing the push at station A, but the line will not be clear for speech until the handle switches on hoth stations are pressed. The latter action is more or less automatically done in the hand. ling of the instrument.
No induction coil is incorporated in this apperatus. as it is only suitable for working over short distances The number of cells
required will depend on the distance and the size of the conductors. but normally two only will he necessary. Such all installation may be fitted entirely with homely tools and by unskilled hands, as it is no more complicated than an ordinary electric hell. The use of twin wire over the longer distances will greatly facilitate the process of installation

Fig. 3 shows how the same instruments employing a slight!y different type of wall push and an extra bell may be made The headphone magnet windings may be to work in hoth directions. It will be seen that wound to have either a low resistance or high the main line now consists of three separate con resistance. High resistance headphones are ductors. and that there are two bells. Such an very sensitive, and are thus particularly suitinstallation is still within the scope of the able for use with crystal receivers. amateur or handyman of the house. In this instance it would be better to use single conductors, either laid side by side along the walls of the house, or elsc enesased in wood or conduit.
The battery can consist of two dry cells of large size. and these should last for nine to twelve months, after which they should be scrapped and replaced. Both the ahove sys-

In the case of a valve receiving set, it is hetter to employ low resistance headphones (which are more robust) in conjunction with a telephone transformer to isolate the magnet windings from the steady current flowing in the anode circuit of the valve. This is highly important in a mains operated wirelesg receiver. See Microphone.
tems may be fitted to existing bell installations with very little addition. All that has to be done is the substitution of one of the telephone appliances for the ordinary bell push.

Telephone Receiver for Wireless. The function of the telephone receivers in wireless reception is to convert the rectified impulses in the detector circuit into audible sound waves

## Telephone Covers and Screens

## Several Attractive Kinds to Make and Decorate

Atractive and practical methods or conc aling the telephone instrument are suggested in this article. For further informatio t the readcr is referred to the contributions on Fretwork; Gesso
Work; Italian Renaissance Work; Lacquer Work; Leather; Pencil Painting; Tarso. See also Work; Italian Renaissance Work $\begin{gathered}\text { Lacquer Work; Leather; Pencil Painting; Tarso. See also } \\ \text { Lampshade ; Writing Table }\end{gathered}$

In some of the newer houses small wall cupboards are fitted into halls and livingrooms for the special purpose of accommodating the telephone, or a compartment is preparcd for its introduction into a bookcase or writing-desk fitment. The flap of the cupboard pulls down, and, by means of a metal arm, forms a convenient little table for the telephone, directory, and a pard with pencil duly attached for taking notes.
Wherc no such arrangement has been thought out a convenient cover for the whole telephone can be made by adapting a small white wood hanging cuphoard. This should be of sufficient height and depth to admit of the instrument standing on a shelf, with space beneath for the directory and pad.
The back is cut out to admit the instrument and a small horizontal slot at one side next the wall for the cord. The cupboard should be brought into the colour scheme of the hall with enamel or stain, and the door presents an excellent panel surface for a piece of well-chosen painted, fretwork or tarso decoration.
There are many rooms in which a wall cupboard is not suitable, but in which an undisguised telephone has too businesslike an air. A dome-shaped oak stand can be obtained which is like a small cabinet, or a cover can be purchascd or made at home after the style illustrated in Fig. 1. The head and arms and also the
wire frame for the billowing skirt which conccals the telephone can be bought for about 5 s . Any silk, velvet, brocade, etc., can be used for the dress, and this can be faslioned in an Elizabethan, early Stuart, Queen Anne, Georgian or early Victorian style, when skirts were worn over farthingales, hoops or crinolines.

If a new piece of material is to be hought $\frac{7}{8} \mathrm{yd}$. of $50-\mathrm{in}$. width is sufficient to make a dress with gimp or tinsel lace for trimming and ribhon for a sash. A shot artificial silk is inexpensive and quite charming in mauve and blue, or rose and gold. A frame measures usually 10 to 12 in . across at the basc and is from 15 to 17 in . high. The wires must be covered in the same way as a lampshade frame and either coloured silk or cambric strips cut on the cross 1 in . wide is hest for the purpose (see page 689).

A variety of heads are obtainable with hair done in different styles and made of silk, of real hair like an ordinary dolls, or with curls of the same composition or china as the face and arms. In some ways the last is the most serviceable choice, as there is nothing to get out of order and the doll has a Dresden china appearance. The head portion is provided with wires which when twisted firmly round the upper wire of the frame attach the two togother. This is done before the wires are bound so that there is
nothing untidy about the inside of the cover.

The skirt is cut from the width of the material in a straight picce merasuring $18-20$ in in deptl. The length depends on the height of the frame, and the skirt should be an inch longer than this, after allowing for turnings. Having heinmed and joined it at the back, it is slipped on to the frame and neatly gathered to fit the waist The hodice on the figure illustrated is simply two doubled strips measured and cut the length reguired to fit from the waist in front to the waist at the lack when crossed back and front. To then are sewn little straight picces to make the sleeves gathered to fit the arms above the clbow. Cut out and adjust the strips in paper first to see the exact length needed, and also what width to cut the slceves.
The frill requires a straight atrip ahout 3 in . wide and cut from the width of the matcrial and half as much again. It may be edged with lace, as may the sleeves, or a tinsel gimp may be used for both. Instead of one wider frill several narrower ones may trim the skirt. A ribbon sash with a bow and long ends completes the dress. A rather more trimmed style has an under petticoat of a lighter shade covered with gathered rows of narrow lace over which the skirt is draped at the sides. The bodice has then a crossed lace fichu and lace frills to the slecves. A woman olever at dressing dolls can design a charming period dress in colours to suit her room.

Telephone Cover. Fir. 1. Period Hrure cover. A doll's body to the waist is used for the upper portion and the silk skirt billows out over a wire frame

Fig. 2. Plywood telephone screen witn painted design and border in bright colours. This screen can be easily made at home ior a trifling cost

Wooden Screens. Small wooden screens are particularly attractive whether painted in plain colours with a scverely geometrical border, or handsomely decorated in gesso, Italian Rcnaissance work. lacquer work, or Tarso.

A screen of the type of that illus trated in Fig. 2 is expensive to buy, but if made at home can he produced for a trifling cost. The materials required are sufficient thin plywood (q.v.) to make the 3 folds, (the middle one being 16 in. high at the top of the curve, and measuring 7 in. across, while the sides each measure $5 \frac{1}{2}$ in.), 4 small screen hinges, sandpaper, enamel or brush lacyuct colour for the ground, and oil colours, liquid oil colours or bronzes for the design. A coat of varnish should be given on completion.

Plywood can be obtained in various thieknesses, but a thin one is best, as it is casier to cut. A small fretsaw will be

Fig. 3. Wooden screen on a revolving base. Tae panels are decorated with painted flowers and gilded edges. The telephone pad has a cover of imitation vellum painted in coloured inks, and is glued on to a gilded wooden base
fretsail. The screen is supported at the base by means of a block of wood glued at the back. The block is large enough for the telephone to stand on, and sufficiently solid to counterweight the screen when the instrument is removed for use. Sometimes the idea of the lady in full skirts is adapted to plywood and paint, and the figure is then cut out and supported in the manner just described.
Care must be taken when drawing the design to see that the telephone will be fully covered by the skirt before the figure tapers ahove the waist-line. The hlock and the back of such screens should be painted the same shadc. In the case of the bouquet designs green or brown is the best choice, as they do
not clash with the brilliant colours employed for the flowers. Metallic paint in silver or gold adds a gay note to the figure design.

Although not so durable, excellent little screens and telephone pads can be olstained in parchinent-covered carlhoard of a heavy make. These are quite inexpensive and can be decorated charmingly with pencil painting. or in any of the ways suggested for decorating parchment in the article on Lampshades. When rarnished, the parchment keeps clean for a long time. Parchment paper screens are also supplied in sliect form, traced ready for colouring. They are designed in 3 sections with a wire frame for mounting the work when completed.

## Telephotography for Amateurs

Practical Details of an Important Branch of Photography
Though at one time thought to be the exclusive province of experts carrying specially cumbersome cameras, teleplootography is now within the raach of all, and its nttrac:ions are clearly set forth in this article. Sec Exposure; Focus; Lens; Photography
Telephotography nay be roughly described $\mathrm{f} / 3 \cdot 5, \mathrm{f} / 5 \cdot 6$ (for reflex cameras) and f 6 5 ) as combining some of the adrantages of a for hand cameras. These are suitable telescope with those of a camera. It provides for use on small 3! in. by $2 \frac{1}{2}$ in. cameras. a means wherely with an ordinary hand $A$ form of the second type is the Adon camern capable of a certain amount of ex- (Fig. 2), which is designed for use by itself tension photographs may be taken on a on all sizes of chmeras possessing focussing much larger scale than with the orilinary screens. It includes a rack and pinion for medium focus lens.

Thus, with an ordinary camera photographs of distant vicus, high mountains, or architectural subjects are not only reproduced on a very small scale, but are liable to be wrong in perspective. With a good telephoto lens distant olijects zan be photographed directly on a large scale. and only require subsequent enlargement. Excellent photographs have, for instance, been taken with telephoto lenses of mountain penks 90 miles away.

With the type of lens usually fitted to a camera the size of the innage given on the focussing sereen depends on the focal length of the lens. Thus, comparing a small pocket camera whose lens is $3 \frac{1}{2}$ in focal length with a large cancra the lens of which has a focal length of 7 in ., the image secn on the focussing screen or negative will be twice as large with the 7 in . lens as it is with the $3 \frac{1}{2} \mathrm{in}$. In order, therefore, to get an image four times the size, a 14 in . lens would be required, and so on in proportion. Now since with the norinal lens the focal length is approximately the distance between the hack of the lens and the focussing screen, the greater the inagnification required the longer the focal length and the bulkier and more unwicldy the camera.
These difficulties are overcome by the tele. photo lens. which consists in principle of two systems of lenses : (1) the normal positive lens, or combination acting as a positive lens, such as is used in every camera; (2) a negative lens, or lens combination, such as is used in opera glasses. The first combination, the positive lens. may be the ordinary lens of the camern, in which case a negative lens is added, such as the Zeiss Distar. In many cases the negative and positive lenses are combined in the telephoto system, which may be used by itself as a complete lens or in rddition to the ordinary lens.

An example of the first is the I)allon (Fig. 1), a series of anastigmatic telephoto lenses of 9 in . and 10 in . focal length working at apertues of

Telephotography. Fig. 1. Dallon telepaoto lens, suitable tor use without any other lens on small cameras, 3$\}$ in. by 2$\}$ in. Fig. 2. Component parts of Adon lens, for use on cameras with focussing screens

Courtesn of J. H. Dallmencr. Lid
sufficient extension. Thus, for a $\ddagger$ plate an extension of $5 \frac{1}{2} \mathrm{in}$. is necessary, which is the normal of a single extension $\frac{1}{4}$-plate camera. Its weight complete is only 7 oz . Of course, it must he remembered that the greater the extension available on the camera the greater the magnification which can lie obtained.

Other good types of telephoto lenses are the Zeiss Magnar and the Dallmeyer Grandac, hoth working at $\mathrm{f} / \mathrm{IO}$; and the Ross Teleros, which is of large aperture working at $\mathrm{f} / 5 \cdot 5$ and $\mathrm{f} / 63$. A narrow angle Zeiss lens is the Tcle-Tessar, working at $f / 6 \cdot 3$. The Dallmeyer Large Adon series work at $f / 4^{-i}$, permitting telcphoto snapshots and requiring extensions of $4 \frac{1}{2} \mathrm{in}$. for a $3.2 \mathrm{in} . \times 21 \mathrm{in}$ camera, and 61 in ., for a quarter plate, the magnification being $\xlongequal{2}$. All the lenses described, with the exception of the Adon (Fig. ') and the Grandac, are of the fixed focus type, focussing being done hy racking the camera front in the ordinary way. Focussing lens mounts can, however, be supplied in most cases.

With telephoto lenses of the fixed focus type, which are used in place of, not in addition to, the ordinary camera lens, there is no complication of any kind. They are used in precisely the same way as the ordinary lens, and exposures are made according to their aperture or $\mathrm{f} / \mathrm{m}$ mimer. When telephoto lenses are used in addition in the normal lens, or when they are of the variable focus type, certain calculations require to be made. With Adon and certain other lenses special calculators, in the nature of ready reckoners, are supplied. The data required are (1) the effective aperture of the combination; (2) its focal length; and (3) the degrec of magnification in use.

The magnification, or size of the image, increases proportionately with the camera cxtension. The degree of magnification is found by dividing the distance between the back of the telephoto attachment and the focussing screcn by the focal length of the telephoto or negative lens and adding 1. Thus, to take as an example, a telephoto lens working at 10 in . extension when combined with a positive lens, the focus of the telephoto negative being $2 \frac{1}{2}$ in. $\frac{10}{2!}$
$+1=5$, i.e. the magni.
fication on the negative
greatly inceren that exposures must be greater increased. and further that the grten the magnification obtained and the xtension used the more the anerture is reduced and the exposure increased. Not only does the exposure increase with increasing extension, but magnification is also limited

Telephotography. Firs. 3-5. Showing magnification obtained with telephoto lens. Fig. 4 represents a magnification twice the size of reppresents a mand Fig. 5 four times the size. both the latter being taken with the same Dallon lens at different extensions
with a magnification factor of 2 , which actually means increasing the area of the inage 4 times, since the magnification factor is a time allowed after focussing, etc., for camera linear one. With some tclephoto lenses mag- and stand to become perfectly steady, fairly nification factors are marked upon the mount. light apparatus may be used. With the

A little practice will soon enable the ainateur higher magnifications an additional strut titted to calculate the exposures required. The basic rule for exposure when using is combination of the telephoto nugative lens and the ordinasy positive camera lens is to multiply the exposure required by the positive by the square of the magnification factor. Thus, if the lens without the telephoto nttachment requirs under certain conditions an exposure of $\& \mathrm{sec}$, and the magnification is three times, the exposure reguired when the telephoto lens is midded will be $\frac{1}{2} \times 3^{2}=\frac{1}{2} \times 9=4 \frac{1}{2}$ sec. This, of course, applies only to telephoto lenses; of the fixed focus type.

When variable focus telephoto lenses are used in combination, it is necessary to find the aperture or $\mathrm{f} /$ number of the whole combination according to the rule already stated. This f/number can then he used with any exposure meter in the ordinaty way. If the telephot.. lens itself is stopped down the length of exposure must be multiplied by the number of the stop used.
It is necessary to calculate exposures with telephoto lenses rather more closely than with ordinary lenses, and it will he found in practice that exposure times given by the calculations refired to are maximum figures, which should not be exceeded, particularly with distant objrets, owing largely to atmospheric haze. It may be found, in fact, that an exposure of half the calculated time will give good results with a distant object. For objects at moderate distances the calculated exposures are correct. When photographing distant objects, results will always be improved by the use of colour screens as used with panchromatic plates. They cut out the atmospheric haze, but must

be of good quality, as any from the front of the camera bascboard to one defects in them are magnified of the logs of the tripod will help considerably

Telephotography. Fig. 6. Nature photograph taken with an ordinary Telephotography. Fig. 6. Nature photograph taken with an ordinary
lens. Fig. 7. Showing how the Dallon telephoto lens obtains a large scale photograph of the central feature from the same standpoint as Fig. to ensure steadiness.

Focussing must, of cosurse, be done very carefully and very finely ground glass used as the scrcen. A magnifying focussing eyepiece used on the focussing screen will be found of great assistance. Such a glass may be purchased from any photographic dealer. All telephoto lenses should be fitted with long hoods, such as that seen in the photograph. Fig. 2; these hoods cut off stray light and greatly improve the brilliancy and contrast of negatives.

The serics of illustrations Figs. 3 to 9 demonstrate some of the varied uses of telephoto lenses. Figs. 8 and 9 show examples of subjects which could not otherwise be satisfactorily photographed at all

For nature photographs (Figs. 6 and 7) the telephoto lens offers the immense advantage of being able to secure pictures on a good scalc at a considerable distance away. Similarly, groups and street scenes are much more easily obtained. Not only, however, are the photographs obtained on a good scale, but the actual perspective rendering is greatly improved.

TELESCOPE. There are two main types of telescope, refracting and reflecting. The former is suitable for either terrestrial or astro nomical observations, and the latter usually for astronomical observations only

In the refracting telescope the light from the object observed passes direct through the object glass, and the image formed is observed through a magnifying cyepiece. In the commonest form of retlecting telescope, known as the Newtonian reflector, the light from the object observed is collected by a mirror at the base of the tube, and reflected into a small mirror. The image formed on the small mirror is observed and magnified through an eyepiece.

The function of the object glass, or the mirror, as the case may be, is to gather sufli- cient light to make a perccptible image in the focal plane. The function of the eyepiece is to enable the eyc to see the image when as near解

## Television in the Home

## The Basic Principles and Methods

+ 

This contribution is complementary to the interco inected series of wireless articles in our work.
It explains the fundamental methods o transmitting an image from studio to receiver. Sec Broadcasting Receiving Sets; also Wireless Reception
In order better to understand the process tenth of a second and the "definition" of the of television we may compare it with that final picture will depend upon the number of involved in telephony. When we speak into light spots into which the subject is scanned a telephone transmitter sound vibrations are At the receiving end the lamp must also be converted into impulses of electrical current, scanned in the same way and the speed must
which at the other end are re-converted into sound vibrations through the electrical currents setting the diaphragm of the telephone receiver in vibration.

Much the same thing happens in the case of television, for instead of sound vibrations we have light of varying brightness acting upon a piece of apparatus which has the property of varying its electrical resistanco to a current with a varying intensity of light. This, in turn, allows electrical currents of varying strength to be set up in the wires connecting the receiver and transmitter, and at the receiving end these currents are utilized to cause a lamp to be illuminated with an intensity which varies in harmony with the changes
 employing kathode ray oscillographs, on the syatem due to von Ardenne Conurtesu of The Wireless World be accurately synchronised with the speed of sranning at the transmitting end, as ctherwise the picture will be hopelessly distorted or will fail to appear at all.

The simplest arrangement of television consists of a powerful source of light focussed on to a disk which has a number of holes in it arranged spirally around the disk. This disk is cansed to rotate, and on the other side of the disk is the obiect to be transmitted. The light passing through the holes illuminates the object in successive strips, and with every revolution of the disk the entire object has been covered. The light, of varying intensity, reflected from the object is conveyed to a light-sensitive cell, which when suitably connceted in an electrical circuit will 1 ransmit electrical impulses corresponding to the light impulses it receives.

In other systems the scanning is done by means of a series of reflecting mirrors arranged around a wheel or disk and tilted at slightly different angles, so that a spot of light reflected from them whilst the disk or wheel is rotating will be deflected at different angles and can be made to scan or traverse the whole of the object. Where it is desired to produce a large image the scanning disk can be replaced by a rotary switeh sweep-
in intensity occurring at the transmitter. ing across a series of contacts connected to a Ncither television nor the cinema would be large number of electric lamps built up into possible if it were not for the fact that the human eye is slow to follow changes; we do not see the individual pictures which, passing in front of the cinema projector, give us the impression on the screen of a continuous moving image. This slowness of the eye is known as "persistence of vision," and the efficet of a continuous picture can be obtained if the successive photographs comprising a cinema film pass before our eyes at the rate of about sixteen per second.

Now, in the case of television we cannot transmit over wires or by wireless a complete subject instantaneously, but have to send it by successive impulses and must, therefore, employ what is known as a "scanning" device, which enables us to illuminate only one spot of the subject to be transmitted at a time, but, by moving the illumination to and fro all over the object, eventually to cover the whole. The travelling spot of light will actuate our light-sensitive apparatus powerfully when the illuminated spot is light in tone and weakiy where the object is dark, and produce corresponding electrical currents The principle of scanning was suggested in 1834 by Nipkow, and is still the basis of most television systems of to-day. Any scanning arrangement has to cover the entire object in something like a
the form of a screen. To produce an image with reasonable definition on a screen 4 ft .6 in . by 2 ft . as many as 2,100 separate lamps have been used. Arrangements such as this are not suitable for enıployment commercially on a big sca!c. and for home reception the scanning
disk is still the most promising device, on account of its simplicity.

The progress which has been made in television of recent years is very largely due to improvements in light-sensitive, or photoelectric cells. The greatest obstacles to the realization of television in a perfected, or even commercial, form are bound up with the inertia or lag in operation of certain of the essential components, and it is for this reason

"Baird Televisor," or home receiving set Baird Television. Ltd.
that much attention is now being paid to the possibilities of using kathode rays. In such a system the image appears on the screen of a kathode ray tube, the illumination being due to the projection of electrons through the tube, scanning being obtained by the deflection of the electron stream by means of a varying magnetic field controlled by the electrical impulses arriving at the receiving end.
Practical Considerations. Since the installation of a television receiver entails a fair outlay, the prospective purchaser may welcome some information on the scope and value of the apparatus from the point of view of entertainment. On the Continent a kathorle ray receiver is available, but in Great Britain the only commercial system is the Baird "Televisor." This is sold as a kit of parts for home assembly, or as a complete receiver. In addition a wireless receiving set is necessary The image as received is quite small, and is magnified by a lens, appearing to the observer as a rectangular light-picture about 5 in . square.
There are obvious limitations to the distance from which the picture can be viewed, and the number who can sec it comfortably at the same time. A varying amount of distortion is often present, and the apparatus needs some care in its manipulation to secure uniform results. As to the programmes which are receivable on the apparatus, these are broadeast from B. B.C. stations on a wave length of 356 metres for vision and 261 metres for sound. The times and other details are given

Television. Schematic diagram to show methoj adopted by Baird to project a television p.cture on to a screen composed of 2,000 small lamps Coutest of The W'irelexs lineld
in the daily broadcasting time-tables. The television programmes include such items as songs before the piano, character sketches, talks on sport and cartoons drawn before the transmitter. Public events are occasionally televised.

Future Possibilities. The Baird company is building its own transmitting studios and, of course, is constantly experimenting with a view to improving its apparatus. Other systems are in course of development, and it is not improbable that the elimination of mechanica! hindrances made possible bv the use of the kathode ray oscillograph may give equally effective if not better results.

TEMPERATURE : Of the Body. The average temperature of human beings in health is $98.4^{\circ} \mathrm{F}$. Usually it rises a little during the day and falls gradually cluring the night, so that the body is hottest in the cvening and coolest in the early morning.

After a meal or aftor exertion the tempera ture is raised a little. In women it gocs up more readily than in men. In children a considerable rise, amounting to slight fever, may occur from such trifling causes as a fit of crying or an attack of indigestion. Uni formity of temperature is maintained by a balance letween the production and the loss of heat by the body.

The temperature may be taken by placing the thermometer in the armpit, the mouth, or the rectum. To take it in the armpit wipe the skin with a soft towel. Place the bulb of the instrument in the hollow. Fold the arm closely across the chest and cover the patient To get a corrcet reading the thermometer should be left in place for a period of ten to fifteen minutes.

A quicker and generally more accurate reading is obtained with the mouth. Carefully wash the thermometer with soap and water Place the bulh under the tongue. Leave it there for 3 min . The patient should kecp his mouth shut and breathe through the nose The clinical thermometer should always be washed after and before use. See Fever Thermometer.

TEMPERATURE: In Gardens.
All greenhouse temperatures and those that are necessary for the well-being of plants, which are given in this Encycloperlia, are those of the Fahrenheit thermometer, with its freczingpoint of $32^{\circ}$ and a boiling. point of $212^{\circ}$

Plants arc liable to severe injury from sudden changes of temperaturc. If venti lators are closed down too precipitately the alteration from an open, free, air to a close, stagnant atmosphere is likely to cause trouble.

TEMPERING AND ANNEALING. The process of heating and cooling steel to give it hardness is known as tempering. lt is the opposite of annealing, by which a metal is softened. Different methods of tempering are employcd according to the size and nature of the stcel, but the principle is the same.

The steel is first hardened by being beated to a dull red glow and plunged into cold water or oil, the rapid cooling thus obtained making the metal dead hard. In this state it is generally too brittle and hard for practical purposes, and it is polished up bright and heated again, but this time by a more gradual process. When it has been hrought to the required heat it is once more immersed in water or oil, which fixes the temper.

The degree of hardness or temper is indicated by the colour of the metal. If a bar of brightly polished cast steel is slowly heated from one end, a series of colour changes will travel along the bar in a definite and regular order. The first colour appearing is a light straw or yellow. Quenching the hardened metal at this state gives the hardest of cutting edges. The light straw is followed by a dark straw colour, giving a rather softer temper Dark straw gives place to brown, a usual
temper for plane irons and wood-cutting tools. Light blue is the next colour, and this is the stage at which most knives are tempered. When it changes to a dark shade a fairly soft temper is obtained for articles such as wood saws and many forms of springs.

Annealing. Metals are annealed to make them softer and more easily workable. Steel and iron are annealed to remove the internal strains that are incident to manufacture. The piece of metal can be brought to a bright red heat in the stove, or in a forge or furnace if available. It is then left in the hot ashes all night, to allow it to cool slowly. Brass is annealed by slow and continued heating, taking care not to burn or melt the metal. Copper is annealed by bringing the metal to a dull red heat and then plunging it into cold water. In the case of pipes and similar objects the worker should beware of the escaping steam. See Case Hardening; Har. dening.

TENANT. A tenant is one who holds land or other real property of another. The terms of a tenancy depend entirely upon contract. In the absence of agreement to the contrary, when a tenant enters upon the land and pays rent for a year, or any aliquot part of a year, he is a yearly tenant, whose tenancy can only be determined by sis months' notice to quit, expiring at the end of a current year of the tenancy. He is also a ycarly tenant if his agrecment is at a yearly rent, though that rent may be payable monthly, weekly, or in any other fashion. But if a tenant agrees to take a house at so much a month or week, he is a inonthly or weekly tenant, entitled only to a month's or weeli's notice.
In the absence of agreement to the contrary, the tenant is liable to pay all rates and taxes except property tax. As to property tax, the tenant is liable to pay it to the tax collector, hut may deduct it from the lirst rent he subsequently pays to the landlord. See Distraint; Landlord : Rent

## Tennis Courts: Grass and Hard Surfaces

## How to Lay Them and Provide the Necessary Accessories

This article describes the laying-out both of a grass and a hard court, afterwards giving directions for marking out a court. Related entries include thosc on Garden Lawn; Spirit Level For the game itself the article Lawn Tennis should be consulted. See also Table Tennis

Provided there is sufficient spacc, any household can, at comparatively small cost, provide itself with a grass tennis court. The chief expense, apart from the preparation of the ground, is caused by the necessity in most cases of providing wire or other fencing around the ground. The laying of a hard court is a more expensive matter, but it can be done by the amateur. The measurements of a standard court are given in the diagram, p. 702.

Laying a Grass Court. If the ground is fairly level the only preparation needed is to cut the grass closely and to water and roll it to as level a surface as possible. Any lad places can be filled in with a few turves cut from unimportant ground, cutting away the turf, making the soil beneath flat and level, and then fitting the new turf and beating it into place.

The preparation of the ground or turf should be carried out in the autumn or very early spring, so that it will have time to settle down before play begins. Slight bumps can be levelled by lifting the turf and scraping out the surplus soil, and immediatcly relaying the turves in the same place. All disturbed turf ought to be wcll watered daily for a few days, beaten flat, and rolled with a heavy roller at two-day intervals until the grass looks healthy. Mowing and rolling are then carried out. and in a sliort time the ground will be in condition for play.

When it is desired to construct a tennis court on a piece of rough meadowland, the nature of

TENCH. This fresh-water fish needs careful cleaning. It is usually boiled or fried, and is in season all the year round.

Before hoiling tench clean it, remove the gills, and then soak it for about an hour in cold salted water. Rinse it in fresh running water, put it in a pan of boiling salted water, covering it completely, and let it cook slowly until it is tender-about $\frac{1}{4}$ hour. Garnish it with parsley and cut lemon, and serve some melted butter sauce separately.
To fry tench cover it with llour, put it into a pan of smoking hot fat, and brown it well on both sides. Then drain it and serve it garnished with fried parsley, and accompanied by some piquant sauce. See Saucc.

TENDON. Sinews or tendons are the strong, tough, fibrous cords by which muscles are united to the bones or other parts on which they act. Rupture of tenclons is a not uncommon accident. In dancing, for instance, the Achilles tendon, which connects the muscles of the calf with the heel, is sometimes ruptured. The patient feels as if he had been struck a severe blow above the heel, and he loses power to use the foot, or may fall to the ground.

TENNIS CAKE. This iced fruit cake can be made in the following way: Beat together jo oz. sugar and ! Ib. butter or margarine until they are like cream; then add 3 eggs, one by one, beating all the time. When they are well mixed, stir in 1 lb . Hour, $\frac{3}{4} \mathrm{If}$. sultanas, 2 oz . pecl, a little milk, and a few drops of essence of lemon.

Turn the mixture into a greased tin and bake it in a moderate oven until it is lightly browned; then let it coot on a sieve. When cold, cover the top with almond paste or marzipan, and over this put some fondant or royal icing. Decorate the border of the cake according to taste, write across it the word Tennis, using pink icing, and complete it with a design of two tennis racquets. See Almond I.aste; Cake; Fondant Icing; Marzipan.
the soil, the gencral position of the site, and the geological conditions should all be taken into account, as well as the amount of money that can be spent in order to lay out the court. On a light or readily and naturally drained site the principal work is levelling, which is generally a inatter of removing the earth from the high parts and depositing it at the lower. It is necessary to consolidate the made-up ground, and preferable to let it stand for a ew weeks to settle down, and then to finish by very carcful levelling. The surface can be made up with turves, or by sowing grass seeds, according to choice. A good result can be obtained by both methods.

When the ground is heavy or likely to become watcrlogged in wet weather, it will be advisable to remove the carth to a depth of 12 in . or so and to make up the bottom with rubble or well-broken soil, adding agricultural drains as necessary. The rubble is raked and roughly levelled and then covered with a good layer of medium soil. This is raked and rolled and covered with a good top soil with an admixture of manure. The whole is levelled and watered, rolled, and allowed to settle. The surface is made good as required, and it can then be covered with turves or sown with grass seed.

Hard Courts. There are several types of hard court, some laid with cement or concrete, others with asphalte or a tar composition or with burnt ballast. A system extensively used
is that developed by the En-Tout-Cas Co., Ltd., of Svston, Leicester.

Courts laid with this patent method permit of play all the year round; they exhibit the characteristics of the best grass courts, and the bound of the ball is absolutely true. They are made with a special material laid on a bed of ashes, and being semi-porous, they can be played on within a very short time after rain. The patent material is only laid by the company's workmen, but the whole of the preparatory work of making up the ground, levelling, and preparing the ash bed can be carried out privately if desired.
The preliminary stages are dealt with on similar lines to the grass courts. The levelled surface is covered with a layer of ashes to a depth of a hout $4 \frac{1}{2} \mathrm{in}$., but local conditions may call for special treatment. These ashes are levelled and rolled. The foundations are covered with the patent material, well graded, screeded, and rolled until a flat and true surface is obtained. The sockets for the posts, previously embedded in concrete, are set at such a height that the top of the socket is about level with the surface. The ash foundation is not laid in a haphazard manner, but is properly graded. Gencrally speaking, when laid on a reasonably wèll-drained subsoil, no additional drainage will be necessary.
The ashes are laid according to the type used, and graded with the largest at the bottom and the smallest at the top. The nature and amount of fine ashes in the bulk determines the manner of laying and keying the top ashes. A considerable quantity of ashes is needed, amounting to something like 65 tons for a court measuring 120 ft . long and 60 ft . wide, calculating on the assumption that the depth of the court will be about $4 \frac{1}{2}$ in.
The surfacing material is a special type of clay burnt in a kiln to such a hardness that it will not weather back after it has been laid and subjected to ground moisture. At the same time, it is not so much burnt as to reach the vitrifying stage, otherwise no binding power will be present. The colour is a shade of red that enables the path of the ball to be seen readily, even in glaring sunlight.

After the court has been made the lines are marked out and permanently defined by the use of metal or painted linen strips, the former composed of compressed lead tape. This is fixed to the court with long galvanized nails, and the tape heaten in level with the surface. The only subsequent attention is a coat of white paint about once a year.

Marking the Court. To mark out a tennis court a start should be made with one intended for the double game, as its markings can easily include those necessary for singles. First determine the position of the net and fix in the line chosen two pegs 27 ft . apart, as in the diagram. Then take two measures and fasten their respective ends to the pegs $A$ and $B$.
On the first measure, which will go diagonally across the court from $A$ to $C$, take a length of 47 ft .5 in . On the second, which will go from $B$ to $C$, take one of 39 ft. Pull both measures taut so that at these distances they meet at C , and this gives one corner of the court. At a point marked F, 21 ft. from $B$, put in a peg to mark the end of the service line. The other corner, $D$, and the other end of the ser vice line, $G$, can be found by repeating the process.
 is shown. A B being the place for the net

The same measurements on the other side of the net will complete the boundaries of the court. By prolonging the base lines $4 \frac{1}{2} \mathrm{ft}$. on each side, and joining the four new points that are thus obtained, the sido lines of a double court are made, and to complete the marking all that remains is to mark the central line by joining the middle points of the side lines.

For double court alone the interior side lines need not be prolonged to meet the base lines. In all cases the net posts must stand at a distance of 3 ft . from the side lines. Therefore, if a single game is played on a double court, the net, unless the posts are shifted and a single court net is used, should be stayed up to the right height by means of single posts placed at a distance 3 ft . from the single court side lines.

Tennis Net. For the purpose of playing lawn tennis a net across the centre of the court is necessary. This is usually fastened to posts, one at either end.
These tennis nets are sold in various qualities. For ordinary use a fine hemp net with lines top and bottom is suit able, but a stronger one can be obtained with a linen band. More expensive ones have a band of woven web and a steel or copper headline with a hempen end and pins. The nets are fastened to posts of wood or metal, the latter being specially suited to hard courts.
Good wooden posts are of ash, fitted with brass ratchets for winding purposes. The posts are fitted into iron sockets which enable them to rest on the ground and these are fastened by pins driven into the soil. Metal posts are of iron or steel. As these cannot be pinned down on hard courts, they are set into an iron receptacle sunk into the ground. Steel posts are also made in the same way as iron ones and with portable iron feet, and ground screws are made for use on grass courts.

The illustrations show the modern methods of fastening the tennis net, both on grass courts and on hard ones. Fig. 1 shows a winding apparatus consisting of a cone drum, which has taken the place of the hollow drum formerly used. In the older types of ratchet the liability of the copper cord to kink and break necessitated the adoption of a rope end for use at the winding post. In the ratchet of the one illustrated a small hook on the drum receives a loop made in the copper cord itself and the winding is accomplished without the slightest danger of kinking or breaking, this being due to the shape of the drum, which allows the coils of
the copper cord to be laid up evenly. The post illustrated, Fig. 1, is $3 \frac{1}{2} \mathrm{in}$. square, and its metal points are of nickel and brass.
Fig. 2 shows the socket for the post of a tennis net. This, suitable for use on grass courts, is usually fastened to the ground by feather pins, as shown, but it can be made secure by ground screws. Fig. 3 shows a socket made to stand on a hard court, especially one where no holes in the ground or flooring are allowed. It is kept in position by the weights, of which there are four to each post.

Another method of fixing the net on a hard court is shown in Fig. 4, but for this a hole must be made in the ground. This done, it gives a thoroughly secure hold. The top of the base is level with the surface of the ground and so offers no projections that will impede the rolling of the court.

With ordinary care a good tennis net will last a long time. The winding arrangement may get out of gear, but usually this is not serious. To take off the strain the net should be lowered after play is finished, never left taut.
TENNIS ELBOW. Strain of the muscles of the forearm below the elbow, often referred to as tennis elbow, is usually treated by strapping the forearm for a short distance with adhesive plaster. It is a painful condition, but does not interfere with

Fig. 2
Tennis Fet. Fig. 1. Sanare jost fitted with patent oone ratchet. Fig. 2. Detail oi gortable loot. Fig. 3. Post and weights for asphalte end hard conrta. Fig. 4. Hard court polt with rotary locking device Courlesy of F. H. Aures, Led.
the stronger movements of the arm, for example, lifting weights, but movements that call for finer adjustment of the muscles are rendered difficult. It has been suggested that the condition may be induced by the handle of the racquet being too bulky for the grip of the player.
The position of the forearm in the back stroke is likely to expose the parts about the upper joint between the two bones of the forearm to injury, and inflammation may occur in the joint itself. Some doctors advise vigorous massage, while others recommend rest. See Elbow; Strain.
TENON: In Woodwork. A mortise and tenon joint is employed in all classes of woodwork. The tenon is that part of it which fits into the slot or cavity cut in another piece of material. The tenon can be shaperl almost entirely with a hand saw, preferably the type known as the tenon saw. In making a tenon the wood is first prepared to, its finished
size and marked out, as in Fig. 1, with a marking gauge and set square. The breadth of the tenon should be about $\$$ the breadth of the wood. Resting the material on the bench against the bench hook, a cut is made with the saw across the grain of the wood at the shoulder or termination of the tenon. This cut must he very carcfully made. If it is even a fraction out of 1ruth or out of square, or not quite perpendicular to the face, a had joint will result, especially if, as is often the case, it should he impracticable to trim up the shoulder with a paring chisel. A similar cut is made on the opposite side.

After this, the work is preferally set upright in the vice, and two cuts are made with the saw at right angles to the first, and in the direction of the grain, as in Fig. 2. Here again it is imperative that the cuts be made very accarately to the lines marked on the work. The aim should be to saw away the exact
amount of wood so that the tenon can be fitted into the mortise with the minimum of trimming and finishing

To ensure a close fit it is desirable to chisel across the grain of the wood, as in Fig. 3, removing the saw cuts, and gencrally smoolhing the surface. It is usual practice to drive a tenon home with a mallet, but common sense must bo employed when doing this, as if the tenon is too tight and driven home too violently, the wood in the vicinity of the mortise will split. The aim should be to make all four sides of the tenon fit snugly against the four walls of the mortise. The example illustrated is the simplest form of tenon. There are many developments of it, according to the nature of the joints which are to be made. The principal forms are described in the article Mortise.
Tenon Saw. For household use the most serviceable size of tenon saw is from 10 to 18 in. long, with about 10 teeth to the inch. The saw blade is reinforced by a backing piece of stecl or brass.

The teeth are bent over to the right and left altcrnately, an arrangement known as the set, which enables the blade to move freely in the slot cut by the teeth. If the set is insufficient, the blade will jam in the slot and probably buckle or distort. It is important to allow for the breadth of the saw kerf, for which reason the wood should be sawn on the waste side of the line and not actually on the line itself.
In use the tenon saw is grasped in the right hand with the right forefinger extended on one side of the handle, and the right thumb on the opposite side. The bulk of the handle is gripped with the second, third, and fourth fingers of the right hand, the first finger and thumb guiding the path of the saw. The blade must bo kept perfectly upright with sufficient ontward pressure to make the teeth bite into the fibres of the wood. The forward stroke does the cutting; the return stroke brings the нaw hack without allowing the teeth to rasp the surface of the wood.

A wooden strip should be made to protect the teeth. It is equal in length to the blade of the saw, as shown in Fig. 4, and measures

Tenon. Fig. 1. Marking out tenon beiore cutting. Fig. 2. Cutting the tenon with a tenon saw. Fig. 3. Finisining the tenon with a chisel. Fig. 4. How a wooden strip is applied to protect the teeth of a tenon saw
about $\frac{3}{4} \mathrm{in}$. hroad and about $\frac{3}{8} \mathrm{in}$. thick. A saw cut is made along one edge for a depth of about $\frac{1}{i n}$. and when the saw is not in use the strip is laid over the teeth of the saw and
secured in place with a piece of tape. Before putting the saw away, the blade should be wiped over with a greasy rag. See Joint; Mortise; Pergola; Saw.

## TENTS FOR HOLIDAY MAKERS

## Their Construction and Erection by the Handy Amateur

An article on this subject will be very ust ful to horidav mikers and others who live tor a time out of doors, or who for one reason or other may wish to sleep in the open. See also Bathing Tent;

Holidav; Mlotoring: Sieep

The main points of utility in tents are the ease with which they can be erected and dismantled, the comparatively light weight of their component parts, and the facility with which they may be packed and transported from one place to another.

A handy bathing tent is illustrated and described on page 68. Tent trailers, for towing behind a motor car, are dealt with in the article on Motoring.
A simple form of bivouac shelter is shown in Fig. 1. It is constructed by first marking out the intended floor space, and then thrusting a long stick into the ground at each corner. These sticks are lashed together at their upper ends, in pairs, then the ends of the ridge pole, which supports the canvas, are placed in the forks as shown. After the canvas sheet has been placed in position its lower sides are secured to the ground by means of wooden pegs or heavy stones. The open triangular ends may be covered with separate sheets, or canvas flaps, as indicated by the dotted lines in the diagram, could be made and sewn in position.

Although it is simply designed all the features which a good canvas shelter should possess are embodied in the example illustrated in Fig. 2. It will house six adults comfortably, with plenty of room for furniture and stores. The canvas is supported by galvanized wrought iron tubes. The covering fabric is light Willesden canvas, which may be obtained in short or long lengths, the widths
stocked ranging from 2 ft . to 8 ft . Sailcloth may be used, but it is not readily procured in greater widths than 2 ft . The following is a list of the inaterials required for this tent.

|  | Long. <br> ft. in | Diameter. in. |
| :---: | :---: | :---: |
| $\underline{2}$ G.W.I. tubes (H) | $10 \quad 5$ | 1 |
| $\cdots$ G.I. T- pieces (.J) | () 3 | 1 |
| 1 G.W.I tube (L) | 1 | 1 |
| 8 G.W.I. tubus (P) | 610 | 1 |
| 8 G.W.I. tubes (Q) | 0 O | d |
| 12 G.W.I. tubes (S) | 13 | 4 |
| Galvanlzed iron wire | 40 | 1 |
| Soft iroll wire | 09 | 右 |
| 42 brass eyclets and washers | - | 3 |
| 8 ditto . | - | 1 |
| 1 iron pipe. . . | 30 | 1 |
| 1 iron rod ... | 20 | , |

1 length of hardwood, 8 ft . long by 1 in . broad and in. thick.

100 ft . of light Willesden canvas, 5 it. wide. 2 or 3 skeins of white sewing twine.
2 or 3 medium sized sacking needles.
1 sewing paltu.
54 vards of 8 in hemp rope.
When purchasing the two tubes $H$, it is advisable, if the necessary appliances are not available at home, to get a thread cut on one end of each tube and the T-pieces fitted. The tube $L$ should also have both ends threaded to screw into the T-pieces. The bores of each T-picce should be screwed.
The arrangement of the tubes is shown in Fig. 3, their sizes and preparation being detailed in Fig. 4. If the

Fig. 5

Fig. 7
two gable tubes ( H ) have not been bought be accidentally driven down entirely into the ready threaded, a thread must be cut on bores of the tubes into which they are fitted. one end of each of them, for about $1 \frac{1}{2}$ in., To mark the depth to which the tubes H and P and a T-piece, J, fitted as in A, Fig. 4.

The Metal Framework. A hole of $\frac{1}{4} \mathrm{in}$. be painted round each tube at a point 18 in . diameter is drilled through the diameter of each T-piece, from a point marked off $\frac{3}{4} \mathrm{in}$. from one end of the T portion. Two 10 in . lengths are cut from the $\ddagger$ in. wire, then each is bent to the size and shape of the shackle K , detailed in diagram B . The upper angles of the shackles are inserted into the holes in the T's and bent over, as shown in diagram C.
Sectional diagram D shows how the angles may be quickly bent by hamnering a short length of iron pipe down the bore of each $T$. The rims of the upper ends of the tubes $P$ should be neatly rounded with a file, then a hole of $\frac{1}{8} \mathrm{in}$. diameter is drilled through the

diameter of each tube, from a point marked off 1 in . from the upper end. Each hole should be slightly counter. sunk with a $\frac{1}{4}$. drill. A tube $Q$ is fitted into the upper end of each tube $P$ and driven down for 3 in.; a hole of $\frac{1}{\frac{1}{a}}$ in. diameter is drilled through the diameter of each of these tubes $Q$, from the holes drilled through the tubes $\mathbf{P}$.

Eight 1 in. lengths are cut from the $\frac{1}{8} \mathrm{in}$. diameter soft iron wire, then a length is fitted into each alinement of holes, as shown in sectional diagram E . The ends of the wires are riveted over into the counter-sinking of the holes in the tubes $P$ by rapid and not too heavy taps from a ball peine hammer. This securing of the small tubes by rivets is necessary, as otherwise they are apt to work loose and be lost or

Fig. 8. Three sheets of canvas for roof. Fig. 9. Shapes of marging on the roof sheets and gable abeets
indented metal disk fastend to a leather circle. the latter being buckled round the right hand by an attached strap. The leather circle. with the disk ontward, rests on the palm of the hand.
In sewing, the point of the needle is inserted into the canvas by the fingers of the right hand, the eye of the needle being received into any one of the indentations in the disk. By pressing up the disk, the needic is casily forced, up to its eyc, into the thickest folds of canvas, after which it is pulled through by the right hand and the twinc drawn taut so as to form a firm stitch

A simple stitch, which will serve for all the sewing required, is shown in Fig. 7. In this diagram the stitches are shown loose, for clearness of illustration, but in practice each stitch must be drawn taut, as it is made, or the seams will not be held firmly together and the sewing will appear unsightly. A firm knot should be made on the long end of the twine before commencing to sew, and better progress will be made if a length of about I yd. is used at a time and rencwed as recuired, instead of one very long length, which will take extra time to draw through the seam after each stitch, and is apt to become tangled during the work, thus involving much delay.

The roof sheet A is composed of 3 separate lengths of canvas, each 14 ft .2 in . long. The centre sheet is $4 \mathrm{ft} .8 \frac{1}{2} \mathrm{in}$. wide, the right and left sheets being both 4 ft . $9_{4}^{1} \mathrm{in}$. in wilth. A $1 \frac{1}{2} \mathrm{in}$. margin is markerl on the right and left sides of the centre sheet, then a 3 in margin is marked off on both ends. A 3 in. margin is marked on the right side and on both ends of the right sheet, and a $1 \frac{1}{2}$ in. margin is marked on the left side.
A 3 in. margin is marked on the left side and on both ends of the left sheet, then a $1 \frac{1}{2} \mathrm{in}$. margin is marked on the right side. A space of 4 in . from the 3 . in. margin line is now marked ofl at both ends of each shect. A space of $3 \frac{3}{3} \mathrm{in}$. is next marked off from the 3 in margin on the right side of the right shect, then a similar space is marked off from the 3 in. margin on the left side of the left sheet. The 3 sheets are shown in Fig. 8, their margins being marked M .

The next step is to cut the ends of the margins to the shapes shown in the diagrams. The measurements from which the cuts $\mathrm{A}, \mathrm{B}$, and C are marked out are detailed at A, B, and C, Fig. 9 After all the cuts have been made, the 3 in . margins are folded double, turnel inwarl, and then sewn to the canvas as shown in lig. 10. The 3 sheets are joined together by first overlapping the $1 \frac{1}{2}$ in. margins on the centre sheet with the $1 \frac{1}{6} \mathrm{in}$. margins on the right and left sheets, and then sewing each pair of overlapped margins together, as shown in Fig. 11. Whan the roof sheet is complete, its dimensions should be $1: 3 \mathrm{ft}$.8 in . by $1: 3 \mathrm{ft}$.
The gahle canvases 13 and C, Fig. 12, are each composed of two sheets of the same size and shape, one bcing detailed in Fig. 13. To avoid waste, the 4 sheets may be cut from a length of canvas 29 ft . 6 in . long by : ft . wide, the sheets being marked out as shown in lig. 14. After the 4 sheets bave been cut to size, a 3 in . margin is marked off on the upper side, lower side, and diagonal side of each sheet.

A $1_{2}^{1}$ in. margin is next marked on the right and left sides of each sheet, then the ends of the rectangular margins are cut as detailed in Fig. 9, the comers of the diagonal margins heing slit and cut as shown in the diagram. The 3 in . upper and lower
margins are now folded double, turned inward, size being measured from the lower edge of the and then sewn to the sheets in the same manner as the 3 in margins on the roof sheet. In sliaping the left corners of the 3 in . upper and lower margins on the right half of each gable sheet, the cuts must be reversed, as shown in diagram C, Fig. 9. It is important to place the shects on a flat surface for accurate marking off, and care should be taken to mark out and shape these cuts correctly. They must be folded and sewn as neatly as possible, so as to lie flat when both sheets are united. The sheets are next joined in pairs, by overlapping the $1 \frac{1}{2} \mathrm{in}$. margin on the long side of each right sheet with the $1 \frac{1}{2} \mathrm{in}$. margin on the long side of each left sheet, and then sewing both overlapper margins together, as shown at A, Fig. 15. After the upper and lower margins have been folded and sewn, the height of each gable sheet should be 8 ft .8 in ., and the breadth, between the $1 \frac{1}{2} \mathrm{in}$. margins on the right and left sides, $9 \mathrm{ft} .4 \frac{1}{2} \mathrm{in}$.

The side sheet 1 , I'ig. 16, is made from a length of canvas $12 \mathrm{ft} .10 \frac{1}{2} \mathrm{in}$. long by $\overline{5} \mathrm{ft}$. wide; a 3 in . margin is marked off on all 4 sides, then the ends of the margins are cut as shown. The lower margin is folded double, turned inward, and sewn. The margin on the right side is overlapped with the $1!\frac{i n}{}$. margin on the left side of the right gable sheet, then both margins are sewn together, as at B, Fig. 15.

The margin on the left sice is next overlapped with the $1 \frac{1}{2} \mathrm{in}$. margin on the left side of the left gable sheet, then both margins are sewn together. After the side sheet has been attached to the gable sheets, its length should be $12 \mathrm{ft} .4 \frac{1}{2} \mathrm{in}$. by 4 ft .6 in . wide, the latter
sheet to the inner line of the upper margin
The two side shects, $E$ and $F$, are the same size and shape, and are both detailed in Fig. 17. Each sheet is cut from a length of canvas 5 ft . 6 in. long by 5 ft . wide. A 3 in . margin is marked on the 4 sides of each sheet, then the ends of the inargins are cut as shown. The left margin and the lower margin of the right sheet, E , are folded double, turned inward, and sewn then the right margin is overlapperl with the $\frac{1}{2}$ in. margin on the right side of the right gable shcel, both margins being sewn together as shown in detail at C, Fig. 15.
The right margin and the lower margin of the left sheet, $F$, are next folded and sewn in the same way, then the left margin is overlapped with the 1.5 in . margin on the right side of the left gable shect, both of these margins being securely scwn together, as described When attached to the gable sheets, the length of each side sheet should be 5 ft. by 4 ft .6 in wide, the latter size being measured from the lower edge to the inner line of the upper margin on each of the sheets.

The door-flap G, Fig. 18, is formed from a shcet of canvas 5 ft . long by 3 ft .6 in . wide. A 3 in . margin is marked ofl on all 4 sides, then the ends of the margins are cut as shown. The right, left, and lower inargins are folded clouble, turned inward, and sewn to the sheet After the 3 margins have been sewn, the dimensions of the flap should be 4 ft .6 in . long by 3 ft . wide; the length being measured from the lower edge of the shect to the inner line of tis upper margin of it.
en holes, each about $\frac{1}{8} \mathrm{in}$. in diameter and 6 in . apart, are now made, in a row, in the

centre of the right and left margins on the door-flap. A $\frac{8}{8}$ in. eyelet is inserted into each hole, from the outer side of the flap, and a washer fitted. The stems of the eyelets are expanded with cone punches and finally riveted over on to the washers by light taps from a ball peine hammer.
